# Table of Contents

<b>What is Amazon SageMaker AI?</b> .....	<b>1</b>
Amazon SageMaker AI rename .....	1
Legacy namespaces remain the same .....	1
Amazon SageMaker and Amazon SageMaker AI .....	2
Pricing for Amazon SageMaker AI .....	2
Recommendations for a first-time user of Amazon SageMaker AI .....	3
Overview of machine learning with Amazon SageMaker AI .....	3
SageMaker AI Features .....	6
New features .....	6
Machine learning environments .....	7
Major features .....	9
<b>Setting up SageMaker AI</b> .....	<b>13</b>
Complete Amazon SageMaker AI prerequisites .....	14
Sign up for an AWS account .....	14
Create a user with administrative access .....	15
(Optional) Configure the AWS CLI .....	17
Use quick setup .....	18
Quick setup .....	18
After quick setup .....	20
Use custom setup .....	20
Authentication methods .....	20
Custom setup .....	22
Access the domain after onboarding .....	29
Domain overview .....	29
SageMaker AI domain entities .....	30
Choose an Amazon VPC .....	91
Supported Regions and Quotas .....	93
Quotas .....	93
<b>Automated ML, no-code, or low-code</b> .....	<b>94</b>
SageMaker Autopilot .....	95
Create Regression or Classification Jobs Using the AutoML API .....	99
Create an Image Classification Job using the AutoML API .....	184
Create a Text Classification job using the AutoML API .....	195
Create a time-series forecasting job using the AutoML API .....	206

Create an LLM fine-tuning job using the AutoML API .....	251
Create a Regression or Classification Job Using the Studio Classic UI .....	276
Example Notebooks .....	288
Videos .....	293
Tutorials .....	294
Quotas .....	294
API reference .....	296
SageMaker JumpStart .....	299
Open and use JumpStart in Studio .....	299
Open and use JumpStart in Studio Classic .....	302
Foundation models .....	305
Access control .....	360
Studio Classic .....	371
<b>Machine learning environments offered by Amazon SageMaker AI .....</b>	<b>416</b>
Studio .....	418
Migration from Amazon SageMaker Studio Classic .....	420
Launch Amazon SageMaker Studio .....	467
Amazon SageMaker Studio UI overview .....	469
Amazon EFS auto-mounting in Studio .....	473
Idle shutdown .....	478
Applications supported in Amazon SageMaker Studio .....	486
Lifecycle configurations .....	487
Amazon SageMaker Studio spaces .....	493
Perform common UI tasks .....	508
NVMe stores with Amazon SageMaker Studio .....	509
Local mode support in Amazon SageMaker Studio .....	511
View your instances, applications, and spaces .....	520
Stop and delete your Studio running applications and spaces .....	521
SageMaker Studio image support policy .....	529
Amazon SageMaker Studio pricing .....	537
Troubleshooting .....	537
Studio Classic .....	541
Studio Classic maintenance phase plan .....	542
Studio Classic Features .....	543
UI Overview .....	543
Launch Amazon SageMaker Studio Classic .....	551

---

JupyterLab Versioning .....	555
Use the Studio Classic Launcher .....	564
Use Studio Classic Notebooks .....	569
Customize Studio Classic .....	655
Perform Common Tasks .....	708
Studio Classic Pricing .....	722
Troubleshooting .....	722
SageMaker JupyterLab .....	728
JupyterLab user guide .....	730
JupyterLab administrator guide .....	740
SageMaker Notebook Instances .....	768
Maintenance .....	769
Machine Learning with the SageMaker Python SDK .....	769
Tutorial for building models with Notebook Instances .....	770
AL2 instances .....	796
JupyterLab versioning .....	800
Create an Amazon SageMaker notebook instance .....	805
Access Notebook Instances .....	810
Update a Notebook Instance .....	812
Customize a Notebook Instance using an LCC .....	812
Access example notebooks .....	825
Set the Notebook Kernel .....	828
Git Repos .....	828
Notebook Instance Metadata .....	840
Monitor Jupyter Logs in Amazon CloudWatch Logs .....	841
SageMaker Studio Lab .....	841
Studio Lab components overview .....	843
Onboard to Studio Lab .....	848
Manage your account .....	849
Launch Studio Lab .....	851
Use Studio Lab starter assets .....	853
Studio Lab pre-installed environments .....	856
Use the Studio Lab project runtime .....	857
Troubleshooting .....	881
SageMaker Canvas .....	884
Are you a first-time SageMaker Canvas user? .....	886

Getting started .....	886
Tutorial: Build a machine learning workflow in Canvas .....	894
Amazon SageMaker Canvas setup and permissions management (for IT administrators) ...	903
Generative AI assistance using Q Developer .....	963
Data import .....	975
Data preparation .....	1014
Generative AI foundation models .....	1116
Ready-to-use models .....	1143
Custom models .....	1153
Logging out .....	1282
Limitations and troubleshooting .....	1283
Billing and cost in SageMaker Canvas .....	1286
SageMaker geospatial capabilities .....	1288
How can I use SageMaker geospatial capabilities? .....	1289
First-time user? .....	1290
Getting started .....	1291
Geospatial processing job .....	1307
Earth Observation Jobs .....	1323
Vector Enrichment Jobs .....	1331
Visualization Using SageMaker geospatial capabilities .....	1332
Amazon SageMaker geospatial Map SDK .....	1336
SageMaker geospatial capabilities FAQ .....	1344
Security and Permissions .....	1345
Types of compute instances .....	1358
Data collections .....	1361
RStudio on Amazon SageMaker AI .....	1366
Region availability .....	1366
RStudio components .....	1367
Differences from Posit Workbench .....	1368
RStudio on SageMaker AI management .....	1368
RStudio on Amazon SageMaker AI user guide .....	1421
SageMaker Code Editor .....	1426
Using the Code Editor .....	1428
Code Editor administrator guide .....	1440
SageMaker HyperPod .....	1458
AWS Regions supported by SageMaker HyperPod .....	1459

Prerequisites .....	1460
IAM for HyperPod .....	1466
SageMaker HyperPod recipes .....	1476
Orchestrating HyperPod clusters with Slurm .....	1525
Orchestrating HyperPod clusters with Amazon EKS .....	1611
HyperPod in Studio .....	1709
References .....	1722
HyperPod release notes .....	1728
HyperPod AMI releases .....	1738
Generative AI in SageMaker notebook environments .....	1753
Installation .....	1754
Access features .....	1755
Model configuration .....	1757
Use Jupyter AI .....	1763
Amazon Q Developer .....	1769
Set up Amazon Q Developer for your users .....	1769
Use Amazon Q to Expedite Your Machine Learning Workflows .....	1774
Amazon SageMaker Partner AI Apps overview .....	1774
How it works .....	1774
Integration with AWS services .....	1775
Supported types .....	1775
Set up Partner AI Apps .....	1777
Partner AI App provisioning .....	1788
Set up the Amazon SageMaker Partner AI Apps SDKs .....	1789
Partner AI Apps in Studio .....	1794
<b>Data labeling with a human-in-the-loop .....</b>	<b>1796</b>
Ground Truth .....	1796
Are You a First-time User of Ground Truth? .....	1797
Getting started: Create a labeling job .....	1798
Label Images .....	1805
Label Text .....	1830
Videos and video frame labeling .....	1844
Label 3D Point Clouds .....	1882
Label verification and adjustment .....	1945
Custom workflows .....	1956
Create a Labeling Job .....	2008

Use input and output data .....	2058
Enhanced data labeling .....	2166
Security and Permissions .....	2182
Monitor Labeling Job Status .....	2221
Ground Truth Plus .....	2225
Getting Started with Amazon SageMaker Ground Truth Plus. ....	2227
Request a Project .....	2229
Create a Project Team .....	2231
Project Portal .....	2234
Create a Batch .....	2235
Batch Metrics .....	2237
Batch Details .....	2239
Accept or Reject Batches .....	2242
Workforces .....	2242
Using the Amazon Mechanical Turk Workforce .....	2243
Subscribe to vendor workforces .....	2248
Private workforce .....	2250
Crowd HTML Elements Reference .....	2282
SageMaker AI Crowd HTML Elements .....	2283
Augmented AI Crowd HTML Elements .....	2385
Augmented AI .....	2394
Get Started with Amazon Augmented AI .....	2396
Use Cases and Examples .....	2428
Create a Human Review Workflow .....	2439
Delete a Human Review Workflow .....	2466
Create and Start a Human Loop .....	2469
Delete a Human Loop .....	2476
Create and Manage Worker Task Templates .....	2480
Monitor and Manage Your Human Loop .....	2495
Output Data .....	2497
Permissions and Security .....	2511
CloudWatch Events .....	2519
API References .....	2522
<b>Prepare data .....</b>	<b>2524</b>
Choose a feature .....	2524
Use cases .....	2524

---

Recommended features .....	2524
Additional options .....	2528
Data preparation with SQL in Studio .....	2529
Quickstart: Query data in Amazon S3 .....	2533
Features overview and usage .....	2540
Configure network access (for administrators) .....	2549
Data source connections .....	2552
FAQs .....	2577
Connection parameters .....	2578
Data preparation at scale using Amazon EMR .....	2593
Configure network access .....	2595
Prepare data using EMR Serverless .....	2600
Data preparation using Amazon EMR .....	2625
Data preparation using AWS Glue interactive sessions .....	2680
Get started with AWS Glue interactive sessions .....	2681
AWS Glue interactive session pricing .....	2688
Prepare Data with Data Wrangler .....	2689
Get Started with Data Wrangler .....	2692
Import .....	2705
Create and Use a Data Wrangler Flow .....	2780
Get Insights On Data and Data Quality .....	2789
Automatically Train Models on Your Data Flow .....	2802
Transform Data .....	2803
Analyze and Visualize .....	2864
Reusing Data Flows for Different Datasets .....	2876
Export .....	2887
Use Data Preparation in a Studio Classic Notebook to Get Data Insights .....	2922
Security and Permissions .....	2928
Release Notes .....	2944
Troubleshoot .....	2950
Increase Amazon EC2 Instance Limit .....	2960
Update Data Wrangler .....	2961
Shut Down Data Wrangler .....	2963
<b>Processing jobs .....</b>	<b>2965</b>
Sample Notebooks .....	2966
CloudWatch Logs and Metrics .....	2967

Run a Processing Job with Apache Spark .....	2967
Run a Processing Job with scikit-learn .....	2968
Data Processing with Framework Processors .....	2969
Hugging Face Framework Processor .....	2970
MXNet Framework Processor .....	2972
PyTorch Framework Processor .....	2973
TensorFlow Framework Processor .....	2974
XGBoost Framework Processor .....	2976
Use Your Own Processing Code .....	2977
Run Scripts with a Processing Container .....	2978
How to Build Your Own Processing Container .....	2980
<b>Create, store, and share features .....</b>	<b>2987</b>
How Feature Store works .....	2988
Create feature groups .....	2989
Find, discover, and share features .....	2989
Real-time inference for features stored in the online store .....	2989
Offline store for model training and batch inference .....	2989
Feature data ingestion .....	2990
Resilience in Feature Store .....	2990
Get started with Amazon SageMaker Feature Store .....	2990
Feature Store concepts .....	2991
Adding policies to your IAM role .....	2998
Use Feature Store with SDK for Python (Boto3) .....	2998
Using Amazon SageMaker Feature Store in the console .....	3016
Delete a feature group .....	3016
Data sources and ingestion .....	3031
Stream ingestion .....	3031
Data Wrangler with Feature Store .....	3032
Feature Store Spark .....	3033
Feature Processing .....	3043
Feature Store Feature Processor SDK .....	3044
Running Feature Store Feature Processor remotely .....	3047
Creating and running Feature Store Feature Processor pipelines .....	3048
Scheduled and event based executions for Feature Processor pipelines .....	3050
Monitor Amazon SageMaker Feature Store Feature Processor pipelines .....	3052
IAM permissions and execution roles .....	3053

Feature Processor restrictions, limits, and quotas .....	3054
Data sources .....	3055
Example Feature Processing code for common use cases .....	3070
Time to live (TTL) duration for records .....	3074
Cross account feature group discoverability and access .....	3076
Enabling cross account discoverability .....	3078
Enabling cross account access .....	3083
Feature Store storage configurations .....	3094
Online store .....	3094
Offline store .....	3096
Throughput modes .....	3097
Collection types .....	3101
Add features and records to a feature group .....	3102
API .....	3102
Example code .....	3103
Find features in your feature groups .....	3105
How to search for your features .....	3106
Find feature groups in your Feature Store .....	3110
How to find feature groups .....	3112
Adding searchable metadata to your features .....	3119
How to add searchable metadata to your features .....	3119
Create a dataset from your feature groups .....	3127
Using the Amazon SageMaker Python SDK to get your data from your feature groups ....	3128
Sample Amazon Athena queries .....	3133
Delete records from your feature groups .....	3134
Delete records from the online store .....	3135
Delete records from the offline store .....	3137
Logging Feature Store operations by using AWS CloudTrail .....	3139
Management events .....	3140
Data events .....	3140
Security and access control .....	3142
Using AWS KMS permissions for Amazon SageMaker Feature Store .....	3142
Authorizing use of a customer managed Key for your online store .....	3143
Using grants to authorize Feature Store .....	3145
Monitoring Feature Store interaction with AWS KMS .....	3146
Accessing data in your online store .....	3146

Authorizing use of a customer managed key for your offline store .....	3146
Quotas, naming rules and data types .....	3147
Quota terminologies .....	3147
Limits and quotas .....	3147
Naming rules .....	3148
Data types .....	3148
Amazon SageMaker Feature Store offline store data format .....	3149
Amazon SageMaker Feature Store offline store URI structures .....	3149
Amazon SageMaker Feature Store resources .....	3151
Feature Store example notebooks and workshops .....	3151
Feature Store Python SDK and API .....	3152
<b>Reserve capacity with SageMaker training plans .....</b>	<b>3153</b>
What is SageMaker training plans .....	3153
Benefits .....	3154
Reservation .....	3154
User workflow .....	3155
Supported instance types, AWS Regions, and pricing .....	3157
Search behavior .....	3158
Considerations .....	3159
IAM for SageMaker training plans .....	3160
Managed policies .....	3161
Individual permissions .....	3161
Training plans creation .....	3165
Create a training plan using the console UI .....	3166
Create a training plan programmatically .....	3173
Training plans utilization for SageMaker training jobs .....	3182
Checkpoint your training job .....	3183
Create a training job using the console UI .....	3185
Create a training job programmatically .....	3187
Training plans utilization for SageMaker HyperPod clusters .....	3190
Create an HyperPod cluster on a training plan using the console UI .....	3191
Update an HyperPod cluster on a training plan using the console UI .....	3192
Create an HyperPod cluster on a training plan programmatically .....	3193
Update an HyperPod cluster on a training plan programmatically .....	3194
Quotas and pricing .....	3195
Release notes .....	3198

December 04, 2024 .....	3198
<b>Model training .....</b>	<b>3199</b>
The basic architecture of SageMaker Training .....	3199
Full view of the SageMaker Training workflow and features .....	3200
Before training .....	3202
During training .....	3204
After training .....	3206
Model Training .....	3208
Choosing a feature within Amazon SageMaker Training .....	3208
Additional options .....	3210
Types of Algorithms .....	3211
Choose an algorithm implementation .....	3212
Problem types for the basic machine learning paradigms .....	3215
Built-in algorithms and pretrained models .....	3218
Use Reinforcement Learning .....	3661
Run local code as a remote job .....	3670
Set up your environment .....	3671
Invoke a remote function .....	3679
Configuration file .....	3690
Customize your runtime environment .....	3692
Container image compatibility .....	3693
Logging parameters and metrics with Amazon SageMaker Experiments .....	3699
Using modular code with the @remote decorator .....	3703
Private repository for runtime dependencies .....	3706
Example notebooks .....	3708
Experiments with MLflow .....	3709
MLflow integrations .....	3709
Supported AWS Regions .....	3710
How it works .....	3710
Tracking servers .....	3715
Launch MLflow UI .....	3728
Integrate MLflow with your environment .....	3731
Tutorials .....	3742
Troubleshooting .....	3743
Cleanup .....	3744
Studio Classic .....	3747

Automatic Model Tuning .....	3751
Hyperparameter tuning strategies .....	3753
Define metrics and environment variables .....	3756
Define Hyperparameter Ranges .....	3759
Track and set completion criteria .....	3765
Tune Multiple Algorithms .....	3769
Example: Hyperparameter Tuning Job .....	3781
Stop Training Jobs Early .....	3798
Run a Warm Start Hyperparameter Tuning Job .....	3800
Resource Limits for Automatic Model Tuning .....	3806
Best Practices for Hyperparameter Tuning .....	3809
Data refining during training .....	3812
How SageMaker smart sifting works .....	3813
Supported frameworks and AWS Regions .....	3815
SageMaker smart sifting within your training script .....	3816
Troubleshooting .....	3827
Security in SageMaker smart sifting .....	3827
SageMaker smart sifting Python SDK reference .....	3828
Release notes .....	3831
Debugging and improving model performance .....	3832
TensorBoard in SageMaker AI .....	3833
SageMaker Debugger .....	3851
Access a training container through SSM for remote debugging .....	4023
Release notes .....	4032
Profile and optimize computational performance .....	4034
SageMaker Profiler .....	4036
Monitor AWS compute resource utilization in SageMaker Studio Classic .....	4060
Release notes .....	4142
Distributed training .....	4143
Distributed training concepts .....	4144
Get started with distributed training in Amazon SageMaker AI .....	4147
Strategies for distributed training .....	4153
Distributed training optimization .....	4155
Scaling training .....	4156
SageMaker AI distributed data parallelism library .....	4159
SageMaker model parallelism library v2 .....	4225

Distributed computing with SageMaker AI best practices .....	4430
Training Compiler .....	4435
What Is SageMaker Training Compiler? .....	4435
How It Works .....	4436
Supported Frameworks, AWS Regions, Instance Types, and Tested Models .....	4438
Bring Your Own Deep Learning Model .....	4472
Enable Training Compiler .....	4484
Example Notebooks and Blogs .....	4505
Best Practices and Considerations .....	4506
Training Compiler FAQ .....	4510
Troubleshooting .....	4512
Release Notes .....	4519
Setting up training jobs to access datasets .....	4525
SageMaker AI input modes and AWS cloud storage options .....	4526
Configure data input mode using the SageMaker Python SDK .....	4528
Configure data input channel to use Amazon FSx for Lustre .....	4530
Choosing an input mode and a storage unit .....	4534
Use attribute-based access control (ABAC) for multi-tenancy training .....	4537
Mapping of training storage paths .....	4541
Overview of how SageMaker AI maps storage paths .....	4542
Uncompressed model output .....	4543
Managing storage paths for different types of instance local storage .....	4544
SageMaker AI environment variables and the default paths for training storage locations .....	4545
Heterogeneous clusters .....	4548
Configure a training job with a heterogeneous cluster in Amazon SageMaker AI .....	4549
Run distributed training on a heterogeneous cluster in Amazon SageMaker AI .....	4553
Modify your training script to assign instance groups .....	4557
Use Incremental Training .....	4559
Perform Incremental Training (Console) .....	4560
Perform Incremental Training (API) .....	4563
Managed Spot Training .....	4566
Managed Spot Training Lifecycle .....	4568
Managed Warm Pools .....	4568
How it works .....	4569
Considerations .....	4574

---

Request a warm pool quota increase .....	4574
Use SageMaker AI managed warm pools .....	4575
CloudWatch Metrics for Training Jobs .....	4581
Define Training Metrics .....	4582
View training job metrics .....	4585
Example: Viewing a Training and Validation Curve .....	4588
Augmented Manifest Files .....	4589
Augmented Manifest File format .....	4590
Augmented Manifest File Format for Pipe Mode Training .....	4591
Use an Augmented Manifest File .....	4592
Checkpoints in SageMaker AI .....	4595
Frameworks and algorithms .....	4596
Considerations for checkpointing .....	4597
Enable checkpointing .....	4598
Browse checkpoint files .....	4600
Resume training from a checkpoint .....	4601
Cluster repairs for GPU errors .....	4601
<b>Deploy models for inference .....</b>	<b>4603</b>
Choosing a feature .....	4603
Use cases .....	4603
Recommended features .....	4604
Additional options .....	4605
Model Deployment .....	4606
Options for deploying models and getting inferences .....	4606
Before you begin .....	4607
Steps for model deployment .....	4607
Inference options .....	4608
Advanced endpoint options .....	4610
Next steps .....	4610
Model creation with ModelBuilder .....	4612
Build your model with ModelBuilder .....	4613
Define serialization and deserialization methods .....	4614
Customize model loading and handling of requests .....	4617
Build your model and deploy .....	4618
Bring your own container (BYOC) .....	4619
Using ModelBuilder in local mode .....	4620

ModelBuilder examples .....	4622
Inference optimization .....	4622
Optimization techniques .....	4623
Deploy a pre-optimized model .....	4625
Create an optimization job .....	4630
View the optimization job results .....	4644
Evaluate performance .....	4644
Supported models reference .....	4648
Options for evaluating your model .....	4656
Inference Recommender .....	4658
How it Works .....	4658
How to Get Started .....	4658
Example notebooks .....	4659
Prerequisites .....	4659
Recommendation jobs .....	4671
Real-time inference .....	4732
Deploy models .....	4733
Invoke models .....	4760
Endpoints .....	4767
Hosting options .....	4775
Automatic scaling .....	4855
Instance storage volumes .....	4884
Validation of models in production .....	4885
Online explainability .....	4898
Fine-tune with adapters .....	4924
Serverless Inference .....	4927
How it works .....	4928
Getting started .....	4931
Serverless endpoint operations .....	4932
Alarms and logs .....	4949
Automatically scale Provisioned Concurrency for a serverless endpoint .....	4951
Troubleshooting .....	4965
Asynchronous inference .....	4966
How It Works .....	4966
How Do I Get Started? .....	4967
Asynchronous endpoint operations .....	4967

Alarms and logs .....	4980
Check prediction results .....	4985
Autoscale an asynchronous endpoint .....	4988
Troubleshooting .....	4992
Batch transform .....	5000
Use batch transform to get inferences from large datasets .....	5001
Speed up a batch transform job .....	5003
Use batch transform to test production variants .....	5003
Sample Notebooks .....	5003
Associate Prediction Results with Input .....	5003
Storage in Batch Transform .....	5011
Troubleshooting .....	5012
Model parallelism and large model inference .....	5013
The LMI container documentation .....	5014
SageMaker AI endpoint parameters for LMI .....	5014
Deploying uncompressed models .....	5016
Deploy large models for inference with TorchServe .....	5017
Deployment guardrails .....	5027
How to get started .....	5028
Auto-Rollback Configuration and Monitoring .....	5029
Blue/Green Deployments .....	5033
Use rolling deployments .....	5048
Exclusions .....	5053
Shadow tests .....	5054
Create a shadow test .....	5055
How to view, monitor, and edit shadow tests .....	5060
Complete a shadow test .....	5067
Best practices .....	5070
Access containers through SSM .....	5070
Allowlist .....	5071
Enable SSM access .....	5071
IAM configuration .....	5072
SSM access with AWS PrivateLink .....	5073
Logging with Amazon CloudWatch Logs .....	5073
Accessing model containers .....	5074
Model servers .....	5075

---

Deploy models with TorchServe .....	5075
Deploy models with DJL Serving .....	5082
Model deployment with Triton Inference Server .....	5088
Model deployment at the edge .....	5097
Why Use Edge Manager? .....	5097
How Does it Work? .....	5097
How Do I Use SageMaker Edge Manager? .....	5098
First Steps .....	5098
Setup for Devices and Fleets .....	5121
How to Package Model .....	5129
The Edge Manager Agent .....	5136
Manage Model .....	5157
SageMaker Edge Manager end of life .....	5169
Model optimization with Neo .....	5171
What is SageMaker Neo? .....	5171
How it Works .....	5172
Compile Models .....	5172
Cloud Instances .....	5194
Edge Devices .....	5233
Troubleshoot Errors .....	5266
Stateful sessions .....	5276
How stateful sessions work .....	5277
Example implementation .....	5280
Best practices .....	5280
Best practices for deploying models on SageMaker AI Hosting Services .....	5280
Monitor Security Best Practices .....	5282
Low latency real-time inference with AWS PrivateLink .....	5282
Migrate inference workload from x86 to AWS Graviton .....	5284
Troubleshoot deployments .....	5288
Inference cost optimization best practices .....	5290
Best practices to minimize interruptions during GPU driver upgrades .....	5293
Best practices for endpoint security .....	5297
Updating containers for the NVIDIA Container Toolkit .....	5299
Supported features .....	5303
Resources .....	5309
Blogs, example notebooks, and additional resources .....	5310

# What is Amazon SageMaker AI?

Amazon SageMaker AI is a fully managed machine learning (ML) service. With SageMaker AI, data scientists and developers can quickly and confidently build, train, and deploy ML models into a production-ready hosted environment. It provides a UI experience for running ML workflows that makes SageMaker AI ML tools available across multiple integrated development environments (IDEs).

With SageMaker AI, you can store and share your data without having to build and manage your own servers. This gives you or your organizations more time to collaboratively build and develop your ML workflow, and do it sooner. SageMaker AI provides managed ML algorithms to run efficiently against extremely large data in a distributed environment. With built-in support for bring-your-own-algorithms and frameworks, SageMaker AI offers flexible distributed training options that adjust to your specific workflows. Within a few steps, you can deploy a model into a secure and scalable environment from the SageMaker AI console.

## Amazon SageMaker AI rename

On December 03, 2024, Amazon SageMaker was renamed to Amazon SageMaker AI. This name change does not apply to any of the existing Amazon SageMaker features.

## Legacy namespaces remain the same

The `sagemaker` API namespaces, along with the following related namespaces, remain unchanged for backward compatibility purposes.

- AWS CLI commands
- [Managed policies](#) containing `AmazonSageMaker` prefixes

- [Service endpoints](#) containing sagemaker
- [AWS CloudFormation](#) resources containing AWS::SageMaker prefixes
- Service-linked role containing AWSServiceRoleForSageMaker
- Console URLs containing sagemaker
- Documentation URLs containing sagemaker

## Amazon SageMaker and Amazon SageMaker AI

On December 03, 2024, Amazon released the next generation of Amazon SageMaker.

Amazon SageMaker is a unified platform for data, analytics, and AI. Bringing together AWS machine learning and analytics capabilities, the next generation of SageMaker delivers an integrated experience for analytics and AI with unified access to all your data.

Amazon SageMaker includes the following capabilities:

- Amazon SageMaker AI (formerly Amazon SageMaker) - Build, train, and deploy ML and foundation models, with fully managed infrastructure, tools, and workflows
- Amazon SageMaker Lakehouse – Unify data access across Amazon S3 data lakes, Amazon Redshift, and other data sources
- Amazon SageMaker Data and AI Governance – Discover, govern, and collaborate on data and AI securely with Amazon SageMaker Catalog, built on Amazon DataZone
- SQL Analytics - Gain insights with the most price-performant SQL engine with Amazon Redshift
- Amazon SageMaker Data Processing - Analyze, prepare, and integrate data for analytics and AI using open-source frameworks on Amazon Athena, Amazon EMR, and AWS Glue
- Amazon SageMaker Unified Studio (preview) – Build with all your data and tools for analytics and AI in a single development environment
- Amazon Bedrock - Build and scale generative AI applications

For more information, refer to [Amazon SageMaker](#).

## Pricing for Amazon SageMaker AI

For information about [AWS Free Tier](#) limits and the cost of using SageMaker AI, see [Amazon SageMaker AI Pricing](#).

# Recommendations for a first-time user of Amazon SageMaker AI

If you're a first-time user of SageMaker AI, we recommend that you complete the following:

1. [Overview of machine learning with Amazon SageMaker AI](#) – Get an overview of the machine learning (ML) lifecycle and learn about solutions that are offered. This page explains key concepts and describes the core components involved in building AI solutions with SageMaker AI.
2. [Guide to getting set up with Amazon SageMaker AI](#) – Learn how to set up and use SageMaker AI based on your needs.
3. [Automated ML, no-code, or low-code](#) – Learn about low-code and no-code ML options that simplify a ML workflow by automating machine learning tasks. These options are helpful ML learning tools because they provide visibility into the code by generating notebooks for each of the automated ML tasks.
4. [Machine learning environments offered by Amazon SageMaker AI](#) – Familiarize yourself with the ML environments that you can use to develop your ML workflow, such as information and examples about ready-to-use and custom models.
5. **Explore other topics** – Use the SageMaker AI Developer Guide's table of contents to explore more topics. For example, you can find information about ML lifecycle stages, in [Overview of machine learning with Amazon SageMaker AI](#), and various solutions that SageMaker AI offers.
6. [Amazon SageMaker AI resources](#) – Refer to the various developer resources that SageMaker AI offers.

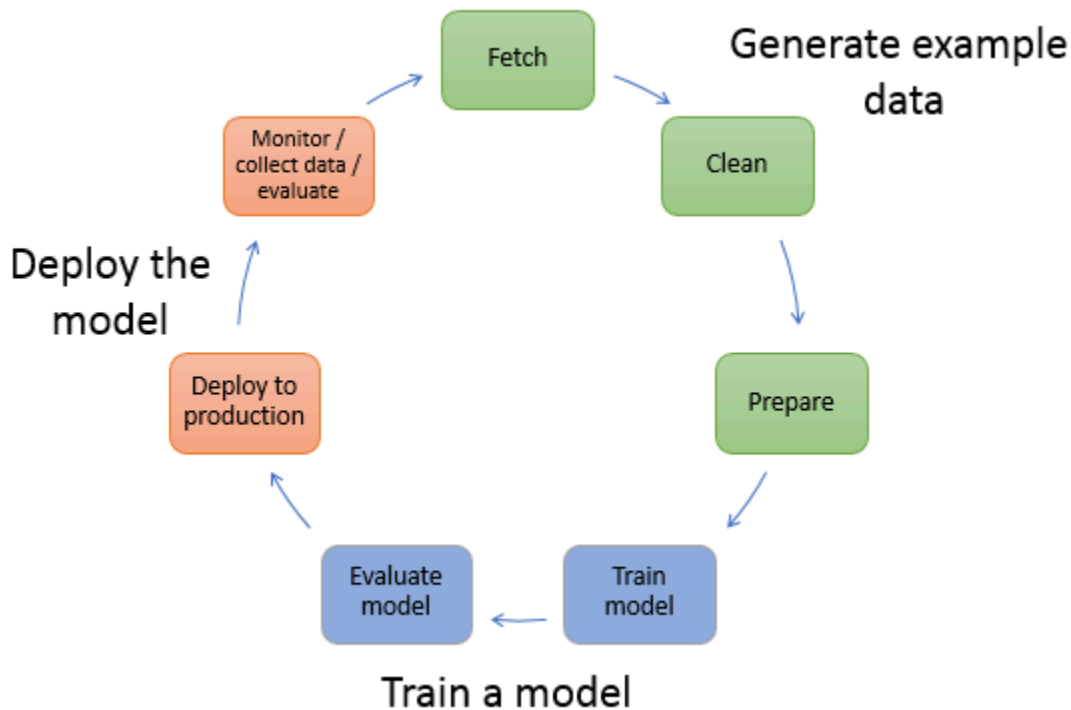

## Overview of machine learning with Amazon SageMaker AI

This section describes a typical machine learning (ML) workflow and describes how to accomplish those tasks with Amazon SageMaker AI.

In machine learning, you *teach* a computer to make predictions or inferences. First, you use an algorithm and example data to train a model. Then, you integrate your model into your application to generate inferences in real time and at scale.

The following diagram shows the typical workflow for creating an ML model. It includes three stages in a circular flow that we cover in more detail proceeding the diagram:

- Generate example data
- Train a model
- Deploy the model

The diagram shows how to perform the following tasks in most typical scenarios:

1. **Generate example data** – To train a model, you need example data. The type of data that you need depends on the business problem that you want the model to solve. This relates to the inferences that you want the model to generate. For example, if you want to create a model that predicts a number from an input image of a handwritten digit. To train this model, you need example images of handwritten numbers.

Data scientists often devote time exploring and preprocessing example data before using it for model training. To preprocess data, you typically do the following:

- a. **Fetch the data** – You might have in-house example data repositories, or you might use datasets that are publicly available. Typically, you pull the dataset or datasets into a single repository.

- b. **Clean the data** – To improve model training, inspect the data and clean it, as needed. For example, if your data has a `country_name` attribute with values `United States` and `US`, you can edit the data to be consistent.
- c. **Prepare or transform the data** – To improve performance, you might perform additional data transformations. For example, you might choose to combine attributes for a model that predicts the conditions that require de-icing an aircraft. Instead of using temperature and humidity attributes separately, you can combine those attributes into a new attribute to get a better model.

In SageMaker AI, you can preprocess example data using [SageMaker APIs](#) with the [SageMaker Python SDK](#) in an integrated development environment (IDE). With SDK for Python (Boto3) you can fetch, explore, and prepare your data for model training. For information about data preparation, processing, and transforming your data, see [Recommendations for choosing the right data preparation tool in SageMaker AI](#), [Data transformation workloads with SageMaker Processing](#), and [Create, store, and share features with Feature Store](#).

2. **Train a model** – Model training includes both training and evaluating the model, as follows:
  - **Training the model** – To train a model, you need an algorithm or a pre-trained base model. The algorithm you choose depends on a number of factors. For a built-in solution, you can use one of the algorithms that SageMaker provides. For a list of algorithms provided by SageMaker and related considerations, see [Built-in algorithms and pretrained models in Amazon SageMaker](#). For a UI-based training solution that provides algorithms and models, see [SageMaker JumpStart pretrained models](#).

You also need compute resources for training. Your resource use depends on the size of your training dataset and how quickly you need the results. You can use resources ranging from a single general-purpose instance to a distributed cluster of GPU instances. For more information, see [Train a Model with Amazon SageMaker](#).

- **Evaluating the model** – After you train your model, you evaluate it to determine whether the accuracy of the inferences is acceptable. To train and evaluate your model, use the [SageMaker Python SDK](#) to send requests to the model for inferences through one of the available IDEs. For more information about evaluating your model, see [Data and model quality monitoring with Amazon SageMaker Model Monitor](#).
3. **Deploy the model** – You traditionally re-engineer a model before you integrate it with your application and deploy it. With SageMaker AI hosting services, you can deploy your model

independently, which decouples it from your application code. For more information, see [Deploy models for inference](#).

Machine learning is a continuous cycle. After deploying a model, you monitor the inferences, collect more high-quality data, and evaluate the model to identify drift. You then increase the accuracy of your inferences by updating your training data to include the newly collected high-quality data. As more example data becomes available, you continue retraining your model to increase accuracy.

## Amazon SageMaker AI Features

Amazon SageMaker AI includes the following features.

### Topics

- [New features for re:Invent 2024](#)
- [Machine learning environments](#)
- [Major features](#)

## New features for re:Invent 2024

SageMaker AI includes the following new features for re:Invent 2024.

### [HyperPod recipes](#)

You can run recipes within Amazon SageMaker HyperPod or as SageMaker training jobs. You use the HyperPod training adapter as the framework to help you run end-to-end training workflows. The training adapter is built on the NVIDIA NeMo framework and Neuronx Distributed Training package.

### [HyperPod in Studio](#)

In Amazon SageMaker Studio, you can launch machine learning workloads on HyperPod clusters and view HyperPod cluster information. The increased visibility into cluster details and hardware metrics can help your team identify the right candidate for your pre-training or fine-tuning workloads.

## [HyperPod task governance](#)

Amazon SageMaker HyperPod task governance is a robust management system designed to streamline resource allocation and ensure efficient utilization of compute resources across teams and projects for your Amazon EKS clusters. HyperPod task governance also provides Amazon EKS cluster Observability, offering real-time visibility into cluster capacity, compute availability and usage, team allocation and utilization, and task run and wait time information.

## [Amazon SageMaker Partner AI Apps](#)

With Amazon SageMaker Partner AI Apps, users get access to generative artificial intelligence (AI) and machine learning (ML) development applications built, published, and distributed by industry-leading application providers. Partner AI Apps are certified to run on SageMaker AI. With Partner AI Apps, users can accelerate and improve how they build solutions based on foundation models (FM) and classic ML models without compromising the security of their sensitive data, which stays completely within their trusted security configuration and is never shared with a third party.

## [Q Developer is available in Canvas](#)

You can chat with Amazon Q Developer in Amazon SageMaker Canvas using natural language for generative AI assistance with solving your machine learning problems. You can converse with Q Developer to discuss the steps of a machine learning workflow and leverage Canvas functionality such as data transforms, model building, and deployment.

## [SageMaker training plans](#)

Amazon SageMaker training plans are a compute reservation capability designed for large-scale AI model training workloads running on SageMaker training jobs and HyperPod clusters. They provide predictable access to high-demand GPU-accelerated computing resources within specified timelines. You can specify a desired timeline, duration, and maximum compute resources, and SageMaker training plans automatically manages infrastructure setup, workload execution, and fault recovery. This allows for efficiently planning and executing mission-critical AI projects with a predictable cost model.

# Machine learning environments

SageMaker AI includes the following machine learning environments.

## [SageMaker Canvas](#)

An auto ML service that gives people with no coding experience the ability to build models and make predictions with them.

## [Code Editor](#)

Code Editor extends Studio so that you can write, test, debug and run your analytics and machine learning code in an environment based on Visual Studio Code - Open Source ("Code-OSS").

## [SageMaker geospatial capabilities](#)

Build, train, and deploy ML models using geospatial data.

## [SageMaker HyperPod](#)

Amazon SageMaker HyperPod is a capability of SageMaker AI that provides an always-on machine learning environment on resilient clusters that you can run any machine learning workloads for developing large machine learning models such as large language models (LLMs) and diffusion models.

## [JupyterLab in Studio](#)

JupyterLab in Studio improves latency and reliability for Studio Notebooks

## [Studio](#)

Studio is the latest web-based experience for running ML workflows. Studio offers a suite of IDEs, including Code Editor, a new Jupyterlab application, RStudio, and Studio Classic.

## [Amazon SageMaker Studio Classic](#)

An integrated machine learning environment where you can build, train, deploy, and analyze your models all in the same application.

## [SageMaker Studio Lab](#)

A free service that gives customers access to AWS compute resources in an environment based on open-source JupyterLab.

## [RStudio on Amazon SageMaker AI](#)

An integrated development environment for R, with a console, syntax-highlighting editor that supports direct code execution, and tools for plotting, history, debugging and workspace management.

## Major features

SageMaker AI includes the following major features in alphabetical order excluding any SageMaker AI prefix.

### [Amazon Augmented AI](#)

Build the workflows required for human review of ML predictions. Amazon A2I brings human review to all developers, removing the undifferentiated heavy lifting associated with building human review systems or managing large numbers of human reviewers.

### [AutoML step](#)

Create an AutoML job to automatically train a model in Pipelines.

### [SageMaker Autopilot](#)

Users without machine learning knowledge can quickly build classification and regression models.

### [Batch Transform](#)

Preprocess datasets, run inference when you don't need a persistent endpoint, and associate input records with inferences to assist the interpretation of results.

### [SageMaker Clarify](#)

Improve your machine learning models by detecting potential bias and help explain the predictions that models make.

### [Collaboration with shared spaces](#)

A shared space consists of a shared JupyterServer application and a shared directory. All user profiles in a Amazon SageMaker AI domain have access to all shared spaces in the domain.

### [SageMaker Data Wrangler](#)

Import, analyze, prepare, and featurize data in SageMaker Studio. You can integrate Data Wrangler into your machine learning workflows to simplify and streamline data pre-processing and feature engineering using little to no coding. You can also add your own Python scripts and transformations to customize your data prep workflow.

### [Data Wrangler data preparation widget](#)

Interact with your data, get visualizations, explore actionable insights, and fix data quality issues.

## [SageMaker Debugger](#)

Inspect training parameters and data throughout the training process. Automatically detect and alert users to commonly occurring errors such as parameter values getting too large or small.

## [SageMaker Edge Manager](#)

Optimize custom models for edge devices, create and manage fleets and run models with an efficient runtime.

## [SageMaker Experiments](#)

Experiment management and tracking. You can use the tracked data to reconstruct an experiment, incrementally build on experiments conducted by peers, and trace model lineage for compliance and audit verifications.

## [SageMaker Feature Store](#)

A centralized store for features and associated metadata so features can be easily discovered and reused. You can create two types of stores, an Online or Offline store. The Online Store can be used for low latency, real-time inference use cases and the Offline Store can be used for training and batch inference.

## [SageMaker Ground Truth](#)

High-quality training datasets by using workers along with machine learning to create labeled datasets.

## [SageMaker Ground Truth Plus](#)

A turnkey data labeling feature to create high-quality training datasets without having to build labeling applications and manage the labeling workforce on your own.

## [SageMaker Inference Recommender](#)

Get recommendations on inference instance types and configurations (e.g. instance count, container parameters and model optimizations) to use your ML models and workloads.

## [Inference shadow tests](#)

Evaluate any changes to your model-serving infrastructure by comparing its performance against the currently deployed infrastructure.

## [SageMaker JumpStart](#)

Learn about SageMaker AI features and capabilities through curated 1-click solutions, example notebooks, and pretrained models that you can deploy. You can also fine-tune the models and deploy them.

## [SageMaker ML Lineage Tracking](#)

Track the lineage of machine learning workflows.

## [SageMaker Model Building Pipelines](#)

Create and manage machine learning pipelines integrated directly with SageMaker AI jobs.

## [SageMaker Model Cards](#)

Document information about your ML models in a single place for streamlined governance and reporting throughout the ML lifecycle.

## [SageMaker Model Dashboard](#)

A pre-built, visual overview of all the models in your account. Model Dashboard integrates information from SageMaker Model Monitor, transform jobs, endpoints, lineage tracking, and CloudWatch so you can access high-level model information and track model performance in one unified view.

## [SageMaker Model Monitor](#)

Monitor and analyze models in production (endpoints) to detect data drift and deviations in model quality.

## [SageMaker Model Registry](#)

Versioning, artifact and lineage tracking, approval workflow, and cross account support for deployment of your machine learning models.

## [SageMaker Neo](#)

Train machine learning models once, then run anywhere in the cloud and at the edge.

## [Notebook-based Workflows](#)

Run your SageMaker Studio notebook as a non-interactive, scheduled job.

## [Preprocessing](#)

Analyze and preprocess data, tackle feature engineering, and evaluate models.

## [SageMaker Projects](#)

Create end-to-end ML solutions with CI/CD by using SageMaker Projects.

## [Reinforcement Learning](#)

Maximize the long-term reward that an agent receives as a result of its actions.

## [SageMaker Role Manager](#)

Administrators can define least-privilege permissions for common ML activities using custom and preconfigured persona-based IAM roles.

## [SageMaker Serverless Endpoints](#)

A serverless endpoint option for hosting your ML model. Automatically scales in capacity to serve your endpoint traffic. Removes the need to select instance types or manage scaling policies on an endpoint.

## [Studio Classic Git extension](#)

A Git extension to enter the URL of a Git repository, clone it into your environment, push changes, and view commit history.

## [SageMaker Studio Notebooks](#)

The next generation of SageMaker notebooks that include AWS IAM Identity Center (IAM Identity Center) integration, fast start-up times, and single-click sharing.

## [SageMaker Studio Notebooks and Amazon EMR](#)

Easily discover, connect to, create, terminate and manage Amazon EMR clusters in single account and cross account configurations directly from SageMaker Studio.

## [SageMaker Training Compiler](#)

Train deep learning models faster on scalable GPU instances managed by SageMaker AI.

# Guide to getting set up with Amazon SageMaker AI

To use the features in Amazon SageMaker AI, you must have access to Amazon SageMaker AI. To set up Amazon SageMaker AI and its features, use one of the following options.

- [Use quick setup](#): Fastest setup for individual users with default settings.
- [Use custom setup](#): Advanced setup for enterprise Machine Learning (ML) administrators. Ideal option for ML administrators setting up SageMaker AI for many users or an organization.

## Note

You do not need to set up SageMaker AI if:

- An email is sent to you inviting you to create a password to use the IAM Identity Center authentication. The email also contains the AWS access portal URL you use to sign in. For more information about signing in to the AWS access portal, see [Sign in to the AWS access portal](#).
- You intend to use the Amazon SageMaker Studio Lab ML environment. Studio Lab does not require you to have an AWS account. For information about Studio Lab, see [Amazon SageMaker Studio Lab](#).
- If you are using the AWS CLI, SageMaker APIs, or SageMaker SDKs

You do not need to set up SageMaker AI if any of the prior situations apply. You can skip the rest of this [Guide to getting set up with Amazon SageMaker AI](#) chapter and navigate to the following:

- [Automated ML, no-code, or low-code](#)
- [Machine learning environments offered by Amazon SageMaker AI](#)
- [APIs, CLI, and SDKs](#)

## Topics

- [Complete Amazon SageMaker AI prerequisites](#)
- [Use quick setup for Amazon SageMaker AI](#)
- [Use custom setup for Amazon SageMaker AI](#)

- [Amazon SageMaker AI domain overview](#)
- [Supported Regions and Quotas](#)

## Complete Amazon SageMaker AI prerequisites

Before you can set up Amazon SageMaker AI, you must complete the following prerequisites.

- **Required:** You will need to create an Amazon Web Services (AWS) account to get access to all of the AWS services and resources for the account.
- **Highly recommended:** We highly recommend that you create an administrative user to manage AWS resources for the account, to adhere to the [Security best practices in IAM](#). It is assumed that you have an administrative user for many of the administrative tasks throughout the SageMaker AI developer guide.
- **Optional:** Configure the AWS Command Line Interface (AWS CLI) if you intend to manage your AWS services and resources for the account using the AWS CLI.

- [Sign up for an AWS account](#)
- [Create a user with administrative access](#)
- [\(Optional\) Configure the AWS CLI](#)

## Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

### To sign up for an AWS account

1. Open <https://portal.aws.amazon.com/billing/signup>.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign

administrative access to a user, and use only the root user to perform [tasks that require root user access](#).

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to <https://aws.amazon.com/> and choosing **My Account**.

## Create a user with administrative access

After you sign up for an AWS account, secure your AWS account root user, enable AWS IAM Identity Center, and create an administrative user so that you don't use the root user for everyday tasks.

### Secure your AWS account root user

1. Sign in to the [AWS Management Console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

For help signing in by using root user, see [Signing in as the root user](#) in the *AWS Sign-In User Guide*.

2. Turn on multi-factor authentication (MFA) for your root user.

For instructions, see [Enable a virtual MFA device for your AWS account root user \(console\)](#) in the *IAM User Guide*.

### Create a user with administrative access

1. Enable IAM Identity Center.

For instructions, see [Enabling AWS IAM Identity Center](#) in the *AWS IAM Identity Center User Guide*.

2. In IAM Identity Center, grant administrative access to a user.

For a tutorial about using the IAM Identity Center directory as your identity source, see [Configure user access with the default IAM Identity Center directory](#) in the *AWS IAM Identity Center User Guide*.

## Sign in as the user with administrative access

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see [Signing in to the AWS access portal](#) in the *AWS Sign-In User Guide*.

## Assign access to additional users

- In IAM Identity Center, create a permission set that follows the best practice of applying least-privilege permissions.

For instructions, see [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

- Assign users to a group, and then assign single sign-on access to the group.

For instructions, see [Add groups](#) in the *AWS IAM Identity Center User Guide*.

When you create an administrative user to set up SageMaker AI, the administrative user should include specific permissions to create SageMaker AI resources. To view the permissions, expand the following administrator permissions section.

## Administrator permissions

When you create your administrative user using the preceding instructions, your administrative user should already include the permissions contained in the [AmazonSageMakerFullAccess](#) policy, as well as the following permissions. These policies are needed to create a SageMaker AI domain among other tasks.

If you intend to create your own custom policy, these permissions are required to create a domain and get set up with SageMaker AI. For information about adding policies, see [Adding and removing IAM identity permissions](#) in the *AWS Identity and Access Management User Guide*.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
```

```

        "sagemaker:*"
    ],
    "Resource": [
        "arn:aws:sagemaker:*:*:domain/*",
        "arn:aws:sagemaker:*:*:user-profile/*",
        "arn:aws:sagemaker:*:*:app/*",
        "arn:aws:sagemaker:*:*:flow-definition/*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "iam:GetRole",
        "servicecatalog:*"
    ],
    "Resource": [
        "*"
    ]
}
]
}

```

**Optional:** If you intend to manage your AWS services and resources for the account using the AWS CLI, proceed to the following instructions ([\(Optional\) Configure the AWS CLI](#)).

**After you have completed your prerequisites,** continue on to the setup instructions. You can continue on to your setup instructions by choosing one of the following options.

- [Use quick setup](#): Fastest setup for individual users with default settings.
- [Use custom setup](#): Advanced setup for enterprise Machine Learning (ML) administrators. Ideal option for ML administrators setting up SageMaker AI for many users or an organization.

## (Optional) Configure the AWS CLI

To manage your domain and other AWS services and resources using the AWS CLI, complete the setup in [Set up the AWS CLI](#) in the *AWS Command Line Interface User Guide for Version 2*.

**After you have completed your prerequisites,** continue on to the setup instructions. You can continue on to your setup instructions by choosing one of the following options.

- [Use quick setup](#): Fastest setup for individual users with default settings.

- [Use custom setup](#): Advanced setup for enterprise Machine Learning (ML) administrators. Ideal option for ML administrators setting up SageMaker AI for many users or an organization.

## Use quick setup for Amazon SageMaker AI

The **Set up for single users** (quick setup) procedure gets you set up with default settings. Use this option if you want to get started with SageMaker AI quickly and you do not intend to customize your settings at this time. The default settings include granting access to the common SageMaker AI services for individual users to get started. For example, Amazon SageMaker Studio and Amazon SageMaker Canvas.

### Setup for single users (Quick setup)

After satisfying the prerequisites in [Complete Amazon SageMaker AI prerequisites](#), use the following instructions.

1. Open the [SageMaker AI console](#).
2. Open the left navigation pane.
3. Under **Admin configurations**, choose **Domains**.
4. Choose **Create domain**.
5. Choose **Set up for single user (Quick setup)**. Your domain and user profile are created automatically.

The **Set up for single user** process creates a domain and user profile for you automatically. If you want to learn about how the domain is set up for you when using the quick setup option, expand the following section.

#### Default settings

When you onboard to Amazon SageMaker AI domain using the **Set up for single user** procedure, your domain is automatically set up with the following default settings. For information about domains, see [Amazon SageMaker AI domain overview](#).

- **Domain name:** SageMaker AI automatically assigns the name of the domain with a timestamp in the following format.

```
QuickSetupDomain-YYYYMMDDTHMMSS
```

- **User profile name:** SageMaker AI automatically assigns the name of the user profile with a timestamp in the following format.

```
default-YYYYMMDDTHHMMSS
```

- **Domain execution role:** SageMaker AI creates a new IAM role and attaches the [AmazonSageMakerFullAccess](#) policy. When using the quick setup and the updated Amazon SageMaker Studio is your default experience, your IAM role also includes the [AmazonSageMakerCanvasFullAccess](#), [AmazonSageMakerCanvasAIServicesAccess](#), [AmazonS3FullAccess](#) policies.
- **User profile execution role:** SageMaker AI sets the user profile execution role to the same IAM role used for the domain execution role.
- **Shared space execution role:** SageMaker AI sets the shared space execution role to the same IAM role used for the domain execution role.
- **SageMaker Canvas time series forecasting role:** SageMaker AI creates a new IAM role with the permissions required to use the SageMaker Canvas time series forecasting feature.
- **Amazon S3 bucket:** SageMaker AI creates an Amazon S3 bucket named with the following format.

```
sagemaker-studio-XXXXXXXXXXXXXXXXXX
```

- **Amazon VPC:** SageMaker AI selects a public VPC with the following logic.
  1. If there is a default VPC with associated subnets in the Region, SageMaker AI uses it.
  2. If there is no default VPC or the default VPC has no associated subnets, then SageMaker AI uses any existing VPC with associated subnets. If there are multiple existing VPCs, SageMaker AI can select any of them.
- **Studio experience:** Amazon SageMaker Studio is set as the UI default experience and Studio Classic is made hidden. That is, in [UserSettings](#):
  - `DefaultLandingUri` is set to `studio:..`
  - [StudioWebPortalSettings](#) `HiddenAppTypes` is set to `["JupyterServer"]`

For information about hidden applications, see [Hide machine learning tools and applications in the Amazon SageMaker Studio UI](#).

After the domain is set up, the administrative user can [Edit domain settings](#).

## After quick setup

Do you want to start SageMaker AI features right away, and do not intend to learn about domains or customize your domain? If so, skip the rest of this [Guide to getting set up with Amazon SageMaker AI](#) chapter and do the following:

- Open the [SageMaker AI console](#) and choose an environment from the left navigation pane.

For example, choose **Studio** from the left navigation pane and choose **Open Studio**.

- Begin learning how to:
  - [Automated ML, no-code, or low-code](#)
  - [Machine learning environments offered by Amazon SageMaker AI](#)

RStudio support is not currently available when onboarding using the **Set up for single users** ([Use quick setup for Amazon SageMaker AI](#)) option. To use RStudio, you must onboard using the **Set up for organizations** ([Use custom setup for Amazon SageMaker AI](#)) option. For more information, see [Use custom setup for Amazon SageMaker AI](#).

## Use custom setup for Amazon SageMaker AI

The **Set up for organizations** (custom setup) guides you through an advanced setup for your Amazon SageMaker AI domain. This option provides information and recommendations to help you understand and control all aspects of the account configuration, including permissions, integrations, and encryption. Use this option if you want to set up a custom domain. For information about domains, see [Amazon SageMaker AI domain overview](#).

### Topics

- [Authentication methods](#)
- [Setup for organizations \(custom setup\)](#)
- [Access the domain after onboarding](#)

## Authentication methods

Before you set up the domain consider the authentication methods for your users to access the domain.

### AWS Identity Center:

- **Helps simplify administration of access permissions to groups of users.** You can grant or deny permissions to groups of users, instead of applying those permissions to each individual user. If a user moves to a different organization, you can move that user to a different AWS Identity and Access Management Identity center (AWS IAM Identity Center) group. The user then automatically receives the permissions that are needed for the new organization.

Note that the IAM Identity Center needs to be in the same AWS Region as the domain.

To set up with IAM Identity Center, use the following instructions from the *AWS IAM Identity Center User Guide*:

- Begin with [Enabling AWS IAM Identity Center](#).
- [Create a permission set](#) that follows the best practice of applying least-privilege permissions.
- [Add groups](#) to your IAM Identity Center directory.
- [Assign single sign-on access](#) to users and groups.
- View the basic workflows to [get started with common tasks in IAM Identity Center](#).
- The users in IAM Identity Center can access the domain using an AWS access portal URL that is emailed to them. The email provides instructions to create an account to access the domain. For more information, see [Sign in to the AWS access portal](#).

As an administrator you can find the AWS access portal URL by navigating to the [IAM Identity Center](#) and finding the **AWS access portal URL** under **Settings summary**.

- Your domain must use AWS Identity and Access Management (IAM) authentication if you wish to restrict access to your domains exclusively to particular Amazon Virtual Private Clouds (VPCs), interface endpoints, or a predefined set of IP addresses. This feature is not supported for domains that use IAM Identity Center authentication. You can still use IAM Identity Center to enable centralized workforce identity control. For instructions on how to implement these restrictions while keeping IAM Identity Center to provide a consistent user sign-in experience, see [Secure access to Amazon SageMaker Studio Classic with IAM Identity Center and a SAML application](#) in the *AWS machine learning blog*. Note that AWS SSO is IAM Identity Center in this blog.

### Login through IAM:

- The user profiles can access the domain through the SageMaker AI console after logging into the account.

- You can restrict access to your domains exclusively to particular Amazon Virtual Private Clouds (VPCs), interface endpoints, or a predefined set of IP addresses when using AWS Identity and Access Management (IAM) authentication. For more information, see [Allow Access Only from Within Your VPC](#).

## Setup for organizations (custom setup)

### Custom setup using the console

After satisfying the prerequisites in [Complete Amazon SageMaker AI prerequisites](#), open the **Set up SageMaker AI Domain** (custom setup) page and expand the following sections for information on the setup.

#### Open the Set up SageMaker AI Domain from the SageMaker AI console

1. Open the [SageMaker AI console](#).
2. On the left navigation pane, choose **Admin configurations** to expand the options.
3. Under **Admin configurations**, choose **Domains**.
4. From the **Domains** page, choose **Create domain**.
5. On the **Set up SageMaker AI domain** page, choose **Set up for organizations**.
6. Choose **Set up**.

Once you opened the **Set up SageMaker AI Domain** page, use the following instructions:

#### Step 1: Domain details

1. For **Domain name**, enter a unique name for your domain. For example, this can be your project or team name.
2. Choose **Next**.

#### Step 2: Users and ML Activities

In this step you set up the authentication method, users, and permissions for your domain.

1. Under **How do you want to access Studio?**, you can choose one of two options. For information on the authentication methods, see [Authentication methods](#). Details on the options are provided in the following:

- **AWS Identity Center:**

Under **Who will use Studio?** choose an AWS IAM Identity Center group that will access the domain.

If you choose **No Identity Center user group** you create a domain with no users. You can add IAM Identity Center groups to the domain after the domain's creation. For more information, see [Edit domain settings](#).

- **Login through IAM:**

Under **Who will use Studio?** choose **+ Add user**, enter a new user profile name, and choose **Add** to create and add a user profile name.

You can repeat this process to create multiple user profiles.

2. Under **Who will use Studio?** select the IAM Identity Center users or groups, then choose **Select**. You need to set up Amazon SageMaker Studio within the same Region in which your IAM Identity Center is configured. You can change the Region of your domain by choosing the Region from the dropdown list on the top right of the console or you can change your IAM Identity Center Region by navigating to the [AWS access portal](#).
3. Under **What ML activities do they perform?** you can use an existing role by choosing **Use an existing role** or you can create a new role by choosing **Create a new role** and checking the ML activities you want the role to have access.
4. While selecting ML activities, you may need to satisfy requirements. To satisfy a requirement, choose **Add** and complete the requirement.
5. After all requirements are satisfied, choose **Next**.

### Step 3: Applications

In this step, you can configure the applications you have enabled in the previous step. For more information on the ML activities, see [ML activity reference](#).

If the application has not been enabled, you receive a warning for that application. To enable an application that has not been enabled, return to the previous step by choosing **Back** and follow the previous instructions.

- **Studio** configuration:

Under **Studio**, you have the option to choose between the newer and classic version of Studio as your default experience. This means choosing which ML environment you interact with when you open Studio.

- **Studio** includes multiple integrated development environments (IDEs) and applications, including Amazon SageMaker Studio Classic. If chosen, the Studio Classic IDE has default settings. For information on the default settings, see [Default settings](#).

For information on Studio, see [Amazon SageMaker Studio](#).

- **Studio Classic** includes the Jupyter IDE. If chosen, you may configure your Studio Classic configuration.

For information on Studio Classic, see [Amazon SageMaker Studio Classic](#).

- **SageMaker Canvas** configuration:

If you have Amazon SageMaker Canvas enabled, see [Getting started with using Amazon SageMaker Canvas](#) for the instructions and configuration details for onboarding.

- **Studio Classic** configuration:

If you chose **Studio** (recommended) as your default experience, the Studio Classic IDE has default settings. For information on the default settings, see [Default settings](#).

If you chose Studio Classic as your default experience, you can choose to enable or disable notebook resource sharing. Notebook resources include artifacts such as cell output and Git repositories. For more information on Notebook resources, see [Share and Use an Amazon SageMaker Studio Classic Notebook](#).

If you enabled notebook resource sharing:

1. Under **S3 location for shareable notebook resources**, input your Amazon S3 location.
2. Under **Encryption key - optional**, leave as **No Custom Encryption** or choose an existing AWS KMS key or choose **Enter a KMS key ARN** and enter your AWS KMS key's ARN.
3. Under **Notebook cell output sharing preference**, choose **Allow users to share cell output** or **Disable cell output sharing**.

- **RStudio** configuration:

To enable RStudio, you need an RStudio license. To set that up, see [Get an RStudio license](#).

1. Under **RStudio Workbench**, verify that your RStudio license is automatically detected. For more information about getting an RStudio license and activating it with SageMaker AI, see [Get an RStudio license](#).
2. Select an instance type to launch your RStudio Server on. For more information, see [RStudioServerPro instance type](#).
3. Under **Permission**, create your role or select an existing role. The role must have the following permissions policy. This policy allows the RStudioServerPro application to access necessary resources. It also allows Amazon SageMaker AI to automatically launch an RStudioServerPro application when the existing RStudioServerPro application is in a Deleted or Failed status. For information about adding permissions to a role, see [Modifying a role permissions policy \(console\)](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "license-manager:ExtendLicenseConsumption",
        "license-manager:ListReceivedLicenses",
        "license-manager:GetLicense",
        "license-manager:CheckoutLicense",
        "license-manager:CheckInLicense",
        "logs:CreateLogDelivery",
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs>DeleteLogDelivery",
        "logs:Describe*",
        "logs:GetLogDelivery",
        "logs:GetLogEvents",
        "logs:ListLogDeliveries",
        "logs:PutLogEvents",
        "logs:PutResourcePolicy",
        "logs:UpdateLogDelivery",
        "sagemaker:CreateApp"
      ],
      "Resource": "*"
    }
  ]
}
```

```
}
```

4. Under **RStudio Connect**, add the URL for your RStudio Connect server. RStudio Connect is a publishing platform for Shiny applications, R Markdown reports, dashboards, plots, and more. When you onboard to RStudio on SageMaker AI, an RStudio Connect server is not created. For more information, see [Add an RStudio Connect URL](#).
  5. Under **RStudio Package Manager**, add the URL for your RStudio Package Manager. SageMaker AI creates a default package repository for the Package Manager when you onboard RStudio. For more information about RStudio Package Manager, see [Update the RStudio Package Manager URL](#).
  6. Select **Next**.
- **Code Editor** configuration:  
  
If you have Code Editor enabled, see [Code Editor in Amazon SageMaker Studio](#) for an overview and the configuration details.

#### Step 4: Customize Studio UI

In this section you can customize the viewable applications and machine learning (ML) tools displayed in Studio. This customization only hides the applications and ML tools in the left navigation pane in Studio. For information on the Studio UI, see [Amazon SageMaker Studio UI overview](#).

For information about the applications, see [Applications supported in Amazon SageMaker Studio](#).

The customize Studio UI feature is not available in Studio Classic. If you wish to set Studio as your default experience, choose **Previous** and to return to the previous step.

1. On the **Customize Studio UI** page you can hide applications and ML tools displayed in Studio by toggling them off.
2. Once you have reviewed your changes, choose **Next**.

#### Step 5: Set up network settings

Choose how you want Studio to connect to other AWS services.

You can choose to disable internet access to your Studio by specifying using **Virtual Private Cloud (VPC) Only** network access type. If you choose this option, you cannot run a Studio notebook unless your VPC has an interface endpoint to the SageMaker API and runtime, or a Network

Address Translation (NAT) gateway with internet access, and your security groups allow outbound connections. For more information on Amazon VPCs, see [Choose an Amazon VPC](#).

If you choose Virtual Private Cloud (VPC) Only the following steps are required. If you choose **Public internet access**, the first two of the following steps are required.

1. Under **VPC**, choose the Amazon VPC ID.
2. Under **Subnet**, choose one or more subnets. If you don't choose any subnets, SageMaker AI uses all the subnets in the Amazon VPC. We recommend that you use multiple subnets that are not created in constrained Availability Zones. Using subnets in these constrained Availability Zones can result in insufficient capacity errors and longer application creation times. For more information about constrained Availability Zones, see [Availability Zones](#).
3. Under **Security group(s)**, choose one or more subnets.

If **VPC only** is selected, SageMaker AI automatically applies the security group settings defined for the domain to all shared spaces created in the domain. If **Public internet only** is selected, SageMaker AI does not apply the security group settings to shared spaces created in the domain.

## Step 6: Configure storage

You have the option to encrypt your data. The [Amazon Elastic File System \(Amazon EFS\)](#) and [Amazon Elastic Block Store \(Amazon EBS\)](#) file systems that are created for you when you create a domain. Amazon EBS sizes are used by both Code Editor and JupyterLab spaces.

You cannot change the encryption key after you encrypt your Amazon EFS and Amazon EBS file systems. To encrypt your Amazon EFS and Amazon EBS file systems, you can use the following configurations.

- Under **Encryption key - optional**, leave as **No Custom Encryption** or choose an existing KMS key or choose **Enter a KMS key ARN** and enter the ARN of your KMS key.
- Under **Default space size - optional**, enter the default space size.
- Under **Maximum space size - optional**, enter the maximum space size.

## Step 7: Review and create

Review your domain settings. If you need to change the settings, choose **Edit** next to the relevant step. Once you confirm that your domain settings are accurate, choose **Submit** and the domain is created for you. This process may take a few minutes.

## Custom setup using the AWS CLI

The following sections provide AWS CLI instructions for the custom setup your domain using the IAM Identity Center or IAM authentication methods.

After satisfying the prerequisites, including setting up your AWS CLI credentials, in [Complete Amazon SageMaker AI prerequisites](#), use the following the steps.

1. Create an execution role that is used to create a domain and attach the [AmazonSageMakerFullAccess](#) policy. You can also use an existing role that has, at a minimum, an attached trust policy that grants SageMaker AI permission to assume the role. For more information, see [How to use SageMaker AI execution roles](#).

```
aws iam create-role --role-name execution-role-name --assume-role-policy-document file://execution-role-trust-policy.json
aws iam attach-role-policy --role-name execution-role-name --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
```

2. Get the default Amazon Virtual Private Cloud (Amazon VPC) of your account.

```
aws --region region ec2 describe-vpcs --filters Name=isDefault,Values=true --query "Vpcs[0].VpcId" --output text
```

3. Get the list of subnets in the default Amazon VPC.

```
aws --region region ec2 describe-subnets --filters Name=vpc-id,Values=default-vpc-id --query "Subnets[*].SubnetId" --output json
```

4. Create a domain by passing the default Amazon VPC ID, subnets, and execution role ARN. You must also pass a SageMaker image ARN. For information on the available JupyterLab version ARNs, see [Setting a default JupyterLab version](#).

For *authentication-mode*, use SSO for IAM Identity Center authentication or IAM for IAM authentication.

```
aws --region region sagemaker create-domain --domain-name domain-name --vpc-id default-vpc-id --subnet-ids subnet-ids --auth-mode authentication-mode --default-user-settings "ExecutionRole=arn:aws:iam::account-number:role/execution-role-name,JupyterServerAppSettings={DefaultResourceSpec={InstanceType=system,SageMakerImageArn=arn}}" \ --query DomainArn --output text
```

You can use the AWS CLI to customize the applications and ML tools displayed in Studio for the domain, using [StudioWebPortalSettings](#). Use `HiddenAppTypes` to hide applications and `HiddenMLTools` to hide ML tools. For more information on customizing the left navigation of the Studio UI, see [Hide machine learning tools and applications in the Amazon SageMaker Studio UI](#). This feature is not available for Studio Classic.

5. Verify that the domain has been created.

```
aws --region region sagemaker list-domains
```

## Custom setup using AWS CloudFormation

For information about creating a domain using AWS CloudFormation, see [AWS::SageMaker::Domain](#) in the *AWS CloudFormation User Guide*.

For an example of an AWS CloudFormation template that you can use to set up your domain, see [Creating Amazon SageMaker AI domains using AWS CloudFormation](#) in the `aws-samples` GitHub repository.

After the domain is set up, the administrative user can view and edit the domain. For information, see [View domains](#) and [Edit domain settings](#).

## Access the domain after onboarding

The users can access SageMaker AI using:

- The sign-in URL if the domain was set up using the IAM Identity Center authentication. For information, see [How to sign in to the user portal](#).
- The [SageMaker AI console](#).

## Amazon SageMaker AI domain overview

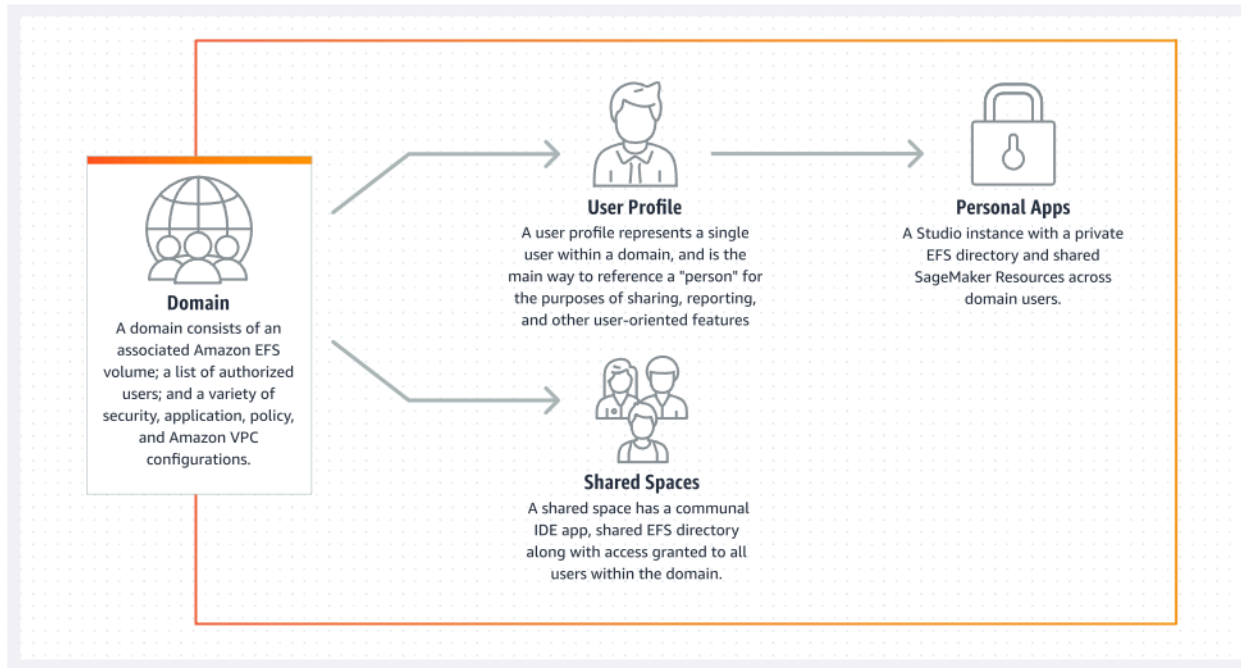

Amazon SageMaker AI uses domains to organize user profiles, applications, and their associated resources. An Amazon SageMaker AI domain consists of the following:

- An associated Amazon Elastic File System (Amazon EFS) volume
- A list of authorized users

- A variety of security, application, policy, and Amazon Virtual Private Cloud (Amazon VPC) configurations

The following diagram provides an overview of private apps and shared spaces within each domain.

To have access to most Amazon SageMaker AI environments and resources, you must complete the Amazon SageMaker AI domain onboarding process using the SageMaker AI console or the AWS CLI. For a guide describing how to get started using SageMaker AI based on how you want to access SageMaker AI, and if necessary how to set up a domain, see [Guide to getting set up with Amazon SageMaker AI](#).

## Topics

- [Amazon SageMaker AI domain entities and statuses](#)
- [Choose an Amazon VPC](#)

## Amazon SageMaker AI domain entities and statuses

Amazon SageMaker AI domain supports SageMaker AI machine learning (ML) environments. A SageMaker AI domain is composed of the following entities and their associated status values. For onboarding steps to create a domain, see [Amazon SageMaker AI domain overview](#).

- **Domain:** A domain consists of the following.

- An associated Amazon Elastic File System (Amazon EFS) volume.
- A list of authorized users.
- A variety of security, application, policy, and Amazon Virtual Private Cloud (Amazon VPC) configurations.

Users within a domain can share notebook files and other artifacts with each other. An account can have multiple domains. For more information about multiple domains, see [Multiple domains overview](#).

- **User profile:** A user profile represents a single user within a domain. It is the main way to reference a user for the purposes of sharing, reporting, and other user-oriented features. This entity is created when a user onboards to the Amazon SageMaker AI domain. For more information about user profiles, see [Domain user profiles](#).
- **Shared space:** A shared space consists of a shared JupyterServer application and shared directory. All users within the domain have access to the shared space. All user profiles in a domain have access to all shared spaces in the domain. For more information about shared spaces, see [Collaboration with shared spaces](#).
- **App:** An app represents an application that supports the reading and execution experience of the user's notebooks, terminals, and consoles. The type of app can be JupyterServer, KernelGateway, RStudioServerPro, or RSession. A user may have multiple apps active simultaneously.

The following tables describe the status values for the domain, UserProfile, shared space, and App entities. Where applicable, they also give troubleshooting steps.

#### domain status values

Value	Description
Pending	Ongoing creation of domain.
InService	Successful creation of domain.
Updating	Ongoing update of domain.
Deleting	Ongoing deletion of domain.
Failed	Unsuccessful creation of domain. Call the DescribeDomain API to see the failure

Value	Description
	reason for domain creation. Delete the failed domain and recreate the domain after fixing the error mentioned in <code>FailureReason</code> .
Update_Failed	Unsuccessful update of domain. Call the <code>DescribeDomain</code> API to see the failure reason for domain update. Call the <code>UpdateDomain</code> API after fixing the error mentioned in <code>FailureReason</code> .
Delete_Failed	Unsuccessful deletion of domain. Call the <code>DescribeDomain</code> API to see the failure reason for domain deletion. Because deletion failed, you might have some resources that are still running, but you cannot use or update the domain. Call the <code>DeleteDomain</code> API again after fixing the error mentioned in <code>FailureReason</code> .

### UserProfile status values

Value	Description
Pending	Ongoing creation of <code>UserProfile</code> .
InService	Successful creation of <code>UserProfile</code> .
Updating	Ongoing update of <code>UserProfile</code> .
Deleting	Ongoing deletion of <code>UserProfile</code> .
Failed	Unsuccessful creation of <code>UserProfile</code> . Call the <code>DescribeUserProfile</code> API to see the failure reason for <code>UserProfile</code> creation. Delete the failed <code>UserProfile</code> and

Value	Description
	recreate it after fixing the error mentioned in <code>FailureReason</code> .
Update_Failed	Unsuccessful update of <code>UserProfile</code> . Call the <code>DescribeUserProfile</code> API to see the failure reason for <code>UserProfile</code> update. Call the <code>UpdateUserProfile</code> API again after fixing the error mentioned in <code>FailureReason</code> .
Delete_Failed	Unsuccessful deletion of <code>UserProfile</code> . Call the <code>DescribeUserProfile</code> API to see the failure reason for <code>UserProfile</code> deletion. Because deletion failed, you might have some resources that are still running, but you cannot use or update the <code>UserProfile</code> . Call the <code>DeleteUserProfile</code> API again after fixing the error mentioned in <code>FailureReason</code> .

### shared space status values

Value	Description
Pending	Ongoing creation of shared space.
InService	Successful creation of shared space.
Deleting	Ongoing deletion of shared space.
Failed	Unsuccessful creation of shared space. Call the <code>DescribeSpace</code> API to see the failure reason for shared space creation. Delete the failed shared space and recreate it after fixing the error mentioned in <code>FailureReason</code> .

Value	Description
Update_Failed	Unsuccessful update of shared space. Call the <code>DescribeSpace</code> API to see the failure reason for shared space update. Call the <code>UpdateSpace</code> API again after fixing the error mentioned in <code>FailureReason</code> .
Delete_Failed	Unsuccessful deletion of shared space. Call the <code>DescribeSpace</code> API to see the failure reason for shared space deletion. Because deletion failed, you might have some resources that are still running, but you cannot use or update the shared space. Call the <code>DeleteSpace</code> API again after fixing the error mentioned in <code>FailureReason</code> .
Deleted	Successful deletion of shared space.

### App status values

Value	Description
Pending	Ongoing creation of App.
InService	Successful creation of App.
Deleting	Ongoing deletion of App.
Failed	Unsuccessful creation of App. Call the <code>DescribeApp</code> API to see the failure reason for App creation. Call the <code>CreateApp</code> API again after fixing the error mentioned in <code>FailureReason</code> .
Deleted	Successful deletion of App.

## Maintenance of applications

At least once every 90 days, SageMaker AI performs security and performance updates to the underlying software for Amazon SageMaker Studio Classic JupyterServer and KernelGateway, SageMaker Canvas, and Amazon SageMaker Data Wrangler applications. Some maintenance items, such as operating system upgrades, require that SageMaker AI takes your application offline for a short time during the maintenance window. Because this maintenance takes the application offline, you cannot perform any operations while the underlying software is being updated. When the maintenance activity is in progress, the state of the application transitions from **InService** to **Pending**. When maintenance is complete, the status of the application transitions back to **InService**. If patching fails, then the status of the application becomes **Failed**. If an application is in the **Failed** state, we recommend creating a new application of the same type. For information about creating Studio Classic applications, see [Shut Down and Update SageMaker Studio Classic and Studio Classic Apps](#). For information about creating SageMaker Canvas applications, see [Applications management](#).

For more information, contact <https://aws.amazon.com/premiumsupport/>.

- [Where to shut down resources per SageMaker AI features](#)

## Complete prerequisites

To use the features available in an Amazon SageMaker AI domain, you must complete the following prerequisites.

- Onboard to a domain. For more information, see [Onboard to Amazon SageMaker AI domain](#).
- (Optional) If you are interacting with your domain using the AWS CLI, you must also complete the following prerequisites.
  - Update the AWS CLI by following the steps in [Installing the current AWS CLI Version](#).
  - From your local machine, run `aws configure` and provide your AWS credentials. For information about AWS credentials, see [Understanding and getting your AWS credentials](#).

## Hide machine learning tools and applications in the Amazon SageMaker Studio UI

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

This topic shows how to hide applications and machine learning (ML) tools displayed in the Amazon SageMaker Studio user interface (UI). For information on the Studio UI, see [Amazon SageMaker Studio UI overview](#).

This customization does not block access to these resources. If, instead, you want to block access to an application, see [Amazon SageMaker Role Manager](#).

For information about the applications, see [Applications supported in Amazon SageMaker Studio](#).

The customize Studio UI feature is not available in Amazon SageMaker Studio Classic.

You can customize the Studio UI on a domain level and a user level:

- Customization on a domain level sets the default for all users in the domain.

These default settings apply for all users in the domain who have *not* had these changes made to their individual user settings.

- Customization on a user level will take priority over the domain level settings.

Use the following topics to learn more on the different customization levels and how to apply them.

## Topics

- [Hide machine learning tools and applications on a domain level](#)
- [Hide machine learning tools and applications on a user level](#)

## Hide machine learning tools and applications on a domain level

The following shows how to use the console to customize the applications and ML tools displayed in Studio on a domain level. For more information, see [Hide machine learning tools and applications in the Amazon SageMaker Studio UI](#).

This feature is not available if Amazon SageMaker Studio Classic is set as your default experience.

## Hide machine learning tools and applications on a domain level instructions (console)

### To hide machine learning tools and applications Studio UI on a domain level (console)

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, choose the link to the domain you wish to edit.
5. On the **Domain details** page, choose the **App Configurations** tab.
6. In the **SageMaker Studio** section, choose **Customize Studio UI**.
7. On the **Customize Studio UI** page you can hide applications and ML tools displayed in Studio by toggling them off.

Note that not all ML features are available in all regions.

8. Once you have reviewed your changes, choose **Save**.

Once completed, you will see a green banner containing a success message at the top of the page.

## Hide machine learning tools and applications on a domain level instructions (AWS CLI)

### Note

To use this feature you may need to update to the latest AWS CLI version. For more information, see [Installing or updating to the latest version of the AWS CLI](#).

You can use the AWS CLI to customize the applications and ML tools displayed in Studio on a domain level, using [StudioWebPortalSettings](#). Use `HiddenAppTypes` to hide applications and `HiddenMLTools` to hide ML tools.

In the following example, SageMaker Canvas and Code Editor are being hidden for users in the domain *domainId*.

```
aws sagemaker update-domain \  
  --domain-id domainId \  
  --default-user-settings '{"StudioWebPortalSettings": {"HiddenAppTypes": ["Canvas",  
  "CodeEditor"]}}'
```

Note that not all ML features are available in all AWS Regions.

## Hide machine learning tools and applications on a user level

The following shows how to customize the applications and ML tools displayed in Studio on a user level. For more information, see [Hide machine learning tools and applications in the Amazon SageMaker Studio UI](#).

This feature is not available if Studio Classic is set as your default experience.

## Hide machine learning tools and applications on a user level instructions (console)

### To hide machine learning tools and applications Studio UI on a user level (console)

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.

4. From the list of domains, choose the link to the domain you wish to edit.
5. On the **Domain details** page, choose the **User profiles** tab.
6. In the **User profiles** section, choose the link to the user profile you wish to edit.
7. Choose the **App Configurations** tab.
8. In the **SageMaker Studio** section, choose **Customize Studio UI**.
9. On the **Customize Studio UI** page you can hide applications and ML tools displayed in Studio by toggling them off.

Note that not all ML features are available in all regions.

10. Once you have reviewed your changes, choose **Save**. This will take you back to the user profile edit flow.
11. Choose **Save changes**.

Once completed, you will see a green banner containing a success message at the top of the page.

### Hide machine learning tools and applications on a user level instructions (AWS CLI)

#### Note

To use this feature you may need to update to the latest AWS CLI version. For more information, see [Installing or updating to the latest version of the AWS CLI](#).

You can use the AWS CLI to customize the applications and ML tools displayed in Studio on a user level, using [StudioWebPortalSettings](#). Use `HiddenAppTypes` to hide applications and `HiddenMLTools` to hide ML tools.

In the following example, SageMaker Canvas and Code Editor are being hidden for user *userProfileName* in the domain *domainId*.

```
aws sagemaker update-user-profile \  
  --domain-id domainId \  
  --user-profile-name userProfileName \  
  --user-settings '{"StudioWebPortalSettings": {"HiddenAppTypes": ["Canvas",  
"CodeEditor"]}}'
```

Note that not all ML features are available in all AWS Regions.

## Hide instance types and images in the Amazon SageMaker Studio UI

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

This topic shows how to hide Amazon SageMaker AI instance types and images displayed in the Amazon SageMaker Studio user interface (UI). For information on the Studio UI, see [Amazon SageMaker Studio UI overview](#).

When you hide SageMaker AI instance types and images:

- The impacted users will not be able to view the hidden resources in the Studio UI.
- The impacted users will not be able to run or create a new space with the hidden configurations.
- Any currently running spaces for the impacted users will not be effected.
- When an impacted user attempts to run a space with the hidden resources, they will be notified that the relevant resources have been disabled by the administrator.

### Note

If, instead of *hiding*, you would like to *restrict* the instance types available to users through an AWS Identity and Access Management policy, see:

- [Can I limit the type of instances that data scientists can launch for training jobs in SageMaker AI?](#) in AWS re:Post.
- [Limiting instances types on Amazon SageMaker AI via IAM policy](#) in StackOverflow.

The customize Studio UI feature is not available in Amazon SageMaker Studio Classic.

You can customize the Studio UI on a domain level and a user level:

- Customization on a domain level sets the default for all users in the domain.
- Customization on a user level will take priority over the domain level settings.

Use the following topics to learn more on the different customization levels and how to apply them.

## Topics

- [Hide instance types and images on a domain level](#)
- [Hide instance types and images on a user level](#)

### Hide instance types and images on a domain level

The following shows how to use the console to set rules to hide Amazon SageMaker AI instance types and images from being displayed in the Amazon SageMaker Studio Classic UI on a *domain level*. For more information, see [Hide instance types and images in the Amazon SageMaker Studio UI](#).

Once these changes are made on a domain level:

- These changes will not effect any currently open spaces.
- These changes will impact the domain's users' *default* visibility from that point onward.

These default settings apply for all users in the domain who have *not* had these changes made to their individual user settings.

- User level settings take priority over the domain level settings.

The customize Studio UI feature is not available in Amazon SageMaker Studio Classic.

### Hide instance types and images on a domain level instructions (console)

#### To hide instance types and images Studio UI on a domain level (console)

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, choose the link to the domain you wish to edit.
5. On the **Domain details** page, choose **Domain settings**.
6. In the **Domain settings** tab, you can view the domain rules in the **Domain rules** section.
7. In the **Domain rules** section choose **Manage rules**.

8. On the **Manage domain rules** page choose a **Rule type**.

Note that not all instance types and images are available in all AWS Regions.

- a. If you choose **Instance type**, you can use the **Hide** action to hide SageMaker AI instance types you choose in the dropdown list under **Instance types**.
  - b. If you choose **Image**, you can use the **Hide** action to hide SageMaker images you choose under the dropdown list under **Image**.
9. (Optional) Choose **+ Add new rule** to add more rules.
10. Once you have reviewed your changes, choose **Submit**.

Once completed, you will see a green banner containing a success message at the top of the page.

### Hide instance types and images on a domain level instructions (AWS CLI)

#### Note

To use this feature you may need to update to the latest AWS CLI version. For more information, see [Installing or updating to the latest version of the AWS CLI](#).

You can use the AWS CLI to customize the SageMaker AI instances and images displayed in the Studio UI on a domain level, using [StudioWebPortalSettings](#). Use `HiddenInstanceTypes` to hide instance types and use `HiddenSageMakerImageVersionAliases` to hide SageMaker images.

Note that when you use `HiddenSageMakerImageVersionAliases`:

- The API only accepts minor `VersionAliases` (for example, 1.9), rather than patch versions (For example, 1.9.1).
- You may enter unpublished versions through the CLI or SDK. However, these versions will not be displayed in the console and will be overwritten after the rules are edited through the console.

In the following example, for Code Editor, based on Code-OSS, Visual Studio Code - Open Source and JupyterLab, the following are being hidden for users by default in the domain `domainId`:

- The instance types `m1.r6id.24xlarge` and `m1.r6id.32xlarge`.
- The image `sagemaker_distribution` versions 1.9 and 1.8.

```
aws sagemaker update-domain \  
  --domain-id domainId \  
  --default-user-settings '{  
    "StudioWebPortalSettings": {  
      "HiddenInstanceTypes": [ "ml.r6id.24xlarge", "ml.r6id.32xlarge" ],  
      "HiddenSageMakerImageVersionAliases": [  
        {  
          "SageMakerImageName": "sagemaker_distribution",  
          "VersionAliases": [ "1.9", "1.8" ]  
        }  
      ]  
    }  
  }'
```

Note that not all instance types and images are available in all AWS Regions.

## Hide instance types and images on a user level

### Warning

Customizing a user profile is a permanent action. If custom settings are saved, this user profile will overwrite the domain settings, and no longer dynamically update with the domain in the future.

The following shows how to use the console to set rules to hide Amazon SageMaker AI instance types and images from being displayed in the Amazon SageMaker Studio Classic UI on a *user level*. For more information, see [Hide instance types and images in the Amazon SageMaker Studio UI](#).

This setting will take priority over the domain level settings.

The customize Studio UI feature is not available in Studio Classic.

## Hide instance types and images on a user level instructions (console)

### To hide instance types and images Studio UI on a user level (console)

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.

4. From the list of domains, choose the link to the domain you wish to edit.
5. On the **Domain details** page, choose the **User profiles** tab.
6. In the **User profiles** section, choose the link to the user profile you wish to edit.
7. On the User details tab, you can view the rules applied to the user in the User profile rules section.
8. In the User profile rules section choose Manage rules.
9. On the Manage user profile rules page choose a Rule type.

Note that not all instance types and images are available in all AWS Regions.

- a. If you choose **Instance type**, you can use the **Hide** action to hide SageMaker AI instance types you choose in the dropdown list under **Instance types**.
  - b. If you choose **Image**, you can use the **Hide** action to hide SageMaker images you choose under the dropdown list under **Image**.
10. (Optional) Choose **+ Add new rule** to add more rules.
  11. Once you have reviewed your changes, choose **Submit**.

Once completed, you will see a green banner containing a success message at the top of the page.

### Hide instance types and images on a user level instructions (AWS CLI)

#### Note

To use this feature you may need to update to the latest AWS CLI version. For more information, see [Installing or updating to the latest version of the AWS CLI](#).

You can use the AWS CLI to customize the applications and ML tools displayed in Studio on a user level, using [StudioWebPortalSettings](#). Use `HiddenInstanceTypes` to hide instance types and use `HiddenSageMakerImageVersionAliases` to hide SageMaker images.

Note that when you use `HiddenSageMakerImageVersionAliases`:

- The API only accepts minor `VersionAliases` (for example, 1.9), rather than patch versions (For example, 1.9.1).
- You may enter unpublished versions through the CLI or SDK. However, these versions will not be displayed in the console and will be overwritten after the rules are edited through the console.

In the following example, for Code Editor, based on Code-OSS, Visual Studio Code - Open Source and JupyterLab, the following are being hidden for user `userProfileName` in the domain `domainId`:

- The instance types `m1.r6id.24xlarge` and `m1.r6id.32xlarge`.
- The image `sagemaker_distribution` versions `1.9` and `1.8`.

```
aws sagemaker update-user-profile \  
  --domain-id domainId \  
  --user-profile-name userProfileName \  
  --user-settings '{  
    "StudioWebPortalSettings": {  
      "HiddenInstanceTypes": [ "m1.r6id.24xlarge", "m1.r6id.32xlarge" ],  
      "HiddenSageMakerImageVersionAliases": [  
        {  
          "SageMakerImageName": "sagemaker_distribution",  
          "VersionAliases": [ "1.9", "1.8" ]  
        }  
      ]  
    }  
  }'  
'
```

Note that not all instance types and images are available in all AWS Regions.

## Multiple domains overview

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

Having multiple Amazon SageMaker AI domain simplifies managing machine learning workflows for administrators of enterprises with diverse business units, teams, or projects. Each domain acts as a logically separate environment with its own configurations, settings, and user access controls. This compartmentalization enables organizations to enforce clear boundaries between different groups, teams, or use cases, enhancing the ability to securely allocate AWS resources and permissions on a broad and granular level.

The following provides information about creating multiple domains.

- Amazon SageMaker AI supports the creation of multiple Amazon SageMaker AI domains in a single AWS Region for each account.
- Additional domains in an AWS Region have the same features and capabilities as the first domain in a Region.
- Each domain can have distinct domain settings.
- The same user profile cannot be added to multiple domains in a single Region within the same account.

For information about domain limits, see [Amazon SageMaker AI endpoints and quotas](#).

The following topics provides information on how to use tags for your domain.

## Topics

- [Automatic tag propagation](#)
- [How domain resource display filtering works](#)
- [Backfill domain tags](#)

## Automatic tag propagation

Tags allow you to categorize and label your resources based on various criteria, such as project, team, environment (For example, dev, staging, prod), or any other custom metadata. You can tag resources by your domain automatically when they are created within your domain. This makes it easier to identify and manage your resources across your domains. You can also use these tags for cost allocation using AWS Billing and Cost Management. For more information, see [Using AWS cost allocation tags](#).

By default, any SageMaker AI resources that support tagging and are created from within the Amazon SageMaker Studio or Amazon SageMaker Studio Classic UI after 11/30/2022 are

automatically tagged with a domain ARN tag. The domain ARN tag is based on the domain ID of the domain that the resource is created in.

To backfill your SageMaker AI resources, you can add the `sagemaker:domain-arn` tag to untagged resources by following the steps in [Backfill domain tags](#).

The following list describes the only SageMaker AI resources that *do not* support automatic tag propagation, as well as the impacted API calls where the tag is not returned because it was not automatically set.

### Note

All SageMaker List APIs do not support tag-based resource isolation. The default app, which manages the Studio UI, is not automatically tagged.

SageMaker AI resource	Affected API calls
ImageVersionArn	<ul style="list-style-type: none"> <li><a href="#">describe-image-version</a></li> <li><a href="#">update-image-version</a></li> <li><a href="#">delete-image-version</a></li> </ul>
ModelCardExportJobArn	<a href="#">describe-model-card-export-job</a>
ModelPackageArn	<a href="#">describe-model-package</a>

## How domain resource display filtering works

Amazon SageMaker AI automatically filters the resources displayed in Studio or Studio Classic based on the Amazon SageMaker AI domain. This filtering is done by using the `sagemaker:domain-arn` tag attached to SageMaker AI resources. Resources created in other domains are automatically hidden.

### Note

This only applies to the Studio or Studio Classic UI. SageMaker AI does not support resource filtering using the AWS CLI by default.

In Amazon SageMaker Studio or Amazon SageMaker Studio Classic, you'll only see resources that:

- Were created within the current domain.
- Don't have the `sagemaker:domain-arn` tag associated with them. These untagged resources are either created outside the context of a domain or were created before 11/30/2022.

To improve resource filtering, you can add the `sagemaker:domain-arn` tag to untagged resources by following the steps in [Backfill domain tags](#).

Additionally, all resources created in shared spaces are automatically filtered to that particular shared space.

### Backfill domain tags

You can improve resource filtering by adding domain tags to untagged resources. If you have resources that are not tagged, you can backfill them.

If you have created resources in a domain before 11/30/2022, those resources are not automatically tagged with the domain Amazon Resource Name (ARN) tag.

To accurately attribute resources to their respective domain, you must add the domain tag to existing resources using the AWS CLI, as follows.

1. Map all existing SageMaker AI resources and their respective ARNs to the domains that exist in your account.
2. Run the following command from your local machine to tag the resource with the ARN of the resource's respective domain. This must be repeated for every SageMaker AI resource in your account.

```
aws resourcegroupstaggingapi tag-resources \  
  --resource-arn-list arn:aws:sagemaker:region:account-id:space/domain-id/space-  
name \  
  --tags sagemaker:domain-arn=arn:aws:sagemaker:region:account-id:domain/domain-  
id
```

## Isolate domain resources

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#). [AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

You can isolate resources between each of the domains in your account and AWS Region using an AWS Identity and Access Management (IAM) policy. The isolated resources will no longer be accessed from other domains. In this topic we will discuss the conditions required for the IAM policy and how to apply them.

The resources that can be isolated by this policy are the resource types that have condition keys containing `aws:ResourceTag/${TagKey}` or `sagemaker:ResourceTag/${TagKey}`. For a reference on the SageMaker AI resources and associated condition keys, see [Actions, resources, and condition keys for Amazon SageMaker AI](#).

### Warning

The resource types that *do not* contain the above condition keys (and therefore the [Actions](#) that use the resource types) are *not* impacted by this resource isolation policy. For example, the [pipeline-execution](#) resource type does *not* contain the above condition keys and is *not* impacted by this policy. Therefore, the following are a few actions, with the pipeline-execution resource type, are *not* supported for resource isolation:

- DescribePipelineExecution
- StopPipelineExecution
- UpdatePipelineExecution
- RetryPipelineExecution

- DescribePipelineDefinitionForExecution
- ListPipelineExecutionSteps
- SendPipelineExecutionStepSuccess
- SendPipelineExecutionStepFailure

The following topic shows how to create a new IAM policy that limits access to resources in the domain to user profiles with the domain tag, as well as how to attach this policy to the IAM execution role of the domain. You must repeat this process for each domain in your account. For more information about domain tags and backfilling these tags, see [Multiple domains overview](#)

## Console

The following section shows how to create a new IAM policy that limits access to resources in the domain to user profiles with the domain tag, as well as how to attach this policy to the IAM execution role of the domain, from the Amazon SageMaker AI console.

### Note

This policy only works in domains that use Amazon SageMaker Studio Classic as the default experience.

1. Create an IAM policy named `StudioDomainResourceIsolationPolicy-domain-id` with the following JSON policy document by completing the steps in [Creating IAM policies \(console\)](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateAPIs",
      "Effect": "Allow",
      "Action": "sagemaker:Create*",
      "NotResource": [
        "arn:aws:sagemaker:*:*:domain/*",
        "arn:aws:sagemaker:*:*:user-profile/*",
        "arn:aws:sagemaker:*:*:space/*"
      ]
    }
  ]
}
```

```

    },
    {
      "Sid": "ResourceAccessRequireDomainTag",
      "Effect": "Allow",
      "Action": [
        "sagemaker:Update*",
        "sagemaker:Delete*",
        "sagemaker:Describe*"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/sagemaker:domain-arn": "domain-arn"
        }
      }
    },
    {
      "Sid": "AllowActionsThatDontSupportTagging",
      "Effect": "Allow",
      "Action": [
        "sagemaker:DescribeImageVersion",
        "sagemaker:UpdateImageVersion",
        "sagemaker:DeleteImageVersion",
        "sagemaker:DescribeModelCardExportJob",
        "sagemaker:DescribeAction"
      ],
      "Resource": "*"
    },
    {
      "Sid": "DeleteDefaultApp",
      "Effect": "Allow",
      "Action": "sagemaker:DeleteApp",
      "Resource": "arn:aws:sagemaker:*:*:app/domain-id/*/jupyterserver/"
    }
  ],
  "default": {}
}

```

2. Attach the StudioDomainResourceIsolationPolicy-*domain-id* policy to the domain's execution role by completing the steps in [Modifying a role \(console\)](#).

## AWS CLI

The following section shows how to create a new IAM policy that limits access to resources in the domain to user profiles with the domain tag, as well as how to attach this policy to the execution role of the domain, from the AWS CLI.

### Note

This policy only works in domains that use Amazon SageMaker Studio Classic as the default experience.

1. Create a file named `StudioDomainResourceIsolationPolicy-domain-id` with the following content from your local machine.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateAPIs",
      "Effect": "Allow",
      "Action": "sagemaker:Create*",
      "NotResource": [
        "arn:aws:sagemaker:*:*:domain/*",
        "arn:aws:sagemaker:*:*:user-profile/*",
        "arn:aws:sagemaker:*:*:space*"
      ]
    },
    {
      "Sid": "ResourceAccessRequireDomainTag",
      "Effect": "Allow",
      "Action": [
        "sagemaker:Update*",
        "sagemaker>Delete*",
        "sagemaker:Describe*"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/sagemaker:domain-arn": "domain-arn"
        }
      }
    }
  ]
}
```

```

    },
    {
      "Sid": "AllowActionsThatDontSupportTagging",
      "Effect": "Allow",
      "Action": [
        "sagemaker:DescribeImageVersion",
        "sagemaker:UpdateImageVersion",
        "sagemaker>DeleteImageVersion",
        "sagemaker:DescribeModelCardExportJob",
        "sagemaker:DescribeAction"
      ],
      "Resource": "*"
    },
  ],
  {
    "Sid": "DeleteDefaultApp",
    "Effect": "Allow",
    "Action": "sagemaker>DeleteApp",
    "Resource": "arn:aws:sagemaker:*:*:app/domain-id*/jupyterserver/
default"
  }
]
}

```

2. Create a new IAM policy using the `StudioDomainResourceIsolationPolicy-domain-id` file.

```
aws iam create-policy --policy-name StudioDomainResourceIsolationPolicy-domain-id
--policy-document file://StudioDomainResourceIsolationPolicy-domain-id
```

3. Attach the newly created policy to a new or existing role that is used as the domain's execution role.

```
aws iam attach-role-policy --policy-arn arn:aws:iam:account-id:policy/StudioDomainResourceIsolationPolicy-domain-id --role-name domain-execution-role
```

## domain default settings

With SageMaker AI, you can set default settings for your resources at the Amazon SageMaker AI domain level. These default settings are used in the creation of resources within the domain. The

following sections list default settings for domain and give information on using context keys when setting defaults.

## Topics

- [Domain default settings](#)
- [Context keys](#)

## Domain default settings

You can set the following defaults when creating or updating a domain. Values passed at the user profile and shared space level override defaults set at the domain level.

- [DefaultUserSettings](#)
- [DefaultSpaceSettings](#)

### Note

DefaultSpaceSettings only supports the use of JupyterLab 3 image ARNs for SageMakerImageArn. For more information, see [JupyterLab Versioning](#).

```
"DefaultSpaceSettings": {
  "ExecutionRole": "string",
  "JupyterServerAppSettings": {
    "DefaultResourceSpec": {
      "InstanceType": "string",
      "LifecycleConfigArn": "string",
      "SageMakerImageArn": "string",
      "SageMakerImageVersionArn": "string"
    },
    "LifecycleConfigArns": [ "string" ]
  },
  "KernelGatewayAppSettings": {
    "CustomImages": [
      {
        "AppImageConfigName": "string",
        "ImageName": "string",
        "ImageVersionNumber": number
      }
    ]
  }
}
```

```
    "DefaultResourceSpec": {
      "InstanceType": "string",
      "LifecycleConfigArn": "string",
      "SageMakerImageArn": "string",
      "SageMakerImageVersionArn": "string"
    },
    "LifecycleConfigArns": [ "string" ]
  },
  "SecurityGroups": [ "string" ]
}
```

## Context keys

You can add context keys to the IAM policy that creates a domain. This restricts the values that users can pass for those fields. The following list shows the context keys that domain supports and where they're implemented.

- `sagemaker:ImageArns`
  - **Implemented as part of `DefaultUserSettings:SagemakerImageArn`** in `DefaultUserSettings.JupyterServerAppSettings` and `DefaultUserSettings.KernelGatewayAppSettings`. CustomImages in `DefaultUserSettings.KernelGatewayAppSettings`.
  - **Implemented as part of `DefaultSpaceSettings:SagemakerImageArn`** in `DefaultSpaceSettings.JupyterServerAppSettings` and `DefaultSpaceSettings.KernelGatewayAppSettings`. CustomImages in `DefaultSpaceSettings.KernelGatewayAppSettings`.
- `sagemaker:VpcSecurityGroupIds`
  - **Implemented as part of `DefaultUserSettings:SecurityGroups`** in `DefaultUserSettings`.
  - **Implemented as part of `DefaultSpaceSettings:SecurityGroups`** in `DefaultSpaceSettings`.
- `sagemaker:DomainSharingOutputKmsKey`
  - **Implemented as part of `DefaultUserSettings:S3KmsKeyId`** in `DefaultSpaceSettings.SharingSettings`.

You cannot restrict users to passing incompatible values when using context keys for the defaults. For example, the values for `SageMakerImageArn` set as part of `DefaultUserSettings` and `DefaultSpaceSettings` must be compatible. You cannot set incompatible default values.

## Custom tag propagation

Amazon SageMaker AI supports the ability to propagate custom tags set at the domain, user profile, and space level to all of the SageMaker AI resources created in the context of Amazon SageMaker Studio, JupyterLab, Code Editor, based on Code-OSS, Visual Studio Code - Open Source, and Amazon SageMaker Canvas. With custom tag propagation, users can propagate their own custom tags to resources to improve cost tracking and tie resources to specific projects and teams.

To activate this feature, use the `TagPropagation` attribute in the [CreateDomain](#) and [UpdateDomain](#) APIs. Custom tag propagation can only be set at the domain level, which means that all users and spaces in a domain use the feature when it is activated. It is not possible to modify custom tag propagation settings at the user profile or space level. For more information about using custom tag propagation, see [Add custom tags to resources](#).

### Note

System tags added by AWS services on a domain, user profile, and space are not propagated.

## Example use cases

Custom tag propagation is particularly useful for the following use cases.

- Track cost across all of the SageMaker AI resources created in Amazon SageMaker Studio.
- Track cost for SageMaker AI resources that are created in Amazon SageMaker Canvas. This includes models deployed on a SageMaker AI endpoint.
- Track cost incurred for an Amazon DataZone project by propagating the Amazon DataZone project ID to all the resources created by Amazon SageMaker Studio.

## Tag merging

With custom tag propagation activated, resources created at the user profile and space level take on the tags specified at the domain level, as well as those specified during user profile or space creation.

SageMaker AI resources have a 50 tag limit. If the number of tags added to a resource exceeds 50, SageMaker AI returns an error during resource creation. We recommend limiting the number of tags to avoid this. For example, assume a user has 25 tags for their domain and 30 tags for their user profile. When the user creates a resource, a total of 55 tags propagate to the resource. Because the aggregate tag total exceeds 50, resource creation fails until the user removes at least 5 tags.

### Note

By default, SageMaker AI automatically adds the `sagemaker:user-profile-arn`, `sagemaker:domain-arn`, or `sagemaker:space-arn` tag to SageMaker AI resources. SageMaker AI adds the ARN tag regardless of whether or not the domain is using custom tag propagation. These ARN tags also contribute toward the 50 tag limit.

## Add custom tags to resources

The following page demonstrates the steps needed to use custom tag propagation. Custom tag propagation requires the following steps:

- Opt-in to custom tag propagation
- Add custom tags to resources

When you activate custom tag propagation in an existing domain, tag propagation does not work for existing applications until the application is restarted. Similarly, tags are not updated on an existing resource when new custom tags are added. For example, assume a domain has two tags and a user creates a resource in that domain. The resource then has two tags. If a new tag is added to the domain, then that new tag is not added to the existing resource. However, any new resource created will have the new tag attached to the resource.

## Prerequisites

- Users must have the `sagemaker:AddTags` permission for any resource creation.
  - For new domains created with the `SageMakerFullAccess` managed policy or using the SageMaker Role Manager, the `sagemaker:AddTags` permission is pre-populated.
  - For existing domains using custom AWS Identity and Access Management policies, you must update the policies to include the `sagemaker:AddTags` permission to allow users to create resources.

## Opt-in to custom tag propagation

The process to opt-in to custom tag propagation differs based on if you are opting-in from the console or from the AWS CLI. From the console, you can only opt-in to custom tag propagation by updating an existing domain. From the AWS CLI, you can opt-in to custom tag propagation when creating a domain or updating an existing domain.

### Opt-in from the console

The following steps outline how to opt-in to custom tag propagation from the console. You can only opt-in to custom tag propagation from the console by updating an existing domain.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation, select **Admin configurations**. Under **Admin configurations**, select **Domains**.
3. On the **Domains** page, select the domain that you want to activate custom tag propagation for.
4. From the **Domain details** page, select the **Domain settings** tab.
5. On the **Domain settings** tab, navigate to **Custom Tag Propagation**.
6. Select **Edit**.
7. From the **Edit custom tag propagation** page, select **Automatically propagate custom tags**.
8. Select **Submit**.

### Opt-in using the AWS CLI

To opt-in to custom tag propagation using the AWS CLI, use the `TagPropagation` attribute in the [CreateDomain](#) and [UpdateDomain](#) APIs. By default, the value of this field is `DISABLED`. An empty value also defaults to `DISABLED`. The following example shows how to activate custom tag propagation.

```
aws sagemaker update-domain \  
--domain-id domain-id \  
--region region \  
--tag-propagation ENABLED
```

## Add custom tags

The process to add custom tags propagation differs based on if you are adding them from the console or from the AWS CLI.

### Add from the console

The following steps outline how to add custom tags to a domain from the console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation, select **Admin configurations**. Under **Admin configurations**, select **Domains**.
3. On the **Domains** page, select the domain that you want to add custom tags to.
4. From the **Domain details** page, select the **Domain settings** tab.
5. On the **Domain settings** tab, navigate to **Tags**.
6. Select **Edit**.
7. From the **Tags** page, select **Add tag**. Add a key and value pair for the custom tag.
8. Select **Save**. This custom tag is now propagated to the SageMaker AI resources created in the domain.

The following steps outline how to add custom tags to a user profile from the console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation, select **Admin configurations**. Under **Admin configurations**, select **Domains**.
3. On the **Domains** page, select the domain containing the user profile that you want to add custom tags to.
4. From the **Domain details** page, select the **User profiles** tab.
5. On the **User profiles** tab, select the user profile you want to add custom tags to.
6. On the **User Details** tab, navigate to the **Details** section.
7. Select **Edit**.
8. From the **Tags** section, select **Add tag**. Add a key and value pair for the custom tag.
9. Select **Submit**. This custom tag is now propagated to the SageMaker AI resources created in the domain.

## Add using the AWS CLI

After you have activated custom tag propagation, you can add custom tags using the AWS CLI at the domain, user profile, or space level during creation or update. The method to add custom tags differs depending on you are creating a new resource or adding tags to an existing resource.

The following example shows how to add custom tags at the domain level during creation.

```
aws sagemaker create-domain \  
  --domain-name domain-id \  
  --auth-mode IAM \  
  --default-user-settings '{"ExecutionRole": "execution-role"}' \  
  --subnet-ids subnet-id \  
  --vpc-id vpc-id \  
  --tags Key=key,Value=value \  
  --tag-propagation ENABLED
```

You must use the [AddTags](#) API to add custom tags for existing domain, user profile, and spaces as follows.

```
aws sagemaker add-tags \  
  --resource-arn resource-arn-to-attach-tags \  
  --tags Key=key, Value=value
```

## Opt-out of custom tag propagation

The process to opt-out of custom tag propagation differs based on if you are opting-out from the console or from the AWS CLI.

### Opt-out from the console

The following steps outline how to opt-out of custom tag propagation from the console. You can only opt-out of custom tag propagation from the console by updating an existing domain.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation, select **Admin configurations**. Under **Admin configurations**, select **Domains**.
3. On the **Domains** page, select the domain that you want to opt-out of custom tag propagation for.
4. From the **Domain details** page, select the **Domain settings** tab.

5. On the **Domain settings** tab, navigate to **Custom Tag Propagation**.
6. Select **Edit**.
7. From the **Edit custom tag propagation** page, select **Automatically propagate custom tags**
8. Select **Submit**.

## Opt-out using the AWS CLI

To opt-out of custom tag propagation, set the `TagPropagation` attribute in the [CreateDomain](#) and [UpdateDomain](#) APIs to `DISABLED` as shown in the following example. By default, the value of this field is `DISABLED`. An empty value also defaults to `DISABLED`.

### Note

Tag propagation is not automatically turned off for existing applications when `TagPropagation` is set to `DISABLED`. Applications must be restarted for opt-out to take effect for existing apps.

```
aws sagemaker update-domain \  
--domain-id domain-id \  
--region region \  
--tag-propagation DISABLED
```

## Adding a custom file system to a domain

When you create a domain, Amazon SageMaker AI adds a default Amazon Elastic File System (Amazon EFS) volume to the domain. SageMaker AI creates this volume for you. You also have the option to add a custom Amazon EFS or a custom Amazon FSx for Lustre file system that you've created. After you add it, your file system is available to users who belong to your domain. Your users can access the file system when they use Amazon SageMaker Studio. They can attach the file system to spaces that they create for the following supported applications:

- JupyterLab
- Code Editor

After running a space and starting the application, your users can access any data, code, or other artifacts that your file system contains.

You can enable your users to access your file system in the following ways:

- Through *shared spaces* – A shared space can be created by any user who belongs to your domain. Then, it can be used by any user who belongs to your domain.
- Through *private spaces* – A private space can be created by any user who belongs to your domain. Then, it can be used by only that user.
- Exclusively as an individual user – If you don't want to enable all of your users to access the file system, you can enable only a specific user to access it. If you do that, the file system is available only in private spaces that the specific user creates.

You can add a custom file system by using the Amazon SageMaker API, the AWS SDKs, or the AWS CLI. You can't add a custom file system by using the SageMaker AI console.

## Prerequisites

Before you can add a custom file system to a domain, you must meet the following requirements:

- You have a domain in SageMaker AI. Before you can add a file system, you need the domain ID. You can look up the ID by using the SageMaker AI console. You can also run the [list-domains](#) command with the AWS CLI.
- You have an Amazon EFS or FSx for Lustre file system in your AWS account.

### For Amazon EFS

- For the steps to create an Amazon EFS, see [Create your Amazon EFS file system](#) in the *Amazon Elastic File System User Guide*.
- Before Studio can access your file system, it must have a mount target in each of the subnets that you associate with the domain. For more information about assigning mount targets to subnets, see [Creating and managing mount targets and security groups](#) in the *Amazon Elastic File System User Guide*.
- For each mount target, you must add the security group that Amazon SageMaker AI created in your AWS account when you created the domain. The security group name has the format `security-group-for-inbound-nfs-domain-id`. For instructions on how to obtain your domain ID, see [View domains](#).
- Your IAM permissions must allow you to use the `elasticfilesystem:DescribeMountTargets` action. For more information about this action, see [Actions, resources, and condition keys for Amazon Elastic File System](#) in the *Service Authorization Reference*.

## For FSx for Lustre

- For the steps to create a FSx for Lustre file system, see [Getting started with Amazon FSx for Lustre](#) in the *Amazon FSx for Lustre User Guide*. Ensure that the FSx for Lustre file system exists in:
  - The same Amazon VPC as your domain.
  - One of the subnets present in your domain.
- Before Studio can access the FSx for Lustre file system, you must add your domain's security group to all of the elastic network interfaces (ENIs) in your FSx for Lustre file system. Without this step, the app creation fails with an error. Use the following instructions to add the domain security group to your FSx for Lustre file system ENIs.

### Add your domain security group to FSx for Lustre file system ENIs (console)

1. Navigate to the [Amazon FSx console](#).
2. Choose **File systems**.
3. Choose your FSx for Lustre file system by using the corresponding link under **File system ID**.
4. If not selected already, choose the **Network & security** tab.
5. Under **Subnet** choose **To see all the ENIs, see the Amazon EC2 console**. This will take you to the Amazon EC2 console and shows all of the ENIs linked to your FSx for Lustre file system.
6. For each ENI:
  - a. Choose the ENI by choosing the corresponding link under **Network interface ID**.
  - b. Choose **Actions** at the top right of the summary page to expand a drop-down menu.
  - c. In the drop-down menu, choose **Choose security group**.
  - d. Search for your domain security group.

The security group name has the format `security-group-for-inbound-nfs-domain-id`. For instructions on how to obtain your domain ID, see [View domains](#).

- e. Choose **Add security group**.

## Adding a custom file system to a domain with the AWS CLI

To add a custom file system to a domain or user profile with the AWS CLI, you pass a `CustomFileSystemConfigs` definition when you use any of the following commands:

- [create-domain](#)
- [update-domain](#)
- [create-user-profile](#)
- [update-user-profile](#)

The following examples show how to add a file system to an existing domain or user profile.

### To add a file system that is accessible in shared spaces

- Update the default space settings for your domain. The following example adds the file system settings to the default space settings:

```
aws sagemaker update-domain --domain-id domain-id \  
--default-space-settings file:///file-system-settings.json
```

This example passes the file system configuration as a JSON file, which is shown in a later example.

### To add a file system that is accessible in private spaces

- Update the default user settings for your domain. The following example adds the file system settings to the default user settings:

```
aws sagemaker update-domain --domain-id domain-id \  
--default-user-settings file:///file-system-settings.json
```

This example passes the file system configuration as a JSON file, which is shown in a later example.

## To add a file system that is accessible only to an individual user

- Update the user profile for the user. The following example adds the file system settings to a user profile:

```
aws sagemaker update-user-profile --domain-id domain-id \  
--user-profile-name user-profile-name \  
--user-settings file:///file-system-settings.json
```

This example passes the file system configuration as a JSON file, which is shown in the following example.

### Example file system settings file

The file in the preceding examples, `file-system-settings.json`, has the following settings:

For your FSx for Lustre file systems

```
{  
  "CustomFileSystemConfigs":  
  [  
    {  
      "FSxLustreFileSystemConfig":  
      {  
        "FileSystemId": "file-system-id",  
        "FileSystemPath": "/"  
      }  
    }  
  ]  
}
```

This example configuration has the following keys:

`CustomFileSystemConfigs`

Settings for custom file systems (only Amazon EFS file systems are supported).

`FSxLustreFileSystemConfig`

Settings for custom FSx for Lustre file systems.

## FileSystemId

The ID of your Amazon EFS file system.

## FileSystemPath

The path to the file system directory that is accessible to the domain users in their spaces in Studio. Permitted users can access only this directory and below. The default path is the file system root: `/`.

## For your Amazon EFS file systems

```
{
  "CustomFileSystemConfigs":
  [
    {
      "EFSFileSystemConfig":
      {
        "FileSystemId": "file-system-id",
        "FileSystemPath": "/"
      }
    }
  ]
}
```

This example configuration has the following keys:

### CustomFileSystemConfigs

Settings for custom file systems (only Amazon EFS file systems are supported).

### EFSFileSystemConfig

Settings for custom Amazon EFS file systems.

### FileSystemId

The ID of your Amazon EFS file system.

### FileSystemPath

The path to the file system directory that is accessible to the domain users in their spaces in Studio. Permitted users can access only this directory and below. The default path is the file system root: `/`.

When you assign a file system to the default space settings for a domain, you must also include the execution role in the settings:

```
{
  "ExecutionRole": "execution-role-arn"
}
```

This example configuration has the following key:

#### ExecutionRole

The default execution role for the users of the domain.

If you want to apply POSIX permissions for your file system, you can also pass the following settings to the `create-domain` or `create-user-profile` commands:

```
{
  "CustomPosixUserConfig":
  {
    "Uid": UID,
    "Gid": GID
  }
}
```

This example configuration has the following keys:

#### CustomPosixUserConfig

The default POSIX identities that are used for file system operations. You can use these settings to apply your existing POSIX permission structure to the user profiles that access the custom file system. At a POSIX permissions level, you can control which users can access the file system and which files or data they can access.

You can also apply `CustomPosixUserConfig` settings when you create a user profile by using the `create-user-profile` command. The settings that you apply to a user profile override those that you apply to the associated domain.

**Note**

You can apply `CustomPosixUserConfig` settings when you use the `create-domain` and `create-user-profile` commands. However, you can't apply these settings when you do the following:

- Use the `update-domain` command for a domain that is already associated with any user profiles. You can apply these settings only to domains that have no user profiles.
- Use the `update-user-profile` command. To apply these settings to profile that you've already created, delete the profile, and create a new one that has the updated settings.

**Uid**

The POSIX user ID. The default is 200001.

**Gid**

The POSIX group ID. The default is 1001.

**Attaching a custom file system to a space with the AWS CLI**

After you add a custom file system to a domain, the domain users can attach the file system to spaces that they create. For instance, they can attach the file system when they use Studio or the [create-space](#) command with the AWS CLI.

**To attach a custom file system to a space**

- Add the file system configuration to the space settings. The following example command attaches a file system to a new space.

```
aws sagemaker create-space \  
--space-name space-name \  
--domain-id domain-id \  
--ownership-settings "OwnerUserProfileName=user-profile-name" \  
--space-sharing-settings "SharingType=Private" \  
--space-settings file://space-settings.json
```

In this example, the file `space-settings.json` has the following settings, which include the `CustomFileSystems` configuration with the `FileSystemId` key.

For your FSx for Lustre file systems

```
{
  "AppType": "JupyterLab",
  "JupyterLabAppSettings":
  {
    "DefaultResourceSpec":
    {
      "InstanceType": "instance-type"
    }
  },
  "CustomFileSystems":
  [
    {
      "FSxLustreFileSystem":
      {
        "FileSystemId": "file-system-id"
      }
    }
  ]
}
```

For your Amazon EFS file systems

```
{
  "AppType": "JupyterLab",
  "JupyterLabAppSettings":
  {
    "DefaultResourceSpec":
    {
      "InstanceType": "instance-type"
    }
  },
  "CustomFileSystems":
  [
    {
      "EFSFileSystem":
      {
        "FileSystemId": "file-system-id"
      }
    }
  ]
}
```

```
}  
  }  
] }  
}
```

SageMaker AI creates a symbolic link at the following path: `/home/sagemaker-user/custom-file-systems/file-system-type/file-system-id`. With this, the domain users can navigate to the custom file system from within their home directory, `/home/sagemaker-user`.

## View domain environment details

This page gives information about modifications to the Amazon SageMaker AI domain environment. Complete the following procedure to view the custom images, lifecycle configurations, and git repositories attached to a domain environment.

### Open the Environment page

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select a domain to open the **Environment** page.
5. On the **domain details** page, choose the **Environment** tab.

For more information about bringing a custom Amazon SageMaker Studio Classic image, see [Bring your own SageMaker image](#).

For more information about bringing a custom RStudio image, see [Bring your own image to RStudio on SageMaker](#).

For instructions on using a lifecycle configuration with Studio Classic, see [Use Lifecycle Configurations with Amazon SageMaker Studio](#).

For information about attaching a git repository to a domain, see [Attach Suggested Git Repos to SageMaker AI](#).

These can also be attached to a shared space using the AWS CLI by passing values to the [create-space](#) command using the `space-settings` parameter.

## View domains

The following section shows how to view a list of your domains, and details of an individual domain from the SageMaker AI console or the AWS CLI.

### Console

The console's domain overview page gives information about the structure of a domain, and it provides a list of your domains. The page's domain structure diagram describes domain components and how they interact with each other.

The following procedure shows how to view a list of your domains from the SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.

To view the details of the domain, complete the following procedure. This page gives information about the general settings for the domain, including the name, domain ID, execution role used to create the domain, and the authentication method of the domain.

1. From the list of domains, select the domain for which you want to open the **domain settings** page.
2. On the **domain details** page, choose the **domain settings** tab.

### AWS CLI

Run the following command from the terminal of your local machine to view a list of domains from the AWS CLI.

```
aws sagemaker list-domains --region region
```

## Edit domain settings

You can edit the settings of a domain from the SageMaker AI console or the AWS CLI. The following considerations apply when updating the settings of a domain.

- If `DefaultUserSettings` and `DefaultSpaceSettings` are set, they cannot be unset.

- `DefaultUserSettings.ExecutionRole` can only be updated if there are no applications running in any user profile within the domain. This value cannot be unset.
- `DefaultSpaceSettings.ExecutionRole` can only be updated if there are no applications running in any of shared spaces within the domain. This value cannot be unset.
- If the domain was created in **VPC only** mode, SageMaker AI automatically applies updates to the security group settings defined for the domain to all shared spaces created in the domain.
- `DomainId` and `DomainName` cannot be edited.

The following section shows how to edit domain settings from the SageMaker AI console or the AWS CLI.

## Console

You can edit the domain from the SageMaker AI console using the following procedure.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain for which you want to open the **domain settings** page.
5. On the **domain details** page, you can configure and manage your domain details by choosing the appropriate tab.
6. To configure the general settings, on the **domain details** page choose the **domain settings** tab then choose **Edit**.

## AWS CLI

Run the following command from the terminal of your local machine to update a domain from the AWS CLI. For more information about the structure of `default-user-settings`, see [CreateDomain](#).

```
aws sagemaker update-domain \  
--domain-id domain-id \  
--default-user-settings default-user-settings \  
--default-space-settings default-space-settings \  
--domain-settings-for-update settings-for-update \  
--region region
```

## Delete an Amazon SageMaker AI domain

This page explains how to delete a domain and the requirements needed. A domain consists of a list of authorized users, configuration settings, and an Amazon Elastic File System (Amazon EFS) volume. The Amazon EFS volume contains data for the users, including notebooks, resources, and artifacts. A user can have multiple applications (apps) which support the reading and execution experience of the user's notebooks, terminals, and consoles. You can delete your domain using one of the following:

- AWS console
- AWS Command Line Interface (AWS CLI)
- SageMaker SDK

### Requirements

You must satisfy the following requirements to delete a domain.

- You must have admin permission to delete a domain.
- You can only delete an app with the status `InService` displayed as **Ready** in the domain. To delete the containing domain, you don't need to delete an app whose status is `Failed`. In the domain, an attempt to delete an app in the failed state results in an error.
- To delete a domain, the domain cannot contain any user profiles or shared spaces. To delete a user profile or shared space, the user profile or space cannot contain any non-failed apps.

When you delete these resources, the following occurs:

- App – The data (files and notebooks) in a user's home directory is saved. Unsaved notebook data is lost.
- User profile – The user can no longer sign in to the domain. The user loses access to their home directory, but the data is not deleted. An admin can retrieve the data from the Amazon EFS volume where it is stored under the user's AWS account.
- To switch authentication modes from IAM to IAM Identity Center, you must delete the domain.

### EFS files

Your files are kept in an Amazon EFS volume as a backup. This backup includes the files in the mounted directory, which is `/home/sagemaker-user` for Amazon SageMaker Studio Classic and `/root` for kernels.

When you delete files from these mounted directories, the kernel or app may move the deleted files into a hidden trash folder. If the trash folder is inside the mounted directory, those files are copied into the Amazon EFS volume and will incur charges. To avoid these Amazon EFS charges, you must identify and clean the trash folder location. The trash folder location for default apps and kernels is `~/ .local/`. This may vary depending on the Linux distribution used for custom apps or kernels. For more information about the Amazon EFS volume, see [Manage Your Amazon EFS Storage Volume in SageMaker Studio Classic](#).

When you use the SageMaker AI console to delete the domain, the Amazon EFS volume is detached but not deleted. The same behavior occurs by default when you use the AWS CLI or the SageMaker Python SDK to delete the domain. However, when you use the AWS CLI or the SageMaker Python SDK, you can set the `RetentionPolicy` to `HomeEfsFileSystem=Delete`. This deletes the Amazon EFS volume along with the domain.

### Delete an Amazon SageMaker AI domain (console)

#### Important

When a user, space, or domain is deleted, the Amazon EFS volume that contains the corresponding data will be lost. This includes notebooks and other artifacts.

### To delete a domain

1. Open the [SageMaker AI console](#).
2. On the left navigation pane, choose **Admin configurations** to expand the options, if not already expanded.
3. Under **Admin configurations**, choose **Domains**.
4. Select the domain name link that you want to delete.
5. Choose the **User profiles** tab.
6. Repeat the following steps for each user in the **User profiles** list.
  - a. Choose the user name link.
  - b. If not already selected, choose the **User Details** tab
  - c. Find any apps and spaces and choose **Delete** under the corresponding **Action** column.
  - d. Follow the delete instructions.

- e. Once all of the app and spaces have **Status** as **Deleted**, choose **Delete** at the top right of the page.
  - f. Follow the delete instructions.
7. When all users are deleted, choose the **Space management** tab.
  8. Repeat the following steps for each space in the **Spaces** list.
    - a. Select the bubble corresponding to the space.
    - b. Choose **Delete**.
    - c. Follow the delete instructions.
  9. When all users and spaces are deleted, choose the **Domain settings** tab.
  10. Find the **Delete domain** section.
  11. Choose **Delete domain**. If this button is not available, you must repeat the previous steps to delete all spaces and users.
  12. Follow the delete instructions.

## Delete an Amazon SageMaker AI domain (AWS CLI)

### To delete a domain

1. Retrieve the list of domains in your account.

```
aws --region Region sagemaker list-domains
```

2. Retrieve the list of applications for the domain to be deleted.

```
aws --region Region sagemaker list-apps \  
--domain-id-equals DomainId
```

3. Delete each application in the list.

```
aws --region Region sagemaker delete-app \  
--domain-id DomainId \  
--app-name AppName \  
--app-type AppType \  
--user-profile-name UserProfileName
```

4. Retrieve the list of user profiles in the domain.

```
aws --region Region sagemaker list-user-profiles \  
  --domain-id-equals DomainId
```

5. Delete each user profile in the list.

```
aws --region Region sagemaker delete-user-profile \  
  --domain-id DomainId \  
  --user-profile-name UserProfileName
```

6. Retrieve the list of shared spaces in the domain.

```
aws --region Region sagemaker list-spaces \  
  --domain-id DomainId
```

7. Delete each shared space in the list.

```
aws --region Region sagemaker delete-space \  
  --domain-id DomainId \  
  --space-name SpaceName
```

8. Delete the domain. To also delete the Amazon EFS volume, specify `HomeEfsFileSystem=Delete`.

```
aws --region Region sagemaker delete-domain \  
  --domain-id DomainId \  
  --retention-policy HomeEfsFileSystem=Retain
```

## Domain user profiles

A user profile represents a single user within an Amazon SageMaker AI domain. The user profile is the main way to reference a user for the purposes of sharing, reporting, and other user-oriented features. This entity is created when a user onboards to the Amazon SageMaker AI domain. A user profile can have (at most) a single JupyterServer application outside the context of a shared space. The user profile's Studio Classic application is directly associated with the user profile and has an isolated Amazon EFS directory, an execution role associated with the user profile, and Kernel Gateway applications. A user profile can also create other applications from the console or from Amazon SageMaker Studio.

## Topics

- [Add user profiles](#)
- [Remove user profiles](#)
- [View user profiles in a domain](#)
- [View user profile details](#)

## Add user profiles

The following section shows how to add user profiles to a domain using the SageMaker AI console or the AWS CLI.

After you add a user profile to the domain, users can login using a URL. If the domain uses AWS IAM Identity Center for authentication, users receive an email that contains the URL to sign in to the domain. If the domain uses AWS Identity and Access Management, you can create a URL for a user profile using [CreatePresignedDomainUrl](#)

## Add user profiles from the console

You can add user profiles to a domain from the SageMaker AI console by following this procedure.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain that you want to add a user profile to.
5. On the **domain details** page, choose the **User profiles** tab.
6. Choose **Add user**. This opens a new page.
7. Use the default name for your user profile or add a custom name.
8. For **Execution role**, choose an option from the role selector. If you choose **Enter a custom IAM role ARN**, the role must have, at a minimum, an attached trust policy that grants SageMaker AI permission to assume the role. For more information, see [SageMaker AI Roles](#).

If you choose **Create a new role**, the **Create an IAM role** dialog box opens:

- a. For **S3 buckets you specify**, specify additional Amazon S3 buckets that users of your notebooks can access. If you don't want to add access to more buckets, choose **None**.
- b. Choose **Create role**. SageMaker AI creates a new IAM role, `AmazonSageMaker-ExecutionPolicy`, with the [AmazonSageMakerFullAccess](#) policy attached.

9. (Optional) Add tags to the user profile. All resources that the user profile creates will have a domain ARN tag and a user profile ARN tag. The domain ARN tag is based on domain ID, while the user profile ARN tag is based on the user profile name.
10. Choose **Next**.
11. In the **SageMaker Studio** section, you have the option to choose between the newer and classic version of Studio as your default experience.
  - If you choose **SageMaker Studio** (recommended) as your default experience, the Studio Classic IDE has default settings. For information on the default settings, see [Default settings](#).

For information on Studio, see [Amazon SageMaker Studio](#).

- If you choose **Studio Classic** as your default experience, you can choose to enable or disable notebook resource sharing. Notebook resources include artifacts such as cell output and Git repositories. For more information on Notebook resources, see [Share and Use an Amazon SageMaker Studio Classic Notebook](#).
12. Under **SageMaker Canvas**, you can configure your SageMaker Canvas settings. For the instructions and configuration details for onboarding, see [Getting started with using Amazon SageMaker Canvas](#).
    - For the **Canvas base permissions configuration**, select whether to establish the minimum required permissions to use the SageMaker Canvas application.
  13. Under **RStudio**, if RStudio license, select whether you want to create the user with one of the following authorizations:
    - Unauthorized
    - RStudio Admin
    - RStudio User

14. Choose **Next**.

15. In the **Customize Studio UI** page you can customize the viewable applications and machine learning (ML) tools displayed in Studio. This customization only hides the applications and ML tools in the left navigation pane in Studio. For information on the Studio UI, see [Amazon SageMaker Studio UI overview](#).

For information about the applications, see [Applications supported in Amazon SageMaker Studio](#).

The customize Studio UI feature is not available in Studio Classic. If you wish to set Studio as your default experience, choose **Previous** and to return to the previous step.

16. Choose **Next**.

17. After you have reviewed your changes, choose **Create user profile**.

## Create user profiles from the AWS CLI

To create a user profile in a domain from the AWS CLI, run the following command from the terminal of your local machine. For information about the available JupyterLab version ARNs, see [Setting a default JupyterLab version](#).

```
aws --region region \  
sagemaker create-user-profile \  
--domain-id domain-id \  
--user-profile-name user-name \  
--user-settings '{  
  "JupyterServerAppSettings": {  
    "DefaultResourceSpec": {  
      "SageMakerImageArn": "sagemaker-image-arn",  
      "InstanceType": "system"  
    }  
  }  
}'
```

You can use the AWS CLI to customize the applications and ML tools displayed in Studio for the user, using [StudioWebPortalSettings](#). Use `HiddenAppTypes` to hide applications and `HiddenMLTools` to hide ML tools. For more information on customizing the left navigation of the Studio UI, see [Hide machine learning tools and applications in the Amazon SageMaker Studio UI](#). This feature is not available for Studio Classic.

## Remove user profiles

All apps launched by a user profile must be deleted to delete the user profile. The following section shows how to remove user profiles from a domain using the SageMaker AI console or AWS CLI.

### Remove user profiles from the console

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.

3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain that you want to remove a user profile from.
5. On the **domain details** page, choose the **User profiles** tab.
6. Select the user profile that you want to delete.
7. On the **User Details** page, for each non-failed app in the **Apps** list, choose **Action**.
8. From the dropdown list, choose **Delete**.
9. On the **Delete app** dialog box, choose **Yes, delete app**. Then enter *delete* in the confirmation field, and choose **Delete**.
10. When **Status** shows as **Deleted** for all apps, choose **Edit**.
11. On the **Edit User** page, choose **Delete user**.
12. On the **Delete user** pop-up, choose **Yes, delete user**.
13. Enter *delete* in the field to confirm deletion.
14. Choose **Delete**.

## Remove user profiles from the AWS CLI

To delete a user profile from the AWS CLI, run the following command from the terminal of your local machine.

```
aws sagemaker delete-user-profile \  
--region region \  
--domain-id domain-id \  
--user-profile-name user-name
```

## View user profiles in a domain

The following section describes how to view a list of user profiles in a domain from the SageMaker AI console or the AWS CLI.

### View user profiles from the console

Complete the following procedure to view a list of user profiles in the domain from the SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.

3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain that you want to view a list of user profiles for.
5. On the **domain details** page, choose the **User profiles** tab.

### View user profiles from the AWS CLI

To view the user profiles in a domain from the AWS CLI, run the following command from the terminal of your local machine.

```
aws sagemaker list-user-profiles \  
--region region \  
--domain-id domain-id
```

### View user profile details

The following section describes how to view the details of a user profile from the SageMaker AI console or the AWS CLI.

#### View user profile details from the console

Complete the following procedure to view the details of a user profile from the SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain that you want to view a list of user profiles for.
5. On the **domain details** page, choose the **User profiles** tab.
6. Select the user profile that you want to view details for.

#### View user profile details from the AWS CLI

To describe a user profile from the AWS CLI, run the following command from the terminal of your local machine.

```
aws sagemaker describe-user-profile \  

```

```
--region region \  
--domain-id domain-id \  
--user-profile-name user-name
```

## IAM Identity Center groups in a domain

AWS IAM Identity Center is the recommended AWS service for managing human user access to AWS resources. It is a single place where you can assign your users consistent access to multiple AWS accounts and applications. For more information about IAM Identity Center authentication, see [What is IAM Identity Center?](#).

If you use AWS IAM Identity Center authentication for your Amazon SageMaker AI domain, you can use the following topics to learn how to view, add, and remove IAM Identity Center groups and users to a domain.

### Topics

- [View groups and users](#)
- [Add groups and users](#)
- [Remove groups](#)

### View groups and users

Complete the following procedure to view a list of IAM Identity Center groups and users from the Amazon SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain that you want to open the **domain settings** page for.
5. On the **domain details** page, choose the **Groups** tab.

### Add groups and users

The following sections show how to add groups and users to a domain from the SageMaker AI console or AWS CLI.

**Note**

If the domain was created before October 1st, 2023, you can only add groups and users to the domain from the SageMaker AI console.

## SageMaker AI console

Complete the following procedure to add groups and users to your domain from the SageMaker AI console.

1. On the **Groups** tab, choose **Assign users and groups**.
2. On the **Assign users and groups** page, select the users and groups that you want to add.
3. Choose **Assign users and groups**.

## AWS CLI

Complete the following procedure to add groups and users to your domain from the AWS CLI.

1. Fetch the `SingleSignOnApplicationArn` of the domain with a call to [describe-domain](#). `SingleSignOnApplicationArn` is the ARN of the application managed in IAM Identity Center.

```
aws sagemaker describe-domain \  
--region region \  
--domain-id domain-id
```

2. Associate the user or group with the domain. To accomplish this, pass the `SingleSignOnApplicationArn` value returned from the [describe-domain](#) command as the `application-arn` parameter in a call to [create-application-assignment](#). You must also pass the type and ID of the entity to associate.

```
aws sso-admin create-application-assignment \  
--application-arn application-arn \  
--principal-id principal-id \  
--principal-type principal-type
```

## Remove groups

Complete the following procedure to remove groups from your domain from the SageMaker AI console. For information about deleting a user, see [Remove user profiles](#).

1. On the **Groups** tab, choose the group that you want to remove.
2. Choose **Unassign groups**.
3. On the pop-up window, choose **Yes, unassign groups**.
4. Enter *unassign* in the field.
5. Choose **Unassign groups**.

## Understanding domain space permissions and execution roles

For many SageMaker AI applications, when you start up a SageMaker AI application within a domain, a space is created for the application. When a user profile creates a space, that space assumes an AWS Identity and Access Management (IAM) role that defines the permissions granted to that space. The following page gives information about space types and the execution roles that define permissions for the space.

An [IAM role](#) is an IAM identity that you can create in your account that has specific permissions. An IAM role is similar to an IAM user in that it is an AWS identity with permissions policies that determine what the identity can and cannot do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. Also, a role does not have standard long-term credentials such as a password or access keys associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session.

### Note

When you start up Amazon SageMaker Canvas or RStudio, it does not create a space that assumes an IAM role. Instead, you change the role associated with the user profile to manage their permissions for the application. For information on obtaining a SageMaker AI user profile's role, see [Get user execution role](#).

For SageMaker Canvas, see [Amazon SageMaker Canvas setup and permissions management \(for IT administrators\)](#).

For RStudio, see [Create Amazon SageMaker AI domain with RStudio App](#).

Users can access their SageMaker AI applications within a shared or private space.

## Shared spaces

- There can only be one space associated with an application. A shared space can be accessed by all of the user profiles within the domain. This grants all user profiles in the domain access to the same underlying file storage system for the application.
- The shared space will be granted the permissions defined by the **space default execution role**. If you wish to modify the shared space's execution role, you must modify the space default execution role.

For information on obtaining the space default execution role, see [Get space execution role](#).

For information on modifying your execution role, see [Modify permissions to execution role](#).

- For information about shared spaces, see [Collaboration with shared spaces](#).
- To create a shared space, see [Create a shared space](#).

## Private spaces

- There can only be one space associated with an application. A private space can only be accessed by the user profile who created it. This space cannot be shared with other users.
- The private space will assume the **user profile execution role** of the user profile that created it. If you wish to modify the private space's execution role, you must modify the user profile's execution role.

For information on obtaining the user profile's execution role, see [Get user execution role](#).

For information on modifying your execution role, see [Modify permissions to execution role](#).

- All applications that support spaces also support private spaces.
- A private space for Studio Classic is already created for each user profile by default.

## Topics

- [SageMaker AI execution roles](#)
- [Example of flexible permissions with execution roles](#)

## SageMaker AI execution roles

A SageMaker AI execution role is an [AWS Identity and Access Management \(IAM\) role](#) that is assigned to an IAM identity that is performing executions in SageMaker AI. An [IAM identity](#) provides access to an AWS account and represents a human user or programmatic workload that can be authenticated and then authorized to perform actions in AWS, that grants permissions to SageMaker AI to access other AWS resources on your behalf. This role allows SageMaker AI to perform actions like launching compute instances, accessing data and model artifacts stored in Amazon S3, or writing logs to CloudWatch. SageMaker AI assumes the execution role at runtime and is temporarily granted the permissions defined in the role's policy. The role should contain the necessary permissions that define the actions the identity can perform and resources the identity has access to. You can assign roles to various identities to provide a flexible and granular approach to managing permissions and access within your domain. For more information on domains, see [Amazon SageMaker AI domain overview](#). For example, you can assign IAM roles to the:

- **Domain execution role** to grant broad permissions to all of the user profiles within the domain.
- **Space execution role** to grant broad permissions for a shared spaces within the domain. All user profiles in the domain can access shared spaces and will use the space's execution role while within the shared space.
- **User profile execution role** to grant fine-grained permissions for specific user profiles. A private space created by a user profile will assume that user profile's execution role.

This enables you to grant the necessary permissions to the domain while still maintaining the principle of least-privilege permissions for user profiles, to adhere to the [security best practices in IAM](#) in the *AWS IAM Identity Center User Guide*.

Any changes or modifications to the execution roles may take a few minutes to propagate. For more information, see [Change your execution role](#) or [Modify permissions to execution role](#), respectively.

### Example of flexible permissions with execution roles

With [IAM roles](#) you can manage and grant permissions on broad and granular levels. The following example includes granting permissions on a space-level and a user-level.

Suppose you are an administrator setting up a domain for a team of data scientists. You can allow the user profiles within the domain to have full access to Amazon Simple Storage Service (Amazon S3) buckets, run SageMaker training jobs, and deploy models using an application in a *shared space*.

In this example, you can create an IAM role called "DataScienceTeamRole" with broad permissions. Then you can assign "DataScienceTeamRole" as the *space default execution role*, granting broad permissions for your team. When a user profile creates a *shared space*, that space will assume the *space default execution role*. For information on assigning an execution role to an existing domain, see [Get space execution role](#).

Instead of allowing any individual user profile working in their own *private space* to have full access to Amazon S3 buckets, you can restrict a user profile's permissions and not allow them to alter the Amazon S3 buckets. In this example, you can give them read access to Amazon S3 buckets to retrieve data, run SageMaker training jobs, and deploy models in their *private space*. You can create a user-level execution role called "DataScientistRole" with the relatively more limited permissions. Then you can assign "DataScientistRole" to the *user profile execution role*, granting the necessary permissions to perform their specific data science tasks within the defined scope. When a user profile creates a *private space*, that space will assume the *user execution role*. For information on assigning an execution role to an existing user profile, see [Get user execution role](#).

For information on SageMaker AI execution roles and adding additional permissions to them, see [How to use SageMaker AI execution roles](#).

## View SageMaker AI resources in your domain

You can view Amazon SageMaker AI resources in your Amazon SageMaker AI domain using the SageMaker AI console. Use the following instructions to learn how to view the resources tagged by the domain ARN.

The displayed SageMaker resources following this procedure are those that have the relevant `sagemaker:domain-arn` tag associated to them. Untagged resources may have been created outside the context of a domain or were created before 11/30/2022, when resources were not automatically tagged with the domain ARN. You can add a tag to untagged resources for better filtration by following the steps in [Backfill domain tags](#). Resources created in other domains are automatically filtered out.

### Note

This is not a complete list of active resources on your domain. For all active SageMaker resources, see [AWS Cost Explorer](#).

## To view SageMaker AI resources in your domain using the console

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. Expand the left navigation pane, if not already expanded.
3. Under **Admin configurations**, choose **Domains**.
4. From the list of domains, select the domain that you want to open the **Domain settings** page for.
5. On the **Domain details** page, choose the **Resources** tab.
6. On the **Domain resources** page, you can view the details of the resources tagged with the relative domain ARN. The running resources are displayed by default.
7. (Optional) You can filter the displayed resources for each resource type by using the search icon or **Filter status** at the top of each resource type.

## Shut down SageMaker AI resources in your domain

You can shut down Amazon SageMaker AI resources in your Amazon SageMaker AI domain using the SageMaker AI console. Use the following instructions to learn how to shut down the resources tagged by the domain ARN.

The displayed SageMaker resources following this procedure are those that have the relevant `sagemaker:domain-arn` tag associated to them. Untagged resources may have been created outside the context of a domain or were created before 11/30/2022, when resources were not automatically tagged with the domain ARN. You can add a tag to untagged resources for better filtration by following the steps in [Backfill domain tags](#). Resources created in other domains are automatically filtered out.

### Note

This is not a complete list of active resources on your domain. For all active SageMaker resources, see [AWS Cost Explorer](#).

## To shut down SageMaker AI resources in your domain using the console

1. [View SageMaker AI resources in your domain](#)
2. Under a resource type section, check the boxes for the resources you wish to shut down.

- Once the resources are selected, a shutdown option will become available at the top of the resource type section. Choose the option and follow the instructions to shut down the selected resources.

For instructions on how to delete your resources per SageMaker AI feature, see [Where to shut down resources per SageMaker AI features](#).

## Where to shut down resources per SageMaker AI features

You can shut down your Amazon SageMaker AI resources to avoid incurring unwanted charges. In the following table we list the SageMaker AI features or resources and provide links to the documentation on how to shut down SageMaker AI resources.

You can also use the [APIs, CLI, and SDKs](#) provided by SageMaker AI. For example, you can search the [Amazon SageMaker API Reference](#) for Delete\* commands to delete some of the resources you have created. More specifically, you can search for the [DeleteDomain](#) API to learn how to delete a Amazon SageMaker AI domain.

### Note

This is not a complete list of active resources on your domain. For all active SageMaker AI resources, see [AWS Cost Explorer](#).

## Choose an Amazon VPC

This topic provides detailed information about choosing an Amazon Virtual Private Cloud (Amazon VPC) when you onboard to Amazon SageMaker AI domain. For more information about onboarding to SageMaker AI domain, see [Amazon SageMaker AI domain overview](#).

By default, SageMaker AI domain uses two Amazon VPCs. One Amazon VPC is managed by Amazon SageMaker AI and provides direct internet access. You specify the other Amazon VPC, which provides encrypted traffic between the domain and your Amazon Elastic File System (Amazon EFS) volume.

You can change this behavior so that SageMaker AI sends all traffic over your specified Amazon VPC. When you choose this option, you must provide the subnets, security groups, and interface endpoints that are necessary to communicate with the SageMaker API and SageMaker AI runtime, and various AWS services, such as Amazon Simple Storage Service (Amazon S3) and Amazon CloudWatch, that are used by Studio.

When you onboard to SageMaker AI domain, you tell SageMaker AI to send all traffic over your Amazon VPC by setting the network access type to **VPC only**.

### To specify the Amazon VPC information

When you specify the Amazon VPC entities (that is, the Amazon VPC, subnet, or security group) in the following procedure, one of three options is presented based on the number of entities you have in the current AWS Region. The behavior is as follows:

- One entity – SageMaker AI uses that entity. This can't be changed.
- Multiple entities – You must choose the entities from the dropdown list.
- No entities – You must create one or more entities in order to use domain. Choose **Create <entity>** to open the VPC console in a new browser tab. After you create the entities, return to the domain **Get started** page to continue the onboarding process.

This procedure is part of the Amazon SageMaker AI domain onboarding process when you choose **Set up for organizations**. Your Amazon VPC information is specified under the **Network** section.

1. Select the network access type.

 **Note**

If **VPC only** is selected, SageMaker AI automatically applies the security group settings defined for the domain to all shared spaces created in the domain. If **Public internet only** is selected, SageMaker AI does not apply the security group settings to shared spaces created in the domain.

- **Public internet only** – Non-Amazon EFS traffic goes through a SageMaker AI managed Amazon VPC, which allows internet access. Traffic between the domain and your Amazon EFS volume is through the specified Amazon VPC.
  - **VPC only** – All SageMaker AI traffic is through the specified Amazon VPC and subnets. You must use a subnet that does not have direct internet access in **VPC only** mode. Internet access is disabled by default.
2. Choose the Amazon VPC.
  3. Choose one or more subnets. If you don't choose any subnets, SageMaker AI uses all the subnets in the Amazon VPC. We recommend that you use multiple subnets that are not created in constrained Availability Zones. Using subnets in these constrained Availability Zones can result in insufficient capacity errors and longer application creation times. For more information about constrained Availability Zones, see [Availability Zones](#).
  4. Choose the security groups. If you chose **Public internet only**, this step is optional. If you chose **VPC only**, this step is required.

 **Note**

For the maximum number of allowed security groups, see [UserSettings](#).

For Amazon VPC requirements in **VPC only** mode, see [Connect Studio notebooks in a VPC to external resources](#).

## Supported Regions and Quotas

This page gives information about the AWS Regions supported by Amazon SageMaker AI and the Amazon Elastic Compute Cloud (Amazon EC2) instance types, as well as quotas for Amazon SageMaker AI resources.

For information about the instance types that are available in each Region, see [Amazon SageMaker Pricing](#).

For a list of the SageMaker AI service endpoints for each Region, see [Amazon SageMaker AI endpoints and quotas](#) in the *AWS General Reference*.

### Quotas

For a list of SageMaker AI quotas, see [Amazon SageMaker AI endpoints and quotas](#) in the *AWS General Reference*.

The [Service Quotas console](#) provides information about your service quotas. You can use the Service Quotas console to view your default service quotas or to request quota increases. To request a quota increase for adjustable quotas, see [Requesting a quota increase](#).

You can set up a quota request template for your AWS Organization that automatically requests quota increases during account creation. For more information, see [Using Service Quotas request templates](#).

# Automated ML, no-code, or low-code

Amazon SageMaker AI offers the following features to automate key machine learning tasks and use no-code or low-code solutions.

- **Amazon SageMaker Canvas:** For a UI-based, no-code AutoML experience, new users should use the [Amazon SageMaker Canvas](#) application in [Amazon SageMaker Studio](#).

Amazon SageMaker Canvas provides analysts and citizen data scientists no-code capabilities for tasks such as data preparation, feature engineering, algorithm selection, training and tuning, inference, and more. Users can leverage built-in visualizations and what-if analysis to explore their data and different scenarios, with automated predictions enabling them to easily productionize their models. SageMaker Canvas supports a variety of use cases, including computer vision, demand forecasting, intelligent search, and generative AI.

- **Amazon SageMaker Autopilot:** [Amazon SageMaker Autopilot](#) is an automated machine learning (AutoML) feature-set that automates the end-to-end process of building, training, tuning, and deploying machine learning models. Amazon SageMaker Autopilot analyzes your data, selects algorithms suitable for your problem type, preprocesses the data to prepare it for training, handles automatic model training, and performs hyperparameter optimization to find the best performing model for your dataset.
  - As of November 30, 2023, the user interface (UI) for Autopilot is integrated into the [Amazon SageMaker Canvas](#) application in Studio.
  - Users of [Amazon SageMaker Studio Classic](#), the previous experience of Studio, can continue using the Autopilot UI in Studio Classic. Users with coding experience can continue using the [AutoML API references](#) in any supported SDK for technical implementation.

## Note

If you have been using Autopilot in Studio Classic until now and want to migrate to SageMaker Canvas, you might have to grant additional permissions to your user profile or IAM role so that you can create and use the SageMaker Canvas application. For more information, see [the section called “\(Optional\) Migrate from Autopilot in Studio Classic to SageMaker Canvas”](#).

- **Amazon SageMaker JumpStart:** SageMaker JumpStart provides pretrained, open-source models for a wide range of problem types to help you get started with machine learning. You can

incrementally train and tune these models before deployment. JumpStart also provides solution templates that set up infrastructure for common use cases, and executable example notebooks for machine learning with SageMaker AI.

# SageMaker Autopilot

### Important

As of November 30, 2023, Autopilot's UI is migrating to [Amazon SageMaker Canvas](#) as part of the updated [Amazon SageMaker Studio](#) experience. SageMaker Canvas provides analysts and citizen data scientists no-code capabilities for tasks such as data preparation, feature engineering, algorithm selection, training and tuning, inference, and more. Users can leverage built-in visualizations and what-if analysis to explore their data and different scenarios, with automated predictions enabling them to easily productionize their models. Canvas supports a variety of use cases, including computer vision, demand forecasting, intelligent search, and generative AI.

Users of [Amazon SageMaker Studio Classic](#), the previous experience of [Studio](#), can continue using the Autopilot UI in Studio Classic. Users with coding experience can continue using all [API references](#) in any supported SDK for technical implementation.

If you have been using Autopilot in Studio Classic until now and want to migrate to SageMaker Canvas, you might have to grant additional permissions to your user profile or IAM role so that you can create and use the SageMaker Canvas application. For more information, see [the section called “\(Optional\) Migrate from Autopilot in Studio Classic to SageMaker Canvas”](#).

All UI-related instructions in this guide pertain to Autopilot's standalone features before migrating to [Amazon SageMaker Canvas](#). Users following these instructions should use [Studio Classic](#).

Amazon SageMaker Autopilot is a feature set that simplifies and accelerates various stages of the machine learning workflow by automating the process of building and deploying machine

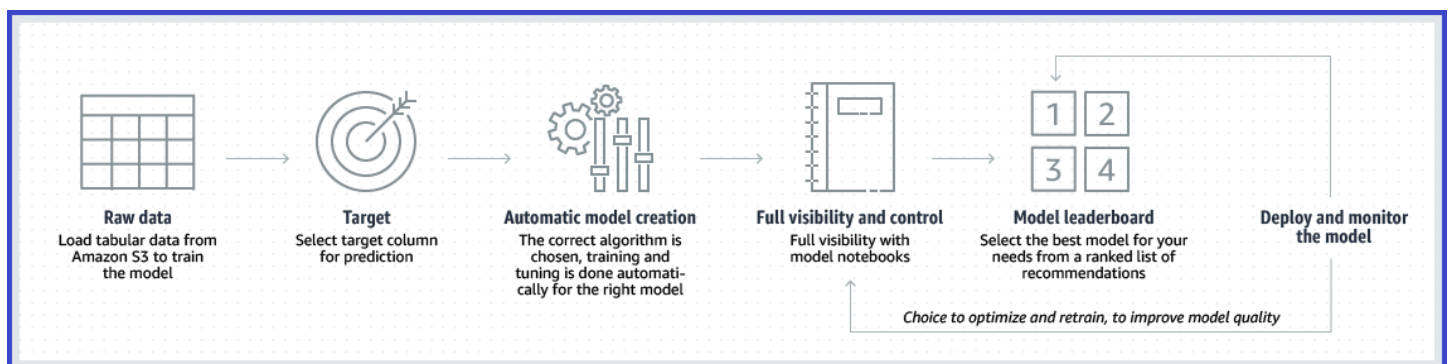

learning models (AutoML). The following page explains key information about Amazon SageMaker Autopilot.

Autopilot performs the following key tasks that you can use on autopilot or with various degrees of human guidance:

- **Data analysis and preprocessing:** Autopilot identifies your specific problem type, handles missing values, normalizes your data, selects features, and overall prepares the data for model training.
- **Model selection:** Autopilot explores a variety of algorithms and uses a cross-validation resampling technique to generate metrics that evaluate the predictive quality of the algorithms based on predefined objective metrics.
- **Hyperparameter optimization:** Autopilot automates the search for optimal hyperparameter configurations.
- **Model training and evaluation:** Autopilot automates the process of training and evaluating various model candidates. It splits the data into training and validation sets, trains the selected model candidates using the training data, and evaluates their performance on the unseen data of the validation set. Lastly, it ranks the optimized model candidates based on their performance and identifies the best performing model.
- **Model deployment:** Once Autopilot has identified the best performing model, it provides the option to deploy the model automatically by generating the model artifacts and the endpoint exposing an API. External applications can send data to the endpoint and receive the corresponding predictions or inferences.

Autopilot supports building machine learning models on large datasets up to hundreds of GBs.

The following diagram outlines the tasks of this AutoML process managed by Autopilot.

Depending on your comfort level with the machine learning process and coding experience, you can use Autopilot in different ways:

- **Using the Studio Classic UI**, users can choose between a no-code experience or have some level of human input.

 **Note**

Only experiments created from tabular data for problem types such as regression or classification are available via the Studio Classic UI.

- **Using the AutoML API**, users with coding experience can use available SDKs to create AutoML jobs. This approach provides greater flexibility and customization options and is available for all problem types.

Autopilot currently supports the following problem types:

 **Note**

For regression or classification problems involving tabular data, users can choose between two options: using the Studio Classic user interface or the [API Reference](#).

Tasks such as text and image classification, time-series forecasting, and fine-tuning of large language models are exclusively available through the version 2 of the [AutoML REST API](#).

If your language of choice is Python, you can refer to [AWS SDK for Python \(Boto3\)](#) or the [AutoMLV2 object](#) of the Amazon SageMaker Python SDK directly.

Users who prefer the convenience of a user interface can use [Amazon SageMaker Canvas](#) to access pre-trained models and generative AI foundation models, or create custom models tailored for specific text, image classification, forecasting needs, or generative AI.

- **Regression, binary, and multiclass classification** with tabular data formatted as CSV or Parquet files in which each column contains a feature with a specific data type and each row contains an observation. The column data types accepted include numerical, categorical, text, and time series that consists of strings of comma-separated numbers.
- To create an Autopilot job as a pilot experiment using the SageMaker API reference, see [Create Regression or Classification Jobs for Tabular Data Using the AutoML API](#).

- To create an Autopilot job as a pilot experiment using the Studio Classic UI, see [Create a Regression or Classification Autopilot experiment for tabular data using the Studio Classic UI](#).
- If you are an administrator looking to pre-configure default infrastructure, networking, or security parameters of Autopilot experiments in Studio Classic UI, see [Configure the default parameters of an Autopilot experiment \(for administrators\)](#).
- **Text classification** with data formatted as CSV or Parquet files in which a column provides the sentences to be classified, while another column should provide the corresponding class label. See [Create an AutoML job for text classification using the API](#).
- **Image classification** with image formats such as PNG, JPEG, or a combination of both. See [Create an Image Classification Job using the AutoML API](#).
- **Time-series forecasting** with time-series data formatted as CSV or Parquet files. See [Create an AutoML job for time-series forecasting using the API](#).
- Fine-tuning of large language models (LLMs) for **text generation** with data formatted as CSV or Parquet files. See [Create an AutoML job to fine-tune text generation models using the API](#).

Additionally, Autopilot helps users understand how models make predictions by automatically generating reports that show the importance of each individual feature. This provides transparency and insights into the factors influencing the predictions, which can be used by risk and compliance teams and external regulators. Autopilot also provides a model performance report, which encompasses a summary of evaluation metrics, a confusion matrix, various visualizations such as receiver operating characteristic curves and precision-recall curves, and more. The specific content of each report vary depending on the problem type of the Autopilot experiment.

The explainability and performance reports for the best model candidate in an Autopilot experiment are available for text, image, and tabular data classification problem types.

For tabular data use cases such as regression or classification, Autopilot offers additional visibility into how the data was wrangled and how the model candidates were selected, trained, and tuned by generating notebooks that contain the code used to explore the data and find the best performing model. These notebooks provide an interactive and exploratory environment to help you learn about the impact of various inputs or the trade-offs made in the experiments. You can experiment further with the higher performing model candidate by making your own modifications to the data exploration and candidate definition notebooks provided by Autopilot.

With Amazon SageMaker AI, you pay only for what you use. You pay for the underlying compute and storage resources within SageMaker AI or other AWS services, based on your usage. For more information about the cost of using SageMaker AI, see [Amazon SageMaker Pricing](#).

## Create Regression or Classification Jobs for Tabular Data Using the AutoML API

You can create an Autopilot regression or classification job for tabular data programmatically by calling the [CreateAutoMLJobV2](#) API action in any language supported by Autopilot or the AWS CLI. The following is a collection of mandatory and optional input request parameters for the `CreateAutoMLJobV2` API action. You can find the alternative information for the previous version of this action, `CreateAutoMLJob`. However, we recommend using `CreateAutoMLJobV2`.

For information on how this API action translates into a function in the language of your choice, see the [See Also](#) section of `CreateAutoMLJobV2` and choose an SDK. As an example, for Python users, see the full request syntax of [create\\_auto\\_ml\\_job\\_v2](#) in AWS SDK for Python (Boto3).

### Note

[CreateAutoMLJobV2](#) and [DescribeAutoMLJobV2](#) are new versions of [CreateAutoMLJob](#) and [DescribeAutoMLJob](#) which offer backward compatibility.

We recommend using the `CreateAutoMLJobV2`. `CreateAutoMLJobV2` can manage tabular problem types identical to those of its previous version `CreateAutoMLJob`, as well as non-tabular problem types such as image or text classification, or time-series forecasting.

At a minimum, all experiments on tabular data require the specification of the experiment name, providing locations for the input and output data, and specifying which target data to predict. Optionally, you can also specify the type of problem that you want to solve (regression, classification, multiclass classification), choose your modeling strategy (*stacked ensembles* or *hyperparameters optimization*), select the list of algorithms used by the Autopilot job to train the data, and more.

After the experiment runs, you can compare trials and delve into the details of the pre-processing steps, algorithms, and hyperparameter ranges of each model. You also have the option to download their [explainability](#) and [performance](#) reports. Use the provided [notebooks](#) to see the results of the automated data exploration or the candidate model definitions.

Find guidelines on how to migrate a `CreateAutoMLJob` to `CreateAutoMLJobV2` in [Migrate a CreateAutoMLJob to CreateAutoMLJobV2](#).

## Required parameters

### CreateAutoMLJobV2

When calling [CreateAutoMLJobV2](#) to create an Autopilot experiment for tabular data, you must provide the following values:

- An [AutoMLJobName](#) to specify the name of your job.
- At least one [AutoMLJobChannel](#) in [AutoMLJobInputDataConfig](#) to specify your data source.
- Both an [AutoMLJobObjective](#) metric and your chosen type of supervised learning problem (binary classification, multiclass classification, regression) in `AutoMLProblemTypeConfig`, or none at all. For tabular data, you must choose [TabularJobConfig](#) as the type of [AutoMLProblemTypeConfig](#). You set the supervised learning problem in the `ProblemType` attribute of `TabularJobConfig`.
- An [OutputDataConfig](#) to specify the Amazon S3 output path to store the artifacts of your AutoML job.

- A [RoleArn](#) to specify the ARN of the role used to access your data.

## CreateAutoMLJob

When calling [CreateAutoMLJob](#) to create an AutoML experiment, you must provide the following four values:

- An [AutoMLJobName](#) to specify the name of your job.
- At least one [AutoMLChannel](#) in [InputDataConfig](#) to specify your data source.
- An [OutputDataConfig](#) to specify the Amazon S3 output path to store the artifacts of your AutoML job.
- A [RoleArn](#) to specify the ARN of the role used to access your data.

All other parameters are optional.

## Optional parameters

The following sections provide details of some optional parameters that you can pass to your `CreateAutoMLJobV2` API action when using tabular data. You can find the alternative information for the previous version of this action, `CreateAutoMLJob`. However, we recommend using `CreateAutoMLJobV2`.

### How to set the training mode of an AutoML job

For tabular data, the set of algorithms run on your data to train your model candidates is dependent on your modeling strategy (ENSEMBLING or HYPERPARAMETER\_TUNING). The following details how to set this training mode.

If you keep blank (or null), the Mode is inferred based on the size of your dataset.

For information on Autopilot's *stacked ensembles* and *hyperparameters optimization* training methods, see [Training modes and algorithm support](#)

## CreateAutoMLJobV2

For tabular data, you must choose [TabularJobConfig](#) as the type of [AutoMLProblemTypeConfig](#).

You can set the [training method](#) of an AutoML job V2 with the [TabularJobConfig.Mode](#) parameter.

## CreateAutoMLJob

You can set the [training method](#) of an AutoML job with the [AutoMLJobConfig.Mode](#) parameter.

## How to select features and algorithms for training an AutoML job

### Features selection

Autopilot provides automatic data-preprocessing steps including feature selection and feature extraction. However, you can manually provide the features to be used in training with the `FeatureSpecificationS3Uri` attribute.

Selected features should be contained within a JSON file in the following format:

```
{ "FeatureAttributeNames":["col1", "col2", ...] }
```

The values listed in `["col1", "col2", ...]` are case sensitive. They should be a list of strings containing unique values that are subsets of the column names in the input data.

#### Note

The list of columns provided as features cannot include the target column.

## CreateAutoMLJobV2

For tabular data, you must choose [TabularJobConfig](#) as the type of [AutoMLProblemTypeConfig](#).

You can set the URL to your selected features with the [TabularJobConfig.FeatureSpecificationS3Uri](#) parameter.

## CreateAutoMLJob

You can set the `FeatureSpecificationS3Uri` attribute of [AutoMLCandidateGenerationConfig](#) within the [CreateAutoMLJob](#) API with the following format:

```
{
  "AutoMLJobConfig": {
    "CandidateGenerationConfig": {
      "FeatureSpecificationS3Uri": "string"
    }
  }
}
```

```

    },
  }
}

```

## Algorithms selection

By default, your Autopilot job runs a pre-defined list of algorithms on your dataset to train model candidates. The list of algorithms depends on the training mode (ENSEMBLING or HYPERPARAMETER\_TUNING) used by the job.

You can provide a subset of the default selection of algorithms.

### CreateAutoMLJobV2

For tabular data, you must choose [TabularJobConfig](#) as the type of [AutoMLProblemTypeConfig](#).

You can specify an array of selected `AutoMLAlgorithms` in the `AlgorithmsConfig` attribute of [CandidateGenerationConfig](#).

The following is an example of an `AlgorithmsConfig` attribute listing exactly three algorithms ("xgboost", "fastai", "catboost") in its `AutoMLAlgorithms` field for the ensembling training mode.

```

{
  "AutoMLProblemTypeConfig": {
    "TabularJobConfig": {
      "Mode": "ENSEMBLING",
      "CandidateGenerationConfig": {
        "AlgorithmsConfig": [
          {"AutoMLAlgorithms": ["xgboost", "fastai", "catboost"]}
        ]
      },
    },
  },
}

```

### CreateAutoMLJob

You can specify an array of selected `AutoMLAlgorithms` in the `AlgorithmsConfig` attribute of [AutoMLCandidateGenerationConfig](#).

The following is an example of an `AlgorithmsConfig` attribute listing exactly three algorithms ("xgboost", "fastai", "catboost") in its `AutoMLAlgorithms` field for the ensembling training mode.

```
{
  "AutoMLJobConfig": {
    "CandidateGenerationConfig": {
      "AlgorithmsConfig": [
        {"AutoMLAlgorithms": ["xgboost", "fastai", "catboost"]}
      ]
    },
    "Mode": "ENSEMBLING"
  }
}
```

For the list of available algorithms per training Mode, see [AutoMLAlgorithms](#). For details on each algorithm, see [Training modes and algorithm support](#).

## How to specify the training and validation datasets of an AutoML job

You can provide your own validation dataset and custom data split ratio, or let Autopilot split the dataset automatically.

### CreateAutoMLJobV2

Each [AutoMLJobChannel](#) object (see the required parameter [AutoMLJobInputDataConfig](#)) has a `ChannelType`, which can be set to either `training` or `validation` values that specify how the data is to be used when building a machine learning model. At least one data source must be provided and a maximum of two data sources is allowed: one for training data and one for validation data.

How you split the data into training and validation datasets depends on whether you have one or two data sources.

- If you only have **one data source**, the `ChannelType` is set to `training` by default and must have this value.
- If the `ValidationFraction` value in [AutoMLDataSplitConfig](#) is not set, 0.2 (20%) of the data from this source is used for validation by default.

- If the `ValidationFraction` is set to a value between 0 and 1, the dataset is split based on the value specified, where the value specifies the fraction of the dataset used for validation.
- If you have **two data sources**, the `ChannelType` of one of the `AutoMLJobChannel` objects must be set to `training`, the default value. The `ChannelType` of the other data source must be set to `validation`. The two data sources must have the same format, either CSV or Parquet, and the same schema. You must not set the value for the `ValidationFraction` in this case because all of the data from each source is used for either training or validation. Setting this value causes an error.

## CreateAutoMLJob

Each [AutoMLChannel](#) object (see the required parameter [InputDataConfig](#)) has a `ChannelType`, which can be set to either `training` or `validation` values that specify how the data is to be used when building a machine learning model. At least one data source must be provided and a maximum of two data sources is allowed: one for training data and one for validation data.

How you split the data into training and validation datasets depends on whether you have one or two data sources.

- If you only have **one data source**, the `ChannelType` is set to `training` by default and must have this value.
  - If the `ValidationFraction` value in [AutoMLDataSplitConfig](#) is not set, 0.2 (20%) of the data from this source is used for validation by default.
  - If the `ValidationFraction` is set to a value between 0 and 1, the dataset is split based on the value specified, where the value specifies the fraction of the dataset used for validation.
- If you have **two data sources**, the `ChannelType` of one of the `AutoMLChannel` objects must be set to `training`, the default value. The `ChannelType` of the other data source must be set to `validation`. The two data sources must have the same format, either CSV or Parquet, and the same schema. You must not set the value for the `ValidationFraction` in this case because all of the data from each source is used for either training or validation. Setting this value causes an error.

For information on split and cross-validation in Autopilot see [Cross-validation in Autopilot](#).

## How to set the problem type of an AutoML job

### CreateAutoMLJobV2

For tabular data, you must choose [TabularJobConfig](#) as the type of [AutoMLProblemTypeConfig](#).

You can further specify the type of supervised learning problem (binary classification, multiclass classification, regression) available for the model candidates of your AutoML job V2 with the [TabularJobConfig.ProblemType](#) parameter.

### CreateAutoMLJob

You can set the [type of problem](#) on an AutoML job with the [CreateAutoPilot.ProblemType](#) parameter. This limits the kind of preprocessing and algorithms that Autopilot tries. After the job is finished, if you had set the [CreateAutoPilot.ProblemType](#), then the [ResolvedAttribute.ProblemType](#) matches the ProblemType you set. If you keep it blank (or null), the ProblemType is inferred on your behalf.

#### Note

In some cases, Autopilot is unable to infer the ProblemType with high enough confidence, in which case you must provide the value for the job to succeed.

## How to add sample weights to an AutoML job

You can add a sample weights column to your tabular dataset and then pass it to your AutoML job to request dataset rows to be weighted during training and evaluation.

Support for sample weights is available in [ensembling mode](#) only. Your weights should be numeric and non-negative. Data points with invalid or no weight value are excluded. For more information on the available objective metrics, see [Autopilot weighted metrics](#).

### CreateAutoMLJobV2

For tabular data, you must choose [TabularJobConfig](#) as the type of [AutoMLProblemTypeConfig](#).

To set sample weights when creating an experiment (see [CreateAutoMLJobV2](#)), you can pass the name of your sample weights column in the SampleWeightAttributeName attribute of the

`TabularJobConfig` object. This ensures that your objective metric uses the weights for the training, evaluation, and selection of model candidates.

## CreateAutoMLJob

To set sample weights when creating an experiment (see [CreateAutoMLJob](#)), you can pass the name of your sample weights column in the `SampleWeightAttributeName` attribute of the [AutoMLChannel](#) object. This ensures that your objective metric uses the weights for the training, evaluation, and selection of model candidates.

## How to configure AutoML to initiate a remote job on EMR Serverless for large datasets

You can configure your AutoML job V2 to automatically initiate a remote job on Amazon EMR Serverless when additional compute resources are needed to process large datasets. By seamlessly transitioning to EMR Serverless when required, the AutoML job can handle datasets that would otherwise exceed the initially provisioned resources, without any manual intervention from you. EMR Serverless is available for the tabular and time series problem types. We recommend setting up this option for tabular datasets larger than 5 GB.

To allow your AutoML job V2 to automatically transition to EMR Serverless for large dataset, you need to provide an `EmrServerlessComputeConfig` object, which includes an `ExecutionRoleARN` field, to the `AutoMLComputeConfig` of the AutoML job V2 input request.

The `ExecutionRoleARN` is the ARN of the IAM role granting the AutoML job V2 the necessary permissions to run EMR Serverless jobs.

This role should have the following trust relationship:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "emr-serverless.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

And grant the permissions to:

- Create, list, and update EMR Serverless applications.
- Start, list, get, or cancel job runs on an EMR Serverless application.
- Tag EMR Serverless resources.
- Pass an IAM role to the EMR Serverless service for execution.

By granting the `iam:PassRole` permission, the AutoML job V2 can temporarily assume the `EMRServerlessRuntimeRole-*` role and pass it to the EMR Serverless service. These are the IAM roles used by the EMR Serverless job execution environments to access other AWS services and resources needed during runtime, such as Amazon S3 for data access, CloudWatch for logging, access to the AWS Glue Data Catalog or other services based on your workload requirements.

See [Job runtime roles for Amazon EMR Serverless](#) for details on this role permissions.

The IAM policy defined in the provided JSON document grants those permissions:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EMRServerlessCreateApplicationOperation",
      "Effect": "Allow",
      "Action": "emr-serverless:CreateApplication",
      "Resource": "arn:aws:emr-serverless:*:*/*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/sagemaker:is-canvas-resource": "True",
          "aws:ResourceAccount": "${aws:PrincipalAccount}"
        }
      }
    },
    {
      "Sid": "EMRServerlessListApplicationOperation",
      "Effect": "Allow",
      "Action": "emr-serverless:ListApplications",
      "Resource": "arn:aws:emr-serverless:*:*/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceAccount": "${aws:PrincipalAccount}"
        }
      }
    }
  ]
}
```

```

+         }
+     }
+ },
+ {
+     "Sid": "EMRServerlessApplicationOperations",
+     "Effect": "Allow",
+     "Action": [
+         "emr-serverless:UpdateApplication",
+         "emr-serverless:GetApplication"
+     ],
+     "Resource": "arn:aws:emr-serverless:*:*/applications/*",
+     "Condition": {
+         "StringEquals": {
+             "aws:ResourceTag/sagemaker:is-canvas-resource": "True",
+             "aws:ResourceAccount": "${aws:PrincipalAccount}"
+         }
+     }
+ },
+ {
+     "Sid": "EMRServerlessStartJobRunOperation",
+     "Effect": "Allow",
+     "Action": "emr-serverless:StartJobRun",
+     "Resource": "arn:aws:emr-serverless:*:*/applications/*",
+     "Condition": {
+         "StringEquals": {
+             "aws:RequestTag/sagemaker:is-canvas-resource": "True",
+             "aws:ResourceAccount": "${aws:PrincipalAccount}"
+         }
+     }
+ },
+ {
+     "Sid": "EMRServerlessListJobRunOperation",
+     "Effect": "Allow",
+     "Action": "emr-serverless:ListJobRuns",
+     "Resource": "arn:aws:emr-serverless:*:*/applications/*",
+     "Condition": {
+         "StringEquals": {
+             "aws:ResourceTag/sagemaker:is-canvas-resource": "True",
+             "aws:ResourceAccount": "${aws:PrincipalAccount}"
+         }
+     }
+ },
+ {
+     "Sid": "EMRServerlessJobRunOperations",

```

```

+     "Effect": "Allow",

## Migrate a CreateAutoMLJob to CreateAutoMLJobV2

We recommend users of CreateAutoMLJob to migrate to CreateAutoMLJobV2.

This section explains the differences in the input parameters between [CreateAutoMLJob](#) and [CreateAutoMLJobV2](#) by highlighting the changes in the position, name, or structure of the objects and attributes of the input request between the two versions.

- **Request attributes that did not change between versions.**

```
{
  "AutoMLJobName": "string",
  "AutoMLJobObjective": {
    "MetricName": "string"
  },
  "ModelDeployConfig": {
    "AutoGenerateEndpointName": boolean,
    "EndpointName": "string"
  },
  "OutputDataConfig": {
    "KmsKeyId": "string",
    "S3OutputPath": "string"
  },
  "RoleArn": "string",
  "Tags": [
    {
      "Key": "string",
      "Value": "string"
    }
  ]
}
```

- **Request attributes that changed position and structure between versions.**

The following attributes changed position: `DataSplitConfig`, `SecurityConfig`, `CompletionCriteria`, `Mode`, `FeatureSpecificationS3Uri`, `SampleWeightAttributeName`, `TargetAttributeName`.

#### CreateAutoMLJob

```
{
  "AutoMLJobConfig": {
    "Mode": "string",
    "CompletionCriteria": {
      "MaxAutoMLJobRuntimeInSeconds": number,
      "MaxCandidates": number,
      "MaxRuntimePerTrainingJobInSeconds": number
    }
  }
}
```

```

    },
    "DataSplitConfig": {
      "ValidationFraction": number
    },
    "SecurityConfig": {
      "EnableInterContainerTrafficEncryption": boolean,
      "VolumeKmsKeyId": "string",
      "VpcConfig": {
        "SecurityGroupIds": [ "string" ],
        "Subnets": [ "string" ]
      }
    },
    "CandidateGenerationConfig": {
      "FeatureSpecificationS3Uri": "string"
    }
  },
  "GenerateCandidateDefinitionsOnly": boolean,
  "ProblemType": "string"
}

```

## CreateAutoMLJobV2

```

{
  "AutoMLProblemTypeConfig": {
    "TabularJobConfig": {
      "Mode": "string",
      "ProblemType": "string",
      "GenerateCandidateDefinitionsOnly": boolean,
      "CompletionCriteria": {
        "MaxAutoMLJobRuntimeInSeconds": number,
        "MaxCandidates": number,
        "MaxRuntimePerTrainingJobInSeconds": number
      }
    },
    "FeatureSpecificationS3Uri": "string",
    "SampleWeightAttributeName": "string",
    "TargetAttributeName": "string"
  }
},
  "DataSplitConfig": {

  "SecurityConfig": {
    "EnableInterContainerTrafficEncryption": boolean,

```

```

    "VolumeKmsKeyId": "string",
    "VpcConfig": {
      "SecurityGroupIds": [ "string" ],
      "Subnets": [ "string" ]
    }
  }
}

```

- **The following attributes changed position and structure between versions.**

The following JSON illustrates how [AutoMLJobConfig.CandidateGenerationConfig](#) of type [AutoMLCandidateGenerationConfig](#) moved to [AutoMLProblemTypeConfig.TabularJobConfig.CandidateGenerationConfig](#) of type [CandidateGenerationConfig](#) in V2.

#### CreateAutoMLJob

```

{
  "AutoMLJobConfig": {
    "CandidateGenerationConfig": {
      "AlgorithmsConfig": [
        {
          "AutoMLAlgorithms": [ "string" ]
        }
      ],
      "FeatureSpecificationS3Uri": "string"
    }
  }
}

```

#### CreateAutoMLJobV2

```

{
  "AutoMLProblemTypeConfig": {
    "TabularJobConfig": {
      "CandidateGenerationConfig": {
        "AlgorithmsConfig": [
          {
            "AutoMLAlgorithms": [ "string" ]
          }
        ],
      },
    },
  },
},

```

```
}
```

- **Request attributes that changed name and structure.**

The following JSON illustrates how [InputDataConfig](#) (An array of [AutoMLChannel](#)) changed to [AutoMLJobInputDataConfig](#) (An array of [AutoMLJobChannel](#)) in V2. Note that the attributes `SampleWeightAttributeName` and `TargetAttributeName` move out of `InputDataConfig` and into `AutoMLProblemTypeConfig`.

#### CreateAutoMLJob

```
{
  "InputDataConfig": [
    {
      "ChannelType": "string",
      "CompressionType": "string",
      "ContentType": "string",
      "DataSource": {
        "S3DataSource": {
          "S3DataType": "string",
          "S3Uri": "string"
        }
      },
      "SampleWeightAttributeName": "string",
      "TargetAttributeName": "string"
    }
  ]
}
```

#### CreateAutoMLJobV2

```
{
  "AutoMLJobInputDataConfig": [
    {
      "ChannelType": "string",
      "CompressionType": "string",
      "ContentType": "string",
      "DataSource": {
        "S3DataSource": {
          "S3DataType": "string",
          "S3Uri": "string"
        }
      }
    }
  ]
}
```

```
    }  
  ]  
}
```

## Autopilot datasets and problem types

For tabular data (that is data in which each column contains a feature with a specific data type and each row contains an observation), Autopilot gives you the option of specifying the type of supervised learning problem available for the model candidates of the AutoML job, such as binary classification or regression, or of detecting it on your behalf based on the data you provide. Autopilot also supports multiple data formats and data types.

### Topics

- [Autopilot datasets, data types, and formats](#)
- [Autopilot problem types](#)

### Autopilot datasets, data types, and formats

Autopilot supports tabular data formatted as CSV files or as Parquet files: each column contains a feature with a specific data type and each row contains an observation. The properties of these two file formats differ considerably.

- **CSV** (comma-separated-values) is a row-based file format that stores data in human readable plaintext which a popular choice for data exchange as they are supported by a wide range of applications.
- **Parquet** is a column-based file format where the data is stored and processed more efficiently than row-based file formats. This makes them a better option for big data problems.

The **data types** accepted for columns include numerical, categorical, text, and time series that consists of strings of comma-separated numbers. If Autopilot detects it is dealing with **time series** sequences, it processes them through specialized feature transformers provided by the [tsfresh](#) library. This library takes the time series as an input and outputs a feature such as the highest absolute value of the time series or descriptive statistics on autocorrelation. These outputted features are then used as inputs to one of the three problem types.

Autopilot supports building machine learning models on large datasets up to hundreds of GBs. For details on the default resource limits for input datasets and how to increase them, see [Autopilot quotas](#).

## Autopilot problem types

For the tabular data, you further specify the type of supervised learning problems available for the model candidates as follows:

### Regression

Regression estimates the values of a dependent target variable based on one or more other variables or attributes that are correlated with it. An example is the prediction of house prices using features like the number of bathrooms and bedrooms, square footage of the house and garden. Regression analysis can create a model that takes one or more of these features as an input and predicts the price of a house.

### Binary classification

Binary classification is a type of supervised learning that assigns an individual to one of two predefined and mutually exclusive classes based on their attributes. It is supervised because the models are trained using examples where the attributes are provided with correctly labeled objects. A medical diagnosis for whether an individual has a disease or not based on the results of diagnostic tests is an example of binary classification.

### Multiclass classification

Multiclass classification is a type of supervised learning that assigns an individual to one of several classes based on their attributes. It is supervised because the models are trained using examples where the attributes are provided with correctly labelled objects. An example is the prediction of the topic most relevant to a text document. A document may be classified as being about, say, religion or politics or finance, or about one of several other predefined topic classes.

## Training modes and algorithm support

Autopilot supports different training modes and algorithms to address machine learning problems, report on quality and objective metrics, and to use cross-validation automatically, when needed.

### Training modes

SageMaker Autopilot can automatically select the training method based on the dataset size, or you can select it manually. The choices are as follows:

- **Ensembling** – Autopilot uses the [AutoGluon](#) library to train several base models. To find the best combination for your dataset, ensemble mode runs 10 trials with different model and meta parameter settings. Then Autopilot combines these models using a stacking ensemble method to create an optimal predictive model. For a list of algorithms that Autopilot supports in ensembling mode for tabular data, see the following **Algorithms support** section.
- **Hyperparameter optimization (HPO)** – Autopilot finds the best version of a model by tuning hyperparameters using Bayesian optimization or multi-fidelity optimization while running training jobs on your dataset. HPO mode selects the algorithms that are most relevant to your dataset and selects the best range of hyperparameters to tune your models. To tune your models, HPO mode runs up to 100 trials (default) to find the optimal hyperparameters settings within the selected range. If your dataset size is less than 100 MB, Autopilot uses Bayesian optimization. Autopilot chooses multi-fidelity optimization if your dataset is larger than 100 MB.

In multi-fidelity optimization, metrics are continuously emitted from the training containers. A trial that is performing poorly against a selected objective metric is stopped early. A trial that is performing well is allocated more resources.

For a list of algorithms that Autopilot supports in HPO mode, see the following **Algorithm support** section.

- **Auto** – Autopilot automatically chooses either ensembling mode or HPO mode based on your dataset size. If your dataset is larger than 100 MB, Autopilot chooses HPO. Otherwise, it chooses ensembling mode. Autopilot can fail to read the size of your dataset in the following cases.
  - If you enable Virtual Private Cloud (VPC) mode, for an AutoML job but the S3 bucket containing the dataset only allows access from the VPC.
  - The input [S3DataType](#) of your dataset is a ManifestFile.
  - The input [S3Uri](#) contains more than 1000 items.

If Autopilot is unable to read your dataset size, it defaults to choosing HPO mode.

#### **Note**

For optimal runtime and performance, use ensemble training mode for datasets that are smaller than 100 MB.

## Algorithms support

In **HPO mode**, Autopilot supports the following types of machine learning algorithms:

- [Linear learner](#) – A supervised learning algorithm that can solve either classification or regression problems.
- [XGBoost](#) – A supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models.
- Deep learning algorithm – A multilayer perceptron (MLP) and feedforward artificial neural network. This algorithm can handle data that is not linearly separable.

### Note

You don't need to specify an algorithm to use for your machine learning problem. Autopilot automatically selects the appropriate algorithm to train.

In **ensembling mode**, Autopilot supports the following types of machine learning algorithms:

- [LightGBM](#) – An optimized framework that uses tree-based algorithms with gradient boosting. This algorithm uses trees that grow in breadth, rather than depth, and is highly optimized for speed.
- [CatBoost](#) – A framework that uses tree-based algorithms with gradient boosting. Optimized for handling categorical variables.
- [XGBoost](#) – A framework that uses tree-based algorithms with gradient boosting that grows in depth, rather than breadth.
- [Random Forest](#) – A tree-based algorithm that uses several decision trees on random sub-samples of the data with replacement. The trees are split into optimal nodes at each level. The decisions of each tree are averaged together to prevent overfitting and improve predictions.
- [Extra Trees](#) – A tree-based algorithm that uses several decision trees on the entire dataset. The trees are split randomly at each level. The decisions of each tree are averaged to prevent overfitting and to improve predictions. Extra trees add a degree of randomization in comparison to the random forest algorithm.
- [Linear Models](#) – A framework that uses a linear equation to model the relationship between two variables in observed data.
- Neural network torch – A neural network model that's implemented using [Pytorch](#).

- Neural network fast.ai – A neural network model that's implemented using [fast.ai](#).

## Metrics and validation

This guide shows metrics and validation techniques that you can use to measure machine learning model performance. Amazon SageMaker Autopilot produces metrics that measure the predictive quality of machine learning model candidates. The metrics calculated for candidates are specified using an array of [MetricDatum](#) types.

### Autopilot metrics

The following list contains the names of the metrics that are currently available to measure model performance within Autopilot.

#### Note

Autopilot supports sample weights. To learn more about sample weights and the available objective metrics, see [Autopilot weighted metrics](#).

The following are the available metrics.

### Accuracy

The ratio of the number of correctly classified items to the total number of (correctly and incorrectly) classified items. It is used for both binary and multiclass classification. Accuracy measures how close the predicted class values are to the actual values. Values for accuracy metrics vary between zero (0) and one (1). A value of 1 indicates perfect accuracy, and 0 indicates perfect inaccuracy.

### AUC

The area under the curve (AUC) metric is used to compare and evaluate binary classification by algorithms that return probabilities, such as logistic regression. To map the probabilities into classifications, these are compared against a threshold value.

The relevant curve is the receiver operating characteristic curve. The curve plots the true positive rate (TPR) of predictions (or recall) against the false positive rate (FPR) as a function of the threshold value, above which a prediction is considered positive. Increasing the threshold results in fewer false positives, but more false negatives.

AUC is the area under this receiver operating characteristic curve. Therefore, AUC provides an aggregated measure of the model performance across all possible classification thresholds. AUC scores vary between 0 and 1. A score of 1 indicates perfect accuracy, and a score of one half (0.5) indicates that the prediction is not better than a random classifier.

## BalancedAccuracy

BalancedAccuracy is a metric that measures the ratio of accurate predictions to all predictions. This ratio is calculated after normalizing true positives (TP) and true negatives (TN) by the total number of positive (P) and negative (N) values. It is used in both binary and multiclass classification and is defined as follows:  $0.5 * ((TP/P) + (TN/N))$ , with values ranging from 0 to 1. BalancedAccuracy gives a better measure of accuracy when the number of positives or negatives differ greatly from each other in an imbalanced dataset, such as when only 1% of email is spam.

## F1

The F1 score is the harmonic mean of the precision and recall, defined as follows:  $F1 = 2 * (\text{precision} * \text{recall}) / (\text{precision} + \text{recall})$ . It is used for binary classification into classes traditionally referred to as positive and negative. Predictions are said to be true when they match their actual (correct) class, and false when they do not.

Precision is the ratio of the true positive predictions to all positive predictions, and it includes the false positives in a dataset. Precision measures the quality of the prediction when it predicts the positive class.

Recall (or sensitivity) is the ratio of the true positive predictions to all actual positive instances. Recall measures how completely a model predicts the actual class members in a dataset.

F1 scores vary between 0 and 1. A score of 1 indicates the best possible performance, and 0 indicates the worst.

## F1macro

The F1macro score applies F1 scoring to multiclass classification problems. It does this by calculating the precision and recall, and then taking their harmonic mean to calculate the F1 score for each class. Lastly, the F1macro averages the individual scores to obtain the F1macro score. F1macro scores vary between 0 and 1. A score of 1 indicates the best possible performance, and 0 indicates the worst.

## InferenceLatency

Inference latency is the approximate amount of time between making a request for a model prediction to receiving it from a real time endpoint to which the model is deployed. This metric is measured in seconds and only available in ensembling mode.

## LogLoss

Log loss, also known as cross-entropy loss, is a metric used to evaluate the quality of the probability outputs, rather than the outputs themselves. It is used in both binary and multiclass classification and in neural nets. It is also the cost function for logistic regression. Log loss is an important metric to indicate when a model makes incorrect predictions with high probabilities. Values range from 0 to infinity. A value of 0 represents a model that perfectly predicts the data.

## MAE

The mean absolute error (MAE) is a measure of how different the predicted and actual values are, when they're averaged over all values. MAE is commonly used in regression analysis to understand model prediction error. If there is linear regression, MAE represents the average distance from a predicted line to the actual value. MAE is defined as the sum of absolute errors divided by the number of observations. Values range from 0 to infinity, with smaller numbers indicating a better model fit to the data.

## MSE

The mean squared error (MSE) is the average of the squared differences between the predicted and actual values. It is used for regression. MSE values are always positive. The better a model is at predicting the actual values, the smaller the MSE value is.

## Precision

Precision measures how well an algorithm predicts the true positives (TP) out of all of the positives that it identifies. It is defined as follows:  $\text{Precision} = \text{TP}/(\text{TP}+\text{FP})$ , with values ranging from zero (0) to one (1), and is used in binary classification. Precision is an important metric when the cost of a false positive is high. For example, the cost of a false positive is very high if an airplane safety system is falsely deemed safe to fly. A false positive (FP) reflects a positive prediction that is actually negative in the data.

## PrecisionMacro

The precision macro computes precision for multiclass classification problems. It does this by calculating precision for each class and averaging scores to obtain precision for several classes. PrecisionMacro scores range from zero (0) to one (1). Higher scores reflect the model's

ability to predict true positives (TP) out of all of the positives that it identifies, averaged across multiple classes.

## R2

$R^2$ , also known as the coefficient of determination, is used in regression to quantify how much a model can explain the variance of a dependent variable. Values range from one (1) to negative one (-1). Higher numbers indicate a higher fraction of explained variability.  $R^2$  values close to zero (0) indicate that very little of the dependent variable can be explained by the model. Negative values indicate a poor fit and that the model is outperformed by a constant function. For linear regression, this is a horizontal line.

## Recall

Recall measures how well an algorithm correctly predicts all of the true positives (TP) in a dataset. A true positive is a positive prediction that is also an actual positive value in the data. Recall is defined as follows:  $\text{Recall} = \text{TP}/(\text{TP}+\text{FN})$ , with values ranging from 0 to 1. Higher scores reflect a better ability of the model to predict true positives (TP) in the data. It is used in binary classification.

Recall is important when testing for cancer because it's used to find all of the true positives. A false positive (FP) reflects a positive prediction that is actually negative in the data. It is often insufficient to measure only recall, because predicting every output as a true positive yields a perfect recall score.

## RecallMacro

The `RecallMacro` computes recall for multiclass classification problems by calculating recall for each class and averaging scores to obtain recall for several classes. `RecallMacro` scores range from 0 to 1. Higher scores reflect the model's ability to predict true positives (TP) in a dataset, whereas a true positive reflects a positive prediction that is also an actual positive value in the data. It is often insufficient to measure only recall, because predicting every output as a true positive will yield a perfect recall score.

## RMSE

Root mean squared error (RMSE) measures the square root of the squared difference between predicted and actual values, and is averaged over all values. It is used in regression analysis to understand model prediction error. It's an important metric to indicate the presence of large model errors and outliers. Values range from zero (0) to infinity, with smaller numbers indicating a better model fit to the data. RMSE is dependent on scale, and should not be used to compare datasets of different sizes.

Metrics that are automatically calculated for a model candidate are determined by the type of problem being addressed.

Refer to the [Amazon SageMaker API reference documentation](#) for the list of available metrics supported by Autopilot.

## Autopilot weighted metrics

### Note

Autopilot supports sample weights in ensembling mode only for all [available metrics](#) with the exception of `Balanced Accuracy` and `InferenceLatency`. `BalanceAccuracy` comes with its own weighting scheme for imbalanced datasets that does not require sample weights. `InferenceLatency` does not support sample weights. Both objective `Balanced Accuracy` and `InferenceLatency` metrics ignore any existing sample weights when training and evaluating a model.

Users can add a sample weights column to their data to ensure that each observation used to train a machine learning model is given a weight corresponding to its perceived importance to the model. This is especially useful in scenarios in which the observations in the dataset have varying degrees of importance, or in which a dataset contains a disproportionate number of samples from one class compared to others. Assigning a weight to each observation based on its importance or greater importance to a minority class can help a model's overall performance, or ensure that a model is not biased toward the majority class.

For information about how to pass sample weights when creating an experiment in the Studio Classic UI, see *Step 7* in [Create an Autopilot experiment using Studio Classic](#).

For information about how to pass sample weights programmatically when creating an Autopilot experiment using the API, see *How to add sample weights to an AutoML job* in [Create an Autopilot experiment programmatically](#).

## Cross-validation in Autopilot

Cross-validation is used in to reduce overfitting and bias in model selection. It is also used to assess how well a model can predict the values of an unseen validation dataset, if the validation dataset is drawn from the same population. This method is especially important when training on datasets that have a limited number of training instances.

Autopilot uses cross-validation to build models in hyperparameter optimization (HPO) and ensemble training mode. The first step in the Autopilot cross-validation process is to split the data into k-folds.

### K-fold splitting

K-fold splitting is a method that separates an input training dataset into multiple training and validation datasets. The dataset is split into k equally-sized sub-samples called folds. Models are then trained on k-1 folds and tested against the remaining k<sup>th</sup> fold, which is the validation dataset. The process is repeated k times using a different data set for validation.

The following image depicts k-fold splitting with k = 4 folds. Each fold is represented as a row. The dark-toned boxes represent the parts of the data used in training. The remaining light-toned boxes indicate the validation datasets.

*4-fold splitting*

Autopilot uses k-fold cross-validation for both hyperparameter optimization (HPO) mode and ensembling mode.

You can deploy Autopilot models that are built using cross-validation like you would with any other Autopilot or SageMaker AI model.

## HPO mode

K-fold cross-validation uses the k-fold splitting method for cross-validation. In HPO mode, Autopilot automatically implements k-fold cross-validation for small datasets with 50,000 or fewer training instances. Performing cross-validation is especially important when training on small datasets because it protects against overfitting and selection bias.

HPO mode uses a  $k$  value of 5 on each of the candidate algorithms that are used to model the dataset. Multiple models are trained on different splits, and the models are stored separately. When training is complete, validation metrics for each of the models are averaged to produce a single estimation metric. Lastly, Autopilot combines the models from the trial with the best validation metric into an ensemble model. Autopilot uses this ensemble model to make predictions.

The validation metric for the models trained by Autopilot is presented as the objective metric in the model leaderboard. Autopilot uses the default validation metric for each problem type that it handles, unless you specify otherwise. For the list of all metrics that Autopilot uses, see [Autopilot metrics](#).

For example, the [Boston Housing dataset](#) contains only 861 samples. If you build a model to predict house sale prices using this dataset without cross-validation, you risk training on a dataset that is not representative of the Boston housing stock. If you split the data only once into training and validation subsets, the training fold may only contain data mainly from the suburbs. As a result, you would train on data that isn't representative of the rest of the city. In this example, your model would likely overfit on this biased selection. K-fold cross-validation can reduce the risk of this kind of error by making full and randomized use of the available data for both training and validation.

Cross-validation can increase training times by an average of 20%. Training times may also increase significantly for complex datasets.

### Note

In HPO mode, you can see the training and validation metrics from each fold in your `/aws/sagemaker/TrainingJobs` CloudWatch Logs. For more information about CloudWatch Logs, see [Log groups and streams that Amazon SageMaker AI sends to Amazon CloudWatch Logs](#).

## Ensembling mode

### Note

Autopilot supports sample weights in ensembling mode. For the list of available metrics supporting sample weights, see [Autopilot metrics](#).

In ensembling mode, cross-validation is performed regardless of dataset size. Customers can either provide their own validation dataset and custom data split ratio, or let Autopilot split the dataset automatically into an 80-20% split ratio. The training data is then split into  $k$ -folds for cross-validation, where the value of  $k$  is determined by the AutoGluon engine. An ensemble consists of multiple machine learning models, where each model is known as the base model. A single base model is trained on  $(k-1)$  folds and makes out-of-fold predictions on the remaining fold. This process is repeated for all  $k$  folds, and the out-of-fold (OOF) predictions are concatenated to form a single set of predictions. All base models in the ensemble follow this same process of generating OOF predictions.

The following image depicts  $k$ -fold validation with  $k = 4$  folds. Each fold is represented as a row. The dark-toned boxes represent the parts of the data used in training. The remaining light-toned boxes indicate the validation datasets.

In the upper part of the image, in each fold, the first base model makes predictions on the validation dataset after training on the training datasets. At each subsequent fold, the datasets change roles. A dataset that was previously used for training is now used for validation, and this also applies in reverse. At the end of  $k$  folds, all of the predictions are concatenated to form a single set of predictions called an out-of-fold (OOF) prediction. This process is repeated for each  $n$  base models.

The OOF predictions for each base model are then used as features to train a stacking model. The stacking model learns the importance weights for each base model. These weights are used to combine the OOF predictions to form the final prediction. Performance on the validation dataset determines which base or stacking model is the best, and this model is returned as the final model.

In ensemble mode, you can either provide your own validation dataset or let Autopilot split the input dataset automatically into 80% train and 20% validation datasets. The training data is then split into k-folds for cross-validation and produces an OOF prediction and a base model for each fold.

These OOF predictions are used as features to train a stacking model, which simultaneously learns weights for each base model. These weights are used to combine the OOF predictions to form the final prediction. The validation datasets for each fold are used for hyperparameter tuning of all base models and the stacking model. Performance on the validation datasets determines which base or stacking model is the best model, and this model is returned as the final model.

## Autopilot model deployment and prediction

This Amazon SageMaker Autopilot guide includes steps for model deployment, setting up real-time inference, and running inference with batch jobs.

After you train your Autopilot models, you can deploy them to get predictions in one of two ways:

1. Use [Deploy models for real-time inference](#) to set up an endpoint and obtain predictions interactively. Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements.
2. Use [Run batch inference jobs](#) to make predictions in parallel on batches of observations on an entire dataset. Batch inference is a good option for large datasets or if you don't need an immediate response to a model prediction request.

### Note

To avoid incurring unnecessary charges: After the endpoints and resources that were created from model deployment are no longer needed, you can delete them. For information about pricing of instances by Region, see [Amazon SageMaker Pricing](#).

## Deploy models for real-time inference

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. This section shows how you can use real-time inferencing to obtain predictions interactively from your model.

To deploy the model that produced the best validation metric in an Autopilot experiment, you have several options. For example, when using Autopilot in SageMaker Studio Classic, you can deploy the model automatically or manually. You can also use SageMaker APIs to manually deploy an Autopilot model.

The following tabs show three options for deploying your model. These instructions assume that you have already created a model in Autopilot. If you don't have a model, see [Create Regression or Classification Jobs for Tabular Data Using the AutoML API](#). To see examples for each option, open each tab.

### Deploy using the Autopilot User Interface (UI)

The Autopilot UI contains helpful dropdown menus, toggles, tooltips, and more to help you navigate through model deployment. You can deploy using either one of the following procedures: Automatic or Manual.

- **Automatic Deployment:** To automatically deploy the best model from an Autopilot experiment to an endpoint

1. [Create an experiment](#) in SageMaker Studio Classic.
2. Toggle the **Auto deploy** value to **Yes**.

**Note**

**Automatic deployment will fail if either the default resource quota or your customer quota for endpoint instances in a Region is too limited.** In hyperparameter optimization (HPO) mode, you are required to have at least two ml.m5.2xlarge instances. In ensembling mode, you are required to have at least one ml.m5.12xlarge instance. If you encounter a failure related to quotas, you can [request a service limit increase](#) for SageMaker AI endpoint instances.

- **Manual Deployment:** To manually deploy the best model from an Autopilot experiment to an endpoint
  1. [Create an experiment](#) in SageMaker Studio Classic.
  2. Toggle the **Auto deploy** value to **No**.
  3. Select the model that you want to deploy under **Model name**.
  4. Select the orange **Deployment and advanced settings** button located on the right of the leaderboard. This opens a new tab.
  5. Configure the endpoint name, instance type, and other optional information.
  6. Select the orange **Deploy model** to deploy to an endpoint.
  7. Check the progress of the endpoint creation process in the <https://console.aws.amazon.com/sagemaker/> by navigating to the Endpoints section. That section is located in the **Inference** dropdown menu in the navigation panel.
  8. After the endpoint status changes from **Creating** to **InService**, as shown below, return to Studio Classic and invoke the endpoint.

## Deploy using SageMaker APIs

You can also obtain real-time inference by deploying your model using **API calls**. This section shows the five steps of this process using AWS Command Line Interface (AWS CLI) code snippets.

For complete code examples for both AWS CLI commands and AWS SDK for Python (boto3), open the tabs directly following these steps.

### 1. Obtain candidate definitions

Obtain the candidate container definitions from [InferenceContainers](#). These candidate definitions are used to create a SageMaker AI model.

The following example uses the [DescribeAutoMLJob](#) API to obtain candidate definitions for the best model candidate. See the following AWS CLI command as an example.

```
aws sagemaker describe-auto-ml-job --auto-ml-job-name <job-name> --region <region>
```

### 2. List candidates

The following example uses the [ListCandidatesForAutoMLJob](#) API to list all candidates. See the following AWS CLI command as an example.

```
aws sagemaker list-candidates-for-auto-ml-job --auto-ml-job-name <job-name> --  
region <region>
```

### 3. Create a SageMaker AI model

Use the container definitions from the previous steps to create a SageMaker AI model by using the [CreateModel](#) API. See the following AWS CLI command as an example.

```
aws sagemaker create-model --model-name '<your-custom-model-name>' \  
    --containers ['<container-definition1>, <container-  
definition2>, <container-definition3>'] \  
    --execution-role-arn '<execution-role-arn>' --region '<region>
```

### 4. Create an endpoint configuration

The following example uses the [CreateEndpointConfig](#) API to create an endpoint configuration. See the following AWS CLI command as an example.

```
aws sagemaker create-endpoint-config --endpoint-config-name '<your-custom-endpoint-
config-name>' \
    --production-variants '<list-of-production-variants>' \
    --region '<region>'
```

## 5. Create the endpoint

The following AWS CLI example uses the [CreateEndpoint](#) API to create the endpoint.

```
aws sagemaker create-endpoint --endpoint-name '<your-custom-endpoint-name>' \
    --endpoint-config-name '<endpoint-config-name-you-just-created>' \
    --region '<region>'
```

Check the progress of your endpoint deployment by using the [DescribeEndpoint](#) API. See the following AWS CLI command as an example.

```
aws sagemaker describe-endpoint --endpoint-name '<endpoint-name>' --region <region>
```

After the EndpointStatus changes to InService, the endpoint is ready to use for real-time inference.

## 6. Invoke the endpoint

The following command structure invokes the endpoint for real-time inferencing.

```
aws sagemaker invoke-endpoint --endpoint-name '<endpoint-name>' \
    --region '<region>' --body '<your-data>' [--content-type]
'<content-type>' <outfile>
```

The following tabs contain complete code examples for deploying a model with AWS SDK for Python (boto3) or the AWS CLI.

### AWS SDK for Python (boto3)

#### 1. Obtain the candidate definitions by using the following code example.

```
import sagemaker
import boto3
```

```

session = sagemaker.session.Session()

sagemaker_client = boto3.client('sagemaker', region_name='us-west-2')
job_name = 'test-auto-ml-job'

describe_response = sm_client.describe_auto_ml_job(AutoMLJobName=job_name)
# extract the best candidate definition from DescribeAutoMLJob response
best_candidate = describe_response['BestCandidate']
# extract the InferenceContainers definition from the candidate definition
inference_containers = best_candidate['InferenceContainers']

```

## 2. Create the model by using the following the code example.

```

# Create Model
model_name = 'test-model'
sagemaker_role = 'arn:aws:iam:444455556666:role/sagemaker-execution-role'
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    Containers = inference_containers
)

```

## 3. Create the endpoint configuration by using the following the code example.

```

endpoint_config_name = 'test-endpoint-config'

instance_type = 'ml.m5.2xlarge'
# for all supported instance types, see
# https://docs.aws.amazon.com/sagemaker/latest/APIReference/
API_ProductionVariant.html#sagemaker-Type-ProductionVariant-InstanceType #
Create endpoint config

endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {
            "VariantName": "variant1",
            "ModelName": model_name,
            "InstanceType": instance_type,
            "InitialInstanceCount": 1
        }
    ]
)

```

```
)

print(f"Created EndpointConfig: {endpoint_config_response['EndpointConfigArn']}")
```

#### 4. Create the endpoint and deploy the model with the following code example.

```
# create endpoint and deploy the model
endpoint_name = 'test-endpoint'
create_endpoint_response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,

    EndpointConfigName=endpoint_config_name)
print(create_endpoint_response)
```

#### Check the status of creating the endpoint by using the following the code example.

```
# describe endpoint creation status
status = sagemaker_client.describe_endpoint(EndpointName=endpoint_name)
["EndpointStatus"]
```

#### 5. Invoke the endpoint for real-time inferencing by using the following command structure.

```
# once endpoint status is InService, you can invoke the endpoint for inferencing
if status == "InService":
    sm_runtime = boto3.Session().client('sagemaker-runtime')
    inference_result = sm_runtime.invoke_endpoint(EndpointName='test-endpoint',
    ContentType='text/csv', Body='1,2,3,4,class')
```

## AWS Command Line Interface (AWS CLI)

### 1. Obtain the candidate definitions by using the following code example.

```
aws sagemaker describe-auto-ml-job --auto-ml-job-name 'test-automl-job' --
region us-west-2
```

### 2. Create the model by using the following code example.

```
aws sagemaker create-model --model-name 'test-sagemaker-model'
--containers '[{
```

```

    "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-
automl:2.5-1-cpu-py3", amzn-s3-demo-bucket1
    "ModelDataUrl": "s3://amzn-s3-demo-bucket/output/model.tar.gz",
    "Environment": {
      "AUTOML_SPARSE_ENCODE_RECORDIO_PROTOBUF": "1",
      "AUTOML_TRANSFORM_MODE": "feature-transform",
      "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "application/x-recordio-protobuf",
      "SAGEMAKER_PROGRAM": "sagemaker_serve",
      "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
    }
  }, {
    "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
xgboost:1.3-1-cpu-py3",
    "ModelDataUrl": "s3://amzn-s3-demo-bucket/output/model.tar.gz",
    "Environment": {
      "MAX_CONTENT_LENGTH": "20971520",
      "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "text/csv",
      "SAGEMAKER_INFERENCE_OUTPUT": "predicted_label",
      "SAGEMAKER_INFERENCE_SUPPORTED":
"predicted_label,probability,probabilities"
    }
  }, {
    "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-
automl:2.5-1-cpu-py3", aws-region
    "ModelDataUrl": "s3://amzn-s3-demo-bucket/output/model.tar.gz",
    "Environment": {
      "AUTOML_TRANSFORM_MODE": "inverse-label-transform",
      "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "text/csv",
      "SAGEMAKER_INFERENCE_INPUT": "predicted_label",
      "SAGEMAKER_INFERENCE_OUTPUT": "predicted_label",
      "SAGEMAKER_INFERENCE_SUPPORTED":
"predicted_label,probability,labels,probabilities",
      "SAGEMAKER_PROGRAM": "sagemaker_serve",
      "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
    }
  }
]}] \
--execution-role-arn 'arn:aws:iam::1234567890:role/sagemaker-execution-role' \
--region 'us-west-2'

```

For additional details, see [creating a model](#).

The `create model` command will return a response in the following format.

```
{
  "ModelArn": "arn:aws:sagemaker:us-west-2:1234567890:model/test-sagemaker-
model"
}
```

### 3. Create an endpoint configuration by using the following code example.

```
aws sagemaker create-endpoint-config --endpoint-config-name 'test-endpoint-config' \
\
--production-variants '[{"VariantName": "variant1",
  "ModelName": "test-sagemaker-model",
  "InitialInstanceCount": 1,
  "InstanceType": "ml.m5.2xlarge"
}]' \
--region us-west-2
```

The `create endpoint configuration` command will return a response in the following format.

```
{
  "EndpointConfigArn": "arn:aws:sagemaker:us-west-2:1234567890:endpoint-config/
test-endpoint-config"
}
```

### 4. Create an endpoint by using the following code example.

```
aws sagemaker create-endpoint --endpoint-name 'test-endpoint' \
--endpoint-config-name 'test-endpoint-config' \
--region us-west-2
```

The `create endpoint` command will return a response in the following format.

```
{
  "EndpointArn": "arn:aws:sagemaker:us-west-2:1234567890:endpoint/test-endpoint"
}
```

Check the progress of the endpoint deployment by using the following [describe-endpoint](#) CLI code example.

```
aws sagemaker describe-endpoint --endpoint-name 'test-endpoint' --region us-west-2
```

The previous progress check will return a response in the following format.

```
{
  "EndpointName": "test-endpoint",
  "EndpointArn": "arn:aws:sagemaker:us-west-2:1234567890:endpoint/test-
endpoint",
  "EndpointConfigName": "test-endpoint-config",
  "EndpointStatus": "Creating",
  "CreationTime": 1660251167.595,
  "LastModifiedTime": 1660251167.595
}
```

After the `EndpointStatus` changes to `InService`, the endpoint is ready for use in real-time inference.

5. **Invoke the endpoint** for real-time inferencing by using the following command structure.

```
aws sagemaker-runtime invoke-endpoint --endpoint-name 'test-endpoint' \
--region 'us-west-2' \
--body '1,51,3.5,1.4,0.2' \
--content-type 'text/csv' \
'/tmp/inference_output'
```

For more options, see [invoking an endpoint](#).

## Deploy models from different accounts

You can deploy an Autopilot model from a different account than the original account that a model was generated in. To implement cross-account model deployment, this section shows how to do the following:

### 1. Grant permission to the deploying account

To assume the role in the generating account, you must grant permission to the deploying account. This allows the deploying account to describe Autopilot jobs in the generating account.

The following example uses a generating account with a trusted `sagemaker-role` entity. The example shows how to give a deploying account with the ID `111122223333` permission to assume the role of the generating account.

```
"Statement": [  
  {  
    "Effect": "Allow",  
    "Principal": {  
      "Service": [  
        "sagemaker.amazonaws.com"  
      ],  
      "AWS": [ "111122223333" ]  
    },  
    "Action": "sts:AssumeRole"  
  }  
]
```

The new account with the ID `111122223333` can now assume the role for the generating account.

Next, call the `DescribeAutoMLJob` API from the deploying account to obtain a description of the job created by the generating account.

The following code example describes the model from the deploying account.

```
import sagemaker  
import boto3  
session = sagemaker.session.Session()  
  
sts_client = boto3.client('sts')  
sts_client.assume_role  
  
role = 'arn:aws:iam::111122223333:role/sagemaker-role'  
role_session_name = "role-session-name"  
_assumed_role = sts_client.assume_role(RoleArn=role,  
    RoleSessionName=role_session_name)  
  
credentials = _assumed_role["Credentials"]  
access_key = credentials["AccessKeyId"]  
secret_key = credentials["SecretAccessKey"]  
session_token = credentials["SessionToken"]
```

```

session = boto3.session.Session()

sm_client = session.client('sagemaker', region_name='us-west-2',
                           aws_access_key_id=access_key,
                           aws_secret_access_key=secret_key,
                           aws_session_token=session_token)

# now you can call describe automl job created in account A

job_name = "test-job"
response= sm_client.describe_auto_ml_job(AutoMLJobName=job_name)

```

## 2. Grant access to the deploying account to the model artifacts in the generating account.

The deploying account only needs access to the model artifacts in the generating account to deploy it. These are located in the [S3OutputPath](#) that was specified in the original CreateAutoMLJob API call during model generation.

To give the deploying account access to the model artifacts, choose one of the following options:

- a. [Give access](#) to the ModelDataUrl from the generating account to the deploying account.

Next, you need to give the deploying account permission to assume the role. follow the [real-time inferencing steps](#) to deploy.

- b. [Copy model artifacts](#) from the generating account's original [S3OutputPath](#) to the generating account.

To grant access to the model artifacts, you must define a best\_candidate model and reassign model containers to the new account.

The following example shows how to define a best\_candidate model and reassign the ModelDataUrl.

```

best_candidate = automl.describe_auto_ml_job()['BestCandidate']

# reassigning ModelDataUrl for best_candidate containers below
new_model_locations = ['new-container-1-ModelDataUrl', 'new-container-2-ModelDataUrl', 'new-container-3-ModelDataUrl']
new_model_locations_index = 0
for container in best_candidate['InferenceContainers']:

```

```
container['ModelDataUrl'] = new_model_locations[new_model_locations_index++]
```

After this assignment of containers, follow the steps in [Deploy using SageMaker APIs](#) to deploy.

To build a payload in real-time inferencing, see the notebook example to [define a test payload](#). To create the payload from a CSV file and invoke an endpoint, see the **Predict with your model** section in [Create a machine learning model automatically](#).

## Run batch inference jobs

Batch inferencing, also known as offline inferencing, generates model predictions on a batch of observations. Batch inference is a good option for large datasets or if you don't need an immediate response to a model prediction request. By contrast, online inference ([real-time inferencing](#)) generates predictions in real time. You can make batch inferences from an Autopilot model using the [SageMaker Python SDK](#), the Autopilot user interface (UI), the [AWS SDK for Python \(boto3\)](#), or the AWS Command Line Interface ([AWS CLI](#)).

The following tabs show three options for deploying your model: Using APIs, Autopilot UI, or using APIs to deploy from different accounts. These instructions assume that you have already created a model in Autopilot. If you don't have a model, see [Create Regression or Classification Jobs for Tabular Data Using the AutoML API](#). To see examples for each option, open each tab.

## Deploy a model using Autopilot UI

The Autopilot UI contains helpful dropdown menus, toggles, tooltips, and more to help you navigate through model deployment.

The following steps show how to deploy a model from an Autopilot experiment for batch predictions.

1. Sign in at <https://console.aws.amazon.com/sagemaker/> and select **Studio** from the navigation pane.
2. On the left navigation pane, choose **Studio**.
3. Under **Get started**, select the Domain that you want to launch the Studio application in. If your user profile only belongs to one Domain, you do not see the option for selecting a Domain.

4. Select the user profile that you want to launch the Studio Classic application for. If there is no user profile in the domain, choose **Create user profile**. For more information, see [Add user profiles](#).
5. Choose **Launch Studio**. If the user profile belongs to a shared space, choose **Open Spaces**.
6. When the SageMaker Studio Classic console opens, choose the **Launch SageMaker Studio** button.
7. Select **AutoML** from the left navigation pane.
8. Under **Name**, select the Autopilot experiment corresponding to the model that you want to deploy. This opens a new **AUTOPILOT JOB** tab.
9. In the **Model name** section, select the model that you want to deploy.
10. Choose **Deploy model**. This opens a new tab.
11. Choose **Make batch predictions** at the top of the page.
12. For **Batch transform job configuration**, input the **Instance type**, **Instance count** and other optional information.
13. In the **Input data configuration** section, open the dropdown menu.
  - a. For **S3 data type**, choose **ManifestFile** or **S3Prefix**.
  - b. For **Split type**, choose **Line**, **RecordIO**, **TFRecord** or **None**.
  - c. For **Compression**, choose **Gzip** or **None**.
14. For **S3 location**, enter the Amazon S3 bucket location of the input data and other optional information.
15. Under **Output data configuration**, enter the S3 bucket for the output data, and choose how to [assemble the output](#) of your job.
  - a. For **Additional configuration (optional)**, you can enter a MIME type and an **S3 Encryption key**.
16. For **Input/output filtering and data joins (optional)**, you enter a JSONpath expression to filter your input data, join the input source data with your output data, and enter a JSONpath expression to filter your output data.
  - a. For examples for each type of filter, see the [DataProcessing API](#).
17. To perform batch predictions on your input dataset, select **Create batch transform job**. A new **Batch Transform Jobs** tab appears.
18. In the **Batch Transform Jobs** tab: Locate the name of your job in **Status** section. Then check the progress of the job.

## Deploy using SageMaker APIs

To use the SageMaker APIs for batch inferencing, there are three steps:

### 1. Obtain candidate definitions

Candidate definitions from [InferenceContainers](#) are used to create a SageMaker AI model.

The following example shows how to use the [DescribeAutoMLJob](#) API to obtain candidate definitions for the best model candidate. See the following AWS CLI command as an example.

```
aws sagemaker describe-auto-ml-job --auto-ml-job-name <job-name> --region <region>
```

Use the [ListCandidatesForAutoMLJob](#) API to list all candidates. See the following AWS CLI command as an example.

```
aws sagemaker list-candidates-for-auto-ml-job --auto-ml-job-name <job-name> --  
region <region>
```

### 2. Create a SageMaker AI model

To create a SageMaker AI model using the [CreateModel](#) API, use the container definitions from the previous steps. See the following AWS CLI command as an example.

```
aws sagemaker create-model --model-name '<your-custom-model-name>' \  
    --containers ['<container-definition1>', <container-  
definition2>', <container-definition3>'] \  
    --execution-role-arn '<execution-role-arn>' --region '<region>
```

### 3. Create a SageMaker AI transform job

The following example creates a SageMaker AI transform job with the [CreateTransformJob](#) API. See the following AWS CLI command as an example.

```
aws sagemaker create-transform-job --transform-job-name '<your-custom-transform-job-  
name>' --model-name '<your-custom-model-name-from-last-step>' \  
--transform-input '{  
    "DataSource": {  
        "S3DataSource": {  
            "S3DataType": "S3Prefix",  
            "S3Uri": "<your-input-data>"  
        }  
    }  
}
```

```

    },
    "ContentType": "text/csv",
    "SplitType": "Line"
  }\
--transform-output '{
  "S3OutputPath": "<your-output-path>",
  "AssembleWith": "Line"
}'\
--transform-resources '{
  "InstanceType": "<instance-type>",
  "InstanceCount": 1
}' --region '<region>'

```

Check the progress of your transform job using the [DescribeTransformJob](#) API. See the following AWS CLI command as an example.

```
aws sagemaker describe-transform-job --transform-job-name '<your-custom-transform-job-name>' --region <region>
```

After the job is finished, the predicted result will be available in `<your-output-path>`.

The output file name has the following format: `<input_data_file_name>.out`. As an example, if your input file is `text_x.csv`, the output name will be `text_x.csv.out`.

The following tabs show code examples for SageMaker Python SDK, AWS SDK for Python (boto3), and the AWS CLI.

### SageMaker Python SDK

The following example uses the [SageMaker Python SDK](#) to make predictions in batches.

```

from sagemaker import AutoML

sagemaker_session= sagemaker.session.Session()

job_name = 'test-auto-ml-job' # your autopilot job name
automl = AutoML.attach(auto_ml_job_name=job_name)
output_path = 's3://test-auto-ml-job/output'
input_data = 's3://test-auto-ml-job/test_X.csv'

# call DescribeAutoMLJob API to get the best candidate definition
best_candidate = automl.describe_auto_ml_job()['BestCandidate']

```

```

best_candidate_name = best_candidate['CandidateName']

# create model
model = automl.create_model(name=best_candidate_name,
                           candidate=best_candidate)

# create transformer
transformer = model.transformer(instance_count=1,
                                instance_type='ml.m5.2xlarge',
                                assemble_with='Line',
                                output_path=output_path)

# do batch transform
transformer.transform(data=input_data,
                     split_type='Line',
                     content_type='text/csv',
                     wait=True)

```

## AWS SDK for Python (boto3)

The following example uses **AWS SDK for Python (boto3)** to make predictions in batches.

```

import sagemaker
import boto3

session = sagemaker.session.Session()

sm_client = boto3.client('sagemaker', region_name='us-west-2')
role = 'arn:aws:iam::1234567890:role/sagemaker-execution-role'
output_path = 's3://test-auto-ml-job/output'
input_data = 's3://test-auto-ml-job/test_X.csv'

best_candidate = sm_client.describe_auto_ml_job(AutoMLJobName=job_name)
['BestCandidate']
best_candidate_containers = best_candidate['InferenceContainers']
best_candidate_name = best_candidate['CandidateName']

# create model
reponse = sm_client.create_model(
    ModelName = best_candidate_name,
    ExecutionRoleArn = role,
    Containers = best_candidate_containers
)

```

```
# Launch Transform Job
response = sm_client.create_transform_job(
    TransformJobName=f'{best_candidate_name}-transform-job',
    ModelName=model_name,
    TransformInput={
        'DataSource': {
            'S3DataSource': {
                'S3DataType': 'S3Prefix',
                'S3Uri': input_data
            }
        },
        'ContentType': "text/csv",
        'SplitType': 'Line'
    },
    TransformOutput={
        'S3OutputPath': output_path,
        'AssembleWith': 'Line',
    },
    TransformResources={
        'InstanceType': 'ml.m5.2xlarge',
        'InstanceCount': 1,
    },
)
```

The batch inference job returns a response in the following format.

```
{'TransformJobArn': 'arn:aws:sagemaker:us-west-2:1234567890:transform-job/test-transform-job',
 'ResponseMetadata': {'RequestId': '659f97fc-28c4-440b-b957-a49733f7c2f2',
 'HTTPStatusCode': 200,
 'HTTPHeaders': {'x-amzn-requestid': '659f97fc-28c4-440b-b957-a49733f7c2f2',
 'content-type': 'application/x-amz-json-1.1',
 'content-length': '96',

## AWS Command Line Interface (AWS CLI)

1. **Obtain the candidate definitions** by using the following the code example.

```
aws sagemaker describe-auto-ml-job --auto-ml-job-name 'test-automl-job' --
region us-west-2
```

## 2. Create the model by using the following the code example.

```
aws sagemaker create-model --model-name 'test-sagemaker-model'
--containers '[{
  "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-
automl:2.5-1-cpu-py3",
  "ModelDataUrl": "s3://amzn-s3-demo-bucket/out/test-job1/data-processor-models/
test-job1-dpp0-1-e569ff7ad77f4e55a7e549a/output/model.tar.gz",
  "Environment": {
    "AUTOML_SPARSE_ENCODE_RECORDIO_PROTOBUF": "1",
    "AUTOML_TRANSFORM_MODE": "feature-transform",
    "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "application/x-recordio-protobuf",
    "SAGEMAKER_PROGRAM": "sagemaker_serve",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
  }
}, {
  "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
xgboost:1.3-1-cpu-py3",
  "ModelDataUrl": "s3://amzn-s3-demo-bucket/out/test-job1/tuning/flicdf10v2-
dpp0-xgb/test-job1E9-244-7490a1c0/output/model.tar.gz",
  "Environment": {
    "MAX_CONTENT_LENGTH": "20971520",
    "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "text/csv",
    "SAGEMAKER_INFERENCE_OUTPUT": "predicted_label",
    "SAGEMAKER_INFERENCE_SUPPORTED":
"predicted_label,probability,probabilities"
  }
}, {
  "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-
automl:2.5-1-cpu-py3",
  "ModelDataUrl": "s3://amzn-s3-demo-bucket/out/test-job1/data-processor-models/

    "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "text/csv",
    "SAGEMAKER_INFERENCE_INPUT": "predicted_label",
    "SAGEMAKER_INFERENCE_OUTPUT": "predicted_label",
    "SAGEMAKER_INFERENCE_SUPPORTED":
"predicted_label,probability,labels,probabilities",
    "SAGEMAKER_PROGRAM": "sagemaker_serve",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
  }
}]' \
```

```
--execution-role-arn 'arn:aws:iam::1234567890:role/sagemaker-execution-role' \
--region 'us-west-2'
```

### 3. Create the transform job by using the following the code example.

```
aws sagemaker create-transform-job --transform-job-name 'test-tranform-job' \
  --model-name 'test-sagemaker-model' \
  --transform-input '{
    "DataSource": {
      "S3DataSource": {
        "S3DataType": "S3Prefix",
        "S3Uri": "s3://amzn-s3-demo-bucket/data.csv"
      }
    },
    "ContentType": "text/csv",
    "SplitType": "Line"
  }' \
  --transform-output '{
    "S3OutputPath": "s3://amzn-s3-demo-bucket/output/",
    "AssembleWith": "Line"
  }' \
  --transform-resources '{
    "InstanceType": "ml.m5.2xlarge",
    "InstanceCount": 1
  }' \
  --region 'us-west-2'
```

### 4. Check the progress of the transform job by using the following the code example.

```
aws sagemaker describe-transform-job --transform-job-name 'test-tranform-job' --
region us-west-2
```

The following is the response from the transform job.

```
{
  "TransformJobName": "test-tranform-job",
  "TransformJobArn": "arn:aws:sagemaker:us-west-2:1234567890:transform-job/test-
  tranform-job",
  "TransformJobStatus": "InProgress",
  "ModelName": "test-model",
  "TransformInput": {
    "DataSource": {
      "S3DataSource": {
```

```

        "S3DataType": "S3Prefix",
        "S3Uri": "s3://amzn-s3-demo-bucket/data.csv"
    },
    "ContentType": "text/csv",
    "CompressionType": "None",
    "SplitType": "Line"
},
"TransformOutput": {
    "S3OutputPath": "s3://amzn-s3-demo-bucket/output/",
    "AssembleWith": "Line",
    "KmsKeyId": ""
},
"TransformResources": {
    "InstanceType": "ml.m5.2xlarge",
    "InstanceCount": 1
},
"CreationTime": 1662495635.679,
"TransformStartTime": 1662495847.496,
"DataProcessing": {
    "InputFilter": "$",
    "OutputFilter": "$",
    "JoinSource": "None"
}
}

```

After the `TransformJobStatus` changes to `Completed`, you can check the inference result in the `S3OutputPath`.

## Deploy models from different accounts

To create a batch inferencing job in a different account than the one that the model was generated in, follow the instructions in [Deploy models from different accounts](#). Then you can create models and transform jobs by following the [Deploy using SageMaker APIs](#).

## View model details

Autopilot generates details about the candidate models that you can obtain. These details include the following:

- A plot of the aggregated SHAP values that indicate the importance of each feature. This helps explain your models predictions.

- The summary statistics for various training and validation metrics, including the objective metric.
- A list of the hyperparameters used to train and tune the model.

To view model details after running an Autopilot job, follow these steps:

1. Choose the **Home** icon

from the left navigation pane to view the top-level **Amazon SageMaker Studio Classic** navigation menu.

2. Select the **AutoML** card from the main working area. This opens a new **Autopilot** tab.
3. In the **Name** section, select the Autopilot job that has the details that you want to examine. This opens a new **Autopilot job** tab.
4. The **Autopilot job** panel lists the metric values including the **Objective** metric for each model under **Model name**. The **Best model** is listed at the top of the list under **Model name** and is also highlighted in the **Models** tab.
  - To review model details, select the model that you are interested in and select **View model details**. This opens a new **Model Details** tab.
5. The **Model Details** tab is divided into four subsections.
  1. The top of the **Explainability** tab contains a plot of aggregated SHAP values that indicate the importance of each feature. Following that are the metrics and hyperparameter values for this model.
  2. The **Performance** tab contains metrics statistics a confusion matrix.
  3. The **Artifacts** tab contains information about model inputs, outputs, and intermediate results.
  4. The **Network** tab summarizes your network isolation and encryption choices.

 **Note**

Feature importance and information in the **Performance** tab is only generated for the **Best model**.

For more information about how the SHAP values help explain predictions based on feature importance, see the whitepaper [Understanding the model explainability](#). Additional information is also available in the [Model Explainability](#) topic in the SageMaker AI Developer Guide.

## View an Autopilot model performance report

An Amazon SageMaker AI model quality report (also referred to as performance report) provides insights and quality information for the best model candidate generated by an AutoML job. This includes information about the job details, model problem type, objective function, and other information related to the problem type. This guide shows how to view Amazon SageMaker Autopilot performance metrics graphically, or view metrics as raw data in a JSON file.

For example, in classification problems, the model quality report includes the following:

- Confusion matrix
- Area under the receiver operating characteristic curve (AUC)
- Information to understand false positives and false negatives
- Tradeoffs between true positives and false positives
- Tradeoffs between precision and recall

Autopilot also provides performance metrics for all of your candidate models. These metrics are calculated using all of the training data and are used to estimate model performance. The main working area includes these metrics by default. The type of metric is determined by the type of problem being addressed.

Refer to the [Amazon SageMaker API reference documentation](#) for the list of available metrics supported by Autopilot.

You can sort your model candidates with the relevant metric to help you select and deploy the model that addresses your business needs. For definitions of these metrics, see the [Autopilot candidate metrics](#) topic.

To view a performance report from an Autopilot job, follow these steps:

1. Choose the **Home** icon

)

from the left navigation pane to view the top-level **Amazon SageMaker Studio Classic** navigation menu.

2. Select the **AutoML** card from the main working area. This opens a new **Autopilot** tab.
3. In the **Name** section, select the Autopilot job that has the details that you want to examine. This opens a new **Autopilot job** tab.
4. The **Autopilot job** panel lists the metric values including the **Objective** metric for each model under **Model name**. The **Best model** is listed at the top of the list under **Model name** and it is highlighted in the **Models** tab.
  - To review model details, select the model that you are interested in and select **View in model details**. This opens a new **Model Details** tab.
5. Choose the **Performance** tab between the **Explainability** and **Artifacts** tab.
  - a. On the top right section of the tab, select the down arrow on the **Download Performance Reports** button.
  - b. The down arrow provides two options to view Autopilot performance metrics:
    - i. You can download a PDF of the performance report to view the metrics graphically.
    - ii. You can view metrics as raw data and download it as a JSON file.

For instructions on how to create and run an AutoML job in SageMaker Studio Classic, see [Create Regression or Classification Jobs for Tabular Data Using the AutoML API](#).

The performance report contains two sections. The first contains details about the Autopilot job that produced the model. The second section contains a model quality report.

### Autopilot Job details

This first section of the report gives some general information about the Autopilot job that produced the model. These job details include the following information:

- Autopilot candidate name
- Autopilot job name
- Problem type

- Objective metric
- Optimization direction

## Model quality report

Model quality information is generated by Autopilot model insights. The report's content that is generated depends on the problem type it addressed: regression, binary classification, or multiclass classification. The report specifies the number of rows that were included in the evaluation dataset and the time at which the evaluation occurred.

### Metrics tables

The first part of the model quality report contains metrics tables. These are appropriate for the type of problem that the model addressed.

The following image is an example of a metrics table that Autopilot generates for a regression problem. It shows the metric name, value, and standard deviation.

#### Metrics table

<b>Metric Name</b>	<b>Value</b>	<b>Standard Deviation</b>
<b>mae</b>	5.347324	0.118636
<b>mse</b>	87.874017	4.346468
<b>rmse</b>	9.374114	0.232349
<b>r2</b>	0.924700	0.003710

The following image is an example of a metrics table generated by Autopilot for a multiclass classification problem. It shows the metric name, value, and standard deviation.

## Metrics table

Metric Name	Value	Standard Deviation
<b>weighted_recall</b>	0.597104	0.005410
<b>weighted_precision</b>	0.591693	0.005729
<b>accuracy</b>	0.597104	0.005410
<b>weighted_f0_5</b>	0.592155	0.005659
<b>weighted_f1</b>	0.593423	0.005554
<b>weighted_f2</b>	0.595392	0.005456
<b>accuracy_best_constant_classifier</b>	0.200699	0.004422
<b>weighted_recall_best_constant_classifier</b>	0.200699	0.004422
<b>weighted_precision_best_constant_classifier</b>	0.040280	0.001753
<b>weighted_f0_5_best_constant_classifier</b>	0.047944	0.002039
<b>weighted_f1_best_constant_classifier</b>	0.067094	0.002684
<b>weighted_f2_best_constant_classifier</b>	0.111716	0.003808

## Graphical model performance information

The second part of the model quality report contains graphical information to help you evaluate model performance. The contents of this section depend on the problem type used in modeling.

### The area under the receiver operating characteristic curve

The area under the receiver operating characteristic curve represents the trade-off between true positive and false positive rates. It is an industry-standard accuracy metric used for binary classification models. AUC (area under the curve) measures the ability the model to predict a higher score for positive examples, as compared to negative examples. The AUC metric provides an aggregated measure of the model performance across all possible classification thresholds.

The AUC metric returns a decimal value from 0 to 1. AUC values near 1 indicate that the machine learning model is highly accurate. Values near 0.5 indicate that the model is performing no better than guessing at random. AUC values close to 0 indicate that the model has learned the correct patterns, but is making predictions that are as inaccurate as possible. Values near zero can indicate a problem with the data. For more information about the AUC metric, see the [Receiver operating characteristic](#) article on Wikipedia.

The following is an example of an area under the receiver operating characteristic curve graph to evaluate predictions made by a binary classification model. The dashed thin line represents the area under the receiver operating characteristic curve that a model which classifies no-better-than-

random guessing would score, with an AUC score of 0.5. The curves of more accurate classification models lie above this random baseline, where the rate of true positives exceeds the rate of false positives. The area under the receiver operating characteristic curve representing the performance of the binary classification model is the thicker solid line.

A summary of the graph's components of **false positive rate (FPR)** and **true positive rate (TPR)** are defined as follows.

- Correct predictions
  - **True positive (TP)**: The predicted value is 1, and the true value is 1.
  - **True negative (TN)**: The predicted value is 0, and the true value is 0.
- Erroneous predictions
  - **False positive (FP)**: The predicted value is 1, but the true value is 0.
  - **False negative (FN)**: The predicted value is 0, but the true value is 1.

The **false positive rate** (FPR) measures the fraction of true negatives (TN) that were falsely predicted as positives (FP), over the sum of FP and TN. The range is 0 to 1. A smaller value indicates better predictive accuracy.

- $FPR = FP / (FP + TN)$

The **true positive rate** (TPR) measures the fraction true positives that were correctly predicted as positives (TP) over the sum of TP and false negatives (FN). The range is 0 to 1. A larger value indicates better predictive accuracy.

- $TPR = TP / (TP + FN)$

## Confusion matrix

A confusion matrix provides a way to visualize the accuracy of the predictions made by a model for binary and multiclass classification for different problems. The confusion matrix in the model quality report contains the following.

- The number and percentage of correct and incorrect predictions for the actual labels
- The number and percentage of accurate predictions on the diagonal from the upper-left to the lower-right corner
- The number and percentage of inaccurate predictions on the diagonal from the upper-right to the lower-left corner

The incorrect predictions on a confusion matrix are the confusion values.

The following diagram is an example of a confusion matrix for a binary classification problem. It contains the following information:

- The vertical axis is divided into two rows containing true and false actual labels.
- The horizontal axis is divided into two columns containing true and false labels that were predicted by the model.
- The color bar assigns a darker tone to a larger number of samples to visually indicate the number of values that were classified in each category.

In this example, the model predicted actual 2817 false values correctly, and 353 actual true values correctly. The model incorrectly predicted 130 actual true values to be false and 33 actual false

values to be true. The difference in tone indicates that the dataset is not balanced. The imbalance is because there are many more actual false labels than actual true labels.

The following diagram is an example of a confusion matrix for a multi-class classification problem. The confusion matrix in the model quality report contains the following.

- The vertical axis is divided into three rows containing three different actual labels.
- The horizontal axis is divided into three columns containing labels that were predicted by the model.
- The color bar assigns a darker tone to a larger number of samples to visually indicate the number of values that were classified in each category.

In the example below, the model correctly predicted actual 354 values for label **f**, 1094 values for label **i** and 852 values for label **m**. The difference in tone indicates that the dataset is not balanced because there are many more labels for the value **i** than for **f** or **m**.

The confusion matrix in the model quality report provided can accommodate a maximum of 15 labels for multiclass classification problem types. If a row corresponding to a label shows a Nan value, it means that the validation dataset used to check model predictions does not contain data with that label.

### Gain curve

In binary classification, a gain curve predicts the cumulative benefit of using a percentage of the dataset to find a positive label. The gain value is calculated during training by dividing the cumulative number of positive observations by the total number of positive observations in the data, at each decile. If the classification model created during training is representative of the unseen data, you can use the gain curve to predict the percentage of data that you must target to obtain a percentage of positive labels. The greater the percentage of the dataset used, the higher the percentage of positive labels found.

In the following example graph, the gain curve is the line with changing slope. The straight line is the percentage of positive labels found by selecting a percentage of data from the dataset at

random. Upon targeting 20% of the dataset, you would expect to find larger than 40% of the positive labels. As an example, you might consider using a gain curve to determine your efforts in a marketing campaign. Using our gain curve example, for 83% of people in a neighborhood to purchase cookies, you'd send an advertisement to about 60% of the neighborhood.

## Lift curve

In binary classification, the lift curve illustrates the uplift of using a trained model to predict the likelihood of finding a positive label compared to a random guess. The lift value is calculated during training using the ratio of percentage gain to the ratio of positive labels at each decile. If the model created during training is representative of the unseen data, use the lift curve to predict the benefit of using the model over randomly guessing.

In the following example graph, the lift curve is the line with changing slope. The straight line is the lift curve associated with selecting the corresponding percentage randomly from the dataset.

Upon targeting 40% of the dataset with your model's classification labels, you would expect to find about 1.7 times the number of the positive labels that you would have found by randomly selecting 40% of the unseen data.

## Precision-recall curve

The precision-recall curve represents the tradeoff between precision and recall for binary classification problems.

**Precision** measures the fraction of actual positives that are predicted as positive (TP) out of all positive predictions (TP and false positive). The range is 0 to 1. A larger value indicates better accuracy in the predicted values.

- Precision =  $TP / (TP + FP)$

**Recall** measures the fraction of actual positives that are predicted as positive (TP) out of all actual positive predictions (TP and false negative). This is also known as the sensitivity or as the true positive rate. The range is 0 to 1. A larger value indicates better detection of positive values from the sample.

- $\text{Recall} = \text{TP}/(\text{TP}+\text{FN})$

The objective of a classification problem is to correctly label as many elements as possible. A system with high recall but low precision returns a high percentage of false positives.

The following graphic depicts a spam filter that marks every email as spam. It has high recall, but low precision, because recall doesn't measure false positives.

Give more weight to recall over precision if your problem has a low penalty for false positive values, but a high penalty for missing a true positive result. For example, detecting an impending collision in a self-driving vehicle.

By contrast, a system with high precision, but low recall, returns a high percentage of false negatives. A spam filter that marks every email as desirable (not spam) has high precision but low recall because precision doesn't measure false negatives.

If your problem has a low penalty for false negative values, but a high penalty for missing a true negative results, give more weight to precision over recall. For example, flagging a suspicious filter for a tax audit.

The following graphic depicts a spam filter that has high precision but low recall, because precision doesn't measure false negatives.

A model that makes predictions with both high precision and high recall produces a high number of correctly labeled results. For more information, see [Precision and recall](#) article in Wikipedia.

### Area under precision-recall curve (AUPRC)

For binary classification problems, Amazon SageMaker Autopilot includes a graph of the area under the precision-recall curve (AUPRC). The AUPRC metric provides an aggregated measure of the model performance across all possible classification thresholds and uses both precision and recall. AUPRC does not take the number of true negatives into account. Therefore, it can be useful to evaluate model performance in cases where there's a large number of true negatives in the data. For example, to model a gene containing a rare mutation.

The following graphic is an example of an AUPRC graph. Precision at its highest value is 1, and recall is at 0. In the lower right corner of the graph, recall is its highest value (1) and precision is 0. In between these two points, the AUPRC curve illustrates the tradeoff between precision and recall at different thresholds.

### Actual against predicted plot

The actual against predicted plot shows the difference between actual and predicted model values. In the following example graph, the solid line is a linear line of best fit. If the model were 100% accurate, each predicted point would equal its corresponding actual point and lie on this line of best fit. The distance away from the line of best fit is a visual indication of model error. The larger the distance away from the line of best fit, the higher the model error.

## Standardized residual plot

A standardized residual plot incorporates the following statistical terms:

### **residual**

A (raw) residual shows the difference between actual and values predicted by your model. The larger the difference, the larger the residual value.

### **standard deviation**

The standard deviation is a measure of how values vary from an average value. A high standard deviation indicates that many values are very different from their average value. A low standard deviation indicates that many values are close to their average value.

## standardized residual

A standardized residual divides the raw residuals by their standard deviation. Standardized residuals have units of standard deviation and are useful in identifying outliers in data regardless of the difference in scale of the raw residuals. If a standardized residual is much smaller or larger than the other standardized residuals, it indicates that the model is not fitting these observations well.

The standardized residual plot measures the strength of the difference between observed and expected values. The actual predicted value is displayed on the x axis. A point with a value larger than an absolute value of 3 is commonly regarded as an outlier.

The following example graph shows that a large number of standardized residuals are clustered around 0 on the horizontal axis. The values close to zero indicate that the model is fitting these points well. The points towards the top and bottom of the plot are not predicted well by the model.

## Residual histogram

A residual histogram incorporates the following statistical terms:

### **residual**

A (raw) residual shows the difference between actual and values predicted by your model. The larger the difference, the larger the residual value.

### **standard deviation**

The standard deviation is a measure of how much values vary from an average value. A high standard deviation indicates that many values are very different from their average value. A low standard deviation indicates that many values are close to their average value.

### **standardized residual**

A standardized residual divides the raw residuals by their standard deviation. Standardized residuals have units of standard deviation. These are useful in identifying outliers in data regardless of the difference in scale of the raw residuals. If a standardized residual is much smaller or larger than the other standardized residuals, it would indicate that the model is not fitting these observations well.

### **histogram**

A histogram is a graph that shows how often a value occurred.

The residual histogram shows the distribution of standardized residual values. A histogram distributed in a bell shape and centered at zero indicates that the model does not systematically overpredict or underpredict any particular range of target values.

In the following graphic, the standardized residual values indicate that the model is fitting the data well. If the graph showed values far away from the center value, it would indicate that those values don't fit the model well.

## Autopilot notebooks generated to manage AutoML tasks

Amazon SageMaker Autopilot manages the key tasks in an automatic machine learning (AutoML) process using an AutoML job. The AutoML job creates three notebook-based reports that describe the plan that Autopilot follows to generate candidate models.

A candidate model consists of a (pipeline, algorithm) pair. First, there's a **data exploration** notebook that describes what Autopilot learned about the data that you provided. Second, there's a **candidate definition** notebook, which uses the information about the data to generate candidates. Third, a **model insights** report that can help detail the performance characteristics of the best model in the leaderboard of an Autopilot experiment.

### Topics

- [Autopilot data exploration report](#)
- [Find and run the candidate definition notebook](#)

You can run these notebooks in Amazon SageMaker AI, or locally, if you have installed the [Amazon SageMaker Python SDK](#). You can share the notebooks just like any other SageMaker Studio Classic notebook. The notebooks are created for you to conduct experiments. For example, you could edit the following items in the notebooks:

- Preprocessors used on the data
- Amount of hyperparameter optimization (HPO) runs and their parallelism
- Algorithms to try
- Instance types used for the HPO jobs
- Hyperparameter ranges

Modifications to the candidate definition notebook are encouraged as a learning tool. With this capability, you learn how decisions made during the machine learning process impact your results.

 **Note**

When you run the notebooks in your default instance, you incur baseline costs. However, when you run HPO jobs from the candidate notebook, these jobs use additional compute resources that incur additional costs.

## Autopilot data exploration report

Amazon SageMaker Autopilot cleans and pre-processes your dataset automatically. High-quality data improves machine learning efficiency and produces models that make more accurate predictions.

There are issues with customer-provided datasets that cannot be fixed automatically without the benefit of some domain knowledge. Large outlier values in the target column for regression problems, for example, may cause suboptimal predictions for the non-outlier values. Outliers may need to be removed depending on the modeling objective. If a target column is included by accident as one of the input features, the final model will validate well, but be of little value for future predictions.

To help customers discover these sorts of issues, Autopilot provides a data exploration report that contains insights into potential issues with their data. The report also suggests how to handle the issues.

A data exploration notebook containing the report is generated for every Autopilot job. The report is stored in an Amazon S3 bucket and can be accessed from your output path. The path of the data exploration report usually adheres to the following pattern.

```
[s3 output path]/[name of the automl job]/sagemaker-automl-candidates/  
[name of processing job used for data analysis]/notebooks/SageMaker  
AIAutopilotDataExplorationNotebook.ipynb
```

The location of the data exploration notebook can be obtained from the Autopilot API using the [DescribeAutoMLJob](#) operation response, which is stored in [DataExplorationNotebookLocation](#).

When running Autopilot from SageMaker Studio Classic, you can open the data exploration report using the following steps:

1. Choose the **Home** icon

from the *left navigation pane* to view the top-level **Amazon SageMaker Studio Classic** navigation menu.

2. Select the **AutoML** card from the main working area. This opens a new **Autopilot** tab.
3. In the **Name** section, select the Autopilot job that has the data exploration notebook that you want to examine. This opens a new **Autopilot job** tab.
4. Select **Open data exploration notebook** from the top right section of the **Autopilot job** tab.

The data exploration report is generated from your data before the training process begins. This allows you to stop Autopilot jobs that might lead to meaningless results. Likewise, you can address any issues or improvements with your dataset before rerunning Autopilot. This way, you can use your domain expertise to improve the data quality manually, before you train a model on a better-curated dataset.

The data report contains only static markdown and can be opened in any Jupyter environment. The notebook that contains the report can be converted to other formats, such as PDF or HTML. For more information about conversions, see [Using the nbconvert script to convert Jupyter notebooks to other formats..](#)

## Topics

- [Dataset Summary](#)
- [Target Analysis](#)

- [Data Sample](#)
- [Duplicate rows](#)
- [Cross column correlations](#)
- [Anomalous Rows](#)
- [Missing values, cardinality, and descriptive statistics](#)

## Dataset Summary

This **Dataset Summary** provides key statistics characterizing your dataset including the number of rows, columns, percent duplicate rows and missing target values. It is intended to provide you with a quick alert when there are issue with your dataset that Amazon SageMaker Autopilot has detected and that are likely to require your intervention. The insights are surfaced as warnings that are classified as being of either “high” or “low” severity. The classification depends on the level of confidence that the issue will adversely impact the performance of the model.

The high and low severity insights appear in the summary as pop-ups. For most of the insights, recommendations are offered for how to confirm that there is an issue with the dataset that requires your attention. Proposals are also provided for how to resolve the issues.

Autopilot provides additional statistics about missing or not valid target values in our dataset to help you detect other issues that may not be captured by high severity insights. An unexpected number of columns of a particular type might indicate that some columns that you want to use may be missing from the dataset. It could also indicate that there was an issue with how the data was prepared or stored. Fixing these data problems brought to your attention by Autopilot can improve the performance of the machine learning models trained on your data.

High severity insights are shown in the summary section and in other relevant sections in the report. Examples of high and low-severity insights are usually given depending on the section of the data report.

## Target Analysis

Various high and low-severity insights are shown in this section related to the distribution of values in the target column. Check that target column contains the correct values. Incorrect values in target column will likely result in a machine learning model that doesn't serve the intended business purpose. Several data insights of high and low severity are present in this section. Here are several examples.

- **Outlier target values** - Skewed or unusual target distribution for regression, such as heavy tailed targets.
- **High or low target cardinality** - Infrequent number of class labels or a large number of unique classes for classification.

For both regression and classification problem types, not valid values such as numeric infinity, NaN or empty space in target column are surfaced. Depending on the problem type, different dataset statistics are presented. A distribution of target column values for a regression problem allows you to verify if the distribution is what you expected.

The following screenshot shows an Autopilot data report, which includes statistics such as the mean, median, minimum, maximum, percentage of outliers in your dataset. The screenshot also includes a histogram showing the distribution of labels in the target column. The histogram shows **Target Column Values** on the horizontal axis and **Count** on the vertical axis. A box highlights the **Outliers Percentage** section of the screenshot to indicate where this statistic appears.

Multiple statistics are shown regarding target values and their distribution. If any of the outliers, not valid values, or missing percentages are greater than zero, these values are surfaced so you can investigate why your data contains unusable target values. Some unusable target values are highlighted as a low severity insight warning.

In the following screenshot, a ` symbol was added accidentally to the target column, which prevented the numeric value of the target from being parsed. A **Low severity insight: "Invalid**

**target values"** warning appears. The warning in this example states "0.14% of the labels in the target column could not be converted to numeric values. The most common non-numeric values are: ["-3.8e-05", "-9-05", "-4.7e-05", "-1.4999999999999999e-05", "-4.3e-05"]. That usually indicates that there are problems with data collection or processing. Amazon SageMaker Autopilot ignores all observations with invalid target label."

**⚠ Low severity insight: "Invalid target values"**

0.14% of the labels in the target column could not be converted to numeric values. The most common non-numeric values are: ["-3.8e-05", "-9e-05", "-4.7e-05", "-1.4999999999999999e-05", "-4.3e-05"]. That usually indicates that there are problems with data collection or processing. Amazon SageMaker Autopilot ignores all observations with invalid target label.

Autopilot also provides a histogram showing the distribution of labels for classification.

The following screenshot shows an example of statistics given for your target column including the number of classes, missing or not valid values. A histogram with **Target Label** on the horizontal axis and **Frequency** on the vertical axis shows the distribution of each label category.

Number of Classes	Invalid Percentage	Missing Percentage
23	0.00%	0.00%

Target Label	Frequency Percentage	Label Count
9	16.55%	230
10	15.18%	211
8	13.60%	189
11	11.65%	162
7	9.35%	130
12	6.40%	89
6	6.19%	86
13	4.89%	68
14	3.02%	42
5	2.73%	38

### **Note**

You can find definitions of all the terms presented in this and other sections in **Definitions** section at the bottom of the report notebook.

## Data Sample

Autopilot presents an actual sample of your data to help you spot issues with your dataset. The sample table scrolls horizontally. Inspect the sample data to verify that all the necessary columns are present in the dataset.

Autopilot also calculates a measure of prediction power, that can be used to identify a linear or nonlinear relationship between a feature and the target variable. A value of 0 indicates that the feature has no predictive value in predicting the target variable. A value of 1 indicates the highest predictive power for the target variable. For more information on predictive power, see the **Definitions** section.

### Note

It is not recommended that you use prediction power as a substitute for feature importance. Only use it if you're certain that prediction power is an appropriate measure for your use case.

The following screenshot shows example data sample. The top row contains the prediction power of each column in your dataset. The second row contains the column data type. Subsequent rows contain the labels. The columns contain the target column followed by each feature column. Each feature column has an associated prediction power, highlighted in this screenshot, with a box. In this example, the column containing the feature x51 has a predictive power of 0.68 for the target variable y. The feature x55 is slightly less predictive with a prediction power of 0.59.

	y	x51	x55	x54	x52	x20	x56	x15
<b>Prediction Power</b>	-	0.680107	0.594356	0.580346	0.548662	0.543034	0.480431	0.448701
<b>Column Types</b>	-	numeric	numeric	numeric	numeric	numeric	numeric	numeric
0	0.0	0.0	2.0	1.4280000000000002	0.0	0.0	10.0	0.0
1	1.0	0.152	19.0	1.357	0.0	1.18	148.0	0.0
2	1.0	0.0	46.0	4.8180000000000005	0.0	2.63	106.0	1.31
3	0.0	0.134	121.0	3.08	0.0	1.56	693.0	0.0
4	0.0	0.377	1.0	1.0	0.0	0.0	33.0	0.0
5	0.0	0.0	1.0	1.0	0.0	0.0	10.0	0.0
6	0.0	0.327	2.0	1.068	0.0	0.61	47.0	0.0
7	0.0	0.039	6.0	1.2919999999999998	0.0	0.42	106.0	0.21

## Duplicate rows

If duplicate rows are present in the dataset, Amazon SageMaker Autopilot displays a sample of them.

### Note

It is not recommended to balance a dataset by up-sampling before providing it to Autopilot. This may result in inaccurate validation scores for the models trained by Autopilot, and the models that are produced may be unusable.

## Cross column correlations

Autopilot uses the Pearson's correlation coefficient, a measure of linear correlation between two features, to populate a correlation matrix. In the correlation matrix, numeric features are plotted on both the horizontal and vertical axes, with the Pearson's correlation coefficient plotted at their intersections. The higher the correlation between two features, the higher the coefficient, with a maximum value of  $|1|$ .

- A value of  $-1$  indicates that the features are perfectly negatively correlated.
- A value of  $1$ , which occurs when a feature is correlated with itself, indicates perfect positive correlation.

You can use the information in the correlation matrix to remove highly correlated features. A smaller number of features reduces chances of overfitting a model and can reduce the costs of production in two ways. It lessens the Autopilot runtime needed and, for some applications, can make data collection procedures cheaper.

The following screenshot shows an example of a correlation matrix between 7 features. Each feature is displayed in a matrix on both the horizontal and vertical axes. The Pearson's correlation coefficient is displayed at the intersection between two features. Each feature intersection has a color tone associated with it. The higher the correlation, the darker the tone. The darkest tones occupy the diagonal of the matrix, where each feature is correlated with itself, representing perfect correlation.

## Anomalous Rows

Amazon SageMaker Autopilot detects which rows in your dataset might be anomalous. It then assigns an anomaly score to each row. Rows with negative anomaly scores are considered anomalous.

The following screenshot shows the output from an Autopilot analysis for rows containing anomalies. A column containing an anomalous score appears next to the dataset columns for each row.

	Anomaly Scores	0	1	2	3	4	5	6	7
1237	-0.215202	F	0.8	0.63	0.195	2.526	0.933	0.59	0.62
405	-0.200257	F	0.815	0.65	0.25	2.255	0.8905	0.42	0.7975

## Missing values, cardinality, and descriptive statistics

Amazon SageMaker Autopilot examines and reports on properties of the individual columns of your dataset. In each section of the data report that presents this analysis, the content is arranged in order. This is so you can check the most “suspicious” values first. Using these statistics you can improve contents of individual columns, and improve the quality of the model produced by Autopilot.

Autopilot calculates several statistics on the categorical values in columns that contain them. These include the number of unique entries and, for text, the number of unique words.

Autopilot calculates several standard statistics on the numerical values in columns that contain them. The following image depicts these statistics, including the mean, median, minimum and maximum values, and the percentages of numerical types and of outlier values.

	% of Numerical Values	Mean	Median	Min	Max	% of Outlier Values
y	100.0%	9.93957	9.0	3.0	27.0	nan
1	100.0%	0.523612	0.545	0.11	0.815	0.0
2	100.0%	0.407799	0.425	0.09	0.65	0.0
3	100.0%	0.13995	0.145	0.015	0.515	0.1
4	100.0%	0.828266	0.81	0.008	2.8255	0.0
5	100.0%	0.358844	0.339	0.0025	1.2395	0.0
6	100.0%	0.180348	0.1725	0.002	0.6415	0.0
7	100.0%	0.238783	0.235	0.003	1.005	0.2

## Find and run the candidate definition notebook

The candidate definition notebook contains each suggested preprocessing step, algorithm, and hyperparameter ranges.

You can choose which candidate to train and tune in two ways. The first, by running sections of the notebook. The second, by running the entire notebook to optimize all candidates to identify a best candidate. If you run the entire notebook, only the best candidate is displayed after job completion.

To run Autopilot from SageMaker Studio Classic, open the candidate definition notebook by following these steps:

1. Choose the **Home** icon

from the left navigation pane to view the top-level **Amazon SageMaker Studio Classic** navigation menu.

2. Select the **AutoML** card from the main working area. This opens a new **Autopilot** tab.
3. In the **Name** section, select the Autopilot job that has the candidate definition notebook that you want to examine. This opens a new **Autopilot job** tab.

4. Choose **Open candidate generation notebook** from the top right section of the **Autopilot job** tab. This opens a new read-only preview of the **Amazon SageMaker Autopilot Candidate Definition Notebook**.

To run the candidate definition notebook, follow these steps:

1. Choose **Import notebook** at the top right of the **Amazon SageMaker Autopilot Candidate Definition Notebook** tab. This opens a tab to set up a new notebook environment to run the notebook.
2. Select an existing SageMaker **Image** or use a **Custom Image**.
3. Select a **Kernel**, an **Instance type**, and an optional **Start-up script**.

You can now run the notebook in this new environment.

## Configure inference output in generated containers

Autopilot generates an ordered [ContainerDefinition](#) list. This can be used to build a model to deploy in a machine learning pipeline. This model can be used for online hosting and inference.

Customers can list inference container definitions with the [ListCandidateForAutoMLJob](#) API. The list of inference container definitions that represent the best candidate is also available in the [DescribeAutoMLJob](#) response.

## Inference container definitions for regression and classification problem types

Autopilot generates inference containers specific to the [training mode](#) and the [problem type](#) of the job.

## Container definitions for hyperparameter optimization (HPO) mode

- **Regression:** HPO generates two containers:
  1. A feature engineering container that transforms the original features into features that the regression algorithms can train on.
  2. An algorithm container that transforms features and generates a regression score for the dataset.
- **Classification:** HPO generates three containers:
  1. A feature engineering container that transforms the original features into features that the classification algorithms can train on.

2. An algorithm container that generates the `predicted_label` with the highest probability. This container can also produce the various probabilities associated with the classification outcomes in the inference response.
3. A feature engineering container that performs post-processing of the algorithm prediction. For example, it can perform an inverse transform on the predicted label and change it to the original label.

## Container definitions for ensembling mode

In ensembling mode, both regression and classification problem types have only one inference container. This inference container transforms the features and generates the predictions based on problem type.

## Inference responses per problem type

### Inference responses for classification models

For classification inference containers, you can select the content of the inference response by using four predefined keys:

- `predicted_label`: The label with the highest probability of predicting the correct label, as determined by Autopilot.
- `probability`:
  - **HPO models**: The probability of the `True` class for binary classification. The probability of the `predicted_label` for multiclass classification.
  - **Ensemble models**: The probability of the `predicted_label` for binary and multiclass classification.
- `probabilities`: The list of probabilities for all corresponding classes.
- `labels`: The list of all labels.

For example, for a binary classification problem, if you pass the inference response keys `['predicted_label', 'probability', 'probabilities', 'labels']` and the output response appears as `[1, 0.1, "[0.9, 0.1]", "['1', '0']"]`, you should interpret it as follows:

1. `predicted_label` equals 1 because label "1" has a higher probability (0.9 in this case).

2. For HPO models, probability equals 0.1 which is the probability of the `positive_class` (0 in this case) selected by Autopilot.

For Ensemble models, probability equals 0.9 which is the probability of the `predicted_label`.

3. `probabilities` lists the probability of each label in `labels`.

4. `labels` are the unique labels in the dataset, where the second label ("0" in this case) is the `positive_class` selected by Autopilot.

By default, inference containers are configured to generate only the `predicted_label`. To select additional inference content, you can update the `inference_response_keys` parameter to include up to these three environment variables:

- `SAGEMAKER_INFERENCE_SUPPORTED`: This is set to provide hints to you about what content each container supports.
- `SAGEMAKER_INFERENCE_INPUT`: This should be set to the keys that the container expects in input payload.
- `SAGEMAKER_INFERENCE_OUTPUT`: This should be populated with the set of keys that the container outputs.

## Inference responses for classification models in HPO mode

This section shows how to configure the inference response from classification models using hyperparameter optimization (HPO) mode.

To choose the inference response content in HPO mode: Add the `SAGEMAKER_INFERENCE_INPUT` and `SAGEMAKER_INFERENCE_OUTPUT` variables to the second and third containers that are generated in HPO mode for classification problems.

The keys supported by the second container (algorithm) are `predicted_label`, `probability`, and `probabilities`. Note that `labels` is deliberately not added to `SAGEMAKER_INFERENCE_SUPPORTED`.

The keys supported by the third classification model container are `predicted_label`, `labels`, `probability`, and `probabilities`. Therefore, the `SAGEMAKER_INFERENCE_SUPPORTED` environment includes the names of these keys.

To update the definition of the inference containers to receive `predicted_label` and `probability`, use the following code example.

```
containers[1]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label,
probability'})
containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_INPUT': 'predicted_label,
probability'})
containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label,
probability'})
```

The following code example updates the definition of the inference containers to receive `predicted_label`, `probabilities`, and `labels`. Do not pass the `labels` to the second container (the algorithm container), because it is generated by the third container independently.

```
containers[1]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT':
'predicted_label,probabilities'})
containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_INPUT':
'predicted_label,probabilities'})
containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label,
probabilities,labels'})
```

The following collapsible sections provide code examples for AWS SDK for Python (Boto3) and for SageMaker SDK for Python. Each section shows how to select the content of the inference responses in HPO mode for the respective code example.

### AWS SDK for Python (Boto3)

```
import boto3

sm_client = boto3.client('sagemaker', region_name='<Region>')

role = '<IAM role>'
input_data = '<S3 input uri>'
output_path = '<S3 output uri>'

best_candidate = sm_client.describe_auto_ml_job(AutoMLJobName='<AutoML Job Name>')
['BestCandidate']
best_candidate_containers = best_candidate['InferenceContainers']
best_candidate_name = best_candidate['CandidateName']

best_candidate_containers[1]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT':
'predicted_label, probability'})
best_candidate_containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_INPUT':
'predicted_label, probability'})
```

```

best_candidate_containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT':
  'predicted_label, probability'})

# create model
response = sm_client.create_model(
    ModelName = '<Model Name>',
    ExecutionRoleArn = role,
    Containers = best_candidate_containers
)

# Launch Transform Job
response = sm_client.create_transform_job(
    TransformJobName='<Transform Job Name>',
    ModelName='<Model Name>',
    TransformInput={
        'DataSource': {
            'S3DataSource': {
                'S3DataType': 'S3Prefix',
                'S3Uri': input_data
            }
        },
        'ContentType': "text/CSV",
        'SplitType': 'Line'
    },
    TransformOutput={
        'S3OutputPath': output_path,
        'AssembleWith': 'Line',
    },
    TransformResources={
        'InstanceType': 'ml.m4.xlarge',
        'InstanceCount': 1,
    },
)

```

## SageMaker SDK for Python

```

from sagemaker import AutoML

aml = AutoML.attach(auto_ml_job_name='<AutoML Job Name>')
aml_best_model = aml.create_model(name='<Model Name>',
                                  candidate=None,
                                  inference_response_keys**=['probabilities',
'labels'])

```

```
aml_transformer = aml_best_model.transformer(accept='text/csv',
                                             assemble_with='Line',
                                             instance_type='ml.m5.xlarge',
                                             instance_count=1,)

aml_transformer.transform('<S3 input uri>',
                          content_type='text/csv',
                          split_type='Line',
                          job_name='<Transform Job Name>',
                          wait=True)
```

## Inference responses for classification models in ensembling mode

This section shows how to configure the inference response from classification models using ensembling mode.

In **ensembling mode**, to choose the content of the inference response, update the `SAGEMAKER_INFERENCE_OUTPUT` environment variable.

The keys supported by the classification model container are `predicted_label`, `labels`, `probability`, and `probabilities`. These keys are included in the `SAGEMAKER_INFERENCE_SUPPORTED` environment.

To update the inference container definition to receive `predicted_label` and `probability`, refer to the following code example.

```
containers[0]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label,
probability'})
```

The following collapsible section provides a code example for selecting the content of the inference responses in ensembling mode. The example uses AWS SDK for Python (Boto3).

### AWS SDK for Python (Boto3)

```
import boto3
sm_client = boto3.client('sagemaker', region_name='<Region>')

role = '<IAM role>'
input_data = '<S3 input uri>'
output_path = '<S3 output uri>'
```

```

best_candidate = sm_client.describe_auto_ml_job(AutoMLJobName='<AutoML Job Name>')
['BestCandidate']
best_candidate_containers = best_candidate['InferenceContainers']
best_candidate_name = best_candidate['CandidateName']

*best_candidate_containers[0]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT':
'predicted_label, probability'})
*
# create model
reponse = sm_client.create_model(
    ModelName = '<Model Name>',
    ExecutionRoleArn = role,
    Containers = best_candidate_containers
)

# Launch Transform Job
response = sm_client.create_transform_job(
    TransformJobName='<Transform Job Name>',
    ModelName='<Model Name>',
    TransformInput={
        'DataSource': {
            'S3DataSource': {
                'S3DataType': 'S3Prefix',
                'S3Uri': input_data
            }
        },
        'ContentType': "text/CSV",
        'SplitType': 'Line'
    },
    TransformOutput={
        'S3OutputPath': output_path,
        'AssembleWith': 'Line',
    },
    TransformResources={
        'InstanceType': 'ml.m4.xlarge',
        'InstanceCount': 1,
    },
)

```

The following collapsible section provides a code example that is identical to the SageMaker SDK for Python example for HPO. It is included for your convenience.

## SageMaker SDK for Python

The following HPO code example uses SageMaker SDK for Python.

```
from sagemaker import AutoML

aml = AutoML.attach(auto_ml_job_name='<AutoML Job Name>')
aml_best_model = aml.create_model(name='<Model Name>',
                                  candidate=None,
                                  *inference_response_keys**=['probabilities',
                                                              'labels'])*

aml_transformer = aml_best_model.transformer(accept='text/csv',
                                              assemble_with='Line',
                                              instance_type='ml.m5.xlarge',
                                              instance_count=1,)

aml_transformer.transform('<S3 input uri>',
                          content_type='text/csv',
                          split_type='Line',
                          job_name='<Transform Job Name>',
                          wait=True)
```

## Create an Image Classification Job using the AutoML API

The following instructions show how to create an Amazon SageMaker Autopilot job as a pilot experiment for image classification problem types using SageMaker [API Reference](#).

### Note

Tasks such as text and image classification, time-series forecasting, and fine-tuning of large language models are exclusively available through the version 2 of the [AutoML REST API](#). If your language of choice is Python, you can refer to [AWS SDK for Python \(Boto3\)](#) or the [AutoMLV2 object](#) of the Amazon SageMaker Python SDK directly.

Users who prefer the convenience of a user interface can use [Amazon SageMaker Canvas](#) to access pre-trained models and generative AI foundation models, or create custom models tailored for specific text, image classification, forecasting needs, or generative AI.

You can create an Autopilot image classification experiment programmatically by calling the [CreateAutoMLJobV2](#) API action in any language supported by Amazon SageMaker Autopilot or the AWS CLI.

For information on how this API action translates into a function in the language of your choice, see the [See Also](#) section of `CreateAutoMLJobV2` and choose an SDK. As an example, for Python users, see the full request syntax of `create_auto_ml_job_v2` in AWS SDK for Python (Boto3).

The following is a collection of mandatory and optional input request parameters for the `CreateAutoMLJobV2` API action used in image classification.

## Required parameters

When calling [CreateAutoMLJobV2](#) to create an Autopilot experiment for image classification, you must provide the following values:

- An [AutoMLJobName](#) to specify the name of your job.
- At least one [AutoMLJobChannel](#) in [AutoMLJobInputDataConfig](#) to specify your data source.
- An [AutoMLProblemTypeConfig](#) of type [ImageClassificationJobConfig](#).
- An [OutputDataConfig](#) to specify the Amazon S3 output path to store the artifacts of your AutoML job.
- A [RoleArn](#) to specify the ARN of the role used to access your data.

All other parameters are optional.

## Optional parameters

The following sections provide details of some optional parameters that you can pass to your image classification AutoML job.

### How to specify the training and validation datasets of an AutoML job

You can provide your own validation dataset and custom data split ratio, or let Autopilot split the dataset automatically.

Each [AutoMLJobChannel](#) object (see the required parameter [AutoMLJobInputDataConfig](#)) has a `ChannelType`, which can be set to either `training` or `validation` values that specify how the data is to be used when building a machine learning model.

At least one data source must be provided and a maximum of two data sources is allowed: one for training data and one for validation data. How you split the data into training and validation datasets depends on whether you have one or two data sources.

How you split the data into training and validation datasets depends on whether you have one or two data sources.

- If you only have **one data source**, the `ChannelType` is set to `training` by default and must have this value.
  - If the `ValidationFraction` value in [AutoMLDataSplitConfig](#) is not set, 0.2 (20%) of the data from this source is used for validation by default.
  - If the `ValidationFraction` is set to a value between 0 and 1, the dataset is split based on the value specified, where the value specifies the fraction of the dataset used for validation.
- If you have **two data sources**, the `ChannelType` of one of the `AutoMLJobChannel` objects must be set to `training`, the default value. The `ChannelType` of the other data source must be set to `validation`. The two data sources must have the same format, either CSV or Parquet, and the same schema. You must not set the value for the `ValidationFraction` in this case because all of the data from each source is used for either training or validation. Setting this value causes an error.

## How to specify the automatic model deployment configuration for an AutoML job

To enable automatic deployment for the best model candidate of an AutoML job, include a [ModelDeployConfig](#) in the AutoML job request. This will allow the deployment of the best model to a SageMaker AI endpoint. Below are the available configurations for customization.

- To let Autopilot generate the endpoint name, set [AutoGenerateEndpointName](#) to `True`.
- To provide your own name for the endpoint, set [AutoGenerateEndpointName](#) to `False` and provide a name of your choice in [EndpointName](#).

## Datasets format and objective metric for image classification

In this section we learn about the available formats for datasets used in image classification as well as the objective metric used to evaluate the predictive quality of machine learning model candidates. The metrics calculated for candidates are specified using an array of [MetricDatum](#) types.

## Datasets formats

Autopilot supports .png, .jpg, and .jpeg image formats. If your dataset contains all .png images use `image/png`, if it contains all .jpg or .jpeg images use `image/jpeg`, and if your dataset contains a mix of image formats use `image/*`.

## Objective metric

The following list contains the names of the metrics that are currently available to measure the performance of models for image classification.

## Accuracy

The ratio of the number of correctly classified items to the total number of (correctly and incorrectly) classified items. Accuracy measures how close the predicted class values are to the actual values. Values for accuracy metrics vary between zero (0) and one (1). A value of 1 indicates perfect accuracy, and 0 indicates perfect inaccuracy.

## Deploy Autopilot models for real-time inference

After you train your Amazon SageMaker Autopilot models, you can set up an endpoint and obtain predictions interactively. The following section describes the steps for deploying your model to a SageMaker AI real-time inference endpoint to get predictions from your model.

## Real-time inferencing

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. This section shows how you can use real-time inferencing to obtain predictions interactively from your model.

You can use SageMaker APIs to manually deploy the model that produced the best validation metric in an Autopilot experiment as follows.

Alternatively, you can chose the automatic deployment option when creating your Autopilot experiment. For information on setting up the automatic deployment of models, see [ModelDeployConfig](#) in the request parameters of [CreateAutoMLJobV2](#). This creates an endpoint automatically.

**Note**

To avoid incurring unnecessary charges, you can delete unneeded endpoint and resources created from model deployment. For information about pricing of instances by Region, see [Amazon SageMaker Pricing](#).

## 1. Obtain the candidate container definitions

Obtain the candidate container definitions from [InferenceContainers](#). A container definition for inference refers to the containerized environment designed for deploying and running your trained SageMaker AI model to make predictions.

The following AWS CLI command example uses the [DescribeAutoMLJobV2](#) API to obtain candidate definitions for the best model candidate.

```
aws sagemaker describe-auto-ml-job-v2 --auto-ml-job-name job-name --region region
```

## 2. List candidates

The following AWS CLI command example uses the [ListCandidatesForAutoMLJob](#) API to list all model candidates.

```
aws sagemaker list-candidates-for-auto-ml-job --auto-ml-job-name <job-name> --  
region <region>
```

## 3. Create a SageMaker AI model

Use the container definitions from the previous steps and a candidate of your choice to create a SageMaker AI model by using the [CreateModel](#) API. See the following AWS CLI command as an example.

```
aws sagemaker create-model --model-name '<your-candidate-name>' \  
    --containers ['<container-definition1>', <container-  
definition2>, <container-definition3>]' \  
    --execution-role-arn '<execution-role-arn>' --region '<region>'
```

## 4. Create an endpoint configuration

The following AWS CLI command example uses the [CreateEndpointConfig](#) API to create an endpoint configuration.

```
aws sagemaker create-endpoint-config --endpoint-config-name '<your-endpoint-config-name>' \  
                                     --production-variants '<list-of-production-variants>' \  
                                     --region '<region>'
```

## 5. Create the endpoint

The following AWS CLI example uses the [CreateEndpoint](#) API to create the endpoint.

```
aws sagemaker create-endpoint --endpoint-name '<your-endpoint-name>' \  
                               --endpoint-config-name '<endpoint-config-name-you-just-created>' \  
                               \  
                               --region '<region>'
```

Check the progress of your endpoint deployment by using the [DescribeEndpoint](#) API. See the following AWS CLI command as an example.

```
aws sagemaker describe-endpoint --endpoint-name '<endpoint-name>' --region <region>
```

After the `EndpointStatus` changes to `InService`, the endpoint is ready to use for real-time inference.

## 6. Invoke the endpoint

The following command structure invokes the endpoint for real-time inferencing.

```
aws sagemaker invoke-endpoint --endpoint-name '<endpoint-name>' \  
                               --region '<region>' --body '<your-data>' [--content-type] \  
                               '<content-type>' <outfile>
```

## Explainability report

Amazon SageMaker Autopilot provides an explainability report to help explain how a best model candidate makes predictions for image classification problems. This report can assist ML engineers, product managers, and other internal stakeholders in understanding the characteristics of the model. Both consumers and regulators rely on transparency in machine learning to trust and

interpret decisions made on model predictions. You can use these explanations for auditing and meeting regulatory requirements, establishing trust in the model, supporting human decision-making, and debugging and improving model performance.

The Autopilot explanatory functionality for image classification uses a visual class activation map (CAM) approach that produces a heatmap where the distribution and intensity of each color highlights the areas of an image that contribute the most to a specific prediction. This approach relies on principal components derived from an implementation of [Eigen-CAM](#).

Autopilot generates the explainability report as a JSON file. The report includes analysis details that are based on the validation dataset. Each image used to generate the report contains the following information:

- `input_image_uri`: The Amazon S3 URI to the input image taken as input for the heatmap.
- `heatmap_image_uri`: The Amazon S3 URI to the heatmap image generated by Autopilot.
- `predicted_label`: The label class predicted by best model trained by Autopilot.
- `probability`: The confidence with which the `predicted_label` is predicted.

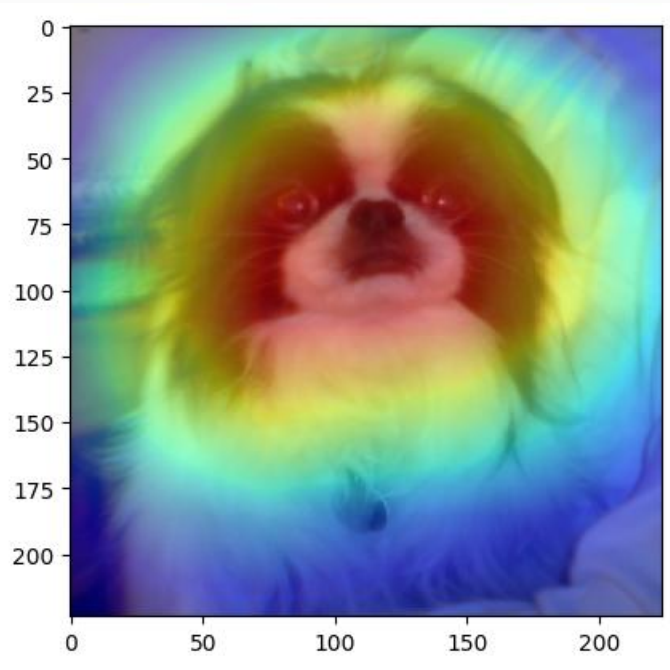

You can find the Amazon S3 prefix to the explainability artifacts generated for the best candidate in the response to [DescribeAutoMLJobV2](#) at [BestCandidate.CandidateProperties.CandidateArtifactLocations.Explainability](#).

The following examples illustrates what the heatmaps look like on few samples from [Oxford-IIIT Pet Dataset](#). The heatmap image displays color gradients that indicate the relative importance of different features within the image. The red color represents regions with greater importance in predicting the "predicted\_label" of the input image compared to the features represented by the blue color.

**Input Image**

**Heatmap Image**

## Model performance report

An Amazon SageMaker AI model quality report (also referred to as performance report) provides insights and quality information for the best model candidate generated by an AutoML job. This includes information about the job details, model problem type, objective function, and various metrics. This section details the content of a performance report for image classification problems and explains how to access the metrics as raw data in a JSON file.

You can find the Amazon S3 prefix to the model quality report artifacts generated for the best candidate in the response to [DescribeAutoMLJobV2](#) at [BestCandidate.CandidateProperties.CandidateArtifactLocations.ModelInsights](#).

The performance report contains two sections:

- The first section contains details about the Autopilot job that produced the model.
- The second section contains a model quality report with various performance metrics.

### Autopilot job details

This first section of the report gives some general information about the Autopilot job that produced the model. These details include the following information:

- Autopilot candidate name: The name of the best model candidate.
- Autopilot job name: The name of the job.
- Problem type: The problem type. In our case, *image classification*.
- Objective metric: The objective metric used to optimize the performance of the model. In our case, *Accuracy*.
- Optimization direction: Indicates whether to minimize or maximize the objective metric.

### Model quality report

Model quality information is generated by Autopilot model insights. The report's content that is generated depends on the problem type it addressed. The report specifies the number of rows that were included in the evaluation dataset and the time at which the evaluation occurred.

### Metrics tables

The first part of the model quality report contains metrics tables. These are appropriate for the type of problem that the model addressed.

The following image is an example of a metrics table generated by Autopilot for an image or text classification problem. It shows the metric name, value, and standard deviation.

### Metrics table

Metric Name	Value	Standard Deviation
<b>weighted_recall</b>	0.597104	0.005410
<b>weighted_precision</b>	0.591693	0.005729
<b>accuracy</b>	0.597104	0.005410
<b>weighted_f0_5</b>	0.592155	0.005659
<b>weighted_f1</b>	0.593423	0.005554
<b>weighted_f2</b>	0.595392	0.005456
<b>accuracy_best_constant_classifier</b>	0.200699	0.004422
<b>weighted_recall_best_constant_classifier</b>	0.200699	0.004422
<b>weighted_precision_best_constant_classifier</b>	0.040280	0.001753
<b>weighted_f0_5_best_constant_classifier</b>	0.047944	0.002039
<b>weighted_f1_best_constant_classifier</b>	0.067094	0.002684
<b>weighted_f2_best_constant_classifier</b>	0.111716	0.003808

### Graphical model performance information

The second part of the model quality report contains graphical information to help you evaluate model performance. The contents of this section depend on the selected problem type.

### Confusion matrix

A confusion matrix provides a way to visualize the accuracy of the predictions made by a model for binary and multiclass classification for different problems.

A summary of the graph's components of **false positive rate (FPR)** and **true positive rate (TPR)** are defined as follows.

- Correct predictions
  - **True positive (TP)**: The predicted the value is 1, and the true value is 1.
  - **True negative (TN)**: The predicted the value is 0, and the true value is 0.
- Erroneous predictions
  - **False positive (FP)**: The predicted the value is 1, but the true value is 0.
  - **False negative (FN)**: The predicted the value is 0, but the true value is 1.

The confusion matrix in the model quality report contains the following.

- The number and percentage of correct and incorrect predictions for the actual labels
- The number and percentage of accurate predictions on the diagonal from the upper-left to the lower-right corner
- The number and percentage of inaccurate predictions on the diagonal from the upper-right to the lower-left corner

The incorrect predictions on a confusion matrix are the confusion values.

The following diagram is an example of a confusion matrix for a multi-class classification problem. The confusion matrix in the model quality report contains the following.

- The vertical axis is divided into three rows containing three different actual labels.
- The horizontal axis is divided into three columns containing labels that were predicted by the model.
- The color bar assigns a darker tone to a larger number of samples to visually indicate the number of values that were classified in each category.

In the example below, the model correctly predicted actual 354 values for label **f**, 1094 values for label **i** and 852 values for label **m**. The difference in tone indicates that the dataset is not balanced because there are many more labels for the value **i** than for **f** or **m**.

The confusion matrix in the model quality report provided can accommodate a maximum of 15 labels for multiclass classification problem types. If a row corresponding to a label shows a Nan value, it means that the validation dataset used to check model predictions does not contain data with that label.

## Create an AutoML job for text classification using the API

The following instructions show how to create an Amazon SageMaker Autopilot job as a pilot experiment for text classification problem types using SageMaker [API Reference](#).

### **Note**

Tasks such as text and image classification, time-series forecasting, and fine-tuning of large language models are exclusively available through the version 2 of the [AutoML REST API](#). If your language of choice is Python, you can refer to [AWS SDK for Python \(Boto3\)](#) or the [AutoMLV2 object](#) of the Amazon SageMaker Python SDK directly.

Users who prefer the convenience of a user interface can use [Amazon SageMaker Canvas](#) to access pre-trained models and generative AI foundation models, or create custom models tailored for specific text, image classification, forecasting needs, or generative AI.

You can create an Autopilot text classification experiment programmatically by calling the [CreateAutoMLJobV2](#) API action in any language supported by Amazon SageMaker Autopilot or the AWS CLI.

For information on how this API action translates into a function in the language of your choice, see the [See Also](#) section of [CreateAutoMLJobV2](#) and choose an SDK. As an example, for Python users, see the full request syntax of [create\\_auto\\_ml\\_job\\_v2](#) in AWS SDK for Python (Boto3).

The following is a collection of mandatory and optional input request parameters for the [CreateAutoMLJobV2](#) API action used in text classification.

## Required parameters

When calling [CreateAutoMLJobV2](#) to create an Autopilot experiment for text classification, you must provide the following values:

- An [AutoMLJobName](#) to specify the name of your job.
- At least one [AutoMLJobChannel](#) in [AutoMLJobInputDataConfig](#) to specify your data source.
- An [AutoMLProblemTypeConfig](#) of type [TextClassificationJobConfig](#).
- An [OutputDataConfig](#) to specify the Amazon S3 output path to store the artifacts of your AutoML job.
- A [RoleArn](#) to specify the ARN of the role used to access your data.

All other parameters are optional.

## Optional parameters

The following sections provide details of some optional parameters that you can pass to your text classification AutoML job.

### How to specify the training and validation datasets of an AutoML job

You can provide your own validation dataset and custom data split ratio, or let Autopilot split the dataset automatically.

Each [AutoMLJobChannel](#) object (see the required parameter [AutoMLJobInputDataConfig](#)) has a `ChannelType`, which can be set to either `training` or `validation` values that specify how the data is to be used when building a machine learning model.

At least one data source must be provided and a maximum of two data sources is allowed: one for training data and one for validation data. How you split the data into training and validation datasets depends on whether you have one or two data sources.

How you split the data into training and validation datasets depends on whether you have one or two data sources.

- If you only have **one data source**, the `ChannelType` is set to `training` by default and must have this value.
  - If the `ValidationFraction` value in [AutoMLDataSplitConfig](#) is not set, 0.2 (20%) of the data from this source is used for validation by default.
  - If the `ValidationFraction` is set to a value between 0 and 1, the dataset is split based on the value specified, where the value specifies the fraction of the dataset used for validation.
- If you have **two data sources**, the `ChannelType` of one of the `AutoMLJobChannel` objects must be set to `training`, the default value. The `ChannelType` of the other data source must be set to `validation`. The two data sources must have the same format, either CSV or Parquet, and the same schema. You must not set the value for the `ValidationFraction` in this case because all of the data from each source is used for either training or validation. Setting this value causes an error.

## How to specify the automatic model deployment configuration for an AutoML job

To enable automatic deployment for the best model candidate of an AutoML job, include a [ModelDeployConfig](#) in the AutoML job request. This will allow the deployment of the best model to a SageMaker AI endpoint. Below are the available configurations for customization.

- To let Autopilot generate the endpoint name, set [AutoGenerateEndpointName](#) to `True`.
- To provide your own name for the endpoint, set [AutoGenerateEndpointName](#) to `False` and provide a name of your choice in [EndpointName](#).

## Datasets format and objective metric for text classification

In this section we learn about the available formats for datasets used in text classification as well as the metric used to evaluate the predictive quality of machine learning model candidates. The metrics calculated for candidates are specified using an array of [MetricDatum](#) types.

### Datasets formats

Autopilot supports tabular data formatted as CSV files or as Parquet files. For tabular data, each column contains a feature with a specific data type and each row contains an observation. The properties of these two file formats differ considerably.

- **CSV** (comma-separated-values) is a row-based file format that stores data in human readable plaintext which is a popular choice for data exchange as they are supported by a wide range of applications.
- **Parquet** is a column-based file format where the data is stored and processed more efficiently than row-based file formats. This makes them a better option for big data problems.

The **data types** accepted for columns include numerical, categorical, text.

Autopilot supports building machine learning models on large datasets up to hundreds of GBs. For details on the default resource limits for input datasets and how to increase them, see [Amazon SageMaker Autopilot quotas](#).

### Objective metric

The following list contains the names of the metrics that are currently available to measure the performance of models for text classification.

#### Accuracy

The ratio of the number of correctly classified items to the total number of (correctly and incorrectly) classified items. Accuracy measures how close the predicted class values are to the actual values. Values for accuracy metrics vary between zero (0) and one (1). A value of 1 indicates perfect accuracy, and 0 indicates perfect inaccuracy.

## Deploy Autopilot models for real-time inference

After you train your Amazon SageMaker Autopilot models, you can set up an endpoint and obtain predictions interactively. The following section describes the steps for deploying your model to a SageMaker AI real-time inference endpoint to get predictions from your model.

### Real-time inferencing

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. This section shows how you can use real-time inferencing to obtain predictions interactively from your model.

You can use SageMaker APIs to manually deploy the model that produced the best validation metric in an Autopilot experiment as follows.

Alternatively, you can choose the automatic deployment option when creating your Autopilot experiment. For information on setting up the automatic deployment of models, see [ModelDeployConfig](#) in the request parameters of [CreateAutoMLJobV2](#). This creates an endpoint automatically.

#### Note

To avoid incurring unnecessary charges, you can delete unneeded endpoint and resources created from model deployment. For information about pricing of instances by Region, see [Amazon SageMaker Pricing](#).

### 1. Obtain the candidate container definitions

Obtain the candidate container definitions from [InferenceContainers](#). A container definition for inference refers to the containerized environment designed for deploying and running your trained SageMaker AI model to make predictions.

The following AWS CLI command example uses the [DescribeAutoMLJobV2](#) API to obtain candidate definitions for the best model candidate.

```
aws sagemaker describe-auto-ml-job-v2 --auto-ml-job-name job-name --region region
```

### 2. List candidates

The following AWS CLI command example uses the [ListCandidatesForAutoMLJob](#) API to list all model candidates.

```
aws sagemaker list-candidates-for-auto-ml-job --auto-ml-job-name <job-name> --  
region <region>
```

### 3. Create a SageMaker AI model

Use the container definitions from the previous steps and a candidate of your choice to create a SageMaker AI model by using the [CreateModel](#) API. See the following AWS CLI command as an example.

```
aws sagemaker create-model --model-name '<your-candidate-name>' \  
    --containers ['<container-definition1>, <container-  
definition2>, <container-definition3>'] \  
    --execution-role-arn '<execution-role-arn>' --region '<region>
```

### 4. Create an endpoint configuration

The following AWS CLI command example uses the [CreateEndpointConfig](#) API to create an endpoint configuration.

```
aws sagemaker create-endpoint-config --endpoint-config-name '<your-endpoint-config-  
name>' \  
    --production-variants '<list-of-production-variants>' \  
    --region '<region>
```

### 5. Create the endpoint

The following AWS CLI example uses the [CreateEndpoint](#) API to create the endpoint.

```
aws sagemaker create-endpoint --endpoint-name '<your-endpoint-name>' \  
    --endpoint-config-name '<endpoint-config-name-you-just-created>' \  
\  
    --region '<region>
```

Check the progress of your endpoint deployment by using the [DescribeEndpoint](#) API. See the following AWS CLI command as an example.

```
aws sagemaker describe-endpoint --endpoint-name '<endpoint-name>' --region <region>
```

After the `EndpointStatus` changes to `InService`, the endpoint is ready to use for real-time inference.

## 6. Invoke the endpoint

The following command structure invokes the endpoint for real-time inferencing.

```
aws sagemaker invoke-endpoint --endpoint-name '<endpoint-name>' \  
    --region '<region>' --body '<your-data>' [--content-type] \  
'<content-type>' <outfile>
```

## Explainability report

Amazon SageMaker Autopilot provides an explainability report to help explain how a best model candidate makes predictions for text classification problems. This report can assist ML engineers, product managers, and other internal stakeholders in understanding the characteristics of the model. Both consumers and regulators rely on transparency in machine learning to trust and interpret decisions made on model predictions. You can use these explanations for auditing and meeting regulatory requirements, establishing trust in the model, supporting human decision-making, and debugging and improving model performance.

The Autopilot explanatory functionality for text classification uses the axiomatic attribution method *Integrated Gradients*. This approach relies on an implementation of [Axiomatic Attribution for Deep Network](#).

Autopilot generates the explainability report as a JSON file. The report includes analysis details that are based on the validation dataset. Each sample used to generate the report contains the following information:

- `text`: The input text content explained.
- `token_scores`: The list of scores for every token in the text.
- `attribution`: The score depicting the importance of the token.
  - `description.partial_text`: The partial substring that represents the token.
- `predicted_label`: The label class predicted by the best model candidate.
- `probability`: The confidence with which the `predicted_label` was predicted.

You can find the Amazon S3 prefix to the explainability artifacts generated for the best candidate in the response to [DescribeAutoMLJobV2](#) at [BestCandidate.CandidateProperties.CandidateArtifactLocations.Explainability](#).

The following is an example of analysis content that you could find in the explainability artifacts.

```
{
  "text": "It was a fantastic movie!",
  "predicted_label": 2,
  "probability": 0.9984835,
  "token_scores": [
    {
      "attribution": 0,
      "description": {
        "partial_text": "It"
      }
    },
    {
      "attribution": -0.022447118861679088,
      "description": {
        "partial_text": "was"
      }
    },
    {
      "attribution": -0.2164326456817965,
      "description": {
        "partial_text": "a"
      }
    },
    {
      "attribution": 0.675,
      "description": {
        "partial_text": "fantastic"
      }
    },
    {
      "attribution": 0.416,
      "description": {
        "partial_text": "movie!"
      }
    }
  ]
}
```

In this sample of the JSON report, the explanatory functionality evaluates the text `It was a fantastic movie!` and scores the contribution of each of its token to the overall predicted label. The predicted label is 2, which is a strong positive sentiment, with a probability of 99.85%. The JSON sample then details the contribution of each individual token to this prediction. For example, the token `fantastic` has a stronger attribution than the token `was`. It is the token that contributed the most to the final prediction.

## Model performance report

An Amazon SageMaker AI model quality report (also referred to as performance report) provides insights and quality information for the best model candidate generated by an AutoML job. This includes information about the job details, model problem type, objective function, and various metrics. This section details the content of a performance report for text classification problems and explains how to access the metrics as raw data in a JSON file.

You can find the Amazon S3 prefix to the model quality report artifacts generated for the best candidate in the response to [DescribeAutoMLJobV2](#) at [BestCandidate.CandidateProperties.CandidateArtifactLocations.ModelInsights](#).

The performance report contains two sections:

- The first section contains details about the Autopilot job that produced the model.
- The second section contains a model quality report with various performance metrics.

### Autopilot job details

This first section of the report gives some general information about the Autopilot job that produced the model. These details include the following information:

- Autopilot candidate name: The name of the best model candidate.
- Autopilot job name: The name of the job.
- Problem type: The problem type. In our case, *text classification*.
- Objective metric: The objective metric used to optimize the performance of the model. In our case, *Accuracy*.
- Optimization direction: Indicates whether to minimize or maximize the objective metric.

## Model quality report

Model quality information is generated by Autopilot model insights. The report's content that is generated depends on the problem type it addressed. The report specifies the number of rows that were included in the evaluation dataset and the time at which the evaluation occurred.

### Metrics tables

The first part of the model quality report contains metrics tables. These are appropriate for the type of problem that the model addressed.

The following image is an example of a metrics table generated by Autopilot for an image or text classification problem. It shows the metric name, value, and standard deviation.

#### Metrics table

Metric Name	Value	Standard Deviation
<b>weighted_recall</b>	0.597104	0.005410
<b>weighted_precision</b>	0.591693	0.005729
<b>accuracy</b>	0.597104	0.005410
<b>weighted_f0_5</b>	0.592155	0.005659
<b>weighted_f1</b>	0.593423	0.005554
<b>weighted_f2</b>	0.595392	0.005456
<b>accuracy_best_constant_classifier</b>	0.200699	0.004422
<b>weighted_recall_best_constant_classifier</b>	0.200699	0.004422
<b>weighted_precision_best_constant_classifier</b>	0.040280	0.001753
<b>weighted_f0_5_best_constant_classifier</b>	0.047944	0.002039
<b>weighted_f1_best_constant_classifier</b>	0.067094	0.002684
<b>weighted_f2_best_constant_classifier</b>	0.111716	0.003808

### Graphical model performance information

The second part of the model quality report contains graphical information to help you evaluate model performance. The contents of this section depend on the selected problem type.

#### Confusion matrix

A confusion matrix provides a way to visualize the accuracy of the predictions made by a model for binary and multiclass classification for different problems.

A summary of the graph's components of **false positive rate (FPR)** and **true positive rate (TPR)** are defined as follows.

- Correct predictions
  - **True positive (TP)**: The predicted the value is 1, and the true value is 1.
  - **True negative (TN)**: The predicted the value is 0, and the true value is 0.
- Erroneous predictions
  - **False positive (FP)**: The predicted the value is 1, but the true value is 0.
  - **False negative (FN)**: The predicted the value is 0, but the true value is 1.

The confusion matrix in the model quality report contains the following.

- The number and percentage of correct and incorrect predictions for the actual labels
- The number and percentage of accurate predictions on the diagonal from the upper-left to the lower-right corner
- The number and percentage of inaccurate predictions on the diagonal from the upper-right to the lower-left corner

The incorrect predictions on a confusion matrix are the confusion values.

The following diagram is an example of a confusion matrix for a multi-class classification problem. The confusion matrix in the model quality report contains the following.

- The vertical axis is divided into three rows containing three different actual labels.
- The horizontal axis is divided into three columns containing labels that were predicted by the model.
- The color bar assigns a darker tone to a larger number of samples to visually indicate the number of values that were classified in each category.

In the example below, the model correctly predicted actual 354 values for label **f**, 1094 values for label **i** and 852 values for label **m**. The difference in tone indicates that the dataset is not balanced because there are many more labels for the value **i** than for **f** or **m**.

The confusion matrix in the model quality report provided can accommodate a maximum of 15 labels for multiclass classification problem types. If a row corresponding to a label shows a Nan value, it means that the validation dataset used to check model predictions does not contain data with that label.

## Create an AutoML job for time-series forecasting using the API

Forecasting in machine learning refers to the process of predicting future outcomes or trends based on historical data and patterns. By analyzing past time-series data and identifying underlying patterns, machine learning algorithms can make predictions and provide valuable insights into future behavior. In forecasting, the goal is to develop models that can accurately capture the relationship between input variables and the target variable over time. This involves examining various factors such as trends, seasonality, and other relevant patterns within the data. The collected information is then used to train a machine learning model. The trained model is capable of generating predictions by taking new input data and applying the learned patterns and

relationships. It can provide forecasts for a wide range of use cases, such as sales projections, stock market trends, weather forecasts, demand forecasting, and many more.

The following instructions show how to create an Amazon SageMaker Autopilot job as a pilot experiment for time-series forecasting problem types using SageMaker [API Reference](#).

### Note

Tasks such as text and image classification, time-series forecasting, and fine-tuning of large language models are exclusively available through the version 2 of the [AutoML REST API](#). If your language of choice is Python, you can refer to [AWS SDK for Python \(Boto3\)](#) or the [AutoMLV2 object](#) of the Amazon SageMaker Python SDK directly. Users who prefer the convenience of a user interface can use [Amazon SageMaker Canvas](#) to access pre-trained models and generative AI foundation models, or create custom models tailored for specific text, image classification, forecasting needs, or generative AI.

You can create an Autopilot time-series forecasting experiment programmatically by calling the [CreateAutoMLJobV2](#) API in any language supported by Amazon SageMaker Autopilot or the AWS CLI.

For information on how this API action translates into a function in the language of your choice, see the [See Also](#) section of [CreateAutoMLJobV2](#) and choose an SDK. As an example, for Python users, see the full request syntax of [create\\_auto\\_ml\\_job\\_v2](#) in AWS SDK for Python (Boto3).

Autopilot trains several model candidates with your target time-series, then selects an optimal forecasting model for a given objective metric. When your model candidates have been trained, you can find the best candidate metrics in the response to [DescribeAutoMLJobV2](#) at [BestCandidate](#).

The following sections define the mandatory and optional input request parameters for the [CreateAutoMLJobV2](#) API used in time-series forecasting.

### Note

Refer to the notebook [Time-Series Forecasting with Amazon SageMaker Autopilot](#) for a practical, hands-on time-series forecasting example. In this notebook, you use Amazon SageMaker Autopilot to train a time-series model and produce predictions using the trained

model. The notebook provides instructions for retrieving a ready-made dataset of tabular historical data on Amazon S3.

## Prerequisites

Before using Autopilot to create a time-series forecasting experiment in SageMaker AI, make sure to:

- Prepare your time-series dataset. Dataset preparation involves collecting relevant data from various sources, cleaning and filtering it to remove noise and inconsistencies, and organizing it into a structured format. See [Time-series datasets format and missing values filling methods](#) to learn more about time-series formats requirements in Autopilot. Optionally, you can supplement your dataset with the public holiday calendar of the country of your choice to capture associated patterns. For more information on holiday calendars, see [National holiday calendars](#).

### Note

We recommend providing at least 3-5 historical data points for each 1 future data point you want to predict. For example, to forecast 7 days ahead (horizon of 1 week) based on daily data, train your model on a minimum of 21-35 days of historical data. Make sure to provide enough data to capture seasonal and recurrent patterns.

- Place your time-series data in an Amazon S3 bucket.
- Grant full access to the Amazon S3 bucket containing your input data for the SageMaker AI execution role used to run your experiment. Once this is done, you can use the ARN of this execution role in Autopilot API requests.
  - For information on retrieving your SageMaker AI execution role, see [Get your execution role](#).
  - For information on granting your SageMaker AI execution role permissions to access one or more specific buckets in Amazon S3, see *Add Additional Amazon S3 Permissions to a SageMaker AI Execution Role* in [Create execution role](#).

## Required parameters

When calling [CreateAutoMLJobV2](#) to create an Autopilot experiment for time-series forecasting, you must provide the following values:

- An [AutoMLJobName](#) to specify the name of your job. The name should be of type string, and should have a minimum length of 1 character and a maximum length of 32.
- At least one [AutoMLJobChannel](#) in [AutoMLJobInputDataConfig](#) in which you specify the name of the Amazon S3 bucket that contains your data. Optionally, you can specify the content (CSV or Parquet files) and compression (GZip) types.
- An [AutoMLProblemTypeConfig](#) of type [TimeSeriesForecastingJobConfig](#) to configure the settings of your time-series forecasting job. In particular, you must specify:
  - The **frequency** of predictions, which refers to the desired granularity (hourly, daily, monthly, etc) of your forecast.

Valid intervals are an integer followed by Y (Year), M (Month), W (Week), D (Day), H (Hour), and min (Minute). For example, 1D indicates every day and 15min indicates every 15 minutes. The value of a frequency must not overlap with the next larger frequency. For example, you must use a frequency of 1H instead of 60min.

The valid values for each frequency are the following:

- Minute - 1-59
- Hour - 1-23
- Day - 1-6
- Week - 1-4
- Month - 1-11
- Year - 1
- The **horizon** of predictions in your forecast, which refers to the number of time-steps that the model predicts. The forecast horizon is also called the prediction length. The maximum forecast horizon is the lesser of 500 time-steps or 1/4 of the time-steps in the dataset.
- A [TimeSeriesConfig](#) in which you define the schema of your dataset to map the column headers to your forecast by specifying:
  - A `TargetAttributeName`: The column that contains historical data of the target field to forecast.
  - A `TimestampAttributeName`: The column that contains a point in time at which the target value of a given item is recorded.
  - A `ItemIdentifierAttributeName`: The column that contains the item identifiers for which you want to predict the target value.

The following is an example of those request parameters. In this example, you are setting up a daily forecast for the expected quantity or level of demand of specific items over a period of 20 days.

```
"AutoMLProblemTypeConfig": {
  "ForecastFrequency": "D",
  "ForecastHorizon": 20,
  "TimeSeriesConfig": {
    "TargetAttributeName": "demand",
    "TimestampAttributeName": "timestamp",
    "ItemIdentifierAttributeName": "item_id"
  },
}
```

- An [OutputDataConfig](#) to specify the Amazon S3 output path to store the artifacts of your AutoML job.
- A [RoleArn](#) to specify the ARN of the role used to access your data. You can use the ARN of the execution role to which you have granted access to your data.

All other parameters are optional. For example, you can set specific forecast quantiles, choose a filling method for missing values in the dataset, or define how to aggregate data that does not align with forecast frequency. To learn how to set those additional parameters, see [Optional parameters](#).

## Optional parameters

The following sections provide details of some optional parameters that you can pass to your time-series forecasting AutoML job.

### How to specify algorithms

By default, your Autopilot job trains a pre-defined list of algorithms on your dataset. However, you can provide a subset of the default selection of algorithms.

For time-series forecasting, you must choose [TimeSeriesForecastingJobConfig](#) as the type of [AutoMLProblemTypeConfig](#).

Then, you can specify an array of selected `AutoMLAlgorithms` in the `AlgorithmsConfig` attribute of [CandidateGenerationConfig](#).

The following is an example of an `AlgorithmsConfig` attribute listing exactly three algorithms ("cnn-qr", "prophet", "arima") in its `AutoMLAlgorithms` field.

```
{
  "AutoMLProblemTypeConfig": {
    "TimeSeriesForecastingJobConfig": {
      "CandidateGenerationConfig": {
        "AlgorithmsConfig": [
          {"AutoMLAlgorithms": ["cnn-qr", "prophet", "arima"]}
        ]
      },
    },
  },
}
```

For the list of available algorithms for time-series forecasting, see [AutoMLAlgorithms](#). For details on each algorithm, see [Algorithms support for time-series forecasting](#).

### How to specify custom quantiles

Autopilot trains 6 models candidates with your target time-series, then combines these models using a stacking ensemble method to create an optimal forecasting model for a given objective metric. Each Autopilot forecasting model generates a probabilistic forecast by producing forecasts at quantiles between P1 and P99. These quantiles are used to account for forecast uncertainty. By default, forecasts will be generated for the 0.1 (p10), 0.5 (p50), and 0.9 (p90). You can choose to specify your own quantiles.

In Autopilot, you can specify up to five forecast quantiles from 0.01 (p1) to 0.99 (p99), by increments of 0.01 or higher in the `ForecastQuantiles` attribute of [TimeSeriesForecastingJobConfig](#).

In the following example, you are setting up a daily 10th, 25th, 50th, 75th, and 90th percentile forecast for the expected quantity or level of demand of specific items over a period of 20 days.

```
"AutoMLProblemTypeConfig": {
  "ForecastFrequency": "D",
  "ForecastHorizon": 20,
  "ForecastQuantiles": ["p10", "p25", "p50", "p75", "p90"],
  "TimeSeriesConfig": {
    "TargetAttributeName": "demand",
    "TimestampAttributeName": "timestamp",
```

```
    "ItemIdentifierAttributeName": "item_id"
  },
```

## How to aggregate data for different forecast frequencies

To create a forecast model (also referred to as the best model candidate from your experiment), you must specify a forecast frequency. The forecast frequency determines the frequency of predictions in your forecasts. For example, monthly sales forecasts. Autopilot best model can generate forecasts for data frequencies that are higher than the frequency at which your data is recorded.

During training, Autopilot aggregates any data that does not align with the forecast frequency you specify. For example, you might have some daily data but specify a weekly forecast frequency. Autopilot aligns the daily data based on the week that it belongs in. Autopilot then combines it into single record for each week.

During aggregation, the default transformation method is to sum the data. You can configure the aggregation when you create your AutoML job in the Transformations attribute of [TimeSeriesForecastingJobConfig](#). The supported aggregation methods are sum (default), avg, first, min, max. Aggregation is only supported for the target column.

In the following example, you configure the aggregation to calculate the average of the individual promo forecasts to provide the final aggregated forecast values.

```
"Transformations": {
  "Aggregation": {
    "promo": "avg"
  }
}
```

## How to handle missing values in your input datasets

Autopilot provides a number of filling methods to handle missing values in the target and other numeric columns of your time-series datasets. For information on the list of supported filling methods and their available filling logic, see [Handle missing values](#).

You configure your filling strategy in the Transformations attribute of [TimeSeriesForecastingJobConfig](#) when creating your AutoML job.

To set a filling method, you need to provide a key-value pair:

- The key is the name of the column for which you want to specify the filling method.
- The value associated with the key is an object that defines the filling strategy for that column.

You can specify multiple filling methods for a single column.

To set a specific value for the filling method, you should set the fill parameter to the desired filling method value (for example "backfill" : "value"), and define the actual filling value in an additional parameter suffixed with "\_value". For example, to set backfill to a value of 2, you must include two parameters: "backfill": "value" and "backfill\_value": "2".

In the following example, you specify the filling strategy for the incomplete data column, "price" as follows: All missing values between the first data point of an item and the last are set to 0 after which all missing values are filled with the value 2 until the end date of the dataset.

```
"Transformations": {
  "Filling": {
    "price": {
      "middlefill" : "zero",
      "backfill" : "value",
      "backfill_value": "2"
    }
  }
}
```

## How to specify an objective metric

Autopilot produces accuracy metrics to evaluate the model candidates and help you choose which to use to generate forecasts. When you run a time-series forecasting experiment, you can either choose AutoML to let Autopilot optimize the predictor for you, or you can manually choose an algorithm for your predictor.

By default, Autopilot uses the Average Weighted Quantile Loss. However, you can configure the objective metric when you create your AutoML job in the `MetricName` attribute of [AutoMLJobObjective](#).

For the list of available algorithms, see [Algorithms support for time-series forecasting](#).

## How to incorporate national holiday information to your dataset

In Autopilot, you can incorporate a feature-engineered dataset of national holiday information to your time-series. Autopilot provide native support for the holiday calendars of over 250 countries.

After you choose a country, Autopilot applies that country's holiday calendar to every item in your dataset during training. This allows the model to identify patterns associated with specific holidays.

You can enable the holiday featurization when you create your AutoML job by passing an [HolidayConfigAttributes](#) object to the `HolidayConfig` attribute of [TimeSeriesForecastingJobConfig](#). The `HolidayConfigAttributes` object contains the two letters `CountryCode` attribute that determines the country of the public national holiday calendar used to augment your time-series dataset.

Refer to [Country Codes](#) for the list of supported calendars and their corresponding country code.

### How to enable automatic deployment

Autopilot allows you to automatically deploy your forecast model to an endpoint. To enable automatic deployment for the best model candidate of an AutoML job, include a [ModelDeployConfig](#) in the AutoML job request. This allows the deployment of the best model to a SageMaker AI endpoint. Below are the available configurations for customization.

- To let Autopilot generate the endpoint name, set [AutoGenerateEndpointName](#) to `True`.
- To provide your own name for the endpoint, set [AutoGenerateEndpointName](#) to `False` and provide a name of your choice in [EndpointName](#).

### How to configure AutoML to initiate a remote job on EMR Serverless for large datasets

You can configure your AutoML job V2 to automatically initiate a remote job on Amazon EMR Serverless when additional compute resources are needed to process large datasets. By seamlessly transitioning to EMR Serverless when required, the AutoML job can handle datasets that would otherwise exceed the initially provisioned resources, without any manual intervention from you. EMR Serverless is available for the tabular and time series problem types. We recommend setting up this option for time-series datasets larger than 30 GB.

To allow your AutoML job V2 to automatically transition to EMR Serverless for large dataset, you need to provide an `EmrServerlessComputeConfig` object, which includes an `ExecutionRoleARN` field, to the `AutoMLComputeConfig` of the AutoML job V2 input request.

The `ExecutionRoleARN` is the ARN of the IAM role granting the AutoML job V2 the necessary permissions to run EMR Serverless jobs.

This role should have the following trust relationship:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "emr-serverless.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

And grant the permissions to:

- Create, list, and update EMR Serverless applications.
- Start, list, get, or cancel job runs on an EMR Serverless application.
- Tag EMR Serverless resources.
- Pass an IAM role to the EMR Serverless service for execution.

By granting the `iam:PassRole` permission, the AutoML job V2 can temporarily assume the `EMRServerlessRuntimeRole-*` role and pass it to the EMR Serverless service. These are the IAM roles used by the EMR Serverless job execution environments to access other AWS services and resources needed during runtime, such as Amazon S3 for data access, CloudWatch for logging, access to the AWS Glue Data Catalog or other services based on your workload requirements.

See [Job runtime roles for Amazon EMR Serverless](#) for details on this role permissions.

The IAM policy defined in the provided JSON document grants those permissions:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "EMRServerlessCreateApplicationOperation",
    "Effect": "Allow",
    "Action": "emr-serverless:CreateApplication",
    "Resource": "arn:aws:emr-serverless:*:*/*",
    "Condition": {
      "StringEquals": {
```

```

        "aws:RequestTag/sagemaker:is-canvas-resource": "True",
        "aws:ResourceAccount": "${aws:PrincipalAccount}"
    }
}
},
{
    "Sid": "EMRServerlessListApplicationOperation",
    "Effect": "Allow",
    "Action": "emr-serverless:ListApplications",
    "Resource": "arn:aws:emr-serverless:*:*/*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceAccount": "${aws:PrincipalAccount}"
        }
    }
},
{
    "Sid": "EMRServerlessApplicationOperations",
    "Effect": "Allow",
    "Action": [
        "emr-serverless:UpdateApplication",
        "emr-serverless:GetApplication"
    ],
    "Resource": "arn:aws:emr-serverless:*:*:/applications/*",
    "Condition": {
        "StringEquals": {
            "aws:RequestTag/sagemaker:is-canvas-resource": "True",
            "aws:ResourceAccount": "${aws:PrincipalAccount}"
        }
    }
},
{
    "Sid": "EMRServerlessStartJobRunOperation",
    "Effect": "Allow",
    "Action": "emr-serverless:StartJobRun",
    "Resource": "arn:aws:emr-serverless:*:*:/applications/*",
    "Condition": {
        "StringEquals": {
            "aws:RequestTag/sagemaker:is-canvas-resource": "True",
            "aws:ResourceAccount": "${aws:PrincipalAccount}"
        }
    }
},
{

```

```

    "Sid": "EMRServerlessListJobRunOperation",
    "Effect": "Allow",
    "Action": "emr-serverless:ListJobRuns",
    "Resource": "arn:aws:emr-serverless:*:*:/applications/*",
    "Condition": {
      "StringEquals": {
        "aws:ResourceTag/sagemaker:is-canvas-resource": "True",
        "aws:ResourceAccount": "${aws:PrincipalAccount}"
      }
    }
  },
  {
    "Sid": "EMRServerlessJobRunOperations",
    "Effect": "Allow",
    "Action": [
      "emr-serverless:GetJobRun",
      "emr-serverless:CancelJobRun"
    ],
    "Resource": "arn:aws:emr-serverless:*:*:/applications/*/jobruns/*",
    "Condition": {
      "StringEquals": {
        "aws:ResourceTag/sagemaker:is-canvas-resource": "True",
        "aws:ResourceAccount": "${aws:PrincipalAccount}"
      }
    }
  },
  {
    "Sid": "EMRServerlessTagResourceOperation",
    "Effect": "Allow",
    "Action": "emr-serverless:TagResource",
    "Resource": "arn:aws:emr-serverless:*:*/*",
    "Condition": {
      "StringEquals": {
        "aws:RequestTag/sagemaker:is-canvas-resource": "True",
        "aws:ResourceAccount": "${aws:PrincipalAccount}"
      }
    }
  },
  {
    "Sid": "IAMPassOperationForEMRServerless",
    "Effect": "Allow",
    "Action": "iam:PassRole",
    "Resource": "arn:aws:iam:*:*:role/EMRServerlessRuntimeRole-*",
    "Condition": {

```

```
        "StringEquals": {
            "iam:PassedToService": "emr-serverless.amazonaws.com",
            "aws:ResourceAccount": "${aws:PrincipalAccount}"
        }
    }
}
]
```

## Time-series datasets format and missing values filling methods

Time-series data refers to a collection of observations or measurements recorded over regular intervals of time. In this type of data, each observation is associated with a specific timestamp or time period, creating a sequence of data points ordered chronologically.

The specific columns you include in your time-series dataset depend on the goals of your analysis and the data available to you. At a minimum, the time-series data is composed of a 3-column table where:

- One column contains unique identifiers assigned to individual items to refer to their value at a specific moment.
- Another column represents the point-in-time value or **target** to log the value of a given item at a specific moment. After the model is trained on those target values, this target column contains the values that the model predicts at a specified frequency within a defined horizon.
- And a timestamp column is included to record the date and time when the value was measured.
- Additional columns can contain other factors that may influence the forecast performance. For example, in a time-series dataset for retail where the target is the sales or revenue, you might include features that provide information about units sold, product ID, store location, customer count, inventory levels, as well as covariate indicators such as weather data or demographic information.

### Note

You can add a feature-engineered dataset of national holiday information to your time-series. By including holidays in your time series model, you can capture the periodic patterns that holidays create. This helps your forecasts better reflect the underlying

seasonality of your data. For information on the available calendars per country, see [National holiday calendars](#)

## Datasets format for time-series forecasting

Autopilot supports numeric, categorical, text, and datetime data types. The data type of the target column must be numeric.

Autopilot supports time-series data formatted as CSV (default) files or as Parquet files.

- **CSV** (comma-separated-values) is a row-based file format that stores data in human readable plaintext which is a popular choice for data exchange as they are supported by a wide range of applications.
- **Parquet** is a column-based file format where the data is stored and processed more efficiently than row-based file formats. This makes them a better option for big data problems.

For more information about the resource limits on time-series datasets for forecasting in Autopilot, see [Time-series forecasting resource limits for Autopilot](#).

## Handle missing values

A common issue in time-series forecasting data is the presence of missing values. Your data might contain missing values for a number of reasons, including measurement failures, formatting problems, human errors, or a lack of information to record. For instance, if you are forecasting product demand for a retail store and an item is sold out or unavailable, there would be no sales data to record while that item is out of stock. If prevalent enough, missing values can significantly impact a model's accuracy.

Autopilot provides a number of filling methods to handle missing values, with distinct approaches for the target column and other additional columns. Filling is the process of adding standardized values to missing entries in your dataset.

Refer to [How to handle missing values in your input datasets](#) to learn how to set the method for filling missing values in your time-series dataset.

Autopilot supports the following filling methods:

- **Front filling:** Fills any missing values between the earliest recorded data point among all items and the starting point of each item (each item can start at a different time). This ensures that the

data for each item is complete and spans from the earliest recorded data point to its respective starting point.

- **Middle filling:** Fills any missing values between the start and end dates of the items in the dataset.
- **Back filling:** Fills any missing values between the last data point of each item (each item can stop at a different time) and the last recorded data point among all items.
- **Future filling:** Fills any missing values between the last recorded data point among all items and the end of the forecast horizon.

The following image provides a visual representation of the different filling methods.

## Choose a filling logic

When choosing a filling logic, you should consider how the logic will be interpreted by your model. For instance, in a retail scenario, recording 0 sales of an available item is different from recording 0 sales of an unavailable item, as the latter does not imply a lack of customer interest in the item. Because of this, 0 filling in the target column of the time-series might cause the predictor to be under-biased in its predictions, while NaN filling might ignore actual occurrences of 0 available items being sold and cause the predictor to be over-biased.

## Filling logic

You can perform filling on the target column and other numeric columns in your datasets. Target columns have different filling guidelines and restrictions than the rest of the numeric columns.

### Filling Guidelines

Column type	Filling by default?	Supported filling methods	Default filling logic	Accepted filling logic
Target column	Yes	Middle and back filling	0	<ul style="list-style-type: none"> <li>• zero - 0 filling.</li> </ul>

Column type	Filling by default?	Supported filling methods	Default filling logic	Accepted filling logic
				<ul style="list-style-type: none"><li>• value - an integer or float number.</li><li>• nan - not a number.</li><li>• mean - the mean value from the data series.</li><li>• median - the median value from the data series.</li><li>• min - the minimum value from the data series.</li><li>• max - the maximum value from the data series.</li></ul>

Column type	Filling by default?	Supported filling methods	Default filling logic	Accepted filling logic
Other numeric columns	No	Middle, back, and future filling	No default	<ul style="list-style-type: none"> <li>• zero - 0 filling.</li> <li>• value - an integer or float value.</li> <li>• mean - the mean value from the data series.</li> <li>• median - the median value from the data series.</li> <li>• min - the minimum value from the data series.</li> <li>• max - the maximum value from the data series.</li> </ul>

 **Note**

For both the target and other numeric columns, mean, median, min, and max are calculated based on a rolling window of the 64 most recent data entries before the missing values.

## National holiday calendars

Autopilot supports a feature-engineered dataset of national holiday information that provides access to the holiday calendars of over 250 countries. Holiday calendar features are especially useful in the retail domain, where public holidays can significantly affect demand. The following section lists the country codes that you can use to access the holiday calendars of each supported country.

Refer to [How to incorporate national holiday information to your dataset](#) to learn how to add a calendar to your dataset.

### Country Codes

Autopilot provides native support for the public holiday calendars of the following countries. Use the **Country Code** when specifying a country with the API.

Country	Country Code
Afghanistan	AF
Åland Islands	AX
Albania	AL
Algeria	DZ
American Samoa	AS
Andorra	AD
Angola	AO
Anguilla	AI

## Objective metrics

Autopilot produces accuracy metrics to evaluate the model candidates and help you choose which to use to generate forecasts. You can either let Autopilot optimize the predictor for you, or you can manually choose an algorithm for your predictor. By default, Autopilot uses the Average Weighted Quantile Loss.

The following list contains the names of the metrics that are currently available to measure the performance of models for time-series forecasting.

### RMSE

Root mean squared error (RMSE) – Measures the square root of the squared difference between predicted and actual values, and is averaged over all values. It's an important metric to indicate the presence of large model errors and outliers. Values range from zero (0) to infinity, with smaller numbers indicating a better model fit to the data. RMSE is dependent on scale, and should not be used to compare datasets of different sizes.

### wQL

Weighted Quantile Loss (wQL) – Assess the accuracy of the forecast by measuring the weighted absolute differences between predicted and actual P10, P50, and P90 quantiles with lower values indicating better performance.

### Average wQL (default)

Average Weighted Quantile Loss (Average wQL) – Evaluates the forecast by averaging the accuracy at the P10, P50, and P90 quantiles. A lower value indicates a more accurate model.

### MASE

Mean Absolute Scaled Error (MASE) – The mean absolute error of the forecast normalized by the mean absolute error of a simple baseline forecasting method. A lower value indicates a more accurate model, where  $MASE < 1$  is estimated to be better than the baseline and  $MASE > 1$  is estimated to be worse than the baseline.

### MAPE

Mean Absolute Percent Error (MAPE) – The percentage error (percent difference of the mean forecasted value versus the actual value) averaged over all time points. A lower value indicates a more accurate model, where  $MAPE = 0$  is a model with no errors.

## WAPE

Weighted Absolute Percent Error (WAPE) – The sum of the absolute error normalized by the sum of the absolute target, which measure the overall deviation of forecasted values from observed values. A lower value indicates a more accurate model.

## Algorithms support for time-series forecasting

Autopilot trains the following six built-in algorithms with your target time-series. Then, using a stacking ensemble method, it combines these model candidates to create an optimal forecasting model for a given objective metric.

- **Convolutional Neural Network - Quantile Regression (CNN-QR)** – CNN-QR is a proprietary machine learning algorithm for forecasting time-series using causal convolutional neural networks (CNNs). CNN-QR works best with large datasets containing hundreds of time-series.
- **DeepAR+** – DeepAR+ is a proprietary machine learning algorithm for forecasting time-series using recurrent neural networks (RNNs). DeepAR+ works best with large datasets containing hundreds of feature time-series.
- **Prophet** – [Prophet](#) is a popular local Bayesian structural time series model based on an additive model where non-linear trends are fit with yearly, weekly, and daily seasonality. The Autopilot Prophet algorithm uses the [Prophet class](#) of the Python implementation of Prophet. It works best with time-series with strong seasonal effects and several seasons of historical data.
- **Non-Parametric Time Series (NPTS)** – The NPTS proprietary algorithm is a scalable, probabilistic baseline forecaster. It predicts the future value distribution of a given time-series by sampling from past observations. NPTS is especially useful when working with sparse or intermittent time series.
- **Autoregressive Integrated Moving Average (ARIMA)** – ARIMA is a commonly used statistical algorithm for time-series forecasting. The algorithm captures standard temporal structures (patterned organizations of time) in the input dataset. It is especially useful for simple datasets with under 100 time series.
- **Exponential Smoothing (ETS)** – ETS is a commonly used statistical algorithm for time-series forecasting. The algorithm is especially useful for simple datasets with under 100 time series, and datasets with seasonality patterns. ETS computes a weighted average over all observations in the time series dataset as its prediction, with exponentially decreasing weights over time.

## Forecast a deployed Autopilot model

After training your models using the AutoML API, you can deploy them for real-time or batch-based forecasting.

The AutoML API trains several model candidates for your time-series data and selects an optimal forecasting model based on your target objective metric. Once your model candidates have been trained, you can find the best candidate in the response [DescribeAutoMLJobV2](#) at [BestCandidate](#).

To get predictions using this best performing model, you can either set up an endpoint to obtain forecasts interactively or use batch forecasting to make predictions on a batch of observations.

### Considerations

- When providing input data for forecasting, the schema of your data should remain the same as the one used to train your model, including the number of columns, column headers, and data types. You can forecast for existing or new item IDs within the same or different timestamp range to predict for a different time period.
- Forecasting models predict for the forecast horizon points in the future specified in the input request at training, which is from the *target end date* to the *target end date + forecast horizon*. To use the model for predicting specific dates, you should provide the data in the same format as the original input data, extending up to a specified *target end date*. In this scenario, the model will start predicting from the new target end date.

For example, if your dataset had monthly data from January to June with a Forecast horizon of 2, then the model would predict the target value for the next 2 months, which would be July and August. If in August, you want to predict for the next 2 months, this time your input data should be from January to August and the model will predict for the next 2 months (September, October).

- When forecasting future data points, there is no set minimum for the amount of historical data to provide. Include enough data to capture seasonal and recurrent patterns in your time-series.

### Topics

- [Real-time forecasting](#)
- [Batch forecasting](#)

## Real-time forecasting

Real-time forecasting is useful when you need to generate predictions on-the-fly, such as for applications that require immediate responses or when forecasting for individual data points.

By deploying your AutoML model as a real-time endpoint, you can generate forecasts on-demand and minimize the latency between receiving new data and obtaining predictions. This makes real-time forecasting well-suited for applications that require immediate, personalized, or event-driven forecasting capabilities.

For real time forecasting, the dataset should be a subset of the input dataset. The real time endpoint has an input data size of approximately 6MB and a response timeout limitation of 60 seconds. We recommend bringing in one or few items at a time.

You can use SageMaker APIs to retrieve the best candidate of an AutoML job and then create a SageMaker AI endpoint using that candidate.

Alternatively, you can choose the automatic deployment option when creating your Autopilot experiment. For information on setting up the automatic deployment of models, see [How to enable automatic deployment](#).

### To create a SageMaker AI endpoint using your best model candidate:

1. **Retrieve the details of the AutoML job.**

The following AWS CLI command example uses the [DescribeAutoMLJobV2](#) API to obtain details of the AutoML job, including the information about the best model candidate.

```
aws sagemaker describe-auto-ml-job-v2 --auto-ml-job-name job-name --region region
```

2. **Extract the container definition from [InferenceContainers](#) for the best model candidate.**

A container definition is the containerized environment used to host the trained SageMaker AI model for making predictions.

```
BEST_CANDIDATE=$(aws sagemaker describe-auto-ml-job-v2 \  
  --auto-ml-job-name job-name \  
  --region region \  
  --query 'BestCandidate.InferenceContainers[0]' \  
  --output json)
```

This command extracts the container definition for the best model candidate and stores it in the `BEST_CANDIDATE` variable.

### 3. Create a SageMaker AI model using the best candidate container definition.

Use the container definitions from the previous steps to create a SageMaker AI model by using the [CreateModel](#) API.

```
aws sagemaker create-model \  
    --model-name 'your-candidate-name>' \  
    --primary-container "$BEST_CANDIDATE"  
    --execution-role-arn 'execution-role-arn>' \  
    --region 'region>
```

The `--execution-role-arn` parameter specifies the IAM role that SageMaker AI assumes when using the model for inference. For details on the permissions required for this role, see [CreateModel API: Execution Role Permissions](#).

### 4. Create a SageMaker AI endpoint configuration using the model.

The following AWS CLI command uses the [CreateEndpointConfig](#) API to create an endpoint configuration.

```
aws sagemaker create-endpoint-config \  
    --production-variants file://production-variants.json \  
    --region 'region'
```

Where the `production-variants.json` file contains the model configuration, including the model name and instance type.

#### Note

We recommend using [m5.12xlarge](#) instances for real-time forecasting.

```
[  
  {  
    "VariantName": "variant-name",  
    "ModelName": "model-name",  
    "InitialInstanceCount": 1,
```

```
        "InstanceType": "m5.12xlarge"  
    }  
]  
}
```

## 5. Create the SageMaker AI endpoint using the endpoint configuration.

The following AWS CLI example uses the [CreateEndpoint](#) API to create the endpoint.

```
aws sagemaker create-endpoint \  
    --endpoint-name 'endpoint-name' \  
    --endpoint-config-name 'endpoint-config-name' \  
    --region 'region'
```

Check the progress of your real-time inference endpoint deployment by using the [DescribeEndpoint](#) API. See the following AWS CLI command as an example.

```
aws sagemaker describe-endpoint \  
    --endpoint-name 'endpoint-name' \  
    --region 'region'
```

After the EndpointStatus changes to InService, the endpoint is ready to use for real-time inference.

## 6. Invoke the SageMaker AI endpoint to make predictions.

```
aws sagemaker invoke-endpoint \  
    --endpoint-name 'endpoint-name' \  
    --region 'region' \  
    --body file://input-data-in-bytes.json \  
    --content-type 'application/json' outfile
```

Where the `input-data-in-bytes.json` file contains the input data for the prediction.

### Batch forecasting

Batch forecasting, also known as offline inferencing, generates model predictions on a batch of observations. Batch inference is a good option for large datasets or if you don't need an immediate response to a model prediction request.

By contrast, online inference (real-time inferencing) generates predictions in real time.

You can use SageMaker APIs to retrieve the best candidate of an AutoML job and then submit a batch of input data for inference using that candidate.

### 1. Retrieve the details of the AutoML job.

The following AWS CLI command example uses the [DescribeAutoMLJobV2](#) API to obtain details of the AutoML job, including the information about the best model candidate.

```
aws sagemaker describe-auto-ml-job-v2 --auto-ml-job-name job-name --region region
```

### 2. Extract the container definition from [InferenceContainers](#) for the best model candidate.

A container definition is the containerized environment used to host the trained SageMaker AI model for making predictions.

```
BEST_CANDIDATE=$(aws sagemaker describe-auto-ml-job-v2 \  
  --auto-ml-job-name job-name \  
  --region region \  
  --query 'BestCandidate.InferenceContainers[0]' \  
  --output json)
```

This command extracts the container definition for the best model candidate and stores it in the BEST\_CANDIDATE variable.

### 3. Create a SageMaker AI model using the best candidate container definition.

Use the container definitions from the previous steps to create a SageMaker AI model by using the [CreateModel](#) API.

```
aws sagemaker create-model \  
  --model-name 'model-name' \  
  --primary-container "$BEST_CANDIDATE" \  
  --execution-role-arn 'execution-role-arn>' \  
  --region 'region>
```

The `--execution-role-arn` parameter specifies the IAM role that SageMaker AI assumes when using the model for inference. For details on the permissions required for this role, see [CreateModel API: Execution Role Permissions](#).

### 4. Create a batch transform job.

The following example creates a transform job using the [CreateTransformJob](#) API.

```
aws sagemaker create-transform-job \  
  --transform-job-name 'transform-job-name' \  
  --model-name 'model-name' \  
  --transform-input file://transform-input.json \  
  --transform-output file://transform-output.json \  
  --transform-resources file://transform-resources.json \  
  --region 'region'
```

The input, output, and resource details are defined in separate JSON files:

- transform-input.json:

```
{  
  "DataSource": {  
    "S3DataSource": {  
      "S3DataType": "S3Prefix",  
      "S3Uri": "s3://my-input-data-bucket/path/to/input/data"  
    }  
  },  
  "ContentType": "text/csv",  
  "SplitType": "None"  
}
```

- transform-output.json:

```
{  
  "S3OutputPath": "s3://my-output-bucket/path/to/output",  
  "AssembleWith": "Line"  
}
```

- transform-resources.json:

 **Note**

We recommend using [m5.12xlarge](#) instances for general-purpose workloads and m5.24xlarge instances for big data forecasting tasks.

```
{  
  "InstanceType": "instance-type",
```

```
"InstanceCount": 1
}
```

## 5. Monitor the progress of your transform job using the [DescribeTransformJob API](#).

See the following AWS CLI command as an example.

```
aws sagemaker describe-transform-job \  
  --transform-job-name 'transform-job-name' \  
  --region region
```

## 6. Retrieve the batch transform output.

After the job is finished, the predicted result is available in the S3OutputPath.

The output file name has the following format: `input_data_file_name.out`. As an example, if your input file is `text_x.csv`, the output name will be `text_x.csv.out`.

```
aws s3 ls s3://my-output-bucket/path/to/output/
```

The following code examples illustrate the use of the AWS SDK for Python (boto3) and the AWS CLI for batch forecasting.

### AWS SDK for Python (boto3)

The following example uses **AWS SDK for Python (boto3)** to make predictions in batches.

```
import sagemaker
import boto3

session = sagemaker.session.Session()

sm_client = boto3.client('sagemaker', region_name='us-west-2')
role = 'arn:aws:iam::1234567890:role/sagemaker-execution-role'
output_path = 's3://test-auto-ml-job/output'
input_data = 's3://test-auto-ml-job/test_X.csv'

best_candidate = sm_client.describe_auto_ml_job_v2(AutoMLJobName=job_name)
['BestCandidate']
best_candidate_containers = best_candidate['InferenceContainers']
best_candidate_name = best_candidate['CandidateName']
```

```

# create model
reponse = sm_client.create_model(
    ModelName = best_candidate_name,
    ExecutionRoleArn = role,
    Containers = best_candidate_containers
)

# Launch Transform Job
response = sm_client.create_transform_job(
    TransformJobName=f'{best_candidate_name}-transform-job',
    ModelName=model_name,
    TransformInput={
        'DataSource': {
            'S3DataSource': {
                'S3DataType': 'S3Prefix',
                'S3Uri': input_data
            }
        },
        'ContentType': "text/csv",
        'SplitType': 'None'
    },
    TransformOutput={
        'S3OutputPath': output_path,
        'AssembleWith': 'Line',
    },
    TransformResources={
        'InstanceType': 'ml.m5.2xlarge',
        'InstanceCount': 1,
    },
)

```

The batch inference job returns a response in the following format.

```

{'TransformJobArn': 'arn:aws:sagemaker:us-west-2:1234567890:transform-job/test-
transform-job',
 'ResponseMetadata': {'RequestId': '659f97fc-28c4-440b-b957-a49733f7c2f2',
 'HTTPStatusCode': 200,
 'HTTPHeaders': {'x-amzn-requestid': '659f97fc-28c4-440b-b957-a49733f7c2f2',
 'content-type': 'application/x-amz-json-1.1',
 'content-length': '96',
 'date': 'Thu, 11 Aug 2022 22:23:49 GMT'},
 'RetryAttempts': 0}}

```

## AWS Command Line Interface (AWS CLI)

### 1. Obtain the best candidate container definitions.

```
aws sagemaker describe-auto-ml-job-v2 --auto-ml-job-name 'test-automl-job' --
region us-west-2
```

### 2. Create the model.

```
aws sagemaker create-model --model-name 'test-sagemaker-model'
--containers '[{
  "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-
automl:2.5-1-cpu-py3",
  "ModelDataUrl": "s3://amzn-s3-demo-bucket/out/test-job1/data-processor-models/
test-job1-dpp0-1-e569ff7ad77f4e55a7e549a/output/model.tar.gz",
  "Environment": {
    "AUTOML_SPARSE_ENCODE_RECORDIO_PROTOBUF": "1",
    "AUTOML_TRANSFORM_MODE": "feature-transform",
    "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "application/x-recordio-protobuf",
    "SAGEMAKER_PROGRAM": "sagemaker_serve",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
  }
}, {
  "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-

```

```

        "SAGEMAKER_INFERENCE_OUTPUT": "predicted_label",
        "SAGEMAKER_INFERENCE_SUPPORTED":
"predicted_label,probability,labels,probabilities",
        "SAGEMAKER_PROGRAM": "sagemaker_serve",
        "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
    }
}]' \
--execution-role-arn 'arn:aws:iam::1234567890:role/sagemaker-execution-role' \
--region 'us-west-2'

```

### 3. Create a transform job.

```

aws sagemaker create-transform-job --transform-job-name 'test-tranform-job' \
--model-name 'test-sagemaker-model' \
--transform-input '{
    "DataSource": {
        "S3DataSource": {
            "S3DataType": "S3Prefix",
            "S3Uri": "s3://amzn-s3-demo-bucket/data.csv"
        }
    },
    "ContentType": "text/csv",
    "SplitType": "None"
}' \
--transform-output '{
    "S3OutputPath": "s3://amzn-s3-demo-bucket/output/",
    "AssembleWith": "Line"
}' \
--transform-resources '{
    "InstanceType": "ml.m5.2xlarge",
    "InstanceCount": 1
}' \
--region 'us-west-2'

```

### 4. Check the progress of the transform job.

```

aws sagemaker describe-transform-job --transform-job-name 'test-tranform-job' --
region us-west-2

```

The following is the response from the transform job.

```

{
    "TransformJobName": "test-tranform-job",

```

```

    "TransformJobArn": "arn:aws:sagemaker:us-west-2:1234567890:transform-job/test-
transform-job",
    "TransformJobStatus": "InProgress",
    "ModelName": "test-model",
    "TransformInput": {
      "DataSource": {
        "S3DataSource": {
          "S3DataType": "S3Prefix",
          "S3Uri": "s3://amzn-s3-demo-bucket/data.csv"
        }
      },
      "ContentType": "text/csv",
      "CompressionType": "None",
      "SplitType": "None"
    },
    "TransformOutput": {
      "S3OutputPath": "s3://amzn-s3-demo-bucket/output/",
      "AssembleWith": "Line",
      "KmsKeyId": ""
    },
    "TransformResources": {
      "InstanceType": "ml.m5.2xlarge",
      "InstanceCount": 1
    },
    "CreationTime": 1662495635.679,
    "TransformStartTime": 1662495847.496,
    "DataProcessing": {
      "InputFilter": "$",
      "OutputFilter": "$",
      "JoinSource": "None"
    }
  }
}

```

After the `TransformJobStatus` changes to `Completed`, you can check the inference result in the `S3OutputPath`.

## Amazon SageMaker Autopilot data exploration notebook

Amazon SageMaker Autopilot cleans and pre-processes your dataset automatically. To help users understand their data, uncover patterns, relationships, and anomalies about the time-series, Amazon SageMaker Autopilot generates a **data exploration** static report in the form of a notebook for users to reference.

The data exploration notebook is generated for every Autopilot job. The report is stored in an Amazon S3 bucket and can be accessed from the job output path.

You can find the Amazon S3 prefix to the data exploration notebook in the response to [DescribeAutoMLJobV2](#) at [AutoMLJobArtifacts.DataExplorationNotebookLocation](#).

## Reports generated by Amazon SageMaker Autopilot

In addition to the data exploration notebook, Autopilot generates various reports for the best model candidate of each experiment.

- An explainability report provides insights into how the model makes forecasts.
- A performance report provides a quantitative assessment of the model's forecasting capabilities.
- A backtest results report is generated after testing the model's performance on historical data.

### Explainability report

Autopilot explainability report helps you better understand how the attributes in your datasets impact forecasts for specific time-series (item and dimension combinations) and time points. Autopilot uses a metric called *Impact scores* to quantify the relative impact of each attribute and determine whether they increase or decrease forecast values.

For example, consider a forecasting scenario where the target is sales and there are two related attributes: price and color. Autopilot may find that the item's color has a high impact on sales for certain items, but a negligible effect for other items. It may also find that a promotion in the summer has a high impact on sales, but a promotion in the winter has little effect.

The explainability report is generated only when:

- The time series dataset includes additional feature columns or is associated with a holiday calendar.
- The base models CNN-QR and DeepAR+ are included in the final ensemble.

### Interpret Impact scores

Impact scores measure the relative impact attributes have on forecast values. For example, if the price attribute has an impact score that is twice as large as the store location attribute, you can conclude that the price of an item has twice the impact on forecast values than the store location.

Impact scores also provide information on whether attributes increase or decrease forecast values.

The Impact scores range from -1 to 1, where the sign denotes the direction of the impact. A score of 0 indicates no impact, while scores close to 1 or -1 indicate a significant impact.

It is important to note that Impact scores measure the relative impact of attributes, not the absolute impact. Therefore, Impact scores cannot be used to determine whether particular attributes improve model accuracy. If an attribute has a low Impact score, that does not necessarily mean that it has a low impact on forecast values; it means that it has a lower impact on forecast values than other attributes used by the predictor.

### Find the explainability report

You can find the Amazon S3 prefix to the explainability artifacts generated for the best candidate in the response to [DescribeAutoMLJobV2](#) at [BestCandidate.CandidateProperties.CandidateArtifactLocations.Explainability](#).

### Model performance report

Autopilot model quality report (also referred to as performance report) provides insights and quality information for the best model candidate (best predictor) generated by an AutoML job. This includes information about the job details, objective function, and accuracy metrics (wQL, MAPE, WAPE, RMSE, MASE).

You can find the Amazon S3 prefix to the model quality report artifacts generated for the best candidate in the response to [DescribeAutoMLJobV2](#) at [BestCandidate.CandidateProperties.CandidateArtifactLocations.ModelInsights](#).

### Backtests results report

Backtests results provide insights into the performance of a time-series forecasting model by evaluating its predictive accuracy and reliability. It helps analysts and data scientists assess its performance on historical data and assists in understanding its potential performance on future, unseen data.

Autopilot uses backtesting to tune parameters and produce accuracy metrics. During backtesting, Autopilot automatically splits your time-series data into two sets, a training set and a testing set. The training set is used to train a model which is then used to generate forecasts for data points in the testing set. Autopilot uses this testing dataset to evaluate the model's accuracy by comparing forecasted values with observed values in the testing set.

You can find the Amazon S3 prefix to the model quality report artifacts generated for the best candidate in the response to [DescribeAutoMLJobV2](#) at [BestCandidate.CandidateProperties.CandidateArtifactLocations.BacktestResults](#).

## Time-series forecasting resource limits for Autopilot

The following table lists the resource limits for time-series forecasting jobs in Amazon SageMaker Autopilot and whether or not you can adjust each limit.

Resource limits	Default limit	Adjustable
Size of input dataset	30 GB	Yes
Size of a single Parquet file	2 GB	No
Maximum number of rows in a dataset	3 billion	Yes
Maximum number of grouping columns	5	No
Maximum number of numerical features	13	No
Maximum number of categorical features	10	No
Maximum number of time-series (unique combinations of item and grouping columns) per dataset	5,000,000	Yes
Maximum Forecast horizon	500	Yes

## Create an AutoML job to fine-tune text generation models using the API

Large language models (LLMs) excel in multiple generative tasks, including text generation, summarization, completion, question answering, and more. Their performance can be attributed to their significant size and extensive training on diverse datasets and various tasks. However, specific

domains, such as healthcare and financial services, may require customized fine-tuning to adapt to unique data and use cases. By tailoring their training to their particular domain, LLMs can improve their performance and provide more accurate outputs for targeted applications.

Autopilot offers the capability to fine-tune a selection of pre-trained generative text models. In particular, Autopilot supports the **instruction-based fine tuning** of a selection of general-purpose large language models (LLMs) powered by JumpStart.

### Note

The text generation models that support fine-tuning in Autopilot are currently accessible exclusively in Regions supported by SageMaker Canvas. See the documentation of SageMaker Canvas for the [full list of its supported Regions](#).

Fine-tuning a pre-trained model requires a specific dataset of clear instructions that guide the model on how to generate output or behave for that task. The model learns from the dataset, adjusting its parameters to conform to the provided instructions. Instruction-based fine-tuning involves using labeled examples formatted as prompt-response pairs and phrased as instructions. For more information about fine-tuning, see [Fine-tune a foundation model](#).

The following guidelines outline the process of creating an Amazon SageMaker Autopilot job as a pilot experiment to fine-tune text generation LLMs using the SageMaker [API Reference](#).

### Note

Tasks such as text and image classification, time-series forecasting, and fine-tuning of large language models are exclusively available through the version 2 of the [AutoML REST API](#). If your language of choice is Python, you can refer to [AWS SDK for Python \(Boto3\)](#) or the [AutoMLV2 object](#) of the Amazon SageMaker Python SDK directly. Users who prefer the convenience of a user interface can use [Amazon SageMaker Canvas](#) to access pre-trained models and generative AI foundation models, or create custom models tailored for specific text, image classification, forecasting needs, or generative AI.

To create an Autopilot experiment programmatically for fine-tuning an LLM, you can call the [CreateAutoMLJobV2](#) API in any language supported by Amazon SageMaker Autopilot or the AWS CLI.

For information about how this API action translates into a function in the language of your choice, see the [See Also](#) section of `CreateAutoMLJobV2` and choose an SDK. As an example, for Python users, see the full request syntax of [create\\_auto\\_ml\\_job\\_v2](#) in AWS SDK for Python (Boto3).

### Note

Autopilot fine-tunes large language models without requiring multiple candidates to be trained and evaluated. Instead, using your dataset, Autopilot directly fine-tunes your target model to enhance a default objective metric, the cross-entropy loss. Fine-tuning language models in Autopilot does not require setting the `AutoMLJobObjective` field.

Once your LLM is fine-tuned, you can evaluate its performance by accessing various ROUGE scores through the [BestCandidate](#) when making a [DescribeAutoMLJobV2](#) API call. The model also provides information about its training and validation loss as well as perplexity. For a comprehensive list of metrics for evaluating the quality of the text generated by the fine-tuned models, see [Metrics for fine-tuning large language models in Autopilot](#).

## Prerequisites

Before using Autopilot to create a fine-tuning experiment in SageMaker AI, make sure to take the following steps:

- (Optional) Choose the pre-trained model you want to fine-tune.

For the list of pre-trained models available for fine-tuning in Amazon SageMaker Autopilot, see [Supported large language models for fine-tuning](#). The selection of a model is not mandatory; if no model is specified, Autopilot automatically defaults to the model *Falcon7BInstruct*.

- Create a dataset of instructions. See [Dataset file types and input data format](#) to learn about the format requirements for your instruction-based dataset.
- Place your dataset in an Amazon S3 bucket.
- Grant full access to the Amazon S3 bucket containing your input data for the SageMaker AI execution role used to run your experiment.
  - For information on retrieving your SageMaker AI execution role, see [Get your execution role](#).
  - For information on granting your SageMaker AI execution role permissions to access one or more specific buckets in Amazon S3, see *Add Additional Amazon S3 Permissions to a SageMaker AI Execution Role* in [Create execution role](#).

- Additionally, you should provide your execution role with the necessary permissions to access the default storage Amazon S3 bucket used by JumpStart. This access is required for storing and retrieving pre-trained model artifacts in JumpStart. To grant access to this Amazon S3 bucket, you must create a new inline custom policy on your execution role.

Here's an example policy that you can use in your JSON editor when configuring AutoML fine-tuning jobs in us-west-2:

*JumpStart's bucket names follow a predetermined pattern that depends on the AWS Regions. You must adjust the name of the bucket accordingly.*

```
{
  "Sid": "Statement1",
  "Effect": "Allow",
  "Action": [
    "s3:GetObject",
    "s3:PutObject",
    "s3:ListBucket"
  ],
  "Resource": [
    "arn:aws:s3:::jumpstart-cache-prod-us-west-2",
    "arn:aws:s3:::jumpstart-cache-prod-us-west-2/*"
  ]
}
```

Once this is done, you can use the ARN of this execution role in Autopilot API requests.

## Required parameters

When calling [CreateAutoMLJobV2](#) to create an Autopilot experiment for LLM fine-tuning, you must provide the following values:

- An [AutoMLJobName](#) to specify the name of your job. The name should be of type string, and should have a minimum length of 1 character and a maximum length of 32.
- At least one [AutoMLJobChannel](#) of the training type within the [AutoMLJobInputDataConfig](#). This channel specifies the name of the Amazon S3 bucket where your fine-tuning dataset is located. You have the option to define a validation channel. If no validation channel is provided, and a `ValidationFraction` is configured in the [AutoMLDataSplitConfig](#), this fraction is utilized to randomly divide the training dataset into

training and validation sets. Additionally, you can specify the type of content (CSV or Parquet files) for the dataset.

- An [AutoMLProblemTypeConfig](#) of type [TextGenerationJobConfig](#) to configure the settings of your training job.

In particular, you can specify the name of the base model to fine-tune in the `BaseModelName` field. For the list of pre-trained models available for fine-tuning in Amazon SageMaker Autopilot, see [Supported large language models for fine-tuning](#).

- An [OutputDataConfig](#) to specify the Amazon S3 output path to store the artifacts of your AutoML job.
- A [RoleArn](#) to specify the ARN of the role used to access your data.

The following is an example of the full request format used when making an API call to `CreateAutoMLJobV2` for fine-tuning a (Falcon7BInstruct) model.

```
{
  "AutoMLJobName": "<job_name>",
  "AutoMLJobInputDataConfig": [
    {
      "ChannelType": "training",
      "CompressionType": "None",
      "ContentType": "text/csv",
      "DataSource": {
        "S3DataSource": {
          "S3DataType": "S3Prefix",
          "S3Uri": "s3://<bucket_name>/<input_data>.csv"
        }
      }
    }
  ],
  "OutputDataConfig": {
    "S3OutputPath": "s3://<bucket_name>/output",
    "KmsKeyId": "arn:aws:kms:<region>:<account_id>:key/<key_value>"
  },
  "RoleArn": "arn:aws:iam::<account_id>:role/<sagemaker_execution_role_name>",
  "AutoMLProblemTypeConfig": {
    "TextGenerationJobConfig": {
      "BaseModelName": "Falcon7BInstruct"
    }
  }
}
```

```
}
```

All other parameters are optional.

## Optional parameters

The following sections provide details of some optional parameters that you can pass to your fine-tuning AutoML job.

### How to specify the training and validation datasets of an AutoML job

You can provide your own validation dataset and custom data split ratio, or let Autopilot split the dataset automatically.

Each [AutoMLJobChannel](#) object (see the required parameter [AutoMLJobInputDataConfig](#)) has a `ChannelType`, which can be set to either `training` or `validation` values that specify how the data is to be used when building a machine learning model.

At least one data source must be provided and a maximum of two data sources is allowed: one for training data and one for validation data. How you split the data into training and validation datasets depends on whether you have one or two data sources.

- If you only have **one data source**, the `ChannelType` is set to `training` by default and must have this value.
  - If the `ValidationFraction` value in [AutoMLDataSplitConfig](#) is not set, 0.2 (20%) of the data from this source is used for validation by default.
  - If the `ValidationFraction` is set to a value between 0 and 1, the dataset is split based on the value specified, where the value specifies the fraction of the dataset used for validation.
- If you have **two data sources**, the `ChannelType` of one of the `AutoMLJobChannel` objects must be set to `training`, the default value. The `ChannelType` of the other data source must be set to `validation`. The two data sources must have the same format, either CSV or Parquet, and the same schema. You must not set the value for the `ValidationFraction` in this case because all of the data from each source is used for either training or validation. Setting this value causes an error.

### How to enable automatic deployment

With Autopilot, you can automatically deploy your fine-tuned model to an endpoint. To enable automatic deployment for your fine-tuned model, include a [ModelDeployConfig](#) in the AutoML

job request. This allows the deployment of your fine-tuned model to a SageMaker AI endpoint. Below are the available configurations for customization.

- To let Autopilot generate the endpoint name, set [AutoGenerateEndpointName](#) to True.
- To provide your own name for the endpoint, set [AutoGenerateEndpointName](#) to False and provide a name of your choice in [EndpointName](#).

### How to set the EULA acceptance when fine-tuning a model using the AutoML API

For models requiring the acceptance of an end-user license agreement before fine-tuning, you can accept the EULA by setting the `AcceptEula` attribute of the [ModelAccessConfig](#) to True in [TextGenerationJobConfig](#) when configuring your [AutoMLProblemTypeConfig](#).

### How to set hyperparameters to optimize the learning process of a model

You can optimize the learning process of your text generation model by setting hyperparameter values in the `TextGenerationHyperParameters` attribute of [TextGenerationJobConfig](#) when configuring your [AutoMLProblemTypeConfig](#).

Autopilot allows for the setting of four common hyperparameters across all models.

- `epochCount`: Its value should be a string containing an integer value within the range of 1 to 10.
- `batchSize`: Its value should be a string containing an integer value within the range of 1 to 64.
- `learningRate`: Its value should be a string containing a floating-point value within the range of 0 to 1.
- `learningRateWarmupSteps`: Its value should be a string containing an integer value within the range of 0 to 250.

For more details on each hyperparameter, see [Hyperparameters for optimizing the learning process of your text generation models](#).

The following JSON example shows a `TextGenerationHyperParameters` field passed to the `TextGenerationJobConfig` where all four hyperparameters are configured.

```
"AutoMLProblemTypeConfig": {
  "TextGenerationJobConfig": {
    "BaseModelName": "Falcon7B",
    "TextGenerationHyperParameters": {"epochCount":"5", "learningRate":"0.000001",
    "batchSize": "32", "learningRateWarmupSteps": "10"}
```

```
}
}
```

## Supported large language models for fine-tuning

Using Autopilot API, users can fine-tune large language models (LLMs) that are powered by Amazon SageMaker JumpStart.

### Note

For fine-tuning models that require the acceptance of an end-user license agreement, you must explicitly declare EULA acceptance when creating your AutoML job. Note that after fine-tuning a pretrained model, the weights of the original model are changed, so you do not need to later accept a EULA when deploying the fine-tuned model.

For information on how to accept the EULA when creating a fine-tuning job using the AutoML API, see [the section called "Set EULA"](#).

You can find the full details of each model by searching for your **JumpStart Model ID** in the following [model table](#), and then following the link in the **Source** column. These details might include the languages supported by the model, biases it may exhibit, the datasets employed for fine-tuning, and more.

The following table lists the supported JumpStart models that you can fine-tune with an AutoML job.

JumpStart Model ID	BaseModelName in API request	Description
huggingface-textgeneration-dolly-v2-3b-bf16	Dolly3B	Dolly 3B is a 2.8 billion parameter instruction-following large language model based on <a href="#">pythia-2.8b</a> . It is trained on the instruction/response fine tuning dataset <a href="#">databricks-dolly-15k</a> and can perform tasks including brainstorming, classification,

JumpStart Model ID	BaseModelName in API request	Description
		questions and answers, text generation, information extraction, and summarization.
huggingface-textgeneration-dolly-v2-7b-bf16	Dolly7B	Dolly 7B is a 6.9 billion parameter instruction-following large language model based on <a href="#">pythia-6.9b</a> . It is trained on the instruction/response fine tuning dataset <a href="#">databricks-dolly-15k</a> and can perform tasks including brainstorming, classification, questions and answers, text generation, information extraction, and summarization.
huggingface-textgeneration-dolly-v2-12b-bf16	Dolly12B	Dolly 12B is a 12 billion parameter instruction-following large language model based on <a href="#">pythia-12b</a> . It is trained on the instruction/response fine tuning dataset <a href="#">databricks-dolly-15k</a> and can perform tasks including brainstorming, classification, questions and answers, text generation, information extraction, and summarization.

JumpStart Model ID	BaseModelName in API request	Description
huggingface-llm-falcon-7b-bf16	Falcon7B	<p>Falcon 7B is a 7 billion parameter causal large language model trained on 1,500 billion tokens enhanced with curated corpora. Falcon-7B is trained on English and French data only, and does not generalize appropriately to other languages. Because the model was trained on large amounts of web data, it carries the stereotypes and biases commonly found online.</p>
huggingface-llm-falcon-7b-instruct-bf16	Falcon7BInstruct	<p>Falcon 7B Instruct is a 7 billion parameter causal large language model built on Falcon 7B and fine-tuned on a 250 million tokens mixture of chat/instruct datasets.</p> <p>Falcon 7B Instruct is mostly trained on English data, and does not generalize appropriately to other languages. Furthermore, as it is trained on a large-scale corpora representative of the web, it carries the stereotypes and biases commonly encountered online.</p>

JumpStart Model ID	BaseModelName in API request	Description
huggingface-llm-falcon-40b-bf16	Falcon40B	Falcon 40B is a 40 billion parameter causal large language model trained on 1,000 billion tokens enhanced with curated corpora. It is trained mostly on English, German, Spanish, and French, with limited capabilities in Italian, Portuguese, Polish, Dutch, Romanian, Czech, and Swedish. It does not generalize appropriately to other languages. Furthermore, as it is trained on a large-scale corpora representative of the web, it carries the stereotypes and biases commonly encountered online.
huggingface-llm-falcon-40b-instruct-bf16	Falcon40BInstruct	Falcon 40B Instruct is a 40 billion parameter causal large language model built on Falcon40B and fine-tuned on a mixture of Baize. It is mostly trained on English and French data, and does not generalize appropriately to other languages. Furthermore, as it is trained on a large-scale corpora representative of the web, it carries the stereotypes and biases commonly encountered online.

JumpStart Model ID	BaseModelName in API request	Description
huggingface-text2text-flan-t5-large	FlanT5L	<p>The <a href="#">Flan-T5</a> model family is a set of large language models that are fine-tuned on multiple tasks and can be further trained. These models are well-suited for tasks such as language translation, text generation, sentence completion, word sense disambiguation, summarization, or question answering . Flan T5 L is a 780 million parameter large language model trained on numerous languages. You can find the list of the languages supported by Flan T5 L in the details of the model retrieved from your search by model ID in JumpStart's <a href="#">model table</a>.</p>

JumpStart Model ID	BaseModelName in API request	Description
huggingface-text2text-flan-t5-xl	FlanT5XL	<p>The <a href="#">Flan-T5</a> model family is a set of large language models that are fine-tuned on multiple tasks and can be further trained. These models are well-suited for tasks such as language translation, text generation, sentence completion, word sense disambiguation, summarization, or question answering. Flan T5 XL is a 3 billion parameter large language model trained on numerous languages. You can find the list of the languages supported by Flan T5 XL in the details of the model retrieved from your search by model ID in JumpStart's <a href="#">model table</a>.</p>

JumpStart Model ID	BaseModelName in API request	Description
huggingface-text2text-flan-t5-xxl	FlanT5XXL	<p>The <a href="#">Flan-T5</a> model family is a set of large language models that are fine-tuned on multiple tasks and can be further trained. These models are well-suited for tasks such as language translation, text generation, sentence completion, word sense disambiguation, summarization, or question answering. Flan T5 XXL is a 11 billion parameter model. You can find the list of the languages supported by Flan T5 XXL in the details of the model retrieved from your search by model ID in JumpStart's <a href="#">model table</a>.</p>
meta-textgeneration-llama-2-7b	Llama2-7B	<p>Llama 2 is a collection of pretrained and fine-tuned generative text models, ranging in scale from 7 billion to 70 billion parameters. Llama2-7B is the 7 billion parameter model that is intended for English use and can be adapted for a variety of natural language generation tasks.</p>

JumpStart Model ID	BaseModelName in API request	Description
meta-textgeneration-llama-2-7b-f	Llama2-7BChat	Llama 2 is a collection of pretrained and fine-tuned generative text models, ranging in scale from 7 billion to 70 billion parameters. Llama2-7B is the 7 billion parameter chat model that is optimized for dialogue use cases.
meta-textgeneration-llama-2-13b	Llama2-13B	Llama 2 is a collection of pretrained and fine-tuned generative text models, ranging in scale from 7 billion to 70 billion parameters. Llama2-13B is the 13 billion parameter model that is intended for English use and can be adapted for a variety of natural language generation tasks.
meta-textgeneration-llama-2-13b-f	Llama2-13BChat	Llama 2 is a collection of pretrained and fine-tuned generative text models, ranging in scale from 7 billion to 70 billion parameters. Llama2-13B is the 13 billion parameter chat model that is optimized for dialogue use cases.

JumpStart Model ID	BaseModelName in API request	Description
huggingface-llm-mistral-7b	Mistral7B	Mistral 7B is a seven billion parameters code and general purpose English text generation model. It can be used in a variety of use cases including text summarization, classification, text completion, or code completion.
huggingface-llm-mistral-7b-instruct	Mistral7BInstruct	Mistral 7B Instruct is the fine-tuned version of Mistral 7B for conversational use cases. It was specialized using a variety of publicly available conversation datasets in English.
huggingface-textgeneration1-mpt-7b-bf16	MPT7B	MPT 7B is a decoder-style transformer large language model with 6.7 billion parameters, pre-trained from scratch on 1 trillion tokens of English text and code. It is prepared to handle long context lengths.
huggingface-textgeneration1-mpt-7b-instruct-bf16	MPT7BInstruct	MPT 7B Instruct is a model for short-form instruction following tasks. It is built by fine-tuning MPT 7B on a dataset derived from <a href="#">databricks-dolly-15k</a> and the <a href="#">Anthropic Helpful and Harmless (HH-RLHF)</a> datasets.

## Dataset file types and input data format

Instruction-based fine-tuning uses labeled datasets to improve the performance of pre-trained LLMs on specific natural language processing (NLP) tasks. The labeled examples are formatted as prompt-response pairs and phrased as instructions.

To learn about the supported dataset file types, see [Supported dataset file types](#).

To learn about input data format, see [Input data format for instruction-based fine-tuning](#).

### Supported dataset file types

Autopilot supports instruction-based fine-tuning datasets formatted as CSV files (default) or as Parquet files.

- **CSV** (comma separated values) is a row-based file format that stores data in human readable plaintext, which is a popular choice for data exchange as it is supported by a wide range of applications.
- **Parquet** is a binary, column-based file format where the data is stored and processed more efficiently than in human readable file formats such as CSV. This makes it a better option for big data problems.

#### Note

The dataset may consist of multiple files, each of which must adhere to a specific template. For information on how to format your input data, see [Input data format for instruction-based fine-tuning](#).

### Input data format for instruction-based fine-tuning

Each file in the dataset must adhere to the following format:

- The dataset must contain exactly two comma-separated and named columns, `input` and `output`. Autopilot does not allow any additional columns.
- The `input` columns contain the prompts, and their corresponding `output` contains the expected answer. Both the `input` and `output` are in string format.

The following example illustrates the input data format for instruction-based fine-tuning in Autopilot.

```
input,output
"<prompt text>","<expected generated text>"
```

### Note

We recommend using datasets with a minimum of 1000 rows to ensure optimal learning and performance of the model.

Additionally, Autopilot sets a maximum limit on the number of rows in the dataset and the context length based on the type of model being used.

- The limits on the number of rows in a dataset apply to the cumulative count of rows across all files within the dataset, including multiple files. If there are two [channel types](#) defined (one for training and one for validation), the limit applies to the total number of rows across all datasets within both channels. When the number of rows exceeds the threshold, the job fails with a validation error.
- When the length of the input or output of a row in the dataset exceeds the limit set on the context of the language model, it is automatically truncated. If more than 60% of the rows in the dataset are truncated, whether in their input or output, Autopilot fails the job with a validation error.

The following table presents those limits for each model.

JumpStart Model ID	BaseModelName in API request	Row Limit	Context Length Limit
huggingface-textgeneration-dolly-v2-3b-bf16	Dolly3B	10,000 rows	1024 tokens
huggingface-textgeneration-dolly-v2-7b-bf16	Dolly7B	10,000 rows	1024 tokens

JumpStart Model ID	BaseModelName in API request	Row Limit	Context Length Limit
huggingface-textgeneration-dolly-v2-12b-bf16	Dolly12B	10,000 rows	1024 tokens
huggingface-llm-falcon-7b-bf16	Falcon7B	1,000 rows	1024 tokens
huggingface-llm-falcon-7b-instruct-bf16	Falcon7BInstruct	1,000 rows	1024 tokens
huggingface-llm-falcon-40b-bf16	Falcon40B	10,000 rows	1024 tokens
huggingface-llm-falcon-40b-instruct-bf16	Falcon40BInstruct	10,000 rows	1024 tokens
huggingface-text2text-flan-t5-large	FlanT5L	10,000 rows	1024 tokens
huggingface-text2text-flan-t5-xl	FlanT5XL	10,000 rows	1024 tokens
huggingface-text2text-flan-t5-xxl	FlanT5XXL	10,000 rows	1024 tokens
meta-textgeneration-llama-2-7b	Llama2-7B	10,000 rows	2048 tokens
meta-textgeneration-llama-2-7b-f	Llama2-7BChat	10,000 rows	2048 tokens
meta-textgeneration-llama-2-13b	Llama2-13B	7,000 rows	2048 tokens

JumpStart Model ID	BaseModelName in API request	Row Limit	Context Length Limit
meta-textgeneration-llama-2-13b-f	Llama2-13BChat	7,000 rows	2048 tokens
huggingface-llm-mistral-7b	Mistral7B	10,000 rows	2048 tokens
huggingface-llm-mistral-7b-instruct	Mistral7B Instruct	10,000 rows	2048 tokens
huggingface-textgeneration1-mpt-7b-bf16	MPT7B	10,000 rows	1024 tokens
huggingface-textgeneration1-mpt-7b-instruct-bf16	MPT7BInstruct	10,000 rows	1024 tokens

## Hyperparameters for optimizing the learning process of your text generation models

You can optimize the learning process of your base model by adjusting any combination of the following hyperparameters. These parameters are available for all models.

- **Epoch Count:** The epochCount hyperparameter determines how many times the model goes through the entire training dataset. It influences the training duration and can prevent overfitting when set appropriately. Large number of epochs may increase the overall runtime of fine-tuning jobs. We recommend setting a large MaxAutoMLJobRuntimeInSeconds within the CompletionCriteria of the [TextGenerationJobConfig](#) to avoid fine-tuning jobs from stopping prematurely.
- **Batch Size:** The batchSize hyperparameter defines the number of data samples used in each iteration of training. It can affect the convergence speed and memory usage. With large batch size, the risk of out of memory (OOM) errors increases, which may surface as an internal server error in Autopilot. To check for such error, check the /aws/sagemaker/TrainingJobs log group for the training jobs launched by your Autopilot job. You can access those logs in

CloudWatch from in the AWS management console. Choose **Logs**, and then choose the `/aws/sagemaker/TrainingJobs` **log group**. To remedy OOM errors, reduce the batch size.

We recommend starting with a batch size of 1, then incrementally increase it until an out of memory error occurs. As a reference, 10 epochs typically takes up to 72h to complete.

- **Learning Rate:** The `learningRate` hyperparameter controls the step size at which a model's parameters are updated during training. It determines how quickly or slowly the model's parameters are updated during training. A high learning rate means that the parameters are updated by a large step size, which can lead to faster convergence but may also cause the optimization process to overshoot the optimal solution and become unstable. A low learning rate means that the parameters are updated by a small step size, which can lead to more stable convergence but at the cost of slower learning.
- **Learning Rate Warmup Steps:** The `learningRateWarmupSteps` hyperparameter specifies the number of training steps during which the learning rate gradually increases before reaching its target or maximum value. This helps the model converge more effectively and avoid issues like divergence or slow convergence that can occur with an initially high learning rate.

To learn about how to adjust hyperparameters for your fine-tuning experiment in Autopilot and discover their possible values, see [How to set hyperparameters to optimize the learning process of a model](#).

## Metrics for fine-tuning large language models in Autopilot

The following section describes the metrics that you can use to understand your fine-tuned large language models (LLMs). Using your dataset, Autopilot directly fine-tunes a target LLM to enhance a default objective metric, the cross-entropy loss.

Cross-entropy loss is a widely used metric to assess the dissimilarity between the predicted probability distribution and the actual distribution of words in the training data. By minimizing cross-entropy loss, the model learns to make more accurate and contextually relevant predictions, particularly in tasks related to text generation.

After fine-tuning an LLM you can evaluate the quality of its generated text using a range of ROUGE scores. Additionally, you can analyze the perplexity and cross-entropy training and validation losses as part of the evaluation process.

- Perplexity loss measures how well the model can predict the next word in a sequence of text, with lower values indicating a better understanding of the language and context.

- Recall-Oriented Understudy for Gisting Evaluation (ROUGE) is a set of metrics used in the field of natural language processing (NLP) and machine learning to evaluate the quality of machine-generated text, such as text summarization or text generation. It primarily assesses the similarities between the generated text and the ground truth reference (human-written) text of a validation dataset. ROUGE measures are designed to assess various aspects of text similarity, including the precision and recall of n-grams (contiguous sequences of words) in the system-generated and reference texts. The goal is to assess how well a model captures the information present in the reference text.

There are several variants of ROUGE metrics, depending on the type of n-grams used and the specific aspects of text quality being evaluated.

The following list contains the name and description of the ROUGE metrics available after the fine-tuning of large language models in Autopilot.

### **ROUGE -1, ROUGE -2**

ROUGE-N, the primary ROUGE metric, measures the overlap of n-grams between the system-generated and reference texts. ROUGE-N can be adjusted to different values of n (here 1 or 2) to evaluate how well the system-generated text captures the n-grams from the reference text.

### **ROUGE -L**

ROUGE-L (ROUGE-Longest Common Subsequence) calculates the longest common subsequence between the system-generated text and the reference text. This variant considers word order in addition to content overlap.

### **ROUGE -L - Sum**

ROUGE-L-SUM (Longest Common Subsequence for Summarization) is designed for the evaluation of text summarization systems. It focuses on measuring the longest common subsequence between the machine-generated summary and the reference summary. ROUGE-L-SUM takes into account the order of words in the text, which is important in text summarization tasks.

## **Autopilot model deployment and predictions**

After fine-tuning a large language model (LLM), you can deploy the model for real-time text generation by setting up an endpoint to obtain interactive predictions.

**Note**

We recommend running real-time inference jobs on `m1.g5.12xlarge` for better performances. Alternatively, `m1.g5.8xlarge` instances are suitable for Falcon-7B-Instruct and MPT-7B-Instruct text generation tasks.

You can find the specifics of these instances within the [Accelerated Computing](#) category in the selection of instance types provided by Amazon EC2.

## Real-time text generation

You can use SageMaker APIs to manually deploy your fine-tuned model to a SageMaker AI Hosting [real-time inference endpoint](#), then begin making predictions by invoking the endpoint as follows.

**Note**

Alternatively, you can choose the automatic deployment option when creating your fine-tuning experiment in Autopilot. For information on setting up the automatic deployment of models, see [How to enable automatic deployment](#).

You can also use the SageMaker Python SDK and the `JumpStartModel` class to perform inferences with models fine-tuned by Autopilot. This can be done by specifying a custom location for the model's artifact in Amazon S3. For information on defining your model as a JumpStart model and deploying your model for inference, see [Low-code deployment with the JumpStartModel class](#).

### 1. Obtain the candidate inference container definitions

You can find the `InferenceContainerDefinitions` within the `BestCandidate` object retrieved from the response to the [DescribeAutoMLJobV2](#) API call. A container definition for inference refers to the containerized environment designed for deploying and running your trained model to make predictions.

The following AWS CLI command example uses the [DescribeAutoMLJobV2](#) API to obtain recommended container definitions for your job name.

```
aws sagemaker describe-auto-ml-job-v2 --auto-ml-job-name job-name --region region
```

### 2. Create a SageMaker AI model

Use the container definitions from the previous step to create a SageMaker AI model by using the [CreateModel](#) API. See the following AWS CLI command as an example. Use the CandidateName for your model name.

```
aws sagemaker create-model --model-name '<your-candidate-name>' \
    --primary-container '<container-definition>' \
    --execution-role-arn '<execution-role-arn>' --region '<region>'
```

### 3. Create an endpoint configuration

The following AWS CLI command example uses the [CreateEndpointConfig](#) API to create an endpoint configuration.

#### Note

To prevent the endpoint creation from timing out due to a lengthy model download, we recommend setting `ModelDataDownloadTimeoutInSeconds = 3600` and `ContainerStartupHealthCheckTimeoutInSeconds = 3600`.

```
aws sagemaker create-endpoint-config --endpoint-config-name '<your-endpoint-config-name>' \
    --production-variants '<list-of-production-variants>' ModelDataDownloadTimeoutInSeconds=3600
    ContainerStartupHealthCheckTimeoutInSeconds=3600 \
    --region '<region>'
```

### 4. Create the endpoint

The following AWS CLI example uses the [CreateEndpoint](#) API to create the endpoint.

```
aws sagemaker create-endpoint --endpoint-name '<your-endpoint-name>' \
    --endpoint-config-name '<endpoint-config-name-you-just-created>' \
    --region '<region>'
```

Check the progress of your endpoint deployment by using the [DescribeEndpoint](#) API. See the following AWS CLI command as an example.

```
aws sagemaker describe-endpoint --endpoint-name '<endpoint-name>' --region <region>
```

After the EndpointStatus changes to InService, the endpoint is ready to use for real-time inference.

## 5. Invoke the endpoint

The following command invokes the endpoint for real-time inferencing. Your prompt needs to be encoded in bytes.

### Note

The format of your input prompt depends on the language model. For more information on the format of text generation prompts, see [Request format for text generation models real-time inference](#).

```
aws sagemaker invoke-endpoint --endpoint-name '<endpoint-name>' \  
    --region '<region>' --body '<your-prompt-in-bytes>' [--content-type]  
'application/json' <outfile>
```

## Request format for text generation models real-time inference

Different large language models (LLMs) may have specific software dependencies, runtime environments, and hardware requirements influencing Autopilot's recommended container to host the model for inference. Additionally, each model dictates the required input data format and the expected format for predictions and outputs.

Here are example inputs for some models and recommended containers.

- For Falcon models with the recommended container `huggingface-pytorch-tgi-inference:2.0.1-tgi1.0.3-gpu-py39-cu118-ubuntu20.04`:

```
payload = {  
    "inputs": "Large language model fine-tuning is defined as",  
    "parameters": {  
        "do_sample": false,  
        "top_p": 0.9,  
    },  
}
```

```
    "temperature": 0.1,  
    "max_new_tokens": 128,  
    "stop": ["<|endoftext|>", "</s>"]  
  }  
}
```

- For all other models with the recommended container `djl-inference:0.22.1-fastertransformer5.3.0-cu118`:

```
payload= {  
  "text_inputs": "Large language model fine-tuning is defined as"  
}
```

## Create a Regression or Classification Autopilot experiment for tabular data using the Studio Classic UI

### Important

As of November 30, 2023, Autopilot's UI is migrating to [Amazon SageMaker Canvas](#) as part of the updated [Amazon SageMaker Studio](#) experience. SageMaker Canvas provides analysts and citizen data scientists no-code capabilities for tasks such as data preparation, feature engineering, algorithm selection, training and tuning, inference, and more. Users can leverage built-in visualizations and what-if analysis to explore their data and different scenarios, with automated predictions enabling them to easily productionize their models. Canvas supports a variety of use cases, including computer vision, demand forecasting, intelligent search, and generative AI.

Users of [Amazon SageMaker Studio Classic](#), the previous experience of [Studio](#), can continue using the Autopilot UI in Studio Classic. Users with coding experience can continue using all [API references](#) in any supported SDK for technical implementation.

If you have been using Autopilot in Studio Classic until now and want to migrate to SageMaker Canvas, you might have to grant additional permissions to your user profile or IAM role so that you can create and use the SageMaker Canvas application. For more information, see [the section called "\(Optional\) Migrate from Autopilot in Studio Classic to SageMaker Canvas"](#).

All UI-related instructions in this guide pertain to Autopilot's standalone features before migrating to [Amazon SageMaker Canvas](#). Users following these instructions should use [Studio Classic](#).

You can use the Amazon SageMaker Studio Classic UI to create Autopilot experiments for classification or regression problems on tabular data. The UI helps you specify the name of your experiment, provide locations for the input and output data, and specify which target data to predict. Optionally, you can also specify the type of problem that you want to solve (regression, classification, multiclass classification), choose your modeling strategy (*stacked ensembles* or *hyperparameters optimization*), select the list of algorithms used by the Autopilot job to train the data, and more.

The UI has descriptions, toggle switches, dropdown menus, radio buttons, and more to help you navigate creating your model candidates. After the experiment runs, you can compare trials and delve into the details of the pre-processing steps, algorithms, and hyperparameter ranges of each model. Optionally, you can download their [explainability](#) and [performance](#) reports. Use the provided [notebooks](#) to see the results of the automated data exploration or the candidate model definitions.

Alternatively, you can use Autopilot AutoML API in [Create Regression or Classification Jobs for Tabular Data Using the AutoML API](#).

## Configure the default parameters of an Autopilot experiment (for administrators)

Autopilot supports setting default values to simplify the configuration of Amazon SageMaker Autopilot when you create an Autopilot experiment using the Studio Classic UI. Administrators can use Studio Classic [lifecycle configurations](#) (LCC) to set infrastructure, networking, and security values in configuration files and pre-populate the [advanced settings](#) of AutoML jobs.

By doing so, they can fully control network connectivity and access permissions for the resources associated with Amazon SageMaker Studio Classic, including SageMaker AI instances, data sources, output data, and other related services. Specifically, administrators can configure a desired network architecture, such as Amazon VPC, subnets, and security groups, for a Studio Classic domain or individual user profiles. Data scientists can focus on data science specific parameters when creating their Autopilot experiments using the Studio Classic UI. Furthermore, administrators can manage the encryption of data on the instance in which Autopilot experiments run by setting default encryption keys.

**Note**

This feature is currently not available in the Asia Pacific (Hong Kong) and Middle East (Bahrain) opt-in Regions.

In the following sections, you can find the full list of parameters supporting the setting of defaults when creating an Autopilot experiment using the Studio Classic UI, and learn how to set those default values.

**Topics**

- [List of default parameters supported](#)
- [Set default Autopilot experiment parameters](#)

**List of default parameters supported**

The following parameters support setting default values with a configuration file for creating an Autopilot experiment using the Studio Classic UI. Once set, the values automatically fill in their corresponding field in the Autopilot' **Create Experiment** tab in the Studio Classic UI. See [Advanced settings \(optional\)](#) for a full description of each field.

- **Security:** Amazon VPC, subnets, and security groups.
- **Access:** AWS IAM role ARNs.
- **Encryption:** AWS KMS key IDs.
- **Tags:** Key-value pairs used to label and organize SageMaker AI resources.

**Set default Autopilot experiment parameters**

Administrators can set default values in a configuration file, then manually place the file in a recommended location within the Studio Classic environment of specific users, or they can pass the file to a lifecycle configuration script (LCC) to automate the customization of the Studio Classic environment for a given domain or user profile.

- To set up the configuration file, start by filling in its default parameters.

To configure any or all default values listed in [List of default parameters supported](#), administrators can create a configuration file named `config.yaml`, the structure of which

should adhere to this [sample configuration file](#). The following snippet shows a sample configuration file with all the supported AutoML parameters. For more information on the format of this file, refer to the [full schema](#).

```
SchemaVersion: '1.0'
SageMaker:
  AutoMLJob:
    # https://docs.aws.amazon.com/sagemaker/latest/APIReference/
    API_CreateAutoMLJob.html
  AutoMLJobConfig:
    SecurityConfig:
      EnableInterContainerTrafficEncryption: true
      VolumeKmsKeyId: 'kms-key-id'
    VpcConfig:
      SecurityGroupIds:
        - 'security-group-id-1'
        - 'security-group-id-2'
      Subnets:
        - 'subnet-1'
        - 'subnet-2'
    OutputDataConfig:
      KmsKeyId: 'kms-key-id'
      RoleArn: 'arn:aws:iam::111222333444:role/Admin'
    Tags:
      - Key: 'tag_key'
        Value: 'tag_value'
```

- Then, place the configuration file in the recommended location by either [manually copying the file](#) to its recommended paths or using a [lifecycle configuration](#) (LCC).

The configuration file needs to be present in at least one of the following locations in the user's Studio Classic environment. By default, SageMaker AI searches for a configuration file in two locations:

- First, in `/etc/xdg/sagemaker/config.yaml`. We refer to this file as the *administrator configuration file*.
- Then, in `/root/.config/sagemaker/config.yaml`. We refer to this file as the *user configuration file*.

Using the *administrator* configuration file, administrators can define a set of default values. Optionally, they can use the *user* configuration file to override values set in the *administrator* configuration file, or set additional default parameter values.

The following snippet shows a sample script which writes the default parameters configuration file to the *administrator* location in the user's Studio Classic environment. You can replace `/etc/xdg/sagemaker` with `/root/.config/sagemaker` to write the file to the *user* location.

```
## Sample script with AutoML intelligent defaults
#!/bin/bash

sudo mkdir -p /etc/xdg/sagemaker

echo "SchemaVersion: '1.0'"
CustomParameters:
  AnyStringKey: 'AnyStringValue'
SageMaker:
  AutoMLJob:
    # https://docs.aws.amazon.com/sagemaker/latest/APIReference/
    API_CreateAutoMLJob.html
  AutoMLJobConfig:
    SecurityConfig:
      EnableInterContainerTrafficEncryption: true
      VolumeKmsKeyId: 'kms-key-id'
    VpcConfig:
      SecurityGroupIds:
        - 'security-group-id-1'
        - 'security-group-id-2'
      Subnets:
        - 'subnet-1'
        - 'subnet-2'
    OutputDataConfig:
      KmsKeyId: 'kms-key-id'
      RoleArn: 'arn:aws:iam::111222333444:role/Admin'
      Tags:
        - Key: 'tag_key'
          Value: 'tag_value'
" | sudo tee /etc/xdg/sagemaker/config.yaml
```

- **Copy the files manually** – To copy the configuration files manually, run the [script](#) created in the previous step from a Studio Classic terminal. In this case, the user profile that executed the script can create Autopilot experiments with the default values applicable only to them.
- **Create a SageMaker AI lifecycle configuration** – Alternatively, you can use a [lifecycle configuration](#) (LCC) to automate the customization of your Studio Classic environment. LCC are shell scripts triggered by Amazon SageMaker Studio Classic lifecycle events such as starting a

Studio Classic application. This customization includes installing custom packages, configuring notebook extensions, pre-loading datasets, setting up source code repositories, or, in our case, pre-populating default parameters. Administrators can attach the LCC to a Studio Classic domain to automate the configuration of default values for each user profile within that domain.

The following sections detail how to create a lifecycle configuration so users can load Autopilot default parameters automatically when launching Studio Classic. You can choose to create an LCC using the SageMaker AI Console or the AWS CLI.

### Create a LCC from the SageMaker AI Console

Use the following steps to create an LCC containing your default parameters, attach the LCC to a domain or a user profile, then launch a Studio Classic application pre-populated with the default parameters set by the LCC using the SageMaker AI Console.

- **To create a lifecycle configuration that runs the [script](#) containing your default values using the SageMaker AI Console**
  - Open the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
  - On the left side, navigate to **Admin configurations**, then **Lifecycle configurations**.
  - From the **Lifecycle configurations** page, navigate to the Studio Classic tab, then choose **Create configuration**.
  - For **Name**, type a name using alphanumeric characters and "-", but no spaces. The name can have a maximum of 63 characters.
  - Paste your [script](#) in the **Scripts** section.
  - Choose **Create configuration** to create the lifecycle configuration. This creates an LCC of type `Kernel gateway app`.
- **To attach the lifecycle configuration to a Studio Classic domain, a space, or a user profile**

Follow the steps in [Attach the lifecycle configuration to Studio Classic domain or user profile](#) to attach your LCC to a Studio Classic domain or a specific user profile.

- **To launch your Studio Classic application with the lifecycle configuration**

Once the LCC is attached to a domain or a user profile, impacted users can start a Studio Classic application from the landing page of Studio Classic in Studio to pick up the defaults set by the LCC automatically. This auto-populates the Studio Classic UI when

[creating an Autopilot experiment](#)

## Create a LCC from the AWS CLI

Use the following snippets to launch a Studio Classic application that runs your [script](#) using the AWS CLI. Note that `lifecycle_config.sh` is the name given to your script in this example.

Before getting started:

- Ensure that you have updated and configured AWS CLI by completing the prerequisites described in [Create a lifecycle configuration from the AWS CLI](#).
- Install [OpenSSL](#) documentation. The AWS CLI command uses the open-source library *OpenSSL* to encode your script in Base64 format. This requirement prevents errors that occur from spacing and line break encoding.

You can now follow these three steps:

- **Create a new lifecycle configuration referencing the configuration script `lifecycle_config.sh`**

```
LCC_CONTENT=`openssl base64 -A -in lifecycle_config.sh`

## Create a new lifecycle config
aws sagemaker create-studio-lifecycle-config --region region \
--studio-lifecycle-config-name lcc-name \
--studio-lifecycle-config-content $LCC_CONTENT \
--studio-lifecycle-config-app-type default
```

Note the ARN of the newly created lifecycle configuration that is returned. This ARN is required to attach the lifecycle configuration to your application.

- **Attach the lifecycle configuration to your JupyterServerApp**

The following example shows how to create a new user profile with a lifecycle configuration attached. To update an existing user profile, use the AWS CLI [update-user-profile](#) command. To create or update a domain, see [create-domain](#) and [update-domain](#). Add the lifecycle configuration ARN from the previous step to the settings of the JupyterServerAppSettings application type. You can add multiple lifecycle configurations at the same time by using a list of lifecycle configurations.

```
# Create a new UserProfile
aws sagemaker create-user-profile --domain-id domain-id \
```

```
--user-profile-name user-profile-name \  
--region region \  
--user-settings '{  
  "JupyterServerAppSettings": {  
    "LifecycleConfigArns":  
      ["lifecycle-configuration-arn"]  
  }  
'
```

Once the LCC is attached to a domain or a user profile, impacted users can shut down and update their existing Studio Classic application by following the steps in [Shut down and Update Amazon SageMaker Studio Classic](#), or start a new Studio Classic application from the AWS Console to pick up the defaults set by the LCC automatically. This auto-populates the Studio Classic UI when creating an Autopilot experiment. Alternatively, they can launch a new Studio Classic application using the AWS CLI as follows.

- **Launch your Studio Classic application with the lifecycle configuration using the AWS CLI**

```
# Create a Jupyter Server application  
aws sagemaker create-app --domain-id domain-id \  
--user-profile-name user-profile-name \  
--region region \  
--app-type JupyterServer \  
--resource-spec LifecycleConfigArn=lifecycle-configuration-arn \  
--app-name default
```

For more information on creating a lifecycle configuration using the AWS CLI, see [Create a Lifecycle Configuration from the AWS CLI](#).

## To create an Autopilot experiment using Studio Classic UI

1. Sign in at <https://console.aws.amazon.com/sagemaker/>, choose **Studio** from the left navigation pane, select your Domain and user profile, then **Open Studio**.
2. In Studio, choose the Studio Classic icon in the top left navigation pane. This opens a Studio Classic app.
3. Run or open a Studio Classic application from the space of your choice, or **Create Studio Classic space**. . On the **Home** tab, choose the **AutoML** card. This opens a new **AutoML** tab.
4. Choose **Create an AutoML experiment**. This opens a new **Create experiment** tab.

5. In the **Experiment and data details** section, enter the following information:
  - a. **Experiment name** – Must be unique to your account in the current AWS Region and contain a maximum of 63 alphanumeric characters. Can include hyphens (-) but not spaces.
  - b. **Input data** – Provide the Amazon Simple Storage Service (Amazon S3) bucket location of your input data. This S3 bucket must be in your current AWS Region. The URL must be in an `s3://` format where Amazon SageMaker AI has write permissions. The file must be in CSV or Parquet format and contain at least 500 rows. Select **Browse** to scroll through available paths and **Preview** to see a sample of your input data.
  - c. **Is your S3 input a manifest file?** – A manifest file includes metadata with your input data. The metadata specifies the location of your data in Amazon S3. It also specifies how the data is formatted and which attributes from the dataset to use when training your model. You can use a manifest file as an alternative to preprocessing when your labeled data is being streamed in Pipe mode.
  - d. **Auto split data?** – Autopilot can split your data into an 80-20% split for training and validation data. If you prefer a custom split, you can choose the **Specify split ratio**. To use a custom dataset for validation, choose **Provide a validation set**.
  - e. **Output data location (S3 bucket)** – The name of the S3 bucket location where you want to store the output data. The URL for this bucket must be in an Amazon S3 format where Amazon SageMaker AI has write permissions. The S3 bucket must be in the current AWS Region. Autopilot can also create this for you in the same location as your input data.
6. Choose **Next: Target and features**. The **Target and features** tab opens.
7. In the **Target and features** section:
  - Select a column to set as a target for model predictions.
  - Optionally, you can pass the name of a sample weights column in the **Sample weight** section to request your dataset rows to be weighted during training and evaluation. For more information on the available objective metrics, see [Autopilot weighted metrics](#).

 **Note**

Support for sample weights is available in [ensembling mode](#) only.

- You can also select features for training and change their data type. The following data types are available: Text, Numerical, Categorical, Datetime, Sequence, and Auto. All features are selected by default.
8. Choose **Next: Training method**. The **Training method** tab opens.
  9. In the **Training method** section, select your training option: **Ensembling**, **Hyperparameter optimization (HPO)**, or **Auto** to let Autopilot choose the training method automatically based on the dataset size. Each training mode runs a pre-defined set of algorithms on your dataset to train model candidates. By default, Autopilot pre-selects all the available algorithms for the given training mode. You can run an Autopilot training experiment with all the algorithms or choose your own subset.

For more information on the training modes and the available algorithms, see the **Autopilot training modes** section in the [Training modes and algorithms](#) page.

10. Choose **Next: Deployment and advanced settings** to open the **Deployment and advanced settings** tab. Settings include the auto-display endpoint name, machine learning problem type, and additional choices for running your experiment.
  - a. **Deployment settings** – Autopilot can automatically create an endpoint and deploy your model for you.

To auto-deploy to an automatically generated endpoint, or to provide an endpoint name for custom deployment, set the toggle to **Yes** under **Auto deploy?** If you are importing data from Amazon SageMaker Data Wrangler, you have additional options to auto-deploy the best model with or without the transforms from Data Wrangler.

 **Note**

If your Data Wrangler flow contains multi-row operations such as `groupby`, `join`, or `concatenate`, you can't auto-deploy with these transforms. For more information, see [Automatically Train Models on Your Data Flow](#).

- b. **Advanced settings (optional)** – Autopilot provides additional controls to manually set experimental parameters such as defining your problem type, time constraints on your Autopilot job and trials, security, and encryption settings.

**Note**

Autopilot supports the setting of default values to simplify the configuration of Autopilot experiments using Studio Classic UI. Administrators can use Studio Classic [lifecycle configurations](#) (LCC) to set infrastructure, networking, and security values in configuration files and pre-populate the *advanced settings* of AutoML jobs.

To learn about how administrators can automate the customization of an Autopilot experiment, see [Configure the default parameters of an Autopilot experiment \(for administrators\)](#).

- i. **Machine learning problem type** – Autopilot can automatically infer the type of supervised learning problem from your dataset. If you prefer to choose it manually, you can use the **Select the machine learning problem type** dropdown menu. Note that it defaults to **Auto**. In some cases, SageMaker AI is unable to infer accurately. When that happens, you must provide the value for the job to succeed. In particular, you can choose from the following types:
  - **Binary classification**– Binary classification assigns input data to one of two predefined and mutually exclusive classes, based on their attributes, such as medical diagnosis based on results of diagnostic tests that determine if someone has a disease.
  - **Regression** – Regression establishes a relationship between the input variables (also known as independent variables or features) and the target variable (also known as the dependent variable). This relationship is captured through a mathematical function or model that maps the input variables to a continuous output. It is commonly used for tasks such as predicting house prices based on features like square footage and the number of bathrooms, stock market trends, or estimating sales figures.
  - **Multiclass classification** – Multiclass classification assigns input data to one of several classes based on their attributes, like the prediction of the topic most relevant to a text document, such as politics, finance, or philosophy.
- ii. **Runtime** – You can define a maximum time limit. Upon reaching the time limit, trials and jobs that exceed the time constraint automatically stop.

- iii. **Access** – You can choose the role that Amazon SageMaker Studio Classic assumes to gain temporary access to AWS services (in particular, SageMaker AI and Amazon S3) on your behalf. If no role is explicitly defined, Studio Classic automatically uses the default SageMaker AI execution role attached to your user profile.
  - iv. **Encryption** – To enhance the security of your data at rest and protect it against unauthorized access, you can specify encryption keys to encrypt data in your Amazon S3 buckets and in the Amazon Elastic Block Store (Amazon EBS) volume attached to your Studio Classic domain.
  - v. **Security** – You can choose the virtual private cloud (Amazon VPC) in which your SageMaker AI job runs. Ensure that the Amazon VPC has access to your input and output Amazon S3 buckets.
  - vi. **Project** – Specify the name of the SageMaker AI project to associate with this Autopilot experiment and model outputs. When you specify a project, Autopilot tags the project to an experiment. This lets you know which model outputs are associated with this project.
  - vii. **Tags** – Tags are an array of key-value pairs. Use tags to categorize your resources from AWS services, such as their purpose, owner, or environment.
- c. Choose **Next: Review and create** to get a summary of your Autopilot experiment before you create it.
11. Select **Create experiment**. The creation of the experiment starts an Autopilot job in SageMaker AI. Autopilot provides the status of the experiment, information on the data exploration process and model candidates in notebooks, a list of generated models and their reports, and the job profile used to create them.

For information on the notebooks generated by an Autopilot job, see [Autopilot notebooks generated to manage AutoML tasks](#). For information on the details of each model candidate and their reports, see [View model details](#) and [View an Autopilot model performance report](#).

 **Note**

To avoid incurring unnecessary charges: If you deploy a model that is no longer needed, delete the endpoints and resources that were created during that deployment. Information about pricing instances by Region is available at [Amazon SageMaker Pricing](#).

## Amazon SageMaker Autopilot example notebooks

The following notebooks serve as practical, hands-on examples that address various use cases of Autopilot.

You can find all of Autopilot's notebooks in the [autopilot](#) directory of SageMaker AI GitHub examples repository.

We recommend cloning the full Git repository within Studio Classic to access and run the notebooks directly. For information on how to clone a Git repository in Studio Classic, see [Clone a Git Repository in SageMaker Studio Classic](#).

Use case	Description
<a href="#">Serverless inference</a>	By default, Autopilot allows deploying generated models to real-time inference endpoints. In this repository, the notebook illustrates how to deploy Autopilot models trained with ENSEMBLING and HYPERPARAMETER OPTIMIZATION (HPO) modes to serverless endpoints. Serverless endpoints automatically launch compute resources and scale them in and out depending on traffic, eliminating the need to choose instance types or manage scaling policies.
<a href="#">Custom feature selection</a>	Autopilot inspects your data set, and runs a number of candidates to figure out the optimal combination of data preprocessing steps, machine learning algorithms, and hyperparameters. You can easily deploy either on a real-time endpoint or for batch processing.  In some cases, you might want to have the flexibility to bring custom data processing code to Autopilot. For example, your datasets might contain a large number of

Use case	Description
	<p>independent variables, and you may wish to incorporate a custom feature selection step to remove irrelevant variables first. The resulting smaller dataset can then be used to launch an Autopilot job. Ultimately, you would also want to include both the custom processing code and models from Autopilot for real-time or batch processing.</p>

Use case	Description
<a href="#">Pipeline example</a>	<p>While Autopilot streamlines the process of building ML models, MLOps engineers are still responsible for creating, automating, and managing end-to-end ML workflows in production. SageMaker Pipelines can assist in automating various steps of the ML lifecycle, such as data preprocessing, model training, hyperparameter tuning, model evaluation, and deployment. This notebook serves as a demonstration of how to incorporate Autopilot into a SageMaker Pipelines end-to-end AutoML training workflow. To launch an Autopilot experiment within Pipelines, you must create a model-building workflow by writing custom integration code using Pipelines <a href="#">Lambda</a> or <a href="#">Processing</a> steps. For more information, refer to <a href="#">Move Amazon SageMaker Autopilot ML models from experimentation to production using Amazon SageMaker Pipelines</a>.</p> <p>Alternatively, when using Autopilot in <a href="#">Ensembling mode</a>, you can refer to the notebook example that demonstrates how to use native AutoML step in <a href="#">SageMaker Pipeline's native AutoML step</a>. With Autopilot supported as a native step within Pipelines, you can now add an automated training step (<a href="#">AutoMLStep</a>) to your Pipelines and invoke an Autopilot experiment in Ensembling mode.</p>

Use case	Description
<a href="#">Direct marketing with Amazon SageMaker Autopilot</a>	<p>This notebook demonstrates how uses the <a href="#">Bank Marketing Data Set</a> to predict whether a customer will enroll for a term deposit at a bank. You can use Autopilot on this dataset to get the most accurate ML pipeline by exploring options contained in various candidate pipelines. Autopilot generates each candidate in a two-step procedure. The first step performs automated feature engineering on the dataset. The second step trains and tunes an algorithm to produce a model. The notebook contains instructions on how to train the model and how to deploy the model to perform batch inference using the best candidate.</p>
<a href="#">Customer Churn Prediction with Amazon SageMaker Autopilot</a>	<p>This notebook describes using machine learning for the automated identification of unhappy customers, also known as customer churn prediction. The example shows how to analyze a publicly available dataset and perform feature engineering on it. Next it shows how to tune a model by selecting the best performing pipeline along with the optimal hyperparameters for the training algorithm. Finally, it shows how to deploy the model to a hosted endpoint and how to evaluate its predictions against ground truth. However, ML models rarely give perfect predictions. That's why this notebook also shows how to incorporate the relative costs of prediction mistakes when determining the financial outcome of using ML.</p>

Use case	Description
<a href="#">Top Candidates Customer Churn Prediction with Amazon SageMaker Autopilot and Batch Transform (Python SDK)</a>	<p>This notebook also describes using machine learning for the automated identification of unhappy customers, also known as customer churn prediction. This notebook demonstrates how to configure the model to obtain the inference probability, select the top N models, and make Batch Transform on a hold-out test set for evaluation.</p> <div data-bbox="829 638 1507 905" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px;"><p> <b>Note</b></p><p>This notebook works with SageMaker Python SDK &gt;= 1.65.1 released on 6/19/2020.</p></div>
<a href="#">Bringing your own data processing code to Amazon SageMaker Autopilot</a>	<p>This notebook demonstrates how to incorporate and deploy custom data processing code when using Amazon SageMaker Autopilot . It adds a custom feature selection step to remove irrelevant variables to an Autopilot job. It then shows how to deploy both the custom processing code and models generated by Autopilot on a real-time endpoint and, alternatively, for batch processing.</p>
More notebooks	<p>You can find more notebooks illustrating other use cases such as <a href="#">batch transform</a>, <a href="#">time-series forecasting</a> and more in the root directory.</p>

## Videos: Use Autopilot to automate and explore the machine learning process

Here is a video series that provides a tour of Amazon SageMaker Autopilot capabilities using Studio Classic. They show how to start an AutoML job, analyze and preprocess data, how to do feature engineering and hyperparameter optimization on candidate models, and how to visualize and compare the resulting model metrics.

### Topics

- [Start an AutoML job with Amazon SageMaker Autopilot](#)
- [Review data exploration and feature engineering automated in Autopilot.](#)
- [Tune models to optimize performance](#)
- [Choose and deploy the best model](#)
- [Amazon SageMaker Autopilot tutorial](#)

### Start an AutoML job with Amazon SageMaker Autopilot

This video shows you to how to start an AutoML job with Autopilot. (Length: 8:41)

[Amazon SageMaker Studio - AutoML with Amazon SageMaker Autopilot \(part 1\)](#)

### Review data exploration and feature engineering automated in Autopilot.

This video shows you how to review the data exploration and candidate definition notebooks generated by Amazon SageMaker Autopilot. (Length: 10:04)

[Amazon SageMaker Studio - AutoML with Amazon SageMaker Autopilot \(part 2\)](#)

### Tune models to optimize performance

This video shows you how to optimize model performance during training using hyperparameter tuning. (Length: 4:59)

[SageMaker Studio - AutoML with Amazon SageMaker Autopilot \(part 3\)](#)

### Choose and deploy the best model

This video shows you how to use job metrics to choose the best model and then how to deploy it. (Length: 5:20)

## [SageMaker Studio - AutoML with Amazon SageMaker Autopilot \(part 4\)](#)

### Amazon SageMaker Autopilot tutorial

This video walks you through an end to end demo where we first build a binary classification model automatically with Amazon SageMaker Autopilot. We see how candidate models have been built and optimized using auto-generated notebooks. We also look at the top candidates with Amazon SageMaker Experiments. Finally, we deploy the top candidate (based on XGBoost), and configure data capture with SageMaker Model Monitor.

#### [End to end demo with AutoML on SageMaker AI](#)

### Tutorials: Get started with Amazon SageMaker Autopilot

Get started tutorials for Autopilot demonstrate how to create a machine learning model automatically without writing code. They show you how Autopilot simplifies the machine learning experience by helping you explore your data and try different algorithms. Autopilot builds the best machine learning model for the problem type using AutoML capabilities while allowing full control and visibility.

- [Create a machine learning model automatically with Autopilot](#): You assume the role of a developer working at a bank in this tutorial. You have been asked to develop a machine learning model to predict if a customer will enroll for a certificate of deposit (CD). This is a binary classification problem. The model is trained on the marketing dataset that contains information on customer demographics, responses to marketing events, and external factors.

### Autopilot quotas

There are quotas that limit the resources available to you when using Amazon SageMaker Autopilot. Some of these limits are increasable and some are not.

#### Note

The resource quotas documented in the following sections are valid for versions of Amazon SageMaker Studio Classic 3.22.2 and higher. For information on updating your version of SageMaker Studio Classic, see [Shut Down and Update SageMaker Studio Classic and Studio Classic Apps](#).

## Topics

- [Quotas that you can increase](#)
- [Resource quotas](#)

## Quotas that you can increase

The following table contains the resource limits for quotas you can increase:

Resource	Regions	Default limits	Can be increased up to
Size of input dataset	All	100 GB	Hundreds of GBs
Size of a single Parquet file*	All	2 GB	N/A
Target dataset size for subsampling**	All	5 GB	Hundreds of GBs
Number of concurrent Autopilot jobs	us-east-1, us-east-2, us-west-2, ap-northeast-1, eu-west-1, eu-central-1	4	Hundreds
Number of concurrent Autopilot jobs	ap-northeast-2, ap-southeast-2, eu-west-2, ap-southeast-1	2	Hundreds
Number of concurrent Autopilot jobs	All other Regions	1	Tens

### Note

\*This 2 GB size limit is for a single compressed Parquet file. You can provide a Parquet dataset that includes multiple compressed Parquet files up to the input dataset maximum size. After the files are decompressed, they may each expand to a larger size.

\*\*Autopilot automatically subsamples input datasets that are larger than the target dataset size while accounting for class imbalance and preserving rare class labels.

### To request a quota increase:

1. Open the [Service Quotas console](#).
2. Select your quota increase, then choose **Request increase at account level**.
3. In the **Increase quota value**, enter the new limit value that you are requesting.
4. Choose **Request**.

## Resource quotas

The following table contains the runtime resource limits for an Amazon SageMaker Autopilot job in an AWS Region.

Resource	Limit per Autopilot job
Maximum runtime for an Autopilot job	30 days

## API Reference guide for Autopilot

This section provides a subset of the HTTP service REST APIs for creating and managing Amazon SageMaker Autopilot resources (AutoML jobs) programmatically.

If your language of choice is Python, you can refer to [AWS SDK for Python \(Boto3\)](#) or the [AutoMLV2 object](#) of the Amazon SageMaker Python SDK directly.

### AutoML API Actions

This list details the operations available in the Reference API to manage AutoML jobs programmatically.

- [CreateAutoMLJob](#)
- [CreateAutoMLJobV2](#)
- [DescribeAutoMLJob](#)

- [DescribeAutoMLJobV2](#)
- [ListAutoMLJobs](#)
- [ListCandidatesForAutoMLJob](#)
- [StopAutoMLJob](#)

**Note**

[CreateAutoMLJobV2](#) and [DescribeAutoMLJobV2](#) are new versions of [CreateAutoMLJob](#) and [DescribeAutoMLJob](#) which offer backward compatibility.

We recommend using the [CreateAutoMLJobV2](#). [CreateAutoMLJobV2](#) can manage tabular problem types identical to those of its previous version [CreateAutoMLJob](#), as well as non-tabular problem types such as image or text classification, or time-series forecasting.

Find guidelines about how to migrate a [CreateAutoMLJob](#) to [CreateAutoMLJobV2](#) in [Migrate a CreateAutoMLJob to CreateAutoMLJobV2](#).

## AutoML API Data Types

This list details the API AutoML objects used by the actions above as inbound requests or outbound responses.

## SageMaker JumpStart pretrained models

Amazon SageMaker JumpStart provides pretrained, open-source models for a wide range of problem types to help you get started with machine learning. You can incrementally train and tune these models before deployment. JumpStart also provides solution templates that set up infrastructure for common use cases, and executable example notebooks for machine learning with SageMaker AI.

You can deploy, fine-tune, and evaluate pretrained models from popular models hubs through the JumpStart landing page in the updated Studio experience.

You can also access pretrained models, solution templates, and examples through the JumpStart landing page in Amazon SageMaker Studio Classic.

The following steps show how to access JumpStart models using Amazon SageMaker Studio and Amazon SageMaker Studio Classic.

You can also access JumpStart models using the SageMaker Python SDK. For information about how to use JumpStart models programmatically, see [Use SageMaker JumpStart Algorithms with Pretrained Models](#).

## Open and use JumpStart in Studio

The following sections give information on how to open, use, and manage JumpStart from the Studio UI.

### Important

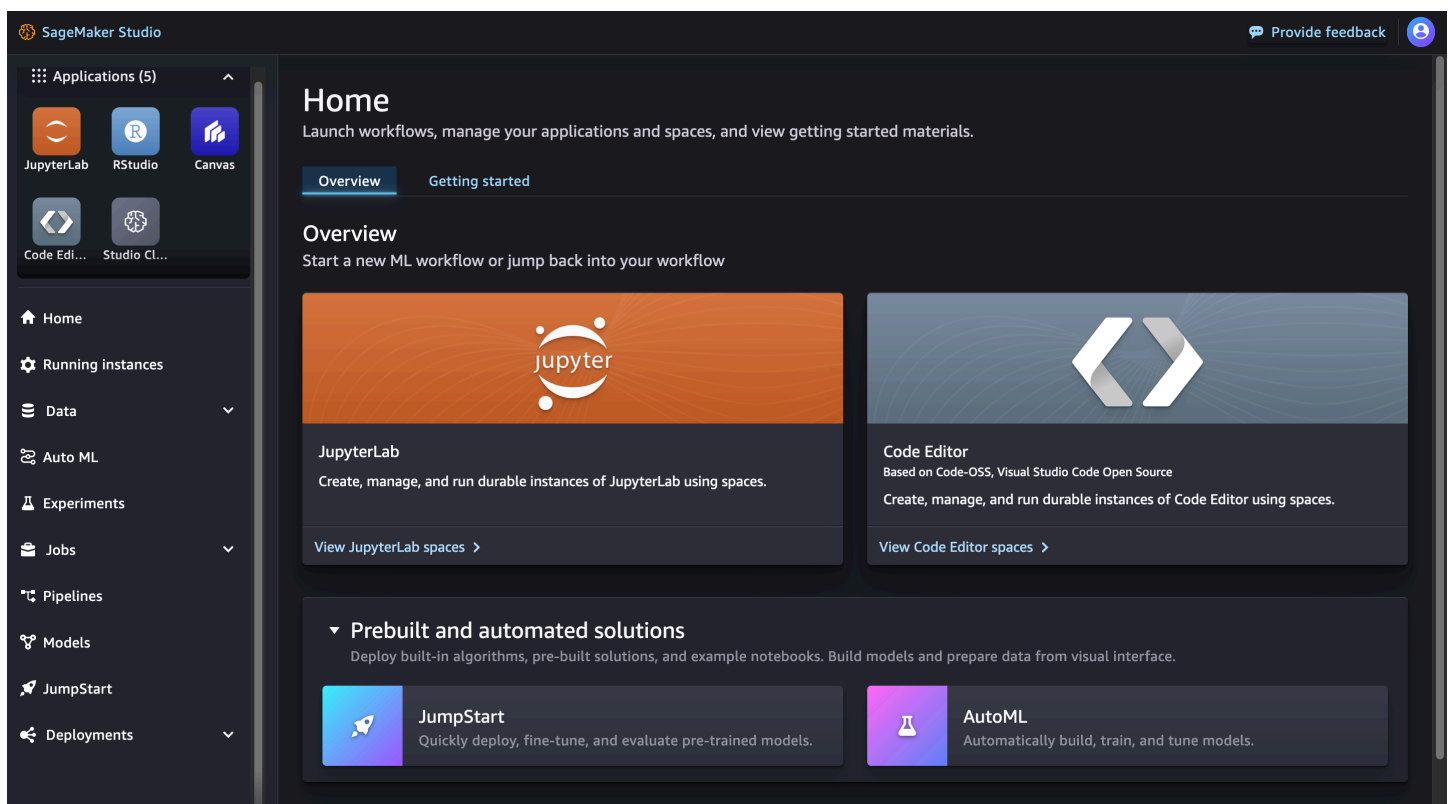

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

## Open JumpStart in Studio

In Amazon SageMaker Studio, open the JumpStart landing page either through the **Home** page or the **Home** menu on the left-side panel. This opens the **SageMaker JumpStart** landing page where you can explore model hubs and search for models.

- From the **Home** page, choose **JumpStart** in the **Prebuilt and automated solutions** pane.
- From the **Home** menu in the left panel, navigate to the **SageMaker JumpStart** node.

For more information on getting started with Amazon SageMaker Studio, see [Amazon SageMaker Studio](#).

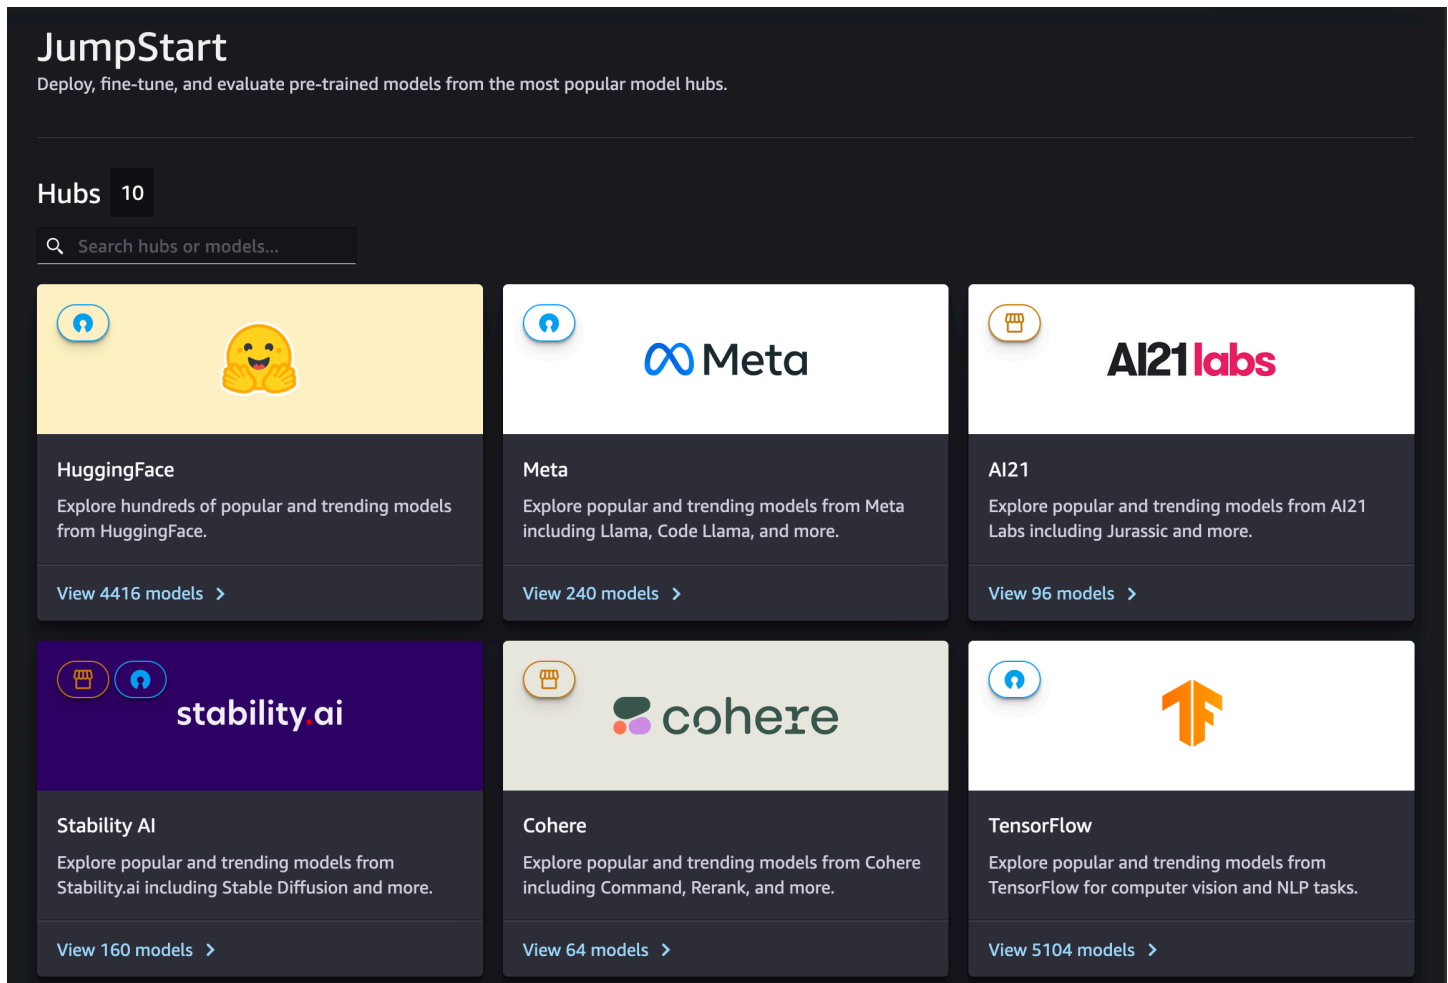

### **⚠ Important**

Before downloading or using third-party content: You are responsible for reviewing and complying with any applicable license terms and making sure that they are acceptable for your use case.

## Use JumpStart in Studio

From the **SageMaker JumpStart** landing page in Studio, you can explore model hubs from providers of both proprietary and publicly available models.

**JumpStart**  
Deploy, fine-tune, and evaluate pre-trained models from the most popular model hubs.

Hubs 10

Search hubs or models...

Hub	Model Count
HuggingFace	4416
Meta	240
AI21	96
Stability AI	160
Cohere	64
TensorFlow	5104

You can find specific hubs or models using the search bar. Within each model hub, you can search directly for models, sort by provided attributes, or filter based on a list of provided model tasks.

## Manage JumpStart in Studio

Choose a model to see its model detail card. In the upper right-hand corner of the model detail card, choose **Fine-tune**, **Deploy**, or **Evaluate** to start working through the fine-tuning, deployment, or evaluation workflows, respectively. Note that not all models are available for fine-tuning or evaluation. For more information on each of these options, see [Use foundation models in Studio](#).

## Open and use JumpStart in Studio Classic

The following sections give information on how to open, use, and manage JumpStart from the Amazon SageMaker Studio Classic UI.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

## Open JumpStart in Studio Classic

In Amazon SageMaker Studio Classic, open the JumpStart landing page either through the **Home** page or the **Home** menu on the left-side panel.

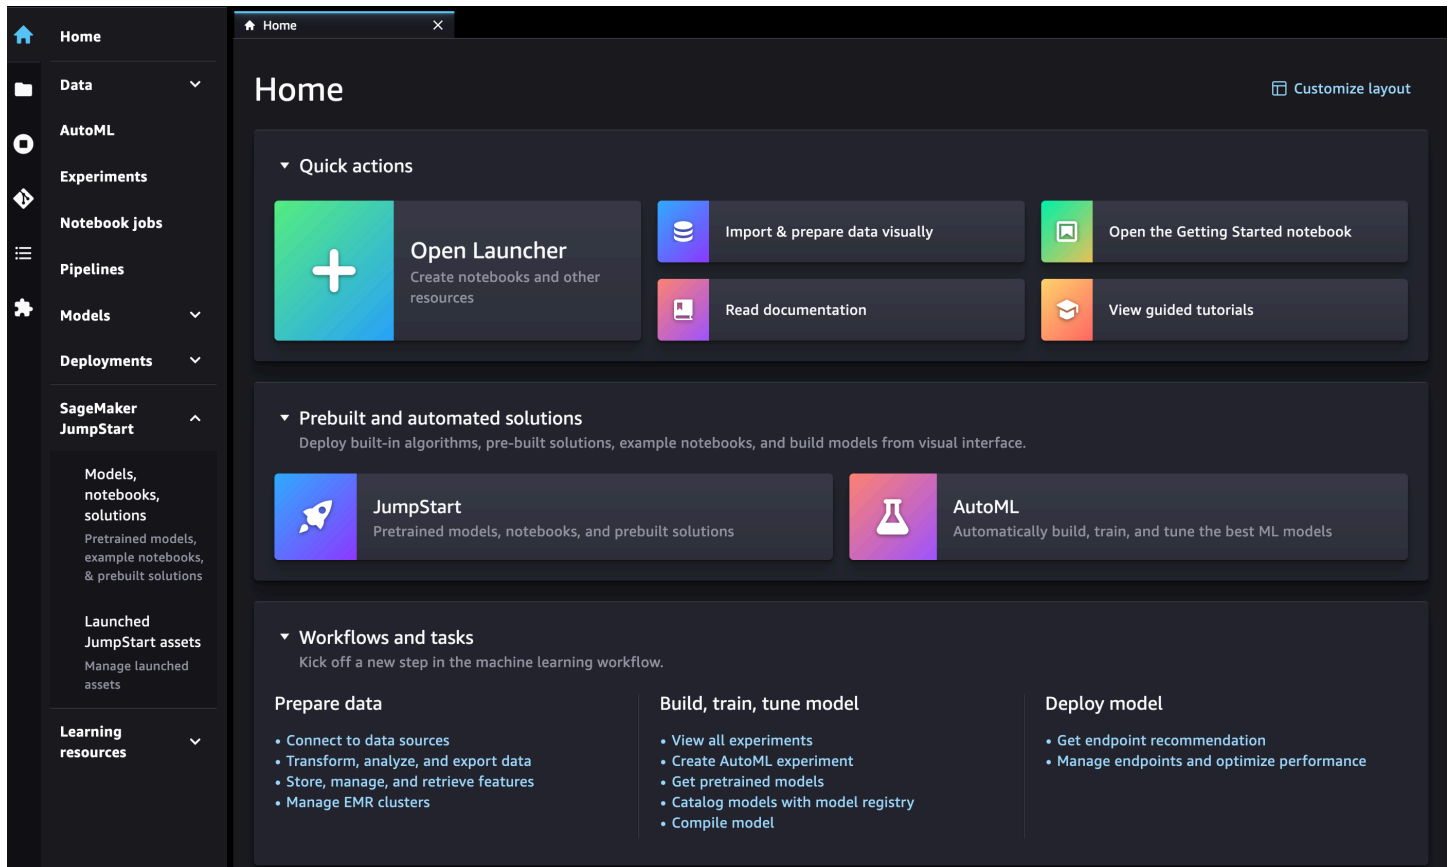

- From the **Home** page you can either:
  - Choose **JumpStart** in the **Prebuilt and automated solutions** pane. This opens the **SageMaker JumpStart** landing page.
  - Choose a model directly in the **SageMaker JumpStart** landing page, or choose the **Explore All** option to see available solutions or models of a specific type.
- From the **Home** menu in the left panel you can either:
  - Navigate to the **SageMaker JumpStart** node, then choose **Models, notebooks, solutions**. This opens the **SageMaker JumpStart** landing page.
  - Navigate to the **JumpStart** node, then choose **Launched JumpStart assets**.

The **Launched JumpStart assets** page lists your currently launched solutions, deployed model endpoints, and training jobs created with JumpStart. You can access the JumpStart landing page from this tab by clicking on the **Browse JumpStart** button at the top right of the tab.

The JumpStart landing page lists available end-to-end machine learning solutions, pretrained models, and example notebooks. From any individual solution or model page, you can choose the **Browse JumpStart** button

at the top right of the tab to return to the **SageMaker JumpStart** page.

**Home** Customize layout

**Quick actions**

- Open Launcher**  
Create notebooks and other resources
- Import & prepare data visually
- Open the Getting Started notebook
- Read documentation
- View guided tutorials

**Prebuilt and automated solutions**  
Deploy built-in algorithms, pre-built solutions, example notebooks, and build models from visual interface.

- JumpStart**  
Pretrained models, notebooks, and prebuilt solutions
- AutoML**  
Automatically build, train, and tune the best ML models

**Workflows and tasks**  
Kick off a new step in the machine learning workflow.

Prepare data	Build, train, tune model	Deploy model
<ul style="list-style-type: none"> <li>Connect to data sources</li> <li>Transform, analyze, and export data</li> <li>Store, manage, and retrieve features</li> <li>Manage EMR clusters</li> </ul>	<ul style="list-style-type: none"> <li>View all experiments</li> <li>Create AutoML experiment</li> <li>Get pretrained models</li> <li>Catalog models with model registry</li> <li>Compile model</li> </ul>	<ul style="list-style-type: none"> <li>Get endpoint recommendation</li> <li>Manage endpoints and optimize performance</li> </ul>

### **⚠ Important**

Before downloading or using third-party content: You are responsible for reviewing and complying with any applicable license terms and making sure that they are acceptable for your use case.

## Use JumpStart in Studio Classic

From the **SageMaker JumpStart** landing page, you can browse for solutions, models, notebooks, and other resources.

You can find JumpStart resources by using the search bar, or by browsing each category. Use the tabs to filter the available solutions by categories:

- **Solutions** – In one step, launch comprehensive machine learning solutions that tie SageMaker AI to other AWS services. Select **Explore All Solutions** to view all available solutions.
- **Resources** – Use example notebooks, blogs, and video tutorials to learn and head start your problem types.
  - **Blogs** – Read details and solutions from machine learning experts.
  - **Video tutorials** – Watch video tutorials for SageMaker AI features and machine learning use cases from machine learning experts.
  - **Example notebooks** – Run example notebooks that use SageMaker AI features like Spot Instance training and experiments over a large variety of model types and use cases.
- **Data types** – Find a model by data type (e.g., Vision, Text, Tabular, Audio, Text Generation). Select **Explore All Models** to view all available models.
- **ML tasks** – Find a model by problem type (e.g., Image Classification, Image Embedding, Object Detection, Text Generation). Select **Explore All Models** to view all available models.
- **Notebooks** – Find example notebooks that use SageMaker AI features across multiple model types and use cases. Select **Explore All Notebooks** to view all available example notebooks.
- **Frameworks** – Find a model by framework (e.g., PyTorch, TensorFlow, Hugging Face).

## Manage JumpStart in Studio Classic

From the **Home** menu in the left panel, navigate to **SageMaker JumpStart**, then choose **Launched JumpStart assets** to list your currently launched solutions, deployed model endpoints, and training jobs created with JumpStart.

### Topics

- [Private curated hubs for foundation model access control in JumpStart](#)
- [Amazon SageMaker JumpStart in Studio Classic](#)

## Amazon SageMaker JumpStart Foundation Models

Amazon SageMaker JumpStart offers state-of-the-art foundation models for use cases such as content writing, code generation, question answering, copywriting, summarization, classification, information retrieval, and more. Use JumpStart foundation models to build your own generative AI solutions and integrate custom solutions with additional SageMaker AI features. For more information, see [Getting started with Amazon SageMaker JumpStart](#).

A foundation model is a large pre-trained model that is adaptable to many downstream tasks and often serves as the starting point for developing more specialized models. Examples of foundation models include LLaMa-3-70b, BLOOM 176B, FLAN-T5 XL, or GPT-J 6B, which are pre-trained on massive amounts of text data and can be fine-tuned for specific language tasks.

Amazon SageMaker JumpStart onboards and maintains publicly available foundation models for you to access, customize, and integrate into your machine learning lifecycles. For more information, see [Publicly available foundation models](#). Amazon SageMaker JumpStart also includes proprietary foundation models from third-party providers. For more information, see [Proprietary foundation models](#).

To get started exploring and experimenting with available models, see [JumpStart foundation model usage](#). All foundation models are available to use programmatically with the SageMaker Python SDK. For more information, see [Use foundation models with the SageMaker Python SDK](#).

For more information on considerations to make when choosing a model, see [Model sources and license agreements](#).

For specifics about customization and fine-tuning foundation models, see [Foundation model customization](#).

For more general information on foundation models, see the paper [On the Opportunities and Risks of Foundation Models](#).

## Topics

- [Available foundation models](#)
- [JumpStart foundation model usage](#)
- [Model sources and license agreements](#)
- [Foundation model customization](#)
- [Evaluate a text generation foundation model in Studio](#)
- [Example notebooks](#)

## Available foundation models

Amazon SageMaker JumpStart offers state-of-the-art, built-in publicly available and proprietary foundation models to customize and integrate into your generative AI workflows.

### Publicly available foundation models

Amazon SageMaker JumpStart onboards and maintains open source foundation models from third-party sources. To get started with one of these publicly available models, see [JumpStart foundation model usage](#) or explore one of the available [Example notebooks](#). In a given example notebook for a publicly available model, try switching out the model ID to experiment with different models within the same model family.

For more information on model IDs and resources on deploying publicly available JumpStart foundation models with the SageMaker Python SDK, see [Use foundation models with the SageMaker Python SDK](#).

By definition, foundation models are adaptable to many downstream tasks. Foundation models are trained on massive amounts of general domain data and the same model can be implemented or customized for multiple use cases. When choosing your foundation model, start with defining a specific task, such as text generation or image generation.

### Publicly available time series forecasting models

Time series forecasting models are designed to analyze and make predictions on sequential data over time. These models can be applied to various domains such as finance, weather forecasting,

or energy demand forecasting. The Chronos models are tailored for time series forecasting tasks, enabling accurate predictions based on historical data patterns.

Model Name	Model ID	Model Source	Fine-tunable
Chronos T5 Small	autogluon-forecasting-chronos-t5-small	Amazon	No
Chronos T5 Base	autogluon-forecasting-chronos-t5-base	Amazon	No
Chronos T5 Large	autogluon-forecasting-chronos-t5-large	Amazon	No
Chronos-Bolt Small	autogluon-forecasting-chronos-bolt-small	Amazon	No
Chronos-Bolt Base	autogluon-forecasting-chronos-bolt-base	Amazon	No

### Publicly available text generation models

Text generation foundation models can be used for a variety of downstream tasks, including text summarization, text classification, question answering, long-form content generation, short-form copywriting, information extraction, and more.

### Publicly available text generation model table

To explore the latest text generation JumpStart foundation models, use the **Text Generation** filter on the [Getting started with Amazon SageMaker JumpStart](#) product description page. You can also explore foundation models based on tasks directly in the Amazon SageMaker Studio UI or SageMaker Studio Classic UI. Only a subset of publicly available text generation models are available for fine-tuning in JumpStart. For more information, see [Use foundation models in Amazon SageMaker Studio Classic](#).

### Publicly available image generation models

JumpStart provides a wide variety of Stable Diffusion image generation foundation models including base models from Stability AI as well as pre-trained models for specific text-to-image tasks from Hugging Face. If you need to fine-tune your text-to-image foundation model, you can use Stable Diffusion 2.1 base from Stability AI. If you want to explore models that are already

trained on specific art styles, you can explore one of the many third-party models from Hugging Face directly in the Amazon SageMaker Studio UI or SageMaker Studio Classic UI.

To explore the latest image generation JumpStart foundation models, use the **Text to Image** filter on the [Getting started with Amazon SageMaker JumpStart](#) product description page. To get started with your chosen text-to-image foundation model, see [JumpStart foundation model usage](#).

## Proprietary foundation models

Amazon SageMaker JumpStart provides access to proprietary foundation models from third-party providers such as [AI21 Labs](#), [Cohere](#), and [LightOn](#).

To get started with one of these proprietary models, see [JumpStart foundation model usage](#). To use a proprietary foundation model, you must first subscribe to the model in AWS Marketplace. After subscribing to the model, locate the foundation model in Studio or SageMaker Studio Classic. For more information, see [SageMaker JumpStart pretrained models](#).

To explore the latest proprietary foundation models for a variety of use cases, see [Getting started with Amazon SageMaker JumpStart](#).

## JumpStart foundation model usage

Choose, train, or deploy foundation models through Amazon SageMaker Studio or Amazon SageMaker Studio Classic, use JumpStart foundation models programmatically with the SageMaker Python SDK, or discover JumpStart foundation models directly through the SageMaker AI console.

### Topics

- [Use foundation models in Studio](#)
- [Use foundation models in Amazon SageMaker Studio Classic](#)
- [Use foundation models with the SageMaker Python SDK](#)
- [Discover foundation models in the SageMaker AI Console](#)

## Use foundation models in Studio

Amazon SageMaker Studio allows you to fine-tune, deploy, and evaluate both publicly available and proprietary JumpStart foundation models directly through the Studio UI.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

To get started, navigate to the JumpStart landing page in Amazon SageMaker Studio. You can access it from the **Home** page or the left-side panel menu. On the **JumpStart** landing page, you can explore model hubs from providers of both publicly available and proprietary models, and search for models.

Within each model hub, you can sort models by **Most likes**, **Most downloads**, **Recently updated**, or filter them by task. Choose a model to view its detail card. On the model detail card, you can choose to **Fine-tune**, **Deploy**, or **Evaluate** the model, depending on the available option. Note that not all models are available for fine-tuning or evaluation.

For more information on getting started with Amazon SageMaker Studio, see [Amazon SageMaker Studio](#).

## Topics

- [Fine-tune a model in Studio](#)
- [Deploy a model in Studio](#)
- [Evaluate a model in Studio](#)
- [Use your SageMaker JumpStart Models in Amazon Bedrock](#)

## Fine-tune a model in Studio

Fine-tuning trains a pre-trained model on a new dataset without training from scratch. This process, also known as transfer learning, can produce accurate models with smaller datasets and less training time. To fine-tune JumpStart foundation models, navigate to a model detail card in the Studio UI. For more information on how to open JumpStart in Studio, see [Open and use JumpStart in Studio](#). After navigating to the model detail card of your choice, choose **Train** in the upper right corner. Note that not all models have fine-tuning available.

**⚠ Important**

Some foundation models require explicit acceptance of an end-user license agreement (EULA) before fine-tuning. For more information, see [EULA acceptance in Amazon SageMaker Studio](#).

**Model settings**

When using a pre-trained JumpStart foundation model in Amazon SageMaker Studio, the **Model artifact location (Amazon S3 URI)** is populated by default. To edit the default Amazon S3 URI, choose **Enter model artifact location**. Not all models support changing the model artifact location.

**Data settings**

In the **Data** field, provide an Amazon S3 URI point to your training dataset location. The default Amazon S3 URI points to an example training dataset. To edit the default Amazon S3 URI, choose **Enter training dataset** and change the URI. Be sure to review the model detail card in Amazon SageMaker Studio for information on formatting training data.

**Hyperparameters**

You can customize the hyperparameters of the training job that are used to fine-tune the model. The hyperparameters available for each fine-tunable model differ depending on the model.

The following hyperparameters are common among models:

- **Epochs** – One epoch is one cycle through the entire dataset. Multiple intervals complete a batch, and multiple batches eventually complete an epoch. Multiple epochs are run until the accuracy of the model reaches an acceptable level, or when the error rate drops below an acceptable level.
- **Learning rate** – The amount that values should be changed between epochs. As the model is refined, its internal weights are being nudged and error rates are checked to see if the model improves. A typical learning rate is 0.1 or 0.01, where 0.01 is a much smaller adjustment and could cause the training to take a long time to converge, whereas 0.1 is much larger and can cause the training to overshoot. It is one of the primary hyperparameters that you might adjust for training your model. Note that for text models, a much smaller learning rate (5e-5 for BERT) can result in a more accurate model.
- **Batch size** – The number of records from the dataset that is to be selected for each interval to send to the GPUs for training.

Review the tool tip prompts and additional information in the model detail card in the Studio UI to learn more about hyperparameters specific to the model of your choice.

For more information on available hyperparameters, see [Commonly supported fine-tuning hyperparameters](#).

## Deployment

Specify the training instance type and output artifact location for your training job. You can only choose from instances that are compatible with the model of your choice within the fine-tuning the Studio UI. The default output artifact location is the SageMaker AI default bucket. To change the output artifact location, choose **Enter output artifact location** and change the Amazon S3 URI.

## Security

Specify the security settings to use for your training job, including the IAM role that SageMaker AI uses to train your model, whether your training job should connect to a virtual private cloud (VPC), and any encryption keys to secure your data.

## Additional information

In the **Additional Information** field you can edit the training job name. You can also add and remove tags in the form of key-value pairs to help organize and categorize your fine-tuning training jobs.

After providing information for your fine-tuning configuration, choose **Submit**. If the pre-trained foundation model that you chose to fine-tune requires explicit agreement of an end-user license agreement (EULA) before training, the EULA is provided in a pop-up window. To accept the terms of the EULA, choose **Accept**. You are responsible for reviewing and complying with any applicable license terms and making sure they are acceptable for your use case before downloading or using a model.

## Deploy a model in Studio

To deploy JumpStart foundation models, navigate to a model detail card in the Studio UI. For more information on how to open JumpStart in Studio, see [Open and use JumpStart in Studio](#). After navigating to the model detail page of your choice, choose **Deploy** in the upper right corner of the Studio UI. Then, follow the steps in [Deploy models with SageMaker Studio](#).

**⚠ Important**

Some foundation models require explicit acceptance of an end-user license agreement (EULA) before deployment. For more information, see [EULA acceptance in Amazon SageMaker Studio](#).

**Evaluate a model in Studio**

Amazon SageMaker JumpStart has integrations with SageMaker Clarify foundation model evaluations (FME) in Studio. If a JumpStart model has built-in evaluation capabilities available, you can choose **Evaluate** in the upper right corner of the model detail page in the JumpStart Studio UI. For more information, see [Evaluate a foundation model](#).

**Use your SageMaker JumpStart Models in Amazon Bedrock**

You can register the models that you've deployed from Amazon SageMaker JumpStart to Amazon Bedrock. With Amazon Bedrock, you can host your model behind multiple endpoints. You can also use Amazon Bedrock features, such as Agents and Knowledge Bases. For more information about using Amazon Bedrock's models, see <https://docs.aws.amazon.com/bedrock/latest/userguide/amazon-bedrock-marketplace.html>.

**⚠ Important**

To migrate your models to Amazon Bedrock, we recommend attaching [AmazonBedrockFullAccess](#) policy to your IAM role. If you can't attach the managed policy, make sure your IAM role has the following permissions:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "BedrockAll",
      "Effect": "Allow",
      "Action": [
        "bedrock:*"
      ],
      "Resource": "*"
    },
    {
      "Sid": "DescribeKey",

    "sagemaker:InvokeEndpointWithResponseStream"
  ],
  "Resource": [
    "arn:aws:sagemaker:*:*:endpoint/*"
  ],
  "Condition": {
    "StringEquals": {
      "aws:CalledViaLast": "bedrock.amazonaws.com"
    }
  }
}

```

```

    }
  },
  {
    "Sid": "DiscoveringMarketplaceModel",
    "Effect": "Allow",
    "Action": [
      "sagemaker:DescribeHubContent"
    ],
    "Resource": [
      "arn:aws:sagemaker:*:aws:hub-content/SageMakerPublicHub/Model/*",
      "arn:aws:sagemaker:*:aws:hub/SageMakerPublicHub"
    ]
  },
  {
    "Sid": "AllowMarketplaceModelsListing",
    "Effect": "Allow",
    "Action": [
      "sagemaker:ListHubContents"
    ],
    "Resource": "arn:aws:sagemaker:*:aws:hub/SageMakerPublicHub"
  },
  {
    "Sid": "RetrieveSubscribedMarketplaceLicenses",
    "Effect": "Allow",
    "Action": [
      "license-manager:ListReceivedLicenses"
    ],
    "Resource": [
      "*"
    ]
  },
  {
    "Sid": "PassRoleToSageMaker",
    "Effect": "Allow",
    "Action": [
      "iam:PassRole"
    ],
    "Resource": [
      "arn:aws:iam::*:role/*Sagemaker*ForBedrock*"
    ],
    "Condition": {
      "StringEquals": {
        "iam:PassedToService": [

```

```

        "sagemaker.amazonaws.com",
        "bedrock.amazonaws.com"
    ]
}
},
{
    "Sid": "PassRoleToBedrock",
    "Effect": "Allow",
    "Action": [
        "iam:PassRole"
    ],
    "Resource": "arn:aws:iam::*:role/*AmazonBedrock*",
    "Condition": {
        "StringEquals": {
            "iam:PassedToService": [
                "bedrock.amazonaws.com"
            ]
        }
    }
}
]
}

```

### Important

The Amazon Bedrock Full Access policy only provides permissions to the Amazon Bedrock API. To use Amazon Bedrock in the AWS Management Console, your IAM role must also have the following permissions:

```

{
    "Sid": "AllowConsoleS3AccessForBedrockMarketplace",
    "Effect": "Allow",
    "Action": [
        "s3:GetObject",
        "s3:GetBucketCORS",
        "s3:ListBucket",
        "s3:ListBucketVersions",
        "s3:GetBucketLocation"
    ],
    "Resource": "*"
}

```

If you're writing your own policy, you must include the policy statement that allows the Amazon Bedrock Marketplace action for the resource. For example, the following policy allows Amazon Bedrock to use the `InvokeModel` operation for a model that you've deployed to an endpoint.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "BedrockAll",
      "Effect": "Allow",
      "Action": [
        "bedrock:InvokeModel"
      ],
      "Resource": [
        "arn:aws:bedrock:AWS
Region:111122223333:marketplace/example-model-endpoint/all-access"
      ]
    },
    {
      "Sid": "VisualEditor1",
      "Effect": "Allow",
      "Action": ["sagemaker:InvokeEndpoint"],
      "Resource": "arn:aws:sagemaker:AWS Region:111122223333:endpoint/
*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/project": "example-project-id",
          "aws:CalledViaLast": "bedrock.amazonaws.com"
        }
      }
    }
  ]
}
```

After you've deployed a model, you might be able to use it in Amazon Bedrock. To see if you can use it in Amazon Bedrock, navigate to the model detail card in the Studio UI. If the model card says that it's **Bedrock Ready**, you can register the model with Amazon Bedrock.

### **Important**

By default Amazon SageMaker JumpStart disables network access for the models that you deploy. If you've enabled network access, you won't be able to use the model with Amazon Bedrock. If you want to use the model with Amazon Bedrock, you must redeploy it with network access disabled.

To use it with Amazon Bedrock, navigate to the **Endpoint details** page and choose **Use with Bedrock** in the upper right corner of the Studio UI. After you see the pop-up, choose **Register to Bedrock**.

## Use foundation models in Amazon SageMaker Studio Classic

You can fine-tune and deploy both publicly available and proprietary JumpStart foundation models through the Studio Classic UI.

### **Important**

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

To get started with Studio Classic, see [Launch Amazon SageMaker Studio Classic](#).

The screenshot displays the SageMaker JumpStart interface. At the top, there's a navigation bar with 'SageMaker JumpStart' on the left and 'Show introduction' and 'Browse Shared Models' on the right. Below the navigation bar are tabs for 'Solutions', 'Resources', 'Data types', 'ML tasks', 'Notebooks', and 'Frameworks'. A search bar is also present. The main content area shows several solution cards, each with a description and a 'View solution' button. The 'Foundation Models: Text Generation' section is highlighted with a yellow border. It features a title, a description, and a link to 'Explore All Text Generation Models (83)'. Below this are four model cards: 'Llama-2-7b-chat' (Meta AI, Text Generation, 7B fine-tuned), 'Llama-2-70b-chat' (Meta AI, Text Generation, 70B fine-tuned), 'Jurassic-2 Ultra' (AI21 Labs, Proprietary, Best-in-class instruction-following), and 'Cohere C' (Cohere, Proprietary, Best-in-class instruction-following). Each card has a 'View model' or 'View notebook' button.

After opening Amazon SageMaker Studio Classic, choose **Models, notebooks, solutions** in the SageMaker JumpStart section of the navigation pane. Then, scroll down to find either the **Foundation Models: Text Generation** or **Foundation Models: Image Generation** section depending on your use case.

You can choose **View model** on a suggested foundation model card, or choose **Explore All Models** to see all available foundation models for either text generation or image generation. If you choose to see all available models, you can further filter available models by task, data type, content type, or framework. You can also search for a model name directly in the **Search** bar. If you need guidance on selecting a model, see [Available foundation models](#).

### **⚠ Important**

Some foundation models require explicit acceptance of an end-user license agreement (EULA). For more information, see [EULA acceptance in Amazon SageMaker Studio](#).

After you choose **View model** for the foundation model of your choice in Studio Classic, you can deploy the model. For more information, see [Deploy a Model](#).

You can also choose **Open notebook** in the **Run in notebook** section to run an example notebook for the foundation model directly in Studio Classic.

### Note

To deploy a proprietary foundation model in Studio Classic, you must first subscribe to the model in AWS Marketplace. The AWS Marketplace link is provided in the associated example notebook within Studio Classic.

If the model is fine-tunable, you can also fine-tune the model. For more information, see [Fine-Tune a Model](#). For a list of which JumpStart foundation models are fine-tunable, see [Foundation models and hyperparameters for fine-tuning](#).

## Use foundation models with the SageMaker Python SDK

All JumpStart foundation models are available for programmatic deployment using the SageMaker Python SDK.

To deploy publicly available foundation models, you can use their model ID. You can find the model IDs for all publicly available foundation models in the [Built-in Algorithms with pre-trained Model Table](#). Search for the name of a foundation model in the **Search** bar. Use the **Show entries** dropdown or the pagination controls to navigate the available models.

Proprietary models must be deployed using the model package information after subscribing to the model in AWS Marketplace.

You can find the list of JumpStart available models in [the section called “Available models”](#).

### Important

Some foundation models require explicit acceptance of an end-user license agreement (EULA). For more information, see [EULA acceptance with the SageMaker Python SDK](#).

The following sections show how to fine-tune publicly available foundation models using the `JumpStartEstimator` class, deploy publicly available foundation models using the `JumpStartModel` class, and deploy proprietary foundation models using the `ModelPackage` class.

## Topics

- [Fine-tune publicly available foundation models with the JumpStartEstimator class](#)
- [Deploy publicly available foundation models with the JumpStartModel class](#)
- [Deploy proprietary foundation models with the ModelPackage class](#)

## Fine-tune publicly available foundation models with the JumpStartEstimator class

You can fine-tune a built-in algorithm or pre-trained model in just a few lines of code using the SageMaker Python SDK.

1. First, find the model ID for the model of your choice in the [Built-in Algorithms with pre-trained Model Table](#).
2. Using the model ID, define your training job as a JumpStart estimator.

```
from sagemaker.jumpstart.estimator import JumpStartEstimator

model_id = "huggingface-textgeneration1-gpt-j-6b"
estimator = JumpStartEstimator(model_id=model_id)
```

3. Run `estimator.fit()` on your model, pointing to the training data to use for fine-tuning.

```
estimator.fit(
    {"train": training_dataset_s3_path, "validation": validation_dataset_s3_path}
)
```

4. Then, use the `deploy` method to automatically deploy your model for inference. In this example, we use the GPT-J 6B model from Hugging Face.

```
predictor = estimator.deploy()
```

5. You can then run inference with the deployed model using the `predict` method.

```
question = "What is Southern California often abbreviated as?"
response = predictor.predict(question)
print(response)
```

**Note**

This example uses the foundation model GPT-J 6B, which is suitable for a wide range of text generation use cases including question answering, named entity recognition, summarization, and more. For more information about model use cases, see [Available foundation models](#).

You can optionally specify model versions or instance types when creating your `JumpStartEstimator`. For more information about the `JumpStartEstimator` class and its parameters, see [JumpStartEstimator](#).

**Check default instance types**

You can optionally include specific model versions or instance types when fine-tuning a pre-trained model using the `JumpStartEstimator` class. All JumpStart models have a default instance type. Retrieve the default training instance type using the following code:

```
from sagemaker import instance_types

instance_type = instance_types.retrieve_default(
    model_id=model_id,
    model_version=model_version,
    scope="training")
print(instance_type)
```

You can see all supported instance types for a given JumpStart model with the `instance_types.retrieve()` method.

**Check default hyperparameters**

To check the default hyperparameters used for training, you can use the `retrieve_default()` method from the `hyperparameters` class.

```
from sagemaker import hyperparameters

my_hyperparameters = hyperparameters.retrieve_default(model_id=model_id,
    model_version=model_version)
print(my_hyperparameters)

# Optionally override default hyperparameters for fine-tuning
```

```
my_hyperparameters["epoch"] = "3"
my_hyperparameters["per_device_train_batch_size"] = "4"

# Optionally validate hyperparameters for the model
hyperparameters.validate(model_id=model_id, model_version=model_version,
    hyperparameters=my_hyperparameters)
```

For more information on available hyperparameters, see [Commonly supported fine-tuning hyperparameters](#).

## Check default metric definitions

You can also check the default metric definitions:

```
print(metric_definitions.retrieve_default(model_id=model_id,
    model_version=model_version))
```

## Deploy publicly available foundation models with the `JumpStartModel` class

You can deploy a built-in algorithm or pre-trained model to a SageMaker AI endpoint in just a few lines of code using the SageMaker Python SDK.

1. First, find the model ID for the model of your choice in the [Built-in Algorithms with pre-trained Model Table](#).
2. Using the model ID, define your model as a `JumpStartModel`.

```
from sagemaker.jumpstart.model import JumpStartModel

model_id = "huggingface-text2text-flan-t5-xl"
my_model = JumpStartModel(model_id=model_id)
```

3. Use the `deploy` method to automatically deploy your model for inference. In this example, we use the FLAN-T5 XL model from Hugging Face.

```
predictor = my_model.deploy()
```

4. You can then run inference with the deployed model using the `predict` method.

```
question = "What is Southern California often abbreviated as?"
response = predictor.predict(question)
print(response)
```

**Note**

This example uses the foundation model FLAN-T5 XL, which is suitable for a wide range of text generation use cases including question answering, summarization, chatbot creation, and more. For more information about model use cases, see [Available foundation models](#).

For more information about the `JumpStartModel` class and its parameters, see [JumpStartModel](#).

**Check default instance types**

You can optionally include specific model versions or instance types when deploying a pre-trained model using the `JumpStartModel` class. All JumpStart models have a default instance type. Retrieve the default deployment instance type using the following code:

```
from sagemaker import instance_types

instance_type = instance_types.retrieve_default(
    model_id=model_id,
    model_version=model_version,
    scope="inference")
print(instance_type)
```

See all supported instance types for a given JumpStart model with the `instance_types.retrieve()` method.

**Use inference components to deploy multiple models to a shared endpoint**

An inference component is a SageMaker AI hosting object that you can use to deploy one or more models to an endpoint for increased flexibility and scalability. You must change the `endpoint_type` for your JumpStart model to be inference-component-based rather than the default model-based endpoint.

```
predictor = my_model.deploy(
    endpoint_name = 'jumpstart-model-id-123456789012',
    endpoint_type = EndpointType.INFERENCE_COMPONENT_BASED
)
```

For more information on creating endpoints with inference components and deploying SageMaker AI models, see [Shared resource utilization with multiple models](#).

## Check valid input and output inference formats

To check valid data input and output formats for inference, you can use the `retrieve_options()` method from the `Serializers` and `Deserializers` classes.

```
print(sagemaker.serializers.retrieve_options(model_id=model_id,
      model_version=model_version))
print(sagemaker.deserializers.retrieve_options(model_id=model_id,
      model_version=model_version))
```

## Check supported content and accept types

Similarly, you can use the `retrieve_options()` method to check the supported content and accept types for a model.

```
print(sagemaker.content_types.retrieve_options(model_id=model_id,
      model_version=model_version))
print(sagemaker.accept_types.retrieve_options(model_id=model_id,
      model_version=model_version))
```

For more information about utilities, see [Utility APIs](#).

## Deploy proprietary foundation models with the `ModelPackage` class

Proprietary models must be deployed using the model package information after subscribing to the model in AWS Marketplace. For more information about SageMaker AI and AWS Marketplace, see [Buy and Sell Amazon SageMaker AI Algorithms and Models in AWS Marketplace](#). To find AWS Marketplace links for the latest proprietary models, see [Getting started with Amazon SageMaker JumpStart](#).

After subscribing to the model of your choice in AWS Marketplace, you can deploy the foundation model using the SageMaker Python SDK and the SDK associated with the model provider. For example, AI21 Labs, Cohere, and LightOn use the "ai21[SM]", cohere-sagemaker, and lightonsage packages, respectively.

For example, to define a JumpStart model using Jurassic-2 Jumbo Instruct from AI21 Labs, use the following code:

```
import sagemaker
import ai21

role = get_execution_role()
```

```
sagemaker_session = sagemaker.Session()
model_package_arn = "arn:aws:sagemaker:us-east-1:865070037744:model-package/j2-jumbo-
instruct-v1-1-43-4e47c49e61743066b9d95efed6882f35"

my_model = ModelPackage(
    role=role, model_package_arn=model_package_arn, sagemaker_session=sagemaker_session
)
```

For step-by-step examples, find and run the notebook associated with the proprietary foundation model of your choice in SageMaker Studio Classic. See [Use foundation models in Amazon SageMaker Studio Classic](#) for more information. For more information on the SageMaker Python SDK, see [ModelPackage](#).

## Discover foundation models in the SageMaker AI Console

You can explore JumpStart foundation models directly through the Amazon SageMaker AI Console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. Find **JumpStart** on the left navigation panel and choose **Foundation models**.
3. Browse models or search for a specific model. If you need guidance for model selection, see [Available foundation models](#). Choose **View model** to view the model detail page for the foundation model of your choice.
4. If the model is a proprietary model, choose **Subscribe** in the upper right corner of the model detail page to subscribe to the model in AWS Marketplace. You should receive an email confirming your subscription to the model of your choice. For more information about SageMaker AI and AWS Marketplace, see [Buy and Sell Amazon SageMaker AI Algorithms and Models in AWS Marketplace](#). Publicly available foundation models do not require a subscription.
5. To view an example notebook in GitHub, choose **View code** in the upper right corner of the model detail page.
6. To view and run an example notebook directly in Amazon SageMaker Studio Classic, choose **Open notebook in Studio** in the upper right corner of the model detail page.

## Model sources and license agreements

Amazon SageMaker JumpStart provides access to hundreds of publicly available and proprietary foundation models from third-party sources and partners. You can explore the JumpStart foundation model selection directly in the SageMaker AI console, Studio, or Studio Classic.

## Licenses and model sources

Amazon SageMaker JumpStart provides access to both publicly available and proprietary foundation models. Foundation models are onboarded and maintained from third-party open source and proprietary providers. As such, they are released under different licenses as designated by the model source. Be sure to review the license for any foundation model that you use. You are responsible for reviewing and complying with any applicable license terms and making sure they are acceptable for your use case before downloading or using the content. Some examples of common foundation model licenses include:

- Alexa Teacher Model
- Apache 2.0
- BigScience Responsible AI License v1.0
- CreativeML Open RAIL++-M license

Similarly, for any proprietary foundation models, be sure to review and comply with any terms of use and usage guidelines from the model provider. If you have questions about license information for a specific proprietary model, reach out to model provider directly. You can find model provider contact information in the **Support** tab of each model page in AWS Marketplace.

## End-user license agreements

Some JumpStart foundation models require explicit acceptance of an end-user license agreement (EULA) before use.

## EULA acceptance in Amazon SageMaker Studio

You may be prompted to accept an end-user license agreement before fine-tuning, deploying, or evaluating a JumpStart foundation model in Studio. To get started with JumpStart foundation models in Studio, see [Use foundation models in Studio](#).

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

Some JumpStart foundation models require acceptance of an end-user license agreement before deployment. If this applies to the foundation model that you choose to use, Studio prompts you with a window containing the EULA content. You are responsible for reviewing and complying with any applicable license terms and making sure they are acceptable for your use case before downloading or using a model.

## EULA acceptance in Amazon SageMaker Studio Classic

You may be prompted to accept an end-user license agreement before deploying a JumpStart foundation model or opening a JumpStart foundation model notebook in Studio Classic. To get started with JumpStart foundation models in Studio Classic, see [Use foundation models in Amazon SageMaker Studio Classic](#).

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Some JumpStart foundation models require acceptance of an end-user license agreement before deployment. If this applies to the foundation model that you choose to use, Studio Classic prompts you with a window titled **Review the End User License Agreement (EULA) and Acceptable Use Policy (AUP) below** after you choose either **Deploy** or **Open notebook**. You are responsible for reviewing and complying with any applicable license terms and making sure they are acceptable for your use case before downloading or using a model.

## EULA acceptance with the SageMaker Python SDK

The following sections show you how to explicitly declare EULA acceptance when deploying or fine-tuning a JumpStart model with the SageMaker Python SDK. For more information on getting started with JumpStart foundation models using the SageMaker Python SDK, see [Use foundation models with the SageMaker Python SDK](#).

Before you begin, make sure that you do the following:

- Upgrade to the latest version of the model that you use.
- Install the latest version of the SageMaker Python SDK.

**⚠ Important**

To use the following workflow you must have [v2.198.0](#) or later of the SageMaker Python SDK installed.

**EULA acceptance when deploying a JumpStart model**

For models that require the acceptance of an end-user license agreement, you must explicitly declare EULA acceptance when deploying your JumpStart model.

```
from sagemaker.jumpstart.model import JumpStartModel
model_id = "meta-textgeneration-llama-2-13b"
my_model = JumpStartModel(model_id=model_id)

# Declare EULA acceptance when deploying your JumpStart model
predictor = my_model.deploy(accept_eula=True)
```

The `accept_eula` value is `None` by default and must be explicitly redefined as `True` in order to accept the end-user license agreement. For more information, see [JumpStartModel](#).

**EULA acceptance when fine-tuning a JumpStart model**

For fine-tuning models that require the acceptance of an end-user license agreement, you must explicitly declare EULA acceptance when defining your JumpStart estimator. After fine-tuning a pre-trained model, the weights of the original model are changed. Therefore, when you deploy the fine-tuned model later, you do not need to accept a EULA.

```
from sagemaker.jumpstart.estimator import JumpStartEstimator
model_id = "meta-textgeneration-llama-2-13b"

# Declare EULA acceptance when defining your JumpStart estimator
estimator = JumpStartEstimator(model_id=model_id, environment={"accept_eula": "true"})
estimator.fit(
    {"train": training_dataset_s3_path, "validation": validation_dataset_s3_path}
)
```

The `accept_eula` value is `None` by default and must be explicitly redefined as `"true"` within the estimator environment in order to accept the end-user license agreement. For more information, see [JumpStartEstimator](#).

## EULA acceptance SageMaker Python SDK versions earlier than 2.198.0

### Important

When using versions earlier than [2.198.0](#) of the SageMaker Python SDK, you must use the SageMaker `Predictor` class to accept a model EULA.

After deploying a JumpStart foundation model programmatically using the SageMaker Python SDK, you can run inference against your deployed endpoint with the SageMaker [Predictor](#) class. For models that require the acceptance of an end-user license agreement, you must explicitly declare EULA acceptance in your call to the `Predictor` class:

```
predictor.predict(payload, custom_attributes="accept_eula=true")
```

The `accept_eula` value is `false` by default and must be explicitly redefined as `true` in order to accept the end-user license agreement. The predictor returns an error if you try to run inference while `accept_eula` is set to `false`. For more information on getting started with JumpStart foundation models using the SageMaker Python SDK, see [Use foundation models with the SageMaker Python SDK](#).

### Important

The `custom_attributes` parameter accepts key-value pairs in the format `"key1=value1;key2=value2"`. If you use the same key multiple times, the inference server uses the last value associated with the key. For example, if you pass `"accept_eula=false;accept_eula=true"` to the `custom_attributes` parameter, then the inference server associates the value `true` with the `accept_eula` key.

## Foundation model customization

Foundation models are extremely powerful models able to solve a wide array of tasks. To solve most tasks effectively, these models require some form of customization.

The recommended way to first customize a foundation model to a specific use case is through prompt engineering. Providing your foundation model with well-engineered, context-rich prompts can help achieve desired results without any fine-tuning or changing of model weights. For more information, see [Prompt engineering for foundation models](#).

If prompt engineering alone is not enough to customize your foundation model to a specific task, you can fine-tune a foundation model on additional domain-specific data. For more information, see [Foundation models and hyperparameters for fine-tuning](#). The fine-tuning process involves changing model weights.

If you want to customize your model with information from a knowledge library without any retraining, see [Retrieval Augmented Generation](#).

## Prompt engineering for foundation models

Prompt engineering is the process of designing and refining the prompts or input stimuli for a language model to generate specific types of output. Prompt engineering involves selecting appropriate keywords, providing context, and shaping the input in a way that encourages the model to produce the desired response and is a vital technique to actively shape the behavior and output of foundation models.

Effective prompt engineering is crucial for directing model behavior and achieving desired responses. Through prompt engineering, you can control a model's tone, style, and domain expertise without more involved customization measures like fine-tuning. We recommend dedicating time to prompt engineering before you consider fine-tuning a model on additional data. The goal is to provide sufficient context and guidance to the model so that it can generalize and perform well on unseen or limited data scenarios.

## Zero-shot learning

Zero-shot learning involves training a model to generalize and make predictions on unseen classes or tasks. To perform prompt engineering in zero-shot learning environments, we recommend constructing prompts that explicitly provide information about the target task and the desired output format. For example, if you want to use a foundation model for zero-shot text classification on a set of classes that the model did not see during training, a well-engineered prompt could be: "Classify the following text as either sports, politics, or entertainment: *[input text]*." By explicitly specifying the target classes and the expected output format, you can guide the model to make accurate predictions even on unseen classes.

## Few-shot learning

Few-shot learning involves training a model with a limited amount of data for new classes or tasks. Prompt engineering in few-shot learning environments focuses on designing prompts that effectively use the limited available training data. For example, if you use a foundation model for an image classification task and only have a few examples of a new image class, you can engineer

a prompt that includes the available labeled examples with a placeholder for the target class. For example, the prompt could be: "[image 1], [image 2], and [image 3] are examples of *[target class]*. Classify the following image as *[target class]*". By incorporating the limited labeled examples and explicitly specifying the target class, you can guide the model to generalize and make accurate predictions even with minimal training data.

## Supported inference parameters

Changing inference parameters might also affect the responses to your prompts. While you can try to add as much specificity and context as possible to your prompts, you can also experiment with supported inference parameters. The following are examples of some commonly supported inference parameters:

Inference Parameter	Description
max_new_tokens	The maximum output length of a foundation model response. Valid values: integer, range: Positive integer.
temperature	Controls the randomness in the output. Higher temperature results in an output sequence with low-probability words and lower temperature results in output sequence with high-probability words. If temperature=0, the response is made up of only the highest probability words (greedy decoding). Valid values: float, range: Positive float.
top_p	In each step of text generation, the model samples from the smallest possible set of words with a cumulative probability of top_p. Valid values: float, range: 0.0, 1.0.
return_full_text	If True, then the input text is part of the generated output text. Valid values: boolean, default: False.

For more information on foundation model inference, see [Deploy publicly available foundation models with the JumpStartModel class](#).

If prompt engineering is not sufficient to adapt your foundation model to specific business needs, domain-specific language, target tasks, or other requirements, you can consider fine-tuning your model on additional data or using Retrieval Augmented Generation (RAG) to augment your model

architecture with enhanced context from archived knowledge sources. For more information, see [Foundation models and hyperparameters for fine-tuning](#) or [Retrieval Augmented Generation](#).

## Foundation models and hyperparameters for fine-tuning

Foundation models are computationally expensive and trained on a large, unlabeled corpus. Fine-tuning a pre-trained foundation model is an affordable way to take advantage of their broad capabilities while customizing a model on your own small, corpus. Fine-tuning is a customization method that involved further training and does change the weights of your model.

Fine-tuning might be useful to you if you need:

- to customize your model to specific business needs
- your model to successfully work with domain-specific language, such as industry jargon, technical terms, or other specialized vocabulary
- enhanced performance for specific tasks
- accurate, relative, and context-aware responses in applications
- responses that are more factual, less toxic, and better-aligned to specific requirements

There are two main approaches that you can take for fine-tuning depending on your use case and chosen foundation model.

1. If you're interested in fine-tuning your model on domain-specific data, see [Fine-tune a large language model \(LLM\) using domain adaptation](#).
2. If you're interested in instruction-based fine-tuning using prompt and response examples, see [Fine-tune a large language model \(LLM\) using prompt instructions](#).

## Foundation models available for fine-tuning

You can fine-tune any of the following JumpStart foundation models:

- Bloom 3B
- Bloom 7B1
- BloomZ 3B FP16
- BloomZ 7B1 FP16
- Code Llama 13B
- Code Llama 13B Python

- Code Llama 34B
- Code Llama 34B Python
- Code Llama 70B
- Code Llama 70B Python
- Code Llama 7B
- Code Llama 7B Python
- CyberAgentLM2-7B-Chat (CALM2-7B-Chat)
- Falcon 40B BF16
- Falcon 40B Instruct BF16
- Falcon 7B BF16
- Falcon 7B Instruct BF16
- Flan-T5 Base
- Flan-T5 Large
- Flan-T5 Small
- Flan-T5 XL
- Flan-T5 XXL
- Gemma 2B
- Gemma 2B Instruct
- Gemma 7B
- Gemma 7B Instruct
- GPT-2 XL
- GPT-J 6B
- GPT-Neo 1.3B
- GPT-Neo 125M
- GPT-NEO 2.7B
- LightGPT Instruct 6B
- Llama 2 13B
- Llama 2 13B Chat
- Llama 2 13B Neuron
- Llama 2 70B

- Llama 2 70B Chat
- Llama 2 7B
- Llama 2 7B Chat
- Llama 2 7B Neuron
- Mistral 7B
- Mixtral 8x7B
- Mixtral 8x7B Instruct
- RedPajama INCITE Base 3B V1
- RedPajama INCITE Base 7B V1
- RedPajama INCITE Chat 3B V1
- RedPajama INCITE Chat 7B V1
- RedPajama INCITE Instruct 3B V1
- RedPajama INCITE Instruct 7B V1
- Stable Diffusion 2.1

### Commonly supported fine-tuning hyperparameters

Different foundation models support different hyperparameters when fine-tuning. The following are commonly-supported hyperparameters that can further customize your model during training:

Inference Parameter	Description
epoch	The number of passes that the model takes through the fine-tuning dataset during training. Must be an integer greater than 1.
learning_rate	The rate at which the model weights are updated after working through each batch of fine-tuning training examples. Must be a positive float greater than 0.
instruction_tuned	Whether to instruction-train the model or not. Must be 'True' or 'False'.
per_device_train_batch_size	The batch size per GPU core or CPU for training. Must be a positive integer.

Inference Parameter	Description
<code>per_device_eval_batch_size</code>	The batch size per GPU core or CPU for evaluation. Must be a positive integer.
<code>max_train_samples</code>	For debugging purposes or quicker training, truncate the number of training examples to this value. Value -1 means that the model uses all of the training samples. Must be a positive integer or -1.
<code>max_val_samples</code>	For debugging purposes or quicker training, truncate the number of validation examples to this value. Value -1 means that the model uses all of the validation samples. Must be a positive integer or -1.
<code>max_input_length</code>	Maximum total input sequence length after tokenization. Sequences longer than this will be truncated. If -1, <code>max_input_length</code> is set to the minimum of 1024 and the <code>model_max_length</code> defined by the tokenizer. If set to a positive value, <code>max_input_length</code> is set to the minimum of the provided value and the <code>model_max_length</code> defined by the tokenizer. Must be a positive integer or -1.
<code>validation_split_ratio</code>	If there is no validation channel, ratio of train-validation split from the training data. Must be between 0 and 1.
<code>train_data_split_seed</code>	If validation data is not present, this fixes the random splitting of the input training data to training and validation data used by the model. Must be an integer.
<code>preprocessing_num_workers</code>	The number of processes to use for the pre-processing. If None, main process is used for pre-processing.
<code>lora_r</code>	Low-rank adaptation (LoRA) r value, which acts as the scaling factor for weight updates. Must be a positive integer.

Inference Parameter	Description
<code>lora_alpha</code>	Low-rank adaptation (LoRA) alpha value, which acts as the scaling factor for weight updates. Generally 2 to 4 times the size of <code>lora_r</code> . Must be a positive integer.
<code>lora_dropout</code>	Dropout value for low-rank adaptation (LoRA) layers. Must be a positive float between 0 and 1.
<code>int8_quantization</code>	If <code>True</code> , model is loaded with 8 bit precision for training.
<code>enable_fsdp</code>	If <code>True</code> , training uses Fully Sharded Data Parallelism.

You can specify hyperparameter values when you fine-tune your model in Studio. For more information, see [Fine-tune a model in Studio](#).

You can also override default hyperparameter values when fine-tuning your model using the SageMaker Python SDK. For more information, see [Fine-tune publicly available foundation models with the `JumpStartEstimator` class](#).

## Fine-tune a large language model (LLM) using domain adaptation

Domain adaptation fine-tuning allows you to leverage pre-trained foundation models and adapt them to specific tasks using limited domain-specific data. If prompt engineering efforts do not provide enough customization, you can use domain adaptation fine-tuning to get your model working with domain-specific language, such as industry jargon, technical terms, or other specialized data. This fine-tuning process modifies the weights of the model.

To fine-tune your model on a domain-specific dataset:

1. Prepare your training data. For instructions, see [the section called "Prepare and upload training data for domain adaptation fine-tuning"](#).
2. Create your fine-tuning training job. For instructions, see [the section called "Create a training job for instruction-based fine-tuning"](#).

You can find end-to-end examples in [the section called "Example notebooks"](#).

Domain adaptation fine-tuning is available with the following foundation models:

**Note**

Some JumpStart foundation models, such as Llama 2 7B, require acceptance of an end-user license agreement before fine-tuning and performing inference. For more information, see [End-user license agreements](#).

- Bloom 3B
- Bloom 7B1
- BloomZ 3B FP16
- BloomZ 7B1 FP16
- GPT-2 XL
- GPT-J 6B
- GPT-Neo 1.3B
- GPT-Neo 125M
- GPT-NEO 2.7B
- Llama 2 13B
- Llama 2 13B Chat
- Llama 2 13B Neuron
- Llama 2 70B
- Llama 2 70B Chat
- Llama 2 7B
- Llama 2 7B Chat
- Llama 2 7B Neuron

**Prepare and upload training data for domain adaptation fine-tuning**

Training data for domain adaptation fine-tuning can be provided in CSV, JSON, or TXT file format. All training data must be in a single file within a single folder.

The training data is taken from the **Text** column for CSV or JSON training data files. If no column is labeled **Text**, then the training data is taken from the first column for CSV or JSON training data files.

The following is an example body of a TXT file to be used for fine-tuning:

```
This report includes estimates, projections, statements relating to our
business plans, objectives, and expected operating results that are "forward-
looking statements" within the meaning of the Private Securities Litigation
Reform Act of 1995, Section 27A of the Securities Act of 1933, and Section 21E
of ....
```

## Split data for training and testing

You can optionally provide another folder containing validation data. This folder should also include one CSV, JSON, or TXT file. If no validation dataset is provided, then a set amount of the training data is set aside for validation purposes. You can adjust the percentage of training data used for validation when you choose the hyperparameters for fine-tuning your model.

## Upload fine-tuning data to Amazon S3

Upload your prepared data to Amazon Simple Storage Service (Amazon S3) to use when fine-tuning a JumpStart foundation model. You can use the following commands to upload your data:

```
from sagemaker.s3 import S3Uploader
import sagemaker
import random

output_bucket = sagemaker.Session().default_bucket()
local_data_file = "train.txt"
train_data_location = f"s3://{output_bucket}/training_folder"
S3Uploader.upload(local_data_file, train_data_location)
S3Uploader.upload("template.json", train_data_location)
print(f"Training data: {train_data_location}")
```

## Create a training job for instruction-based fine-tuning

After your data is uploaded to Amazon S3, you can fine-tune and deploy your JumpStart foundation model. To fine-tune your model in Studio, see [Fine-tune a model in Studio](#). To fine-tune your model using the SageMaker Python SDK, see [Fine-tune publicly available foundation models with the JumpStartEstimator class](#).

## Example notebooks

For more information on domain adaptation fine-tuning, see the following example notebooks:

- [SageMaker JumpStart Foundation Models - Fine-tuning text generation GPT-J 6B model on domain specific dataset](#)
- [Fine-tune LLaMA 2 models on JumpStart](#)

## Fine-tune a large language model (LLM) using prompt instructions

Instruction-based fine-tuning uses labeled examples to improve the performance of a pre-trained foundation model on a specific task. The labeled examples are formatted as prompt, response pairs and phrased as instructions. This fine-tuning process modifies the weights of the model. For more information on instruction-based fine-tuning, see the papers [Introducing FLAN: More generalizable Language Models with Instruction Fine-Tuning](#) and [Scaling Instruction-Finetuned Language Models](#).

Fine-tuned LLanguage Net (FLAN) models use instruction tuning to make models more amenable to solving general downstream NLP tasks. Amazon SageMaker JumpStart provides a number of foundation models in the FLAN model family. For example, FLAN-T5 models are instruction fine-tuned on a wide range of tasks to increase zero-shot performance for a variety of common use cases. With additional data and fine-tuning, instruction-based models can be further adapted to more specific tasks that weren't considered during pre-training.

To fine-tune a LLM on a specific task using prompt-response pairs task instructions:

1. Prepare your instructions in JSON files. For more information about the required format for the prompt-response pair files and the structure of the data folder, see [the section called "Prepare and upload training data for instruction-based fine-tuning"](#).
2. Create your fine-tuning training job. For instructions, see [the section called "Create a training job for instruction-based fine-tuning"](#).

You can find end-to-end examples in [the section called "Example notebooks"](#).

Only a subset of JumpStart foundation models are compatible with instruction-based fine-tuning. Instruction-based fine-tuning is available with the following foundation models:

**Note**

Some JumpStart foundation models, such as Llama 2 7B, require acceptance of an end-user license agreement before fine-tuning and performing inference. For more information, see [End-user license agreements](#).

- Flan-T5 Base
- Flan-T5 Large
- Flan-T5 Small
- Flan-T5 XL
- Flan-T5 XXL
- Llama 2 13B
- Llama 2 13B Chat
- Llama 2 13B Neuron
- Llama 2 70B
- Llama 2 70B Chat
- Llama 2 7B

**Prepare and upload training data for instruction-based fine-tuning**

Training data for instruction-based fine-tuning must be provided in JSON Lines text file format, where each line is a dictionary. All training data must be in a single folder. The folder can include multiple .jsonl files.

The training folder can also include a template JSON file (`template.json`) that describes the input and output formats of your data. If no template file is provided, the following template file is used:

```
{
  "prompt": "Below is an instruction that describes a task, paired with an input that provides further context. Write a response that appropriately completes the request.\n\n### Instruction:\n{instruction}\n\n### Input:\n{context}",
  "completion": "{response}"
}
```

According to the `template.json` file, each `.jsonl` entry of the training data must include `{instruction}`, `{context}`, and `{response}` fields.

If you provide a custom template JSON file, use the `"prompt"` and `"completion"` keys to define your own required fields. According to the following custom template JSON file, each `.jsonl` entry of the training data must include `{question}`, `{context}`, and `{answer}` fields:

```
{
  "prompt": "question: {question} context: {context}",
  "completion": "{answer}"
}
```

## Split data for training and testing

You can optionally provide another folder containing validation data. This folder should also include one or more `.jsonl` files. If no validation dataset is provided, then a set amount of the training data is set aside for validation purposes. You can adjust the percentage of training data used for validation when you choose the hyperparameters for fine-tuning your model.

## Upload fine-tuning data to Amazon S3

Upload your prepared data to Amazon Simple Storage Service (Amazon S3) to use when fine-tuning a JumpStart foundation model. You can use the following commands to upload your data:

```
from sagemaker.s3 import S3Uploader
import sagemaker
import random

output_bucket = sagemaker.Session().default_bucket()
```

```
local_data_file = "train.jsonl"
train_data_location = f"s3://{output_bucket}/dolly_dataset"
S3Uploader.upload(local_data_file, train_data_location)
S3Uploader.upload("template.json", train_data_location)
print(f"Training data: {train_data_location}")
```

## Create a training job for instruction-based fine-tuning

After your data is uploaded to Amazon S3, you can fine-tune and deploy your JumpStart foundation model. To fine-tune your model in Studio, see [Fine-tune a model in Studio](#). To fine-tune your model using the SageMaker Python SDK, see [Fine-tune publicly available foundation models with the JumpStartEstimator class](#).

### Example notebooks

For more information on instruction-based fine-tuning, see the following example notebooks:

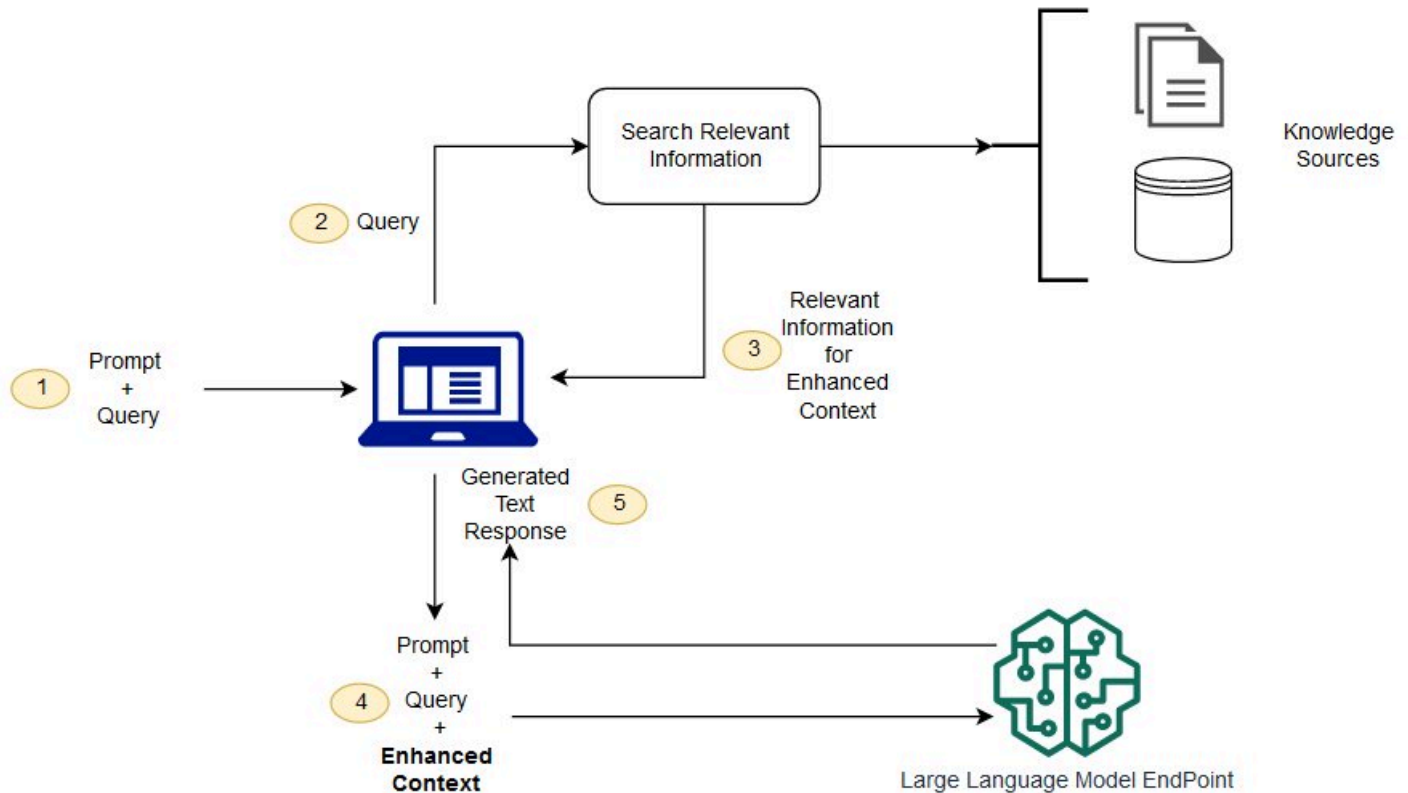

- [Fine-tune LLaMA 2 models on JumpStart](#)
- [Introduction to SageMaker JumpStart - Text Generation with Mistral models](#)
- [Introduction to SageMaker JumpStart - Text Generation with Falcon models](#)
- [SageMaker JumpStart Foundation Models - HuggingFace Text2Text Instruction Fine-Tuning](#)

## Retrieval Augmented Generation

Foundation models are usually trained offline, making the model agnostic to any data that is created after the model was trained. Additionally, foundation models are trained on very general domain corpora, making them less effective for domain-specific tasks. You can use Retrieval Augmented Generation (RAG) to retrieve data from outside a foundation model and augment your prompts by adding the relevant retrieved data in context. For more information about RAG model architectures, see [Retrieval-Augmented Generation for Knowledge-Intensive NLP Tasks](#).

With RAG, the external data used to augment your prompts can come from multiple data sources, such as a document repositories, databases, or APIs. The first step is to convert your documents and any user queries into a compatible format to perform relevancy search. To make the formats compatible, a document collection, or knowledge library, and user-submitted queries are converted to numerical representations using embedding language models. *Embedding* is the process by which text is given numerical representation in a vector space. RAG model architectures compare the embeddings of user queries within the vector of the knowledge library. The original user prompt is then appended with relevant context from similar documents within the knowledge

library. This augmented prompt is then sent to the foundation model. You can update knowledge libraries and their relevant embeddings asynchronously.

The retrieved document should be large enough to contain useful context to help augment the prompt, but small enough to fit into the maximum sequence length of the prompt. You can use task-specific JumpStart models, such as the General Text Embeddings (GTE) model from Hugging Face, to provide the embeddings for your prompts and knowledge library documents. After comparing the prompt and document embeddings to find the most relevant documents, construct a new prompt with the supplemental context. Then, pass the augmented prompt to a text generation model of your choosing.

### Example notebooks

For more information on RAG foundation model solutions, see the following example notebooks:

- [Retrieval-Augmented Generation: Question Answering using LangChain and Cohere's Generate and Embedding Models from SageMaker JumpStart](#)
- [Retrieval-Augmented Generation: Question Answering using LLama-2, Pinecone and Custom Dataset](#)

- [Retrieval-Augmented Generation: Question Answering based on Custom Dataset with Open-sourced LangChain Library](#)
- [Retrieval-Augmented Generation: Question Answering based on Custom Dataset](#)
- [Retrieval-Augmented Generation: Question Answering using Llama-2 and Text Embedding Models](#)
- [Amazon SageMaker JumpStart - Text Embedding and Sentence Similarity](#)

You can clone the [Amazon SageMaker AI examples repository](#) to run the available JumpStart foundation model examples in the Jupyter environment of your choice within Studio. For more information on applications that you can use to create and access Jupyter in SageMaker AI, see [Applications supported in Amazon SageMaker Studio](#).

## Evaluate a text generation foundation model in Studio

### Note

Foundation Model Evaluations (FMEval) is in preview release for Amazon SageMaker Clarify and is subject to change.

### Important

In order to use SageMaker Clarify Foundation Model Evaluations, you must upgrade to the new Studio experience. As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The foundation evaluation feature can only be used in the updated experience. For information about how to update Studio, see [Migration from Amazon SageMaker Studio Classic](#). For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

Amazon SageMaker JumpStart has integrations with SageMaker Clarify Foundation Model Evaluations (FMEval) in Studio. If a JumpStart model has built-in evaluation capabilities available, you can choose **Evaluate** in the upper right corner of the model detail page in the JumpStart Studio UI. For more information on navigating the JumpStart Studio UI, see [Open and use JumpStart in Studio](#),

Use Amazon SageMaker JumpStart to evaluate text-based foundation models with FMEval. You can use these model evaluations to compare model quality and responsibility metrics for one model, between two models, or between different versions of the same model, to help you quantify model risks. FMEval can evaluate text-based models that perform the following tasks:

- **Open-ended generation** – The production of natural human responses to text that does not have a pre-defined structure.
- **Text summarization** – The generation of a concise and condensed summary while retaining the meaning and key information contained in larger text.
- **Question Answering** – The generation of an answer in natural language to a question.
- **Classification** – The assignment of a class, such as positive versus negative to a text passage based on its content.

You can use FMEval to automatically evaluate model responses based on specific benchmarks. You can also evaluate model responses against your own criteria by bringing your own prompt datasets. FMEval provides a user interface (UI) that guides you through the setup and configuration of an evaluation job. You can also use the FMEval library inside your own code.

Every evaluation requires quota for two instances:

- **Hosting instance** – An instance that hosts and deploys an LLM.
- **Evaluation instance** – An instance that is used to prompt and perform an evaluation of an LLM on the hosting instance.

If your LLM is already deployed, provide the endpoint, and SageMaker AI will use your **hosting instance** to host and deploy the LLM.

If you are evaluating a JumpStart model that is not yet deployed to your account, FMEval creates a temporary **hosting instance** for you in your account, and keeps it deployed only for the length of your evaluation. FMEval uses the default instance that JumpStart recommends for the chosen LLM as your hosting instance. You must have sufficient quota for this recommended instance.

Every evaluation also uses an evaluation instance to provide prompts to and score the responses from the LLM. You must also have sufficient quota and memory to run the evaluation algorithms. The quota and memory requirements of the evaluation instance are generally smaller than those required for a hosting instance. We recommend selecting the `m1.m5.2xlarge` instance. For more

information about quota and memory, see [Resolve errors when creating a model evaluation job in Amazon SageMaker AI](#).

Automatic evaluations can be used to score LLMs across the following dimensions:

- Accuracy – For text summarization, question answering, and text classification
- Semantic robustness – For open-ended generation, text summarization and text classification tasks
- Factual knowledge – For open-ended generation
- Prompt stereotyping – For open-ended generation
- Toxicity – For open-ended generation, text summarization, and question answering

You can also use human evaluations to manually evaluate model responses. The FMEval UI guides you through a workflow of selecting one or more models, provisioning resources, and writing instructions for and contacting your human workforce. After the human evaluation is complete, the results are displayed in FMEval.

You can access model evaluation through the JumpStart landing page in Studio by selecting a model to evaluate and then choosing **Evaluate**. Note that not all JumpStart models have evaluation capabilities available. For more information about how to configure, provision and run FMEval, see [What are Foundation Model Evaluations?](#)

## Example notebooks

For step-by-step examples on how to use publicly available JumpStart foundation models with the SageMaker Python SDK, refer to the following notebooks on text generation, image generation, and model customization.

### Note

Proprietary and publicly available JumpStart foundation models have different SageMaker AI Python SDK deployment workflows. Discover proprietary foundation model example notebooks through Amazon SageMaker Studio Classic or the SageMaker AI console. For more information, see [JumpStart foundation model usage](#).

You can clone the [Amazon SageMaker AI examples repository](#) to run the available JumpStart foundation model examples in the Jupyter environment of your choice within Studio. For more

information on applications that you can use to create and access Jupyter in SageMaker AI, see [Applications supported in Amazon SageMaker Studio](#).

## Time series forecasting

You can use the Chronos models to forecast time series data. They're based on the language model architecture. Use the [Introduction to SageMaker JumpStart - Time Series Forecasting with Chronos](#) notebook to get started.

For information about the available Chronos models, see [Available foundation models](#).

## Text generation

Explore text generation example notebooks, including guidance on general text generation workflows, multilingual text classification, real-time batch inference, few-shot learning, chatbot interactions, and more.

- [SageMaker JumpStart Foundation Models - HuggingFace Text2Text Generation with FLAN-T5 XL as an example](#)
- [SageMaker JumpStart Foundation Models - BloomZ: Multilingual Text Classification, Question and Answering, Code Generation, Paragraph rephrase, and More](#)
- [SageMaker JumpStart Foundation Models - HuggingFace Text2Text Generation Batch Transform and Real-Time Batch Inference](#)
- [SageMaker JumpStart Foundation Models - GPT-J, GPT-Neo Few-shot learning](#)
- [SageMaker JumpStart Foundation Models - Chatbots](#)
- [Introduction to SageMaker JumpStart - Text Generation with Mistral models](#)
- [Introduction to SageMaker JumpStart - Text Generation with Falcon models](#)

## Image generation

Get started with text-to-image Stable Diffusion models, learn how to deploy an inpainting model, and experiment with a simple workflow to generate images of your dog.

- [Introduction to JumpStart - Text to Image](#)
- [Introduction to JumpStart Image editing - Stable Diffusion Inpainting](#)
- [Generate fun images of your dog](#)

## Model customization

Sometimes your use case requires greater foundation model customization for specific tasks. For more information on model customization approaches, see [Foundation model customization](#) or explore one of the following example notebooks.

- [SageMaker JumpStart Foundation Models - Fine-tuning text generation GPT-J 6B model on domain specific dataset](#)
- [SageMaker JumpStart Foundation Models - HuggingFace Text2Text Instruction Fine-Tuning](#)
- [Retrieval-Augmented Generation: Question Answering using LangChain and Cohere's Generate and Embedding Models from SageMaker JumpStart](#)
- [Retrieval-Augmented Generation: Question Answering using LLama-2, Pinecone and Custom Dataset](#)
- [Retrieval-Augmented Generation: Question Answering based on Custom Dataset with Open-sourced LangChain Library](#)
- [Retrieval-Augmented Generation: Question Answering based on Custom Dataset](#)
- [Retrieval-Augmented Generation: Question Answering using Llama-2 and Text Embedding Models](#)
- [Amazon SageMaker JumpStart - Text Embedding and Sentence Similarity](#)

## Private curated hubs for foundation model access control in JumpStart

Curate pretrained JumpStart foundation models for your organization with private hubs. Use the latest publicly available and proprietary foundation models while enforcing governance guardrails and ensuring that your organization can only access approved models.

Use private model hubs to share models and notebooks, centralize model artifacts, improve model discoverability, and streamline model use within your organization. Administrators can create private hubs that include subsets of models tailored to different teams, use cases, or security requirements. Administrators can create a JumpStart private model hub using the SageMaker Python SDK. Users can then browse, train, and deploy the curated set of models using Amazon SageMaker Studio or the SageMaker Python SDK.

For more information on creating a private model hub, see [Admin guide for private model hubs in Amazon SageMaker JumpStart](#).

For more information on sharing private model hubs across accounts, see [Cross-account sharing for private model hubs with AWS Resource Access Manager](#).

For more information on accessing a private model hub, see [Access curated model hubs in Amazon SageMaker JumpStart](#).

## Admin guide for private model hubs in Amazon SageMaker JumpStart

There are actions that administrators can take related to curated model hubs that users within your organization can access. This includes creating, adding, deleting, and managing access of private hubs. This page also includes information about the supported AWS Regions for curated private hubs, as well as the prerequisites needed to use curated private model hubs.

### Supported AWS Regions

Curated private hubs are currently generally available in the following AWS commercial Regions:

- us-east-1
- us-east-2
- us-west-2
- eu-west-1
- eu-central-1
- ap-northeast-1
- ap-northeast-2
- ap-south-1
- ap-southeast-1
- ap-southeast-2
- il-central-1 (SDK only)

The default maximum number of hubs allowed in a single Region is 50.

### Prerequisites

To use a curated private hub in Studio, you must have the following prerequisites:

- An AWS account with administrator access
- An AWS Identity and Access Management (IAM) role with access to Amazon SageMaker Studio
- An Amazon SageMaker AI domain with JumpStart enabled

- If your users try to use proprietary models, they must have subscriptions to those models in AWS Marketplace.
- AWS accounts that are deploying proprietary models must have subscriptions to those models in AWS Marketplace.

For more information on getting started with Studio, see [Amazon SageMaker Studio](#).

## Create a private model hub

Use the following steps to create a private hub to manage access control for pretrained JumpStart foundation models for your organization. You must install the SageMaker Python SDK and configure the necessary IAM permissions before creating a model hub.

### Create a private hub

1. Install the SageMaker Python SDK and import the necessary Python packages.

```
# Install the SageMaker Python SDK
!pip3 install sagemaker --force-reinstall --quiet

# Import the necessary Python packages
import boto3
from sagemaker import Session
from sagemaker.jumpstart.hub import Hub
```

2. Initialize a SageMaker AI Session.

```
sm_client = boto3.client('sagemaker')
session = Session(sagemaker_client=sm_client)
session.get_caller_identity_arn()
```

3. Configure the details of your private hub such as the internal hub name, UI display name, and UI hub description.

#### Note

If you do not specify an Amazon S3 bucket name when creating your hub, the SageMaker hub service creates a new bucket on your behalf. The new bucket has the following naming structure: `sagemaker-hubs-REGION-ACCOUNT_ID`.

```
HUB_NAME="Example-Hub"
HUB_DISPLAY_NAME="Example Hub UI Name"
HUB_DESCRIPTION="A description of the example private curated hub."
REGION="us-west-2"
```

4. Check that your **Admin** IAM role has the necessary Amazon S3 permissions to create a private hub. If your role does not have the necessary permissions, navigate to the **Roles** page in the IAM console. Choose the **Admin** role and then choose **Add permissions** in the **Permissions policies** pane to create an inline policy with the following permissions using the JSON editor:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "s3:ListBucket",
        "s3:GetObject",
        "s3:GetObjectTagging"
      ],
      "Resource": [
        "arn:aws:s3:::jumpstart-cache-prod-REGION",
        "arn:aws:s3:::jumpstart-cache-prod-REGION/*"
      ],
      "Effect": "Allow"
    }
  ]
}
```

5. Create a private model hub using your configurations from **Step 3** using `hub.create()`.

```
hub = Hub(hub_name=HUB_NAME, sagemaker_session=session)

try:
    # Create the private hub
    hub.create(
        description=HUB_DESCRIPTION,
        display_name=HUB_DISPLAY_NAME
    )
    print(f"Successfully created Hub with name {HUB_NAME} in {REGION}")
# Check that no other hubs with this internal name exist
except Exception as e:
```

```

if "ResourceInUse" in str(e):
    print(f"A hub with the name {HUB_NAME} already exists in your account.")
else:
    raise e

```

6. Verify the configuration of your new private hub with the following describe command:

```
hub.describe()
```

## Add models to a private hub

After creating a private hub, you can then add allow-listed models. For the full list of available JumpStart models, see the [Built-in Algorithms with pre-trained Model Table](#) in the SageMaker Python SDK reference.

1. You can filter through the available models programmatically using the `hub.list_sagemaker_public_hub_models()` method. You can optionally filter by categories such as `framework == pytorch`, tasks such as image classification (`task == ic`), and more. For more information about filters, see [notebook\\_utils.py](#). The filter parameter in the `hub.list_sagemaker_public_hub_models()` method is optional.

```

filter_value = "framework == meta"
response = hub.list_sagemaker_public_hub_models(filter=filter_value)
models = response["hub_content_summaries"]
while response["next_token"]:
    response = hub.list_sagemaker_public_hub_models(filter=filter_value,
                                                    next_token=response["next_token"])
    models.extend(response["hub_content_summaries"])

print(models)

```

2. You can then add the filtered models by specifying the model ARN in the `hub.create_model_reference()` method.

```

for model in models:
    print(f"Adding {model.get('hub_content_name')} to Hub")
    hub.create_model_reference(model_arn=model.get("hub_content_arn"),
                              model_name=model.get("hub_content_name"))

```

## Cross-account sharing for private model hubs with AWS Resource Access Manager

After creating a private model hub, you can share the hub to the necessary accounts using AWS Resource Access Manager (AWS RAM). For more information on creating a private hub, see [Create a private model hub](#). The following page gives in-depth information about managed permissions related to private hubs within AWS RAM. For information about how to create a resource share within AWS RAM, see [Set up cross-account hub sharing](#).

### Managed permissions for curated private hubs

The available access permissions are read, read and use, and full access permissions. The permission name, description, and list of specific APIs available for each permission are listed in the following:

- Read permission (`AWSRAMPermissionSageMaker_AIHubRead`): The read privilege allows resource consumer accounts to read contents in the shared hubs and view details and metadata.
  - `DescribeHub`: Retrieves details about a hub and its configuration
  - `DescribeHubContent`: Retrieves details about a model available in a specific hub
  - `ListHubContent`: Lists all models available in a hub
  - `ListHubContentVersions`: Lists the version of all models available in a hub
- Read and use permission (`AWSRAMPermissionSageMaker_AIHubReadAndUse`): The read and use privilege allows resource consumer accounts to read contents in the shared hubs and deploy available models for inference.
  - `DescribeHub`: Retrieves details about a hub and its configuration
  - `DescribeHubContent`: Retrieves details about a model available in a specific hub
  - `ListHubContent`: Lists all models available in a hub
  - `ListHubContentVersions`: Lists the version of all models available in a hub
  - `DeployHubModel`: Allows access to deploy available open-weight hub models for inference
- Full access permission (`AWSRAMPermissionSageMaker_AIHubFullAccessPolicy`): The full access privilege allows resource consumer accounts to read contents in the shared hubs, add and remove hub content, and deploy available models for inference.
  - `DescribeHub`: Retrieves details about a hub and its configuration
  - `DescribeHubContent`: Retrieves details about a model available in a specific hub
  - `ListHubContent`: Lists all models available in a hub
  - `ListHubContentVersions`: Lists the version of all models available in a hub
  - `ImportHubContent`: Imports hub content

- `DeleteHubContent`: Deletes hub content
- `CreateHubContentReference`: Creates a hub content reference that shares a model from the SageMaker AI **Public models** hub to a private hub
- `DeleteHubContentReference`: Delete a hub content reference that shares a model from the SageMaker AI **Public models** hub to a private hub
- `DeployHubModel`: Allows access to deploy available open-weight hub models for inference

`DeployHubModel` permissions are not required for proprietary models.

## Set up cross-account hub sharing

SageMaker uses [AWS Resource Access Manager \(AWS RAM\)](#) to help you securely share your private hubs across accounts. Set up cross-account hub sharing using the following instructions along with the [Sharing your AWS resources](#) instructions in the *AWS RAM User Guide*.

### Create a resource share

1. Select **Create resource share** through the [AWS RAM console](#).
2. When specifying resource share details, choose the **SageMaker Hubs** resource type and select one more private hubs that you want to share. When you share a hub with any other account, all of its contents are also shared implicitly.
3. Associate permissions with your resources share. For more information about managed permissions, see [Managed permissions for curated private hubs](#)
4. Use AWS account IDs to specify the accounts to which you want to grant access to your shared resources.
5. Review your resource share configuration and select **Create resource share**. It may take a few minutes for the resource share and principal associations to complete.

For more information, see [Sharing your AWS resources](#) in the *AWS Resource Access Manager User Guide*.

After the resource share and principal associations are set, the specified AWS accounts receive an invitation to join the resource share. The AWS accounts must accept the invite to gain access to any shared resources.

For more information on accepting a resource share invite through AWS RAM, see [Using shared AWS resources](#) in the *AWS Resource Access Manager User Guide*.

## Delete models from a private hub

You can delete models from a private hub used by your organization by specifying the model ARN in the `hub.delete_model_reference()` method. This removes access to the model from the private hub.

```
hub.delete_model_reference(model-name)
```

## Remove access to the SageMaker Public models hub

In addition to adding a private curated hub to JumpStart in Studio, you can also remove access to the SageMaker **Public models** hub for your users. The SageMaker **Public models** hub has access to all available JumpStart foundation models.

If you remove access to the SageMaker **Public models** hub and a user has access to only one private hub, then the user is taken directly into that private hub when they choose **JumpStart** in the left navigation pane in Studio. If a user has access to multiple private hubs, then the user is taken to a **Hubs** menu page when they choose **JumpStart** in the left navigation pane in Studio.

Remove access to the SageMaker **Public models** hub for your users with the following inline policy:

### Note

You can specify any additional Amazon S3 buckets that you want your hub to access in the policy below. Be sure to replace *REGION* with the Region of your hub.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": "s3:*",
      "Effect": "Deny",
      "NotResource": [
        "arn:aws:s3:::jumpstart-cache-prod-REGION/*.ipynb",
        "arn:aws:s3:::jumpstart-cache-prod-REGION/*eula*",
        "Additional-S3-bucket-ARNs-as-needed"
      ],
    },
  ],
}
```

```

        "Action": "sagemaker:*",
        "Effect": "Deny",
        "Resource": [
            "arn:aws:sagemaker:REGION:aws:hub/SageMakerPublicHub",
            "arn:aws:sagemaker:REGION:aws:hub-content/SageMakerPublicHub/*/*"
        ]
    }
]
}

```

## Delete a private hub

You can delete a private hub from your admin account. Before deleting a private hub, you must first remove any content in that hub. Delete hub contents and hubs with the following commands:

```

# List the model references in the private hub
response = hub.list_models()
models = response["hub_content_summaries"]
while response["next_token"]:
    response = hub.list_models(next_token=response["next_token"])
    models.extend(response["hub_content_summaries"])

# Delete all model references in the hub
for model in models:
    hub.delete_model_reference(model_name=model.get('HubContentName'))

# Delete the private hub
hub.delete()

```

## Troubleshooting

The following sections give information about IAM permissions issues that might arise when creating a private model hub, as well as information about how to resolve those issues.

### ValidationException when calling the CreateModel operation: Could not access model data

This exception arises when you do not have the appropriate Amazon S3 permissions configured for your **Admin** role. For more information on the Amazon S3 permissions needed to create a private hub, see **Step 3** in [Create a private model hub](#).

### Access Denied or Forbidden when calling create()

You are denied access when creating a private hub if you do not have the appropriate permissions to access the Amazon S3 bucket associated with the SageMaker **Public models** hub. For more information on the Amazon S3 permissions needed to create a private hub, see **Step 3** in [Create a private model hub](#).

## Access curated model hubs in Amazon SageMaker JumpStart

You can access a private model hub either through Studio or through the SageMaker Python SDK.

### Access your private model hub in Studio

#### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

In Amazon SageMaker Studio, open the JumpStart landing page either through the **Home** page or the **Home** menu on the left-side panel. This opens the **SageMaker JumpStart** landing page where you can explore model hubs and search for models.

- From the **Home** page, choose **JumpStart** in the **Prebuilt and automated solutions** pane.
- From the **Home** menu in the left panel, navigate to the **JumpStart** node.

For more information on getting started with Amazon SageMaker Studio, see [Amazon SageMaker Studio](#).

From the **SageMaker JumpStart** landing page in Studio, you can explore any private model hubs that include allow-listed models for your organization. If you only have access to one model hub, then the **SageMaker JumpStart** landing page takes you directly into that hub. If you have access to multiple hubs, you are taken to the **Hubs** page.

For more information on fine-tuning, deploying, and evaluating models that you have access to in Studio, see [Use foundation models in Studio](#).

## Access your private model hub using the SageMaker Python SDK

You can access your private model hub using the SageMaker Python SDK. Your access to read, use, or edit your curated hub is provided by your administrator.

### Note

If a hub is shared across accounts, then the HUB\_NAME must be the hub ARN. If a hub is not shared across accounts, then the HUB\_NAME can be the hub name.

1. Install the SageMaker Python SDK and import the necessary Python packages.

```
# Install the SageMaker Python SDK
!pip3 install sagemaker --force-reinstall --quiet

# Import the necessary Python packages
import boto3
from sagemaker import Session
from sagemaker.jumpstart.hub.hub import Hub
from sagemaker.jumpstart.model import JumpStartModel
from sagemaker.jumpstart.estimator import JumpStartEstimator
```

2. Initialize a SageMaker AI session and connect to your private hub using the hub name and Region.

```
# If a hub is shared across accounts, then the HUB_NAME must be the hub ARN
HUB_NAME="Example-Hub-ARN"
REGION="us-west-2"

# Initialize a SageMaker session
sm_client = boto3.client('sagemaker')
sm_runtime_client = boto3.client('sagemaker-runtime')
session = Session(sagemaker_client=sm_client,
                  sagemaker_runtime_client=sm_runtime_client)

# Initialize the private hub
hub = Hub(hub_name=HUB_NAME, sagemaker_session=session)
```

3. After connecting to a private hub, you can list all available models in that hub using the following commands:

```
response = hub.list_models()
models = response["hub_content_summaries"]
while response["next_token"]:
    response = hub.list_models(next_token=response["next_token"])
    models.extend(response["hub_content_summaries"])

print(models)
```

4. You can get more information about a specific model using the model name with the following command:

```
response = hub.describe_model(model_name="example-model")
print(response)
```

For more information on fine-tuning and deploying models that you have access to using the SageMaker Python SDK, see [Use foundation models with the SageMaker Python SDK](#).

## Amazon SageMaker JumpStart in Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following JumpStart features are only available in Amazon SageMaker Studio Classic.

- [Task-Specific Models](#)
- [Shared Models and Notebooks](#)
- [End-to-end JumpStart solution templates](#)
- [Amazon SageMaker JumpStart Industry: Financial](#)

## Task-Specific Models

JumpStart supports task-specific models across fifteen of the most popular problem types. Of the supported problem types, Vision and NLP-related types total thirteen. There are eight problem types that support incremental training and fine-tuning. For more information about incremental training and hyper-parameter tuning, see [SageMaker AI Automatic Model Tuning](#). JumpStart also supports four popular algorithms for tabular data modeling.

You can search and browse models from the JumpStart landing page in Studio or Studio Classic. When you select a model, the model detail page provides information about the model, and you can train and deploy your model in a few steps. The description section describes what you can do with the model, the expected types of inputs and outputs, and the data type needed for fine-tuning your model.

You can also programmatically utilize models with the [SageMaker Python SDK](#). For a list of all available models, see the [JumpStart Available Model Table](#).

The list of problem types and links to their example Jupyter notebooks are summarized in the following table.

Problem types	Supports inference with pre-trained models	Trainable on a custom dataset	Supported frameworks	Example Notebooks
Image classification	Yes	Yes	PyTorch, TensorFlow	<a href="#">Introduction to JumpStart - Image Classification</a>
Object detection	Yes	Yes	PyTorch, TensorFlow, MXNet	<a href="#">Introduction to JumpStart - Object Detection</a>
Semantic segmentation	Yes	Yes	MXNet	<a href="#">Introduction to JumpStart - Semantic Segmentation</a>

<b>Problem types</b>	<b>Supports inference with pre-trained models</b>	<b>Trainable on a custom dataset</b>	<b>Supported frameworks</b>	<b>Example Notebooks</b>
Instance segmentation	Yes	Yes	MXNet	<a href="#">Introduction to JumpStart - Instance Segmentation</a>
Image embedding	Yes	No	TensorFlow, MXNet	<a href="#">Introduction to JumpStart - Image Embedding</a>
Text classification	Yes	Yes	TensorFlow	<a href="#">Introduction to JumpStart - Text Classification</a>
Sentence pair classification	Yes	Yes	TensorFlow, Hugging Face	<a href="#">Introduction to JumpStart - Sentence Pair Classification</a>

## Deploy a Model

When you deploy a model from JumpStart, SageMaker AI hosts the model and deploys an endpoint that you can use for inference. JumpStart also provides an example notebook that you can use to access the model after it's deployed.

### Important

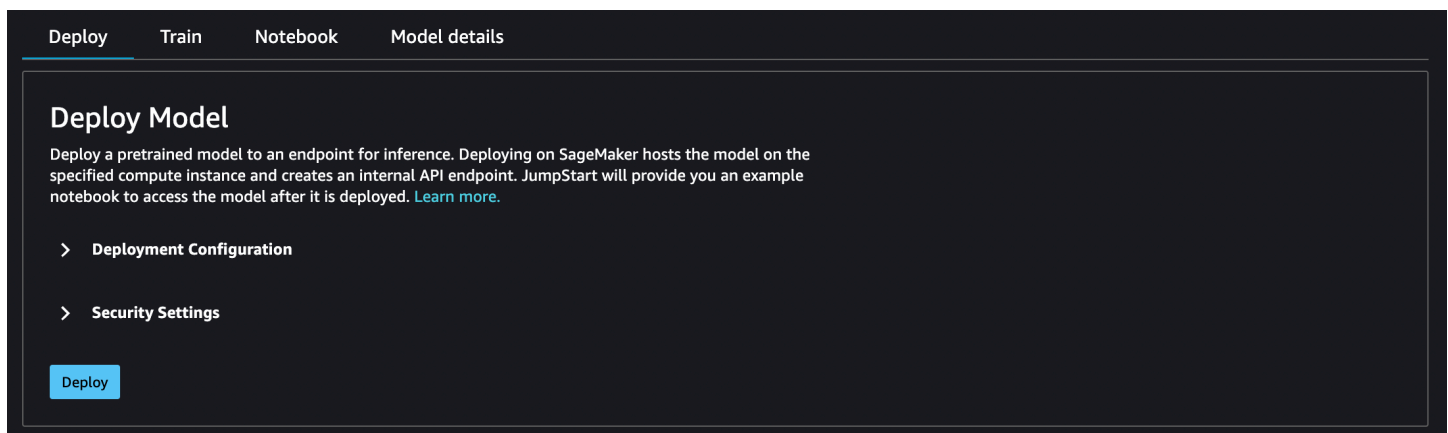

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

### Note

For more information on JumpStart model deployment in Studio, see [Deploy a model in Studio](#)

## Model deployment configuration

After you choose a model, the model's tab opens. In the **Deploy Model** pane, choose **Deployment Configuration** to configure your model deployment.

The default instance type for deploying a model depends on the model. The instance type is the hardware that the training job runs on. In the following example, the `m1.p2.xlarge` instance is the default for this particular BERT model.

You can also change the endpoint name, add `key;value` resource tags, activate or deactivate the `jumpstart` - prefix for any JumpStart resources related to the model, and specify an Amazon S3 bucket for storing model artifacts used by your SageMaker AI endpoint.

### Deployment Configuration

Customize the machine type and endpoint name. [Learn more.](#)

SageMaker hosting instance ⓘ

ml.p2.xlarge ▼

Endpoint name

tf-tc-bert-en-uncased-l-12-h-768-a-12-2

Custom resource tags ⓘ

*key;value* Add

Use JumpStart prefix ⓘ

Custom model artifact S3 bucket ⓘ

Default model artifact S3 bucket     Find S3 bucket     Enter S3 bucket location

The model artifact used by your SageMaker endpoint will be stored in your SageMaker default bucket.

*s3://sagemaker-us-west-2-671655899342*

Reset to default

Choose **Security Settings** to specify the AWS Identity and Access Management (IAM ) role, Amazon Virtual Private Cloud (Amazon VPC), and encryption keys for the model.

## Security Settings

This model runs in network isolation. [Learn more.](#)

Specify the IAM role that Amazon SageMaker should use to deploy your model. [Learn more.](#)

Default IAM role    Find IAM role    Input IAM role

Amazon SageMaker will deploy your model using your Studio execution role.

Specify whether your model should connect to a virtual private cloud (VPC). [Learn more.](#)

No VPC    Find VPC    Input VPC

No VPC will be used to access your model container.

Specify the encryption keys to secure your data. [Learn more.](#)

Default encryption keys    Find encryption keys    Input encryption keys

Encrypt your model artifact at rest using your account's default KMS key for S3. [Learn more.](#)

## Model deployment security

When you deploy a model with JumpStart, you can specify an IAM role, Amazon VPC, and encryption keys for the model. If you don't specify any values for these entries: The default IAM role is your Studio Classic runtime role; default encryption is used; no Amazon VPC is used.

### IAM role

You can select an IAM role that is passed as part of training jobs and hosting jobs. SageMaker AI uses this role to access training data and model artifacts. If you don't select an IAM role, SageMaker AI deploys the model using your Studio Classic runtime role. For more information about IAM roles, see [AWS Identity and Access Management for Amazon SageMaker AI](#).

The role that you pass must have access to the resources that the model needs, and must include all of the following.

- For training jobs: [CreateTrainingJob API: Execution Role Permissions](#).
- For hosting jobs: [CreateModel API: Execution Role Permissions](#).

**Note**

You can scope down the Amazon S3 permissions granted in each of the following roles. Do this by using the ARN of your Amazon Simple Storage Service (Amazon S3) bucket and the JumpStart Amazon S3 bucket.

```
[
  {
    "Effect": "Allow",
    "Action": [
      "s3:GetObject",
      "s3:ListBucket"
    ],
    "Resource": [
      "arn:aws:s3:::jumpstart-cache-prod-<region>/*",
      "arn:aws:s3:::jumpstart-cache-prod-<region>",
      "arn:aws:s3:::<bucket>/*"
    ]
  },
  {
    "Effect": "Allow",
    "Action": [
      "cloudwatch:PutMetricData",
      "logs:CreateLogStream",
      "logs:PutLogEvents",
      "logs:CreateLogGroup",
      "logs:DescribeLogStreams",
      "ecr:GetAuthorizationToken"
    ],
    "Resource": [
      "*"
    ]
  },
  {
    "Effect": "Allow",
    "Action": [
      "ecr:BatchGetImage",
      "ecr:BatchCheckLayerAvailability",
      "ecr:GetDownloadUrlForLayer"
    ],
    "Resource": [
      "*"
    ]
  }
]
```

```

    },
  ]
}

```

## Find IAM role

If you select this option, you must select an existing IAM role from the dropdown list.

**Specify the IAM role that Amazon SageMaker should use to deploy your model. [Learn more.](#)**

Default IAM role
  Find IAM role
  Input IAM role

Amazon SageMaker will deploy your model using the IAM role you select below.

**Execution role** ⓘ

Select... ▼

## Input IAM role

If you select this option, you must manually enter the ARN for an existing IAM role. If your Studio Classic runtime role or Amazon VPC block the `iam:list*` call, you must use this option to use an existing IAM role.

**Specify the IAM role that Amazon SageMaker should use to deploy your model. [Learn more.](#)**

Default IAM role
  Find IAM role
  Input IAM role

Amazon SageMaker will deploy your model using the IAM role you type below.

**Execution role arn** ⓘ

`arn:aws:iam::account-id:role/role-name`

## Amazon VPC

All JumpStart models run in network isolation mode. After the model container is created, no more calls can be made. You can select an Amazon VPC that is passed as part of training jobs and

hosting jobs. SageMaker AI uses this Amazon VPC to push and pull resources from your Amazon S3 bucket. This Amazon VPC is different from the Amazon VPC that limits access to the public internet from your Studio Classic instance. For more information about the Studio Classic Amazon VPC, see [Connect Studio notebooks in a VPC to external resources](#).

The Amazon VPC that you pass does not need access to the public internet, but it does need access to Amazon S3. The Amazon VPC endpoint for Amazon S3 must allow access to at least the following resources that the model needs.

```
{
  "Effect": "Allow",
  "Action": [
    "s3:GetObject",
    "s3:PutObject",
    "s3:ListMultipartUploadParts",
    "s3:ListBucket"
  ],
  "Resources": [
    "arn:aws:s3:::jumpstart-cache-prod-<region>/*",
    "arn:aws:s3:::jumpstart-cache-prod-<region>",
    "arn:aws:s3:::bucket/*"
  ]
}
```

If you do not select an Amazon VPC, no Amazon VPC is used.

## Find VPC

If you select this option, you must select an existing Amazon VPC from the dropdown list. After you select an Amazon VPC, you must select a subnet and security group for your Amazon VPC. For more information about subnets and security groups, see [Overview of VPCs and subnets](#).

**Specify whether your model should connect to a virtual private cloud (VPC). [Learn more.](#)**

No VPC    Find VPC    Input VPC

The VPC you select below will control access to and from your model container.

**VPC ID** ⓘ

Select...

## Input VPC

If you select this option, you must manually select the subnet and security group that compose your Amazon VPC. If your Studio Classic runtime role or Amazon VPC blocks the `ec2:list*` call, you must use this option to select the subnet and security group.

**Specify whether your model should connect to a virtual private cloud (VPC).** [Learn more.](#)

No VPC    Find VPC    Input VPC

The subnets and security groups you type below will control access to and from your model container.

Subnet(s) ⓘ

Security group(s) ⓘ

## Encryption keys

You can select an AWS KMS key that is passed as part of training jobs and hosting jobs. SageMaker AI uses this key to encrypt the Amazon EBS volume for the container, and the repackaged model in Amazon S3 for hosting jobs and the output for training jobs. For more information about AWS KMS keys, see [AWS KMS keys](#).

The key that you pass must trust the IAM role that you pass. If you do not specify an IAM role, the AWS KMS key must trust your Studio Classic runtime role.

If you do not select an AWS KMS key, SageMaker AI provides default encryption for the data in the Amazon EBS volume and the Amazon S3 artifacts.

## Find encryption keys

If you select this option, you must select existing AWS KMS keys from the dropdown list.

### Specify the encryption keys to secure your data. [Learn more.](#)

### Configure default values for JumpStart models

You can configure default values for parameters such as IAM roles, VPCs, and KMS keys to pre-populate for JumpStart model deployment and training. After configuring default values, the Studio Classic UI automatically provides your specified security settings and tags to JumpStart

models to simplify deployment and training workflows. Administrators and end-users can initialize default values specified in a configuration file in YAML format.

By default, the SageMaker Python SDK uses two configuration files: one for the administrator and one for the user. Using the administrator configuration file, administrators can define a set of default values. End-users can override values set in the administrator configuration file and set additional default values using the end-user configuration file. For more information, see [Default configuration file location](#).

The following code sample lists the default locations of the configuration files when using the SageMaker Python SDK in Amazon SageMaker Studio Classic.

```
# Location of the admin config file
/etc/xdg/sagemaker/config.yaml

# Location of the user config file
/root/.config/sagemaker/config.yaml
```

Values specified in the user configuration file override values set in the administrator configuration file. The configuration file is unique to each user profile within an Amazon SageMaker AI domain. The user profile's Studio Classic application is directly associated with the user profile. For more information, see [Domain user profiles](#).

Administrators can optionally set configuration defaults for JumpStart model training and deployment through JupyterServer lifecycle configurations. For more information, see [Create and associate a lifecycle configuration](#).

### Default value configuration YAML file

Your configuration file should adhere to the SageMaker Python SDK [configuration file structure](#). Note that specific fields in the TrainingJob, Model, and EndpointConfig configurations apply to JumpStart model training and deployment default values.

```
SchemaVersion: '1.0'

```

## Fine-Tune a Model

Fine-tuning trains a pretrained model on a new dataset without training from scratch. This process, also known as transfer learning, can produce accurate models with smaller datasets and less training time. You can fine-tune a model if its card shows a **fine-tunable** attribute set to **Yes**.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

### Note

For more information on JumpStart model fine-tuning in Studio, see [Fine-tune a model in Studio](#)

## Fine-Tuning data source

When you fine-tune a model, you can use the default dataset or choose your own data, which is located in an Amazon S3 bucket.

To browse the buckets available to you, choose **Find S3 bucket**. These buckets are limited by the permissions used to set up your Studio Classic account. You can also specify an Amazon S3 URI by choosing **Enter Amazon S3 bucket location**.

## Train Model

Create a training job to fit this model to your own data. This model is pretrained, you will fine-tune its parameters instead of starting from scratch. Fine-tuning can produce accurate models with smaller datasets and less training time. [Learn more](#).

- > **Data Source**
- > **Deployment Configuration**
- > **Hyper-parameters**
- > **Security Settings**

**Train**

### Tip

To find out how to format the data in your bucket, choose **Learn more**. The description section for the model has detailed information about inputs and outputs.

For text models:

- The bucket must have a data.csv file.
- The first column must be a unique integer for the class label. For example: 1, 2, 3, 4, n
- The second column must be a string.
- The second column should have the corresponding text that matches the type and language for the model.

For vision models:

- The bucket must have as many subdirectories as the number of classes.
- Each subdirectory should contain images that belong to that class in .jpg format.

**Note**

The Amazon S3 bucket must be in the same AWS Region where you're running SageMaker Studio Classic because SageMaker AI doesn't allow cross-Region requests.

## Fine-Tuning deployment configuration

The p3 family is recommended as the fastest for deep learning training, and this is recommended for fine-tuning a model. The following chart shows the number of GPUs in each instance type. There are other available options that you can choose from, including p2 and g4 instance types.

Instance type	GPUs
p3.2xlarge	1
p3.8xlarge	4
p3.16xlarge	8
p3dn.24xlarge	8

## Hyperparameters

You can customize the hyperparameters of the training job that are used to fine-tune the model. The hyperparameters available for each fine-tunable model differ depending on the model. For information on each available hyperparameter, reference the hyperparameters documentation for the model of your choosing in [Built-in algorithms and pretrained models in Amazon SageMaker](#). For example, see [Image Classification - TensorFlow Hyperparameters](#) for details on the fine-tunable Image Classification - TensorFlow hyperparameters.

If you use the default dataset for text models without changing the hyperparameters, you get a nearly identical model as a result. For vision models, the default dataset is different from the dataset used to train the pretrained models, so your model is different as a result.

The following hyperparameters are common among models:

- **Epochs** – One epoch is one cycle through the entire dataset. Multiple intervals complete a batch, and multiple batches eventually complete an epoch. Multiple epochs are run until the accuracy of the model reaches an acceptable level, or when the error rate drops below an acceptable level.
- **Learning rate** – The amount that values should be changed between epochs. As the model is refined, its internal weights are being nudged and error rates are checked to see if the model improves. A typical learning rate is 0.1 or 0.01, where 0.01 is a much smaller adjustment and could cause the training to take a long time to converge, whereas 0.1 is much larger and can cause the training to overshoot. It is one of the primary hyperparameters that you might adjust for training your model. Note that for text models, a much smaller learning rate (5e-5 for BERT) can result in a more accurate model.
- **Batch size** – The number of records from the dataset that is to be selected for each interval to send to the GPUs for training.

In an image example, you might send out 32 images per GPU, so 32 would be your batch size. If you choose an instance type with more than one GPU, the batch is divided by the number of GPUs. Suggested batch size varies depending on the data and the model that you are using. For example, how you optimize for image data differs from how you handle language data.

In the instance type chart in the deployment configuration section, you can see the number of GPUs per instance type. Start with a standard recommended batch size (for example, 32 for a vision model). Then, multiply this by the number of GPUs in the instance type that you selected. For example, if you're using a `p3.8xlarge`, this would be 32(batch size) multiplied by 4 (GPUs), for a total of 128, as your batch size adjusts for the number of GPUs. For a text model like BERT, try starting with a batch size of 64, and then reduce as needed.

## Training output

When the fine-tuning process is complete, JumpStart provides information about the model: parent model, training job name, training job ARN, training time, and output path. The output path is where you can find your new model in an Amazon S3 bucket. The folder structure uses the model name that you provided and the model file is in an `/output` subfolder and it's always named `model.tar.gz`.

Example: `s3://bucket/model-name/output/model.tar.gz`

## Configure default values for model training

You can configure default values for parameters such as IAM roles, VPCs, and KMS keys to pre-populate for JumpStart model deployment and training. For more information, see, [Configure default values for JumpStart models](#).

## Share Models

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

You can share JumpStart models through the Studio Classic UI directly from the **Launched JumpStart assets** page using the following procedure:

1. Open Amazon SageMaker Studio Classic and choose **Launched JumpStart assets** in the **JumpStart** section of the lefthand navigation pane.
2. Select the **Training jobs** tab to view the list of your model training jobs.
3. Under the **Training jobs** list, select the training job that you want to share. This opens the training job details page. You cannot share more than one training job at a time.
4. In the header for the training job, choose **Share**, and select **Share with my organization**.

For more information about sharing models with your organization, see [Shared Models and Notebooks](#).

## Shared Models and Notebooks

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Share your models and notebooks to centralize model artifacts, facilitate discoverability, and increase the reuse of models within your organization. When sharing your models, you can provide training and inference environment information and allow collaborators to use these environments for their own training and inference jobs.

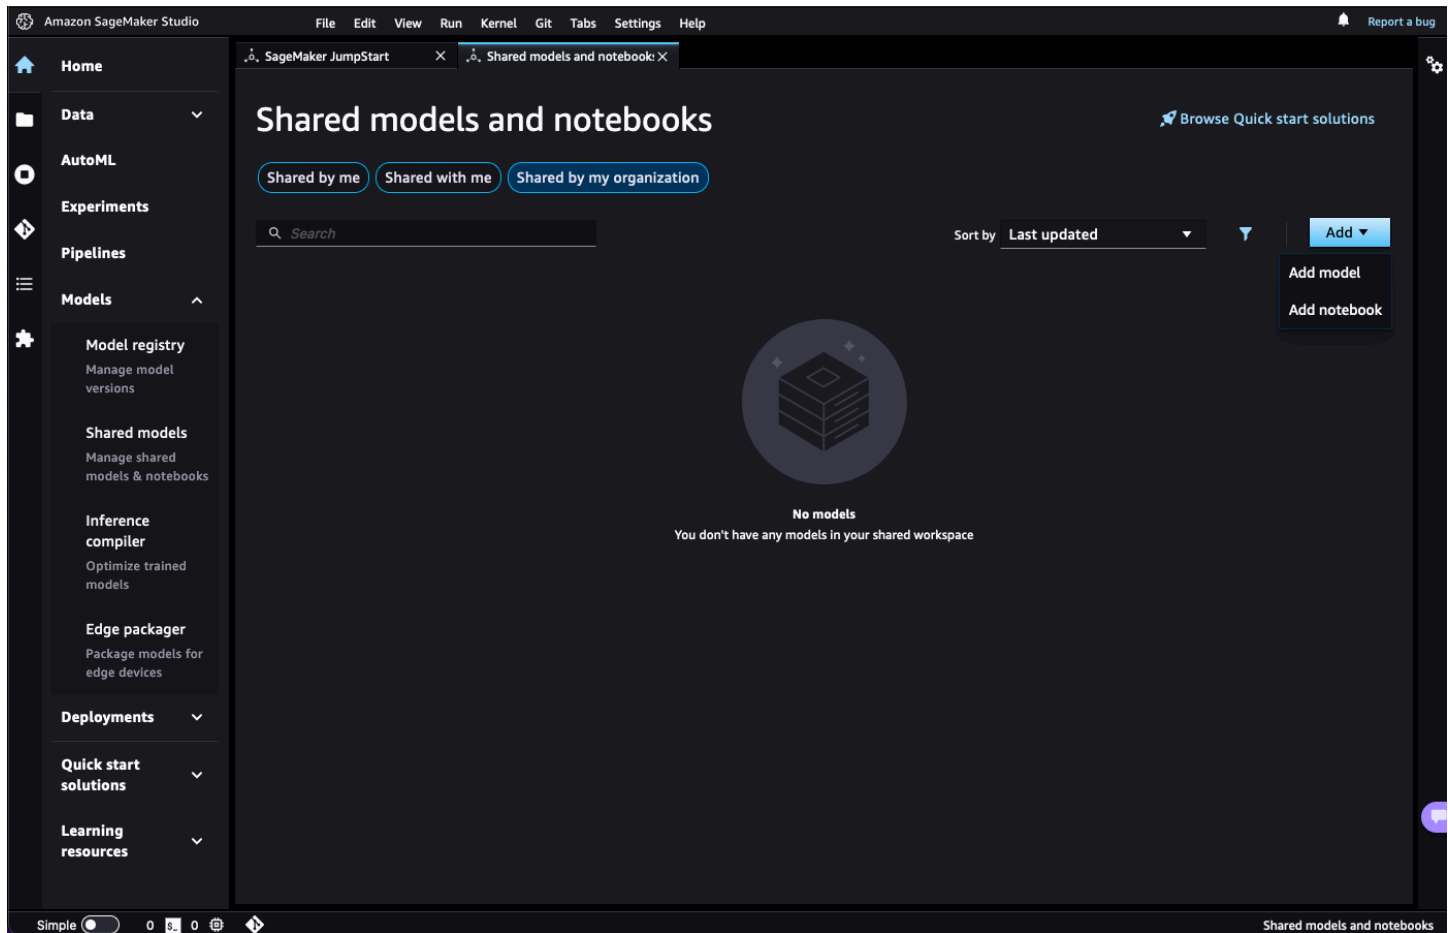

All models that you share and models that are shared with you are searchable in a centralized location directly in Amazon SageMaker Studio Classic. For information on the onboarding steps to sign into Amazon SageMaker Studio Classic, see [Onboard to Amazon SageMaker AI Domain](#).

## Topics

- [Model and notebook sharing](#)
- [Access shared content](#)
- [Add a model](#)

## Model and notebook sharing

To share models and notebooks, navigate to the **Shared models** section in Amazon SageMaker Studio Classic, choose **Shared by my organization**, and then select the **Add** dropdown list. Choose to either add a model or add a notebook.

## Access shared content

From the Amazon SageMaker Studio Classic UI, you can access shared content and filter what you see.

There are three main options for filtering shared models and notebooks:

1. **Shared by me** – Models and notebooks that you shared to JumpStart.
2. **Shared with me** – Models and notebooks shared with you
3. **Shared by my organization** – All models and notebooks that are shared to anyone in your organization

You can also sort your models and notebooks based on the time they were last updated or by ascending or descending alphabetical order. Choose the filter icon

to further sort your selections.

## Add a model

To add a model, choose **Shared by my organization**, and then select **Add model** from the **Add** dropdown list. Enter the basic information for your model, and add any training or inference information you want to share with collaborators to train or deploy your model. After you enter all the necessary information, choose **Add model** in the lower right corner of the screen.

### Topics

- [Add basic information](#)
- [Enable training](#)
- [Enable deployment](#)
- [Add a notebook](#)

### Add basic information

Adding a model in JumpStart involves providing some basic information about the model you want to train. This information helps define the characteristics and capabilities of your model, as well as improving its discoverability and searchability. To create a new model, follow these steps:

1. Add a title for this model. Adding a title automatically populates a unique identifier in the ID field based on the model title.
2. Add a description of the model.
3. Select a data type from the options: *text*, *vision*, *tabular*, or *audio*.
4. Select a machine learning task from the list of available tasks, such as *image classification* or *text generation*.
5. Select a machine learning framework.
6. Add metadata information with keywords or phrases to use when searching for a model. Use commas to separate keywords. Any spaces are automatically replaced with commas.

### Enable training

When adding a model to share, you can optionally provide a training environment and allow collaborators in your organization to train the shared model.

**Note**

If you are adding a tabular model, you also need to specify a column format and target column to enable training.

After providing the basic details about your model, you'll need to configure the settings for the training job that will be used to train your model. This involves specifying the container environment, code scripts, datasets, output locations, and various other parameters to control how the training job is executed. To configure the training job settings, follow these steps:

1. Add a container to use for model training. You can select a container used for an existing training job, bring your own container in Amazon ECR, or use an Amazon SageMaker Deep Learning Container.
2. Add environment variables.
3. Provide a training script location.
4. Provide a script mode entry point.
5. Provide an Amazon S3 URI for model artifacts generated during training.
6. Provide the Amazon S3 URI to the default training dataset.
7. Provide a model output path. The model output path should be the Amazon S3 URI path for any model artifacts generated from training. SageMaker AI saves the model artifacts as a single compressed TAR file in Amazon S3.
8. Provide a validation dataset to use for evaluating your model during training. Validation datasets must contain the same number of columns and the same feature headers as the training dataset.
9. Turn on network isolation. Network isolation isolates the model container so that no inbound or outbound network calls can be made to or from the model container.
10. Provide training channels through which SageMaker AI can access your data. For example, you might specify input channels named `train` or `test`. For each channel, specify a channel name and a URI to the location of your data. Choose **Browse** to search for Amazon S3 locations.
11. Provide hyperparameters. Add any hyperparameters with which collaborators should experiment during training. Provide a range of valid values for these hyperparameters. This range is used for training job hyperparameter validation. You can define ranges based on the datatype of the hyperparameter.

12. Select an instance type. We recommend a GPU instance with more memory for training with large batch sizes. For a comprehensive list of SageMaker training instances across AWS Regions, see the **On-Demand Pricing** table in [Amazon SageMaker Pricing](#).
13. Provide metrics. Define metrics for a training job by specifying a name and a regular expression for each metric that your training monitors. Design the regular expressions to capture the values of metrics that your algorithm emits. For example, the metric `Loss` might have the regular expression `"Loss = (. *?);"`.

## Enable deployment

When adding a model to share, you can optionally provide an inference environment in which collaborators in your organization can deploy the shared model for inference.

After training your machine learning model, you'll need to deploy it to an Amazon SageMaker AI endpoint for inference. This involves providing a container environment, an inference script, the model artifacts generated during training, and selecting an appropriate compute instance type. Configuring these settings properly is crucial for ensuring your deployed model can make accurate predictions and handle inference requests efficiently. To set up your model for inference, follow these steps:

1. Add a container to use for inference. You can bring your own container in Amazon ECR or use an Amazon SageMaker Deep Learning Container.
2. Provide the Amazon S3 URI to an inference script. Custom inference scripts run inside your chosen container. Your inference script should include a function for model loading, and optionally functions generating predictions, and input and output processing. For more information on creating inference scripts for the framework of your choice, see [Frameworks](#) in the SageMaker Python SDK documentation. For example, for TensorFlow, see [How to implement the pre- and/or post-processing handler\(s\)](#).
3. Provide an Amazon S3 URI for model artifacts. Model artifacts are the output that results from training a model, and typically consist of trained parameters, a model definition that describes how to compute inferences, and other metadata. If you trained your model in SageMaker AI, the model artifacts are saved as a single compressed TAR file in Amazon S3. If you trained your model outside SageMaker AI, you need to create this single compressed TAR file and save it in an Amazon S3 location.
4. Select an instance type. We recommend a GPU instance with more memory for training with large batch sizes. For a comprehensive list of SageMaker training instances across AWS Regions, see the **On-Demand Pricing** table in [Amazon SageMaker Pricing](#).

## Add a notebook

To add a notebook, choose **Shared by my organization**, and then select **Add notebook** from the **Add** dropdown list. Enter the basic information for your notebook and provide an Amazon S3 URI for the location of that notebook.

First, add the basic descriptive information about your notebook. This information is used to improve the searchability of your notebook.

1. Add a title for this notebook. Adding a title automatically populates a unique identifier in the ID field based on the notebook title.
2. Add a description of the notebook.
3. Select a data type from the options: *text*, *vision*, *tabular*, or *audio*.
4. Select an ML task from the list of available tasks, such as *image classification* or *text generation*.
5. Select an ML framework.
6. Add metadata information with keywords or phrases to use when searching for a notebook. Use commas to separate keywords. Any spaces are automatically replaced with commas.

After you've specified the basic information, you can provide an Amazon S3 URI for the location of that notebook. You can choose **Browse** to search through your Amazon S3 buckets for your notebook file location. After you find your notebook, copy the Amazon S3 URI, choose **Cancel**, and then add the Amazon S3 URI to the **Notebook Location** field.

After you enter all the necessary information, choose **Add notebook** in the lower right corner.

## End-to-end JumpStart solution templates

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

**Note**

JumpStart Solutions are only available in Studio Classic.

SageMaker JumpStart provides one-click, end-to-end solutions that are designed to address common machine learning use cases. They use proven algorithms for their domains and provide a complete workflow which typically includes data processing, model training, deployment, inference, and monitoring. Explore the following use cases for more information on available solution templates.

- [Demand forecasting](#)
- [Credit rating prediction](#)
- [Fraud detection](#)
- [Computer vision](#)
- [Extract and analyze data from documents](#)
- [Predictive maintenance](#)
- [Churn prediction](#)
- [Personalized recommendations](#)
- [Reinforcement learning](#)
- [Healthcare and life sciences](#)
- [Financial pricing](#)
- [Causal inference](#)

Choose the solution template that best fits your use case from the JumpStart landing page. When you choose a solution template, JumpStart opens a new tab showing a description of the solution and a **Launch** button. When you select **Launch**, JumpStart creates all of the resources that you need to run the solution, including training and model hosting instances. For more information on launching a JumpStart solution, see [the section called "Launch a Solution"](#).

After launching the solution, you can explore solution features and any generated artifacts in JumpStart. Use the **Launched JumpStart assets** menu to find your solution. In your solution's tab, select **Open Notebook** to use provided notebooks and explore the solution's features. When artifacts are generated during launch or after running the provided notebooks, they're

listed in the **Generated Artifacts** table. You can delete individual artifacts with the trash icon

).

You can delete all of the solution's resources by choosing **Delete solution resources**.

## Demand forecasting

Demand forecasting uses historical time series data in order to make future estimations in relation to customer demand over a specific period and streamline the supply-demand decision-making process across businesses.

Demand forecasting use cases include predicting ticket sales in the transportation industry, stock prices, number of hospital visits, number of customer representatives to hire for multiple locations in the next month, product sales across multiple regions in the next quarter, cloud server usage for the next day for a video streaming service, electricity consumption for multiple regions over the next week, number of IoT devices and sensors such as energy consumption, and more.

Time series data is categorized as *univariate* and *multi-variate*. For example, the total electricity consumption for a single household is a univariate time series over a period of time. When multiple univariate time series are stacked on each other, it's called a multi-variate time series. For example, the total electricity consumption of 10 different (but correlated) households in a single neighborhood make up a multi-variate time series dataset.

Solution name	Description	Get started
Demand forecasting	Demand forecasting for multivariate time series data using three state-of-the-art time series forecasting algorithms: <a href="#">LSTNet</a> , <a href="#">Prophet</a> , and <a href="#">SageMaker AI DeepAR</a> .	<a href="#">GitHub »</a>

## Credit rating prediction

Use JumpStart's credit rating prediction solutions to predict corporate credit ratings or to explain credit prediction decisions made by machine learning models. Compared to traditional credit rating modeling methods, machine learning models can automate and improve the accuracy of credit prediction.

Solution name	Description	Get started
Corporate credit rating prediction	Multimodal (long text and tabular) machine learning for quality credit predictions using AWS <a href="#">AutoGluon Tabular</a> .	<a href="#">GitHub »</a>
Graph-based credit scoring	Predict corporate credit ratings using tabular data and a corporate network by training a <a href="#">Graph Neural Network GraphSAGE</a> and AWS <a href="#">AutoGluon Tabular</a> model.	Find in Amazon SageMaker Studio Classic.
Explain credit decisions	Predict credit default in credit applications and provide explanations using <a href="#">LightGBM</a> and <a href="#">SHAP (SHapley Additive exPlanations)</a> .	<a href="#">GitHub »</a>

## Fraud detection

Many businesses lose billions annually to fraud. Machine learning based fraud detection models can help systematically identify likely fraudulent activities from a tremendous amount of data. The following solutions use transaction and user identity datasets to identify fraudulent transactions.

Solution name	Description	Get started
Detect malicious users and transactions	Automatically detect potentially fraudulent activity in transactions using <a href="#">SageMaker AI XGBoost</a> with the over-sampling technique <a href="#">Synthetic Minority Over-sampling (SMOTE)</a> .	<a href="#">GitHub »</a>

Solution name	Description	Get started
Fraud detection in financial transactions using deep graph library	Detect fraud in financial transactions by training a <a href="#">graph convolutional network</a> with the <a href="#">deep graph library</a> and a <a href="#">SageMaker AI XGBoost</a> model.	<a href="#">GitHub »</a>
Financial payment classification	Classify financial payments based on transaction information using <a href="#">SageMaker AI XGBoost</a> . Use this solution template as an intermediate step in fraud detection, personalization, or anomaly detection.	Find in Amazon SageMaker Studio Classic.

## Computer vision

With the rise of business use cases such as autonomous vehicles, smart video surveillance, healthcare monitoring and various object counting tasks, fast and accurate object detection systems are rising in demand. These systems involve not only recognizing and classifying every object in an image, but localizing each one by drawing the appropriate bounding box around it. In the last decade, the rapid advances of deep learning techniques greatly accelerated the momentum of object detection.

Solution name	Description	Get started
Visual product defect detection	Identify defective regions in product images either by training an <a href="#">object detection model from scratch</a> or fine-tuning pretrained SageMaker AI models.	<a href="#">GitHub »</a>

Solution name	Description	Get started
Handwriting recognition	Recognize handwritten text in images by training an <a href="#">object detection model</a> and <a href="#">handwriting recognition model</a> . Label your own data using <a href="#">SageMaker Ground Truth</a> .	<a href="#">GitHub »</a>
Object detection for bird species	Identify birds species in a scene using a <a href="#">SageMaker AI object detection model</a> .	Find in Amazon SageMaker Studio Classic.

## Extract and analyze data from documents

JumpStart provides solutions for you to uncover valuable insights and connections in business-critical documents. Use cases include text classification, document summarization, handwriting recognition, relationship extraction, question and answering, and filling in missing values in tabular records.

Solution name	Description	Get started
Privacy for sentiment classification	<a href="#">Anonymize text</a> to better preserve user privacy in sentiment classification.	<a href="#">GitHub »</a>
Document understanding	Document summarization, entity, and relationship extraction using the <a href="#">transformers</a> library in PyTorch.	<a href="#">GitHub »</a>
Handwriting recognition	Recognize handwritten text in images by training an <a href="#">object detection model</a> and <a href="#">handwriting recognition</a>	<a href="#">GitHub »</a>

Solution name	Description	Get started
	<a href="#">model</a> . Label your own data using <a href="#">SageMaker Ground Truth</a> .	
Filling in missing values in tabular records	Fill missing values in tabular records by training a <a href="#">SageMaker Autopilot</a> model.	<a href="#">GitHub »</a>

## Predictive maintenance

Predictive maintenance aims to optimize the balance between corrective and preventative maintenance by facilitating the timely replacement of components. The following solutions use sensor data from industrial assets to predict machine failures, unplanned downtime, and repair costs.

Solution name	Description	Get started
Predictive maintenance for vehicle fleets	Predict vehicle fleet failures using vehicle sensor and maintenance information with a convolutional neural network model.	<a href="#">GitHub »</a>
Predictive maintenance for manufacturing	Predict the remaining useful life for each sensor by training a <a href="#">stacked Bidirectional LSTM neural network</a> model using historical sensor readings.	<a href="#">GitHub »</a>

## Churn prediction

Customer churn, or rate of attrition, is a costly problem faced by a wide range of companies. In an effort to reduce churn, companies can identify customers that are likely to leave their service in order to focus their efforts on customer retention. Use a JumpStart churn prediction solution to

analyze data sources such as user behavior and customer support chat logs to identify customers that are at a high risk of cancelling a subscription or service.

Solution name	Description	Get started
Churn prediction with text	Predict churn using numerical , categorical, and textual features with <a href="#">BERT encoder</a> and <a href="#">RandomForestClassifier</a> .	<a href="#">GitHub »</a>
Churn prediction for mobile phone customers	Identify unhappy mobile phone customers using <a href="#">SageMaker AI XGBoost</a> .	Find in Amazon SageMaker Studio Classic.

## Personalized recommendations

You can use JumpStart solutions to analyze customer identity graphs or user sessions to better understand and predict customer behavior. Use the following solutions for personalized recommendations to model customer identity across multiple devices, to determine the likelihood of a customer making a purchase, or to create a custom movie recommender based on past customer behavior.

Solution name	Description	Get started
Entity resolution in identity graphs with deep graph library	Perform cross-device entity linking for online advertising by training a <a href="#">graph convolutional network</a> with <a href="#">deep graph library</a> .	<a href="#">GitHub »</a>
Purchase modeling	Predict whether a customer will make a purchase by training a <a href="#">SageMaker AI XGBoost</a> model.	<a href="#">GitHub »</a>
Customized recommender system	Train and deploy a custom recommender system that	Find in Amazon SageMaker Studio Classic.

Solution name	Description	Get started
	generates movie suggestions for a customer based on past behavior using Neural Collaborative Filtering in SageMaker AI.	

## Reinforcement learning

Reinforcement learning (RL) is a type of learning that is based on interaction with the environment. This type of learning is used by an agent that must learn behavior through trial-and-error interactions with a dynamic environment in which the goal is to maximize the long-term rewards that the agent receives as a result of its actions. Rewards are maximized by trading off exploring actions that have uncertain rewards with exploiting actions that have known rewards.

RL is well-suited for solving large, complex problems, such as supply chain management, HVAC systems, industrial robotics, game artificial intelligence, dialog systems, and autonomous vehicles.

Solution name	Description	Get started
Reinforcement learning for Battlesnake AI competitions	Provide a reinforcement learning workflow for training and inference with the <a href="#">BattleSnake</a> AI competitions.	<a href="#">GitHub »</a>
Distributed reinforcement learning for Procggen challenge	Distributed reinforcement learning starter kit for <a href="#">NeurIPS 2020 Procggen</a> Reinforcement learning challenge.	<a href="#">GitHub »</a>

## Healthcare and life sciences

Clinicians and researchers can use JumpStart solutions to analyze medical imagery, genomic information, and clinical health records.

Solution name	Description	Get started
Lung cancer survival prediction	Predict non-small cell lung cancer patient survival status with 3-dimensional lung computerized tomography (CT) scans, genomic data, and clinical health records using <a href="#">SageMaker AI XGBoost</a> .	<a href="#">GitHub »</a>

## Financial pricing

Many businesses dynamically adjust pricing on a regular basis in order to maximize their returns. Use the following JumpStart solutions for price optimization, dynamic pricing, option pricing, or portfolio optimization use cases.

Solution name	Description	Get started
Price optimization	Estimate price elasticity using Double Machine Learning (ML) for causal inference and the <a href="#">Prophet</a> forecasting procedure. Use these estimates to optimize daily prices.	Find in Amazon SageMaker Studio Classic.

## Causal inference

Researchers can use machine learning models such as Bayesian networks to represent causal dependencies and draw causal conclusions based on data. Use the following JumpStart solution to understand the causal relationship between Nitrogen-based fertilizer application and corn crop yields.

Solution name	Description	Get started
Crop yield counterfactuals	Generate a counterfactual analysis of corn response to nitrogen. This solution learns the crop phenology cycle in its entirety using multi-spectral satellite imagery and <a href="#">ground-level observations</a> .	Find in Amazon SageMaker Studio Classic.

## Launch a Solution

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

### Note

JumpStart Solutions are only available in Studio Classic.

First, choose a solution through the SageMaker JumpStart landing page in the Amazon SageMaker Studio Classic UI. For information on the onboarding steps to sign in to Amazon SageMaker Studio Classic, see [Onboard to Amazon SageMaker AI domain](#). For details on getting to the SageMaker JumpStart landing page, see [Open and use JumpStart in Studio Classic](#).

After you choose a solution, a solution's tab opens showing a description of the solution and a Launch button. To launch a solution, select Launch in the **Launch Solution** section. JumpStart then creates all of the resources needed to run the solution. This includes training and model hosting instances.

## Advanced parameters

The solution that you choose may have advanced parameters that you can select. Choose **Advanced Parameters** to specify the AWS Identity and Access Management role for the solution.

Solutions are able to launch resources across 9 AWS services that interact with each other. For the solution to work as expected, newly created components from one service must be able to act on newly created components from another service. We recommend that you use the default IAM role to ensure that all needed permissions are added. For more information about IAM roles, see [AWS Identity and Access Management for Amazon SageMaker AI](#).

## Default IAM role

If you select this option, the default IAM roles that are required by this solution are used. Each solution requires different resources. The following list describes the default roles that are used for the solutions based on the service needed. For a description of the permissions required for each service, see [AWS Managed Policies for SageMaker Projects and JumpStart](#).

- **API Gateway** – AmazonSageMakerServiceCatalogProductsApiGatewayRole
- **CloudFormation** – AmazonSageMakerServiceCatalogProductsCloudformationRole
- **CodeBuild** – AmazonSageMakerServiceCatalogProductsCodeBuildRole
- **CodePipeline** – AmazonSageMakerServiceCatalogProductsCodePipelineRole
- **Events** – AmazonSageMakerServiceCatalogProductsEventsRole
- **Firehose** – AmazonSageMakerServiceCatalogProductsFirehoseRole
- **Glue** – AmazonSageMakerServiceCatalogProductsGlueRole
- **Lambda** – AmazonSageMakerServiceCatalogProductsLambdaRole
- **SageMaker AI** – AmazonSageMakerServiceCatalogProductsExecutionRole

If you are using a new SageMaker AI domain with JumpStart project templates enabled, these roles are automatically created in your account.

If you are using an existing SageMaker AI domain, these roles may not exist in your account. If this is the case, you will receive the following error when launching the solution.

```
Unable to locate the updated roles required to launch this solution, a general role '/service-role/AmazonSageMakerServiceCatalogProductsUseRole' will be used. Please update your studio domain to generate these roles.
```

You can still launch a solution without the needed role, but the legacy default role `AmazonSageMakerServiceCatalogProductsUseRole` is used in place of the needed role. The legacy default role has trust relationships with all of the services that JumpStart solutions need to interact with. For the best security, we recommend that you update your domain to have the newly created default roles for each AWS service.

If you have already onboarded to a SageMaker AI domain, you can update your domain to generate the default roles using the following procedure.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. Choose **Control Panel** at the top left of the page.
3. From the **domain** page, choose the **Settings** icon  to edit the domain settings.
4. On **General Settings** choose **Next**.
5. Under **SageMaker Projects and JumpStart**, select **Enable Amazon SageMaker project templates and Amazon SageMaker JumpStart for this account** and **Enable Amazon SageMaker project templates and Amazon SageMaker JumpStart for Studio Classic users**, choose **Next**.
6. Select **Submit**.

You should be able to see the default roles listed in **Projects - Amazon SageMaker project templates enabled for this account** under the **Apps - Studio** tab.

### Find IAM role

If you select this option, you must select an existing IAM role from the dropdown list for each of the required services. The selected role must have at least the minimum permissions required for the corresponding service. For a description of the permissions required for each service, see [AWS Managed Policies for SageMaker Projects and JumpStart](#).

### Input IAM role

If you select this option, you must manually enter the ARN for an existing IAM role. The selected role must have at least the minimum permissions required for the corresponding service. For a description of the permissions required for each service, see [AWS Managed Policies for SageMaker Projects and JumpStart](#).

## Amazon SageMaker JumpStart Industry: Financial

Use SageMaker JumpStart Industry: Financial solutions, models, and example notebooks to learn about SageMaker AI features and capabilities through curated one-step solutions and example notebooks of industry-focused machine learning (ML) problems. The notebooks also walk through how to use the SageMaker JumpStart Industry Python SDK to enhance industry text data and fine-tune pretrained models.

### Topics

- [Amazon SageMaker JumpStart Industry Python SDK](#)
- [Amazon SageMaker JumpStart Industry: Financial Solution](#)
- [Amazon SageMaker JumpStart Industry: Financial Models](#)
- [Amazon SageMaker JumpStart Industry: Financial Example Notebooks](#)
- [Amazon SageMaker JumpStart Industry: Financial Blog Posts](#)
- [Amazon SageMaker JumpStart Industry: Financial Related Research](#)
- [Amazon SageMaker JumpStart Industry: Financial Additional Resources](#)

### Amazon SageMaker JumpStart Industry Python SDK

SageMaker Runtime JumpStart provides processing tools for curating industry datasets and fine-tuning pretrained models through its client library called SageMaker JumpStart Industry Python SDK. For detailed API documentation of the SDK, and to learn more about processing and enhancing industry text datasets for improving the performance of state-of-the-art models on SageMaker JumpStart, see the [SageMaker JumpStart Industry Python SDK open source documentation](#).

### Amazon SageMaker JumpStart Industry: Financial Solution

SageMaker JumpStart Industry: Financial provides the following solution notebooks:

- **Corporate Credit Rating Prediction**

This SageMaker JumpStart Industry: Financial solution provides a template for a text-enhanced corporate credit rating model. It shows how to take a model based on numeric features (in this case, Altman's famous 5 financial ratios) combined with texts from SEC filings to achieve an improvement in the prediction of credit ratings. In addition to the 5 Altman ratios, you can add more variables as needed or set custom variables. This solution notebook shows how SageMaker

JumpStart Industry Python SDK helps process Natural Language Processing (NLP) scoring of texts from SEC filings. Furthermore, the solution demonstrates how to train a model using the enhanced dataset to achieve a best-in-class model, deploy the model to a SageMaker AI endpoint for production, and receive improved predictions in real time.

- **Graph-Based Credit Scoring**

Credit ratings are traditionally generated using models that use financial statement data and market data, which is tabular only (numeric and categorical). This solution constructs a network of firms using [SEC filings](#) and shows how to use the network of firm relationships with tabular data to generate accurate rating predictions. This solution demonstrates a methodology to use data on firm linkages to extend the traditionally tabular-based credit scoring models, which have been used by the ratings industry for decades, to the class of machine learning models on networks.

 **Note**

The solution notebooks are for demonstration purposes only. They should not be relied on as financial or investment advice.

You can find these financial services solutions through the SageMaker JumpStart page in Studio Classic.

 **Important**

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

 **Note**

The SageMaker JumpStart Industry: Financial solutions, model cards, and example notebooks are hosted and runnable only through SageMaker Studio Classic. Log in to the [SageMaker AI console](#), and launch SageMaker Studio Classic. For more information about how to find the solution card, see the previous topic at [SageMaker JumpStart](#).

## Amazon SageMaker JumpStart Industry: Financial Models

SageMaker JumpStart Industry: Financial provides the following pretrained [Robustly Optimized BERT approach \(RoBERTa\)](#) models:

- **Financial Text Embedding (RoBERTa-SEC-Base)**
- **RoBERTa-SEC-WIKI-Base**
- **RoBERTa-SEC-Large**
- **RoBERTa-SEC-WIKI-Large**

The RoBERTa-SEC-Base and RoBERTa-SEC-Large models are the text embedding models based on [GluonNLP's RoBERTa model](#) and pretrained on S&P 500 SEC 10-K/10-Q reports of the decade of the 2010's (from 2010 to 2019). In addition to these, SageMaker AI JumpStart Industry: Financial provides two more RoBERTa variations, RoBERTa-SEC-WIKI-Base and RoBERTa-SEC-WIKI-Large, which are pretrained on the SEC filings and common texts of Wikipedia.

You can find these models in SageMaker JumpStart by navigating to the **Text Models** node, choosing **Explore All Text Models**, and then filtering for the ML Task **Text Embedding**. You can access any corresponding notebooks after selecting the model of your choice. The paired notebooks will walk you through how the pretrained models can be fine-tuned for specific classification tasks on multimodal datasets, which are enhanced by the SageMaker JumpStart Industry Python SDK.

### **Note**

The model notebooks are for demonstration purposes only. They should not be relied on as financial or investment advice.

The following screenshot shows the pretrained model cards provided through the SageMaker AI JumpStart page on Studio Classic.

Model Name	Type	Pre-training Dataset	Fine-tunable	Source	Action
Financial Text Embedding	Roberta-Sec-Base	S&P 500 10-K/10-Q (2010-...)	No	Gluon NLP	View model >
RoBERTa-SEC-WIKI-Base	Text Embedding	S&P 500 10-K/10-Q (2010-...)	No	Gluon NLP	View model >
RoBERTa-SEC-Large	Text Embedding	S&P 500 10-K/10-Q (2010-...)	No	Gluon NLP	View model >
RoBERTa-SEC-WIKI-Large	Text Embedding	S&P 500 10-K/10-Q (2010-...)	No	Gluon NLP	View model >

### Note

The SageMaker JumpStart Industry: Financial solutions, model cards, and example notebooks are hosted and runnable only through SageMaker Studio Classic. Log in to the [SageMaker AI console](#), and launch SageMaker Studio Classic. For more information about how to find the model cards, see the previous topic at [SageMaker JumpStart](#).

## Amazon SageMaker JumpStart Industry: Financial Example Notebooks

SageMaker JumpStart Industry: Financial provides the following example notebooks to demonstrate solutions to industry-focused ML problems:

- **Financial TabText Data Construction** – This example introduces how to use the SageMaker JumpStart Industry Python SDK for processing the SEC filings, such as text summarization and scoring texts based on NLP score types and their corresponding word lists. To preview the content of this notebook, see [Simple Construction of a Multimodal Dataset from SEC Filings and NLP Scores](#).

- **Multimodal ML on TabText Data** – This example shows how to merge different types of datasets into a single dataframe called TabText and perform multimodal ML. To preview the content of this notebook, see [Machine Learning on a TabText Dataframe – An Example Based on the Paycheck Protection Program](#).
- **Multi-category ML on SEC filings data** – This example shows how to train an AutoGluon NLP model over the multimodal (TabText) datasets curated from SEC filings for a multiclass classification task. [Classify SEC 10K/Q Filings to Industry Codes Based on the MDNA Text Column](#).

**Note**

The example notebooks are for demonstrative purposes only. They should not be relied on as financial or investment advice.

**Note**

The SageMaker JumpStart Industry: Financial solutions, model cards, and example notebooks are hosted and runnable only through SageMaker Studio Classic. Log in to the [SageMaker AI console](#), and launch SageMaker Studio Classic. For more information about how to find the example notebooks, see the previous topic at [SageMaker JumpStart](#).

To preview the content of the example notebooks, see [Tutorials – Finance](#) in the *SageMaker JumpStart Industry Python SDK documentation*.

## Amazon SageMaker JumpStart Industry: Financial Blog Posts

For thorough applications of using SageMaker JumpStart Industry: Financial solutions, models, examples, and the SDK, see the following blog posts:

# Machine learning environments offered by Amazon SageMaker AI

## Important

Amazon SageMaker Studio and Amazon SageMaker Studio Classic are two of the machine learning environments that you can use to interact with SageMaker AI.

If your domain was created after November 30, 2023, Studio is your default experience.

If your domain was created before November 30, 2023, Amazon SageMaker Studio Classic is your default experience. To use Studio if Amazon SageMaker Studio Classic is your default experience, see [Migration from Amazon SageMaker Studio Classic](#).

When you migrate from Amazon SageMaker Studio Classic to Amazon SageMaker Studio, there is no loss in feature availability. Studio Classic also exists as an IDE within Amazon SageMaker Studio to help you run your legacy machine learning workflows.

SageMaker AI supports the following machine learning environments:

- *Amazon SageMaker Studio* (Recommended): The latest web-based experience for running ML workflows with a suite of IDEs. Studio supports the following applications:
  - Amazon SageMaker Studio Classic
  - Code Editor, based on Code-OSS, Visual Studio Code - Open Source
  - JupyterLab
  - Amazon SageMaker Canvas
  - RStudio
- *Amazon SageMaker Studio Classic*: Lets you build, train, debug, deploy, and monitor your machine learning models.
- *Amazon SageMaker Notebook Instances*: Lets you prepare and process data, and train and deploy machine learning models from a compute instance running the Jupyter Notebook application.
- *Amazon SageMaker Studio Lab*: Studio Lab is a free service that gives you access to AWS compute resources, in an environment based on open-source JupyterLab, without requiring an AWS account.
- *Amazon SageMaker Canvas*: Gives you the ability to use machine learning to generate predictions without needing to code.

- *Amazon SageMaker geospatial*: Gives you the ability to build, train, and deploy geospatial models.
- *RStudio on Amazon SageMaker AI*: RStudio is an IDE for [R](#), with a console, syntax-highlighting editor that supports direct code execution, and tools for plotting, history, debugging and workspace management.
- *SageMaker HyperPod*: SageMaker HyperPod lets you provision resilient clusters for running machine learning (ML) workloads and developing state-of-the-art models such as large language models (LLMs), diffusion models, and foundation models (FMs).

To use these machine learning environments, you or your organization's administrator must create an Amazon SageMaker AI domain. The exceptions are Studio Lab, SageMaker Notebook Instances, and SageMaker HyperPod.

Instead of manually provisioning resources and managing permissions for yourself and your users, you can create a Amazon DataZone domain. The process of creating a Amazon DataZone domain creates a corresponding Amazon SageMaker AI domain with AWS Glue or Amazon Redshift databases for your ETL workflows. Setting up a domain through Amazon DataZone reduces the amount of time it takes to set up SageMaker AI environments for your users. For more information about setting up a Amazon SageMaker AI domain within Amazon DataZone, see [Set up SageMaker Assets \(administrator guide\)](#).

Users within the Amazon DataZone domain have permissions to all Amazon SageMaker AI actions, but their permissions are scoped down to resources within the Amazon DataZone domain.

Creating a Amazon DataZone domain streamlines creating a domain that allows your users to share data and models with each other. For information about how they can share data and models, see [Controlled access to assets with Amazon SageMaker Assets](#).

## Amazon SageMaker Studio

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

Amazon SageMaker Studio is the latest web-based experience for running ML workflows. Studio offers a suite of integrated development environments (IDEs). These include Code Editor, based on Code-OSS, Visual Studio Code - Open Source, a new JupyterLab application, RStudio, and Amazon SageMaker Studio Classic. For more information, see [Applications supported in Amazon SageMaker Studio](#).

The new web-based UI in Studio is faster and provides access to all SageMaker AI resources, including jobs and endpoints, in one interface. ML practitioners can also choose their preferred IDE to accelerate ML development. A data scientist can use JupyterLab to explore data and tune models. In addition, a machine learning operations (MLOps) engineer can use Code Editor with the pipelines tool in Studio to deploy and monitor models in production.

The previous Studio experience is still being supported as Amazon SageMaker Studio Classic. Studio Classic is the default experience for existing customers, and is available as an application in Studio. For more information about Studio Classic, see [Amazon SageMaker Studio Classic](#). For information about how to migrate from Studio Classic to Studio, see [Migration from Amazon SageMaker Studio Classic](#).

Studio offers the following benefits:

- A new JupyterLab application that has a faster start-up time and is more reliable than the existing Studio Classic application. For more information, see [SageMaker JupyterLab](#).
- A suite of IDEs that open in a separate tab, including the new Code Editor, based on Code-OSS, Visual Studio Code - Open Source application. Users can interact with supported IDEs in a full screen experience. For more information, see [Applications supported in Amazon SageMaker Studio](#).
- Access to all of your SageMaker AI resources in one place. Studio displays running instances across all of your applications.
- Access to all training jobs in a single view, regardless of whether they were scheduled from notebooks or initiated from Amazon SageMaker JumpStart.
- Simplified model deployment workflows and endpoint management and monitoring directly from Studio. You don't need to access the SageMaker AI console.
- Automatic creation of all configured applications when you onboard to a domain. For information about onboarding to a domain, see [Amazon SageMaker AI domain overview](#).
- An improved JumpStart experience where you can discover, import, register, fine tune, and deploy a foundation model. For more information, see [SageMaker JumpStart pretrained models](#).

## Migration from Amazon SageMaker Studio Classic

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

When you open Amazon SageMaker Studio, the web-based UI is based on the chosen default experience. Amazon SageMaker AI currently supports two different default experiences: the Amazon SageMaker Studio experience and the Amazon SageMaker Studio Classic experience. To access the latest Amazon SageMaker Studio features, you must migrate existing domains from the Amazon SageMaker Studio Classic experience. When you migrate your default experience from Studio Classic to Studio, you don't lose any features, and can still access the Studio Classic IDE within Studio. For information about the added benefits of the Studio experience, see [Amazon SageMaker Studio](#).

### Note

- For existing customers that created their accounts before November 30, 2023, Studio Classic may be the default experience. You can enable Studio as your default experience using the AWS Command Line Interface (AWS CLI) or the Amazon SageMaker AI console. For more information about Studio Classic, see [Amazon SageMaker Studio Classic](#).
- For customers that created their accounts after November 30, 2023, we recommend using Studio as the default experience because it contains various integrated

development environments (IDEs), including the Studio Classic IDE, and other new features.

JupyterLab 3 reached its end of maintenance date on May 15, 2024. After December 31, 2024, you can only create new Studio Classic notebooks on JupyterLab 3 for a limited period. However after December 31, 2024, SageMaker AI will no longer provide fixes for critical issues on Studio Classic notebooks on JupyterLab 3. We recommend that you migrate your workloads to the new Studio experience, which supports JupyterLab 4.

- If Studio is your default experience, the UI is similar to the images found in [Amazon SageMaker Studio UI overview](#).
- If Studio Classic is your default experience, the UI is similar to the images found in [Amazon SageMaker Studio Classic UI Overview](#).

To migrate, you must update an existing domain. Migrating an existing domain from Studio Classic to Studio requires three distinct phases:

1. **Migrate the UI from Studio Classic to Studio:** One time, low lift task that requires creating a test domain to ensure Studio is compliant with your organization's network configurations before migrating the existing domain's UI from Studio Classic to Studio.
2. **(Optional) Migrate custom images and lifecycle configuration scripts:** Medium lift task for migrating your custom images and LCC scripts from Studio Classic to Studio.
3. **(Optional) Migrate data from Studio Classic to Studio:** Heavy lift task that requires using AWS DataSync to migrate data from the Studio Classic Amazon Elastic File System volume to either a target Amazon EFS or Amazon Elastic Block Store volume.
  - **(Optional) Migrate data flows from Data Wrangler in Studio Classic:** One time, low lift task for migrating your data flows from Data Wrangler in Studio Classic to Studio, which you can then access in the latest version of Studio through SageMaker Canvas. For more information, see [Migrate data flows from Data Wrangler](#).

The following topics show how to complete these phases to migrate an existing domain from Studio Classic to Studio.

## Automatic migration

Between July 2024 and August 2024, we are automatically upgrading the default landing experience for users to the new Studio experience. This only changes the default landing UI to the updated Studio UI. The Studio Classic application is still accessible from the new Studio UI.

To ensure that migration works successfully for your users, see [Migrate the UI from Studio Classic to Studio](#). In particular, ensure the following:

- the domain's execution role has the right permissions
- the default landing experience is set to Studio
- the domain's Amazon VPC, if applicable, is configured to Studio using the Studio VPC endpoint

However, if you need to continue having Studio Classic as your default UI for a limited time, set the landing experience to Studio Classic explicitly. For more information, see [Set Studio Classic as the default experience](#).

### Topics

- [Complete prerequisites to migrate the Studio experience](#)
- [Migrate the UI from Studio Classic to Studio](#)
- [\(Optional\) Migrate custom images and lifecycle configurations](#)
- [\(Optional\) Migrate data from Studio Classic to Studio](#)

## Complete prerequisites to migrate the Studio experience

Migration of the default experience from Studio Classic to Studio is managed by the administrator of the existing domain. If you do not have permissions to set Studio as the default experience for the existing domain, contact your administrator. To migrate your default experience, you must have administrator permissions or at least have permissions to update the existing domain, AWS Identity and Access Management (IAM), and Amazon Simple Storage Service (Amazon S3). Complete the following prerequisites before migrating an existing domain from Studio Classic to Studio.

- The AWS Identity and Access Management role used to complete migration must have a policy attached with at least the following permissions. For information about creating an IAM policy, see [Creating IAM policies](#).

**Note**

The release of Studio includes updates to the AWS managed policies. For more information, see [SageMaker AI Updates to AWS Managed Policies](#).

- Phase 1 required permissions:
  - `iam:CreateServiceLinkedRole`
  - `iam:PassRole`
  - `sagemaker:DescribeDomain`
  - `sagemaker:UpdateDomain`
  - `sagemaker>CreateDomain`
  - `sagemaker>CreateUserProfile`
  - `sagemaker:ListApps`
  - `sagemaker:AddTags`
  - `sagemaker>DeleteApp`
  - `sagemaker>DeleteSpace`
  - `sagemaker:UpdateSpace`
  - `sagemaker>DeleteUserProfile`
  - `sagemaker>DeleteDomain`
  - `s3:PutBucketCORS`
- Phase 2 required permissions (Optional, only if using lifecycle configuration scripts):

No additional permissions needed. If the existing domain has lifecycle configurations and custom images, the admin will already have the required permissions.

- Phase 3 using custom Amazon Elastic File System required permissions (Optional, only if transferring data):
  - `efs:CreateFileSystem`
  - `efs:CreateMountTarget`
  - `efs:DescribeFileSystems`
  - `efs:DescribeMountTargets`

- `efs:ModifyMountTargetSecurityGroups`
- `ec2:DescribeSubnets`
- `ec2:DescribeSecurityGroups`
- `ec2:DescribeNetworkInterfaceAttribute`
- `ec2:DescribeNetworkInterfaces`
- `ec2:AuthorizeSecurityGroupEgress`
- `ec2:AuthorizeSecurityGroupIngress`
- `ec2:CreateNetworkInterface`
- `ec2:CreateNetworkInterfacePermission`
- `ec2:RevokeSecurityGroupIngress`
- `ec2:RevokeSecurityGroupEgress`
- `ec2>DeleteSecurityGroup`
- `datasync:CreateLocationEfs`
- `datasync:CreateTask`
- `datasync:StartTaskExecution`
- `datasync>DeleteTask`
- `datasync>DeleteLocation`
- `sagemaker:ListUserProfiles`
- `sagemaker:DescribeUserProfile`
- `sagemaker:UpdateDomain`
- `sagemaker:UpdateUserProfile`
- Phase 3 using Amazon Simple Storage Service required permissions (Optional, only if transferring data):
  - `iam:CreateRole`
  - `iam:GetRole`
  - `iam:AttachRolePolicy`
  - `iam:DetachRolePolicy`
  - `iam>DeleteRole`
  - `efs:DescribeFileSystems`
  - `efs:DescribeMountTargets`

- `efs:DescribeMountTargetSecurityGroups`
- `ec2:DescribeSubnets`
- `ec2:CreateSecurityGroup`
- `ec2:DescribeSecurityGroups`
- `ec2:DescribeNetworkInterfaces`
- `ec2:CreateNetworkInterface`
- `ec2:CreateNetworkInterfacePermission`
- `ec2:DetachNetworkInterfaces`
- `ec2>DeleteNetworkInterface`
- `ec2>DeleteNetworkInterfacePermission`
- `ec2:CreateTags`
- `ec2:AuthorizeSecurityGroupEgress`
- `ec2:AuthorizeSecurityGroupIngress`
- `ec2:RevokeSecurityGroupIngress`
- `ec2:RevokeSecurityGroupEgress`
- `ec2>DeleteSecurityGroup`
- `datasync:CreateLocationEfs`
- `datasync:CreateLocationS3`
- `datasync:CreateTask`
- `datasync:StartTaskExecution`
- `datasync:DescribeTaskExecution`
- `datasync>DeleteTask`
- `datasync>DeleteLocation`
- `sagemaker:CreateStudioLifecycleConfig`
- `sagemaker:UpdateDomain`
- `s3:ListBucket`
- `s3:GetObject`
- Access to AWS services from a terminal environment on either:
  - **Your local machine using the AWS CLI version 2.13+.** Use the following command to verify the AWS CLI version.

```
aws --version
```

- AWS CloudShell. For more information, see [What is AWS CloudShell?](#)
- From your local machine or AWS CloudShell, run the following command and provide your AWS credentials. For information about AWS credentials, see [Understanding and getting your AWS credentials](#).

```
aws configure
```

- Verify that the lightweight JSON processor, jq, is installed in the terminal environment. jq is required to parse AWS CLI responses.

```
jq --version
```

If jq is not installed, install it using one of the following commands:

- ```
sudo apt-get install -y jq
```
- ```
sudo yum install -y jq
```

## Migrate the UI from Studio Classic to Studio

The first phase for migrating an existing domain involves migrating the UI from Amazon SageMaker Studio Classic to Amazon SageMaker Studio. This phase does not include the migration of data. Users can continue working with their data the same way as they were before migration. For information about migrating data, see [\(Optional\) Migrate data from Studio Classic to Studio](#).

Phase 1 consists of the following steps:

1. Update application creation permissions for new applications available in Studio.
2. Update the VPC configuration for the domain.
3. Upgrade the domain to use the Studio UI.

### Prerequisites

Before running these steps, complete the prerequisites in [Complete prerequisites to migrate the Studio experience](#).

## Step 1: Update application creation permissions

Before migrating the domain, update the domain's execution role to grant users permissions to create applications.

1. Create an AWS Identity and Access Management policy with one of the following contents by following the steps in [Creating IAM policies](#):
  - Use the following policy to grant permissions for all application types and spaces.

### Note

If the domain uses the `SageMakerFullAccess` policy, you do not need to perform this action. `SageMakerFullAccess` grants permissions to create all applications.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "SMStudioUserProfileAppPermissionsCreateAndDelete",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateApp",
        "sagemaker>DeleteApp"
      ],
      "Resource": "arn:aws:sagemaker:region:account-id:app/*",
      "Condition": {
        "Null": {
          "sagemaker:OwnerUserProfileArn": "true"
        }
      }
    },

${sagemaker:DomainId}/*",
      "Condition": {
        "Null": {
          "sagemaker:OwnerUserProfileArn": "true"
        }
      }
    }
  ],

```

```

    {
      "Sid": "SMStudioRestrictSpacesToOwnerUserProfile",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateSpace",
        "sagemaker:UpdateSpace",
        "sagemaker>DeleteSpace"
      ],
      "Resource": "arn:aws:sagemaker:region:account-id:space/
${sagemaker:DomainId}/*",
      "Condition": {
        "ArnLike": {
          "sagemaker:OwnerUserProfileArn": "arn:aws:sagemaker:us-
east-1:account-id:user-profile/${sagemaker:DomainId}/
${sagemaker:UserProfileName}"
        },
        "StringEquals": {
          "sagemaker:SpaceSharingType": [
            "Private",
            "Shared"
          ]
        }
      }
    },
    {
      "Sid": "SMStudioRestrictCreatePrivateSpaceAppsToOwnerUserProfile",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateApp",
        "sagemaker>DeleteApp"
      ],
      "Resource": "arn:aws:sagemaker:region:account-id:app/
${sagemaker:DomainId}/*",
      "Condition": {
        "ArnLike": {
          "sagemaker:OwnerUserProfileArn": "arn:aws:sagemaker:us-
east-1:account-id:user-profile/${sagemaker:DomainId}/
${sagemaker:UserProfileName}"
        },
        "StringEquals": {
          "sagemaker:SpaceSharingType": [
            "Private"
          ]
        }
      }
    }
  ]
}

```

```

    }
  },
  {
    "Sid": "AllowAppActionsForSharedSpaces",
    "Effect": "Allow",
    "Action": [
      "sagemaker:CreateApp",
      "sagemaker>DeleteApp"
    ],
    "Resource": "arn:aws:sagemaker:*:*:app/${sagemaker:DomainId}/*/*/*",
    "Condition": {
      "StringEquals": {
        "sagemaker:SpaceSharingType": [
          "Shared"
        ]
      }
    }
  }
]
}

```

- Because Studio shows an expanded set of applications, users may have access to applications that weren't displayed before. Administrators can limit access to these default applications by creating an AWS Identity and Access Management (IAM) policy that grants denies permissions for some applications to specific users.

#### Note

Application type can be either `jupyterlab` or `codeeditor`.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenySageMakerCreateAppForSpecificAppTypes",
      "Effect": "Deny",
      "Action": "sagemaker:CreateApp",
      "Resource": "arn:aws:sagemaker:region:account-id:app/domain-id/*/app-type/
**
    }
  ]
}

```

```
}

```

2. Attach the policy to the execution role of the domain. For instructions, follow the steps in [Adding IAM identity permissions \(console\)](#).

## Step 2: Update VPC configuration

If you use your domain in VPC-Only mode, ensure your VPC configuration meets the requirements for using Studio in VPC-Only mode. For more information, see [Connect Amazon SageMaker Studio in a VPC to External Resources](#).

## Step 3: Upgrade to the Studio UI

Before you migrate your existing domain from Studio Classic to Studio, we recommend creating a test domain using Studio with the same configurations as your existing domain.

### (Optional) Create a test domain

Use this test domain to interact with Studio, test out networking configurations, and launch applications, before migrating the existing domain.

1. Get the domain ID of your existing domain.
  - a. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
  - b. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
  - c. Choose the existing domain.
  - d. On the **Domain details** page, choose the **Domain settings** tab.
  - e. Copy the **Domain ID**.
2. Add the domain ID of your existing domain.

```
export REF_DOMAIN_ID="domain-id"
export SM_REGION="region"
```

3. Use `describe-domain` to get important information about the existing domain.

```
export REF_EXECROLE=$(aws sagemaker describe-domain --region=$SM_REGION --domain-id=$REF_DOMAIN_ID | jq -r '.DefaultUserSettings.ExecutionRole')
export REF_VPC=$(aws sagemaker describe-domain --region=$SM_REGION --domain-id=$REF_DOMAIN_ID | jq -r '.VpcId')
```

```
export REF_SIDS=$(aws sagemaker describe-domain --region=$SM_REGION --domain-id=
$REF_DOMAIN_ID | jq -r '.SubnetIds | join(",")')
export REF_SGS=$(aws sagemaker describe-domain --region=$SM_REGION --domain-id=
$REF_DOMAIN_ID | jq -r '.DefaultUserSettings.SecurityGroups | join(",")')
export AUTHMODE=$(aws sagemaker describe-domain --region=$SM_REGION --domain-id=
$REF_DOMAIN_ID | jq -r '.AuthMode')
```

#### 4. Validate the parameters.

```
echo "Execution Role: $REF_EXECROLE || VPCID: $REF_VPC || SubnetIDs: $REF_SIDS ||
Security GroupIDs: $REF_SGS || AuthMode: $AUTHMODE"
```

#### 5. Create a test domain using the configurations from the existing domain.

```
IFS=',' read -r -a subnet_ids <<< "$REF_SIDS"
IFS=',' read -r -a security_groups <<< "$REF_SGS"
security_groups_json=$(printf '%s\n' "${security_groups[@]}" | jq -R . | jq -s .)

aws sagemaker create-domain \
--domain-name "TestV2Config" \
--vpc-id $REF_VPC \
--auth-mode $AUTHMODE \
--subnet-ids "${subnet_ids[@]}" \
--app-network-access-type VpcOnly \
--default-user-settings "
{
  \"ExecutionRole\": \"$REF_EXECROLE\",
  \"StudioWebPortal\": \"ENABLED\",
  \"DefaultLandingUri\": \"studio:\",
  \"SecurityGroups\": $security_groups_json
}
"
```

#### 6. After the test domain is In Service, use the test domain's ID to create a user profile. This user profile is used to launch and test applications.

```
aws sagemaker create-user-profile \
--region="$SM_REGION" --domain-id=test-domain-id \
--user-profile-name test-network-user
```

## Test Studio functionality

Launch the test domain using the `test-network-user` user profile. We suggest that you thoroughly test the Studio UI and create applications to test Studio functionality in VPCOnly mode. Test the following workflows:

- Create a new JupyterLab Space, test environment and connectivity.
- Create a new Code Editor, based on Code-OSS, Visual Studio Code - Open Source Space, test environment and connectivity.
- Launch a new Studio Classic App, test environment and connectivity.
- Test Amazon Simple Storage Service connectivity with test read and write actions.

If these tests are successful, then upgrade the existing domain. If you encounter any failures, we recommended fixing your environment and connectivity issues before updating the existing domain.

## Clean up test domain resources

After you have migrated the existing domain, clean up test domain resources.

1. Add the test domain's ID.

```
export TEST_DOMAIN="test-domain-id"
export SM_REGION="region"
```

2. List all applications in the domain that are in a running state.

```
active_apps_json=$(aws sagemaker list-apps --region=$SM_REGION --domain-id=
$TEST_DOMAIN)
echo $active_apps_json
```

3. Parse the JSON list of running applications and delete them. If users attempted to create an application that they do not have permissions for, there may be spaces that are not captured in the following script. You must manually delete these spaces.

```
echo "$active_apps_json" | jq -c '.Apps[]' | while read -r app;
do
    if echo "$app" | jq -e '. | has("SpaceName")' > /dev/null;
    then
```

```

app_type=$(echo "$app" | jq -r '.AppType')
app_name=$(echo "$app" | jq -r '.AppName')
domain_id=$(echo "$app" | jq -r '.DomainId')
space_name=$(echo "$app" | jq -r '.SpaceName')

echo "Deleting App - AppType: $app_type || AppName: $app_name || DomainId:
$domain_id || SpaceName: $space_name"
aws sagemaker delete-app --region=$SM_REGION --domain-id=$domain_id \
--app-type $app_type --app-name $app_name --space-name $space_name

echo "Deleting Space - AppType: $app_type || AppName: $app_name ||
DomainId: $domain_id || SpaceName: $space_name"
aws sagemaker delete-space --region=$SM_REGION --domain-id=$domain_id \
--space-name $space_name
else

app_type=$(echo "$app" | jq -r '.AppType')
app_name=$(echo "$app" | jq -r '.AppName')
domain_id=$(echo "$app" | jq -r '.DomainId')
user_profile_name=$(echo "$app" | jq -r '.UserProfileName')

echo "Deleting Studio Classic - AppType: $app_type || AppName: $app_name ||
DomainId: $domain_id || UserProfileName: $user_profile_name"
aws sagemaker delete-app --region=$SM_REGION --domain-id=$domain_id \
--app-type $app_type --app-name $app_name --user-profile-name
$user_profile_name

fi

done

```

#### 4. Delete the test user profile.

```

aws sagemaker delete-user-profile \
--region=$SM_REGION --domain-id=$TEST_DOMAIN \
--user-profile-name "test-network-user"

```

#### 5. Delete the test domain.

```

aws sagemaker delete-domain \
--region=$SM_REGION --domain-id=$TEST_DOMAIN

```

After you have tested Studio functionality with the configurations in your test domain, migrate the existing domain. When Studio is the default experience for a domain, Studio is the default experience for all users in the domain. However, the user settings takes precedence over the domain settings. Therefore, if a user has their default experience set to Studio Classic in their user settings, then that user will have Studio Classic as their default experience.

You can migrate the existing domain by updating it from the SageMaker AI console, the AWS CLI, or AWS CloudFormation. Choose one of the following tabs to view the relevant instructions.

### Set Studio as the default experience for the existing domain using the SageMaker AI console

You can set Studio as the default experience for the existing domain by using the SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
  2. From the left navigation pane expand **Admin configurations** and choose **Domains**.
  3. Choose the existing domain that you want to enable Studio as the default experience for.
  4. On the **Domain details** page expand **Enable the new Studio**.
  5. (Optional) To view the details about the steps involved in enabling Studio as your default experience, choose **View details**. The page shows the following.
    - In the **SageMaker Studio Overview** section you can view the applications that are included or available in the Studio web-based interface.
    - In the **Enablement process** section you can view descriptions of the workflow tasks to enable Studio.
-  **Note**

You will need to migrate your data manually. For instructions about migrating your data, see [\(Optional\) Migrate data from Studio Classic to Studio](#).
- In the **Revert to Studio Classic experience** section you can view how to revert back to Studio Classic after enabling Studio as your default experience.
  6. To begin the process to enable Studio as your default experience, choose **Enable the new Studio**.
  7. In the **Specify and configure role** section, you can view the default applications that are automatically included in Studio.

To prevent users from running these applications, choose the AWS Identity and Access Management (IAM) Role that has an IAM policy that denies access. For information about how to create a policy to limit access, see [Step 1: Update application creation permissions](#).

8. In the **Choose default S3 bucket to attach CORS policy** section, you can give Studio access to Amazon S3 buckets. The default Amazon S3 bucket, in this case, is the default Amazon S3 bucket for your Studio Classic. In this step you can do the following:
  - Verify the domain's default Amazon S3 bucket to attach the CORS policy to. If your domain does not have a default Amazon S3 bucket, SageMaker AI creates an Amazon S3 bucket with the correct CORS policy attached.
  - You can include 10 additional Amazon S3 buckets to attach the CORS policy to.

If you wish to include more than 10 buckets, you can add them manually. For more information about manually attaching the CORS policy to your Amazon S3 buckets, see [\(Optional\) Update your CORS policy to access Amazon S3 buckets](#).

To proceed, select the check box next to **Do you agree to overriding any existing CORS policy on the chosen Amazon S3 buckets?**

9. The **Migrate data** section contains information about the different data storage volumes for Studio Classic and Studio. Your data will not be migrated automatically through this process. For instructions about migrating your data, lifecycle configurations, and JupyterLab extensions, see [\(Optional\) Migrate data from Studio Classic to Studio](#).
10. Once you have completed the tasks on the page and verified your configuration, choose **Enable the new Studio**.

## Set Studio as the default experience for the existing domain using the AWS CLI

To set Studio as the default experience for the existing domain using the AWS CLI, use the [update-domain](#) call. You must set `ENABLED` as the value for `StudioWebPortal`, and set `studio::` as the value for `DefaultLandingUri` as part of the `default-user-settings` parameter.

`StudioWebPortal` indicates if the Studio experience is the default experience and `DefaultLandingUri` indicates the default experience that the user is directed to when accessing the domain. In this example, setting these values on a domain level (in `default-user-settings`) makes Studio the default experience for users within the domain.

If a user within the domain has their `StudioWebPortal` set to `DISABLED` and `DefaultLandingUri` set to `app:JupyterServer:` on a user level (in `UserSettings`), this takes precedence over the domain settings. In other words, that user will have Studio Classic as their default experience, regardless of the domain settings.

The following code example shows how to set Studio as the default experience for users within the domain:

```
aws sagemaker update-domain \  
--domain-id existing-domain-id \  
--region AWS Region \  
--default-user-settings '  
{  
  "StudioWebPortal": "ENABLED",  
  "DefaultLandingUri": "studio::"  
}  
'
```

- To obtain your *existing-domain-id*, use the following instructions:

#### To get *existing-domain-id*

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
  2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
  3. Choose the existing domain.
  4. On the **Domain details** page, choose the **Domain settings** tab.
  5. Copy the **Domain ID**.
- To ensure you are using the correct AWS Region for your domain, use the following instructions:

#### To get *AWS Region*

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
3. Choose the existing domain.
4. On the **Domain details** page, verify that this is the existing domain.
5. Expand the AWS Region dropdown list from the top right of the SageMaker AI console, and use the corresponding AWS Region ID to the right of your AWS Region name. For example, `us-west-1`.

After you migrate your default experience to Studio, you can give Studio access to Amazon S3 buckets. For example, you can include access to your Studio Classic default Amazon S3 bucket and additional Amazon S3 buckets. To do so, you must manually attach a [Cross-Origin Resource Sharing](#) (CORS) configuration to the Amazon S3 buckets. For more information about how to manually attach the CORS policy to your Amazon S3 buckets, see [\(Optional\) Update your CORS policy to access Amazon S3 buckets](#).

Similarly, you can set Studio as the default experience when you create a domain from the AWS CLI using the [create-domain](#) call.

### **Set Studio as the default experience for the existing domain using the AWS CloudFormation**

You can set the default experience when creating a domain using the AWS CloudFormation. For an AWS CloudFormation migration template, see [SageMaker Studio Administrator IaC Templates](#). For more information about creating a domain using AWS CloudFormation, see [Creating Amazon SageMaker AI domain using AWS CloudFormation](#).

For information about the domain resource supported by AWS CloudFormation, see [AWS::SageMaker AI::Domain](#).

After you migrate your default experience to Studio, you can give Studio access to Amazon S3 buckets. For example, you can include access to your Studio Classic default Amazon S3 bucket and additional Amazon S3 buckets. To do so, you must manually attach a [Cross-Origin Resource Sharing](#) (CORS) configuration to the Amazon S3 buckets. For information about how to manually attach the CORS policy to your Amazon S3 buckets, see [\(Optional\) Update your CORS policy to access Amazon S3 buckets](#).

### **(Optional) Update your CORS policy to access Amazon S3 buckets**

In Studio Classic, users can create, list, and upload files to Amazon Simple Storage Service (Amazon S3) buckets. To support the same experience in Studio, administrators must attach a [Cross-Origin Resource Sharing](#) (CORS) configuration to the Amazon S3 buckets. This is required because Studio makes Amazon S3 calls from the internet browser. The browser invokes CORS on behalf of users. As a result, all of the requests to Amazon S3 buckets fail unless the CORS policy is attached to the Amazon S3 buckets.

You may need to manually attach the CORS policy to Amazon S3 buckets for the following reasons.

- If there is already an existing Amazon S3 default bucket that doesn't have the correct CORS policy attached when you migrate the existing domain's default experience to Studio.

- If you are using the AWS CLI to migrate the existing domain's default experience to Studio. For information about using the AWS CLI to migrate, see [Set Studio as the default experience for the existing domain using the AWS CLI](#).
- If you want to attach the CORS policy to additional Amazon S3 buckets.

**Note**

If you plan to use the SageMaker AI console to enable Studio as your default experience, the Amazon S3 buckets that you attach the CORS policy to will have their existing CORS policies overridden during the migration. For this reason, you can ignore the following manual instructions.

However, if you have already used the SageMaker AI console to migrate and want to include more Amazon S3 buckets to attach the CORS policy to, then continue with the following manual instructions.

The following procedure shows how to manually add a CORS configuration to an Amazon S3 bucket.

**To add a CORS configuration to an Amazon S3 bucket**

1. Verify that there is an Amazon S3 bucket in the same AWS Region as the existing domain with the following name. For instructions, see [Viewing the properties for an Amazon S3 bucket](#).

```
sagemaker-region-account-id
```

2. Add a CORS configuration with the following content to the default Amazon S3 bucket. For instructions, see [Configuring cross-origin resource sharing \(CORS\)](#).

```
[
  {
    "AllowedHeaders": [
      "*"
    ],
    "AllowedMethods": [
      "POST",
      "PUT",
      "GET",
      "HEAD",
```

```

        "DELETE"
    ],
    "AllowedOrigins": [
        "https://*.sagemaker.aws"
    ],
    "ExposeHeaders": [
        "ETag",
        "x-amz-delete-marker",
        "x-amz-id-2",
        "x-amz-request-id",
        "x-amz-server-side-encryption",
        "x-amz-version-id"
    ]
}
]

```

### (Optional) Migrate from Data Wrangler in Studio Classic to SageMaker Canvas

Amazon SageMaker Data Wrangler exists as its own feature in the Studio Classic experience. When you enable Studio as your default experience, use the [Amazon SageMaker Canvas](#) application to access Data Wrangler functionality. SageMaker Canvas is an application in which you can train and deploy machine learning models without writing any code, and Canvas provides data preparation features powered by Data Wrangler.

The new Studio experience doesn't support the classic Data Wrangler UI, and you must create a Canvas application if you want to continue using Data Wrangler. However, you must have the necessary permissions to create and use Canvas applications.

Complete the following steps to attach the necessary permissions policies to your SageMaker AI domain's or user's AWS IAM role.

#### To grant permissions for Data Wrangler functionality inside Canvas

1. Attach the AWS managed policy [AmazonSageMakerFullAccess](#) to your user's IAM role. For a procedure that shows you how to attach IAM policies to a role, see [Adding IAM identity permissions \(console\)](#) in the *AWS IAM User Guide*.

If this permissions policy is too permissive for your use case, you can create scoped-down policies that include at least the following permissions:

```
{
```

```

    "Sid": "AllowStudioActions",
    "Effect": "Allow",
    "Action": [
        "sagemaker:CreatePresignedDomainUrl",
        "sagemaker:DescribeDomain",
        "sagemaker:ListDomains",
        "sagemaker:DescribeUserProfile",
        "sagemaker:ListUserProfiles",
        "sagemaker:DescribeSpace",
        "sagemaker:ListSpaces",
        "sagemaker:DescribeApp",
        "sagemaker:ListApps"
    ],
    "Resource": "*"
},
{
    "Sid": "AllowAppActionsForUserProfile",
    "Effect": "Allow",
    "Action": [
        "sagemaker:CreateApp",
        "sagemaker>DeleteApp"
    ],
    "Resource": "arn:aws:sagemaker:region:account-id:app/domain-id/user-profile-name/canvas/*",
    "Condition": {
        "Null": {
            "sagemaker:OwnerUserProfileArn": "true"
        }
    }
}
}

```

2. Attach the AWS managed policy [AmazonSageMakerCanvasDataPrepFullAccess](#) to your user's IAM role.

After attaching the necessary permissions, you can create a Canvas application and log in. For more information, see [Getting started with using Amazon SageMaker Canvas](#).

When you've logged into Canvas, you can directly access Data Wrangler and begin creating data flows. For more information, see [Data preparation](#) in the Canvas documentation.

## (Optional) Migrate from Autopilot in Studio Classic to SageMaker Canvas

[Amazon SageMaker Autopilot](#) exists as its own feature in the Studio Classic experience. When you migrate to using the updated Studio experience, use the [Amazon SageMaker Canvas](#) application to continue using the same automated machine learning (AutoML) capabilities via a user interface (UI). SageMaker Canvas is an application in which you can train and deploy machine learning models without writing any code, and Canvas provides a UI to run your AutoML tasks.

The new Studio experience doesn't support the classic Autopilot UI. You must create a Canvas application if you want to continue using Autopilot's AutoML features via a UI.

However, you must have the necessary permissions to create and use Canvas applications.

- If you are accessing SageMaker Canvas from Studio, add those permissions to the execution role of your SageMaker AI domain or user profile.
- If you are accessing SageMaker Canvas from the Console, add those permissions to your user's AWS IAM role.
- If you are accessing SageMaker Canvas via a [presigned URL](#), add those permissions to the IAM role that you're using for Okta SSO access.

To enable AutoML capabilities in Canvas, add the following policies to your execution role or IAM user role.

- AWS managed policy: [CanvasFullAccess](#).
- Inline policy:

```
{
  "Sid": "AllowAppActionsForUserProfile",
  "Effect": "Allow",
  "Action": [
    "sagemaker:CreateApp",
    "sagemaker>DeleteApp"
  ],
  "Resource": "arn:aws:sagemaker:region:account-id:app/domain-id/user-profile-name/canvas/*",
  "Condition": {
    "Null": {
      "sagemaker:OwnerUserProfileArn": "true"
    }
  }
}
```

```
}
```

## To attach IAM policies to an execution role

### 1. Find the execution role attached to your SageMaker AI user profile

- a. In the SageMaker AI console <https://console.aws.amazon.com/sagemaker/>, navigate to **Domains**, then choose your SageMaker AI domain.
- b. The execution role ARN is listed under *Execution role* on the **User Details** page of your user profile. Make note of the execution role name in the ARN.
- c. In the IAM console <https://console.aws.amazon.com/iam/>, choose **Roles**.
- d. Search for your role by name in the search field.
- e. Select the role.

### 2. Add policies to the role

- a. In the IAM console <https://console.aws.amazon.com/iam/>, choose **Roles**.
- b. Search for your role by name in the search field.
- c. Select the role.
- d. In the **Permissions** tab, navigate to the dropdown menu **Add permissions**.
- e.
  - For managed policies: Select **Attach policies**, search for the name of the manage policy you want to attach.  
  
Select the policy then choose **Add permissions**.
  - For inline policies: Select **Create inline policy**, paste your policy in the JSON tab, choose next, name your policy, and choose **Create**.

For a procedure that shows you how to attach IAM policies to a role, see [Adding IAM identity permissions \(console\)](#) in the *AWS IAM User Guide*.

After attaching the necessary permissions, you can create a Canvas application and log in. For more information, see [Getting started with using Amazon SageMaker Canvas](#).

## Set Studio Classic as the default experience

Administrators can revert to Studio Classic as the default experience for an existing domain. This can be done through the AWS CLI.

**Note**

When Studio Classic is set as the default experience on a domain level, Studio Classic is the default experience for all users in the domain. However, settings on a user level takes precedence over the domain level settings. So if a user has their default experience set to Studio, then that user will have Studio as their default experience.

To revert to Studio Classic as the default experience for the existing domain using the AWS CLI, use the [update-domain](#) call. As part of the `default-user-settings` field, you must set:

- `StudioWebPortal` value to `DISABLED`.
- `DefaultLandingUri` value to `app:JupyterServer`:

`StudioWebPortal` indicates if the Studio experience is the default experience and `DefaultLandingUri` indicates the default experience that the user is directed to when accessing the domain. In this example, setting these values on a domain level (in `default-user-settings`) makes Studio Classic the default experience for users within the domain.

If a user within the domain has their `StudioWebPortal` set to `ENABLED` and `DefaultLandingUri` set to `studio::` on a user level (in `UserSettings`), this takes precedence over the domain level settings. In other words, that user will have Studio as their default experience, regardless of the domain level settings.

The following code example shows how to set Studio Classic as the default experience for users within the domain:

```
aws sagemaker update-domain \  
--domain-id existing-domain-id \  
--region AWS Region \  
--default-user-settings '  
{  
  "StudioWebPortal": "DISABLED",  
  "DefaultLandingUri": "app:JupyterServer:"  
}  
'
```

Use the following instructions to obtain your *existing-domain-id*.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
3. Choose the existing domain.
4. On the **Domain details** page, choose the **Domain settings** tab.
5. Copy the **Domain ID**.

To obtain your *AWS Region*, use the following instructions to ensure you are using the correct AWS Region for your domain.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
3. Choose the existing domain.
4. On the **Domain details** page, verify that this is the existing domain.
5. Expand the AWS Region dropdown list from the top right of the SageMaker AI console, and use the corresponding AWS Region ID to the right of your AWS Region name. For example, us-west-1.

## (Optional) Migrate custom images and lifecycle configurations

You must update your custom images and lifecycle configuration (LCC) scripts to work with the simplified local run model in Amazon SageMaker Studio. If you have not created custom images or lifecycle configurations in your domain, skip this phase.

Amazon SageMaker Studio Classic operates in a split environment with:

- A `JupyterServer` application running the Jupyter Server.
- Studio Classic notebooks running on one or more `KernelGateway` applications.

Studio has shifted away from a split environment. Studio runs the JupyterLab and Code Editor, based on Code-OSS, Visual Studio Code - Open Source applications in a local runtime model. For more information about the change in architecture, see [Boost productivity on Amazon SageMaker Studio](#).

## Migrate custom images

Your existing Studio Classic custom images may not work in Studio. We recommend creating a new custom image that satisfies the requirements for use in Studio. The release of Studio simplifies the process to build custom images by providing [SageMaker Studio image support policy](#). SageMaker AI Distribution images include popular libraries and packages for machine learning, data science, and data analytics visualization. For a list of base SageMaker Distribution images and Amazon Elastic Container Registry account information, see [Amazon SageMaker images available for use with Studio Classic](#).

To build a custom image, complete one of the following.

- Extend a SageMaker Distribution image with custom packages and modules. These images are pre-configured with JupyterLab and Code Editor, based on Code-OSS, Visual Studio Code - Open Source.
- Build a custom Dockerfile file by following the instructions in [Dockerfile specifications](#). You must install JupyterLab and the open source CodeServer on the image to make it compatible with Studio.

## Migrate lifecycle configurations

Because of the simplified local runtime model in Studio, we recommend migrating the structure of your existing Studio Classic LCCs. In Studio Classic, you often have to create separate lifecycle configurations for both KernelGateway and JupyterServer applications. Because the JupyterServer and KernelGateway applications run on separate compute resources within Studio Classic, Studio Classic LCCs can be one of either type:

- JupyterServer LCC: These LCCs mostly govern a user's home actions, including setting proxy, creating environment variables, and auto-shutdown of resources.
- KernelGateway LCC: These LCCs govern Studio Classic notebook environment optimizations. This includes updating numpy package versions in the Data Science 3.0 kernel and installing the snowflake package in Pytorch 2.0 GPU kernel.

In the simplified Studio architecture, you only need one LCC script that runs at application start up. While migration of your LCC scripts varies based on development environment, we recommend combining JupyterServer and KernelGateway LCCs to build a combined LCC.

LCCs in Studio can be associated with one of the following applications:

- JupyterLab
- Code Editor

Users can select the LCC for the respective application type when creating a space or use the default LCC set by the admin.

### Note

Existing Studio Classic auto-shutdown scripts do not work with Studio. For an example Studio auto-shutdown script, see [SageMaker Studio Lifecycle Configuration examples](#).

## Considerations when refactoring LCCs

Consider the following differences between Studio Classic and Studio when refactoring your LCCs.

- JupyterLab and Code Editor applications, when created, are run as `sagemaker-user` with `UID:1001` and `GID:101`. By default, `sagemaker-user` has permissions to assume `sudo/root` permissions. KernelGateway applications are run as `root` by default.
- SageMaker Distribution images that run inside JupyterLab and Code Editor apps use the Debian-based package manager, `apt-get`.
- Studio JupyterLab and Code Editor applications use the Conda package manager. SageMaker AI creates a single base Python3 Conda environment when a Studio application is launched. For information about updating packages in the base Conda environment and creating new Conda environments, see [JupyterLab user guide](#). In contrast, not all KernelGateway applications use Conda as a package manager.
- The Studio JupyterLab application uses `JupyterLab 4.0`, while Studio Classic uses `JupyterLab 3.0`. Validate that all JupyterLab extensions you use are compatible with `JupyterLab 4.0`. For more information about extensions, see [Extension Compatibility with JupyterLab 4.0](#).

## (Optional) Migrate data from Studio Classic to Studio

Studio Classic and Studio use two different types of storage volumes. Studio Classic uses a single Amazon Elastic File System (Amazon EFS) volume to store data across all users and shared spaces in the domain. In Studio, each space gets its own Amazon Elastic Block Store (Amazon EBS) volume.

When you update the default experience of an existing domain, SageMaker AI automatically mounts a folder in an Amazon EFS volume for each user in a domain. As a result, users are able to access files from Studio Classic in their Studio applications. For more information, see [Amazon EFS auto-mounting in Studio](#).

You can also opt out of Amazon EFS auto-mounting and manually migrate the data to give users access to files from Studio Classic in Studio applications. To accomplish this, you must transfer the files from the user home directories to the Amazon EBS volumes associated with those spaces. The following section gives information about this workflow. For more information about opting out of Amazon EFS auto-mounting, see [Opt out of Amazon EFS auto-mounting](#).

## Manually migrate all of your data from Studio Classic

The following section describes how to migrate all of the data from your Studio Classic storage volume to the new Studio experience.

When manually migrating a user's data, code, and artifacts from Studio Classic to Studio, we recommend one of the following approaches:

1. Using a custom Amazon EFS volume
2. Using Amazon Simple Storage Service (Amazon S3)

If you used Amazon SageMaker Data Wrangler in Studio Classic and want to migrate your data flow files, then choose one of the following options for migration:

- If you want to migrate all of the data from your Studio Classic storage volume, including your data flow files, go to [Manually migrate all of your data from Studio Classic](#) and complete the section **Use Amazon S3 to migrate data**. Then, skip to the [Import the flow files into Canvas](#) section.
- If you only want to migrate your data flow files and no other data from your Studio Classic storage volume, skip to the [Migrate data flows from Data Wrangler](#) section.

## Prerequisites

Before running these steps, complete the prerequisites in [Complete prerequisites to migrate the Studio experience](#). You must also complete the steps in [Migrate the UI from Studio Classic to Studio](#).

## Choosing an approach

Consider the following when choosing an approach to migrate your Studio Classic data.

### Pros and cons of using a custom Amazon EFS volume

In this approach, you use an Amazon EFS-to-Amazon EFS AWS DataSync task (one time or cadence) to copy data, then mount the target Amazon EFS volume to a user's spaces. This gives users access to data from Studio Classic in their Studio compute environments.

Pros:

- Only the user's home directory data is visible in the user's spaces. There is no data cross-pollination.
- Syncing from the source Amazon EFS volume to a target Amazon EFS volume is safer than directly mounting the source Amazon EFS volume managed by SageMaker AI into spaces. This avoids the potential to impact home directory user files.
- Users have the flexibility to continue working in Studio Classic and Studio applications, while having their data available in both applications if AWS DataSync is set up on a regular cadence.
- No need for repeated push and pull with Amazon S3.

Cons:

- No write access to the target Amazon EFS volume mounted to user's spaces. To get write access to the target Amazon EFS volume, customers would need to mount the target Amazon EFS volume to an Amazon Elastic Compute Cloud instance and provide appropriate permissions for users to write to the Amazon EFS prefix.
- Requires modification to the security groups managed by SageMaker AI to allow network file system (NFS) inbound and outbound flow.
- Costs more than using Amazon S3.
- If [migrating data flows from Data Wrangler in Studio Classic](#), you must follow the steps for manually exporting flow files.

### Pros and cons of using Amazon S3

In this approach, you use an Amazon EFS-to-Amazon S3 AWS DataSync task (one time or cadence) to copy data, then create a lifecycle configuration to copy the user's data from Amazon S3 to their private space's Amazon EBS volume.

## Pros:

- If the LCC is attached to the domain, users can choose to use the LCC to copy data to their space or to run the space with no LCC script. This gives users the choice to copy their files only to the spaces they need.
- If an AWS DataSync task is set up on a cadence, users can restart their Studio application to get the latest files.
- Because the data is copied over to Amazon EBS, users have write permissions on the files.
- Amazon S3 storage is cheaper than Amazon EFS.
- If [migrating data flows from Data Wrangler in Studio Classic](#), you can skip the manual export steps and directly import the data flows into SageMaker Canvas from Amazon S3.

## Cons:

- If administrators need to prevent cross-pollination, they must create AWS Identity and Access Management policies at the user level to ensure users can only access the Amazon S3 prefix that contains their files.

## Use a custom Amazon EFS volume to migrate data

In this approach, you use an Amazon EFS-to-Amazon EFS AWS DataSync to copy the contents of a Studio Classic Amazon EFS volume to a target Amazon EFS volume once or in a regular cadence, then mount the target Amazon EFS volume to a user's spaces. This gives users access to data from Studio Classic in their Studio compute environments.

1. Create a target Amazon EFS volume. You will transfer data into this Amazon EFS volume and mount it to a corresponding user's space using prefix-level mounting.

```
export SOURCE_DOMAIN_ID="domain-id"
export REGION="region"

export TARGET_EFS=$(aws efs create-file-system --performance-mode generalPurpose --
throughput-mode bursting --encrypted --region $REGION | jq -r '.FileSystemId')

echo "Target EFS volume Created: $TARGET_EFS"
```

2. Add variables for the source Amazon EFS volume currently attached to the domain and used by all users. The domain's Amazon Virtual Private Cloud information is required to ensure the

target Amazon EFS is created in the same Amazon VPC and subnet, with the same security group configuration.

```
export SOURCE_EFS=$(aws sagemaker describe-domain --domain-id $SOURCE_DOMAIN_ID |
jq -r '.HomeEfsFileSystemId')
export VPC_ID=$(aws sagemaker describe-domain --domain-id $SOURCE_DOMAIN_ID | jq -r
'.VpcId')

echo "EFS managed by SageMaker: $SOURCE_EFS | VPC: $VPC_ID"
```

3. Create an Amazon EFS mount target in the same Amazon VPC and subnet as the source Amazon EFS volume, with the same security group configuration. The mount target takes a few minutes to be available.

```
export EFS_VPC_ID=$(aws efs describe-mount-targets --file-system-id $SOURCE_EFS |
jq -r ".MountTargets[0].VpcId")
export EFS_AZ_NAME=$(aws efs describe-mount-targets --file-system-id $SOURCE_EFS |
jq -r ".MountTargets[0].AvailabilityZoneName")
export EFS_AZ_ID=$(aws efs describe-mount-targets --file-system-id $SOURCE_EFS | jq
-r ".MountTargets[0].AvailabilityZoneId")
export EFS_SUBNET_ID=$(aws efs describe-mount-targets --file-system-id $SOURCE_EFS
| jq -r ".MountTargets[0].SubnetId")
export EFS_MOUNT_TARG_ID=$(aws efs describe-mount-targets --file-system-id
$SOURCE_EFS | jq -r ".MountTargets[0].MountTargetId")
export EFS_SG_IDS=$(aws efs describe-mount-target-security-groups --mount-target-id
$EFS_MOUNT_TARG_ID | jq -r '.SecurityGroups[]')

aws efs create-mount-target \
--file-system-id $TARGET_EFS \
--subnet-id $EFS_SUBNET_ID \
--security-groups $EFS_SG_IDS
```

4. Create Amazon EFS source and destination locations for the AWS DataSync task.

```
export SOURCE_EFS_ARN=$(aws efs describe-file-systems --file-system-id $SOURCE_EFS
| jq -r ".FileSystems[0].FileSystemArn")
export TARGET_EFS_ARN=$(aws efs describe-file-systems --file-system-id $TARGET_EFS
| jq -r ".FileSystems[0].FileSystemArn")
export EFS_SUBNET_ID_ARN=$(aws ec2 describe-subnets --subnet-ids $EFS_SUBNET_ID |
jq -r ".Subnets[0].SubnetArn")
export ACCOUNT_ID=$(aws ec2 describe-security-groups --group-id $EFS_SG_IDS | jq -r
".SecurityGroups[0].OwnerId")
```

```
export EFS_SG_ID_ARN=arn:aws:ec2:$REGION:$ACCOUNT_ID:security-group/$EFS_SG_IDS

export SOURCE_LOCATION_ARN=$(aws datasync create-location-efs --subdirectory
"/" --efs-file-system-arn $SOURCE_EFS_ARN --ec2-config SubnetArn=
$EFS_SUBNET_ID_ARN,SecurityGroupArns=$EFS_SG_ID_ARN --region $REGION | jq -r
".LocationArn")
export DESTINATION_LOCATION_ARN=$(aws datasync create-location-efs --
subdirectory "/" --efs-file-system-arn $TARGET_EFS_ARN --ec2-config SubnetArn=
$EFS_SUBNET_ID_ARN,SecurityGroupArns=$EFS_SG_ID_ARN --region $REGION | jq -r
".LocationArn")
```

5. Allow traffic between the source and target network file system (NFS) mounts. When a new domain is created, SageMaker AI creates 2 security groups.
  - NFS inbound security group with only inbound traffic.
  - NFS outbound security group with only outbound traffic.

The source and target NFS are placed inside the same security groups. You can allow traffic between these mounts from the AWS Management Console or AWS CLI.

- Allow traffic from the AWS Management Console
  1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
  2. Choose **Security Groups**.
  3. Search for the existing domain's ID on the **Security Groups** page.

d-*xxxxxxx*

The results should return two security groups that include the domain ID in the name.

- security-group-for-inbound-nfs-*domain-id*
  - security-group-for-outbound-nfs-*domain-id*
4. Select the inbound security group ID. This opens a new page with details about the security group.
  5. Select the **Outbound Rules** tab.
  6. Select **Edit outbound rules**.

7. Update the existing outbound rules or add a new outbound rule with the following values:
    - **Type:** NFS
    - **Protocol:** TCP
    - **Port range:** 2049
    - **Destination:** security-group-for-outbound-nfs-*domain-id* | *security-group-id*
  8. Choose **Save rules**.
  9. Select the **Inbound Rules** tab.
  10. Select **Edit inbound rules**.
  11. Update the existing inbound rules or add a new outbound rule with the following values:
    - **Type:** NFS
    - **Protocol:** TCP
    - **Port range:** 2049
    - **Destination:** security-group-for-outbound-nfs-*domain-id* | *security-group-id*
  12. Choose **Save rules**.
- Allow traffic from the AWS CLI
    1. Update the security group inbound and outbound rules with the following values:
      - **Protocol:** TCP
      - **Port range:** 2049
      - **Group ID:** Inbound security group ID or outbound security group ID

```
export INBOUND_SG_ID=$(aws ec2 describe-security-groups --filters
  "Name=group-name,Values=security-group-for-inbound-nfs-$SOURCE_DOMAIN_ID" |
jq -r ".SecurityGroups[0].GroupId")
export OUTBOUND_SG_ID=$(aws ec2 describe-security-groups --filters
  "Name=group-name,Values=security-group-for-outbound-nfs-$SOURCE_DOMAIN_ID" |
jq -r ".SecurityGroups[0].GroupId")

echo "Outbound SG ID: $OUTBOUND_SG_ID | Inbound SG ID: $INBOUND_SG_ID"
aws ec2 authorize-security-group-egress \
--group-id $INBOUND_SG_ID \
--protocol tcp --port 2049 \
--source-group $OUTBOUND_SG_ID
```

```
aws ec2 authorize-security-group-ingress \
--group-id $OUTBOUND_SG_ID \
--protocol tcp --port 2049 \
--source-group $INBOUND_SG_ID
```

2. Add both the inbound and outbound security groups to the source and target Amazon EFS mount targets. This allows traffic between the 2 Amazon EFS mounts.

```
export SOURCE_EFS_MOUNT_TARGET=$(aws efs describe-mount-targets --file-
system-id $SOURCE_EFS | jq -r ".MountTargets[0].MountTargetId")
export TARGET_EFS_MOUNT_TARGET=$(aws efs describe-mount-targets --file-
system-id $TARGET_EFS | jq -r ".MountTargets[0].MountTargetId")
```

```
aws efs modify-mount-target-security-groups \
--mount-target-id $SOURCE_EFS_MOUNT_TARGET \
--security-groups $INBOUND_SG_ID $OUTBOUND_SG_ID
```

```
aws efs modify-mount-target-security-groups \
--mount-target-id $TARGET_EFS_MOUNT_TARGET \
--security-groups $INBOUND_SG_ID $OUTBOUND_SG_ID
```

6. Create a AWS DataSync task. This returns a task ARN that can be used to run the task on-demand or as part of a regular cadence.

```
export
EXTRA_XFER_OPTIONS='VerifyMode=ONLY_FILES_TRANSFERRED,OverwriteMode=ALWAYS,Atime=NONE,Mtime=
export DATASYNC_TASK_ARN=$(aws datasync create-task --source-location-arn
$SOURCE_LOCATION_ARN --destination-location-arn $DESTINATION_LOCATION_ARN --name
"SMEFS_to_CustomEFS_Sync" --region $REGION --options $EXTRA_XFER_OPTIONS | jq -r
".TaskArn")
```

7. Start a AWS DataSync task to automatically copy data from the source Amazon EFS to the target Amazon EFS mount. This does not retain the file's POSIX permissions, which allows users to read from the target Amazon EFS mount, but not write to it.

```
aws datasync start-task-execution --task-arn $DATASYNC_TASK_ARN
```

8. Mount the target Amazon EFS volume on the domain at the root level.

```
aws sagemaker update-domain --domain-id $SOURCE_DOMAIN_ID \
```

```
--default-user-settings '{"CustomFileSystemConfigs": [{"EFSFileSystemConfig": {"FileSystemId": "'"$TARGET_EFS"'", "FileSystemPath": "/"}}]}'
```

9. Overwrite every user profile with a `FileSystemPath` prefix. The prefix includes the user's UID, which is created by SageMaker AI. This ensure user's only have access to their data and prevents cross-pollination. When a space is created in the domain and the target Amazon EFS volume is mounted to the application, the user's prefix overwrites the domain prefix. As a result, SageMaker AI only mounts the `/user-id` directory on the user's application.

```
aws sagemaker list-user-profiles --domain-id $SOURCE_DOMAIN_ID | jq -r
'.UserProfiles[] | "\(.UserProfileName)"' | while read user; do
export uid=$(aws sagemaker describe-user-profile --domain-id $SOURCE_DOMAIN_ID --
user-profile-name $user | jq -r ".HomeEfsFileSystemUid")
echo "$user $uid"
aws sagemaker update-user-profile --domain-id $SOURCE_DOMAIN_ID --user-profile-
name $user --user-settings '{"CustomFileSystemConfigs": [{"EFSFileSystemConfig": {"FileSystemId": "'"$TARGET_EFS"'", "FileSystemPath": "'"/$uid/"'"}]}]'
done
```

10. Users can then select the custom Amazon EFS filesystem when launching an application. For more information, see [JupyterLab user guide](#) or [Launch a Code Editor application in Studio](#).

## Use Amazon S3 to migrate data

In this approach, you use an Amazon EFS-to-Amazon S3 AWS DataSync task to copy the contents of a Studio Classic Amazon EFS volume to an Amazon S3 bucket once or in a regular cadence, then create a lifecycle configuration to copy the user's data from Amazon S3 to their private space's Amazon EBS volume.

### Note

This approach only works for domains that have internet access.

1. Set the source Amazon EFS volume ID from the domain containing the data that you are migrating.

```
timestamp=$(date +%Y%m%d%H%M%S)
export SOURCE_DOMAIN_ID="domain-id"
export REGION="region"
```

```
export ACCOUNT_ID=$(aws sts get-caller-identity --query Account --output text)
export EFS_ID=$(aws sagemaker describe-domain --domain-id $SOURCE_DOMAIN_ID | jq -r
'.HomeEfsFileSystemId')
```

2. Set the target Amazon S3 bucket name. For information about creating an Amazon S3 bucket, see [Creating a bucket](#). The bucket used must have a CORS policy as described in [\(Optional\) Update your CORS policy to access Amazon S3 buckets](#). Users in the domain must also have permissions to access the Amazon S3 bucket.

In this example, we are copying files to a prefix named `studio-new`. If you are using a single Amazon S3 bucket to migrate multiple domains, use the `studio-new/<domain-id>` prefix to restrict permissions to the files using IAM.

```
export BUCKET_NAME=s3-bucket-name
export S3_DESTINATION_PATH=studio-new
```

3. Create a trust policy that gives AWS DataSync permissions to assume the execution role of your account.

```
export TRUST_POLICY=$(cat <<EOF
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "datasync.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "$ACCOUNT_ID"
        },
        "ArnLike": {
          "aws:SourceArn": "arn:aws:datasync:$REGION:$ACCOUNT_ID:*"
        }
      }
    }
  ]
}
EOF
)
```

#### 4. Create an IAM role and attach the trust policy.

```
export timestamp=$(date +%Y%m%d%H%M%S)
export ROLE_NAME="DataSyncS3Role-$timestamp"

aws iam create-role --role-name $ROLE_NAME --assume-role-policy-document
"$TRUST_POLICY"
aws iam attach-role-policy --role-name $ROLE_NAME --policy-arn
arn:aws:iam::aws:policy/AmazonS3FullAccess
echo "Attached IAM Policy AmazonS3FullAccess"
aws iam attach-role-policy --role-name $ROLE_NAME --policy-arn
arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
echo "Attached IAM Policy AmazonSageMakerFullAccess"
export ROLE_ARN=$(aws iam get-role --role-name $ROLE_NAME --query 'Role.Arn' --
output text)
echo "Created IAM Role $ROLE_ARN"
```

#### 5. Create a security group to give access to the Amazon EFS location.

```
export EFS_ARN=$(aws efs describe-file-systems --file-system-id $EFS_ID | jq -r
'.FileSystems[0].FileSystemArn' )
export EFS_SUBNET_ID=$(aws efs describe-mount-targets --file-system-id $EFS_ID | jq
-r '.MountTargets[0].SubnetId')
export EFS_VPC_ID=$(aws efs describe-mount-targets --file-system-id $EFS_ID | jq -r
'.MountTargets[0].VpcId')
export MOUNT_TARGET_ID=$(aws efs describe-mount-targets --file-system-id $EFS_ID |
jq -r '.MountTargets[0].MountTargetId' )
export EFS_SECURITY_GROUP_ID=$(aws efs describe-mount-target-security-groups --
mount-target-id $MOUNT_TARGET_ID | jq -r '.SecurityGroups[0]')
export EFS_SUBNET_ARN=$(aws ec2 describe-subnets --subnet-ids $EFS_SUBNET_ID | jq -
r '.Subnets[0].SubnetArn')
echo "Subnet ID: $EFS_SUBNET_ID"
echo "Security Group ID: $EFS_SECURITY_GROUP_ID"
echo "Subnet ARN: $EFS_SUBNET_ARN"

timestamp=$(date +%Y%m%d%H%M%S)
sg_name="datasync-sg-$timestamp"
export DATASYNC_SG_ID=$(aws ec2 create-security-group --vpc-id $EFS_VPC_ID --group-
name $sg_name --description "DataSync SG" --output text --query 'GroupId')
aws ec2 authorize-security-group-egress --group-id $DATASYNC_SG_ID --protocol tcp
--port 2049 --source-group $EFS_SECURITY_GROUP_ID
aws ec2 authorize-security-group-ingress --group-id $EFS_SECURITY_GROUP_ID --
protocol tcp --port 2049 --source-group $DATASYNC_SG_ID
```

```
export DATASYNC_SG_ARN="arn:aws:ec2:$REGION:$ACCOUNT_ID:security-group/
$DATASYNC_SG_ID"
echo "Security Group ARN: $DATASYNC_SG_ARN"
```

## 6. Create a source Amazon EFS location for the AWS DataSync task.

```
export SOURCE_ARN=$(aws datasync create-location-efs --efs-filesystem-arn $EFS_ARN
--ec2-config "{\"SubnetArn\": \"\$EFS_SUBNET_ARN\", \"SecurityGroupArns\":
[\"$DATASYNC_SG_ARN\"]}" | jq -r '.LocationArn')
echo "Source Location ARN: $SOURCE_ARN"
```

## 7. Create a target Amazon S3 location for the AWS DataSync task.

```
export BUCKET_ARN="arn:aws:s3:::$BUCKET_NAME"
export DESTINATION_ARN=$(aws datasync create-location-s3 --s3-bucket-arn
$BUCKET_ARN --s3-config "{\"BucketAccessRoleArn\": \"\$ROLE_ARN\"}" --subdirectory
$S3_DESTINATION_PATH | jq -r '.LocationArn')
echo "Destination Location ARN: $DESTINATION_ARN"
```

## 8. Create a AWS DataSync task.

```
export TASK_ARN=$(aws datasync create-task --source-location-arn $SOURCE_ARN --
destination-location-arn $DESTINATION_ARN | jq -r '.TaskArn')
echo "DataSync Task: $TASK_ARN"
```

## 9. Start the AWS DataSync task. This task automatically copies data from the source Amazon EFS volume to the target Amazon S3 bucket. Wait for the task to be complete.

```
aws datasync start-task-execution --task-arn $TASK_ARN
```

## 10. Check the status of the AWS DataSync task to verify that it is complete. Pass the ARN returned in the previous step.

```
export TASK_EXEC_ARN=datasync-task-arn
echo "Task execution ARN: $TASK_EXEC_ARN"
export STATUS=$(aws datasync describe-task-execution --task-execution-arn
$TASK_EXEC_ARN | jq -r '.Status')
echo "Execution status: $STATUS"
while [ "$STATUS" = "QUEUED" ] || [ "$STATUS" = "LAUNCHING" ] || [ "$STATUS" =
"PREPARING" ] || [ "$STATUS" = "TRANSFERRING" ] || [ "$STATUS" = "VERIFYING" ]; do
    STATUS=$(aws datasync describe-task-execution --task-execution-arn
$TASK_EXEC_ARN | jq -r '.Status')
```

```

if [ $? -ne 0 ]; then
    echo "Error Running DataSync Task"
    exit 1
fi
echo "Execution status: $STATUS"
sleep 30
done

```

11. After the AWS DataSync task is complete, clean up the previously created resources.

```

aws datasync delete-task --task-arn $TASK_ARN
echo "Deleted task $TASK_ARN"
aws datasync delete-location --location-arn $SOURCE_ARN
echo "Deleted location source $SOURCE_ARN"
aws datasync delete-location --location-arn $DESTINATION_ARN
echo "Deleted location source $DESTINATION_ARN"
aws iam detach-role-policy --role-name $ROLE_NAME --policy-arn
arn:aws:iam::aws:policy/AmazonS3FullAccess
aws iam detach-role-policy --role-name $ROLE_NAME --policy-arn
arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
aws iam delete-role --role-name $ROLE_NAME
echo "Deleted IAM Role $ROLE_NAME"
echo "Wait 5 minutes for the elastic network interface to detach..."
start_time=$(date +%s)
while [[ ((${(date +%s) - start_time}) -lt 300 )]]; do
    sleep 1
done
aws ec2 revoke-security-group-ingress --group-id $EFS_SECURITY_GROUP_ID --protocol
tcp --port 2049 --source-group $DATASYNC_SG_ID
echo "Revoked Ingress from $EFS_SECURITY_GROUP_ID"
aws ec2 revoke-security-group-egress --group-id $DATASYNC_SG_ID --protocol tcp --
port 2049 --source-group $EFS_SECURITY_GROUP_ID
echo "Revoked Egress from $DATASYNC_SG_ID"
aws ec2 delete-security-group --group-id $DATASYNC_SG_ID
echo "Deleted DataSync SG $DATASYNC_SG_ID"

```

12. From your local machine, create a file named `on-start.sh` with the following content. This script copies the user's Amazon EFS home directory in Amazon S3 to the user's Amazon EBS volume in Studio and creates a prefix for each user profile.

```

#!/bin/bash
set -eo pipefail

```

```

sudo apt-get install -y jq

# Studio Variables
DOMAIN_ID=$(cat /opt/ml/metadata/resource-metadata.json | jq -r '.DomainId')
SPACE_NAME=$(cat /opt/ml/metadata/resource-metadata.json | jq -r '.SpaceName')
USER_PROFILE_NAME=$(aws sagemaker describe-space --domain-id=$DOMAIN_ID --space-
name=$SPACE_NAME | jq -r '.OwnershipSettings.OwnerUserProfileName')

# S3 bucket to copy from
BUCKET=s3-bucket-name
# Subfolder in bucket to copy
PREFIX=studio-new

# Getting HomeEfsFileSystemUid for the current user-profile
EFS_FOLDER_ID=$(aws sagemaker describe-user-profile --domain-id $DOMAIN_ID --user-
profile-name $USER_PROFILE_NAME | jq -r '.HomeEfsFileSystemUid')

# Local destination directory
DEST=./studio-classic-efs-backup
mkdir -p $DEST

echo "Bucket: s3://$BUCKET/$PREFIX/$EFS_FOLDER_ID/"
echo "Destination $DEST/"
echo "Excluding *.*"
echo "Excluding */*"

aws s3 cp s3://$BUCKET/$PREFIX/$EFS_FOLDER_ID/ $DEST/ \
  --exclude "*" \
  --exclude "**/*.*" \
  --recursive

```

- Convert your script into base64 format. This requirement prevents errors that occur from spacing and line break encoding. The script type can be either JupyterLab or CodeEditor.

```

export LCC_SCRIPT_NAME='studio-classic-sync'
export SCRIPT_FILE_NAME='on-start.sh'
export SCRIPT_TYPE='JupyterLab-or-CodeEditor'
LCC_CONTENT=`openssl base64 -A -in ${SCRIPT_FILE_NAME}`

```

- Verify the following before you use the script:

- The Amazon EBS volume is large enough to store the objects that you're exporting.

- You aren't migrating hidden files and folders, such as `.bashrc` and `.condarc` if you aren't intending to do so.
- The AWS Identity and Access Management (IAM) execution role that's associated with Studio user profiles has the policies configured to access only the respective home directory in Amazon S3.

#### 15. Create a lifecycle configuration using your script.

```
aws sagemaker create-studio-lifecycle-config \  
  --studio-lifecycle-config-name $LCC_SCRIPT_NAME \  
  --studio-lifecycle-config-content $LCC_CONTENT \  
  --studio-lifecycle-config-app-type $SCRIPT_TYPE
```

#### 16. Attach the LCC to your domain.

```
aws sagemaker update-domain \  
  --domain-id $SOURCE_DOMAIN_ID \  
  --default-user-settings '  
    {"JupyterLabAppSettings":  
      {"LifecycleConfigArns":  
        [  
          "lifecycle-config-arn"  
        ]  
      }  
    }'  
'
```

17. Users can then select the LCC script when launching an application. For more information, see [JupyterLab user guide](#) or [Launch a Code Editor application in Studio](#). This automatically syncs the files from Amazon S3 to the Amazon EBS storage for the user's space.

## Migrate data flows from Data Wrangler

If you have previously used Amazon SageMaker Data Wrangler in Amazon SageMaker Studio Classic for data preparation tasks, you can migrate to the new Amazon SageMaker Studio and access the latest version of Data Wrangler in Amazon SageMaker Canvas. Data Wrangler in SageMaker Canvas provides you with an enhanced user experience and access to the latest features, such as a natural language interface and faster performance.

You can onboard to SageMaker Canvas at any time to begin using the new Data Wrangler experience. For more information, see [Getting started with using Amazon SageMaker Canvas](#).

If you have data flow files saved in Studio Classic that you were previously working on, you can onboard to Studio and then import the flow files into Canvas. You have the following options for migration:

- **One-click migration:** When you sign in to Canvas, you can use a one-time import option that migrates all of your flow files on your behalf.
- **Manual migration:** You can manually import your flow files into Canvas. From Studio Classic, either export the files to Amazon S3 or download them to your local machine. Then, you sign in to the SageMaker Canvas application, import the flow files, and continue your data preparation tasks.

The following guide describes the prerequisites to migration and how to migrate your data flow files using either the one-click or manual option.

## Prerequisites

Review the following prerequisites before you begin migrating your flow files.

### Step 1. Migrate the domain and grant permissions

Before migrating data flow files, you need to follow specific steps of the [Migration from Amazon SageMaker Studio Classic](#) guide to ensure that your user profile's AWS IAM execution role has the required permissions. Follow the [Prerequisites](#) and [Migrate the UI from Studio Classic to Studio](#) before proceeding, which describe how to grant the required permissions, configure Studio as the new experience, and migrate your existing domain.

Specifically, you must have permissions to create a SageMaker Canvas application and use the SageMaker Canvas data preparation features. To obtain these permissions, you can either:

- Add the [AmazonSageMakerCanvasDataPrepFullAccess](#) policy to your IAM role, or
- Attach a least-permissions policy, as shown in the **(Optional) Migrate from Data Wrangler in Studio Classic to SageMaker Canvas** section of the page [Migrate the UI from Studio Classic to Studio](#).

Make sure to use the same user profile for both Studio and SageMaker Canvas.

After completing the prerequisites outlined in the migration guide, you should have a new domain with the required permissions to access SageMaker Canvas through Studio.

## Step 2. (Optional) Prepare an Amazon S3 location

If you are doing a manual migration and plan to use Amazon S3 to transfer your flow files instead of using the local download option, you should have an Amazon S3 bucket in your account that you'd like to use for storing the flow files.

### One-click migration method

SageMaker Canvas offers a one-time import option for migrating your data flows from Data Wrangler in Studio Classic to Data Wrangler in SageMaker Canvas. As long as your Studio Classic and Canvas applications share the same Amazon EFS storage volume, you can migrate in one click from Canvas. This streamlined process eliminates the need for manual export and import steps, and you can import all of your flows at once.

Use the following procedure to migrate all of your flow files:

1. Open your latest version of Studio.
2. In Studio, in the left navigation pane, choose the **Data** dropdown menu.
3. From the navigation options, choose **Data Wrangler**.
4. On the **Data Wrangler** page, choose **Run in Canvas**. If you have successfully set up the permissions, this creates a Canvas application for you. The Canvas application may take a few minutes before it's ready.
5. When Canvas is ready, choose **Open in Canvas**.
6. Canvas opens to the **Data Wrangler** page, and a banner at the top of the page appears that says Import your data flows from Data Wrangler in Studio Classic to Canvas. This is a one time import. Learn more. In the banner, choose **Import All**.

#### **Warning**

If you close the banner notification, you won't be able to re-open it or use the one-click migration method anymore.

A pop-up notification appears, indicating that Canvas is importing your flow files from Studio Classic. If the import is fully successful, you receive another notification that X number of flow files were imported, and you can see your flow files on the **Data Wrangler** page of the Canvas application. Any imported flow files that have the same name as existing data flows in your Canvas application are renamed with a postfix. You can open a data flow to verify that it looks as expected.

In case any of your flow files don't import successfully, you receive a notification that the import was either partially successful or failed. Choose **View errors** on the notification message to check the individual error messages for guidance on how to reformat any incorrectly formatted flow files.

After importing your flow files, you should now be able to continue using Data Wrangler to prepare data in SageMaker Canvas.

## Manual migration method

The following sections describe how to manually import your flow files into Canvas in case the one-click migration method didn't work.

### Export the flow files from Studio Classic

#### Note

If you've already migrated your Studio Classic data to Amazon S3 by following the instructions in [\(Optional\) Migrate data from Studio Classic to Studio](#), you can skip this step and go straight to the [Import the flow files into Canvas](#) section in which you import your flow files from the Amazon S3 location where your Studio Classic data is stored.

You can export your flow files by either saving them to Amazon S3 or downloading them to your local machine. When you import your flow files into SageMaker Canvas in the next step, if you choose the local upload option, then you can only upload 20 flow files at a time. If you have a large number of flow files to import, we recommend that you use Amazon S3 instead.

Follow the instructions in either [Method 1: Use Amazon S3 to transfer flow files](#) or [Method 2: Use your local machine to transfer flow files](#) to proceed.

#### Method 1: Use Amazon S3 to transfer flow files

With this method, you use Amazon S3 as the intermediary between Data Wrangler in Studio Classic and Data Wrangler in SageMaker Canvas (accessed through the latest version of Studio). You export the flow files from Studio Classic to Amazon S3, and then in the next step, you access Canvas through Studio and import the flow files from Amazon S3.

Make sure that you have an Amazon S3 bucket prepared as the storage location for the flow files.

Use the following procedure to export your flow files from Studio Classic to Amazon S3:

1. Open Studio Classic.
2. Open a new terminal by doing the following:
  - a. On the top navigation bar, choose **File**.
  - b. In the context menu, hover over **New**, and then select **Terminal**.
3. By default, the terminal should open in your home directory. Navigate to the folder that contains all of the flow files that you want to migrate.
4. Use the following command to synchronize all of the flow files to the specified Amazon S3 location. Replace `{bucket-name}` and `{folder}` with the path to your desired Amazon S3 location. For more information about the command and parameters, see the [sync](#) command in the AWS CLI Command Reference.

```
aws s3 sync . s3://{bucket-name}/{folder}/ --exclude "*" --include "*.flow"
```

If you are using your own AWS KMS key, then use the following command instead to synchronize the files, and specify your KMS key ID. Make sure that the user's IAM execution role (which should be the same role used in **Step 1. Migrate the domain and grant permissions** of the preceding [Prerequisites](#)) has been granted access to use the KMS key.

```
aws s3 sync . s3://{bucket-name}/{folder}/ --exclude "*" --include "*.flow" --sse-kms-key-id {your-key-id}
```

Your flow files should now be exported. You can check your Amazon S3 bucket to make sure that the flow files synchronized successfully.

To import these files in the latest version of Data Wrangler, follow the steps in [Import the flow files into Canvas](#).

## Method 2: Use your local machine to transfer flow files

With this method, you download the flow files from Studio Classic to your local machine. You can download the files directly, or you can compress them as a zip archive. Then, you unpack the zip file locally (if applicable), sign in to Canvas, and import the flow files by uploading them from your local machine.

Use the following procedure to download your flow files from Studio Classic:

1. Open Studio Classic.

2. (Optional) If you want to compress multiple flow files into a zip archive and download them all at once, then do the following:
  - a. On the top navigation bar of Studio Classic, choose **File**.
  - b. In the context menu, hover over **New**, and then select **Terminal**.
  - c. By default, the terminal opens in your home directory. Navigate to the folder that contains all of the flow files that you want to migrate.
  - d. Use the following command to pack the flow files in the current directory as a zip. The command excludes any hidden files:

```
find . -not -path "*/.*" -name "*.flow" -print0 | xargs -0 zip my_archive.zip
```

3. Download the zip archive or individual flow files to your local machine by doing the following:
  - a. In the left navigation pane of Studio Classic, choose **File Browser**.
  - b. Find the file you want to download in the file browser.
  - c. Right click the file, and in the context menu, select **Download**.

The file should download to your local machine. If you packed them as a zip archive, extract the files locally. After the files are extracted, to import these files in the latest version of Data Wrangler, follow the steps in [Import the flow files into Canvas](#).

### Import the flow files into Canvas

After exporting your flow files, access Canvas through Studio and import the files.

Use the following procedure to import flow files into Canvas:

1. Open your latest version of Studio.
2. In Studio, in the left navigation pane, choose the **Data** dropdown menu.
3. From the navigation options, choose **Data Wrangler**.
4. On the **Data Wrangler** page, choose **Run in Canvas**. If you have successfully set up the permissions, this creates a Canvas application for you. The Canvas application may take a few minutes before it's ready.
5. When Canvas is ready, choose **Open in Canvas**.
6. Canvas opens to the **Data Wrangler** page. In the top pane, choose **Import data flows**.

7. For **Data source**, choose either **Amazon S3** or **Local upload**.
8. Select your flow files from your Amazon S3 bucket, or upload the files from your local machine.

 **Note**

For local upload, you can upload a maximum of 20 flow files at a time. For larger imports, use Amazon S3. If you select a folder to import, any flow files in sub-folders are also imported.

9. Choose **Import data**.

If the import was successful, you receive a notification that X number of flow files were successfully imported.

In case your flow files don't import successfully, you receive a notification in the SageMaker Canvas application. Choose **View errors** on the notification message to check the individual error messages for guidance on how to reformat any incorrectly formatted flow files.

After your flow files are done importing, go to the **Data Wrangler** page of the SageMaker Canvas application to view your data flows. You can try opening a data flow to verify that it looks as expected.

## Launch Amazon SageMaker Studio

 **Important**

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

This page's topics demonstrate how to launch Amazon SageMaker Studio from the Amazon SageMaker AI console and the AWS Command Line Interface (AWS CLI).

## Topics

- [Prerequisites](#)
- [Launch from the Amazon SageMaker AI console](#)
- [Launch using the AWS CLI](#)

## Prerequisites

Before you begin, complete the following prerequisites:

- Onboard to a SageMaker AI domain with Studio access. If you don't have permissions to set Studio as the default experience for your domain, contact your administrator. For more information, see [Amazon SageMaker AI domain overview](#).
- Update the AWS CLI by following the steps in [Installing the current AWS CLI Version](#).
- From your local machine, run `aws configure` and provide your AWS credentials. For information about AWS credentials, see [Understanding and getting your AWS credentials](#).

## Launch from the Amazon SageMaker AI console

Complete the following procedure to launch Studio from the Amazon SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. From the left navigation pane, choose Studio.
3. From the Studio landing page, select the domain and user profile for launching Studio.
4. Choose **Open Studio**.
5. To launch Studio, choose **Launch personal Studio**.

## Launch using the AWS CLI

This section demonstrates how to launch Studio using the AWS CLI. The procedure to access Studio using the AWS CLI depends if the domain uses AWS Identity and Access Management (IAM) authentication or AWS IAM Identity Center authentication. You can use the AWS CLI to launch Studio by creating a presigned domain URL when your domain uses IAM authentication. For information about launching Studio with IAM Identity Center authentication, see [Use custom setup for Amazon SageMaker AI](#).

### Launch if Studio is the default experience

The following code snippet demonstrates how to launch Studio from the AWS CLI using a presigned domain URL if Studio is the default experience. For more information, see [create-presigned-domain-url](#).

```
aws sagemaker create-presigned-domain-url \  
--region region \  
--domain-id domain-id \  
--user-profile-name user-profile-name \  
--session-expiration-duration-in-seconds 43200
```

### Launch if Amazon SageMaker Studio Classic is your default experience

The following code snippet demonstrates how to launch Studio from the AWS CLI using a presigned domain URL if Studio Classic is the default experience. For more information, see [create-presigned-domain-url](#).

```
aws sagemaker create-presigned-domain-url \  
--region region \  
--domain-id domain-id \  
--user-profile-name user-profile-name \  
--session-expiration-duration-in-seconds 43200 \  
--landing-uri studio::
```

## Amazon SageMaker Studio UI overview

### Important

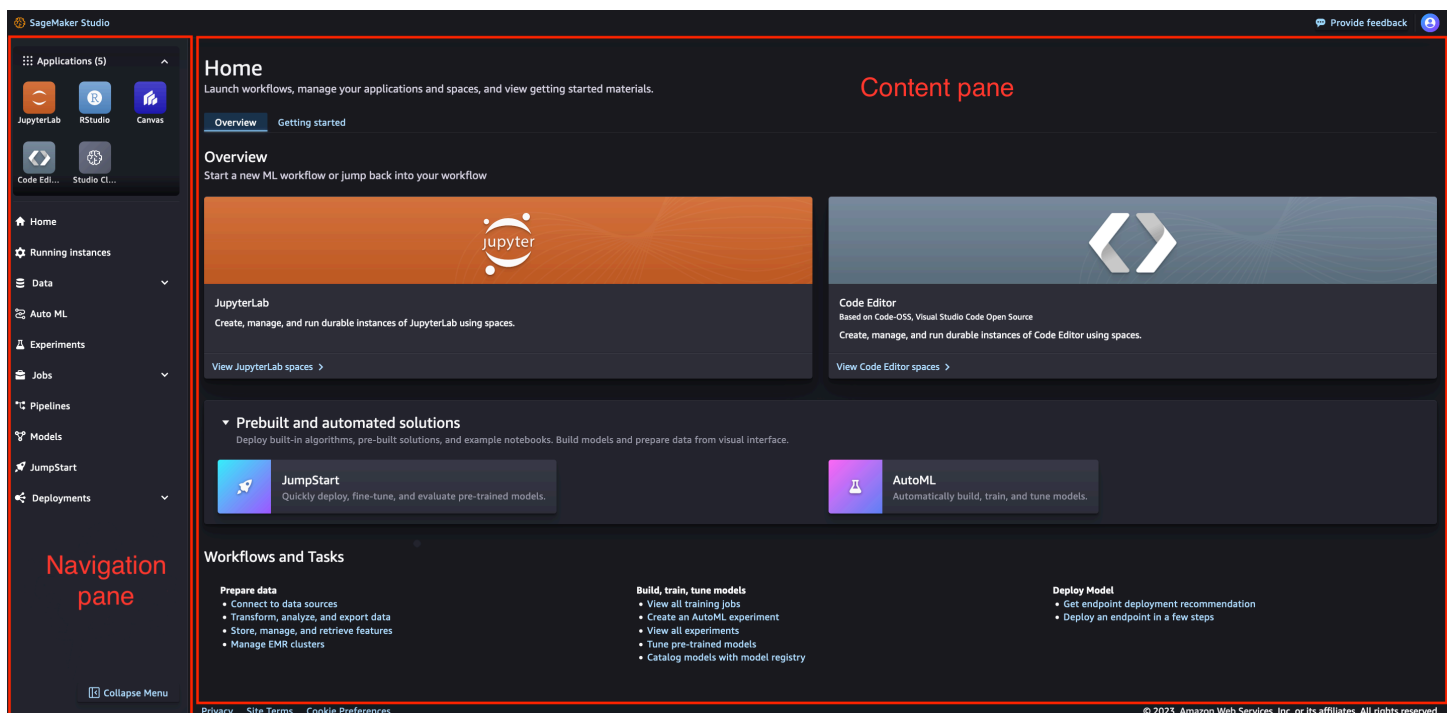

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the

updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

The Amazon SageMaker Studio user interface is split into three distinct parts. This page gives information about the distinct parts and their components.

- **Navigation bar**– This section of the UI includes the URL, breadcrumbs, notifications, and user options.
- **Navigation pane**– This section of the UI includes a list of the applications that are supported in Studio and options for the main workflows in Studio.
- **Content pane**– The main working area that displays the current page of the Studio UI that you have open.

## Topics

- [Amazon SageMaker Studio navigation bar](#)
- [Amazon SageMaker Studio navigation pane](#)
- [Studio content pane](#)

## Amazon SageMaker Studio navigation bar

The navigation bar of the Studio UI includes the URL, breadcrumbs, notifications, and user options.

### URL Structure

The URL of Studio changes as you navigate the UI. When you navigate to a different page in the UI, the URL changes to reflect that page. With the updated URL, you open any page in the Studio UI directly without navigating to the landing page first.

### Breadcrumbs

As you navigate through the Studio UI, the breadcrumbs keep track of the parent pages of the current page. By choosing one of these breadcrumbs, you can navigate to parent pages in the UI.

### Notifications

The notifications section of the UI gives information about important changes to Studio, updates to applications, and issues to resolve.

### User options

Choose the user options icon

to get information about the user profile that is currently using Studio, and gives the option to sign out of Studio.

## Amazon SageMaker Studio navigation pane

### Navigation pane

The navigation pane of the UI includes a list of the applications that are supported in Studio. It also provides options for the main workflows in Studio.

This section of the UI can be used in an expanded or collapsed state. To change whether the section is expanded or collapsed, select the **Collapse** icon

### Applications

The applications section lists the applications that are available in Studio. If you choose one of the application types, you are directed to the landing page for that application.

## Workflows

The list of workflows includes all of the available actions that you can take in Studio. Choose one of the options to navigate to the landing page for that workflow. If there are multiple workflows available for that option, choosing the option opens a dropdown menu where you can select the desired landing page.

The following list describes the options and provides a link for more information.

- **Home**– The main landing page with an overview, getting started, and what's new.
- **Running instances**– All of the instances that are currently running in Studio. For more information, see [View your Studio running instances, applications, and spaces](#).
- **Data**– Data preparation options where you can collaborate to store, explore, prepare, transform, and share your data.
  - For more information about Amazon SageMaker Data Wrangler, see [Data preparation](#).
  - For more information about Amazon SageMaker Feature Store, see [Create, store, and share features with Feature Store](#).
  - For more information about Amazon EMR clusters, see [Data preparation using Amazon EMR](#).
- **Auto ML**– Automatically build, train, tune, and deploy machine learning (ML) models. For more information, see [Amazon SageMaker Canvas](#).
- **Experiments**– Create, manage, analyze, and compare your machine learning experiments using Amazon SageMaker Experiments. For more information, see [Amazon SageMaker Experiments in Studio Classic](#).
- **Jobs**– View jobs created in Studio.
  - For more information about training, see [Model training](#).
  - For more information about model evaluation, see [Understand options for evaluating large language models with SageMaker Clarify](#).
- **Pipelines**– Automate your ML workflow with Amazon SageMaker Pipelines, which provides resources to help you build, track, and manage your pipeline resources. For more information, see [Pipelines](#).
- **Models**– Organize your models into groups and collections in the model registry, where you can manage model versions, view metadata, and deploy models to production. For more information, see [Model Registration Deployment with Model Registry](#).

- **JumpStart**– Amazon SageMaker JumpStart provides pretrained, open-source models for a wide range of problem types to help you get started with machine learning. For more information, see [SageMaker JumpStart pretrained models](#).
- **Deployments**– Deploy your machine learning (ML) models for inference.
  - For more information about Amazon SageMaker Inference Recommender, see [Amazon SageMaker Inference Recommender](#).
  - For more information about endpoints, see [Deploy models for inference](#).

## Studio content pane

The main working area is also called the content pane. It displays the current page of the Studio UI that you have open.

### Studio home page

The Studio home page is the primary landing page in the main working area. The home page includes two distinct tabs. There is an **Overview** tab and a **Getting started** tab.

#### Overview

The **Overview** tab includes options to start spaces for popular application types, get started with pre-built and automated solutions for ML workflows, and links to common tasks in the Studio UI.

#### Getting started

The **Getting started** tab includes information, guidance, and resources on how to begin with Studio. This includes a guided tour of the Studio UI, a link to documentation about Studio, and a selection of quick tips.

## Amazon EFS auto-mounting in Studio

Amazon SageMaker AI supports automatically mounting a folder in an Amazon EFS volume for each user in a domain. Using this folder, users can share data between their own private spaces. However, users cannot share data with other users in the domain. Users only have access to their own folder.

The user's folder can be accessed through a folder named `user-default-efs`. This folder is present in the `$HOME` directory of the Studio application.

For information about opting out of Amazon EFS auto-mounting, see [Opt out of Amazon EFS auto-mounting](#).

Amazon EFS auto-mounting also facilitates the migration of data from Studio Classic to Studio. For more information, see [\(Optional\) Migrate data from Studio Classic to Studio](#).

## Access point information

When auto-mounting is activated, SageMaker AI uses an Amazon EFS access point to facilitate access to the data in the Amazon EFS volume. For more information about access points, see [Working with Amazon EFS access points](#). SageMaker AI creates a unique access point for each user profile in the domain during user profile creation or during application creation for an existing user profile. The POSIX user value of the access point matches the `HomeEfsFileSystemUid` value of the user profile that SageMaker AI creates the access point for. To get the value of the user, see [DescribeUserProfile](#). The root directory path is also set to the same value as the POSIX user value.

SageMaker AI sets the permissions of the new directory to the following values:

- Owner user ID: *POSIX user value*
- Owner group ID: `0`
- Permissions `700`

The access point is required to access the Amazon EFS volume. As a result, you cannot delete or update the access point without losing access to the Amazon EFS volume.

## Error resolution

If SageMaker AI encounters an issue when auto-mounting the Amazon EFS user folder during application creation, the application is still created. However, in this case, SageMaker AI creates a file named `error.txt` instead of mounting the Amazon EFS folder. This file describes the error encountered, as well as steps to resolve it. SageMaker AI creates the `error.txt` file in the `user-default-efs` folder located in the `$HOME` directory of the application.

## Opt out of Amazon EFS auto-mounting

You can opt-out of Amazon SageMaker AI auto-mounting Amazon EFS user folders during domain and user profile creation or for an existing domain or user profile.

## Opt out during domain creation

You can opt out of Amazon EFS auto-mounting when creating a domain using either the console or the AWS Command Line Interface.

### Console

Complete the following steps to opt out of Amazon EFS auto-mounting when creating a domain from the console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. Complete the steps in [Use custom setup for Amazon SageMaker AI](#) with the following modification to set up a domain.
  - On the **Configure storage** step, turn off **Automatically mount EFS storage and data**.

### AWS CLI

Use the following command to opt out of Amazon EFS auto-mounting during domain creation using the AWS CLI. For more information about creating a domain using the AWS CLI, see [Use custom setup for Amazon SageMaker AI](#).

```
aws --region region sagemaker create-domain \  
--domain-name "my-domain-$(date +%s)" \  
--vpc-id default-vpc-id \  
--subnet-ids subnet-ids \  
--auth-mode IAM \  
--default-user-settings "ExecutionRole=execution-role-arn,AutoMountHomeEFS=Disabled" \  
--default-space-settings "ExecutionRole=execution-role-arn"
```

## Opt out for an existing domain

You can opt out of Amazon EFS auto-mounting for an existing domain using either the console or the AWS CLI.

### Console

Complete the following steps to opt out of Amazon EFS auto-mounting when updating a domain from the console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.

2. On the left navigation under **Admin configurations**, choose **Domains**.
3. On the **Domains** page, select the domain that you want to opt out of Amazon EFS auto-mounting for.
4. On the **Domain details** page, select the **Domain settings** tab.
5. Navigate to the **Storage configurations** section.
6. Select **Edit**.
7. From the **Edit storage settings** page, turn off **Automatically mount EFS storage and data**.
8. Select **Submit**.

## AWS CLI

Use the following command to opt out of Amazon EFS auto-mounting while updating an existing domain using the AWS CLI.

```
aws --region region sagemaker update-domain \  
--domain-id domain-id \  
--default-user-settings "AutoMountHomeEFS=Disabled"
```

## Opt out during user profile creation

You can opt out of Amazon EFS auto-mounting when creating a user profile using either the console or the AWS CLI.

### Console

Complete the following steps to opt out of Amazon EFS auto-mounting when creating a user profile from the console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. Complete the steps in [Add user profiles](#) with the following modification to create a user profile.
  - On the **Data and Storage** step, turn off **Inherit settings from domain**. This allows the user to have a different value than the defaults that are set for the domain.
  - Turn off **Automatically mount EFS storage and data**.

## AWS CLI

Use the following command to opt out of Amazon EFS auto-mounting during user profile creation using the AWS CLI. For more information about creating a user profile using the AWS CLI, see [Add user profiles](#).

```
aws --region region sagemaker create-user-profile \  
--domain-id domain-id \  
--user-profile-name "user-profile-${date +%s}" \  
--user-settings "ExecutionRole=arn:aws:iam::account-id:role/execution-role-  
name,AutoMountHomeEFS=Enabled/Disabled/DefaultAsDomain"
```

## Opt out for an existing user profile

You can opt out of Amazon EFS auto-mounting for an existing user profile using either the console or the AWS CLI.

### Console

Complete the following steps to opt out of Amazon EFS auto-mounting when updating a user profile from the console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation under **Admin configurations**, choose **Domains**.
3. On the **Domains** page, select the domain containing the user profile that you want to opt out of Amazon EFS auto-mounting for.
4. On the **Domains details** page, select the **User profiles** tab.
5. Select the user profile to update.
6. From the **User Details** tab, navigate to the **AutoMountHomeEFS** section.
7. Select **Edit**.
8. From the **Edit storage settings** page, turn off **Inherit settings from domain**. This allows the user to have a different value than the defaults that are set for the domain.
9. Turn off **Automatically mount EFS storage and data**.
10. Select **Submit**.

## AWS CLI

Use the following command to opt out of Amazon EFS auto-mounting while updating an existing user profile using the AWS CLI.

```
aws --region region sagemaker update-user-profile \  
--domain-id domain-id \  
--user-profile-name user-profile-name \  
--user-settings "AutoMountHomeEFS=DefaultAsDomain"
```

## Idle shutdown

Amazon SageMaker AI supports shutting down idle resources to manage costs and prevent cost overruns due to cost accrued by idle, billable resources. It accomplishes this by detecting an app's idle state and performing an app shutdown when idle criteria are met.

SageMaker AI supports idle shutdown for the following applications. Idle shutdown must be set for each application type independently.

- JupyterLab
- Code Editor, based on Code-OSS, Visual Studio Code - Open Source

Idle shutdown can be set at either the domain or user profile level. When idle shutdown is set at the domain level, the idle shutdown settings apply to all applications created in the domain. When set at the user profile level, the idle shutdown settings apply only to the specific users that they are set for. User profile settings override domain settings.

### Note

Idle shutdown requires the usage of the SageMaker-distribution (SMD) image with v2.0 or newer. Domains using an older SMD version can't use the feature. These users must use an LCC to manage auto-shutdown instead.

## Definition of idle

Idle shutdown settings only apply when the application becomes idle with no jobs running. SageMaker AI doesn't start the idle shutdown timing until the instance becomes idle. The definition on idle differs based on whether the application type is JupyterLab or Code Editor.

For JupyterLab applications, the instance is considered idle when the following conditions are met:

- No active Jupyter kernel sessions
- No active Jupyter terminal sessions

For Code Editor applications, the instance is considered idle when the following conditions are met:

- No text file or notebook changes
- No files being viewed
- No interaction with the terminal
- No background processes running
- No notebook kernels processing
- No unsaved work

## Set up idle shutdown

The following sections show how to set up idle shutdown from either the console or using the AWS CLI. Idle shutdown can be set at either the domain or user profile level.

### Prerequisites

To use idle shutdown with your application, you must complete the following prerequisites.

- Ensure that your application is using the SageMaker Distribution (SMD) version 2.0. You can select this version during application creation or update the image version of the application after creation. For more information, see [Update the SageMaker Distribution Image](#).
- For applications built with custom images, idle shutdown is supported if your custom image is created with SageMaker Distribution (SMD) version 2.0 or later as the base image. If the custom image is created with a different base image, then you must install the [jupyter-activity-monitor-extension >= 0.3.1](#) extension on the image and attach the image to your Amazon SageMaker AI domain for JupyterLab applications. For more information about custom images for JupyterLab applications, see [Provide users with access to custom images](#). For more information about custom images for Code Editor applications, see [Environment customization using custom images](#).

## From the Console

The following sections show how to enable idle shutdown from the console.

### Add when creating a new domain

1. Create a domain by following the steps in [Use custom setup for Amazon SageMaker AI](#)
2. When configuring the application settings in the domain, navigate to either the Code Editor or JupyterLab section.
3. Select **Enable idle shutdown**.
4. Enter a default idle shutdown time in minutes. This value defaults to 10,080 if no value is entered.
5. (Optional) Select **Allow users to set custom idle shutdown time** to allow users to modify the idle shutdown time.
  - Enter a maximum value that users can set the default idle shutdown time to. You must enter a maximum value. The minimum value is set by Amazon SageMaker AI and must be 60.

### Add to an existing domain

#### Note

If idle shutdown is set when applications are running, they must be restarted for idle shutdown settings to take effect.

1. Navigate to the domain.
2. Choose the **App Configurations** tab.
3. From the **App Configurations** tab, navigate to either the Code Editor or JupyterLab section.
4. Select **Edit**.
5. Select **Enable idle shutdown**.
6. Enter a default idle shutdown time in minutes. This value defaults to 10,080 if no value is entered.
7. (Optional) Select **Allow users to set custom idle shutdown time** to allow users to modify the idle shutdown time.

- Enter a maximum value that users can set the default idle shutdown time to. You must enter a maximum value. The minimum value is set by Amazon SageMaker AI and must be 60.
8. Select **Submit**.

### Add when creating a new user profile

1. Add a user profile by following the steps at [Add user profiles](#)
2. When configuring the application settings for the user profile, navigate to either the Code Editor or JupyterLab section.
3. Select **Enable idle shutdown**.
4. Enter a default idle shutdown time in minutes. This value defaults to 10,080 if no value is entered.
5. (Optional) Select **Allow users to set custom idle shutdown time** to allow users to modify the idle shutdown time.
  - Enter a maximum value that users can set the default idle shutdown time to. You must enter a maximum value. The minimum value is set by Amazon SageMaker AI and must be 60.
6. Select "Save Changes".

### Add to an existing user profile

Note: If idle shutdown is set when applications are running, they must be restarted for idle shutdown settings to take effect.

1. Navigate to the user profile.
2. Choose the **App Configurations** tab.
3. From the **App Configurations** tab, navigate to either the Code Editor or JupyterLab section.
4. Select **Edit**.
5. Idle shutdown settings will show domain settings by default if configured for the domain.
6. Select **Enable idle shutdown**.
7. Enter a default idle shutdown time in minutes. This value defaults to 10,080 if no value is entered.
8. (Optional) Select **Allow users to set custom idle shutdown time** to allow users to modify the idle shutdown time.

- Enter a maximum value that users can set the default idle shutdown time to. You must enter a maximum value. The minimum value is set by Amazon SageMaker AI and must be 60.

## 9. Select **Save Changes**.

### From the AWS CLI

The following sections show how to enable idle shutdown using the AWS CLI.

#### **Note**

To enforce a specific timeout value from the AWS CLI, you must set `IdleTimeoutInMinutes`, `MaxIdleTimeoutInMinutes`, and `MinIdleTimeoutInMinutes` to the same value.

### Domain

The following command shows how to enable idle shutdown when updating an existing domain. To add idle shutdown for a new domain, use the `create-domain` command instead.

#### **Note**

If idle shutdown is set when applications are running, they must be restarted for idle shutdown settings to take effect.

```
aws sagemaker update-domain --region region --domain-id domain-id \  
--default-user-settings file://default-user-settings.json  
  
## default-user-settings.json example for enforcing the default timeout  
{  
  "JupyterLabAppSettings": {  
    "AppLifecycleManagement": {  
      "IdleSettings": {  
        "LifecycleManagement": "ENABLED",  
        "IdleTimeoutInMinutes": 120,  
        "MaxIdleTimeoutInMinutes": 120,  
        "MinIdleTimeoutInMinutes": 120  
      }  
    }  
  }  
}
```

```

    }
  }
}

## default-user-settings.json example for letting users customize the default timeout,
  between 2-5 hours
{
  "JupyterLabAppSettings": {
    "AppLifecycleManagement": {
      "IdleSettings": {
        "LifecycleManagement": "ENABLED",
        "IdleTimeoutInMinutes": 120,
        "MinIdleTimeoutInMinutes": 120,
        "MaxIdleTimeoutInMinutes": 300
      }
    }
  }
}

```

## User profile

The following command shows how to enable idle shutdown when updating an existing user profile. To add idle shutdown for a new user profile, use the `create-user-profile` command instead.

### Note

If idle shutdown is set when applications are running, they must be restarted for idle shutdown settings to take effect.

```

aws sagemaker update-user-profile --region region --domain-id domain-id \
--user-profile-name user-profile-name --user-settings file://user-settings.json

## user-settings.json example for enforcing the default timeout
{
  "JupyterLabAppSettings": {
    "AppLifecycleManagement": {
      "IdleSettings": {
        "LifecycleManagement": "ENABLED",
        "IdleTimeoutInMinutes": 120,
        "MaxIdleTimeoutInMinutes": 120,
        "MinIdleTimeoutInMinutes": 120
      }
    }
  }
}

```

```
    }  
  }  
}  
  
## user-settings.json example for letting users customize the default timeout, between  
2-5 hours  
{  
  "JupyterLabAppSettings": {  
    "AppLifecycleManagement": {  
      "IdleSettings": {  
        "LifecycleManagement": "ENABLED",  
        "IdleTimeoutInMinutes": 120,  
        "MinIdleTimeoutInMinutes": 120,  
        "MaxIdleTimeoutInMinutes": 300  
      }  
    }  
  }  
}
```

## Update default idle shutdown settings

You can update the default idle shutdown settings at either the domain or user profile level.

### Note

If idle shutdown is set when applications are running, they must be restarted for idle shutdown settings to take effect.

## Update domain settings

1. Navigate to the domain.
2. Choose the **App Configurations** tab.
3. From the **App Configurations** tab, navigate to either the Code Editor or JupyterLab section.
4. In the section for the application that you want to modify the idle shutdown time limit for, select **Edit**.
5. Update the idle shutdown settings for the domain.
6. Select **Save Changes**.

## Update user profile settings

1. Navigate to the domain.
2. Choose the **User profiles** tab.
3. From the **User profiles** tab, select the user profile to edit.
4. From the **User profile** page, choose the **Applications** tab.
5. On the **Applications** tab, navigate to either the Code Editor or JupyterLab section.
6. In the section for the application that you want to modify the idle shutdown time limit for, select **Edit**.
7. Update the idle shutdown settings for the user profile.
8. Select **Save Changes**.

## Modify your idle shutdown time limit

Users may be able to modify the idle shutdown time limit if the admin gives access when adding support for idle shutdown. If support for idle shutdown is added, there may be a limit applied to the maximum time for idle shutdown. A user can set the value anywhere between the lower limit and upper limit.

1. Launch Amazon SageMaker Studio by following the steps in [Launch Amazon SageMaker Studio](#).
2. From the **Applications** section, select the application type to update the idle shutdown time for.
3. Select the space to update.
4. Update **Idle shutdown (mins)** with your desired value.

### Note

If idle shutdown is set when applications are running, they must be restarted for idle shutdown settings to take effect.

## Applications supported in Amazon SageMaker Studio

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

Amazon SageMaker Studio supports the following applications:

- **Code Editor, based on Code-OSS, Visual Studio Code - Open Source**– Code Editor offers a lightweight and powerful integrated development environment (IDE) with familiar shortcuts, terminal, and advanced debugging capabilities and refactoring tools. It is a fully managed, browser-based application in Studio. For more information, see [Code Editor in Amazon SageMaker Studio](#).
- **Amazon SageMaker Studio Classic**– Amazon SageMaker Studio Classic is a web-based IDE for machine learning. With Studio Classic, you can build, train, debug, deploy, and monitor your machine learning models. For more information, see [Amazon SageMaker Studio Classic](#).
- **JupyterLab**–JupyterLab offers a set of capabilities that augment the fully managed notebook offering. It includes kernels that start in seconds, a pre-configured runtime with popular data science, machine learning frameworks, and high performance block storage. For more information, see [SageMaker JupyterLab](#).
- **Amazon SageMaker Canvas**– With SageMaker Canvas, you can use machine learning to generate predictions without writing code. With Canvas, you can chat with popular large language models (LLMs), access ready-to-use models, or build a custom model that's trained on your data. For more information, see [Amazon SageMaker Canvas](#).
- **RStudio**– RStudio is an integrated development environment for R. It includes a console and syntax-highlighting editor that supports running code directly. It also includes tools for plotting, history, debugging, and workspace management. For more information, see [RStudio on Amazon SageMaker AI](#).

## Lifecycle configurations within Amazon SageMaker Studio

Administrators and users can create and attach lifecycle configurations (LCCs) to automate the customization of the following applications within your Amazon SageMaker Studio environment:

- Amazon SageMaker AI JupyterLab
- Code Editor, based on Code-OSS, Visual Studio Code - Open Source
- Studio Classic
- Notebook instance

Customizing your application includes:

- Installing custom packages
- Configuring extensions
- Preloading datasets
- Setting up source code repositories

Users create and attach built-in lifecycle configurations to their own user profiles. Administrators create and attach default or built-in lifecycle configurations at the domain, space, or user profile level.

### Important

Amazon SageMaker Studio first runs the built-in lifecycle configuration and then runs the default LCC. Amazon SageMaker AI won't resolve package conflicts between the user and administrator LCCs. For example, if the built-in LCC installs `python3.11` and the default LCC installs `python3.12`, Studio installs `python3.12`.

## Create and attach lifecycle configurations

You can create and attach lifecycle configurations using either the AWS Management Console or the AWS Command Line Interface.

### Topics

- [Create and attach lifecycle configurations \(AWS CLI\)](#)

- [Create and attach lifecycle configurations \(console\)](#)

## Create and attach lifecycle configurations (AWS CLI)

### Important

Before you begin, complete the following prerequisites:

- Update the AWS CLI by following the steps in [Installing the current AWS CLI Version](#).
- From your local machine, run `aws configure` and provide your AWS credentials. For information about AWS credentials, see [Understanding and getting your AWS credentials](#).
- Onboard to Amazon SageMaker AI domain. For conceptual information, see [Amazon SageMaker AI domain overview](#). For a quickstart guide, see [Use quick setup for Amazon SageMaker AI](#).

The following procedure shows how to create a lifecycle configuration script that prints Hello World within Code Editor or JupyterLab.

### Note

Each script can have up to **16,384 characters**.

1. From your local machine, create a file named `my-script.sh` with the following content:

```
#!/bin/bash
set -eux
echo 'Hello World!'
```

2. Use the following to convert your `my-script.sh` file into base64 format. This requirement prevents errors that occur from spacing and line break encoding.

```
LCC_CONTENT=`openssl base64 -A -in my-script.sh`
```

3. Create a lifecycle configuration for use with Studio. The following command creates a lifecycle configuration that runs when you launch an associated JupyterLab application:

```
aws sagemaker create-studio-lifecycle-config \  
--region region \  
--studio-lifecycle-config-name my-lcc \  
--studio-lifecycle-config-content $LCC_CONTENT \  
--studio-lifecycle-config-app-type application-type
```

For `studio-lifecycle-config-app-type`, specify either *CodeEditor* or *JupyterLab*.

### Note

The ARN of the newly created lifecycle configuration that is returned. This ARN is required to attach the lifecycle configuration to your application.

To ensure that the environments are customized properly, users and administrators use different commands to attach lifecycle configurations.

## Attach default lifecycle configurations (administrator)

To attach the lifecycle configuration, you must update the `UserSettings` for your domain or user profile. Lifecycle configuration scripts that are associated at the domain level are inherited by all users. However, scripts that are associated at the user profile level are scoped to a specific user.

You can create a new user profile, domain, or space with a lifecycle configuration attached by using the following commands:

- [create-user-profile](#)
- [create-domain](#)
- [create-space](#)

The following command creates a user profile with a lifecycle configuration for a JupyterLab application. Add the lifecycle configuration ARN from the preceding step to the `JupyterLabAppSettings` of the user. You can add multiple lifecycle configurations at the same time by passing a list of them. When a user launches a JupyterLab application with the AWS CLI, they can specify a lifecycle configuration instead of using the default one. The lifecycle configuration that the user passes must belong to the list of lifecycle configurations in `JupyterLabAppSettings`.

```
# Create a new UserProfile
aws sagemaker create-user-profile --domain-id domain-id \
--user-profile-name user-profile-name \
--region region \
--user-settings '{
  "JupyterLabAppSettings": {
    "LifecycleConfigArns":
      [lifecycle-configuration-arn-list]
  }
}'
```

The following command creates a user profile with a lifecycle configuration for a Code Editor application. Add the lifecycle configuration ARN from the preceding step to the `CodeEditorAppSettings` of the user. You can add multiple lifecycle configurations at the same time by passing a list of them. When a user launches a Code Editor application with the AWS CLI, they can specify a lifecycle configuration instead of using the default one. The lifecycle configuration that the user passes must belong to the list of lifecycle configurations in `CodeEditorAppSettings`.

```
# Create a new UserProfile
aws sagemaker create-user-profile --domain-id domain-id \
--user-profile-name user-profile-name \
--region region \
--user-settings '{
  "CodeEditorAppSettings": {
    "LifecycleConfigArns":
      [lifecycle-configuration-arn-list]
  }
}'
```

### Attach built-in lifecycle configurations (user)

To attach the lifecycle configuration, you must update the `UserSettings` for your user profile.

The following command creates a user profile with a lifecycle configuration for a JupyterLab application. Add the lifecycle configuration ARN from the preceding step to the `JupyterLabAppSettings` of your user profile.

```
# Update a UserProfile
aws sagemaker update-user-profile --domain-id domain-id \
```

```
--user-profile-name user-profile-name \  
--region region \  
--user-settings '{  
  "JupyterLabAppSettings": {  
    "BuiltInLifecycleConfigArn": "lifecycle-configuration-arn"  
  }  
'
```

The following command creates a user profile with a lifecycle configuration for a Code Editor application. Add the lifecycle configuration ARN from the preceding step to the `CodeEditorAppSettings` of your user profile. The lifecycle configuration that the user passes must belong to the list of lifecycle configurations in `CodeEditorAppSettings`.

```
# Update a UserProfile  
aws sagemaker update-user-profile --domain-id domain-id \  
--user-profile-name user-profile-name \  
--region region \  
--user-settings '{  
  "CodeEditorAppSettings": {  
    "BuiltInLifecycleConfigArn": "lifecycle-configuration-arn"  
  }  
'
```

## Create and attach lifecycle configurations (console)

To create and attach lifecycle configurations in the AWS Management Console, navigate to the [Amazon SageMaker AI console](#) and choose **Lifecycle configurations** in the left-hand navigation. The console will guide you through the process of creating the lifecycle configuration.

## Debug lifecycle configurations

The following topics show how to get information about and debug your lifecycle configurations.

### Topics

- [Verify lifecycle configuration process from CloudWatch Logs](#)
- [Lifecycle configuration timeout](#)

## Verify lifecycle configuration process from CloudWatch Logs

Lifecycle configurations only log STDOUT and STDERR.

STDOUT is the default output for bash scripts. You can write to STDERR by appending `>&2` to the end of a bash command. For example, `echo 'hello'>&2`.

Logs for your lifecycle configurations are published to your AWS account using Amazon CloudWatch. These logs can be found in the `/aws/sagemaker/studio` log stream in the CloudWatch console.

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Choose **Logs** from the left navigation pane. From the dropdown menu, select **Log groups**.
3. On the **Log groups** page, search for `aws/sagemaker/studio`.
4. Select the log group.
5. On the **Log group details** page, choose the **Log streams** tab.
6. To find the logs for a specific app, search the log streams using the following format:

```
domain-id/user-profile-name/app-type/app-name
```

The following search string finds the lifecycle configuration logs for the domain `d-m851cu8vbqmqz`, user profile `i-sonic-js`, application type `JupyterLab`, and application name `test-lcc-echo`:

```
d-m851cu8vbqmqz/i-sonic-js/JupyterLab/test-lcc-echo
```

7. To view the script execution logs, select the log stream appended with `LifecycleConfigOnStart`.

## Lifecycle configuration timeout

There is a lifecycle configuration timeout limitation of 5 minutes. If a lifecycle configuration script takes longer than 5 minutes to run, you get an error.

To resolve this error, make sure that your lifecycle configuration script completes in less than 5 minutes.

To help decrease the runtime of scripts, try the following:

- Reduce unnecessary steps. For example, limit which conda environments to install large packages in.

- Run tasks in parallel processes.
- Use the `nohup` command in your script to make sure that hangup signals are ignored so that the script runs without stopping.

## Amazon SageMaker Studio spaces

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#). [AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

Spaces are used to manage the storage and resource needs of some Amazon SageMaker Studio applications. Each space is composed of multiple resources and can be either private or shared. Each space has a 1:1 relationship with an instance of an application. Every supported application that is created gets its own space. The following applications in Studio run on spaces:

- [Code Editor in Amazon SageMaker Studio](#)
- [SageMaker JupyterLab](#)
- [Amazon SageMaker Studio Classic](#)

A space is composed of the following resources:

- A storage volume.
  - For Studio Classic, the space is connected to the shared Amazon Elastic File System (Amazon EFS) volume for the domain.
  - For other applications, a distinct Amazon Elastic Block Store (Amazon EBS) volume is attached to the space. All applications are given their own Amazon EBS volume. Applications do not have access to the Amazon EBS volume of other applications. For more information about Amazon EBS volumes, see [Amazon Elastic Block Store \(Amazon EBS\)](#).
- The application type of the space.
- The image that the application is based on.

Spaces can be either private or shared:

- **Private:** Private spaces are scoped to a single user in a domain. Private spaces cannot be shared with other users. All applications that support spaces also support private spaces.
- **Shared:** Shared spaces are accessible by all users in the domain. For more information about shared spaces, see [Collaboration with shared spaces](#).

Spaces can be created in domains that use either AWS IAM Identity Center or AWS Identity and Access Management (IAM) authentication. The following sections give general information about how to access spaces. For specific information about creating and accessing a space, see the documentation for the respective application type of the space that you're creating.

For information about viewing, stopping, or deleting your applications, instances, or spaces, see [Stop and delete your Studio running applications and spaces](#).

## Topics

- [Launch spaces](#)
- [Collaboration with shared spaces](#)

## Launch spaces

The following sections give information about accessing spaces in a domain. Spaces can be accessed in one of the following ways:

- from the Amazon SageMaker AI console
- from Studio
- using the AWS CLI

## Accessing spaces from the Amazon SageMaker AI console

### To access spaces from the Amazon SageMaker AI console

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. Under **Admin configurations**, choose **Domains**.
3. From the list of domains, select the domain that contains the spaces.
4. On the **Domain details** page, select the **Space management** tab. For more information about managing spaces, see [Collaboration with shared spaces](#).
5. From the list of spaces for that domain, select the space to launch.
6. Choose **Launch Studio** for the space that you want to launch.

## Accessing spaces from Studio

Follow these steps to access spaces from Studio for a specific application type.

### To access spaces from Studio

1. Open Studio by following the steps in [Launch Amazon SageMaker Studio](#).
2. Select the application type with spaces that you want to access.

## Accessing spaces using the AWS CLI

The following sections show how to access a space from the AWS Command Line Interface (AWS CLI). The procedures are for domains that use AWS Identity and Access Management (IAM) or AWS IAM Identity Center authentication.

### IAM authentication

The following procedure outlines generally how to access a space using IAM authentication from the AWS CLI.

1. Create a presigned domain URL specifying the name of the space that you want to access.

```
aws \  
  --region region \  
  sagemaker \  
  create-presigned-domain-url \  
  --domain-id domain-id \  
  --user-profile-name user-profile-name \  
  --space-name space-name
```

2. Navigate to the URL.

## Accessing a space in IAM Identity Center authentication

The following procedure outlines how to access a space using IAM Identity Center authentication from the AWS CLI.

1. Use the following command to return the URL associated with the space.

```
aws \  
  --region region \  
  sagemaker \  
  describe-space \  
  --domain-id domain-id \  
  --space-name space-name
```

2. Append the respective redirect parameter for the application type to the URL to be federated through IAM Identity Center. For more information about the redirect parameters, see [describe-space](#).
3. Navigate to the URL to be federated through IAM Identity Center.

## Collaboration with shared spaces

An Amazon SageMaker Studio Classic shared space consists of a shared JupyterServer application and a shared directory. A JupyterLab shared space consists of a shared JupyterLab application and a shared directory within Amazon SageMaker Studio. All user profiles in a domain have access to all shared spaces in the domain. Amazon SageMaker AI automatically scopes resources in a shared space within the context of the Amazon SageMaker Studio Classic application that you launch in that shared space. Resources in a shared space include notebooks, files, experiments, and models. Use shared spaces to collaborate with other users in real-time using features like automatic tagging, real time co-editing of notebooks, and customization.

Shared spaces are available in:

- Amazon SageMaker Studio Classic
- JupyterLab

A Studio Classic shared space only supports Studio Classic and KernelGateway applications. A shared space only supports the use of a JupyterLab 3 image Amazon Resource Name (ARN). For more information, see [JupyterLab Versioning](#).

Amazon SageMaker AI automatically tags all SageMaker AI resources that you create within the scope of a shared space. You can use these tags to monitor costs and plan budgets using tools, such as AWS Budgets.

A shared space uses the same VPC settings as the domain that it's created in.

#### Note

Shared spaces do not support the use of Amazon SageMaker Data Wrangler or Amazon EMR cross-account clusters.

## Automatic tagging

All resources created in a shared space are automatically tagged with a domain ARN tag and shared space ARN tag. The domain ARN tag is based on the domain ID, while the shared space ARN tag is based on the shared space name.

You can use these tags to monitor AWS CloudTrail usage. For more information, see [Log Amazon SageMaker API Calls with AWS CloudTrail](#).

You can also use these tags to monitor costs with AWS Billing and Cost Management. For more information, see [Using AWS cost allocation tags](#).

## Real time co-editing of notebooks

A key benefit of a shared space is that it facilitates collaboration between members of the shared space in real time. Users collaborating in a workspace get access to a shared Studio Classic application where they can access, read, and edit their notebooks in real time. Real time collaboration is only supported for JupyterServer applications within a shared space.

Users with access to a shared space can simultaneously open, view, edit, and execute Jupyter notebooks in the shared Studio Classic or JupyterLab application in that space.

The notebook indicates each co-editing user with a different cursor that shows the user profile name. While multiple users can view the same notebook, co-editing is best suited for small groups of two to five users.

To track changes being made by multiple users, we strongly recommended using Studio Classic's built-in Git-based version control.

## JupyterServer 2

To use shared spaces in Studio Classic, Jupyter Server version 2 is required. Certain JupyterLab extensions and packages can forcefully downgrade Jupyter Server to version 1. This prevents the use of shared space. Run the following from the command prompt to change the version number and continue using shared spaces.

```
conda activate studio
pip install jupyter-server==2.0.0rc3
```

## Customize a shared space

To attach a lifecycle configuration or custom image to a shared space, you must use the AWS CLI. For more information about creating and attaching lifecycle configurations, see [Create and associate a lifecycle configuration](#). For more information about creating and attaching custom images, see [Bring your own SageMaker image](#).

## Create a shared space

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

The following topic demonstrates how to create a shared space in an existing Amazon SageMaker AI domain. If you created your domain without support for shared spaces, you must add support for shared spaces to your existing domain before you can create a shared space.

## Topics

- [Add shared space support to an existing domain](#)
- [Create a shared space](#)

## Add shared space support to an existing domain

You can use the SageMaker AI console or the AWS CLI to add support for shared spaces to an existing domain. If the domain is using VPC only network access, then you can only add shared space support using the AWS CLI.

## Console

Complete the following procedure to add support for Studio Classic shared spaces to an existing domain from the SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain that you want to open the **domain settings** page for.
5. On the **domain details** page, choose the **domain settings** tab.
6. Choose **Edit**.
7. For **Space default execution role**, set an IAM role that is used by default for all shared spaces created in the domain.
8. Choose **Next**.
9. Choose **Next**.

10. Choose **Next**.

11. Choose **Submit**.

## AWS CLI

### Studio Classic

Run the following command from the terminal of your local machine to add default shared space settings to a domain from the AWS CLI. If you are adding default shared space settings to a domain within an Amazon VPC, you must also include a list of security groups. Studio Classic shared spaces only support the use of JupyterLab 3 image ARNs. For more information, see [JupyterLab Versioning](#).

```
# Public Internet domain
aws --region region \
sagemaker update-domain \
--domain-id domain-id \
--default-space-settings "ExecutionRole=execution-role-arn,JupyterServerAppSettings={DefaultResourceSpec={InstanceType=example-instance-type,SageMakerImageArn=sagemaker-image-arn}}"

# VPCOnly domain
aws --region region \
sagemaker update-domain \
--domain-id domain-id \
--default-space-settings "ExecutionRole=execution-role-arn,JupyterServerAppSettings={DefaultResourceSpec={InstanceType=system,SageMakerImageArn=sagemaker-image-arn}},SecurityGroups=[security-groups]"
```

Use the following command to verify that the default shared space settings have been updated.

```
aws --region region \
sagemaker describe-domain \
--domain-id domain-id
```

### JupyterLab

Run the following command from the terminal of your local machine to add default shared space settings to a domain from the AWS CLI. If you are adding default shared space settings to

a domain within an Amazon VPC, you must also include a list of security groups. Studio Classic shared spaces only support the use of JupyterLab 4 image ARNs. For more information, see [JupyterLab Versioning](#).

```
# Public Internet domain
aws --region region \
sagemaker update-domain \
--domain-id domain-id \
--default-space-settings "ExecutionRole=execution-role-arn",
  JupyterLabAppSettings={DefaultResourceSpec={InstanceType=example-instance-type,SageMakerImageArn=sagemaker-image-arn}}"

# VPCOnly domain
aws --region region \
sagemaker update-domain \
--domain-id domain-id \
--default-space-settings "ExecutionRole=execution-role-arn,
  SecurityGroups=[security-groups]"
```

Use the following command to verify that the default shared space settings have been updated.

```
aws --region region \
sagemaker describe-domain \
--domain-id domain-id
```

## Create a shared space

The following sections demonstrate how to create a shared space from the Amazon SageMaker AI console, Amazon SageMaker Studio, or the AWS CLI.

### Create from Studio

Use the following procedures to create a shared space in a domain from Studio.

#### Studio Classic

1. Navigate to Studio following the steps in [Launch Amazon SageMaker Studio](#).
2. From the Studio UI, find the applications pane on the left side.
3. From the applications pane, select **Studio Classic**.

4. Choose **Create Studio Classic space**
5. In the pop up window, enter a name for the space.
6. Choose **Create space**.

## JupyterLab

1. Navigate to Studio following the steps in [Launch Amazon SageMaker Studio](#).
2. From the Studio UI, find the applications pane on the left side.
3. From the applications pane, select **JupyterLab**.
4. Choose **Create JupyterLab space**
5. In the pop up window, enter a name for the space.
6. Choose **Create space**.

## Create from the console

Complete the following procedure to create a shared space in a domain from the SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain that you want to create a shared space for.
5. On the **domain details** page, choose the **Space management** tab.
6. Choose **Create**.
7. Enter a name for your shared space. shared space names within a domain must be unique. The execution role for the shared space is set to the domain IAM execution role.

## Create from AWS CLI

This section shows how to create a shared space from the AWS CLI.

You cannot set the execution role of a shared space when creating or updating it.

The `DefaultDomainExecRole` can only be set when creating or updating the domain. shared spaces only support the use of JupyterLab 3 image ARNs. For more information, see [JupyterLab Versioning](#).

To create a shared space from the AWS CLI, run one of the following commands from the terminal of your local machine.

## Studio Classic

```
aws --region region \  
sagemaker create-space \  
--domain-id domain-id \  
--space-name space-name \  
--space-settings '{  
  "JupyterServerAppSettings": {  
    "DefaultResourceSpec": {  
      "SageMakerImageArn": "sagemaker-image-arn",  
      "InstanceType": "system"  
    }  
  }  
}'
```

## JupyterLab

```
aws --region region \  
sagemaker create-space \  
--domain-id domain-id \  
--space-name space-name \  
--ownership-settings '{"OwnerUserProfileName": "user-profile-name"}' \  
--space-sharing-settings '{"SharingType": "Shared"}' \  
--space-settings '{"AppType": "JupyterLab}"
```

## Get information about shared spaces

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

This guide shows how to access a list of shared spaces in an Amazon SageMaker AI domain with the Amazon SageMaker AI console, Amazon SageMaker Studio, or the AWS CLI. It also shows how to view details of a shared space from the AWS CLI.

## Topics

- [List shared spaces](#)
- [View shared space details](#)

### List shared spaces

The following topic describes how to view a list of shared spaces within a domain from the SageMaker AI console or the AWS CLI.

#### List shared spaces from Studio

Complete the following procedure to view a list of the shared spaces in a domain from Studio.

1. Navigate to Studio following the steps in [Launch Amazon SageMaker Studio](#).
2. From the Studio UI, find the applications pane on the left side.
3. From the applications pane, select **Studio Classic** or **JupyterLab**. You can view the spaces that are being used to run the application type.

#### List shared spaces from the console

Complete the following procedure to view a list of the shared spaces in a domain from the SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain that you want to view the list of shared spaces for.
5. On the **domain details** page, choose the **Space management** tab.

#### List shared spaces from the AWS CLI

To list the shared spaces in a domain from the AWS CLI, run the following command from the terminal of your local machine.

```
aws --region region \  
sagemaker list-spaces \  
--domain-id domain-id
```

## View shared space details

The following section describes how to view shared space details from the SageMaker AI console, Studio, or the AWS CLI.

### View shared spaces details from Studio

Complete the following procedure to view the details of a shared spaces in a domain from Studio.

1. Navigate to Studio following the steps in [Launch Amazon SageMaker Studio](#).
2. From the Studio UI, find the applications pane on the left side.
3. From the applications pane, select **Studio Classic** or **JupyterLab**. You can view the spaces that are running the application.
4. Select the name of the space that you want to view more details for.

### View shared space details from the console

You can view the details of a shared space from the SageMaker AI console using the following procedure.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain that you want to view the list of shared spaces for.
5. On the **domain details** page, choose the **Space management** tab.
6. Select the name of the space to open a new page that lists details about the shared space.

### View shared space details from the AWS CLI

To view the details of a shared space from the AWS CLI, run the following command from the terminal of your local machine.

```
aws --region region \  
sagemaker describe-space \  
--domain-id domain-id \  
--space-name space-name
```

## Edit a shared space

You can only edit the details for an Amazon SageMaker Studio Classic or JupyterLab shared space using the AWS CLI. You can't edit the details of a shared space from the Amazon SageMaker AI console. You can only update workspace attributes when there are no running applications in the shared space.

### Studio Classic

To edit the details of a Studio Classic shared space from the AWS CLI, run the following one of the following commands from the terminal of your local machine. shared spaces only support the use of JupyterLab 3 image ARNs. For more information, see [JupyterLab Versioning](#).

```
aws --region region \  
sagemaker update-space \  
--domain-id domain-id \  
--space-name space-name \  
--query SpaceArn --output text \  
--space-settings '{  
  "JupyterServerAppSettings": {  
    "DefaultResourceSpec": {  
      "SageMakerImageArn": "sagemaker-image-arn",  
      "InstanceType": "system"  
    }  
  }  
}'
```

### JupyterLab

To edit the details of a JupyterLab shared space from the AWS CLI, run the following one of the following commands from the terminal of your local machine. shared spaces only support the use of JupyterLab 4 image ARNs. For more information, see [SageMaker JupyterLab](#).

```
aws --region region \  
sagemaker update-space \  

```

```
--domain-id domain-id \  
--space-name space-name \  
--space-settings "{  
    "SpaceStorageSettings": {  
    "EbsStorageSettings": {  
    "EbsVolumeSizeInGb":100  
    }  
    }  
}"
```

## Delete a shared space

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following topic shows how to delete an Amazon SageMaker Studio Classic shared space from the Amazon SageMaker AI console or AWS CLI. A shared space can only be deleted if it has no running applications.

### Topics

- [Console](#)
- [AWS CLI](#)

### Console

Complete the following procedure to delete a shared space in the Amazon SageMaker AI domain from the SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain that you want to create a shared space for.

5. On the **domain details** page, choose the **Space management** tab.
6. Select the shared space that you want to delete. The shared space must not contain any non-failed apps.
7. Choose **Delete**. This opens a new window.
8. Choose **Yes, delete space**.
9. Enter *delete* in the field.
10. Choose **Delete space**.

## AWS CLI

To delete a shared space from the AWS CLI, run the following command from the terminal of your local machine.

```
aws --region region \  
sagemaker delete-space \  
--domain-id domain-id \  
--space-name space-name
```

## Perform common UI tasks

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

The following sections describe how to perform common tasks in the Amazon SageMaker Studio UI. For an overview of the Studio user interface, see [Amazon SageMaker Studio UI overview](#).

### Set cookie preferences

1. Launch Studio following the steps in [Launch Amazon SageMaker Studio](#).
2. At the bottom of the Studio user interface, choose **Cookie Preferences**.
3. Select the check box for each type of cookie that you want Amazon SageMaker AI to use.

#### 4. Choose **Save preferences**.

### Manage notifications

Notifications give information about important changes to Studio, updates to applications, and issues to resolve.

1. Launch Studio following the steps in [Launch Amazon SageMaker Studio](#).
2. On the top navigation bar, choose the **Notifications**

3. From the list of notifications, select the notification to get information about it.

### Leave feedback

We take your feedback seriously. We encourage you to provide feedback.

At the top navigation of Studio, choose **Provide feedback**.

### Sign out

Signing out of the Studio UI is different than closing the browser window. Signing out clears session data from the browser and deletes unsaved changes.

This same behavior also happens when the Studio session times out. This happens after 5 minutes.

1. Launch Studio following the steps in [Launch Amazon SageMaker Studio](#).
2. Choose the **User options** icon

3. Choose **Sign out**.
4. In the pop-up window, choose **Sign out**.

## NVMe stores with Amazon SageMaker Studio

Amazon SageMaker Studio applications and their associated notebooks run on Amazon Elastic Compute Cloud (Amazon EC2) instances. Some of the Amazon EC2 instance types, such as the m1.m5d instance family, offer non-volatile memory express (NVMe) solid state drives (SSD) instance

stores. NVMe instance stores are local ephemeral disk stores that are physically connected to an instance for fast temporary storage. Studio applications support NVMe instance stores for supported instance types. For more information about instance types and their associated NVMe store volumes, see the [Amazon Elastic Compute Cloud Instance Type Details](#). This topic provides information about accessing and using NVMe instance stores, as well as considerations when using NVMe instance stores with Studio.

## Considerations

The following considerations apply when using NVMe instance stores with Studio.

- An NVMe instance store is temporary storage. The data stored on the NVMe store is deleted when the instance is terminated, stopped, or hibernated. When using NVMe stores with Studio applications, the data on the NVMe instance store is lost whenever the application is deleted, restarted, or patched. We recommend that you back up valuable data to persistent storage solutions, such as Amazon Elastic Block Store, Amazon Elastic File System, or Amazon Simple Storage Service.
- Studio patches instances periodically to install new security updates. When an instance is patched, the instance is restarted. This restart results in the deletion of data stored in the NVMe instance store. We recommend that you frequently back up necessary data from the NVMe instance store to persistent storage solutions, such as Amazon Elastic Block Store, Amazon Elastic File System, or Amazon Simple Storage Service.
- The following Studio applications support using NVMe storage:
  - JupyterLab
  - Code Editor, based on Code-OSS, Visual Studio Code - Open Source
  - KernelGateway

## Access NVMe instance stores

When you select an instance type with attached NVMe instance stores to host a Studio application, the NVMe instance store directory is mounted to the application container at the following location:

```
/mnt/sagemaker-nvme
```

If an instance has more than 1 NVMe instance store attached to it, Studio creates a striped logical volume that spans all of the local disks attached. Studio then mounts this striped logical volume

to the `/mnt/sagemaker-nvme` directory. As a result, the directory storage size is the sum of all NVMe instance store volume sizes attached to the instance.

If the `/mnt/sagemaker-nvme` directory does not exist, verify that the instance type hosting your application has an attached NVMe instance store volume.

## Local mode support in Amazon SageMaker Studio

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

Amazon SageMaker Studio applications support the use of local mode to create estimators, processors, and pipelines, then deploy them to a local environment. With local mode, you can test machine learning scripts before running them in Amazon SageMaker AI managed training or hosting environments. Studio supports local mode in the following applications:

- Amazon SageMaker Studio Classic
- JupyterLab
- Code Editor, based on Code-OSS, Visual Studio Code - Open Source

Local mode in Studio applications is invoked using the SageMaker Python SDK. In Studio applications, local mode functions similarly to how it functions in Amazon SageMaker notebook instances, with some differences. For more information about using local mode with the SageMaker Python SDK, see [Local Mode](#).

**Note**

Studio applications do not support multi-container jobs in local mode. Local mode jobs are limited to a single instance for training, inference, and processing jobs. When creating a local mode job, the instance count configuration must be 1.

## Docker support

As part of local mode support, Studio applications support limited Docker access capabilities. With this support, users can interact with the Docker API from Jupyter notebooks or the image terminal of the application. Customers can interact with Docker using one of the following:

- [Docker CLI](#)
- [Docker Compose CLI](#)
- Language specific Docker SDK clients

Studio also supports limited Docker access capabilities with the following restrictions:

- Usage of Docker networks is not supported.
- Docker [volume](#) usage is not supported during container run. Only volume bind mount inputs are allowed during container orchestration. The volume bind mount inputs must be located on the Amazon Elastic File System (Amazon EFS) volume for Studio Classic. For JupyterLab and Code Editor applications, it must be located on the Amazon Elastic Block Store (Amazon EBS) volume.
- Container inspect operations are allowed.
- Container port to host mapping is not allowed. However, you can specify a port for hosting. The endpoint is then accessible from Studio using the following URL:

```
http://localhost:port
```

## Docker operations supported

The following table lists all of the Docker API endpoints that are supported in Studio, including any support limitations. If an API endpoint is missing from the table, Studio doesn't support it.

API Documentation	Limitations
<a href="#">SystemAuth</a>	
<a href="#">SystemEvents</a>	
<a href="#">SystemVersion</a>	
<a href="#">SystemPing</a>	
<a href="#">SystemPingHead</a>	
<a href="#">ContainerCreate</a>	<ul style="list-style-type: none"> <li>Containers cannot be run in Docker default bridge or custom Docker networks. Containers are run in the same network as the Studio application container.</li> <li>Users can only use the following value for the network name: <code>sagemaker</code> . ## Topics

- [Getting started with local mode](#)

## Getting started with local mode

The following sections outline the steps needed to get started with local mode in Amazon SageMaker Studio, including:

- Completing prerequisites
- Setting `EnableDockerAccess`
- Docker installation

### Prerequisites

Complete the following prerequisites to use local mode in Studio applications:

- To pull images from an Amazon Elastic Container Registry repository, the account hosting the Amazon ECR image must provide access permission for the user's execution role. The domain's execution role must also allow Amazon ECR access.
- Verify that you are using the latest version of the Studio Python SDK by using the following command:

```
pip install -U sagemaker
```

- To use local mode and Docker capabilities, set the following parameter of the domain's `DockerSettings` using the AWS Command Line Interface (AWS CLI):

```
EnableDockerAccess : ENABLED
```

- Using `EnableDockerAccess`, you can also control whether users in the domain can use local mode. By default, local mode and Docker capabilities aren't allowed in Studio applications. For more information, see [Setting EnableDockerAccess](#).
- Install the Docker CLI in the Studio application by following the steps in [Docker installation](#).

## Setting EnableDockerAccess

The following sections show how to set `EnableDockerAccess` when the domain has public internet access or is in VPC-only mode.

### Note

Changes to `EnableDockerAccess` only apply to applications created after the domain is updated. You must create a new application after updating the domain.

### Public internet access

The following example commands show how to set `EnableDockerAccess` when creating a new domain or updating an existing domain with public internet access:

```
# create new domain
aws --region region \
  sagemaker create-domain --domain-name domain-name \
  --vpc-id vpc-id \
  --subnet-ids subnet-ids \
  --auth-mode IAM \
  --default-user-settings "ExecutionRole=execution-role" \
  --domain-settings '{"DockerSettings": {"EnableDockerAccess": "ENABLED"}}' \
  --query DomainArn \
  --output text

# update domain
aws --region region \
  sagemaker update-domain --domain-id domain-id \
  --domain-settings-for-update '{"DockerSettings": {"EnableDockerAccess":
  "ENABLED"}}'
```

### VPC-only mode

When using a domain in VPC-only mode, Docker image push and pull requests are routed through the service VPC instead of the VPC configured by the customer. Because of this functionality, administrators can configure a list of trusted AWS accounts that users can make Amazon ECR Docker pull and push operations requests to.

If a Docker image push or pull request is made to an AWS account that is not in the list of trusted AWS accounts, the request fails. Docker pull and push operations outside of Amazon Elastic Container Registry (Amazon ECR) aren't supported in VPC-only mode.

The following AWS accounts are trusted by default:

- The account hosting the SageMaker AI domain.
- SageMaker AI accounts that host the following SageMaker images:
  - DLC framework images
  - Sklearn, Spark, XGBoost processing images

To configure a list of additional trusted AWS accounts, specify the `VpcOnlyTrustedAccounts` value as follows:

```
aws --region region \  
    sagemaker update-domain --domain-id domain-id \  
    --domain-settings-for-update '{"DockerSettings": {"EnableDockerAccess": "ENABLED",  
"VpcOnlyTrustedAccounts": [account-list]}}'
```

## Docker installation

To use Docker, you must manually install Docker from the terminal of your Studio application. The steps to install Docker are different if the domain has access to the internet or not.

### Internet access

If the domain is created with public internet access or in VPC-only mode with limited internet access, use the following steps to install Docker.

1. (Optional) If your domain is created in VPC-only mode with limited internet access, create a public NAT gateway with access to the Docker website. For instructions, see [NAT gateways](#).
2. Navigate to the terminal of the Studio application that you want to install Docker in.
3. To return the operating system of the application, run the following command from the terminal:

```
cat /etc/os-release
```

4. Install Docker following the instructions for the operating system of the application in the [Amazon SageMaker AI Local Mode Examples repository](#).

For example, install Docker on Ubuntu following the script at [https://github.com/aws-samples/amazon-sagemaker-local-mode/blob/main/sagemaker\\_studio\\_docker\\_cli\\_install/sagemaker-ubuntu-focal-docker-cli-install.sh](https://github.com/aws-samples/amazon-sagemaker-local-mode/blob/main/sagemaker_studio_docker_cli_install/sagemaker-ubuntu-focal-docker-cli-install.sh) with the following considerations:

- If chained commands fail, run commands one at a time.
- Studio only supports Docker version 20.10.X. and Docker Engine API version 1.41.
- The following packages aren't required to use the Docker CLI in Studio and their installation can be skipped:
  - `containerd.io`
  - `docker-ce`
  - `docker-buildx-plugin`

#### Note

You do not need to start the Docker service in your applications. The instance that hosts the Studio application runs Docker service by default. All Docker API calls are routed through the Docker service automatically.

5. Use the exposed Docker socket for Docker interactions within Studio applications. By default, the following socket is exposed:

```
unix:///docker/proxy.sock
```

The following Studio application environmental variable for the default USER uses this exposed socket:

```
DOCKER_HOST
```

## No internet access

If the domain is created in VPC-only mode with no internet access, use the following steps to install Docker.

1. Navigate to the terminal of the Studio application that you want to install Docker in.

2. Run the following command from the terminal to return the operating system of the application:

```
cat /etc/os-release
```

3. Download the required Docker .deb files to your local machine. For instructions about downloading the required files for the operating system of the Studio application, see [Install Docker Engine](#).

For example, install Docker from a package on Ubuntu following the steps 1–4 in [Install from a package](#) with the following considerations:

- Install Docker from a package. Using other methods to install Docker will fail.
- Install the latest packages corresponding to Docker version 20.10.X.
- The following packages aren't required to use the Docker CLI in Studio. You don't need to install the following:
  - containerd.io
  - docker-ce
  - docker-buildx-plugin

**Note**

You do not need to start the Docker service in your applications. The instance that hosts the Studio application runs Docker service by default. All Docker API calls are routed through the Docker service automatically.

4. Upload the .deb files to the Amazon EFS file system or to the Amazon EBS file system of the application.
5. Manually install the docker-ce-cli and docker-compose-plugin .deb packages from the Studio application terminal. For more information and instructions, see step 5 in [Install from a package](#) on the Docker docs website.
6. Use the exposed Docker socket for Docker interactions within Studio applications. By default, the following socket is exposed:

```
unix:///docker/proxy.sock
```

The following Studio application environmental variable for the default USER uses this exposed socket:

```
DOCKER_HOST
```

## View your Studio running instances, applications, and spaces

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

The following topics include information and instructions about how to view your Studio running instances, applications, and spaces. For more information about Studio spaces, see [Amazon SageMaker Studio spaces](#).

## View your Studio running instances and applications

The **Running instances** page gives information about all running application instances that were created in Amazon SageMaker Studio by the user, or were shared with the user.

You can view and stop running instances for all of your applications and spaces. If an instance is stopped, it does not appear on this page. Stopped instances can be viewed from the landing page for their respective application types.

You can view a list of running applications and their details in Studio.

### To view running instances

1. Launch Studio following the steps in [Launch Amazon SageMaker Studio](#).
2. On the left navigation pane, choose **Running instances**.
3. From the **Running instances** page, you can view a list of running applications and details about those applications.

To view non-running instances, from the left navigation pane choose, the relevant application under **Applications**. The non-running applications will have the **Stopped** status under the **Status** column.

## View your Studio spaces

The **Spaces** section within your **Domain details** page gives information about Studio spaces within your domain. You can view, create, and delete spaces on this page.

The spaces that you can view in the **Spaces** section are running spaces for the following:

- JupyterLab private space. For information about JupyterLab, see [SageMaker JupyterLab](#).
- Code Editor private space. For information about Code Editor, based on Code-OSS, Visual Studio Code - Open Source, see [Code Editor in Amazon SageMaker Studio](#).
- Studio Classic shared space. For information about Studio Classic shared space, see [Collaboration with shared spaces](#).

There are no spaces for SageMaker Canvas, Studio Classic (private), or RStudio.

### To view Studio spaces in a domain

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
3. Choose the domain where you want to view the spaces.
4. On the **Domain details** page, choose the **Space management** tab to open the **Spaces** section.

## Stop and delete your Studio running applications and spaces

The following page includes information and instructions on how to stop and delete unused Amazon SageMaker Studio resources to avoid unwanted additional costs. For the Studio resources you no longer wish to use, you will need to both:

- Stop the application: This stops both the application and deletes the instance that the application is running on. Once you stop an application you can start it back up again.
- Delete the space: This deletes the Amazon EBS volume that was created for the application and instance.

**⚠ Important**

If you delete the space, you will lose access to the data within that space. Do not delete the space unless you're sure that you want to.

For more information about the differences between Studio spaces and applications, see [View your Studio running instances, applications, and spaces](#).

**Topics**

- [Stop your Amazon SageMaker Studio application](#)
- [Delete a Studio space](#)

**Stop your Amazon SageMaker Studio application**

To avoid additional charges from unused running applications, you must stop them. The following includes information on what stopping an application does and how to do it.

- The following instructions uses the [DeleteApp](#) API to stop the application. This also stops the instance that the application is running on.
- After you stop an application, you can start up the application again later.
  - When you stop an application, the files in the space will persist. You can run the application again and expect to have access to the same files that are stored in the space, as you did before deleting the application.
  - When you stop an application, the *metadata* for the application will be deleted within 24 hours. For more information, see the note in the `CreationTime` response element for the [DescribeApp](#) API.

**ℹ Note**

If the service detects that an application is unhealthy, it assumes the [AmazonSageMakerNotebooksServiceRolePolicy](#) service linked role and deletes the application using the [DeleteApp](#) API.

The following tabs provide instructions to stop an application from your domain using the Studio UI, the SageMaker AI console, or the AWS CLI.

### Note

To view and stop all of your Studio running instances in one location, we recommend the [Stop applications using the Studio UI](#) workflow from the following options.

## Stop applications using the Studio UI

To stop your Studio applications using the Studio UI, use the following instructions.

### To delete your applications (Studio UI)

1. Launch Studio. This process may differ depending on your setup. For information about launching Studio, see [Launch Amazon SageMaker Studio](#).
2. From the left navigation pane, choose **Running instances**.

If the table on the page is empty, you don't have any running instances or applications in your spaces.

3. In the table under the **Name** and **Application** columns, find the space name and the application that you want to stop.
4. Choose the corresponding **Stop** button to stop the application.

## Stop applications using the SageMaker AI console

To view or stop Studio running instances from a centralized location, see [Stop applications using the Studio UI](#). Otherwise, use the following instructions.

In the SageMaker AI console, you can only stop the running Studio applications for the spaces that you are able to view in the **Spaces** section of the console. For a list of the viewable spaces, see [View your Studio spaces](#).

These steps show how to stop your Studio applications by using the SageMaker AI console.

### To stop your applications (SageMaker AI console)

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.

2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
3. Choose the domain that you want to revert.
4. On the **Domain details** page, choose the **Space management** tab.
- 5.

**⚠ Important**

In the **Space management** tab, you have the option to delete the space. There is a difference between deleting the space and deleting an application. If you delete the space, you will lose access to the data within that space. Do not delete the space unless you're sure that you want to.

To stop the application, in the **Space management** tab and under the **Name** column, choose the space for the application.

6. In the **Apps** section and under the **App type** column, search for the app to stop.
7. Under the **Action** column, choose the corresponding **Delete app** button.
8. In the pop-up box, choose **Yes, delete app**. After you do so the delete input field becomes available.
9. Enter **delete** in the delete input field to confirm deletion.
10. Choose **Delete**.

### Stop your domain applications using the AWS CLI

To view or stop any of your Studio running instances from a centralized location, see [Stop applications using the Studio UI](#). Otherwise, use the following instructions.

The following code examples use the [DeleteApp](#) API to stop an application in an example domain.

To stop your running **JupyterLab** or **Code Editor** instances, use the following code example:

```
aws sagemaker delete-app \  
--domain-id example-domain-id \  
--region AWS Region \  
--app-name default \  
--app-type example-app-type \  
--space-name example-space-name
```

- To obtain your *example-domain-id*, use the following instructions:

**To get *example-domain-id***

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
  2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
  3. Choose the relevant domain.
  4. On the **Domain details** page, choose the **Domain settings** tab.
  5. Copy the **Domain ID**.
- To obtain your *AWS Region*, use the following instructions to ensure you are using the correct AWS Region for your domain:

**To get *AWS Region***

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
  2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
  3. Choose the relevant domain.
  4. On the **Domain details** page, verify that this is the relevant domain.
  5. Expand the region dropdown list from the top right of the SageMaker AI console, and use the corresponding AWS Region ID to the right of your AWS Region name. For example, us-west-1.
- For *example-app-type*, use the application type that's relevant to the application that you want to stop. For example, replace *example-app-type* with one of the following application types:
    - JupyterLab application type: JupyterLab. For information about JupyterLab, see [SageMaker JupyterLab](#).
    - Code Editor application type: CodeEditor. For information about Code Editor, based on Code-OSS, Visual Studio Code - Open Source, see [Code Editor in Amazon SageMaker Studio](#).
  - To obtain your *example-space-name*, use the following steps:

**To get *example-space-name***

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
3. Choose the relevant domain.
4. On the **Domain details** page, choose the **Space management** tab.

## 5. Copy the relevant space name.

To stop running instances for **SageMaker Canvas**, **Studio Classic**, or **RStudio**, use the following code example:

```
aws sagemaker delete-app \  
--domain-id example-domain-id \  
--region AWS Region \  
--app-name default \  
--app-type example-app-type \  
--user-profile example-user-name
```

- For *example-app-type*, use the application type relevant to the application that you want to stop. For example, replace *example-app-type* with one of the following application types:
  - SageMaker Canvas application type: Canvas. For information about SageMaker Canvas, see [Amazon SageMaker Canvas](#).
  - Studio Classic application type: JupyterServer. For information about Studio Classic, see [Amazon SageMaker Studio Classic](#).
  - RStudio application type: RStudioServerPro. For information about RStudio, see [RStudio on Amazon SageMaker AI](#).
- To obtain your *example-user-name*, navigate to the **Domain details** page.
  - Next, choose the **User profiles** tab, and copy the relevant space name.

For alternative instructions to stop your running Studio applications, see:

- JupyterLab: [Delete unused resources](#).
- Code Editor: [Shut down Code Editor resources](#).
- SageMaker Canvas: [Logging out of Amazon SageMaker Canvas](#).
- Studio Classic: [Shut Down and Update SageMaker Studio Classic and Studio Classic Apps](#).
- RStudio: [Shut down RStudio](#).

## Delete a Studio space

### Important

After you delete your space, you will lose all of the data stored in the space. We recommend that you back up your data before deleting your space.

You will need to have administrator permissions, or at least have permissions to update domain, IAM, and Amazon S3, to delete a Studio space.

- Spaces are used to manage the storage and resource needs of the relevant application. When you delete a space, the storage volume also deletes. Therefore, you lose access to the files stored on that space. For more information about Studio spaces, see [Amazon SageMaker Studio spaces](#).

We recommend that you back up your data if you choose to delete a space.

- After you delete a space, you can't access that space again.

You can delete the Studio spaces that are viewable in the **Spaces** section of the console. For a list of the viewable spaces, see [View your Studio spaces](#).

There are no spaces for SageMaker Canvas, Studio Classic (private), and RStudio. To stop and delete your SageMaker Canvas, Studio Classic (private), or RStudio applications, see [Stop your Amazon SageMaker Studio application](#).

### Delete a space using the SageMaker AI console

The **Spaces** section within your **Domain details** page gives information about Studio spaces within your domain. You can view, create, and delete spaces on this page.

#### To view Studio spaces in a domain

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
3. Choose the domain where you want to view the spaces.
4. On the **Domain details**, choose **Space management** to open the **Spaces** section.
5. Select the space to delete.

6. Choose **Delete**.
7. In the pop-up box titled **Delete space**, you have two options:
  - If you already shut down all applications in the space, choose **Yes, delete space**.
  - If you still have applications running in the space, choose **Yes, shut down all apps and delete space**.
8. Enter **delete** in the delete input field to confirm deletion.
9. To delete the space, you have two options:
  - If you already shut down all applications in the space, choose **Delete space**.
  - If you still have applications running in the space, choose **Shut down all apps and delete space**.

## Delete a space using the AWS CLI

Before you can delete a space using the AWS CLI, you must delete the application associated with it. For information about stopping your Studio applications, see [Stop your Amazon SageMaker Studio application](#).

Use the following AWS CLI command to delete a space within a domain:

```
aws sagemaker delete-space \  
--domain-id example-domain-id \  
--region AWS Region \  
--space-name example-space-name
```

- To obtain your *example-domain-id*, use the following instructions:

### To get *example-domain-id*

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
  2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
  3. Choose the relevant domain.
  4. On the **Domain details** page, choose the **Domain settings** tab.
  5. Copy the **Domain ID**.
- To obtain your *AWS Region*, use the following instructions to ensure you are using the correct AWS Region for your domain:

### To get *AWS Region*

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
  2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
  3. Choose the relevant domain.
  4. On the **Domain details** page, verify that this is the relevant domain.
  5. Expand the region dropdown list from the top right of the SageMaker AI console, and use the corresponding AWS Region ID to the right of your AWS Region name. For example, us-west-1.
- To obtain your *example-space-name*, use the following steps:

### To get *example-space-name*

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. From the left navigation pane, expand **Admin configurations** and choose **Domains**.
3. Choose the relevant domain.
4. On the **Domain details** page, choose the **Space management** tab.
5. Copy the relevant space name.

## SageMaker Studio image support policy

### Important

Currently, all packages in SageMaker Distribution images are licensed for use with Amazon SageMaker AI and do not require additional commercial licenses. However, this might be subject to change in the future, and we recommend reviewing the licensing terms regularly for any updates.

Amazon SageMaker Distribution is a set of Docker images available on SageMaker Studio that include popular frameworks for machine learning, data science, and visualization.

The images include deep learning frameworks like PyTorch, TensorFlow and Keras; popular Python packages like numpy, scikit-learn and pandas; and IDEs like JupyterLab and Code Editor, based on

Code-OSS, Visual Studio Code - Open Source. The distribution contains the latest versions of all these packages such that they are mutually compatible.

This page details the support policy and availability for SageMaker Distribution Images on SageMaker Studio.

## Versioning, release cadence, and support policy

The table below outlines the release schedule for SageMaker Distribution Image versions and their planned support. AWS provides ongoing functionality and security updates for supported image versions. New minor versions are released for supported major versions, and supported minor versions receive ongoing functionality and security patches. In some cases, an image version may need to be designated end of support earlier than originally planned if (a) security issues cannot be addressed while maintaining semantic versioning guidelines or (b) any of our major dependencies, like Python, reach end-of-life. AWS releases ad-hoc major or minor versions on an as-needed basis.

Version	Description	Release cadence	Planned support
Major	Amazon SageMaker Distribution's major version releases involve upgrading all of its core dependencies to the latest compatible versions. These major releases may also add or remove packages as part of the update. Major versions are denoted by the first number in the version string, such as 1.0, 2.0, or 3.0.	6 months	12 months
Minor	Amazon SageMaker Distribution's minor version releases include upgrading all of its core dependencies to the latest compatible minor versions within the same major version. SageMaker Distribution can add new packages during a minor version release. Minor versions are denoted by the second number in the version string, for example, 1.1, 1.2, or 2.1.	1 month	6 months

Version	Description	Release cadence	Planned support
Patch	Amazon SageMaker Distribution's patch version releases include updating all of its core dependencies to the latest compatible patch versions within the same minor version. SageMaker Distribution does not add or remove any packages during a patch version release. Patch versions are denoted by the third number in the version string, for example, 1.1.1, 1.2.1, or 2.1.3. Since patch versions are generally released for fixing security vulnerabilities, we recommend always upgrading to the newest patch version when they become available.	As necessary for fixing security vulnerabilities	Until new patch version is released

Each major version of the Amazon SageMaker Distribution is available for 18 months. During the first 12 months, new minor versions are released monthly. For the remaining 6 months, the existing minor versions continue to be supported.

## Supported image versions

The tables below list the supported SageMaker Distribution image versions, their planned end of support dates, and their availability on SageMaker Studio. For image versions where support ends sooner than the planned end of support date, the versions continue to be available on Studio until the designated availability date. You can continue using the image to launch applications for up to 90 days or until the availability date on Studio, whichever comes first. For more information about such cases, reach out to Support.

You can migrate to a newer supported version as soon as possible to ensure that you receive ongoing functionality and security updates. When choosing an image version in SageMaker Studio, we recommend that you choose a supported image version from the tables below.

## Supported major versions

The following table lists the supported SageMaker Distribution major image versions.

Image version	Supported until	Description
1.x.x	Apr 30th, 2025	SageMaker Distribution major version 1 is built with Python 3.10.
2.x.x	Aug 25th, 2025	SageMaker Distribution major version 2 is built with Python 3.11.

## CPU image minor versions

The following table lists the supported SageMaker Distribution minor image versions for CPUs.

Image version	Amazon ECR image URI	Planned end of support date	Availability on Studio until	Release notes
2.3.x	public.ecr.aws/sagemaker/sagemaker-distribution:2.3-cpu	July 27th, 2025	July 27th, 2025	<a href="#">Release notes</a>
2.2.x	public.ecr.aws/sagemaker/sagemaker-distribution:2.2-cpu	May 15th, 2025	May 15th, 2025	<a href="#">Release notes</a>
2.1.x	public.ecr.aws/sagemaker/sagemaker-distribution:2.1-cpu	Apr 25th, 2025	May 12th, 2025	<a href="#">Release notes</a>
2.0.x	public.ecr.aws/sagemaker/sagemaker-distribution:2.0-cpu	Feb 25th, 2025	Apr 21st, 2025	<a href="#">Release notes</a>
1.12.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.12-cpu	July 23rd, 2025	July 23rd, 2025	<a href="#">Release notes</a>
1.11.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.11-cpu	Apr 1st, 2025	May 12th, 2025	<a href="#">Release notes</a>
1.10.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.10-cpu	Feb 5th, 2025	Apr 10th, 2025	<a href="#">Release notes</a>

Image version	Amazon ECR image URI	Planned end of support date	Availability on Studio until	Release notes
1.9.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.9-cpu	Jan 15th, 2025	Apr 10th, 2025	<a href="#">Release notes</a>
1.8.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.8-cpu	Dec 31st, 2024	Apr 10th, 2025	<a href="#">Release notes</a>
1.7.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.7-cpu	Dec 15th, 2024	Apr 10th, 2025	<a href="#">Release notes</a>
1.6.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.6-cpu	Dec 15th, 2024	Apr 10th, 2025	<a href="#">Release notes</a>

## GPU image minor versions

The following table lists the supported SageMaker Distribution minor image versions for GPUs.

Image version	Amazon ECR image URI	Planned end of support date	Availability on Studio until	Release notes for newest patch
2.3.x	public.ecr.aws/sagemaker/sagemaker-distribution:2.3-gpu	July 27th, 2025	July 27th, 2025	<a href="#">Release notes</a>
2.2.x	public.ecr.aws/sagemaker/sagemaker-distribution:2.2-gpu	May 15th, 2025	May 15th, 2025	<a href="#">Release notes</a>
2.1.x	public.ecr.aws/sagemaker/sagemaker-distribution:2.1-gpu	Apr 25th, 2025	May 12th, 2025	<a href="#">Release notes</a>
2.0.x	public.ecr.aws/sagemaker/sagemaker-distribution:2.0-gpu	Feb 25th, 2025	Apr 21st, 2025	<a href="#">Release notes</a>

Image version	Amazon ECR image URI	Planned end of support date	Availability on Studio until	Release notes for newest patch
1.12.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.12-gpu	July 23rd, 2025	July 23rd, 2025	<a href="#">Release notes</a>
1.11.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.11-gpu	Apr 1st, 2025	May 12th, 2025	<a href="#">Release notes</a>
1.10.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.10-gpu	Feb 5th, 2025	Apr 10th, 2025	<a href="#">Release notes</a>
1.9.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.9-gpu	Jan 15th, 2025	Apr 10th, 2025	<a href="#">Release notes</a>
1.8.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.8-gpu	Dec 31st, 2024	Apr 10th, 2025	<a href="#">Release notes</a>
1.7.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.7-gpu	Dec 15th, 2024	Apr 10th, 2025	<a href="#">Release notes</a>
1.6.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.6-gpu	Dec 15th, 2024	Apr 10th, 2025	<a href="#">Release notes</a>

## Unsupported images

The following table lists unsupported SageMaker Distribution image versions.

Image version	Amazon ECR image URI	End of support date	Availability on Studio until
1.5.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.5-cpu	Oct 31st, 2024	Nov 1st, 2024

Image version	Amazon ECR image URI	End of support date	Availability on Studio until
	public.ecr.aws/sagemaker/sagemaker-distribution:1.5-gpu		
1.4.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.4-cpu public.ecr.aws/sagemaker/sagemaker-distribution:1.4-gpu	Oct 31st, 2024	Nov 1st, 2024
1.3.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.3-cpu	June 28th, 2024	Oct 18th, 2024
1.2.x	public.ecr.aws/sagemaker/sagemaker-distribution:1.2-cpu	June 28th, 2024	Oct 18th, 2024

## Frequently asked questions

### What constitutes a major image version release?

Major image versions are released every 6 months. A major image version release for Amazon SageMaker Distribution involves upgrading all core dependencies to the latest compatible versions and may include adding or removing packages. Python framework is only upgraded with new major version releases. For example, with major version 2 release, Python framework was upgraded from 3.10 to 3.11, PyTorch was upgraded from 2.0 to 2.3, TensorFlow was upgraded from 2.14 to 2.17, Autogluon was upgraded from 0.8 to 1.1, and 4 packages were added to the image.

### What constitutes a minor image version release?

Minor image versions are released for all supported major versions monthly. A minor image version release for Amazon SageMaker Distribution involves upgrading all core dependencies except Python and CUDA to the latest compatible minor versions within the same major version and may include adding new packages. For example, with a minor version release, langchain might be upgraded from 0.1 to 0.2 and jupyter-ai from 2.18 to 2.20.

### What constitutes a patch image version release?

Patch image versions are released as necessary to fix security vulnerabilities. A patch image version release for Amazon SageMaker Distribution involves updating all of its core dependencies to the latest compatible patch versions within the same minor version. SageMaker Distribution does not add or remove any packages during a patch version release. For example, with a patch version release, matplotlib might be upgraded from 3.9.1 to 3.9.2 and boto3 from 1.34.131 to 1.34.162.

### Where can I find the packages available in a specific image version?

Each image version has a `release.md` file in the [GitHub repository's](#) `build_artifacts` folder, showing all packages and package versions for CPU and GPU images. Separate changelog files for CPU and GPU versions detail package upgrades. Changelogs compare the new image version to the previous. For example, version 1.9.0 compares to the latest patch version of 1.8, version 1.9.1 compares to 1.9.0, and version 2.0.0 compares to the latest patch version of the latest minor version available at the time.

### How are images scanned for Common Vulnerabilities and Exposures (CVEs)?

Amazon SageMaker AI leverages [Amazon Elastic Container Registry \(Amazon ECR\) enhanced scanning](#) to automatically detect vulnerabilities and fixes for SageMaker Distribution Images. AWS continuously runs ECR enhanced scanning for the latest patch version of all supported image versions. When vulnerabilities are detected and a fix is available, AWS releases an updated image version to remediate the issue.

### Can I still use older images after an image is no longer supported?

Images are available on SageMaker Studio until the designated availability date. Older images remain available in ECR after they reach end of support and are removed from Studio. You can download older image versions from ECR and [create a custom SageMaker image](#). However, we highly recommend upgrading to a supported image version that continuously receives security updates and bug fixes. Customers who build their own custom images are responsible for scanning and patching their images. For more information, see the [AWS Shared Responsibility model](#).

#### Important

SageMaker Distribution v0.x.y is only used in Studio Classic. SageMaker Distribution v1.x.y is only used in JupyterLab.

## Amazon SageMaker Studio pricing

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

There is no additional charge for using the Amazon SageMaker Studio UI.

The following do incur costs:

- Amazon Elastic Block Store or Amazon Elastic File System volumes that are mounted with your applications.
- Any jobs and resources that users launch from Studio applications.
- Launching a JupyterLab application, even if no resources or jobs launched in the application.

For information about how Amazon SageMaker Studio Classic is billed, see [Amazon SageMaker Studio Classic Pricing](#).

For more information about billing along with pricing examples, see [Amazon SageMaker Pricing](#).

## Troubleshooting

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see [Amazon SageMaker Studio Classic](#).

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to

those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#). [AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

This section shows how to troubleshoot common problems in Amazon SageMaker Studio.

### **Cannot delete Code Editor, based on Code-OSS, Visual Studio Code - Open Source or JupyterLab application**

This issue occurs when a user creates an application from Amazon SageMaker Studio that is only available in Studio, then reverts to the Studio Classic experience as their default. As a result, the user cannot delete an application for Code Editor, based on Code-OSS, Visual Studio Code - Open Source or JupyterLab because they can't access the Studio UI.

To resolve this issue, notify your administrator so that they can delete the application manually using the AWS Command Line Interface (AWS CLI).

### **EC2InsufficientCapacityError**

This issue occurs when you try to run a space and AWS does not currently have enough available on-demand capacity to fulfill your request.

To resolve this issue, complete the following.

- Wait a few minutes, then resubmit your request. Capacity can shift frequently.
- Run the space with an alternate instance size or type.

#### **Note**

Capacity is available in different Availability Zones. To maximize capacity availability for users, we recommend setting up subnets in all Availability Zones. Studio retries all available Availability Zones for the domain.

Instance type availability differs between regions. For a list of supported instances types per Region, see [Amazon SageMaker AI pricing](#))

The following table lists instance families and their recommended alternatives.

Instance family	CPU Type	vCPUs	Memory (GiB)	GPU type	GPUs	GPU Memory (GiB)	Recommended alternative
G4dn	2nd Generation Intel Xeon Scalable Processors	4 to 96	16 to 384	NVIDIA T4 Tensor Core	1 to 8	16 per GPU	G6
G5	2nd generation AMD EPYC processors	4 to 192	16 to 768	NVIDIA A10G Tensor core	1 to 8	24 per GPU	G6e
G6	3rd generation AMD EPYC processors	4 to 192	16 to 768	NVIDIA L4 Tensor Core	1 to 8	24 per GPU	G4dn
G6e	3rd generation AMD EPYC	4 to 192	32 to 1536	NVIDIA L40S Tensor Core	1 to 8	48 per GPU	G5, P4

Instance family	CPU Type	vCPUs	Memory (GiB)	GPU type	GPUs	GPU Memory (GiB)	Recommended alternative
	processors						
P3	Intel Xeon Scalable Processors	8 to 96	61 to 768	NVIDIA Tesla V100	1 to 8	16 per GPU (32 per GPU for P3dn)	G6e, P4
P4	2nd Generation Intel Xeon Scalable processors	96	1152	NVIDIA A100 Tensor Core	8	320 (640 for P4de)	G6e
P5	3rd Gen AMD EPYC processors	192	2000	NVIDIA H100 Tensor Core	8	640	P4de

### Insufficient limit (quota increase required)

This issue occurs when you get the following error when running a space. This error means that you have reached the limit on the number of instances of that type that you can launch in a Region. When you create your AWS account, we set default limits on the number of instances you can run in each Region.

```
Error when creating application for space: ... : The account-level service limit is X Apps, with current utilization Y Apps and a request delta of 1 Apps. Please use Service Quotas to request an increase for this quota.
```

To resolve this issue, request an instance limit increase for the Region that you are launching the space in. For more information, see [Requesting a quota increase](#).

## Amazon SageMaker Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Amazon SageMaker Studio Classic is a web-based integrated development environment (IDE) for machine learning (ML). Studio Classic lets you build, train, debug, deploy, and monitor your ML models. Studio Classic includes all of the tools you need to take your models from data preparation to experimentation to production with increased productivity. In a single visual interface, you can do the following tasks:

- Write and run code in Jupyter notebooks
- Prepare data for machine learning
- Build and train ML models
- Deploy the models and monitor the performance of their predictions
- Track and debug ML experiments
- Collaborate with other users in real time

For information on the onboarding steps for Studio Classic, see [Amazon SageMaker AI domain overview](#).

For information about collaborating with other users in real time, see [Collaboration with shared spaces](#).

For the AWS Regions supported by Studio Classic, see [Supported Regions and Quotas](#).

## Studio Classic maintenance phase plan

The following table gives information about the timeline for when Amazon SageMaker Studio Classic entered its extended maintenance phase.

Date	Description
12/31/2024	Starting December 31st, Studio Classic reaches end of maintenance. At this point, Studio Classic will no longer receive updates and security fixes. All new domains will be created with Amazon SageMaker Studio as the default.
1/31/2025	Starting January 31st, users will no longer be able to create new JupyterLab 3 notebooks in Studio Classic. Users will also not be able to restart or update existing notebooks. Users will be able to access existing Studio Classic applications from Studio only to delete or stop existing notebooks.

### Note

Your existing Studio Classic domain is not automatically migrated to Studio. For information about migrating, see [Migration from Amazon SageMaker Studio Classic](#).

### Topics

- [Studio Classic Features](#)
- [Amazon SageMaker Studio Classic UI Overview](#)
- [Launch Amazon SageMaker Studio Classic](#)
- [JupyterLab Versioning](#)
- [Use the Amazon SageMaker Studio Classic Launcher](#)

- [Customize Amazon SageMaker Studio Classic](#)
- [Perform Common Tasks in Amazon SageMaker Studio Classic](#)
- [Amazon SageMaker Studio Classic Pricing](#)

- [Troubleshooting Amazon SageMaker Studio Classic](#)

## Studio Classic Features

Studio Classic includes the following features:

- [SageMaker Autopilot](#)
- [SageMaker Clarify](#)
- [SageMaker Data Wrangler](#)
- [SageMaker Debugger](#)
- [SageMaker Experiments](#)
- [SageMaker Feature Store](#)
- [SageMaker JumpStart](#)
- [Amazon SageMaker Pipelines](#)
- [SageMaker Model Registry](#)
- [SageMaker Projects](#)
- [SageMaker Studio Classic Notebooks](#)
- [SageMaker Studio Universal Notebook](#)

## Amazon SageMaker Studio Classic UI Overview

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

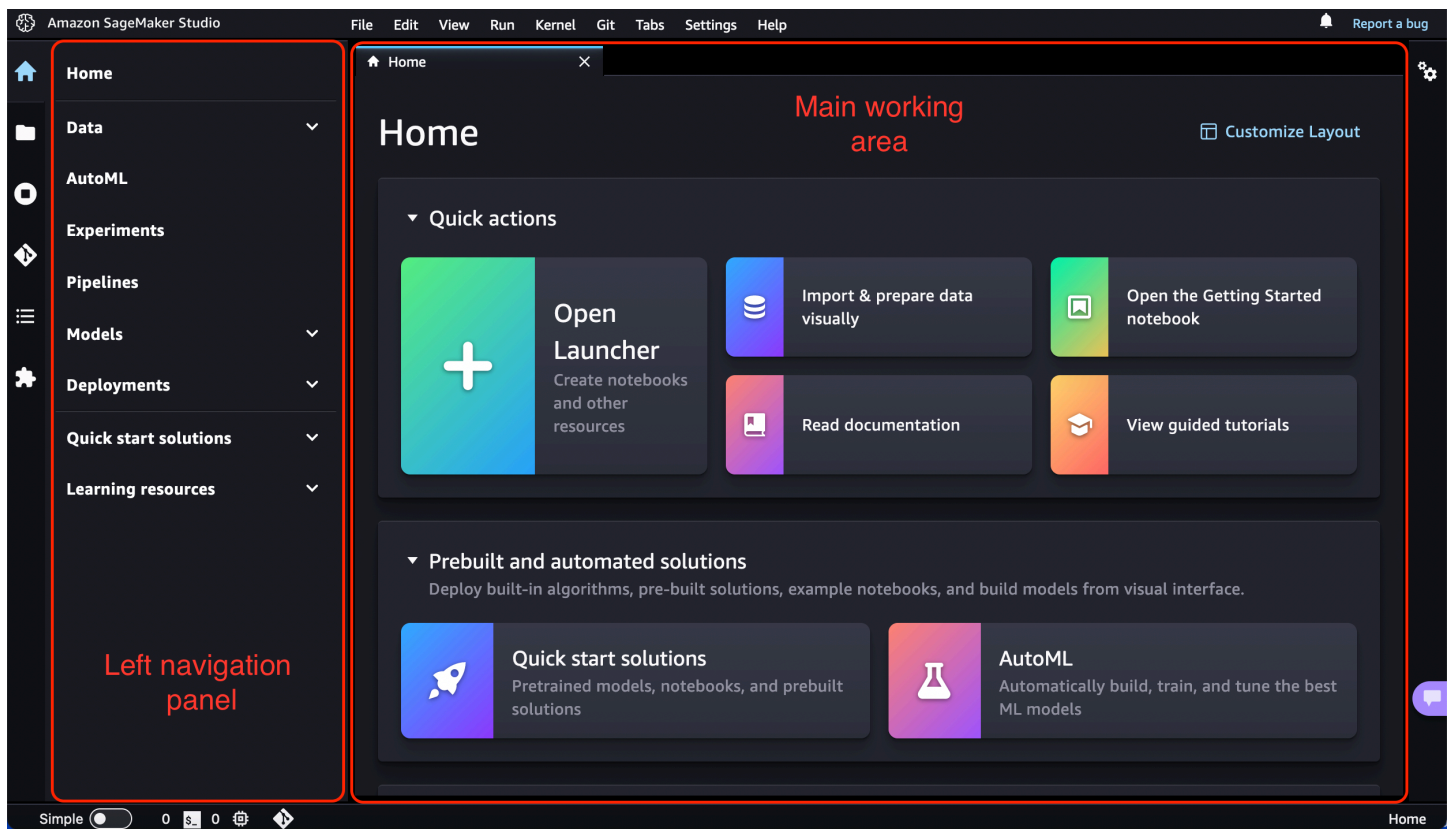

Amazon SageMaker Studio Classic extends the capabilities of JupyterLab with custom resources that can speed up your Machine Learning (ML) process by harnessing the power of AWS compute. Previous users of JupyterLab will notice the similarity of the user interface. The most prominent additions are detailed in the following sections. For an overview of the original JupyterLab interface, see [The JupyterLab Interface](#).

The following image shows the default view upon launching Amazon SageMaker Studio Classic. The *left navigation* panel displays all top-level categories of features, and a [Studio Classic Home page](#) is open in the *main working area*. Come back to this central point of orientation by choosing the **Home** icon

at any time, then selecting the **Home** node in the navigation menu.

Try the **Getting started notebook** for an in-product hands-on guide on how to set up and get familiar with Amazon SageMaker Studio Classic features. On the **Quick actions** section of the Studio Classic Home page, choose **Open the Getting started notebook**.

### Note

This chapter is based on Studio Classic's updated user interface (UI) available on version v5.38.x and above on JupyterLab3.

- To retrieve your version of Studio Classic UI, from the [Studio Classic Launcher](#), open a System Terminal, then

- Run `conda activate studio`

2. Run `jupyter labextension list`
  3. Search for the version displayed after `@amzn/sagemaker-ui` version in the output.
- For information about updating Amazon SageMaker Studio Classic, see [Shut down and Update SageMaker Studio Classic](#).

## Topics

- [Studio Classic Home page](#)
- [Studio Classic layout](#)

## Studio Classic Home page

The Home page provides access to common tasks and workflows. In particular, it includes a list of **Quick actions** for common tasks such as **Open Launcher** to create notebooks and other resources and **Import & prepare data visually** to create a new flow in Data Wrangler. The **Home** page also offers tooltips on key controls in the UI.

The **Prebuilt and automated solutions** help you get started quickly with SageMaker AI's low-code solutions such as Amazon SageMaker JumpStart and Autopilot.

In **Workflows and tasks**, you can find a list of relevant tasks for each step of your ML workflow that takes you to the right tool for the job. For example, **Transform, analyse, and export data** takes you to Amazon SageMaker Data Wrangler and opens the workflow to create a new data flow, or **View all experiments** takes you to SageMaker Experiments and opens the experiments list view.

Upon Studio Classic launch, the **Home** page is open in the main working area. You can customize your SageMaker AI **Home** page by choosing the **Customize Layout** icon

at the top right of the **Home** tab.

## Studio Classic layout

The Amazon SageMaker Studio Classic interface consists of a *menu bar* at the top, a collapsible *left sidebar* displaying a variety of icons such as the **Home** icon and the **File Browser**, a *status bar* at the bottom of the screen, and a *central area* divided horizontally into two panes. The left pane is

a collapsible *navigation panel*. The right pane, or main working area, contains one or more tabs for resources such as launchers, notebooks, terminals, metrics, and graphs, and can be further divided.

**Report a bug** in Studio Classic or choose the notification icon

to view notifications from Studio Classic, such as new Studio Classic versions and new SageMaker AI features, on the right corner of the menu bar. To update to a new version of Studio Classic, see [Shut Down and Update SageMaker Studio Classic and Studio Classic Apps](#).

The following sections describe the Studio Classic main user interface areas.

## Left sidebar

The *left sidebar* includes the following icons. When hovering over an icon, a tooltip displays the icon name. A single click on an icon opens up the left navigation panel with the described functionality. A double click minimizes the left navigation panel.

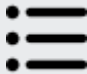

Icon	Description
	<p><b>Home</b></p> <p>Choose the <b>Home</b> icon to open a top-level navigation menu in the <i>left navigation</i> panel.</p> <p>Using the <b>Home</b> navigation menu, you can discover and navigate to the right tools for each step of your ML workflow. The menu also provides shortcuts to quick-start solutions and learning resources such as documentation and guided tutorials.</p> <p>The menu categories group relevant features together. Choosing <b>Data</b>, for example, expands the relevant SageMaker AI capabilities for your data preparations tasks. From here, you can prepare your data with Data Wrangler, create and store ML features with Amazon SageMaker Feature Store, and manage Amazon EMR clusters for large-scale data processing. The categories are ordered following a typical ML workflow from preparing data, to building, training, and deploying ML models (data, pipelines, models, and deployments).</p> <p>When you choose a specific node (such as Data Wrangler), a corresponding page opens in the main working area.</p>

Icon	Description
	Choose <b>Home</b> in the navigation menu to open the <a href="#">Studio Classic Home page</a>

Icon	Description
	<p data-bbox="472 226 659 260"><b>File Browser</b></p> <p data-bbox="472 306 1471 390">The <b>File Browser</b> displays lists of your notebooks, experiments, trials, trial components, endpoints, and low-code solutions.</p> <p data-bbox="472 436 1495 709">Whether you are in a personal or shared space determines who has access to your files. You can identify which type of space you are in by looking at the top right corner. If you are in a personal app, you see a user icon followed by <i>[user_name]</i> / <b>Personal Studio</b> and if you are in a collaborative space, you see a globe icon followed by "<i>[user_name]</i> / <i>[space_name]</i>."</p> <ul data-bbox="472 751 1503 1717" style="list-style-type: none"> <li data-bbox="472 751 1458 835">• <b>Personal Studio Classic app:</b> A private Amazon EFS directory that only you can access.</li> <li data-bbox="472 915 1495 1087">• <b>Collaborative space:</b> A shared Amazon EFS directory with other members of your team for group access to notebooks and resources. Working in a shared space allows for real-time team collaboration on notebooks.</li> <li data-bbox="472 1167 1503 1297">• <b>Studio Classic launcher:</b> Choose the plus (+) sign on the menu at the top of the file browser to open the <a href="#">Amazon SageMaker Studio Classic Launcher</a>.</li> <li data-bbox="472 1377 1529 1562">• <b>Upload files:</b> Choose the <b>Upload Files</b> icon  to add files to Studio Classic or drag and drop them from your desktop.</li> <li data-bbox="472 1642 1474 1717">• <b>Open files:</b> Double-click a file to open the file in a new tab or right-click and select <b>Open</b>.</li> </ul>

Icon	Description
	<ul style="list-style-type: none"><li>• <b>Panel management:</b> To work in adjacent files, choose a tab that contains a notebook, Python, or text file, then choose <b>New View for File</b>.</li></ul> <p>For hierarchical entries, a selectable breadcrumb at the top of the browser shows your location in the hierarchy.</p>
	<h3>Property Inspector</h3> <p>The Property Inspector is a notebook cell tools inspector which displays contextual property settings when open.</p>
	<h3>Running Terminals and Kernels</h3> <p>You can check the list of all the <i>kernels</i> and <i>terminals</i> currently running across all notebooks, code consoles, and directories. You can shut down individual resources, including notebooks, terminals, kernels, apps, and instances. You can also shut down all resources in one of these categories at the same time.</p> <p>For more information, see <a href="#">Shut down resources from Amazon SageMaker Studio Classic</a>.</p>
	<h3>Git</h3> <p>You can connect to a Git repository and then access a full range of Git tools and operations.</p> <p>For more information, see <a href="#">Clone a Git Repository in SageMaker Studio Classic</a>.</p>

Icon	Description
	<p><b>Table of Contents</b></p> <p>You can navigate the structure of a document when a notebook or Python files are open.</p> <p>A table of contents is auto-generated in the left navigation panel when you have a notebook, Markdown files, or Python files opened. The entries are clickable and scroll the document to the heading in question.</p>
	<p><b>Extensions</b></p> <p>You can turn on and manage third-party JupyterLab extensions. You can check the already installed extensions and search for extensions by typing the name in the search bar. When you have found the extension you want to install, choose <b>Install</b>. After installing your new extensions, be sure to restart JupyterLab by refreshing your browser.</p> <p>For more information, see <a href="#">JupyterLab Extensions documentation</a>.</p>

## Left navigation panel

The left navigation panel content varies with the Icon selected in the left sidebar.

For example, choosing the **Home** icon displays the navigation menu. Choosing **File browser** lists all the files and directories available in your workspace (notebooks, experiments, data flows, trials, trial components, endpoints, or low-code solutions).

In the navigation menu, choosing a node brings up the corresponding feature page in the main working area. For example, choosing **Data Wrangler** in the **Data** menu opens up the **Data Wrangler** tab listing all existing flows.

## Main working area

The main working area consists of multiple tabs that contain your open notebooks, terminals, and detailed information about your experiments and endpoints. In the main working area, you can arrange documents (such as notebooks and text files) and other activities (such as terminals and code consoles) into panels of tabs that you can resize or subdivide. Drag a tab to the center of a tab

panel to move the tab to the panel. Subdivide a tab panel by dragging a tab to the left, right, top, or bottom of the panel. The tab for the current activity is marked with a colored top border (blue by default).

### Note

All feature pages provide in-product contextual help. To access help, choose **Show information**. The help interface provides a brief introduction to the tool and links to additional resources, such as videos, tutorials, or blogs.

## Launch Amazon SageMaker Studio Classic

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

After you have onboarded to an Amazon SageMaker AI domain, you can launch an Amazon SageMaker Studio Classic application from either the SageMaker AI console or the AWS CLI. For more information about onboarding to a domain, see [Amazon SageMaker AI domain overview](#).

## Topics

- [Launch Studio Classic Using the Amazon SageMaker AI Console](#)
- [Launch Studio Classic Using the AWS CLI](#)

## Launch Studio Classic Using the Amazon SageMaker AI Console

The process to navigate to Studio Classic from the Amazon SageMaker AI Console differs depending on if Studio Classic or Amazon SageMaker Studio are set as the default experience for your domain. For more information about setting the default experience for your domain, see [Migration from Amazon SageMaker Studio Classic](#).

## Topics

- [Prerequisite](#)

## Prerequisite

To complete this procedure, you must onboard to a domain by following the steps in [Onboard to Amazon SageMaker AI domain](#).

## Launch Studio Classic if Studio is your default experience

1. Navigate to Studio following the steps in [Launch Amazon SageMaker Studio](#).
2. From the Studio UI, find the applications pane on the left side.
3. From the applications pane, select **Studio Classic**.
4. From the Studio Classic landing page, select the Studio Classic instance to open.
5. Choose "Open".

## Launch Studio Classic if Studio Classic is your default experience

When Studio Classic is your default experience, you can launch a Amazon SageMaker Studio Classic application from the SageMaker AI console using the Studio Classic landing page or the Amazon SageMaker AI domain details page. The following sections demonstrate how to launch the Studio Classic application from the SageMaker AI console.

## Launch Studio Classic from the domain details page

The following sections describe how to launch a Studio Classic application from the domain details page. The steps to launch the Studio Classic application after you have navigated to the domain details page differ depending on if you're launching a personal application or a shared space.

### Navigate to the domain details page

The following procedure shows how to navigate to the domain details page.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domain, select the domain that you want to launch the Studio Classic application in.

### Launch a user profile app

The following procedure shows how to launch a Studio Classic application that is scoped to a user profile.

1. On the domain details page, choose the **User profiles** tab.
2. Identify the user profile that you want to launch the Studio Classic application for.
3. Choose **Launch** for your selected user profile, then choose **Studio Classic**.

### Launch a shared space app

The following procedure shows how to launch a Studio Classic application that is scoped to a shared space.

1. On the domain details page, choose the **Space management** tab.
2. Identify the shared space that you want to launch the Studio Classic application for.
3. Choose **Launch Studio Classic** for your selected shared space.

## Launch Studio Classic from the Studio Classic landing page

The following procedure describes how to launch a Studio Classic application from the Studio Classic landing page.

## Launch Studio Classic

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose Studio Classic.
3. Under **Get started**, select the domain that you want to launch the Studio Classic application in. If your user profile only belongs to one domain, you do not see the option for selecting a domain.
4. Select the user profile that you want to launch the Studio Classic application for. If there is no user profile in the domain, choose **Create user profile**. For more information, see [Add user profiles](#).
5. Choose **Launch Studio Classic**. If the user profile belongs to a shared space, choose **Open Spaces**.
6. To launch a Studio Classic application scoped to a user profile, choose **Launch personal Studio Classic**.
7. To launch a shared Studio Classic application, choose the **Launch shared Studio Classic** button next to the shared space that you want to launch into.

## Launch Studio Classic Using the AWS CLI

You can use the AWS Command Line Interface (AWS CLI) to launch Amazon SageMaker Studio Classic by creating a presigned domain URL.

### Prerequisites

Before you begin, complete the following prerequisites:

- Onboard to Amazon SageMaker AI domain. For more information, see [Onboard to Amazon SageMaker AI domain](#).
- Update the AWS CLI by following the steps in [Installing the current AWS CLI Version](#).
- From your local machine, run `aws configure` and provide your AWS credentials. For information about AWS credentials, see [Understanding and getting your AWS credentials](#).

The following code snippet demonstrates how to launch Amazon SageMaker Studio Classic from the AWS CLI using a presigned domain URL. For more information, see [create-presigned-domain-url](#).

```
aws sagemaker create-presigned-domain-url \  
--region region \  
--domain-id domain-id \  
--space-name space-name \  
--user-profile-name user-profile-name \  
--session-expiration-duration-in-seconds 43200
```

## JupyterLab Versioning

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The Amazon SageMaker Studio Classic interface is based on JupyterLab, which is a web-based interactive development environment for notebooks, code, and data. Studio Classic only supports using JupyterLab 3.

If you created your domain and user profile using the AWS Management Console before 08/31/2022 or using the AWS Command Line Interface before 02/22/23, then your Studio Classic

instance defaulted to JupyterLab 1. After 07/01/2024, you cannot create any Studio Classic applications that run JupyterLab 1.

## JupyterLab 3

JupyterLab 3 includes the following features that are not available in previous versions. For more information about these features, see [JupyterLab 3.0 is released!](#).

- Visual debugger when using the Base Python 2.0 and Data Science 2.0 kernels.
- File browser filter
- Table of Contents (TOC)
- Multi-language support
- Simple mode
- Single interface mode

### Important changes to JupyterLab 3

Consider the following when using JupyterLab 3:

- When setting the JupyterLab version using the AWS CLI, select the corresponding image for your Region and JupyterLab version from the image list in [From the AWS CLI](#).
- In JupyterLab 3, you must activate the `studio conda` environment before installing extensions. For more information, see [Installing JupyterLab and Jupyter Server extensions](#).
- Debugger is only supported when using the following images:
  - Base Python 2.0
  - Data Science 2.0
  - Base Python 3.0
  - Data Science 3.0

### Restricting default JupyterLab version using an IAM policy condition key

You can use IAM policy condition keys to restrict the version of JupyterLab that your users can launch.

The following policy shows how to limit the JupyterLab version at the domain level.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Block users from creating JupyterLab 3 apps at the domain level",
      "Effect": "Deny",
      "Action": [
        "sagemaker:CreateDomain",
        "sagemaker:UpdateDomain"
      ],
      "Resource": "*",
      "Condition": {
        "ForAnyValue:StringLike": {
          "sagemaker:ImageArns": "*image/jupyter-server-3"
        }
      }
    }
  ]
}
```

The following policy shows how to limit the JupyterLab version at the user profile level.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Block users from creating JupyterLab 3 apps at the user profile
level",
      "Effect": "Deny",
      "Action": [
        "sagemaker:CreateUserProfile",
        "sagemaker:UpdateUserProfile"
      ],
      "Resource": "*",
      "Condition": {
        "ForAnyValue:StringLike": {
          "sagemaker:ImageArns": "*image/jupyter-server-3"
        }
      }
    }
  ]
}
```

The following policy shows how to limit the JupyterLab version at the application level. The CreateApp request must include the image ARN for this policy to apply.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Block users from creating JupyterLab 3 apps at the application
level",
      "Effect": "Deny",
      "Action": "sagemaker:CreateApp",
      "Resource": "*",
      "Condition": {
        "ForAnyValue:StringLike": {
          "sagemaker:ImageArns": "*image/jupyter-server-3"
        }
      }
    }
  ]
}
```

## Setting a default JupyterLab version

The following sections show how to set a default JupyterLab version for Studio Classic using either the console or the AWS CLI.

### From the console

You can select the default JupyterLab version to use on either the domain or user profile level during resource creation. To set the default JupyterLab version using the console, see [Amazon SageMaker AI domain overview](#).

### From the AWS CLI

You can select the default JupyterLab version to use on either the domain or user profile level using the AWS CLI.

To set the default JupyterLab version using the AWS CLI, you must include the ARN of the desired default JupyterLab version as part of an AWS CLI command. This ARN differs based on the version and the Region of the SageMaker AI domain.

The following table lists the ARNs of the available JupyterLab versions for each Region:

Region	JL3
us-east-1	arn:aws:sagemaker:us-east-1:081325390199:image/jupyter-server-3
us-east-2	arn:aws:sagemaker:us-east-2:429704687514:image/jupyter-server-3
us-west-1	arn:aws:sagemaker:us-west-1:742091327244:image/jupyter-server-3
us-west-2	arn:aws:sagemaker:us-west-2:236514542706:image/jupyter-server-3
af-south-1	arn:aws:sagemaker:af-south-1:559312083959:image/jupyter-server-3
ap-east-1	arn:aws:sagemaker:ap-east-1:493642496378:image/jupyter-server-3
ap-south-1	arn:aws:sagemaker:ap-south-1:394103062818:image/jupyter-server-3
ap-northeast-2	arn:aws:sagemaker:ap-northeast-2:806072073708:image/jupyter-server-3
ap-southeast-1	arn:aws:sagemaker:ap-southeast-1:492261229750:image/jupyter-server-3
ap-southeast-2	arn:aws:sagemaker:ap-southeast-2:452832661640:image/jupyter-server-3
ap-northeast-1	arn:aws:sagemaker:ap-northeast-1:102112518831:image/jupyter-server-3
ca-central-1	arn:aws:sagemaker:ca-central-1:310906938811:image/jupyter-server-3

Region	JL3
eu-central-1	arn:aws:sagemaker:eu-central-1:936697816551:image/jupyter-server-3
eu-west-1	arn:aws:sagemaker:eu-west-1:470317259841:image/jupyter-server-3
eu-west-2	arn:aws:sagemaker:eu-west-2:712779665605:image/jupyter-server-3
eu-west-3	arn:aws:sagemaker:eu-west-3:615547856133:image/jupyter-server-3
eu-north-1	arn:aws:sagemaker:eu-north-1:243637512696:image/jupyter-server-3
eu-south-1	arn:aws:sagemaker:eu-south-1:592751261982:image/jupyter-server-3
eu-south-2	arn:aws:sagemaker:eu-south-2:127363102723:image/jupyter-server-3
sa-east-1	arn:aws:sagemaker:sa-east-1:782484402741:image/jupyter-server-3
cn-north-1	arn:aws-cn:sagemaker:cn-north-1:390048526115:image/jupyter-server-3
cn-northwest-1	arn:aws-cn:sagemaker:cn-northwest-1:390780980154:image/jupyter-server-3

## Create or update domain

You can set a default JupyterServer version at the domain level by invoking [CreateDomain](#) or [UpdateDomain](#) and passing the `UserSettings.JupyterServerAppSettings.DefaultResourceSpec.SageMakerImageArn` field.

The following shows how to create a domain with JupyterLab 3 as the default, using the AWS CLI:

```
aws --region <REGION> \
sagemaker create-domain \
--domain-name <NEW_DOMAIN_NAME> \
--auth-mode <AUTHENTICATION_MODE> \
--subnet-ids <SUBNET-IDS> \
--vpc-id <VPC-ID> \
--default-user-settings '{
  "JupyterServerAppSettings": {
    "DefaultResourceSpec": {
      "SageMakerImageArn": "arn:aws:sagemaker:<REGION>:<ACCOUNT_ID>:image/jupyter-
server-3",
      "InstanceType": "system"
    }
  }
}'
```

The following shows how to update a domain to use JupyterLab 3 as the default, using the AWS CLI:

```
aws --region <REGION> \
sagemaker update-domain \
--domain-id <YOUR_DOMAIN_ID> \
--default-user-settings '{
  "JupyterServerAppSettings": {
    "DefaultResourceSpec": {
      "SageMakerImageArn": "arn:aws:sagemaker:<REGION>:<ACCOUNT_ID>:image/jupyter-
server-3",
      "InstanceType": "system"
    }
  }
}'
```

## Create or update user profile

You can set a default JupyterServer version at the user profile level by invoking [CreateUserProfile](#) or [UpdateUserProfile](#) and passing the `UserSettings.JupyterServerAppSettings.DefaultResourceSpec.SageMakerImageArn` field.

The following shows how to create a user profile with JupyterLab 3 as the default on an existing domain, using the AWS CLI:

```
aws --region <REGION> \
sagemaker create-user-profile \
--domain-id <YOUR_DOMAIN_ID> \
--user-profile-name <NEW_USERPROFILE_NAME> \
--query UserProfileArn --output text \
--user-settings '{
  "JupyterServerAppSettings": {
    "DefaultResourceSpec": {
      "SageMakerImageArn": "arn:aws:sagemaker:<REGION>:<ACCOUNT_ID>:image/jupyter-
server-3",
      "InstanceType": "system"
    }
  }
}'
```

The following shows how to update a user profile to use JupyterLab 3 as the default, using the AWS CLI:

```
aws --region <REGION> \
sagemaker update-user-profile \
--domain-id <YOUR_DOMAIN_ID> \
--user-profile-name <EXISTING_USERPROFILE_NAME> \
--user-settings '{
  "JupyterServerAppSettings": {
    "DefaultResourceSpec": {
      "SageMakerImageArn": "arn:aws:sagemaker:<REGION>:<ACCOUNT_ID>:image/jupyter-
server-3",
      "InstanceType": "system"
    }
  }
}'
```

## View and update the JupyterLab version of an application from the console

The following shows how to view and update the JupyterLab version of an application.

1. Navigate to the SageMaker AI **domains** page.
2. Select a domain to view its user profiles.
3. Select a user to view their applications.
4. To view the JupyterLab version of an application, select the application's name.

5. To update the JupyterLab version, select **Action**.
6. From the dropdown menu, select **Change JupyterLab version**.
7. From the **Studio Classic settings** page, select the JupyterLab version from the dropdown menu.
8. After the JupyterLab version for the user profile has been successfully updated, restart the JupyterServer application to make the version changes effective. For more information about restarting a JupyterServer application, see [Shut down and Update SageMaker Studio Classic](#).

## Installing JupyterLab and Jupyter Server extensions

In JupyterLab 3, you must activate the `studio` conda environment before installing extensions. The method for this differs if you're installing the extensions from within Studio Classic or using a lifecycle configuration script.

### Installing Extension from within Studio Classic

To install extensions from within Studio Classic, you must activate the `studio` environment before you install extensions.

```
# Before installing extensions
conda activate studio

# Install your extensions
pip install <JUPYTER_EXTENSION>

# After installing extensions
conda deactivate
```

### Installing Extensions using a lifecycle configuration script

If you're installing JupyterLab and Jupyter Server extensions in your lifecycle configuration script, you must modify your script so that it works with JupyterLab 3. The following sections show the code needed for existing and new lifecycle configuration scripts.

#### Existing lifecycle configuration script

If you're reusing an existing lifecycle configuration script that must work with both versions of JupyterLab, use the following code in your script:

```
# Before installing extension
```

```
export
  AWS_SAGEMAKER_JUPYTERSERVER_IMAGE="${AWS_SAGEMAKER_JUPYTERSERVER_IMAGE:-'jupyter-
server'}"
if [ "$AWS_SAGEMAKER_JUPYTERSERVER_IMAGE" = "jupyter-server-3" ] ; then
  eval "$(conda shell.bash hook)"
  conda activate studio
fi;

# Install your extensions
pip install <JUPYTER_EXTENSION>

# After installing extension
if [ "$AWS_SAGEMAKER_JUPYTERSERVER_IMAGE" = "jupyter-server-3" ]; then
  conda deactivate
fi;
```

## New lifecycle configuration script

If you're writing a new lifecycle configuration script that only uses JupyterLab 3, you can use the following code in your script:

```
# Before installing extension
eval "$(conda shell.bash hook)"
conda activate studio

# Install your extensions
pip install <JUPYTER_EXTENSION>

conda deactivate
```

## Use the Amazon SageMaker Studio Classic Launcher

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

You can use the Amazon SageMaker Studio Classic Launcher to create notebooks and text files, and to launch terminals and interactive Python shells.

You can open Studio Classic Launcher in any of the following ways:

- Choose **Amazon SageMaker Studio Classic** at the top left of the Studio Classic interface.
- Use the keyboard shortcut **Ctrl + Shift + L**.
- From the Studio Classic menu, choose **File** and then choose **New Launcher**.
- If the SageMaker AI file browser is open, choose the plus (+) sign in the Studio Classic file browser menu.
- In the **Quick actions** section of the **Home** tab, choose **Open Launcher**. The Launcher opens in a new tab. The **Quick actions** section is visible by default but can be toggled off. Choose **Customize Layout** to turn this section back on.

The Launcher consists of the following two sections:

## Topics

- [Notebooks and compute resources](#)

- [Utilities and files](#)

## Notebooks and compute resources

In this section, you can create a notebook, open an image terminal, or open a Python console.

To create or launch one of those items:

1. Choose **Change environment** to select a SageMaker image, a kernel, an instance type, and, optionally, add a lifecycle configuration script that runs on image start-up. For more information on lifecycle configuration scripts, see [Use lifecycle configurations to customize Studio Classic](#). For more information about kernel updates, see [Change an Image or a Kernel](#).
2. Select an item.

### Note

When you choose an item from this section, you might incur additional usage charges. For more information, see [Usage Metering](#).

The following items are available:

- **Notebook**

Launches the notebook in a kernel session on the chosen SageMaker image.

Creates the notebook in the folder that you have currently selected in the file browser. To view the file browser, in the left sidebar of Studio Classic, choose the **File Browser** icon.

- **Console**

Launches the shell in a kernel session on the chosen SageMaker image.

Opens the shell in the folder that you have currently selected in the file browser.

- **Image terminal**

Launches the terminal in a terminal session on the chosen SageMaker image.

Opens the terminal in the root folder for the user (as shown by the **Home** folder in the file browser).

**Note**

By default, CPU instances launch on a `m1.t3.medium` instance, while GPU instances launch on a `m1.g4dn.xlarge` instance.

## Utilities and files

In this section, you can add contextual help in a notebook; create Python, Markdown and text files; and open a system terminal.

**Note**

Items in this section run in the context of Amazon SageMaker Studio Classic and don't incur usage charges.

The following items are available:

- **Show Contextual Help**

Opens a new tab that displays contextual help for functions in a Studio Classic notebook. To display the help, choose a function in an active notebook. To make it easier to see the help in context, drag the help tab so that it's adjacent to the notebook tab. To open the help tab from within a notebook, press `Ctrl + I`.

The following screenshot shows the contextual help for the `Experiment.create` method.

The screenshot shows the Amazon SageMaker Studio interface. At the top, there is a tab titled "mnist-handwritten-digits-clas" and a toolbar with icons for file operations and a "Code" dropdown menu. The main area displays a code editor with the following Python code:

```
[ ]: mnist_experiment = Experiment.create(
    experiment_name=f"mnist-hand-written-digits-classification-{int(time.time())}",
    description="Classification of mnist hand-written digits",
    sagemaker_boto_client=sm)
print(mnist_experiment)
```

Below the code editor, a "Show Contextual Help" window is open, displaying the signature and docstring for the `Experiment.create` method:

```
Signature:
Experiment.create(
    experiment_name=None,
    description=None,
    sagemaker_boto_client=None,
)
Docstring:
Create a new experiment in SageMaker and return an ``Experiment`` object.
Args:
    experiment_name: (str): Name of the experiment. Must be unique. Required.
    experiment_description: (str, optional): Description of the experiment
    sagemaker_boto_client (SageMaker.Client, optional): Boto3 client for SageMaker. If not
        supplied, a default boto3 client will be created and used.
Returns:
    sagemaker.experiments.experiment.Experiment: A SageMaker ``Experiment`` object
File: /opt/conda/lib/python3.7/site-packages/sagemaker/experiments/experiment.py
Type: method
```

- **System terminal**

Opens a bash shell in the root folder for the user (as shown by the **Home** folder in the file browser).

- **Text File and Markdown File**

Creates a file of the associated type in the folder that you have currently selected in the file browser. To view the file browser, in the left sidebar, choose the **File Browser** icon

).

## Use Amazon SageMaker Studio Classic Notebooks

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Amazon SageMaker Studio Classic notebooks are collaborative notebooks that you can launch quickly because you don't need to set up compute instances and file storage beforehand. Studio Classic notebooks provide persistent storage, which enables you to view and share notebooks even if the instances that the notebooks run on are shut down.

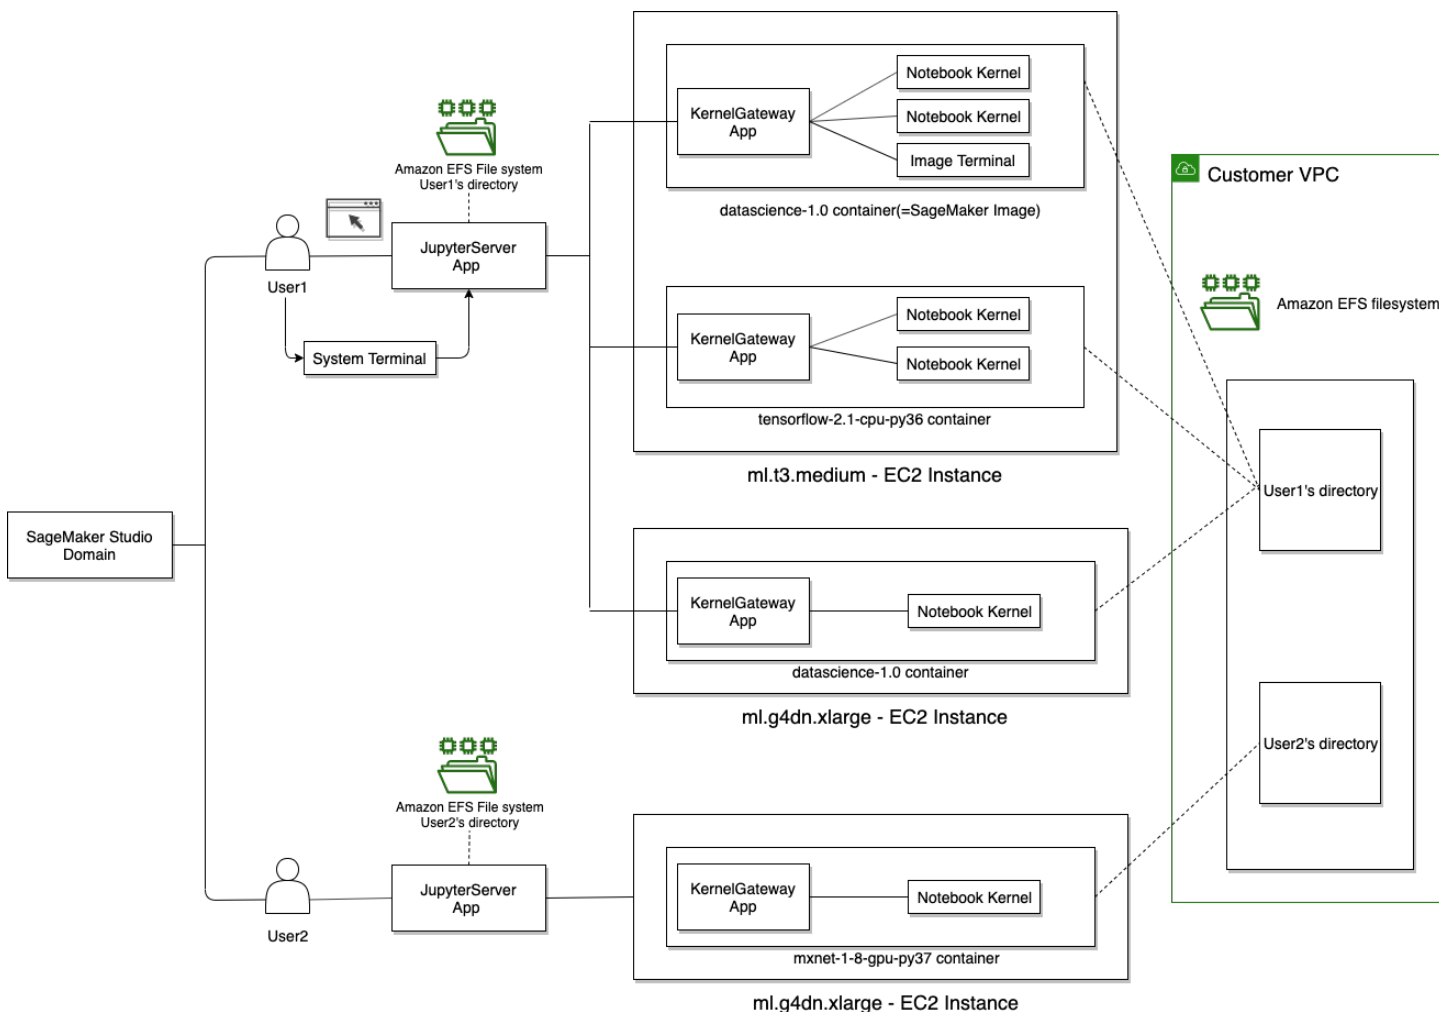

You can share your notebooks with others, so that they can easily reproduce your results and collaborate while building models and exploring your data. You provide access to a read-only copy of the notebook through a secure URL. Dependencies for your notebook are included in the notebook's metadata. When your colleagues copy the notebook, it opens in the same environment as the original notebook.

A Studio Classic notebook runs in an environment defined by the following:

- Amazon EC2 instance type – The hardware configuration the notebook runs on. The configuration includes the number and type of processors (vCPU and GPU), and the amount and type of memory. The instance type determines the pricing rate.
- SageMaker image – A container image that is compatible with SageMaker Studio Classic. The image consists of the kernels, language packages, and other files required to run a notebook in Studio Classic. There can be multiple images in an instance. For more information, see [Bring your own SageMaker image](#).
- KernelGateway app – A SageMaker image runs as a KernelGateway app. The app provides access to the kernels in the image. There is a one-to-one correspondence between a SageMaker AI image and a KernelGateway app.
- Kernel – The process that inspects and runs the code contained in the notebook. A kernel is defined by a *kernel spec* in the image. There can be multiple kernels in an image.

You can change any of these resources from within the notebook.

The following diagram outlines how a notebook kernel runs in relation to the KernelGateway App, User, and domain.

Sample SageMaker Studio Classic notebooks are available in the [aws\\_sagemaker\\_studio](#) folder of the [Amazon SageMaker example GitHub repository](#). Each notebook comes with the necessary SageMaker image that opens the notebook with the appropriate kernel.

We recommend that you familiarize yourself with the SageMaker Studio Classic interface and the Studio Classic notebook toolbar before creating or using a Studio Classic notebook. For more information, see [Amazon SageMaker Studio Classic UI Overview](#) and [Use the Studio Classic Notebook Toolbar](#).

## How Are Amazon SageMaker Studio Classic Notebooks Different from Notebook Instances?

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

When you're starting a new notebook, we recommend that you create the notebook in Amazon SageMaker Studio Classic instead of launching a notebook instance from the Amazon SageMaker AI console. There are many benefits to using a Studio Classic notebook, including the following:

- **Faster:** Starting a Studio Classic notebook is faster than launching an instance-based notebook. Typically, it is 5-10 times faster than instance-based notebooks.
- **Easy notebook sharing:** Notebook sharing is an integrated feature in Studio Classic. Users can generate a shareable link that reproduces the notebook code and also the SageMaker image required to execute it, in just a few clicks.
- **Latest Python SDK:** Studio Classic notebooks come pre-installed with the latest [Amazon SageMaker Python SDK](#).
- **Access all Studio Classic features:** Studio Classic notebooks are accessed from within Studio Classic. This enables you to build, train, debug, track, and monitor your models without leaving Studio Classic.

- **Persistent user directories:** Each member of a Studio team gets their own home directory to store their notebooks and other files. The directory is automatically mounted onto all instances and kernels as they're started, so their notebooks and other files are always available. The home directories are stored in Amazon Elastic File System (Amazon EFS) so that you can access them from other services.
- **Direct access:** When using IAM Identity Center, you use your IAM Identity Center credentials through a unique URL to directly access Studio Classic. You don't have to interact with the AWS Management Console to run your notebooks.
- **Optimized images:** Studio Classic notebooks are equipped with a set of predefined SageMaker image settings to get you started faster.

### Note

Studio Classic notebooks don't support *local mode*. However, you can use a notebook instance to train a sample of your dataset locally, and then use the same code in a Studio Classic notebook to train on the full dataset.

When you open a notebook in SageMaker Studio Classic, the view is an extension of the JupyterLab interface. The primary features are the same, so you'll find the typical features of a Jupyter notebook and JupyterLab. For more information about the Studio Classic interface, see [Amazon SageMaker Studio Classic UI Overview](#).

## Get Started

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

To get started, you or your organization's administrator need to complete the SageMaker AI domain onboarding process. For more information, see [Amazon SageMaker AI domain overview](#).

You can access a Studio Classic notebook in any of the following ways:

- You receive an email invitation to access Studio Classic through your organization's IAM Identity Center, which includes a direct link to login to Studio Classic without having to use the Amazon SageMaker AI console. You can proceed to the [the section called "Next Steps"](#).
- You receive a link to a shared Studio Classic notebook, which includes a direct link to log in to Studio Classic without having to use the SageMaker AI console. You can proceed to the [the section called "Next Steps"](#).
- You onboard to a domain and then log in to the SageMaker AI console. For more information, see [Amazon SageMaker AI domain overview](#).

## Launch Amazon SageMaker AI

Complete the steps in [Launch Amazon SageMaker Studio Classic](#) to launch Studio Classic.

### Next Steps

Now that you're in Studio Classic, you can try any of the following options:

- To create a Studio Classic notebook or explore Studio Classic end-to-end tutorial notebooks – See [Amazon SageMaker Studio Classic Tour](#) in the next section.
- To familiarize yourself with the Studio Classic interface – See [Amazon SageMaker Studio Classic UI Overview](#) or try the **Getting started notebook** by selecting **Open the Getting started notebook** in the **Quick actions** section of the Studio Classic Home page.

## Amazon SageMaker Studio Classic Tour

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

For a walkthrough that takes you on a tour of the main features of Amazon SageMaker Studio Classic, see the [xgboost\\_customer\\_churn\\_studio.ipynb](#) sample notebook from the [aws/amazon-sagemaker-examples](#) GitHub repository. The code in the notebook trains multiple models and sets up the SageMaker Debugger and SageMaker Model Monitor. The walkthrough shows you

how to view the trials, compare the resulting models, show the debugger results, and deploy the best model using the Studio Classic UI. You don't need to understand the code to follow this walkthrough.

## Prerequisites

To run the notebook for this tour, you need:

- An IAM account to sign in to Studio. For information, see [Amazon SageMaker AI domain overview](#).
- Basic familiarity with the Studio user interface and Jupyter notebooks. For information, see [Amazon SageMaker Studio Classic UI Overview](#).
- A copy of the [aws/amazon-sagemaker-examples](#) repository in your Studio environment.

## To clone the repository

1. Launch Studio Classic following the steps in [Launch Amazon SageMaker Studio Classic](#) For users in IAM Identity Center, sign in using the URL from your invitation email.
2. On the top menu, choose **File**, then **New**, then **Terminal**.
3. At the command prompt, run the following command to clone the [aws/amazon-sagemaker-examples](#) GitHub repository.

```
$ git clone https://github.com/aws/amazon-sagemaker-examples.git
```

## To navigate to the sample notebook

1. From the **File Browser** on the left menu, select **amazon-sagemaker-examples**.
2. Navigate to the example notebook with the following path.  

```
~/amazon-sagemaker-examples/aws_sagemaker_studio/getting_started/xgboost_customer_churn_studio.ipynb
```
3. Follow the notebook to learn about Studio Classic's main features.

**Note**

If you encounter an error when you run the sample notebook, and some time has passed from when you cloned the repository, review the notebook on the remote repository for updates.

## Create or Open an Amazon SageMaker Studio Classic Notebook

**Important**

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

**Important**

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

When you [Create a Notebook from the File Menu](#) in Amazon SageMaker Studio Classic or [Open a notebook in Studio Classic](#) for the first time, you are prompted to set up your environment by choosing a SageMaker image, a kernel, an instance type, and, optionally, a lifecycle configuration script that runs on image start-up. SageMaker AI launches the notebook on an instance of the chosen type. By default, the instance type is set to `m1.t3.medium` (available as part of

the [AWS Free Tier](#)) for CPU-based images. For GPU-based images, the default instance type is `m1.g4dn.xlarge`.

If you create or open additional notebooks that use the same instance type, whether or not the notebooks use the same kernel, the notebooks run on the same instance of that instance type.

After you launch a notebook, you can change its instance type, SageMaker image, and kernel from within the notebook. For more information, see [Change an Instance Type](#) and [Change an Image or a Kernel](#).

### **Note**

You can have only one instance of each instance type. Each instance can have multiple SageMaker images running on it. Each SageMaker image can run multiple kernels or terminal instances.

Billing occurs per instance and starts when the first instance of a given instance type is launched. If you want to create or open a notebook without the risk of incurring charges, open the notebook from the **File** menu and choose **No Kernel** from the **Select Kernel** dialog box. You can read and edit a notebook without a running kernel but you can't run cells.

Billing ends when the SageMaker image for the instance is shut down. For more information, see [Usage Metering](#).

For information about shutting down the notebook, see [Shut down resources](#).

## Topics

- [Open a notebook in Studio Classic](#)
- [Create a Notebook from the File Menu](#)
- [Create a Notebook from the Launcher](#)
- [List of the available instance types, images, and kernels](#)

## Open a notebook in Studio Classic

Amazon SageMaker Studio Classic can only open notebooks listed in the Studio Classic file browser. For instructions on uploading a notebook to the file browser, see [Upload Files to SageMaker Studio Classic](#) or [Clone a Git Repository in SageMaker Studio Classic](#).

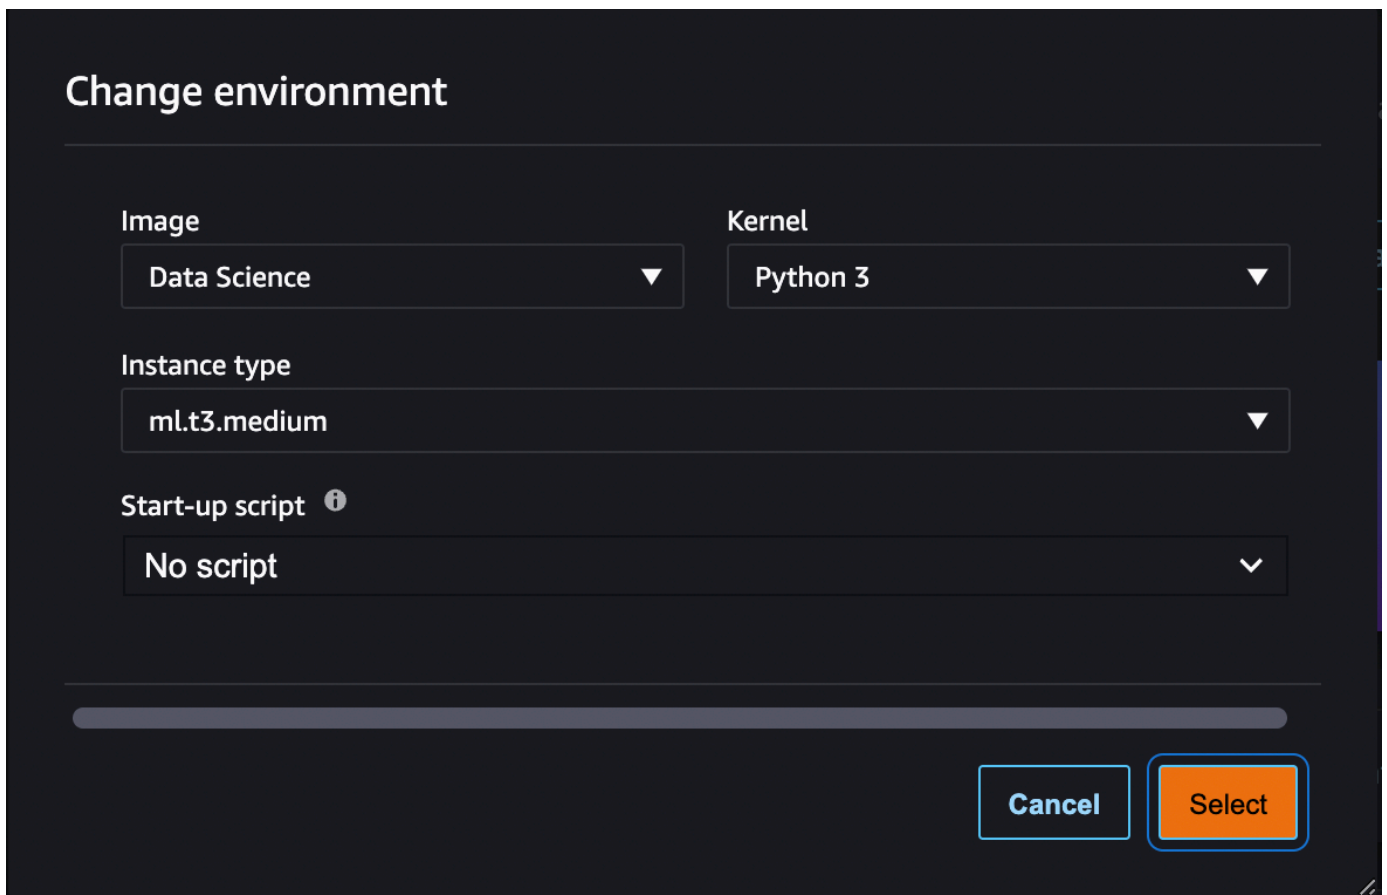

## To open a notebook

1. In the left sidebar, choose the **File Browser** icon (  ) to display the file browser.
2. Browse to a notebook file and double-click it to open the notebook in a new tab.

## Create a Notebook from the File Menu

### To create a notebook from the File menu

1. From the Studio Classic menu, choose **File**, choose **New**, and then choose **Notebook**.
2. In the **Change environment** dialog box, use the dropdown menus to select your **Image**, **Kernel**, **Instance type**, and **Start-up script**, then choose **Select**. Your notebook launches and opens in a new Studio Classic tab.

## Create a Notebook from the Launcher

### To create a notebook from the Launcher

1. To open the Launcher, choose **Amazon SageMaker Studio Classic** at the top left of the Studio Classic interface or use the keyboard shortcut `Ctrl + Shift + L`.

To learn about all the available ways to open the Launcher, see [Use the Amazon SageMaker Studio Classic Launcher](#)

2. In the Launcher, in the **Notebooks and compute resources** section, choose **Change environment**.

3. In the **Change environment** dialog box, use the dropdown menus to select your **Image**, **Kernel**, **Instance type**, and **Start-up script**, then choose **Select**.
4. In the Launcher, choose **Create notebook**. Your notebook launches and opens in a new Studio Classic tab.

To view the notebook's kernel session, in the left sidebar, choose the **Running Terminals and Kernels** icon

You can stop the notebook's kernel session from this view.

### List of the available instance types, images, and kernels

For a list of all available resources, see:

- [Instance types available for use with Studio Classic](#)
- [Amazon SageMaker images available for use with Studio Classic](#)

## Use the Studio Classic Notebook Toolbar

### Important

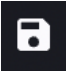

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Amazon SageMaker Studio Classic notebooks extend the JupyterLab interface. For an overview of the original JupyterLab interface, see [The JupyterLab Interface](#).

The following image shows the toolbar and an empty cell from a Studio Classic notebook.

When you pause on a toolbar icon, a tooltip displays the icon function. Additional notebook commands are found in the Studio Classic main menu. The toolbar includes the following icons:

Icon	Description
	<p><b>Save and checkpoint</b></p> <p>Saves the notebook and updates the checkpoint file. For more information, see <a href="#">Get the Difference Between the Last Checkpoint</a>.</p>
	<p><b>Insert cell</b></p> <p>Inserts a code cell below the current cell. The current cell is noted by the blue vertical marker in the left margin.</p>
	<p><b>Cut, copy, and paste cells</b></p>

Icon	Description
	Cuts, copies, and pastes the selected cells.
	<p><b>Run cells</b></p> <p>Runs the selected cells and then makes the cell that follows the last selected cell the new selected cell.</p>
	<p><b>Interrupt kernel</b></p> <p>Interrupts the kernel, which cancels the currently running operation. The kernel remains active.</p>
	<p><b>Restart kernel</b></p> <p>Restarts the kernel. Variables are reset. Unsaved information is not affected.</p>
	<p><b>Restart kernel and run all cells</b></p> <p>Restarts the kernel, then run all the cells of the notebook.</p>
	<p><b>Cell type</b></p> <p>Displays or changes the current cell type. The cell types are:</p> <ul style="list-style-type: none"> <li>• Code – Code that the kernel runs.</li> <li>• Markdown – Text rendered as markdown.</li> <li>• Raw – Content, including Markdown markup, that's displayed as text.</li> </ul>
	<p><b>Launch terminal</b></p> <p>Launches a terminal in the SageMaker image hosting the notebook. For an example, see <a href="#">Get App Metadata</a>.</p>
	<p><b>Checkpoint diff</b></p> <p>Opens a new tab that displays the difference between the notebook and the checkpoint file. For more information, see <a href="#">Get the Difference Between the Last Checkpoint</a>.</p>

Icon	Description
	<p><b>Git diff</b></p> <p>Only enabled if the notebook is opened from a Git repository. Opens a new tab that displays the difference between the notebook and the last Git commit. For more information, see <a href="#">Get the Difference Between the Last Commit</a>.</p>
<p><b>2 vCPU + 4 GiB</b></p>	<p><b>Instance type</b></p> <p>Displays or changes the instance type the notebook runs in. The format is as follows:</p> <p>number of vCPUs + amount of memory + number of GPUs</p> <p>Unknown indicates the notebook was opened without specifying a kernel. The notebook runs on the SageMaker Studio instance and doesn't accrue runtime charges. You can't assign the notebook to an instance type. You must specify a kernel and then Studio assigns the notebook to a default type.</p> <p>For more information, see <a href="#">Create or Open an Amazon SageMaker Studio Classic Notebook</a> and <a href="#">Change an Instance Type</a>.</p>
	<p><b>Cluster</b></p> <p>Connect your notebook to an Amazon EMR cluster and scale your ETL jobs or run large-scale model training using Apache Spark, Hive, or Presto.</p> <p>For more information, see <a href="#">Data preparation using Amazon EMR</a>.</p>

Icon	Description
<b>Python 3 (Data Science)</b>	<p><b>Kernel and SageMaker Image</b></p> <p>Displays or changes the kernel that processes the cells in the notebook. The format is as follows:</p> <p>Kernel (SageMaker Image)</p> <p>No Kernel indicates the notebook was opened without specifying a kernel. You can edit the notebook but you can't run any cells.</p> <p>For more information, see <a href="#">Change an Image or a Kernel</a>.</p>
	<p><b>Kernel busy status</b></p> <p>Displays the busy status of the kernel. When the edge of the circle and its interior are the same color, the kernel is busy. The kernel is busy when it is starting and when it is processing cells. Additional kernel states are displayed in the status bar at the bottom-left corner of SageMaker Studio.</p>
	<p><b>Share notebook</b></p> <p>Shares the notebook. For more information, see <a href="#">Share and Use an Amazon SageMaker Studio Classic Notebook</a>.</p>

To select multiple cells, click in the left margin outside of a cell. Hold down the Shift key and use K or the Up key to select previous cells, or use J or the Down key to select following cells.

## Install External Libraries and Kernels in Amazon SageMaker Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Amazon SageMaker Studio Classic notebooks come with multiple images already installed. These images contain kernels and Python packages including scikit-learn, Pandas, NumPy, TensorFlow, PyTorch, and MXNet. You can also install your own images that contain your choice of packages and kernels. For more information on installing your own image, see [Bring your own SageMaker image](#).

The different Jupyter kernels in Amazon SageMaker Studio Classic notebooks are separate conda environments. For information about conda environments, see [Managing environments](#).

## Package installation tools

### Important

Currently, all packages in Amazon SageMaker notebooks are licensed for use with Amazon SageMaker AI and do not require additional commercial licenses. However, this might be subject to change in the future, and we recommend reviewing the licensing terms regularly for any updates.

The method that you use to install Python packages from the terminal differs depending on the image. Studio Classic supports the following package installation tools:

- **Notebooks** – The following commands are supported. If one of the following does not work on your image, try the other one.
  - `%conda install`
  - `%pip install`
- **The Jupyter terminal** – You can install packages using pip and conda directly. You can also use `apt-get install` to install system packages from the terminal.

### Note

We do not recommend using `pip install -u` or `pip install --user`, because those commands install packages on the user's Amazon EFS volume and can potentially block JupyterServer app restarts. Instead, use a lifecycle configuration to reinstall the required packages on app restarts as shown in [Install packages using lifecycle configurations](#).

We recommend using `%pip` and `%conda` to install packages from within a notebook because they correctly take into account the active environment or interpreter being used. For more information, see [Add %pip and %conda magic functions](#). You can also use the system command syntax (lines starting with `!`) to install packages. For example, `!pip install` and `!conda install`.

## Conda

Conda is an open source package management system and environment management system that can install packages and their dependencies. SageMaker AI supports using conda with the conda-forge channel. For more information, see [Conda channels](#). The conda-forge channel is a community channel where contributors can upload packages.

### Note

Installing packages from conda-forge can take up to 10 minutes. Timing relates to how conda resolves the dependency graph.

All of the SageMaker AI provided environments are functional. User installed packages may not function correctly.

Conda has two methods for activating environments: `conda activate`, and `source activate`. For more information, see [Managing environment](#).

## Supported conda operations

- `conda install` of a package in a single environment
- `conda install` of a package in all environments
- Installing a package from the main conda repository
- Installing a package from conda-forge
- Changing the conda install location to use Amazon EBS
- Supporting both `conda activate` and `source activate`

## Pip

Pip is the tool for installing and managing Python packages. Pip searches for packages on the Python Package Index (PyPI) by default. Unlike conda, pip doesn't have built in environment

support. Therefore, pip isn't as thorough as conda when it comes to packages with native or system library dependencies. Pip can be used to install packages in conda environments. You can use alternative package repositories with pip instead of the PyPI.

### Supported pip operations

- Using pip to install a package without an active conda environment
- Using pip to install a package in a conda environment
- Using pip to install a package in all conda environments
- Changing the pip install location to use Amazon EBS
- Using an alternative repository to install packages with pip

### Unsupported

SageMaker AI aims to support as many package installation operations as possible. However, if the packages were installed by SageMaker AI and you use the following operations on these packages, it might make your environment unstable:

- Uninstalling
- Downgrading
- Upgrading

Due to potential issues with network conditions or configurations, or the availability of conda or PyPi, packages may not install in a fixed or deterministic amount of time.

#### Note

Attempting to install a package in an environment with incompatible dependencies can result in a failure. If issues occur, you can contact the library maintainer about updating the package dependencies. When you modify the environment, such as removing or updating existing packages, this may result in instability of that environment.

### Install packages using lifecycle configurations

Install custom images and kernels on the Studio Classic instance's Amazon EBS volume so that they persist when you stop and restart the notebook, and that any external libraries you install

are not updated by SageMaker AI. To do that, use a lifecycle configuration that includes both a script that runs when you create the notebook (on-create) and a script that runs each time you restart the notebook (on-start). For more information about using lifecycle configurations with Studio Classic, see [Use lifecycle configurations to customize Studio Classic](#). For sample lifecycle configuration scripts, see [SageMaker AI Studio Classic Lifecycle Configuration Samples](#).

## Share and Use an Amazon SageMaker Studio Classic Notebook

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

You can share your Amazon SageMaker Studio Classic notebooks with your colleagues. The shared notebook is a copy. After you share your notebook, any changes you make to your original notebook aren't reflected in the shared notebook and any changes your colleague's make in their shared copies of the notebook aren't reflected in your original notebook. If you want to share your latest version, you must create a new snapshot and then share it.

## Topics

- [Share a Notebook](#)

- [Use a Shared Notebook](#)
- [Shared spaces and realtime collaboration](#)

## Share a Notebook

The following screenshot shows the menu from a Studio Classic notebook.

### To share a notebook

1. In the upper-right corner of the notebook, choose **Share**.
2. (Optional) In **Create shareable snapshot**, choose any of the following items:
  - **Include Git repo information** – Includes a link to the Git repository that contains the notebook. This enables you and your colleague to collaborate and contribute to the same Git repository.
  - **Include output** – Includes all notebook output that has been saved.

#### Note

If you're an user in IAM Identity Center and you don't see these options, your IAM Identity Center administrator probably disabled the feature. Contact your administrator.

3. Choose **Create**.
4. After the snapshot is created, choose **Copy link** and then choose **Close**.
5. Share the link with your colleague.

After selecting your sharing options, you are provided with a URL. You can share this link with users that have access to Amazon SageMaker Studio Classic. When the user opens the URL, they're prompted to log in using IAM Identity Center or IAM authentication. This shared notebook becomes a copy, so changes made by the recipient will not be reproduced in your original notebook.

## Use a Shared Notebook

You use a shared notebook in the same way you would with a notebook that you created yourself. You must first login to your account, then open the shared link. If you don't have an active session, you receive an error.

When you choose a link to a shared notebook for the first time, a read-only version of the notebook opens. To edit the shared notebook, choose **Create a Copy**. This copies the shared notebook to your personal storage.

The copied notebook launches on an instance of the instance type and SageMaker image that the notebook was using when the sender shared it. If you aren't currently running an instance of the instance type, a new instance is started. Customization to the SageMaker image isn't shared. You can also inspect the notebook snapshot by choosing **Snapshot Details**.

The following are some important considerations about sharing and authentication:

- If you have an active session, you see a read-only view of the notebook until you choose **Create a Copy**.
- If you don't have an active session, you need to log in.
- If you use IAM to login, after you login, select your user profile then choose **Open Studio Classic**. Then you need to choose the link you were sent.
- If you use IAM Identity Center to login, after you login the shared notebook is opened automatically in Studio.

## Shared spaces and realtime collaboration

A shared space consists of a shared JupyterServer application and a shared directory. A key benefit of a shared space is that it facilitates collaboration between members of the shared space in real time. Users collaborating in a workspace get access to a shared Studio Classic application where they can access, read, and edit their notebooks in real time. Real time collaboration is only supported for JupyterServer applications within a shared space. Users with access to a shared space can simultaneously open, view, edit, and execute Jupyter notebooks in the shared Studio Classic application in that space. For more information about shared spaced and real time collaboration, see [Collaboration with shared spaces](#).

## Get Studio Classic Notebook and App Metadata

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

You can access notebook metadata and App metadata using the Amazon SageMaker Studio Classic UI.

### Topics

- [Get Studio Classic Notebook Metadata](#)
- [Get App Metadata](#)

### Get Studio Classic Notebook Metadata

Jupyter notebooks contain optional metadata that you can access through the Amazon SageMaker Studio Classic UI.

#### To view the notebook metadata:

1. In the right sidebar, choose the **Property Inspector** icon

2. Open the **Advanced Tools** section.

The metadata should look similar to the following.

```
{
  "instance_type": "ml.t3.medium",
  "kernel_spec": {
    "display_name": "Python 3 (Data Science)",
    "language": "python",
    "name": "python3__SAGEMAKER_INTERNAL__arn:aws:sagemaker:us-west-2:<acct-id>:image/datascience-1.0"
  },
}
```

```
"language_info": {
  "codemirror_mode": {
    "name": "ipython",
    "version": 3
  },
  "file_extension": ".py",
  "mimetype": "text/x-python",
  "name": "python",
  "nbconvert_exporter": "python",
  "pygments_lexer": "ipython3",
  "version": "3.7.10"
}
```

## Get App Metadata

When you create a notebook in Amazon SageMaker Studio Classic, the App metadata is written to a file named `resource-metadata.json` in the folder `/opt/ml/metadata/`. You can get the App metadata by opening an Image terminal from within the notebook. The metadata gives you the following information, which includes the SageMaker image and instance type the notebook runs in:

- **AppType** – KernelGateway
- **DomainId** – Same as the Studio ClassicID
- **UserProfileName** – The profile name of the current user
- **ResourceArn** – The Amazon Resource Name (ARN) of the App, which includes the instance type
- **ResourceName** – The name of the SageMaker image

Additional metadata might be included for internal use by Studio Classic and is subject to change.

### To get the App metadata

1. In the center of the notebook menu, choose the **Launch Terminal** icon

).

This opens a terminal in the SageMaker image that the notebook runs in.

2. Run the following commands to display the contents of the `resource-metadata.json` file.

```
$ cd /opt/ml/metadata/
```

```
cat resource-metadata.json
```

The file should look similar to the following.

```
{
  "AppType": "KernelGateway",
  "DomainId": "d-xxxxxxxxxxxx",
  "UserProfileName": "profile-name",
  "ResourceArn": "arn:aws:sagemaker:us-east-2:account-id:app/d-xxxxxxxxxxxx/
profile-name/KernelGateway/datascience--1-0-ml-t3-medium",
  "ResourceName": "datascience--1-0-ml",
  "AppImageVersion":""
}
```

## Get Notebook Differences

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#). [AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

You can display the difference between the current notebook and the last checkpoint or the last Git commit using the Amazon SageMaker AI UI.

The following screenshot shows the menu from a Studio Classic notebook.

## Topics

- [Get the Difference Between the Last Checkpoint](#)
- [Get the Difference Between the Last Commit](#)

### Get the Difference Between the Last Checkpoint

When you create a notebook, a hidden checkpoint file that matches the notebook is created. You can view changes between the notebook and the checkpoint file or revert the notebook to match the checkpoint file.

By default, a notebook is auto-saved every 120 seconds and also when you close the notebook. However, the checkpoint file isn't updated to match the notebook. To save the notebook and update the checkpoint file to match, you must choose the **Save notebook and create checkpoint** icon (

) on the left of the notebook menu or use the `Ctrl + S` keyboard shortcut.

To view the changes between the notebook and the checkpoint file, choose the **Checkpoint diff** icon

) in the center of the notebook menu.

To revert the notebook to the checkpoint file, from the main Studio Classic menu, choose **File** then **Revert Notebook to Checkpoint**.

### Get the Difference Between the Last Commit

If a notebook is opened from a Git repository, you can view the difference between the notebook and the last Git commit.

To view the changes in the notebook from the last Git commit, choose the **Git diff** icon

in the center of the notebook menu.

## Manage Resources

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

You can change the instance type, and SageMaker image and kernel from within an Amazon SageMaker Studio Classic notebook. To create a custom kernel to use with your notebooks, see [Bring your own SageMaker image](#).

### Topics

- [Change an Instance Type](#)
- [Change an Image or a Kernel](#)
- [Shut down resources from Amazon SageMaker Studio Classic](#)

## Change an Instance Type

When you open a new Studio Classic notebook for the first time, you are assigned a default Amazon Elastic Compute Cloud (Amazon EC2) instance type to run the notebook. When you open additional notebooks on the same instance type, the notebooks run on the same instance as the first notebook, even if the notebooks use different kernels.

You can change the instance type that your Studio Classic notebook runs on from within the notebook.

The following information only applies to Studio Classic notebooks. For information about how to change the instance type of a Amazon SageMaker notebook instance, see [Update a Notebook Instance](#).

### **⚠ Important**

If you change the instance type, unsaved information and existing settings for the notebook are lost, and installed packages must be re-installed.

The previous instance type continues to run even if no kernel sessions or apps are active. You must explicitly stop the instance to stop accruing charges. To stop the instance, see [Shut down resources](#).

The following screenshot shows the menu from a Studio Classic notebook. The processor and memory of the instance type powering the notebook are displayed as **2 vCPU + 4 GiB**.

### **To change the instance type**

1. Choose the processor and memory of the instance type powering the notebook. This opens a pop up window.
2. From the **Set up notebook environment** pop up window, select the **Instance type** dropdown menu.
3. From the **Instance type** dropdown, choose one of the instance types that are listed.
4. After choosing a type, choose **Select**.
5. Wait for the new instance to become enabled, and then the new instance type information is displayed.

For a list of the available instance types, see [Instance types available for use with Studio Classic](#).

### **Change an Image or a Kernel**

### **⚠ Important**

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the

Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

With Amazon SageMaker Studio Classic notebooks, you can change the notebook's image or kernel from within the notebook.

The following screenshot shows the menu from a Studio Classic notebook. The current SageMaker AI kernel and image are displayed as **Python 3 (Data Science)**, where Python 3 denotes the kernel and Data Science denotes the SageMaker AI image that contains the kernel. The color of the circle to the right indicates the kernel is idle or busy. The kernel is busy when the center and the edge of the circle are the same color.

## To change a notebook's image or kernel

1. Choose the image/kernel name in the notebook menu.
2. From the **Set up notebook environment** pop up window, select the **Image** or **Kernel** dropdown menu.
3. From the dropdown menu, choose one of the images or kernels that are listed.
4. After choosing an image or kernel, choose **Select**.
5. Wait for the kernel's status to show as idle, which indicates the kernel has started.

For a list of available SageMaker images and kernels, see [Amazon SageMaker images available for use with Studio Classic](#).

## Shut down resources from Amazon SageMaker Studio Classic

### **⚠ Important**

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

You can shut down individual Amazon SageMaker AI resources, including notebooks, terminals, kernels, apps, and instances from Studio Classic. You can also shut down all of the resources in one of these categories at the same time. Amazon SageMaker Studio Classic does not support shutting down resources from within a notebook.

### Note

When you shut down a Studio Classic notebook instance, additional resources that you created in Studio Classic are not deleted. For example, additional resources can include SageMaker AI endpoints, Amazon EMR clusters, and Amazon S3 buckets. To stop the accrual of charges, you must manually delete these resources. For information about finding resources that are accruing charges, see [Analyzing your costs with AWS Cost Explorer](#).

The following topics demonstrate how to delete these SageMaker AI resources.

## Topics

- [Shut down an open notebook](#)
- [Shut down resources](#)

## Shut down an open notebook

When you shut down a Studio Classic notebook, the notebook is not deleted. The kernel that the notebook is running on is shut down and any unsaved information in the notebook is lost. You can shut down an open notebook from the Studio Classic **File** menu or from the Running Terminal and Kernels pane. The following procedure shows how to shut down an open notebook from the Studio Classic **File** menu.

### To shut down an open notebook from the File menu

1. Launch Studio Classic by following the steps in [Launch Amazon SageMaker Studio Classic](#).
2. (Optional) Save the notebook contents by choosing **File**, then **Save Notebook**.
3. Choose **File**.
4. Choose **Close and Shutdown Notebook**. This opens a pop-up window.
5. From the pop-up window, choose **OK**.

## Shut down resources

You can reach the **Running Terminals and Kernels** pane of Amazon SageMaker Studio Classic by selecting the **Running Terminals and Kernels** icon

The **Running Terminals and Kernels** pane consists of four sections. Each section lists all the resources of that type. You can shut down each resource individually or shut down all the resources in a section at the same time.

When you choose to shut down all resources in a section, the following occurs:

- **RUNNING INSTANCES/RUNNING APPS** – All instances, apps, notebooks, kernel sessions, consoles/shells, and image terminals are shut down. System terminals aren't shut down.
- **KERNEL SESSIONS** – All kernels, notebooks and consoles/shells are shut down.
- **TERMINAL SESSIONS** – All image terminals and system terminals are shut down.

### To shut down resources

1. Launch Studio Classic by following the steps in [Launch Amazon SageMaker Studio Classic](#).
2. Choose the **Running Terminals and Kernels** icon.
3. Do either of the following:
  - To shut down a specific resource, choose the **Shut Down** icon on the same row as the resource.

For running instances, a confirmation dialog box lists all of the resources that SageMaker AI will shut down. A confirmation dialog box displays all running apps. To proceed, choose **Shut down all**.

#### Note

A confirmation dialog box isn't displayed for kernel sessions or terminal sessions.

- To shut down all resources in a section, choose the **X** to the right of the section label. A confirmation dialog box is displayed. Choose **Shut down all** to proceed.

**Note**

When you shut down these Studio Classic resources, any additional resources created from Studio Classic, such as SageMaker AI endpoints, Amazon EMR clusters, and Amazon S3 buckets are not deleted. You must manually delete these resources to stop the accrual of charges. For information about finding resources that are accruing charges, see [Analyzing your costs with AWS Cost Explorer](#).

## Usage Metering

**Important**

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

There is no additional charge for using Amazon SageMaker Studio Classic. The costs incurred for running Amazon SageMaker Studio Classic notebooks, interactive shells, consoles, and terminals are based on Amazon Elastic Compute Cloud (Amazon EC2) instance usage.

When you run the following resources, you must choose a SageMaker image and kernel:

### From the Studio Classic Launcher

- Notebook
- Interactive Shell
- Image Terminal

### From the File menu

- Notebook
- Console

When launched, the resource is run on an Amazon EC2 instance of the chosen instance type. If an instance of that type was previously launched and is available, the resource is run on that instance.

For CPU based images, the default suggested instance type is `m1.t3.medium`. For GPU based images, the default suggested instance type is `m1.g4dn.xlarge`.

The costs incurred are based on the instance type. You are billed separately for each instance.

Metering starts when an instance is created. Metering ends when all the apps on the instance are shut down, or the instance is shut down. For information about how to shut down an instance, see [Shut down resources from Amazon SageMaker Studio Classic](#).

### Important

You must shut down the instance to stop incurring charges. If you shut down the notebook running on the instance but don't shut down the instance, you will still incur charges. When you shut down the Studio Classic notebook instances, any additional resources, such as SageMaker AI endpoints, Amazon EMR clusters, and Amazon S3 buckets created from Studio Classic are not deleted. Delete those resources to stop accrual of charges.

When you open multiple notebooks on the same instance type, the notebooks run on the same instance even if they are using different kernels. You are billed only for the time that one instance is running.

You can change the instance type from within the notebook after you open it. For more information, see [Change an Instance Type](#).

For information about billing along with pricing examples, see [Amazon SageMaker Pricing](#).

## Available Resources

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following sections list the available resources for Amazon SageMaker Studio Classic notebooks.

## Topics

- [Instance types available for use with Studio Classic](#)
- [Amazon SageMaker images available for use with Studio Classic](#)

## Instance types available for use with Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Amazon SageMaker Studio Classic notebooks run on Amazon Elastic Compute Cloud (Amazon EC2) instances. The following Amazon EC2 instance types are available for use with Studio Classic notebooks. For detailed information on which instance types fit your use case, and their performance capabilities, see [Amazon Elastic Compute Cloud Instance types](#). For information about pricing for these instance types, see [Amazon EC2 Pricing](#).

For information about available Amazon SageMaker Notebook Instance types, see [CreateNotebookInstance](#).

### Note

For most use cases, you should use a `m1.t3.medium`. This is the default instance type for CPU-based SageMaker images, and is available as part of the [AWS Free Tier](#).

## Topics

- [CPU instances](#)
- [Instances with 1 or more GPUs](#)

## CPU instances

The following table lists the Amazon EC2 CPU instance types with no GPU attached that are available for use with Studio Classic notebooks. It also lists information about the specifications of each instance type. The default instance type for CPU-based images is `m1.t3.medium`.

For detailed information on which instance types fit your use case, and their performance capabilities, see [Amazon Elastic Compute Cloud Instance types](#). For information about pricing for these instance types, see [Amazon EC2 Pricing](#).

### CPU instances

Instance	Use case	Fast launch	vCPU	Memory (GiB)	Instance Storage (GB)
<code>m1.t3.medium</code>	General purpose	Yes	2	4	Amazon EBS Only
<code>m1.t3.large</code>	General purpose	No	2	8	Amazon EBS Only
<code>m1.t3.xlarge</code>	General purpose	No	4	16	Amazon EBS Only
<code>m1.t3.2xlarge</code>	General purpose	No	8	32	Amazon EBS Only
<code>m1.m5.large</code>	General purpose	Yes	2	8	Amazon EBS Only
<code>m1.m5.xlarge</code>	General purpose	No	4	16	Amazon EBS Only

Instance	Use case	Fast launch	vCPU	Memory (GiB)	Instance Storage (GB)
ml.m5.2xlarge	General purpose	No	8	32	Amazon EBS Only
ml.m5.4xlarge	General purpose	No	16	64	Amazon EBS Only
ml.m5.8xlarge	General purpose	No	32	128	Amazon EBS Only
ml.m5.12xlarge	General purpose	No	48	192	Amazon EBS Only
ml.m5.16xlarge	General purpose	No	64	256	Amazon EBS Only
ml.m5.24xlarge	General purpose	No	96	384	Amazon EBS Only
ml.m5d.large	General purpose	No	2	8	1 x 75 NVMe SSD
ml.m5d.xlarge	General purpose	No	4	16	1 x 150 NVMe SSD
ml.m5d.2xlarge	General purpose	No	8	32	1 x 300 NVMe SSD

Instance	Use case	Fast launch	vCPU	Memory (GiB)	Instance Storage (GB)
ml.m5d.4xlarge	General purpose	No	16	64	2 x 300 NVMe SSD
ml.m5d.8xlarge	General purpose	No	32	128	2 x 600 NVMe SSD
ml.m5d.12xlarge	General purpose	No	48	192	2 x 900 NVMe SSD
ml.m5d.16xlarge	General purpose	No	64	256	4 x 600 NVMe SSD
ml.m5d.24xlarge	General purpose	No	96	384	4 x 900 NVMe SSD
ml.c5.large	Compute optimized	Yes	2	4	Amazon EBS Only
ml.c5.xlarge	Compute optimized	No	4	8	Amazon EBS Only
ml.c5.2xlarge	Compute optimized	No	8	16	Amazon EBS Only
ml.c5.4xlarge	Compute optimized	No	16	32	Amazon EBS Only

Instance	Use case	Fast launch	vCPU	Memory (GiB)	Instance Storage (GB)
ml.c5.9xlarge	Compute optimized	No	36	72	Amazon EBS Only
ml.c5.12xlarge	Compute optimized	No	48	96	Amazon EBS Only
ml.c5.18xlarge	Compute optimized	No	72	144	Amazon EBS Only
ml.c5.24xlarge	Compute optimized	No	96	192	Amazon EBS Only
ml.r5.large	Memory optimized	No	2	16	Amazon EBS Only
ml.r5.xlarge	Memory optimized	No	4	32	Amazon EBS Only
ml.r5.2xlarge	Memory optimized	No	8	64	Amazon EBS Only
ml.r5.4xlarge	Memory optimized	No	16	128	Amazon EBS Only
ml.r5.8xlarge	Memory optimized	No	32	256	Amazon EBS Only

Instance	Use case	Fast launch	vCPU	Memory (GiB)	Instance Storage (GB)
ml.r5.12xlarge	Memory optimized	No	48	384	Amazon EBS Only
ml.r5.16xlarge	Memory optimized	No	64	512	Amazon EBS Only
ml.r5.24xlarge	Memory optimized	No	96	768	Amazon EBS Only

### Instances with 1 or more GPUs

The following table lists the Amazon EC2 instance types with 1 or more GPUs attached that are available for use with Studio Classic notebooks. It also lists information about the specifications of each instance type. The default instance type for GPU-based images is `ml.g4dn.xlarge`.

For detailed information on which instance types fit your use case, and their performance capabilities, see [Amazon Elastic Compute Cloud Instance types](#). For information about pricing for these instance types, see [Amazon EC2 Pricing](#).

### Instances with 1 or more GPUs

Instance	Use case	Fast launch	GPUs	vCPU	Memor (GiB)	GPU Memor (GiB)	Instance Storage (GB)
ml.p3.2xlarge	Accelerated computing	No	1	8	61	16	Amazon EBS Only

Instance	Use case	Fast launch	GPUs	vCPU	Memor (GiB)	GPU Memor (GiB)	Instance Storage (GB)
ml.p3.8xlarge	Accelerated computing	No	4	32	244	64	Amazon EBS Only
ml.p3.16xlarge	Accelerated computing	No	8	64	488	128	Amazon EBS Only
ml.p3dn.24xlarge	Accelerated computing	No	8	96	768	256	2 x 900 NVMe SSD
ml.p4d.24xlarge	Accelerated computing	No	8	96	1152	320 GB HBM2	8 x 1000 NVMe SSD

## Amazon SageMaker images available for use with Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

This page lists the SageMaker images and associated kernels that are available in Amazon SageMaker Studio Classic. This page also gives information about the format needed to create the ARN for each image. SageMaker images contain the latest [Amazon SageMaker Python SDK](#) and the latest version of the kernel. For more information, see [Deep Learning Containers Images](#).

## Topics

- [Image ARN format](#)
- [Supported URI tags](#)
- [Supported images](#)
- [Images slated for deprecation](#)
- [Deprecated images](#)

## Image ARN format

The following table lists the image ARN and URI format for each Region. To create the full ARN for an image, replace the *resource-identifier* placeholder with the corresponding resource identifier for the image. The resource identifier is found in the SageMaker images and kernels table. To create the full URI for an image, replace the *tag* placeholder with the corresponding cpu or gpu tag. For the list of tags you can use, see [Supported URI tags](#).

### Note

SageMaker Distribution images use a distinct set of image ARNs, which are listed in the following table.

Region	Image ARN Format	SageMaker Distribution Image ARN Format	SageMaker Distribution Image URI Format
us-east-1	arn:aws:sagemaker:us-east-1:081325390199:image/ <i>resource-identifier</i>	arn:aws:sagemaker:us-east-1:885854791233:image/ <i>resource-identifier</i>	885854791233.dkr.ecr.us-east-1.amazonaws.com/sagemaker-distribution-prod: <i>tag</i>

## Supported URI tags

The following list shows the tags you can include in your image URI.

- 1-cpu
- 1-gpu
- 0-cpu
- 0-gpu

The following examples show URIs with various tag formats:

- 542918446943.dkr.ecr.us-west-2.amazonaws.com/sagemaker-distribution-prod:1-cpu
- 542918446943.dkr.ecr.us-west-2.amazonaws.com/sagemaker-distribution-prod:0-gpu

## Supported images

The following table gives information about the SageMaker images and associated kernels that are available in Amazon SageMaker Studio Classic. It also gives information about the resource identifier and Python version included in the image.

### SageMaker images and kernels

SageMaker Image	Description	Resource Identifier	Kernels (and Identifier)	Python Version
SageMaker Distribution v1 CPU	SageMaker Distribution v1 CPU is a Python 3.10 image that includes popular frameworks for machine learning, data science and data analytics on CPU. This includes deep learning frameworks like PyTorch, TensorFlow and Keras; popular Python packages like numpy, scikit-learn and pandas; and IDEs like Jupyter Lab. For more information, see the <a href="#">Amazon SageMaker Distribution</a> repo.	sagemaker-distribution-cpu-v1	Python 3 (python3)	Python 3.10
SageMaker Distribution v1 GPU	SageMaker Distribution v1 GPU is a Python 3.10 image that includes popular frameworks for	sagemaker-distribution-gpu-v1	Python 3 (python3)	Python 3.10

### Images slated for deprecation

SageMaker AI ends support for images the day after any of the packages in the image reach end-of-life by their publisher. The following SageMaker images are slated for deprecation.

Images based on Python 3.8 reached [end-of-life](#) on October 31st, 2024. Starting on November 1, 2024, SageMaker AI will discontinue support for these images and they will not be selectable from the Studio Classic UI. To avoid non-compliance issues, if you're using any of these images, we recommend that you move to an image with a later version.

### SageMaker images slated for deprecation

SageMaker Image	Deprecation date	Description	Resource Identifier	Kernels	Python Version
SageMaker Distribution v0.12 CPU	November 1, 2024	SageMaker Distribution v0 CPU is a Python 3.8 image that includes popular frameworks for machine learning, data science and visualization on CPU. This includes deep learning frameworks like PyTorch, TensorFlow and Keras; popular Python packages like numpy, scikit-learn and pandas; and IDEs like Jupyter Lab. For more information, see the <a href="#">Amazon</a>	sagemaker-distribution-cpu-v0	Python 3 (python3)	Python 3.8

SageMaker Image	Deprecation date	Description	Resource Identifier	Kernels	Python Version

## Customize Amazon SageMaker Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

There are four options for customizing your Amazon SageMaker Studio Classic environment. You bring your own SageMaker image, use a lifecycle configuration script, attach suggested Git repos to Studio Classic, or create kernels using persistent Conda environments in Amazon EFS. Use each option individually, or together.

- **Bring your own SageMaker image:** A SageMaker image is a file that identifies the kernels, language packages, and other dependencies required to run a Jupyter notebook in Amazon SageMaker Studio Classic. Amazon SageMaker AI provides many built-in images for you to use. If you need different functionality, you can bring your own custom images to Studio Classic.
- **Use lifecycle configurations with Amazon SageMaker Studio Classic:** Lifecycle configurations are shell scripts triggered by Amazon SageMaker Studio Classic lifecycle events, such as starting a new Studio Classic notebook. You can use lifecycle configurations to automate customization for your Studio Classic environment. For example, you can install custom packages, configure notebook extensions, preload datasets, and set up source code repositories.
- **Attach suggested Git repos to Studio Classic:** You can attach suggested Git repository URLs at the Amazon SageMaker AI domain or user profile level. Then, you can select the repo URL from the list of suggestions and clone that into your environment using the Git extension in Studio Classic.
- **Persist Conda environments to the Studio Classic Amazon EFS volume:** Studio Classic uses an Amazon EFS volume as a persistent storage layer. You can save your Conda environment on this Amazon EFS volume, then use the saved environment to create kernels. Studio Classic automatically picks up all valid environments saved in Amazon EFS as KernelGateway kernels. These kernels persist through restart of the kernel, app, and Studio Classic. For more information, see the **Persist Conda environments to the Studio Classic EFS volume** section in [Four approaches to manage Python packages in Amazon SageMaker Studio Classic notebooks](#).

The following topics show how to use these three options to customize your Amazon SageMaker Studio Classic environment.

## Topics

- [Bring your own SageMaker image](#)
- [Use lifecycle configurations to customize Studio Classic](#)
- [Attach Suggested Git Repos to Studio Classic](#)

## Bring your own SageMaker image

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the

Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

A SageMaker image is a file that identifies the kernels, language packages, and other dependencies required to run a Jupyter notebook in Amazon SageMaker Studio Classic. These images are used to create an environment that you then run Jupyter notebooks from. Amazon SageMaker AI provides many built-in images for you to use. For the list of built-in images, see [Amazon SageMaker images available for use with Studio Classic](#).

If you need different functionality, you can bring your own custom images to Studio Classic. You can create images and image versions, and attach image versions to your domain or shared space, using the SageMaker AI control panel, the [AWS SDK for Python \(Boto3\)](#), and the [AWS Command Line Interface \(AWS CLI\)](#). You can also create images and image versions using the SageMaker AI console, even if you haven't onboarded to a SageMaker AI domain. SageMaker AI provides sample Dockerfiles to use as a starting point for your custom SageMaker images in the [SageMaker Studio Classic Custom Image Samples](#) repository.

The following topics explain how to bring your own image using the SageMaker AI console or AWS CLI, then launch the image in Studio Classic. For a similar blog article, see [Bringing your own R environment to Amazon SageMaker Studio Classic](#). For notebooks that show how to bring your own image for use in training and inference, see [Amazon SageMaker Studio Classic Container Build CLI](#).

## Key terminology

The following section defines key terms for bringing your own image to use with Studio Classic.

- **Dockerfile:** A Dockerfile is a file that identifies the language packages and other dependencies for your Docker image.
- **Docker image:** The Docker image is a built Dockerfile. This image is checked into Amazon ECR and serves as the basis of the SageMaker AI image.
- **SageMaker image:** A SageMaker image is a holder for a set of SageMaker AI image versions based on Docker images. Each image version is immutable.
- **Image version:** An image version of a SageMaker image represents a Docker image and is stored in an Amazon ECR repository. Each image version is immutable. These image versions can be attached to a domain or shared space and used with Studio Classic.

## Topics

- [Custom SageMaker image specifications](#)
- [Prerequisites](#)
- [Add a Docker image compatible with Studio Classic to Amazon ECR](#)
- [Create a custom SageMaker image](#)
- [Attach a custom SageMaker image](#)
- [Launch a custom SageMaker image in Amazon SageMaker Studio Classic](#)
- [Clean up resources](#)

## Custom SageMaker image specifications

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following specifications apply to the container image that is represented by a SageMaker AI image version.

### Running the image

ENTRYPOINT and CMD instructions are overridden to enable the image to run as a KernelGateway app.

Port 8888 in the image is reserved for running the KernelGateway web server.

### Stopping the image

The DeleteApp API issues the equivalent of a `docker stop` command. Other processes in the container won't get the SIGKILL/SIGTERM signals.

### Kernel discovery

SageMaker AI recognizes kernels as defined by Jupyter [kernel specs](#).

You can specify a list of kernels to display before running the image. If not specified, python3 is displayed. Use the [DescribeAppImageConfig](#) API to view the list of kernels.

Conda environments are recognized as kernel specs by default.

## File system

The `/opt/.sagemakerinternal` and `/opt/ml` directories are reserved. Any data in these directories might not be visible at runtime.

## User data

Each user in a domain gets a user directory on a shared Amazon Elastic File System volume in the image. The location of the current user's directory on the Amazon EFS volume is configurable. By default, the location of the directory is `/home/sagemaker-user`.

SageMaker AI configures POSIX UID/GID mappings between the image and the host. This defaults to mapping the root user's UID/GID (0/0) to the UID/GID on the host.

You can specify these values using the [CreateAppImageConfig](#) API.

## GID/UID limits

Amazon SageMaker Studio Classic only supports the following `DefaultUID` and `DefaultGID` combinations:

- `DefaultUID: 1000` and `DefaultGID: 100`, which corresponds to a non-privileged user.
- `DefaultUID: 0` and `DefaultGID: 0`, which corresponds to root access.

## Metadata

A metadata file is located at `/opt/ml/metadata/resource-metadata.json`. No additional environment variables are added to the variables defined in the image. For more information, see [Get App Metadata](#).

## GPU

On a GPU instance, the image is run with the `--gpus` option. Only the CUDA toolkit should be included in the image not the NVIDIA drivers. For more information, see [NVIDIA User Guide](#).

## Metrics and logging

Logs from the `KernelGateway` process are sent to Amazon CloudWatch in the customer's account. The name of the log group is `/aws/sagemaker/studio`. The name of the log stream is `$domainID/$UserProfileName/KernelGateway/$appName`.

## Image size

Limited to 35 GB. To view the size of your image, run `docker image ls`.

## Sample Dockerfile

The following sample Dockerfile creates an image based Amazon Linux 2, installs third party packages and the python3 kernel, and sets the scope to the non-privileged user.

```
FROM public.ecr.aws/amazonlinux/amazonlinux:2

ARG NB_USER="sagemaker-user"
ARG NB_UID="1000"
ARG NB_GID="100"

RUN \
    yum install --assumeyes python3 shadow-utils && \
    useradd --create-home --shell /bin/bash --gid "${NB_GID}" --uid ${NB_UID} \
    ${NB_USER} && \
    yum clean all && \
    python3 -m pip install ipykernel && \
    python3 -m ipykernel install

USER ${NB_UID}
```

## Prerequisites

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

You must satisfy the following prerequisites to bring your own container for use with Amazon SageMaker Studio Classic.

- The Docker application. For information about setting up Docker, see [Orientation and setup](#).
- Install the AWS CLI by following the steps in [Getting started with the AWS CLI](#).
- A local copy of any Dockerfile for creating a Studio Classic compatible image. For sample custom images, see the [SageMaker AI Studio Classic custom image samples](#) repository.
- Permissions to access the Amazon Elastic Container Registry (Amazon ECR) service. For more information, see [Amazon ECR Managed Policies](#).

- An AWS Identity and Access Management execution role that has the [AmazonSageMakerFullAccess](#) policy attached. If you have onboarded to Amazon SageMaker AI domain, you can get the role from the **Domain Summary** section of the SageMaker AI control panel.
- Install the Studio Classic image build CLI by following the steps in [SageMaker Docker Build](#). This CLI enables you to build a Dockerfile using AWS CodeBuild.

## Add a Docker image compatible with Studio Classic to Amazon ECR

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

You perform the following steps to add a container image to Amazon ECR:

- Create an Amazon ECR repository.
- Authenticate to Amazon ECR.
- Build a Docker image compatible with Studio Classic.
- Push the image to the Amazon ECR repository.

### Note

The Amazon ECR repository must be in the same AWS Region as Studio Classic.

## To build and add a container image to Amazon ECR

1. Create an Amazon ECR repository using the AWS CLI. To create the repository using the Amazon ECR console, see [Creating a repository](#).

```
aws ecr create-repository \  
  --repository-name smstudio-custom \  
  --image-tag   
  --image-uri   
  --image-uri   
  --image-uri
```

```
--image-scanning-configuration scanOnPush=true
```

The response should look similar to the following.

```
{
  "repository": {
    "repositoryArn": "arn:aws:ecr:us-east-2:acct-id:repository/smstudio-
custom",
    "registryId": "acct-id",
    "repositoryName": "smstudio-custom",
    "repositoryUri": "acct-id.dkr.ecr.us-east-2.amazonaws.com/smstudio-custom",
    ...
  }
}
```

2. Build the Dockerfile using the Studio Classic image build CLI. The period (.) specifies that the Dockerfile should be in the context of the build command. This command builds the image and uploads the built image to the ECR repo. It then outputs the image URI.

```
sm-docker build . --repository smstudio-custom:custom
```

The response should look similar to the following.

```
Image URI: <acct-id>.dkr.ecr.<region>.amazonaws.com/<image_name>
```

## Create a custom SageMaker image

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

This topic describes how you can create a custom SageMaker image using the SageMaker AI console or AWS CLI.

When you create an image from the console, SageMaker AI also creates an initial image version. The image version represents a container image in [Amazon Elastic Container Registry \(ECR\)](#). The container image must satisfy the requirements to be used in Amazon SageMaker Studio Classic. For more information, see [Custom SageMaker image specifications](#). For information on testing your image locally and resolving common issues, see the [SageMaker Studio Classic Custom Image Samples repo](#).

After you have created your custom SageMaker image, you must attach it to your domain or shared space to use it with Studio Classic. For more information, see [Attach a custom SageMaker image](#).

## Create a SageMaker image from the console

The following section demonstrates how to create a custom SageMaker image from the SageMaker AI console.

### To create an image

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Images**.
4. On the **Custom images** page, choose **Create image**.

5. For **Image source**, enter the registry path to the container image in Amazon ECR. The path is in the following format:

*acct-id.dkr.ecr.region.amazonaws.com/repo-name[:tag] or [@digest]*

6. Choose **Next**.

7. Under **Image properties**, enter the following:

- Image name – The name must be unique to your account in the current AWS Region.
- (Optional) Display name – The name displayed in the Studio Classic user interface. When not provided, Image name is displayed.
- (Optional) Description – A description of the image.
- IAM role – The role must have the [AmazonSageMakerFullAccess](#) policy attached. Use the dropdown menu to choose one of the following options:
  - Create a new role – Specify any additional Amazon Simple Storage Service (Amazon S3) buckets that you want users of your notebooks to have access to. If you don't want to allow access to additional buckets, choose **None**.

SageMaker AI attaches the `AmazonSageMakerFullAccess` policy to the role. The role allows users of your notebooks access to the S3 buckets listed next to the checkmarks.

- Enter a custom IAM role ARN – Enter the Amazon Resource Name (ARN) of your IAM role.
  - Use existing role – Choose one of your existing roles from the list.
  - (Optional) Image tags – Choose **Add new tag**. You can add up to 50 tags. Tags are searchable using the Studio Classic user interface, the SageMaker AI console, or the SageMaker AI Search API.
8. Choose **Submit**.

The new image is displayed in the **Custom images** list and briefly highlighted. After the image has been successfully created, you can choose the image name to view its properties or choose **Create version** to create another version.

### To create another image version

1. Choose **Create version** on the same row as the image.
2. For **Image source**, enter the registry path to the Amazon ECR container image. The container image shouldn't be the same image as used in a previous version of the SageMaker image.

## Create a SageMaker image from the AWS CLI

You perform the following steps to create a SageMaker image from the container image using the AWS CLI.

- Create an Image.
- Create an ImageVersion.
- Create a configuration file.
- Create an AppImageConfig.

### To create the SageMaker image entities

1. Create a SageMaker image.

```
aws sagemaker create-image \  
  --image-name custom-image \  
  --role-arn arn:aws:iam::<acct-id>:role/service-role/<execution-role>
```

The response should look similar to the following.

```
{  
  "ImageArn": "arn:aws:sagemaker:us-east-2:acct-id:image/custom-image"  
}
```

2. Create a SageMaker image version from the container image.

```
aws sagemaker create-image-version \  
  --image-name custom-image \  
  --base-image <acct-id>.dkr.ecr.<region>.amazonaws.com/sfstudio-custom:custom-  
image
```

The response should look similar to the following.

```
{  
  "ImageVersionArn": "arn:aws:sagemaker:us-east-2:acct-id:image-version/custom-  
image/1"  
}
```

3. Check that the image version was successfully created.

```
aws sagemaker describe-image-version \  
  --image-name custom-image \  
  --version-number 1
```

The response should look similar to the following.

```
{  
  "ImageVersionArn": "arn:aws:sagemaker:us-east-2:acct-id:image-version/custom-  
image/1",  
  "ImageVersionStatus": "CREATED"  
}
```

#### Note

If the response is "ImageVersionStatus": "CREATED\_FAILED", the response also includes the failure reason. A permissions issue is a common cause of failure. You also can check your Amazon CloudWatch logs if you experience a failure when starting or running the KernelGateway app for a custom image. The name of the log group is `/aws/sagemaker/studio`. The name of the log stream is `$domainID/$userProfileName/KernelGateway/$appName`.

4. Create a configuration file, named `app-image-config-input.json`. The `Name` value of `KernelSpecs` must match the name of the `kernelSpec` available in the `Image` associated with this `AppImageConfig`. This value is case sensitive. You can find the available `kernelSpecs` in an image by running `jupyter-kernel-spec list` from a shell inside the container. `MountPath` is the path within the image to mount your Amazon Elastic File System (Amazon EFS) home directory. It needs to be different from the path you use inside the container because that path will be overridden when your Amazon EFS home directory is mounted.

#### Note

The following `DefaultUID` and `DefaultGID` combinations are the only accepted values:

- `DefaultUID: 1000` and `DefaultGID: 100`
- `DefaultUID: 0` and `DefaultGID: 0`

```
{
  "AppImageConfigName": "custom-image-config",
  "KernelGatewayImageConfig": {
    "KernelSpecs": [
      {
        "Name": "python3",
        "DisplayName": "Python 3 (ipykernel)"
      }
    ],
    "FileSystemConfig": {
      "MountPath": "/home/sagemaker-user",
      "DefaultUid": 1000,
      "DefaultGid": 100
    }
  }
}
```

5. Create the AppImageConfig using the file created in the previous step.

```
aws sagemaker create-app-image-config \
  --cli-input-json file://app-image-config-input.json
```

The response should look similar to the following.

```
{
  "AppImageConfigArn": "arn:aws:sagemaker:us-east-2:acct-id:app-image-config/
  custom-image-config"
}
```

## Attach a custom SageMaker image

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can

occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

To use a custom SageMaker image, you must attach a version of the image to your domain or shared space. When you attach an image version, it appears in the SageMaker Studio Classic Launcher and is available in the **Select image** dropdown list, which users use to launch an activity or change the image used by a notebook.

To make a custom SageMaker image available to all users within a domain, you attach the image to the domain. To make an image available to all users within a shared space, you can attach the image to the shared space. To make an image available to a single user, you attach the image to the user's profile. When you attach an image, SageMaker AI uses the latest image version by default. You can also attach a specific image version. After you attach the version, you can choose the version from the SageMaker AI Launcher or the image selector when you launch a notebook.

There is a limit to the number of image versions that can be attached at any given time. After you reach the limit, you must detach a version in order to attach another version of the image.

The following sections demonstrate how to attach a custom SageMaker image to your domain using either the SageMaker AI console or the AWS CLI. You can only attach a custom image to a share space using the AWS CLI.

## Attach the SageMaker image to a domain

### Attach the SageMaker image using the Console

This topic describes how you can attach an existing custom SageMaker image version to your domain using the SageMaker AI control panel. You can also create a custom SageMaker image and image version, and then attach that version to your domain. For the procedure to create an image and image version, see [Create a custom SageMaker image](#).

#### To attach an existing image

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the **Domains** page, select the domain to attach the image to.
5. From the **Domain details** page, select the **Environment** tab.
6. On the **Environment** tab, under **Custom SageMaker Studio Classic images attached to domain**, choose **Attach image**.
7. For **Image source**, choose **Existing image**.
8. Choose an existing image from the list.
9. Choose a version of the image from the list.
10. Choose **Next**.
11. Verify the values for **Image name**, **Image display name**, and **Description**.
12. Choose the IAM role. For more information, see [Create a custom SageMaker image](#).
13. (Optional) Add tags for the image.
14. Specify the EFS mount path. This is the path within the image to mount the user's Amazon Elastic File System (EFS) home directory.
15. For **Image type**, select **SageMaker Studio image**
16. For **Kernel name**, enter the name of an existing kernel in the image. For information on how to get the kernel information from the image, see [DEVELOPMENT](#) in the SageMaker Studio Classic Custom Image Samples repository. For more information, see the **Kernel discovery** and **User data** sections of [Custom SageMaker image specifications](#).
17. (Optional) For **Kernel display name**, enter the display name for the kernel.
18. Choose **Add kernel**.

## 19. Choose **Submit**.

- Wait for the image version to be attached to the domain. When attached, the version is displayed in the **Custom images** list and briefly highlighted.

### Attach the SageMaker image using the AWS CLI

The following sections demonstrate how to attach a custom SageMaker image when creating a new domain or updating your existing domain using the AWS CLI.

#### Attach the SageMaker image to a new domain

The following section demonstrates how to create a new domain with the version attached. These steps require that you specify the Amazon Virtual Private Cloud (VPC) information and execution role required to create the domain. You perform the following steps to create the domain and attach the custom SageMaker image:

- Get your default VPC ID and subnet IDs.
- Create the configuration file for the domain, which specifies the image.
- Create the domain with the configuration file.

#### To add the custom SageMaker image to your domain

1. Get your default VPC ID.

```
aws ec2 describe-vpcs \  
  --filters Name=isDefault,Values=true \  
  --query "Vpcs[0].VpcId" --output text
```

The response should look similar to the following.

```
vpc-xxxxxxxx
```

2. Get your default subnet IDs using the VPC ID from the previous step.

```
aws ec2 describe-subnets \  
  --filters Name=vpc-id,Values=<vpc-id> \  
  --query "Subnets[*].SubnetId" --output json
```

The response should look similar to the following.

```
[
  "subnet-b55171dd",
  "subnet-8a5f99c6",
  "subnet-e88d1392"
]
```

3. Create a configuration file named `create-domain-input.json`. Insert the VPC ID, subnet IDs, `ImageName`, and `AppImageConfigName` from the previous steps. Because `ImageVersionNumber` isn't specified, the latest version of the image is used, which is the only version in this case.

```
{
  "DomainName": "domain-with-custom-image",
  "VpcId": "<vpc-id>",
  "SubnetIds": [
    "<subnet-ids>"
  ],
  "DefaultUserSettings": {
    "ExecutionRole": "<execution-role>",
    "KernelGatewayAppSettings": {
      "CustomImages": [
        {
          "ImageName": "custom-image",
          "AppImageConfigName": "custom-image-config"
        }
      ]
    }
  },
  "AuthMode": "IAM"
}
```

4. Create the domain with the attached custom SageMaker image.

```
aws sagemaker create-domain \
  --cli-input-json file://create-domain-input.json
```

The response should look similar to the following.

```
{
```

```
"DomainArn": "arn:aws:sagemaker:us-east-2:acct-id:domain/d-xxxxxxxxxxxxx",  
"Url": "https://d-xxxxxxxxxxxxx.studio.us-east-2.sagemaker.aws/..."  
}
```

## Attach the SageMaker image to your current domain

If you have onboarded to a SageMaker AI domain, you can attach the custom image to your current domain. For more information about onboarding to a SageMaker AI domain, see [Amazon SageMaker AI domain overview](#). You don't need to specify the VPC information and execution role when attaching a custom image to your current domain. After you attach the version, you must delete all the apps in your domain and reopen Studio Classic. For information about deleting the apps, see [Delete an Amazon SageMaker AI domain](#).

You perform the following steps to add the SageMaker image to your current domain.

- Get your DomainID from SageMaker AI control panel.
- Use the DomainID to get the DefaultUserSettings for the domain.
- Add the ImageName and AppImageConfig as a CustomImage to the DefaultUserSettings.
- Update your domain to include the custom image.

## To add the custom SageMaker image to your domain

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the **Domains** page, select the domain to attach the image to.
5. From the **Domain details** page, select the **Domain settings** tab.
6. From the **Domain settings** tab, under **General settings**, find the DomainId. The ID is in the following format: d-xxxxxxxxxxxxx.
7. Use the domain ID to get the description of the domain.

```
aws sagemaker describe-domain \  
  --domain-id <d-xxxxxxxxxxxxx>
```

The response should look similar to the following.

```
{
  "DomainId": "d-xxxxxxxxxxxx",
  "DefaultUserSettings": {
    "KernelGatewayAppSettings": {
      "CustomImages": [
        ],
        ...
      }
    }
  }
}
```

8. Save the default user settings section of the response to a file named `default-user-settings.json`.
9. Insert the `ImageName` and `AppImageConfigName` from the previous steps as a custom image. Because `ImageVersionNumber` isn't specified, the latest version of the image is used, which is the only version in this case.

```
{
  "DefaultUserSettings": {
    "KernelGatewayAppSettings": {
      "CustomImages": [
        {
          "ImageName": "string",
          "AppImageConfigName": "string"
        }
      ],
      ...
    }
  }
}
```

10. Use the domain ID and default user settings file to update your domain.

```
aws sagemaker update-domain \
  --domain-id <d-xxxxxxxxxxxx> \
  --cli-input-json file://default-user-settings.json
```

The response should look similar to the following.

```
{
```

```
"DomainArn": "arn:aws:sagemaker:us-east-2:acct-id:domain/d-xxxxxxxxxxxxx"
}
```

## Attach the SageMaker image to a shared space

You can only attach the SageMaker image to a shared space using the AWS CLI. After you attach the version, you must delete all of the applications in your shared space and reopen Studio Classic. For information about deleting the apps, see [Delete an Amazon SageMaker AI domain](#).

You perform the following steps to add the SageMaker image to a shared space.

- Get your DomainID from SageMaker AI control panel.
- Use the DomainID to get the DefaultSpaceSettings for the domain.
- Add the ImageName and AppImageConfig as a CustomImage to the DefaultSpaceSettings.
- Update your domain to include the custom image for the shared space.

## To add the custom SageMaker image to your shared space

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the **Domains** page, select the domain to attach the image to.
5. From the **Domain details** page, select the **Domain settings** tab.
6. From the **Domain settings** tab, under **General settings**, find the DomainId. The ID is in the following format: d-xxxxxxxxxxxxx.
7. Use the domain ID to get the description of the domain.

```
aws sagemaker describe-domain \  
  --domain-id <d-xxxxxxxxxxxxx>
```

The response should look similar to the following.

```
{  
  "DomainId": "d-xxxxxxxxxxxxx",  
  ...  
}
```

```

    "DefaultSpaceSettings": {
      "KernelGatewayAppSettings": {
        "CustomImages": [
          ],
          ...
        ]
      }
    }
  }
}

```

8. Save the default space settings section of the response to a file named `default-space-settings.json`.
9. Insert the `ImageName` and `AppImageConfigName` from the previous steps as a custom image. Because `ImageVersionNumber` isn't specified, the latest version of the image is used, which is the only version in this case.

```

{
  "DefaultSpaceSettings": {
    "KernelGatewayAppSettings": {
      "CustomImages": [
        {
          "ImageName": "string",
          "AppImageConfigName": "string"
        }
      ],
      ...
    }
  }
}

```

10. Use the domain ID and default space settings file to update your domain.

```

aws sagemaker update-domain \
  --domain-id <d-xxxxxxxxxxxx> \
  --cli-input-json file://default-space-settings.json

```

The response should look similar to the following.

```

{
  "DomainArn": "arn:aws:sagemaker:us-east-2:acct-id:domain/d-xxxxxxxxxxxx"
}

```

## View the attached image in SageMaker AI

After you create the custom SageMaker image and attach it to your domain, the image appears in the **Environment** tab of the domain. You can only view the attached images for shared spaces using the AWS CLI by using the following command.

```
aws sagemaker describe-domain \  
  --domain-id <d-xxxxxxxxxxxx>
```

## Launch a custom SageMaker image in Amazon SageMaker Studio Classic

### Important

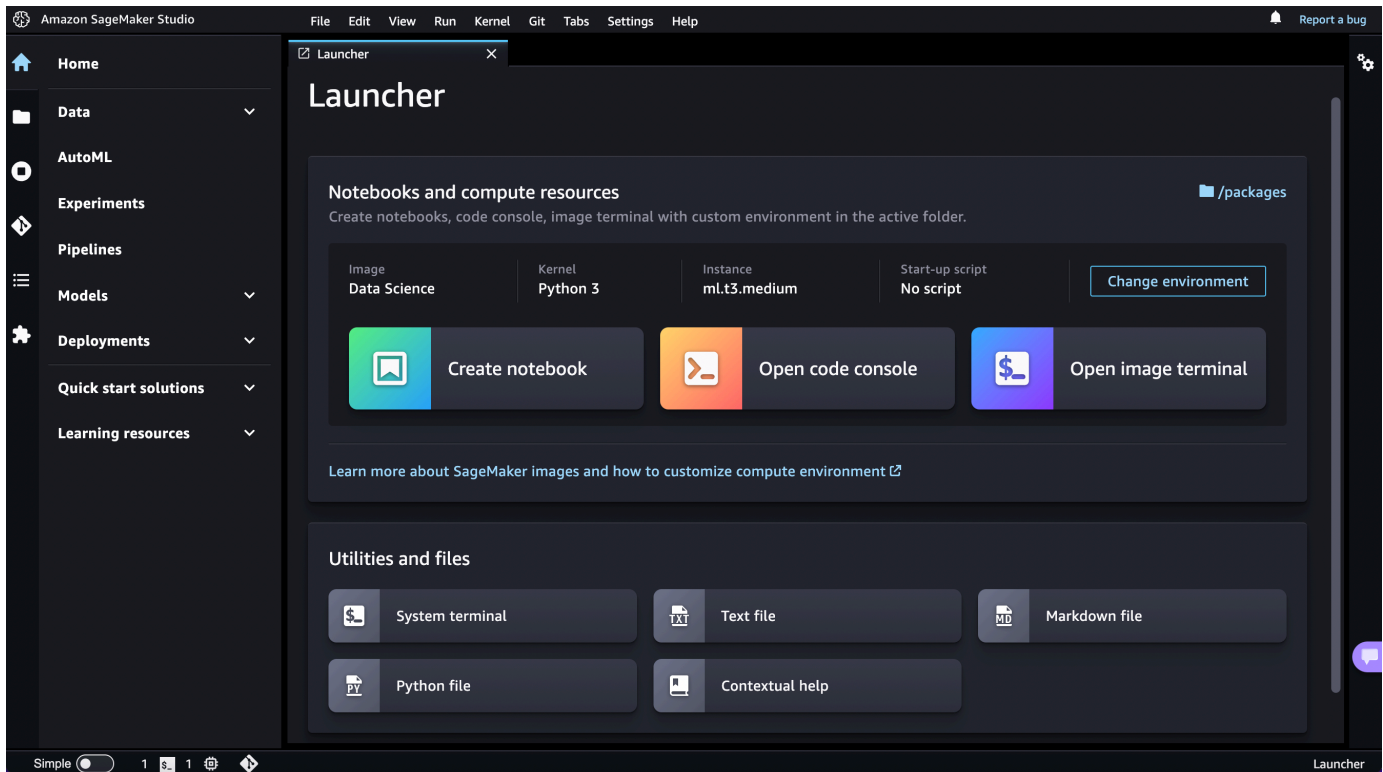

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

After you create your custom SageMaker image and attach it to your domain or shared space, the custom image and kernel appear in selectors in the **Change environment** dialog box of the Studio Classic Launcher.

### To launch and select your custom image and kernel

1. In Amazon SageMaker Studio Classic, open the Launcher. To open the Launcher, choose **Amazon SageMaker Studio Classic** at the top left of the Studio Classic interface or use the keyboard shortcut `Ctrl + Shift + L`.

To learn about all the available ways to open the Launcher, see [Use the Amazon SageMaker Studio Classic Launcher](#)

2. In the Launcher, in the **Notebooks and compute resources** section, choose **Change environment**.
3. In the **Change environment** dialog, use the dropdown menus to select your **Image** from the **Custom Image** section, and your **Kernel**, then choose **Select**.
4. In the Launcher, choose **Create notebook** or **Open image terminal**. Your notebook or terminal launches in the selected custom image and kernel.

To change your image or kernel in an open notebook, see [Change an Image or a Kernel](#).

### **Note**

If you encounter an error when launching the image, check your Amazon CloudWatch logs. The name of the log group is `/aws/sagemaker/studio`. The name of the log stream is `$domainID/$userProfileName/KernelGateway/$appName`.

## Clean up resources

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following sections show how to clean up the resources you created in the previous sections from the SageMaker AI console or AWS CLI. You perform the following steps to clean up the resources:

- Detach the image and image versions from your domain.
- Delete the image, image version, and app image config.
- Delete the container image and repository from Amazon ECR. For more information, see [Deleting a repository](#).

### Clean up resources from the SageMaker AI console

The following section shows how to clean up resources from the SageMaker AI console.

When you detach an image from a domain, all versions of the image are detached. When an image is detached, all users of the domain lose access to the image versions. A running notebook that has a kernel session on an image version when the version is detached, continues to run. When the notebook is stopped or the kernel is shut down, the image version becomes unavailable.

#### To detach an image

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Images**.
4. Under **Custom SageMaker Studio Classic images attached to domain**, choose the image and then choose **Detach**.
5. (Optional) To delete the image and all versions from SageMaker AI, select **Also delete the selected images ...**. This does not delete the associated container images from Amazon ECR.

## 6. Choose **Detach**.

### Clean up resources from the AWS CLI

The following section shows how to clean up resources from the AWS CLI.

#### To clean up resources

1. Detach the image and image versions from your domain by passing an empty custom image list to the domain. Open the `default-user-settings.json` file you created in [Attach the SageMaker image to your current domain](#). To detach the image and image version from a shared space, open the `default-space-settings.json` file.
2. Delete the custom images and then save the file.

```
"DefaultUserSettings": {
  "KernelGatewayAppSettings": {
    "CustomImages": [
      ],
      ...
    },
    ...
  }
}
```

3. Use the domain ID and default user settings file to update your domain. To update your shared space, use the default space settings file.

```
aws sagemaker update-domain \
  --domain-id <d-xxxxxxxxxxxx> \
  --cli-input-json file://default-user-settings.json
```

The response should look similar to the following.

```
{
  "DomainArn": "arn:aws:sagemaker:us-east-2:acct-id:domain/d-xxxxxxxxxxxx"
}
```

4. Delete the app image config.

```
aws sagemaker delete-app-image-config \
  --app-image-config-name custom-image-config
```

5. Delete the SageMaker image, which also deletes all image versions. The container images in ECR that are represented by the image versions are not deleted.

```
aws sagemaker delete-image \  
  --image-name custom-image
```

## Use lifecycle configurations to customize Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Amazon SageMaker Studio Classic triggers lifecycle configurations shell scripts during important lifecycle events, such as starting a new Studio Classic notebook. You can use lifecycle configurations to automate customization for your Studio Classic environment. This customization includes installing custom packages, configuring notebook extensions, preloading datasets, and setting up source code repositories.

Using lifecycle configurations gives you flexibility and control to configure Studio Classic to meet your specific needs. For example, you can use customized container images with lifecycle configuration scripts to modify your environment. First, create a minimal set of base container images, then install the most commonly used packages and libraries in those images. After you have completed your images, use lifecycle configurations to install additional packages for specific use cases. This gives you the flexibility to modify your environment across your data science and machine learning teams based on need.

Users can only select lifecycle configuration scripts that they are given access to. While you can give access to multiple lifecycle configuration scripts, you can also set default lifecycle configuration scripts for resources. Based on the resource that the default lifecycle configuration is set for, the default either runs automatically or is the first option shown.

For example lifecycle configuration scripts, see the [Studio Classic Lifecycle Configuration examples GitHub repository](#). For a blog on implementing lifecycle configuration, see [Customize Amazon SageMaker Studio Classic using Lifecycle Configurations](#).

**Note**

Each script has a limit of **16384 characters**.

**Topics**

- [Create and associate a lifecycle configuration](#)
- [Set default lifecycle configurations](#)
- [Debug lifecycle configurations](#)
- [Update and detach lifecycle configurations](#)

**Create and associate a lifecycle configuration****⚠ Important**

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Amazon SageMaker AI provides interactive applications that enable Studio Classic's visual interface, code authoring, and run experience. This series shows how to create a lifecycle configuration and associate it with a SageMaker AI domain.

Application types can be either `JupyterServer` or `KernelGateway`.

- **JupyterServer applications:** This application type enables access to the visual interface for Studio Classic. Every user and shared space in Studio Classic gets its own JupyterServer application.
- **KernelGateway applications:** This application type enables access to the code run environment and kernels for your Studio Classic notebooks and terminals. For more information, see [Jupyter Kernel Gateway](#).

For more information about Studio Classic's architecture and Studio Classic applications, see [Use Amazon SageMaker Studio Classic Notebooks](#).

## Topics

- [Create a lifecycle configuration from the AWS CLI](#)
- [Create a lifecycle configuration from the SageMaker AI console](#)

## Create a lifecycle configuration from the AWS CLI

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following topic shows how to create a lifecycle configuration using the AWS CLI to automate customization for your Studio Classic environment.

## Prerequisites

Before you begin, complete the following prerequisites:

- Update the AWS CLI by following the steps in [Installing the current AWS CLI Version](#).
- From your local machine, run `aws configure` and provide your AWS credentials. For information about AWS credentials, see [Understanding and getting your AWS credentials](#).

- Onboard to SageMaker AI domain by following the steps in [Amazon SageMaker AI domain overview](#).

## Step 1: Create a lifecycle configuration

The following procedure shows how to create a lifecycle configuration script that prints Hello World.

### Note

Each script can have up to **16,384 characters**.

1. From your local machine, create a file named `my-script.sh` with the following content.

```
#!/bin/bash
set -eux
echo 'Hello World!'
```

2. Convert your `my-script.sh` file into base64 format. This requirement prevents errors that occur from spacing and line break encoding.

```
LCC_CONTENT=`openssl base64 -A -in my-script.sh`
```

3. Create a lifecycle configuration for use with Studio Classic. The following command creates a lifecycle configuration that runs when you launch an associated KernelGateway application.

```
aws sagemaker create-studio-lifecycle-config \
--region region \
--studio-lifecycle-config-name my-studio-lcc \
--studio-lifecycle-config-content $LCC_CONTENT \
--studio-lifecycle-config-app-type KernelGateway
```

Note the ARN of the newly created lifecycle configuration that is returned. This ARN is required to attach the lifecycle configuration to your application.

## Step 2: Attach the lifecycle configuration to your domain, user profile, or shared space

To attach the lifecycle configuration, you must update the `UserSettings` for your domain or user profile, or the `SpaceSettings` for a shared space. Lifecycle configuration scripts that are associated at the domain level are inherited by all users. However, scripts that are associated at the user profile level are scoped to a specific user, while scripts that are associated at the shared space level are scoped to the shared space.

The following example shows how to create a new user profile with the lifecycle configuration attached. You can also create a new domain or space with a lifecycle configuration attached by using the [create-domain](#) and [create-space](#) commands, respectively.

Add the lifecycle configuration ARN from the previous step to the settings for the appropriate app type. For example, place it in the `JupyterServerAppSettings` of the user. You can add multiple lifecycle configurations at the same time by passing a list of lifecycle configurations. When a user launches a JupyterServer application with the AWS CLI, they can pass a lifecycle configuration to use instead of the default. The lifecycle configuration that the user passes must belong to the list of lifecycle configurations in `JupyterServerAppSettings`.

```
# Create a new UserProfile
aws sagemaker create-user-profile --domain-id domain-id \
--user-profile-name user-profile-name \
--region region \
--user-settings '{
  "JupyterServerAppSettings": {
    "LifecycleConfigArns":
      [lifecycle-configuration-arn-list]
  }
}'
```

The following example shows how to update an existing shared space to attach the lifecycle configuration. You can also update an existing domain or user profile with a lifecycle configuration attached by using the [update-domain](#) or [update-user-profile](#) command. When you update the list of lifecycle configurations attached, you must pass all lifecycle configurations as part of the list. If a lifecycle configuration is not part of this list, it will not be attached to the application.

```
aws sagemaker update-space --domain-id domain-id \
--space-name space-name \
--region region \
--space-settings '{
  "JupyterServerAppSettings": {
```

```
"LifecycleConfigArns":
  [lifecycle-configuration-arn-list]
}
}'
```

For information about setting a default lifecycle configuration for a resource, see [Set default lifecycle configurations](#).

### Step 3: Launch application with lifecycle configuration

After you attach a lifecycle configuration to a domain, user profile, or space, the user can select it when launching an application with the AWS CLI. This section describes how to launch an application with an attached lifecycle configuration. For information about changing the default lifecycle configuration after launching a JupyterServer application, see [Set default lifecycle configurations](#).

Launch the desired application type using the `create-app` command and specify the lifecycle configuration ARN in the `resource-spec` argument.

- The following example shows how to create a JupyterServer application with an associated lifecycle configuration. When creating the JupyterServer, the `app-name` must be `default`. The lifecycle configuration ARN passed as part of the `resource-spec` parameter must be part of the list of lifecycle configuration ARNs specified in `UserSettings` for your domain or user profile, or `SpaceSettings` for a shared space.

```
aws sagemaker create-app --domain-id domain-id \
--region region \
--user-profile-name user-profile-name \
--app-type JupyterServer \
--resource-spec LifecycleConfigArn=lifecycle-configuration-arn \
--app-name default
```

- The following example shows how to create a KernelGateway application with an associated lifecycle configuration.

```
aws sagemaker create-app --domain-id domain-id \
--region region \
--user-profile-name user-profile-name \
--app-type KernelGateway \
--resource-spec LifecycleConfigArn=lifecycle-configuration-arn,SageMakerImageArn=sagemaker-image-arn,InstanceType=instance-type \
```

```
--app-name app-name
```

## Create a lifecycle configuration from the SageMaker AI console

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following topic shows how to create a lifecycle configuration from the Amazon SageMaker AI console to automate customization for your Studio Classic environment.

## Prerequisites

Before you can begin this tutorial, complete the following prerequisite:

- Onboard to Amazon SageMaker Studio Classic. For more information, see [Onboard to Amazon SageMaker Studio Classic](#).

## Step 1: Create a new lifecycle configuration

You can create a lifecycle configuration by entering a script from the Amazon SageMaker AI console.

### Note

Each script can have up to **16,384 characters**.

The following procedure shows how to create a lifecycle configuration script that prints Hello World.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Lifecycle configurations**.
4. Choose the **Studio** tab.
5. Choose **Create configuration**.
6. Under **Select configuration type**, select the type of application that the lifecycle configuration should be attached to. For more information about selecting which application to attach the lifecycle configuration to, see [Set default lifecycle configurations](#).
7. Choose **Next**.
8. In the section called **Configuration settings**, enter a name for your lifecycle configuration.
9. In the **Scripts** section, enter the following content.

```
#!/bin/bash
set -eux
echo 'Hello World!'
```

10. (Optional) Create a tag for your lifecycle configuration.
11. Choose **Submit**.

## Step 2: Attach the lifecycle configuration to a domain or user profile

Lifecycle configuration scripts associated at the domain level are inherited by all users. However, scripts that are associated at the user profile level are scoped to a specific user.

You can attach multiple lifecycle configurations to a domain or user profile for both JupyterServer and KernelGateway applications.

**Note**

To attach a lifecycle configuration to a shared space, you must use the AWS CLI. For more information, see [Create a lifecycle configuration from the AWS CLI](#).

The following sections show how to attach a lifecycle configuration to your domain or user profile.

### Attach to a domain

The following shows how to attach a lifecycle configuration to your existing domain from the SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain to attach the lifecycle configuration to.
5. From the **Domain details**, choose the **Environment** tab.
6. Under **Lifecycle configurations for personal Studio apps**, choose **Attach**.
7. Under **Source**, choose **Existing configuration**.
8. Under **Studio lifecycle configurations**, select the lifecycle configuration that you created in the previous step.
9. Select **Attach to domain**.

### Attach to your user profile

The following shows how to attach a lifecycle configuration to your existing user profile.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain that contains the user profile to attach the lifecycle configuration to.

5. Under **User profiles**, select the user profile.
6. From the **User Details** page, choose **Edit**.
7. On the left navigation, choose **Studio settings**.
8. Under **Lifecycle configurations attached to user**, choose **Attach**.
9. Under **Source**, choose **Existing configuration**.
10. Under **Studio lifecycle configurations**, select the lifecycle configuration that you created in the previous step.
11. Choose **Attach to user profile**.

### Step 3: Launch an application with the lifecycle configuration

After you attach a lifecycle configuration to a domain or user profile, you can launch an application with that attached lifecycle configuration. Choosing which lifecycle configuration to launch with depends on the application type.

- **JupyterServer:** When launching a JupyterServer application from the console, SageMaker AI always uses the default lifecycle configuration. You can't use a different lifecycle configuration when launching from the console. For information about changing the default lifecycle configuration after launching a JupyterServer application, see [Set default lifecycle configurations](#).

To select a different attached lifecycle configuration, you must launch with the AWS CLI. For more information about launching a JupyterServer application with an attached lifecycle configuration from the AWS CLI, see [Create a lifecycle configuration from the AWS CLI](#).

- **KernelGateway:** You can select any of the attached lifecycle configurations when launching a KernelGateway application using the Studio Classic Launcher.

The following procedure describes how to launch a KernelGateway application with an attached lifecycle configuration from the SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. Launch Studio Classic. For more information, see [Launch Amazon SageMaker Studio Classic](#).
3. In the Studio Classic UI, open the Studio Classic Launcher. For more information, see [Use the Amazon SageMaker Studio Classic Launcher](#).
4. In the Studio Classic Launcher, navigate to the **Notebooks and compute resources** section.

5. Click the **Change environment** button.
6. On the **Change environment** dialog, use the dropdown menus to select your **Image**, **Kernel**, **Instance type**, and a **Start-up script**. If there is no default lifecycle configuration, the **Start-up script** value defaults to `No script`. Otherwise, the **Start-up script** value is your default lifecycle configuration. After you select a lifecycle configuration, you can view the entire script.
7. Click **Select**.
8. Back to the Launcher, click the **Create notebook** to launch a new notebook kernel with your selected image and lifecycle configuration.

#### Step 4: View logs for a lifecycle configuration

You can view the logs for your lifecycle configuration after it has been attached to a domain or user profile.

1. First, provide access to CloudWatch for your AWS Identity and Access Management (IAM) role. Add read permissions for the following log group and log stream.
  - **Log group:** `/aws/sagemaker/studio`
  - **Log stream:** `domain/user-profile/app-type/app-name/LifecycleConfigOnStart`

For information about adding permissions, see [Enabling logging from certain AWS services](#).

2. From within Studio Classic, navigate to the **Running Terminals and Kernels** icon  to monitor your lifecycle configuration.
3. Select an application from the list of running applications. Applications with attached lifecycle configurations have an attached indicator icon .
4. Select the indicator icon for your application. This opens a new panel that lists the lifecycle configuration.
5. From the new panel, select **View logs**. This opens a new tab that displays the logs.

## Set default lifecycle configurations

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Although you can attach multiple lifecycle configuration scripts to a single resource, you can only set one default lifecycle configuration for each JupyterServer or KernelGateway application. The behavior of the default lifecycle configuration depends on whether it is set for JupyterServer or KernelGateway apps.

- **JupyterServer apps:** When set as the default lifecycle configuration script for JupyterServer apps, the lifecycle configuration script runs automatically when the user signs in to Studio Classic for the first time or restarts Studio Classic. Use this default lifecycle configuration to automate one-time setup actions for the Studio Classic developer environment, such as installing notebook extensions or setting up a GitHub repo. For an example of this, see [Customize Amazon SageMaker Studio using Lifecycle Configurations](#).
- **KernelGateway apps:** When set as the default lifecycle configuration script for KernelGateway apps, the lifecycle configuration is selected by default in the Studio Classic launcher. Users can launch a notebook or terminal with the default script selected, or they can select a different one from the list of lifecycle configurations.

SageMaker AI supports setting a default lifecycle configuration for the following resources:

- Domains
- User profiles
- Shared spaces

While domains and user profiles support setting a default lifecycle configuration from both the Amazon SageMaker AI console and AWS Command Line Interface, shared spaces only support setting a default lifecycle configuration from the AWS CLI.

You can set a lifecycle configuration as the default when creating a new resource or updating an existing resource. The following topics demonstrate how to set a default lifecycle configuration using the SageMaker AI console and AWS CLI.

## Default lifecycle configuration inheritance

Default lifecycle configurations set at the *domain* level are inherited by all users and shared spaces. Default lifecycle configurations set at the *user* and *shared space* level are scoped to only that user or shared space. User and space defaults override defaults set at the domain level.

A default KernelGateway lifecycle configuration set for a domain applies to all KernelGateway applications launched in the domain. Unless the user selects a different lifecycle configuration from the list presented in the Studio Classic launcher, the default lifecycle configuration is used. The default script also runs if No Script is selected by the user. For more information about selecting a script, see [Step 3: Launch an application with the lifecycle configuration](#).

## Topics

- [Set defaults from the AWS CLI](#)
- [Set defaults from the SageMaker AI console](#)

## Set defaults from the AWS CLI

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

**⚠ Important**

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

You can set default lifecycle configuration scripts from the AWS CLI for the following resources:

- Domains
- User profiles
- Shared spaces

The following sections outline how to set default lifecycle configuration scripts from the AWS CLI.

**Topics**

- [Prerequisites](#)
- [Set a default lifecycle configuration when creating a new resource](#)
- [Set a default lifecycle configuration for an existing resource](#)

**Prerequisites**

Before you begin, complete the following prerequisites:

- Update the AWS CLI by following the steps in [Installing the current AWS CLI version](#).
- From your local machine, run `aws configure` and provide your AWS credentials. For information about AWS credentials, see [Understanding and getting your AWS credentials](#).
- Onboard to SageMaker AI domain by following the steps in [Amazon SageMaker AI domain overview](#).
- Create a lifecycle configuration following the steps in [Create and associate a lifecycle configuration](#).

## Set a default lifecycle configuration when creating a new resource

To set a default lifecycle configuration when creating a new domain, user profile, or space, pass the ARN of your previously created lifecycle configuration as part of one of the following AWS CLI commands:

- [create-user-profile](#)
- [create-domain](#)
- [create-space](#)

You must pass the lifecycle configuration ARN for the following values in the KernelGateway or JupyterServer default settings:

- `DefaultResourceSpec:LifecycleConfigArn` - This specifies the default lifecycle configuration for the application type.
- `LifecycleConfigArns` - This is the list of all lifecycle configurations attached to the application type. The default lifecycle configuration must also be part of this list.

For example, the following API call creates a new user profile with a default lifecycle configuration.

```
aws sagemaker create-user-profile --domain-id domain-id \  
--user-profile-name user-profile-name \  
--region region \  
--user-settings '{  
  "KernelGatewayAppSettings": {  
    "DefaultResourceSpec": {  
      "InstanceType": "ml.t3.medium",  
      "LifecycleConfigArn": "lifecycle-configuration-arn"  
    },  
    "LifecycleConfigArns": [lifecycle-configuration-arn-list]  
  }  
'
```

## Set a default lifecycle configuration for an existing resource

To set or update the default lifecycle configuration for an existing resource, pass the ARN of your previously created lifecycle configuration as part of one of the following AWS CLI commands:

- [update-user-profile](#)
- [update-domain](#)
- [update-space](#)

You must pass the lifecycle configuration ARN for the following values in the KernelGateway or JupyterServer default settings:

- `DefaultResourceSpec:LifecycleConfigArn` - This specifies the default lifecycle configuration for the application type.
- `LifecycleConfigArns` - This is the list of all lifecycle configurations attached to the application type. The default lifecycle configuration must also be part of this list.

For example, the following API call updates a user profile with a default lifecycle configuration.

```
aws sagemaker update-user-profile --domain-id domain-id \  
--user-profile-name user-profile-name \  
--region region \  
--user-settings '{  
  "KernelGatewayAppSettings": {  
    "DefaultResourceSpec": {  
      "InstanceType": "ml.t3.medium",  
      "LifecycleConfigArn": "lifecycle-configuration-arn"  
    },  
    "LifecycleConfigArns": [lifecycle-configuration-arn-list]  
  }  
'
```

The following API call updates a domain to set a new default lifecycle configuration.

```
aws sagemaker update-domain --domain-id domain-id \  
--region region \  
--default-user-settings '{  
  "JupyterServerAppSettings": {  
    "DefaultResourceSpec": {  
      "InstanceType": "system",  
      "LifecycleConfigArn": "lifecycle-configuration-arn"  
    },  
    "LifecycleConfigArns": [lifecycle-configuration-arn-list]  
  }  
'
```

```
}  
}'
```

## Set defaults from the SageMaker AI console

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

You can set default lifecycle configuration scripts from the SageMaker AI console for the following resources.

- Domains
- User profiles

You cannot set default lifecycle configuration scripts for shared spaces from the SageMaker AI console. For information about setting defaults for shared spaces, see [Set defaults from the AWS CLI](#).

The following sections outline how to set default lifecycle configuration scripts from the SageMaker AI console.

## Topics

- [Prerequisites](#)
- [Set a default lifecycle configuration for a domain](#)
- [Set a default lifecycle configuration for a user profile](#)

## Prerequisites

Before you begin, complete the following prerequisites:

- Onboard to SageMaker AI domain by following the steps in [Amazon SageMaker AI domain overview](#).
- Create a lifecycle configuration following the steps in [Create and associate a lifecycle configuration](#).

## Set a default lifecycle configuration for a domain

The following procedure shows how to set a default lifecycle configuration for a domain from the SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. From the list of domains, select the name of the domain to set the default lifecycle configuration for.
3. From the **Domain details** page, choose the **Environment** tab.
4. Under **Lifecycle configurations for personal Studio apps**, select the lifecycle configuration that you want to set as the default for the domain. You can set distinct defaults for JupyterServer and KernelGateway applications.
5. Choose **Set as default**. This opens a pop up window that lists the current defaults for JupyterServer and KernelGateway applications.
6. Choose **Set as default** to set the lifecycle configuration as the default for its respective application type.

## Set a default lifecycle configuration for a user profile

The following procedure shows how to set a default lifecycle configuration for a user profile from the SageMaker AI console.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. From the list of domains, select the name of the domain that contains the user profile that you want to set the default lifecycle configuration for.
3. From the **Domain details** page, choose the **User profiles** tab.
4. Select the name of the user profile to set the default lifecycle configuration for. This opens a **User Details** page.
5. From the **User Details** page, choose **Edit**. This opens an **Edit user profile** page.
6. From the **Edit user profile** page, choose **Step 2 Studio settings**.
7. Under **Lifecycle configurations attached to user**, select the lifecycle configuration that you want to set as the default for the user profile. You can set distinct defaults for JupyterServer and KernelGateway applications.
8. Choose **Set as default**. This opens a pop up window that lists the current defaults for JupyterServer and KernelGateway applications.
9. Choose **Set as default** to set the lifecycle configuration as the default for its respective application type.

## Debug lifecycle configurations

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following topics show how to get information about and debug your lifecycle configurations.

## Topics

- [Verify lifecycle configuration process from CloudWatch Logs](#)

- [JupyterServer app failure](#)
- [KernelGateway app failure](#)
- [Lifecycle configuration timeout](#)

## Verify lifecycle configuration process from CloudWatch Logs

Lifecycle configurations only log STDOUT and STDERR.

STDOUT is the default output for bash scripts. You can write to STDERR by appending `>&2` to the end of a bash command. For example, `echo 'hello'>&2`.

Logs for your lifecycle configurations are published to your AWS account using Amazon CloudWatch. These logs can be found in the `/aws/sagemaker/studio` log stream in the CloudWatch console.

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Choose **Logs** from the left side. From the dropdown menu, select **Log groups**.
3. On the **Log groups** page, search for `aws/sagemaker/studio`.
4. Select the log group.
5. On the **Log group details** page, choose the **Log streams** tab.
6. To find the logs for a specific app, search the log streams using the following format:

```
domain-id/user-profile-name/app-type/app-name
```

For example, to find the lifecycle configuration logs for domain `d-m851cu8vbqmqz`, user profile `i-sonic-js`, application type `JupyterServer` and application name `test-lcc-echo`, use the following search string:

```
d-m851cu8vbqmqz/i-sonic-js/JupyterServer/test-lcc-echo
```

7. Select the log stream appended with `LifecycleConfigOnStart` to view the script execution logs.

## JupyterServer app failure

If your JupyterServer app crashes because of an issue with the attached lifecycle configuration, Studio Classic displays the following error message on the Studio Classic startup screen.

Failed to create SageMaker Studio due to start-up script failure

Select the `View script logs` link to view the CloudWatch logs for your JupyterServer app.

In the case where the faulty lifecycle configuration is specified in the `DefaultResourceSpec` of your domain, user profile, or shared space, Studio Classic continues to use the lifecycle configuration even after restarting Studio Classic.

To resolve this error, follow the steps in [Set default lifecycle configurations](#) to remove the lifecycle configuration script from the `DefaultResourceSpec` or select another script as the default. Then launch a new JupyterServer app.

### KernelGateway app failure

If your KernelGateway app crashes because of an issue with the attached lifecycle configuration, Studio Classic displays the error message in your Studio Classic Notebook.

Choose `View script logs` to view the CloudWatch logs for your KernelGateway app.

In this case, your lifecycle configuration is specified in the Studio Classic Launcher when launching a new Studio Classic Notebook.

To resolve this error, use the Studio Classic launcher to select a different lifecycle configuration or select `No script`.

#### Note

A default KernelGateway lifecycle configuration specified in `DefaultResourceSpec` applies to all KernelGateway images in the domain, user profile, or shared space unless the user selects a different script from the list presented in the Studio Classic launcher. The default script also runs if `No Script` is selected by the user. For more information on selecting a script, see [Step 3: Launch an application with the lifecycle configuration](#).

### Lifecycle configuration timeout

There is a lifecycle configuration timeout limitation of 5 minutes. If a lifecycle configuration script takes longer than 5 minutes to run, Studio Classic throws an error.

To resolve this error, ensure that your lifecycle configuration script completes in less than 5 minutes.

To help decrease the run time of scripts, try the following:

- Cut down on necessary steps. For example, limit which conda environments to install large packages in.
- Run tasks in parallel processes.
- Use the `nohup` command in your script to ensure that hangup signals are ignored and do not stop the execution of the script.

## Update and detach lifecycle configurations

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

A lifecycle configuration script can't be changed after it's created. To update your script, you must create a new lifecycle configuration script and attach it to the respective domain, user profile, or shared space. For more information about creating and attaching the lifecycle configuration, see [Create and associate a lifecycle configuration](#).

The following topic shows how to detach a lifecycle configuration using the AWS CLI and SageMaker AI console.

### Topics

- [Prerequisites](#)
- [Detach using the AWS CLI](#)

### Prerequisites

Before detaching a lifecycle configuration, you must complete the following prerequisite.

- To successfully detach a lifecycle configuration, no running application can be using the lifecycle configuration. You must first shut down the running applications as shown in [Shut Down and Update SageMaker Studio Classic and Studio Classic Apps](#).

## Detach using the AWS CLI

To detach a lifecycle configuration using the AWS CLI, remove the desired lifecycle configuration from the list of lifecycle configurations attached to the resource and pass the list as part of the respective command:

- [update-user-profile](#)
- [update-domain](#)
- [update-space](#)

For example, the following command removes all lifecycle configurations for KernelGateways attached to the domain.

```
aws sagemaker update-domain --domain-id domain-id \  
--region region \  
--default-user-settings '{  
"KernelGatewayAppSettings": {  
  "LifecycleConfigArns":  
    []  
  }  
}'
```

## Attach Suggested Git Repos to Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Amazon SageMaker Studio Classic offers a Git extension for you to enter the URL of a Git repository (repo), clone it into your environment, push changes, and view commit history. In addition to this Git extension, you can also attach suggested Git repository URLs at the Amazon SageMaker AI domain or user profile level. Then, you can select the repo URL from the list of suggestions and clone that into your environment using the Git extension in Studio Classic.

The following topics show how to attach Git repo URLs to a domain or user profile from the AWS CLI and SageMaker AI console. You'll also learn how to detach these repository URLs.

## Topics

- [Attach a Git Repository from the AWS CLI](#)
- [Attach a Git Repository from the SageMaker AI Console](#)
- [Detach Git Repos](#)

## Attach a Git Repository from the AWS CLI

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following topic shows how to attach a Git repository URL using the AWS CLI, so that Amazon SageMaker Studio Classic automatically suggests it for cloning. After you attach the Git repository URL, you can clone it by following the steps in [Clone a Git Repository in SageMaker Studio Classic](#).

## Prerequisites

Before you begin, complete the following prerequisites:

- Update the AWS CLI by following the steps in [Installing the current AWS CLI Version](#).
- From your local machine, run `aws configure` and provide your AWS credentials. For information about AWS credentials, see [Understanding and getting your AWS credentials](#).
- Onboard to Amazon SageMaker AI domain. For more information, see [Amazon SageMaker AI domain overview](#).

## Attach the Git repo to a domain or user profile

Git repo URLs associated at the domain level are inherited by all users. However, Git repo URLs that are associated at the user profile level are scoped to a specific user. You can attach multiple Git repo URLs to a domain or user profile by passing a list of repository URLs.

The following sections show how to attach a Git repo URL to your domain and user profile.

## Attach to a domain

The following command attaches a Git repo URL to an existing domain.

```
aws sagemaker update-domain --region region --domain-id domain-id \  
  --default-user-settings  
  JupyterServerAppSettings={CodeRepositories=[{RepositoryUrl="repository"}]}
```

## Attach to a user profile

The following shows how to attach a Git repo URL to an existing user profile.

```
aws sagemaker update-user-profile --domain-id domain-id --user-profile-name user-name \  
  --user-settings  
  JupyterServerAppSettings={CodeRepositories=[{RepositoryUrl="repository"}]}
```

## Attach a Git Repository from the SageMaker AI Console

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following topic shows how to associate a Git repository URL from the Amazon SageMaker AI console to clone it in your Studio Classic environment. After you associate the Git repository URL, you can clone it by following the steps in [Clone a Git Repository in SageMaker Studio Classic](#).

## Prerequisites

Before you can begin this tutorial, you must onboard to Amazon SageMaker AI domain. For more information, see [Amazon SageMaker AI domain overview](#).

## Attach the Git repo to a domain or user profile

Git repo URLs associated at the domain level are inherited by all users. However, Git repo URL that are associated at the user profile level are scoped to a specific user.

The following sections show how to attach a Git repo URL to a domain and user profile.

## Attach to a domain

### To attach a Git repo URL to an existing domain

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. Select the domain to attach the Git repo to.
5. On the **domain details** page, choose the **Environment** tab.
6. On the **Suggested code repositories for the domain** tab, choose **Attach**.
7. Under **Source**, enter the Git repository URL.
8. Select **Attach to domain**.

## Attach to a user profile

The following shows how to attach a Git repository URL to an existing user profile.

### To attach a Git repository URL to a user profile

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. Select the domain that includes the user profile to attach the Git repo to.
5. On the **domain details** page, choose the **User profiles** tab.
6. Select the user profile to attach the Git repo URL to.
7. On the **User details** page, choose **Edit**.
8. On the **Studio settings** page, choose **Attach** from the **Suggested code repositories for the user** section.
9. Under **Source**, enter the Git repository URL.
10. Choose **Attach to user**.

## Detach Git Repos

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

This guide shows how to detach Git repository URLs from an Amazon SageMaker AI domain or user profile using the AWS CLI or Amazon SageMaker AI console.

### Topics

- [Detach a Git repo using the AWS CLI](#)
- [Detach the Git repo using the SageMaker AI console](#)

### Detach a Git repo using the AWS CLI

To detach all Git repo URLs from a domain or user profile, you must pass an empty list of code repositories. This list is passed as part of the `JupyterServerAppSettings` parameter in an `update-domain` or `update-user-profile` command. To detach only one Git repo URL, pass the code repositories list without the desired Git repo URL. This section shows how to detach all Git repo URLs from your domain or user profile using the AWS Command Line Interface (AWS CLI).

#### Detach from a domain

The following command detaches all Git repo URLs from a domain.

```
aws sagemaker update-domain --region region --domain-name domain-name \  
  --domain-settings JupyterServerAppSettings={CodeRepositories=[]}
```

#### Detach from a user profile

The following command detaches all Git repo URLs from a user profile.

```
aws sagemaker update-user-profile --domain-name domain-name --user-profile-name user-  
name \  
  --domain-settings JupyterServerAppSettings={CodeRepositories=[]}
```

```
--user-settings JupyterServerAppSettings={CodeRepositories=[]}
```

## Detach the Git repo using the SageMaker AI console

The following sections show how to detach a Git repo URL from a domain or user profile using the SageMaker AI console.

### Detach from a domain

Use the following steps to detach a Git repo URL from an existing domain.

#### To detach a Git repo URL from an existing domain

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. Select the domain with the Git repo URL that you want to detach.
5. On the **domain details** page, choose the **Environment** tab.
6. On the **Suggested code repositories for the domain** tab, select the Git repository URL to detach.
7. Choose **Detach**.
8. From the new window, choose **Detach**.

### Detach from a user profile

Use the following steps to detach a Git repo URL from a user profile.

#### To detach a Git repo URL from a user profile

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. Select the domain that includes the user profile with the Git repo URL that you want to detach.
5. On the **domain details** page, choose the **User profiles** tab.
6. Select the user profile with the Git repo URL that you want to detach.
7. On the **User details** page, choose **Edit**.

8. On the **Studio settings** page, select the Git repo URL to detach from the **Suggested code repositories for the user** tab.
9. Choose **Detach**.
10. From the new window, choose **Detach**.

## Perform Common Tasks in Amazon SageMaker Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following sections describe how to perform common tasks in Amazon SageMaker Studio Classic. For an overview of the Studio Classic interface, see [Amazon SageMaker Studio Classic UI Overview](#).

### Topics

- [Upload Files to SageMaker Studio Classic](#)
- [Clone a Git Repository in SageMaker Studio Classic](#)
- [Stop a Training Job in SageMaker Studio Classic](#)
- [Use TensorBoard in Amazon SageMaker Studio Classic](#)
- [Amazon Q Developer with Amazon SageMaker Studio Classic](#)
- [Manage Your Amazon EFS Storage Volume in SageMaker Studio Classic](#)
- [Provide Feedback on SageMaker Studio Classic](#)
- [Shut Down and Update SageMaker Studio Classic and Studio Classic Apps](#)

## Upload Files to SageMaker Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the

Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

When you onboard to Amazon SageMaker Studio Classic, a home directory is created for you in the Amazon Elastic File System (Amazon EFS) volume that was created for your team. Studio Classic can only open files that have been uploaded to your directory. The Studio Classic file browser maps to your home directory.

#### Note

Studio Classic does not support uploading folders. While you can only upload individual files, you can upload multiple files at the same time.

### To upload files to your home directory

1. In the left sidebar, choose the **File Browser** icon (  ).
2. In the file browser, choose the **Upload Files** icon (  ).
3. Select the files you want to upload and then choose **Open**.
4. Double-click a file to open the file in a new tab in Studio Classic.

### Clone a Git Repository in SageMaker Studio Classic

#### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Amazon SageMaker Studio Classic can only connect only to a local Git repository (repo). This means that you must clone the Git repo from within Studio Classic to access the files in the repo. Studio

Classic offers a Git extension for you to enter the URL of a Git repo, clone it into your environment, push changes, and view commit history. If the repo is private and requires credentials to access, then you are prompted to enter your user credentials. This includes your username and personal access token. For more information about personal access tokens, see [Managing your personal access tokens](#).

Admins can also attach suggested Git repository URLs at the Amazon SageMaker AI domain or user profile level. Users can then select the repo URL from the list of suggestions and clone that into Studio Classic. For more information about attaching suggested repos, see [Attach Suggested Git Repos to Studio Classic](#).

The following procedure shows how to clone a GitHub repo from Studio Classic.

### To clone the repo

1. In the left sidebar, choose the **Git** icon (  ).
2. Choose **Clone a Repository**. This opens a new window.
3. In the **Clone Git Repository** window, enter the URL in the following format for the Git repo that you want to clone or select a repository from the list of **Suggested repositories**.  

```
https://github.com/path-to-git-repo/repo.git
```
4. If you entered the URL of the Git repo manually, select **Clone "git-url"** from the dropdown menu.
5. Under **Project directory to clone into**, enter the path to the local directory that you want to clone the Git repo into. If this value is left empty, Studio Classic clones the repo into JupyterLab's root directory.
6. Choose **Clone**. This opens a new terminal window.
7. If the repo requires credentials, you are prompted to enter your username and personal access token. This prompt does not accept passwords, you must use a personal access token. For more information about personal access tokens, see [Managing your personal access tokens](#).
8. Wait for the download to finish. After the repo has been cloned, the **File Browser** opens to display the cloned repo.
9. Double click the repo to open it.
10. Choose the **Git** icon to view the Git user interface which now tracks the repo.

11. To track a different repo, open the repo in the file browser and then choose the **Git** icon.

## Stop a Training Job in SageMaker Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

You can stop a training job with the Amazon SageMaker Studio Classic UI. When you stop a training job, its status changes to **Stopping** at which time billing ceases. An algorithm can delay termination in order to save model artifacts after which the job status changes to **Stopped**. For more information, see the [stop\\_training\\_job](#) method in the AWS SDK for Python (Boto3).

### To stop a training job

1. Follow the [View experiments and runs](#) procedure on this page until you open the **Describe Trial Component** tab.
2. At the upper-right side of the tab, choose **Stop training job**. The **Status** at the top left of the tab changes to **Stopped**.
3. To view the training time and billing time, choose **AWS Settings**.

## Use TensorBoard in Amazon SageMaker Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following doc outlines how to install and run TensorBoard in Amazon SageMaker Studio Classic.

**Note**

This guide shows how to open the TensorBoard application through a SageMaker Studio Classic notebook server of an individual SageMaker AI domain user profile. For a more comprehensive TensorBoard experience integrated with SageMaker Training and the access control functionalities of SageMaker AI domain, see [TensorBoard in Amazon SageMaker AI](#).

**Prerequisites**

This tutorial requires a SageMaker AI domain. For more information, see [Amazon SageMaker AI domain overview](#)

**Set Up TensorBoardCallback**

1. Launch Studio Classic, and open the Launcher. For more information, see [Use the Amazon SageMaker Studio Classic Launcher](#)
2. In the Amazon SageMaker Studio Classic Launcher, under Notebooks and compute resources, choose the **Change environment** button.
3. On the **Change environment** dialog, use the dropdown menus to select the TensorFlow 2.6 Python 3.8 CPU Optimized Studio Classic **Image**.
4. Back to the Launcher, click the **Create notebook** tile. Your notebook launches and opens in a new Studio Classic tab.
5. Run this code from within your notebook cells.
6. Import the required packages.

```
import os
import datetime
import tensorflow as tf
```

7. Create a Keras model.

```
mnist = tf.keras.datasets.mnist

(x_train, y_train),(x_test, y_test) = mnist.load_data()
x_train, x_test = x_train / 255.0, x_test / 255.0

def create_model():
```

```
return tf.keras.models.Sequential([
    tf.keras.layers.Flatten(input_shape=(28, 28)),
    tf.keras.layers.Dense(512, activation='relu'),
    tf.keras.layers.Dropout(0.2),
    tf.keras.layers.Dense(10, activation='softmax')
])
```

## 8. Create a directory for your TensorBoard logs

```
LOG_DIR = os.path.join(os.getcwd(), "logs/fit/" +
    datetime.datetime.now().strftime("%Y%m%d-%H%M%S"))
```

## 9. Run training with TensorBoard.

```
model = create_model()
model.compile(optimizer='adam',
              loss='sparse_categorical_crossentropy',
              metrics=['accuracy'])

tensorboard_callback = tf.keras.callbacks.TensorBoard(log_dir=LOG_DIR,
              histogram_freq=1)

model.fit(x=x_train,
          y=y_train,
          epochs=5,
          validation_data=(x_test, y_test),
          callbacks=[tensorboard_callback])
```

## 10. Generate the EFS path for the TensorBoard logs. You use this path to set up your logs from the terminal.

```
EFS_PATH_LOG_DIR = "/".join(LOG_DIR.strip("/").split('/')[1:-1])
print (EFS_PATH_LOG_DIR)
```

Retrieve the `EFS_PATH_LOG_DIR`. You will need it in the TensorBoard installation section.

## Install TensorBoard

1. Click on the Amazon SageMaker Studio Classic button on the top left corner of Studio Classic to open the Amazon SageMaker Studio Classic Launcher. This launcher must be opened

from your root directory. For more information, see [Use the Amazon SageMaker Studio Classic Launcher](#)

2. In the Launcher, under Utilities and files, click System terminal.
3. From the terminal, run the following commands. Copy EFS\_PATH\_LOG\_DIR from the Jupyter notebook. You must run this from the /home/sagemaker-user root directory.

```
pip install tensorboard
tensorboard --logdir <EFS_PATH_LOG_DIR>
```

## Launch TensorBoard

1. To launch TensorBoard, copy your Studio Classic URL and replace lab? with proxy/6006/ as follows. You must include the trailing / character.

```
https://<YOUR_URL>.studio.<region>.sagemaker.aws/jupyter/default/proxy/6006/
```

2. Navigate to the URL to examine your results.

## Amazon Q Developer with Amazon SageMaker Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Amazon SageMaker Studio Classic is an integrated machine learning environment where you can build, train, deploy, and analyze your models all in the same application. You can generate code recommendations and suggest improvements related to code issues by using Amazon Q Developer with Amazon SageMaker AI.

Amazon Q Developer is a generative artificial intelligence (AI) powered conversational assistant that can help you understand, build, extend, and operate AWS applications. In the context of an integrated AWS coding environment, Amazon Q can generate code recommendations based on developers' code, as well as their comments in natural language.

Amazon Q has the most support for Java, Python, JavaScript, TypeScript, C#, Go, PHP, Rust, Kotlin, and SQL, as well as the Infrastructure as Code (IaC) languages JSON (AWS CloudFormation), YAML (AWS CloudFormation), HCL (Terraform), and CDK (Typescript, Python). It also supports code generation for Ruby, C++, C, Shell, and Scala. For examples of how Amazon Q integrates with Amazon SageMaker AI and displays code suggestions in the Amazon SageMaker Studio Classic IDE, see [Code Examples](#) in the *Amazon Q Developer User Guide*.

For more information on using Amazon Q with Amazon SageMaker Studio Classic, see the [Amazon Q Developer User Guide](#).

## Manage Your Amazon EFS Storage Volume in SageMaker Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The first time a user on your team onboards to Amazon SageMaker Studio Classic, Amazon SageMaker AI creates an Amazon Elastic File System (Amazon EFS) volume for the team. A home directory is created in the volume for each user who onboards to Studio Classic as part of your team. Notebook files and data files are stored in these directories. Users don't have access to other team member's home directories. Amazon SageMaker AI domain does not support mounting custom or additional Amazon EFS volumes.

### Important

Don't delete the Amazon EFS volume. If you delete it, the domain will no longer function and all of your users will lose their work.

### To find your Amazon EFS volume

1. Open the [SageMaker AI console](#).
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.

4. From the **Domains** page, select the domain to find the ID for.
5. From the **Domain details** page, select the **Domain settings** tab.
6. Under **General settings**, find the **Domain ID**. The ID will be in the following format: d-xxxxxxxxxxxxx.
7. Pass the Domain ID, as `DomainId`, to the [describe\\_domain](#) method.
8. In the response from `describe_domain`, note the value for the `HomeEfsFileSystemId` key. This is the Amazon EFS file system ID.
9. Open the [Amazon EFS console](#). Make sure the AWS Region is the same Region that's used by Studio Classic.
10. Under **File systems**, choose the file system ID from the previous step.
11. To verify that you've chosen the correct file system, select the **Tags** heading. The value corresponding to the `ManagedByAmazonSageMakerResource` key should match the Studio Classic ID.

For information on how to access the Amazon EFS volume, see [Using file systems in Amazon EFS](#).

To delete the Amazon EFS volume, see [Deleting an Amazon EFS file system](#).

## Provide Feedback on SageMaker Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

Amazon SageMaker AI takes your feedback seriously. We encourage you to provide feedback.

### To provide feedback

1. At the right of SageMaker Studio Classic, find the **Feedback** icon

).

2. Choose a smiley emoji to let us know how satisfied you are with SageMaker Studio Classic and add any feedback you'd care to share with us.
3. Decide whether to share your identity with us, then choose **Submit**.

## Shut Down and Update SageMaker Studio Classic and Studio Classic Apps

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

The following topics show how to shut down and update SageMaker Studio Classic and Studio Classic Apps.

Studio Classic provides a notification icon

in the upper-right corner of the Studio Classic UI. This notification icon displays the number of unread notices. To read the notices, select the icon.

Studio Classic provides two types of notifications:

- Upgrade – Displayed when Studio Classic or one of the Studio Classic apps have released a new version. To update Studio Classic, see [Shut down and Update SageMaker Studio Classic](#). To update Studio Classic apps, see [Shut down and Update Studio Classic Apps](#).
- Information – Displayed for new features and other information.

To reset the notification icon, you must select the link in each notice. Read notifications may still display in the icon. This does not indicate that updates are still needed after you have updated Studio Classic and Studio Classic Apps.

To learn how to update [Amazon SageMaker Data Wrangler](#), see [Shut down and Update Studio Classic Apps](#).

To ensure that you have the most recent software updates, update Amazon SageMaker Studio Classic and your Studio Classic apps using the methods outlined in the following topics.

## Topics

- [Shut down and Update SageMaker Studio Classic](#)
- [Shut down and Update Studio Classic Apps](#)

## Shut down and Update SageMaker Studio Classic

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

To update Amazon SageMaker Studio Classic to the latest release, you must shut down the JupyterServer app. You can shut down the JupyterServer app from the SageMaker AI console, from Amazon SageMaker Studio or from within Studio Classic. After the JupyterServer app is shut down, you must reopen Studio Classic through the SageMaker AI console or from Studio which creates a new version of the JupyterServer app.

You cannot delete the JupyterServer application while the Studio Classic UI is still open in the browser. If you delete the JupyterServer application while the Studio Classic UI is still open in the browser, SageMaker AI automatically re-creates the JupyterServer application.

Any unsaved notebook information is lost in the process. The user data in the Amazon EFS volume isn't impacted.

Some of the services within Studio Classic, like Data Wrangler, run on their own app. To update these services you must delete the app for that service. To learn more, see [Shut down and Update Studio Classic Apps](#).

 **Note**

A JupyterServer app is associated with a single Studio Classic user. When you update the app for one user it doesn't affect other users.

The following page shows how to update the JupyterServer App from the SageMaker AI console, from Studio, or from inside Studio Classic.

### Shut down and update from the SageMaker AI console

1. Navigate to <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. Select the domain that includes the Studio Classic application that you want to update.
5. Under **User profiles**, select your user name.
6. Under **Apps**, in the row displaying **JupyterServer**, choose **Action**, then choose **Delete**.
7. Choose **Yes, delete app**.
8. Type **delete** in the confirmation box.
9. Choose **Delete**.
10. After the app has been deleted, launch a new Studio Classic app to get the latest version.

### Shut down and update from Studio

1. Navigate to Studio following the steps in [Launch Amazon SageMaker Studio](#).
2. From the Studio UI, find the applications pane on the left side.
3. From the applications pane, select **Studio Classic**.
4. From the Studio Classic landing page, select the Studio Classic instance to stop.
5. Choose **Stop**.

6. After the app has been stopped, select **Run** to use the latest version.

### Shut down and update from inside Studio Classic

1. Launch Studio Classic.
2. On the top menu, choose **File** then **Shut Down**.
3. Choose one of the following options:
  - **Shutdown Server** – Shuts down the JupyterServer app. Terminal sessions, kernel sessions, SageMaker images, and instances aren't shut down. These resources continue to accrue charges.
  - **Shutdown All** – Shuts down all apps, terminal sessions, kernel sessions, SageMaker images, and instances. These resources no longer accrue charges.
4. Close the window.
5. After the app has been deleted, launch a new Studio Classic app to use the latest version.

### Shut down and Update Studio Classic Apps

#### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#). [AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

#### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the

Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

To update an Amazon SageMaker Studio Classic app to the latest release, you must first shut down the corresponding KernelGateway app from the SageMaker AI console. After the KernelGateway app is shut down, you must reopen it through SageMaker Studio Classic by running a new kernel. The kernel automatically updates. Any unsaved notebook information is lost in the process. The user data in the Amazon EFS volume isn't impacted.

After an application has been shut down for 24 hours, SageMaker AI deletes all metadata for the application. To be considered an update and retain application metadata, applications must be restarted within 24 hours after the previous application has been shut down. After this time window, creation of an application is considered a new application rather than an update of the previous application.

 **Note**

A KernelGateway app is associated with a single Studio Classic user. When you update the app for one user it doesn't effect other users.

### To update the KernelGateway app

1. Navigate to <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. Select the domain that includes the application that you want to update.
5. Under **User profiles**, select your user name.
6. Under **Apps**, in the row displaying the **App name**, choose **Action**, then choose **Delete**

To update Data Wrangler, delete the app that starts with **sagemaker-data-wrang**.

7. Choose **Yes, delete app**.
8. Type **delete** in the confirmation box.
9. Choose **Delete**.

10. After the app has been deleted, launch a new kernel from within Studio Classic to use the latest version.

## Amazon SageMaker Studio Classic Pricing

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

When the first member of your team onboards to Amazon SageMaker Studio Classic, Amazon SageMaker AI creates an Amazon Elastic File System (Amazon EFS) volume for the team. When this member, or any member of the team, opens Studio Classic, a home directory is created in the volume for the member. A storage charge is incurred for this directory. Subsequently, additional storage charges are incurred for the notebooks and data files stored in the member's home directory. For pricing information on Amazon EFS, see [Amazon EFS Pricing](#).

Additional costs are incurred when other operations are run inside Studio Classic, for example, running a notebook, running training jobs, and hosting a model.

For information on the costs associated with using Studio Classic notebooks, see [Usage Metering](#).

For information about billing along with pricing examples, see [Amazon SageMaker Pricing](#).

If Amazon SageMaker Studio is your default experience, see [Amazon SageMaker Studio pricing](#) for more pricing information.

## Troubleshooting Amazon SageMaker Studio Classic

### Important

As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see [Amazon SageMaker Studio](#).

**⚠ Important**

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

This topic describes how to troubleshoot common Amazon SageMaker Studio Classic issues during setup and use. The following are common errors that might occur while using Amazon SageMaker Studio Classic. Each error is followed by its solution.

## Studio Classic application issues

The following issues occur when launching and using the Studio Classic application.

- **Screen not loading: Clearing workspace and waiting doesn't help**

When launching the Studio Classic application, a pop-up displays the following message. No matter which option is selected, Studio Classic does not load.

```
Loading...  
The loading screen is taking a long time. Would you like to clear the workspace or  
keep waiting?
```

The Studio Classic application can have a launch delay if multiple tabs are open in the Studio Classic workspace or several files are on Amazon EFS. This pop-up should disappear in a few seconds after the Studio Classic workspace is ready.

If you continue to see a loading screen with a spinner after selecting either of the options, there could be connectivity issues with the Amazon Virtual Private Cloud used by Studio Classic.

To resolve connectivity issues with the Amazon Virtual Private Cloud (Amazon VPC) used by Studio Classic, verify the following networking configurations:

- If your domain is set up in `VpcOnly` mode: Verify that there is an Amazon VPC endpoint for AWS STS, or a NAT Gateway for outbound traffic, including traffic over the internet. To do this, follow the steps in [Connect Studio notebooks in a VPC to external resources](#).
- If your Amazon VPC is set up with a custom DNS instead of the DNS provided by Amazon: Verify that the routes are configured using Dynamic Host Configuration Protocol (DHCP) for each Amazon VPC endpoint added to the Amazon VPC used by Studio Classic. For more information about setting default and custom DHCP option sets, see [DHCP option sets in Amazon VPC](#).
- **Internal Failure when launching Studio Classic**

When launching Studio Classic, you are unable to view the Studio Classic UI. You also see an error similar to the following, with **Internal Failure** as the error detail.

```
Amazon SageMaker Studio
The JupyterServer app default encountered a problem and was stopped.
```

This error can be caused by multiple factors. If completion of these steps does not resolve your issue, create an issue with <https://aws.amazon.com/premiumsupport/>.

- **Missing Amazon EFS mount target:** Studio Classic uses Amazon EFS for storage. The Amazon EFS volume needs a mount target for each subnet that the Amazon SageMaker AI domain is created in. If this Amazon EFS mount target is deleted accidentally, the Studio Classic application cannot load because it cannot mount the user's file directory. To resolve this issue, complete the following steps.

#### To verify or create mount targets.

1. Find the Amazon EFS volume that is associated with the domain by using the [DescribeDomain](#) API call.
2. Sign in to the AWS Management Console and open the Amazon EFS console at <https://console.aws.amazon.com/efs/>.
3. From the list of Amazon EFS volumes, select the Amazon EFS volume that is associated with the domain.
4. On the Amazon EFS details page, select the **Network** tab. Verify that there are mount targets for all of the subnets that the domain is set up in.

5. If mount targets are missing, add the missing Amazon EFS mount targets. For instructions, see [Creating and managing mount targets and security groups](#).
  6. After the missing mount targets are created, launch the Studio Classic application.
- **Conflicting files in the user's `.local` folder:** If you're using JupyterLab version 1 on Studio Classic, conflicting libraries in your `.local` folder can cause issues when launching the Studio Classic application. To resolve this, update your user profile's default JupyterLab version to JupyterLab 3.0. For more information about viewing and updating the JupyterLab version, see [JupyterLab Versioning](#).
  - **ConfigurationError: LifecycleConfig when launching Studio Classic**

You can't view the Studio Classic UI when launching Studio Classic. This is caused by issues with the default lifecycle configuration script attached to the domain.

### To resolve lifecycle configuration issues

1. View the Amazon CloudWatch Logs for the lifecycle configuration to trace the command that caused the failure. To view the log, follow the steps in [Verify lifecycle configuration process from CloudWatch Logs](#).
  2. Detach the default script from the user profile or domain. For more information, see [Update and detach lifecycle configurations](#).
  3. Launch the Studio Classic application.
  4. Debug your lifecycle configuration script. You can run the lifecycle configuration script from the system terminal to troubleshoot. When the script runs successfully from the terminal, you can attach the script to the user profile or the domain.
- **SageMaker Studio Classic core functionalities are not available.**

If you get this error message when opening Studio Classic, it may be due to Python package version conflicts. This occurs if you used the following commands in a notebook or terminal to install Python packages that have version conflicts with SageMaker AI package dependencies.

```
!pip install
```

```
pip install --user
```

To resolve this issue, complete the following steps:

1. Uninstall recently installed Python packages. If you're not sure which package to uninstall, create an issue with <https://aws.amazon.com/premiumsupport/>.
2. Restart Studio Classic:
  - a. Shut down Studio Classic from the **File** menu.
  - b. Wait for one minute.
  - c. Reopen Studio Classic by refreshing the page or opening it from the AWS Management Console.

The problem should be resolved if you have uninstalled the package which caused the conflict. To install packages without causing this issue again, use `pip install` without the `--user` flag.

If the issue persists, create a new user profile and set up your environment with that user profile.

If these solutions don't fix the issue, create an issue with <https://aws.amazon.com/premiumsupport/>.

- **Unable to open Studio Classic from the AWS Management Console.**

If you are unable to open Studio Classic and cannot make a new running instance with all default settings, create an issue with <https://aws.amazon.com/premiumsupport/>.

## KernelGateway application issues

The following issues are specific to KernelGateway applications that are launched in Studio Classic.

- **Cannot access the Kernel session**

When the user launches a new notebook, they are unable to connect to the notebook session. If the KernelGateway application's status is `In Service`, you can verify the following to resolve the issue.

- **Check Security Group configurations**

If the domain is set up in `VPCOnly` mode, the security group associated with the domain must allow traffic between the ports in the range 8192-65535 for connectivity between the JupyterServer and KernelGateway apps.

## To verify the security group rules

1. Get the security groups associated with the domain using the [DescribeDomain](#) API call.
2. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
3. From the left navigation, under **Security**, choose **Security Groups**.
4. Filter by the IDs of the security groups that are associated with the domain.
5. For each security group:
  - a. Select the security group.
  - b. From the security group details page, view the **Inbound rules**. Verify that traffic is allowed between ports in the range 8192-65535.

For more information about security group rules, see [Control traffic to resources using security groups](#). For more information about requirements to use Studio Classic in VPCOnly mode, see [Connect Studio notebooks in a VPC to external resources](#).

- **Verify firewall and WebSocket connections**

If the KernelGateway apps have an InService status and the user is unable to connect to the Studio Classic notebook session, verify the firewall and WebSocket settings.

1. Launch the Studio Classic application. For more information, see [Launch Amazon SageMaker Studio Classic](#).
2. Open your web browser's developer tools.
3. Choose the **Network** tab.
4. Search for an entry that matches the following format.

```
wss://<domain-id>.studio.<region>.sagemaker.aws/jupyter/default/api/kernels/  
<unique-code>/channels?session_id=<unique-code>
```

If the status or response code for the entry is anything other than 101, then your network settings are preventing the connection between the Studio Classic application and the KernelGateway apps.

To resolve this issue, contact the team that manages your networking settings to allow list the Studio Classic URL and enable WebSocket connections.

- **Unable to launch an app caused by exceeded resource quotas**

When a user tries to launch a new notebook, the notebook creation fails with either of the following errors. This is caused by exceeding resource quotas.

- `Unable to start more Apps of AppType [KernelGateway] and ResourceSpec(instanceType=[]) for UserProfile []. Please delete an App with a matching AppType and ResourceSpec, then try again`

Studio Classic supports up to four running KernelGateway apps on the same instance. To resolve this issue, you can do either of the following:

- Delete an existing KernelGateway application running on the instance, then restart the new notebook.
- Start the new notebook on a different instance type

For more information, see [Change an Instance Type](#).

- `An error occurred (ResourceLimitExceeded) when calling the CreateApp operation`

In this case, the account does not have sufficient limits to create a Studio Classic application on the specified instance type. To resolve this, navigate to the Service Quotas console at <https://console.aws.amazon.com/servicequotas/>. In that console, request to increase the Studio KernelGateway Apps running on *instance-type* instance limit. For more information, see [AWS service quotas](#).

## SageMaker JupyterLab

Create a JupyterLab space within Amazon SageMaker Studio to launch the JupyterLab application. A JupyterLab space is a private or shared space within Studio that manages the storage and compute resources needed to run the JupyterLab application. The JupyterLab application is a web-based interactive development environment (IDE) for notebooks, code, and data. Use the JupyterLab application's flexible and extensive interface to configure and arrange machine learning (ML) workflows.

By default, the JupyterLab application comes with the SageMaker Distribution image. The distribution image has popular packages, such as the following:

- PyTorch
- TensorFlow
- Keras
- NumPy
- Pandas
- Scikit-learn

You can use shared spaces to collaborate on your Jupyter notebooks with other users in real time. For more information about shared spaces, see [Collaboration with shared spaces](#).

Within the JupyterLab application, you can use Amazon Q Developer, a generative AI powered code companion to generate, debug, and explain your code. For information about using Amazon Q Developer, see [JupyterLab user guide](#). For information about setting up Amazon Q Developer, see [JupyterLab administrator guide](#).

Build unified analytics and ML workflows in same Jupyter notebook. Run interactive Spark jobs on Amazon EMR and AWS Glue serverless infrastructure, right from your notebook. Monitor and debug jobs faster using the inline Spark UI. In a few steps, you can automate your data prep by scheduling the notebook as a job.

The JupyterLab application helps you work collaboratively with your peers. Use the built-in Git integration within the JupyterLab IDE to share and version code. Bring your own file storage system if you have an Amazon EFS volume.

The JupyterLab application runs on a single Amazon Elastic Compute Cloud (Amazon EC2) instance and uses a single Amazon Elastic Block Store (Amazon EBS) volume for storage. You can switch faster instances or increase the Amazon EBS volume size for your needs.

The JupyterLab 4 application runs in a JupyterLab space within Studio. Studio Classic uses the JupyterLab 3 application. JupyterLab 4 provides the following benefits:

- A faster IDE than Amazon SageMaker Studio Classic, especially with large notebooks
- Improved document search
- A more performant and accessible text editor

For more information about JupyterLab, see [JupyterLab Documentation](#).

## Topics

- [JupyterLab user guide](#)
- [JupyterLab administrator guide](#)

## JupyterLab user guide

This guide shows JupyterLab users how to run analytics and machine learning workflows within SageMaker Studio. You can get fast storage and scale your compute up or down, depending on your needs.

JupyterLab supports both private and shared spaces. Private spaces are scoped to a single user in a domain. Shared spaces let other users in your domain collaborate with you in real time. For information about Studio spaces, see [Amazon SageMaker Studio spaces](#).

To get started using JupyterLab, create a space and launch your JupyterLab application. The space running your JupyterLab application is a JupyterLab space. The JupyterLab space uses a single Amazon EC2 instance for your compute and a single Amazon EBS volume for your storage. Everything in your space such as your code, git profile, and environment variables are stored on the same Amazon EBS volume. The volume has 3000 IOPS and a throughput of 125 megabytes per second (MBps). You can use the fast storage to open and run multiple Jupyter notebooks on the same instance. You can also switch kernels in a notebook very quickly.

Your administrator has configured the default Amazon EBS storage settings for your space. The default storage size is 5 GB, but you can increase the amount of space that you get. You can talk to your administrator to provide you with guidelines.

You can switch the Amazon EC2 instance type that you're using to run JupyterLab, scaling your compute up or down depending on your needs. The **Fast launch** instances start up much faster than the other instances.

Your administrator might provide you with a lifecycle configuration that customizes your environment. You can specify the lifecycle configuration when you create the space.

If your administrator gives you access to an Amazon EFS, you can configure your JupyterLab space to access it.

By default, the JupyterLab application uses the SageMaker distribution image. This includes support for many machine learning, analytics, and deep learning packages. However, if you need a custom image, your administrator can help provide access to the custom images.

The Amazon EBS volume persists independently from the life of an instance. You won't lose your data when you change instances. Use the conda and pip package management libraries to create reproducible custom environments that persist even when you switch instance types.

After you open JupyterLab, you can configure your environment using the terminal. To open the terminal, navigate to the **Launcher** and choose **Terminal**.

The following are examples of different ways that you can configure an environment in JupyterLab.

### Note

Within Studio, you can use lifecycle configurations to customize your environment, but we recommend using a package manager instead. Using lifecycle configurations is a more error-prone method. It's easier to add or remove dependencies than it is to debug a lifecycle configuration script. It can also increase the JupyterLab startup time. For information about lifecycle configurations, see [Lifecycle configurations with JupyterLab](#).

## Topics

- [Create a space](#)
- [Configure a space](#)
- [Customize your environment using a package manager](#)
- [Clean up a conda environment](#)
- [Share conda environments between instance types](#)
- [Use Amazon Q to Expedite Your Machine Learning Workflows](#)

## Create a space

To get started using JupyterLab, create a space or choose the space that your administrator created for you and open JupyterLab.

Use the following procedure to create a space and open JupyterLab.

## To create a space and open JupyterLab

1. Open Studio. For information about opening Studio, see [Launch Amazon SageMaker Studio](#).
2. Choose **JupyterLab**.
3. Choose **Create JupyterLab space**.
4. For **Name**, specify the name of the space.
5. (Optional) Select **Share with my domain** to create a shared space.
6. Choose **Create space**.
7. (Optional) For **Instance**, specify the Amazon EC2 instance that runs the space.
8. (Optional) For **Image**, specify an image that your administrator provided to customize your environment.

### Important

Custom IAM policies that allow Studio users to create spaces must also grant permissions to list images (`sagemaker: ListImage`) to view custom images. To add the permission, see [Add or remove identity permissions](#) in the *AWS Identity and Access Management User Guide*.

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker AI resources already include permissions to list images while creating those resources.

9. (Optional) For **Space Settings**, specify the following:
  - **Storage (GB)** – Up to 100 GB or the amount that your administrator specifies.
  - **Lifecycle Configuration** – A lifecycle configuration that your administrator specifies.
  - **Attach custom EFS filesystem** – An Amazon EFS to which your administrator provides access.
10. Choose **Run space**.
11. Choose **Open JupyterLab**.

## Configure a space

After you create a JupyterLab space, you can configure it to do the following:

- Change the instance type.

- Change the storage volume.
- (Admin set up required) Use a custom image.
- (Admin set up required) Use a lifecycle configuration.
- (Admin set up required) Attach a custom Amazon EFS.

### Important

You must stop the JupyterLab space every time you configure it. Use the following procedure to configure the space.

## To configure a space

1. Within Studio, navigate to the JupyterLab application page.
2. Choose the name of the space.
3. (Optional) For **Image**, specify an image that your administrator provided to customize your environment.

### Important

Custom IAM policies that allow Studio users to create spaces must also grant permissions to list images (`sagemaker: ListImage`) to view custom images. To add the permission, see [Add or remove identity permissions](#) in the *AWS Identity and Access Management User Guide*.

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker AI resources already include permissions to list images while creating those resources.

4. (Optional) For **Space Settings**, specify the following:
  - **Storage (GB)** – Up to 100 GB or the amount that your administrator configured for the space.
  - **Lifecycle Configuration** – A lifecycle configuration that your administrator provides.
  - **Attach custom EFS filesystem** – An Amazon EFS to which your administrator provides access.
5. Choose **Run space**.

When you open the JupyterLab application, your space has the updated configuration.

## Customize your environment using a package manager

Use pip or conda to customize your environment. We recommend using package managers instead of lifecycle configuration scripts.

### Create and activate your custom environment

This section provides examples of different ways that you can configure an environment in JupyterLab.

A basic conda environment has the minimum number of packages that are required for your workflows in SageMaker AI. Use the following template to create a basic conda environment:

```
# initialize conda for shell interaction
conda init

# create a new fresh environment
conda create --name test-env

# check if your new environment is created successfully
conda info --envs

# activate the new environment
conda activate test-env

# install packages in your new conda environment
conda install pip boto3 pandas ipykernel

# list all packages install in your new environment
conda list

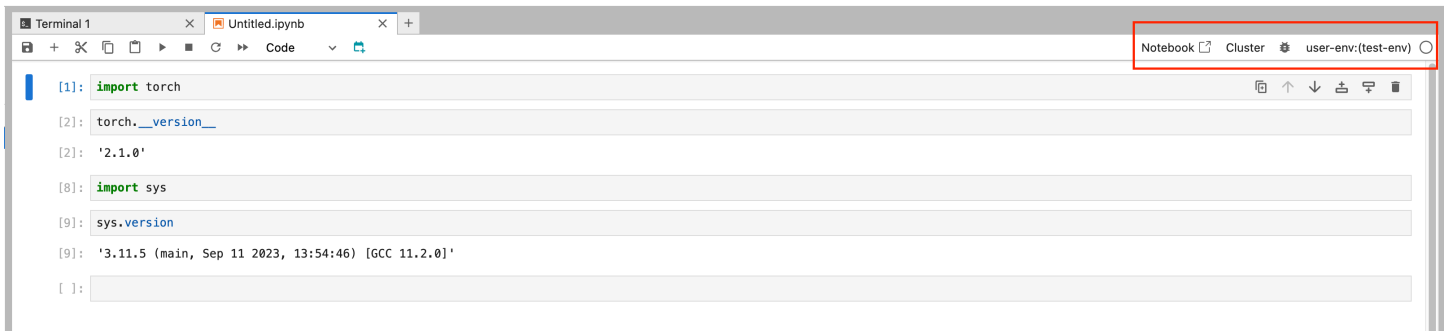

# parse env name information from your new environment
export CURRENT_ENV_NAME=$(conda info | grep "active environment" | cut -d : -f 2 | tr -d ' ')

# register your new environment as Jupyter Kernel for execution
python3 -m ipykernel install --user --name $CURRENT_ENV_NAME --display-name "user-env:
($CURRENT_ENV_NAME)"

# to exit your new environment
```

```
conda deactivate
```

The following image shows the location of the environment that you've created.

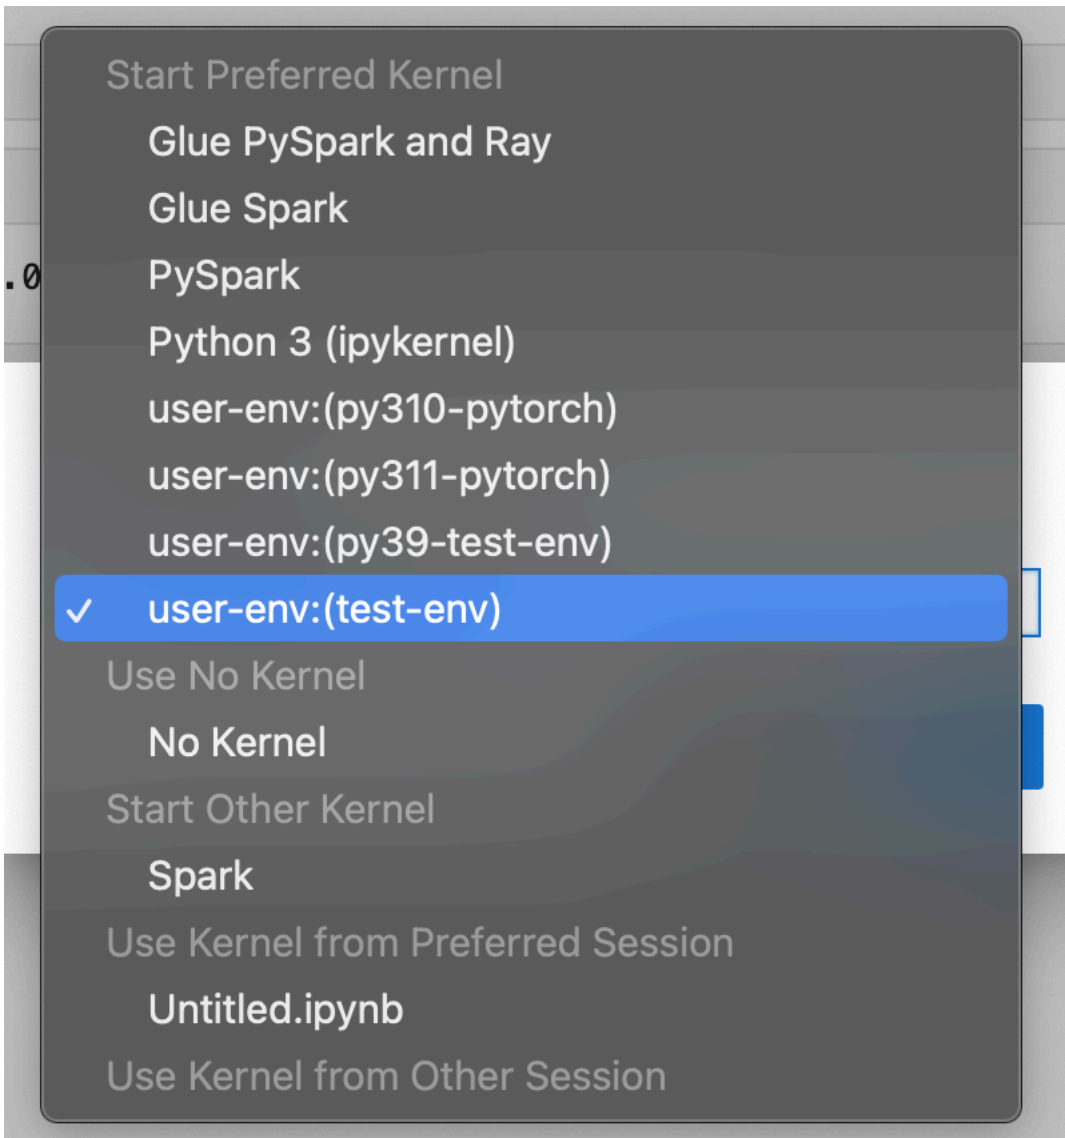

The screenshot shows a JupyterLab interface with a terminal window. The terminal displays the following code and output:

```
[1]: import torch
[2]: torch.__version__
[2]: '2.1.0'
[8]: import sys
[9]: sys.version
[9]: '3.11.5 (main, Sep 11 2023, 13:54:46) [GCC 11.2.0]'
[ ]:
```

In the top right corner, a dropdown menu is open, showing the current environment: `user-env:(test-env)`. The menu options include:

- Notebook
- Cluster
- user-env:(test-env)

To change your environment, choose it and select an option from the dropdown menu.

Choose **Select** to select a kernel for the environment.

## Create a conda environment with a specific Python version

Cleaning up conda environments that you're not using can help free up disk space and improve performance. Use the following template to clean up a conda environment:

```
# create a conda environment with a specific python version
conda create --name py38-test-env python=3.8.10

# activate and test your new python version
conda activate py38-test-env & python3 --version

# Install ipykernel to facilitate env registration
conda install ipykernel

# parse env name information from your new environment
export CURRENT_ENV_NAME=$(conda info | grep "active environment" | cut -d : -f 2 | tr -d ' ')

# register your new environment as Jupyter Kernel for execution
python3 -m ipykernel install --user --name $CURRENT_ENV_NAME --display-name "user-env: ($CURRENT_ENV_NAME)"

# deactivate your py38 test environment
conda deactivate
```

## Create a conda environment with a specific set of packages

Use the following template to create a conda environment with a specific version of Python and set of packages:

```
# prefill your conda environment with a set of packages,
conda create --name py38-test-env python=3.8.10 pandas matplotlib=3.7 scipy ipykernel

# activate your conda environment and ensure these packages exist
conda activate py38-test-env

# check if these packages exist
```

```
conda list | grep -E 'pandas|matplotlib|scipy'

# parse env name information from your new environment
export CURRENT_ENV_NAME=$(conda info | grep "active environment" | cut -d : -f 2 | tr -
d ' ')

# register your new environment as Jupyter Kernel for execution
python3 -m ipykernel install --user --name $CURRENT_ENV_NAME --display-name "user-env:
($CURRENT_ENV_NAME)"

# deactivate your conda environment
conda deactivate
```

## Clone conda from an existing environment

Clone your conda environment to preserve its working state. You experiment in the cloned environment without having to worry about introducing breaking changes in your test environment.

Use the following command to clone an environment.

```
# create a fresh env from a base environment
conda create --name py310-base-ext --clone base # replace 'base' with another env

# activate your conda environment and ensure these packages exist
conda activate py310-base-ext

# install ipykernel to register your env
conda install ipykernel

# parse env name information from your new environment
export CURRENT_ENV_NAME=$(conda info | grep "active environment" | cut -d : -f 2 | tr -
d ' ')

# register your new environment as Jupyter Kernel for execution
python3 -m ipykernel install --user --name $CURRENT_ENV_NAME --display-name "user-env:
($CURRENT_ENV_NAME)"

# deactivate your conda environment
conda deactivate
```

## Clone conda from a reference YAML file

Create a conda environment from a reference YAML file. The following is an example of a YAML file that you can use.

```
# anatomy of a reference environment.yml
name: py311-new-env
channels:
  - conda-forge
dependencies:
  - python=3.11
  - numpy
  - pandas
  - scipy
  - matplotlib
  - pip
  - ipykernel
  - pip:
    - git+https://github.com/huggingface/transformers
```

Under pip, we recommend specifying only the dependencies that aren't available with conda.

Use the following commands to create a conda environment from a YAML file.

```
# create your conda environment
conda env create -f environment.yml

# activate your env
conda activate py311-new-env
```

## Clean up a conda environment

Cleaning up conda environments that you're not using can help free up disk space and improve performance. Use the following template to clean up a conda environment:

```
# list your environments to select an environment to clean
conda info --envs # or conda info -e
```

```
# once you've selected your environment to purge
conda remove --name test-env --all

# run conda environment list to ensure the target environment is purged
conda info --envs # or conda info -e
```

## Share conda environments between instance types

You can share conda environments by saving them to an Amazon EFS directory outside of your Amazon EBS volume. Another user can access the environment in the directory where you saved it.

### Important

There are limitations with sharing your environments. For example, we don't recommend an environment meant to run on a GPU Amazon EC2 instance over an environment running on a CPU instance.

Use the following commands as a template to specify the target directory where you're creating a custom environment. You're creating a conda within a particular path. You create it within the Amazon EFS directory. You can spin up a new instance and do `conda activate path` and do it within the Amazon EFS.

```
# if you know your environment path for your conda environment
conda create --prefix /home/sagemaker-user/my-project/py39-test python=3.9

# activate the env with full path from prefix
conda activate home/sagemaker-user/my-project/py39-test

# parse env name information from your new environment
export CURRENT_ENV_NAME=$(conda info | grep "active environment" | awk -F' : ' '{print $2}' | awk -F'/' '{print $NF}')

# register your new environment as Jupyter Kernel for execution
python3 -m ipykernel install --user --name $CURRENT_ENV_NAME --display-name "user-env-
prefix:($CURRENT_ENV_NAME)"

# deactivate your conda environment
```

```
conda deactivate
```

## Use Amazon Q to Expedite Your Machine Learning Workflows

Amazon Q Developer is your AI-powered companion for machine learning development. With Amazon Q Developer, you can:

- Receive step-by-step guidance on using SageMaker AI features independently or in combination with other AWS services.
- Get sample code to get started on your ML tasks such as data preparation, training, inference, and MLOps.
- Receive troubleshooting assistance to debug and resolve errors encountered while running code.

Amazon Q Developer seamlessly integrates into your JupyterLab environment. To use Amazon Q Developer, choose the **Q** from the left-hand navigation of your JupyterLab environment or Code Editor environment.

If you don't see the **Q** icon, your administrator needs to set it up for you. For more information about setting up Amazon Q Developer, see [Set up Amazon Q Developer for your users](#).

Amazon Q automatically provides suggestions to help you write your code. You can also ask for suggestions through the chat interface.

## JupyterLab administrator guide

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

This guide for administrators describes SageMaker AI JupyterLab resources, such as those from Amazon Elastic Block Store (Amazon EBS) and Amazon Elastic Compute Cloud (Amazon EC2). The topics also show how to provide user access and change storage size.

A SageMaker AI JupyterLab space is composed of the following resources:

- A distinct Amazon EBS volume that stores all of the data, such as the code and the environment variables.
- The Amazon EC2 instance used to run the space.
- The image used to run JupyterLab.

 **Note**

Applications do not have access to the EBS volume of other applications. For example, Code Editor, based on Code-OSS, Visual Studio Code - Open Source doesn't have access to the EBS volume for JupyterLab. For more information about EBS volumes, see [Amazon Elastic Block Store \(Amazon EBS\)](#).

You can use the Amazon SageMaker API to do the following:

- Change the default storage size of the EBS volume for your users.
- Change the maximum size of the EBS storage
- Specify the user settings for the application. For example, you can specify whether the user is using a custom image or a code repository.
- Specify the support application type.

The default size of the Amazon EBS volume is 5 GB. You can increase the volume size to a maximum of 16,384 GB. If you don't do anything, your users can increase their volume size to 100 GB. The volume size can be changed only once within a six hour period.

The kernels associated with the JupyterLab application run on the same Amazon EC2 instance that runs JupyterLab. When you create a space, the latest version of the SageMaker Distribution Image is used by default. For more information about SageMaker Distribution Images, see [SageMaker Studio image support policy](#).

**⚠ Important**

For information about updating the space to use the latest version of the SageMaker AI Distribution Image, see [Update the SageMaker Distribution Image](#).

The working directory of your users within the storage volume is `/home/sagemaker-user`. If you specify your own AWS KMS key to encrypt the volume, everything in the working directory is encrypted using your customer managed key. If you don't specify an AWS KMS key, the data inside `/home/sagemaker-user` is encrypted with an AWS managed key. Regardless of whether you specify an AWS KMS key, all of the data outside of the working directory is encrypted with an AWS Managed Key.

The following sections walk you through the configurations that you need to perform as an administrator.

**Topics**

- [Give your users access to spaces](#)
- [Change the default storage size for your JupyterLab users](#)
- [Lifecycle configurations with JupyterLab](#)
- [Git repos in JupyterLab](#)
- [Customize environments using custom images](#)
- [Update the SageMaker Distribution Image](#)
- [Delete unused resources](#)
- [Quotas](#)

**Give your users access to spaces**

To give users access to private or shared spaces, you must attach a permissions policy to their IAM roles. You can also use the permissions policy to restrict private spaces and their associated applications to a specific user profile.

The following permissions policy grants access to private and shared spaces. This allows users to create their own space and list other spaces within their domain. A user with this policy can't access the private space of a different user. For information about Studio spaces, see [Amazon SageMaker Studio spaces](#).

The policy provides users with permissions to the following:

- Private spaces or shared spaces.
- A user profile for accessing those spaces.

To provide permissions, you can scope down the permissions of the following policy and add it to the IAM roles of your users. You can also use this policy to restrict your spaces, and their associated applications, to a specific user profile.

```

## Change the default storage size for your JupyterLab users

You can change the default storage settings for your users. You can also change the default storage settings based on your organizational requirements and the needs of your users.

To change the storage size, this section provides commands to do the following:

1. Update the Amazon EBS storage settings in the Amazon SageMaker AI domain (domain).
2. Create a user profile and specify the storage settings within it.

Use the following AWS Command Line Interface (AWS CLI) commands to change the default storage size.

Use the following AWS CLI command to update the domain:

```
aws --region AWS Region sagemaker update-domain \  
--domain-id domain-id \  
--default-user-settings '{  
  "SpaceStorageSettings": {  
    "DefaultEbsStorageSettings":{  
      "DefaultEbsVolumeSizeInGb":5,  
      "MaximumEbsVolumeSizeInGb":100  
    }  
  }  
'
```

Use the following AWS CLI command to create the user profile and specify the default storage settings:

```
aws --region AWS Region sagemaker create-user-profile \  
--domain-id domain-id \  
--user-profile-name user-profile-name \  
--user-settings '{  
  "SpaceStorageSettings": {  
    "DefaultEbsStorageSettings":{  
      "DefaultEbsVolumeSizeInGb":5,  
      "MaximumEbsVolumeSizeInGb":100  
    }  
  }  
'
```

```
}'
```

Use the following AWS CLI commands to update the default storage settings in the user profile:

```
aws --region AWS Region sagemaker update-user-profile \  
--domain-id domain-id \  
--user-profile-name user-profile-name \  
--user-settings '{  
  "SpaceStorageSettings": {  
    "DefaultEbsStorageSettings":{  
      "DefaultEbsVolumeSizeInGb":25,  
      "MaximumEbsVolumeSizeInGb":200  
    }  
  }  
'
```

## Lifecycle configurations with JupyterLab

Lifecycle configurations are shell scripts that are triggered by JupyterLab lifecycle events, such as starting a new JupyterLab notebook. You can use lifecycle configurations to automate customization for your JupyterLab environment. This customization includes installing custom packages, configuring notebook extensions, preloading datasets, and setting up source code repositories.

Using lifecycle configurations gives you flexibility and control to configure JupyterLab to meet your specific needs. For example, you can create a minimal set of base container images with the most commonly used packages and libraries. Then you can use lifecycle configurations to install additional packages for specific use cases across your data science and machine learning teams.

### Note

Each script has a limit of **16,384 characters**.

## Topics

- [Lifecycle configuration creation](#)
- [Debug lifecycle configurations](#)

- [Detach lifecycle configurations](#)

## Lifecycle configuration creation

This topic includes instructions for creating and associating a lifecycle configuration with JupyterLab. You use the AWS Command Line Interface (AWS CLI) or the AWS Management Console to automate customization for your JupyterLab environment.

Lifecycle configurations are shell scripts triggered by JupyterLab lifecycle events, such as starting a new JupyterLab notebook. For more information about lifecycle configurations, see [Lifecycle configurations with JupyterLab](#).

### Create a lifecycle configuration (AWS CLI)

Learn how to create a lifecycle configuration using the AWS Command Line Interface (AWS CLI) to automate customization for your Studio environment.

### Prerequisites

Before you begin, complete the following prerequisites:

- Update the AWS CLI by following the steps in [Installing the current AWS CLI Version](#).
- From your local machine, run `aws configure` and provide your AWS credentials. For information about AWS credentials, see [Understanding and getting your AWS credentials](#).
- Onboard to Amazon SageMaker AI domain. For conceptual information, see [Amazon SageMaker AI domain overview](#). For a quickstart guide, see [Use quick setup for Amazon SageMaker AI](#).

### Step 1: Create a lifecycle configuration

The following procedure shows how to create a lifecycle configuration script that prints Hello World.

#### Note

Each script can have up to **16,384 characters**.

1. From your local machine, create a file named `my-script.sh` with the following content:

```
#!/bin/bash
```

```
set -eux
echo 'Hello World!'
```

2. Use the following to convert your `my-script.sh` file into base64 format. This requirement prevents errors that occur from spacing and line break encoding.

```
LCC_CONTENT=`openssl base64 -A -in my-script.sh`
```

3. Create a lifecycle configuration for use with Studio. The following command creates a lifecycle configuration that runs when you launch an associated JupyterLab application:

```
aws sagemaker create-studio-lifecycle-config \
--region region \
--studio-lifecycle-config-name my-jl-lcc \
--studio-lifecycle-config-content $LCC_CONTENT \
--studio-lifecycle-config-app-type JupyterLab
```

Note the ARN of the newly created lifecycle configuration that is returned. This ARN is required to attach the lifecycle configuration to your application.

## Step 2: Attach the lifecycle configuration to your Amazon SageMaker AI domain (domain) and user profile

To attach the lifecycle configuration, you must update the `UserSettings` for your domain or user profile. Lifecycle configuration scripts that are associated at the domain level are inherited by all users. However, scripts that are associated at the user profile level are scoped to a specific user.

You can create a new user profile, domain, or space with a lifecycle configuration attached by using the following commands:

- [create-user-profile](#)
- [create-domain](#)
- [create-space](#)

The following command creates a user profile with a lifecycle configuration. Add the lifecycle configuration ARN from the preceding step to the `JupyterLabAppSettings` of the user. You can add multiple lifecycle configurations at the same time by passing a list of them. When a user launches a JupyterLab application with the AWS CLI, they can specify a lifecycle configuration

instead of using the default one. The lifecycle configuration that the user passes must belong to the list of lifecycle configurations in `JupyterLabAppSettings`.

```
# Create a new UserProfile
aws sagemaker create-user-profile --domain-id domain-id \
--user-profile-name user-profile-name \
--region region \
--user-settings '{
  "JupyterLabAppSettings": {
    "LifecycleConfigArns":
      [lifecycle-configuration-arn-list]
  }
}'
```

## Create a lifecycle configuration (Console)

Learn how to create a lifecycle configuration using the AWS Management Console to automate customization for your Studio environment.

### Step 1: Create a lifecycle configuration

Use the following procedure to create a lifecycle configuration script that prints Hello World.

#### To create a lifecycle configuration

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Lifecycle configurations**.
4. Choose the **JupyterLab** tab.
5. Choose **Create configuration**.
6. For **Name**, specify the name of the lifecycle configuration.
7. For the text box under **Scripts**, specify the following lifecycle configuration:

```
#!/bin/bash
set -eux
echo 'Hello World!'
```

8. Choose **Create configuration**.

## Step 2: Attach the lifecycle configuration to your Amazon SageMaker AI domain (domain) and user profile

Lifecycle configuration scripts associated at the domain level are inherited by all users. However, scripts that are associated at the user profile level are scoped to a specific user.

You can attach multiple lifecycle configurations to a domain or user profile for JupyterLab.

Use the following procedure to attach a lifecycle configuration to a domain.

### To attach a lifecycle configuration to a domain

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain to attach the lifecycle configuration to.
5. From the **Domain details**, choose the **Environment** tab.
6. Under **Lifecycle configurations for personal Studio apps**, choose **Attach**.
7. Under **Source**, choose **Existing configuration**.
8. Under **Studio lifecycle configurations**, select the lifecycle configuration that you created in the previous step.
9. Select **Attach to domain**.

Use the following procedure to attach a lifecycle configuration to a user profile.

### To attach a lifecycle configuration to a user profile

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain that contains the user profile to attach the lifecycle configuration to.
5. Under **User profiles**, select the user profile.
6. From the **User Details** page, choose **Edit**.
7. On the left navigation, choose **Studio settings**.
8. Under **Lifecycle configurations attached to user**, choose **Attach**.

9. Under **Source**, choose **Existing configuration**.
10. Under **Studio lifecycle configurations**, select the lifecycle configuration that you created in the previous step.
11. Choose **Attach to user profile**.

## Debug lifecycle configurations

The following topics show how to get information about and debug your lifecycle configurations.

### Topics

- [Verify lifecycle configuration process from CloudWatch Logs](#)
- [Lifecycle configuration timeout](#)

## Verify lifecycle configuration process from CloudWatch Logs

Lifecycle configurations only log STDOUT and STDERR.

STDOUT is the default output for bash scripts. You can write to STDERR by appending `>&2` to the end of a bash command. For example, `echo 'hello'>&2`.

Logs for your lifecycle configurations are published to your AWS account using Amazon CloudWatch. These logs can be found in the `/aws/sagemaker/studio` log stream in the CloudWatch console.

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Choose **Logs** from the left navigation pane. From the dropdown menu, select **Log groups**.
3. On the **Log groups** page, search for `aws/sagemaker/studio`.
4. Select the log group.
5. On the **Log group details** page, choose the **Log streams** tab.
6. To find the logs for a specific app, search the log streams using the following format:

```
domain-id/user-profile-name/app-type/app-name
```

The following search string finds the lifecycle configuration logs for the domain `d-m851cu8vbqmqz`, user profile `i-sonic-js`, application type `JupyterLab`, and application name `test-lcc-echo`:

```
d-m851cu8vbqz/i-sonic-js/JupyterLab/test-lcc-echo
```

7. To view the script execution logs, select the log stream appended with `LifecycleConfigOnStart`.

## Lifecycle configuration timeout

There is a lifecycle configuration timeout limitation of 5 minutes. If a lifecycle configuration script takes longer than 5 minutes to run, you get an error.

To resolve this error, make sure that your lifecycle configuration script completes in less than 5 minutes.

To help decrease the runtime of scripts, try the following:

- Reduce unnecessary steps. For example, limit which conda environments to install large packages in.
- Run tasks in parallel processes.
- Use the `nohup` command in your script to make sure that hangup signals are ignored so that the script runs without stopping.

## Detach lifecycle configurations

To update your script, you must create a new lifecycle configuration script and attach it to the respective Amazon SageMaker AI domain (domain), user profile, or shared space. A lifecycle configuration script can't be changed after it's created. For more information about creating and attaching the lifecycle configuration, see [Lifecycle configuration creation](#).

The following section shows how to detach a lifecycle configuration using the AWS Command Line Interface (AWS CLI).

### Detach using the AWS CLI

To detach a lifecycle configuration using the (AWS CLI), remove the desired lifecycle configuration from the list of lifecycle configurations attached to the resource. You then pass the list as part of the respective command:

- [update-user-profile](#)

- [update-domain](#)
- [update-space](#)

For example, the following command removes all lifecycle configurations for the JupyterLab application that's attached to the domain.

```
aws sagemaker update-domain --domain-id domain-id \  
--region region \  
--default-user-settings '{  
  "JupyterLabAppSettings": {  
    "LifecycleConfigArns":  
      []  
  }  
'
```

## Git repos in JupyterLab

JupyterLab offers a Git extension to enter the URL of a Git repository (repo), clone it into an environment, push changes, and view the commit history. You can also attach suggested Git repo URLs to a Amazon SageMaker AI domain (domain) or user profile.

The following sections show how to attach or detach Git repo URLs.

### Topics

- [Attach a Git repository \(AWS CLI\)](#)
- [Detach Git repo URLs](#)

### Attach a Git repository (AWS CLI)

This section shows how to attach a Git repository (repo) URL using the AWS CLI. After you attach the Git repo URL, you can clone it by following the steps in [Clone a Git repo in Amazon SageMaker Studio](#).

### Prerequisites

Before you begin, complete the following prerequisites:

- Update the AWS CLI by following the steps in [Installing the current AWS Command Line Interface Version](#).

- From your local machine, run `aws configure` and provide your AWS credentials. For information about AWS credentials, see [Understanding and getting your AWS credentials](#).
- Onboard to Amazon SageMaker AI domain. For more information, see [Amazon SageMaker AI domain overview](#).

## Attach the Git repo to a Amazon SageMaker AI domain (domain) or user profile

Git repo URLs that are associated at the domain level are inherited by all users. However, Git repo URLs that are associated at the user profile level are scoped to a specific user. You can attach multiple Git repo URLs to a Amazon SageMaker AI domain or to a user profile by passing a list of repository URLs.

The following sections show how to attach a Git repo URL to your domain and your user profile.

### Attach to a Amazon SageMaker AI domain

The following command attaches a Git repo URL to an existing domain:

```
aws sagemaker update-domain --region region --domain-id domain-id \  
  --default-user-settings  
  JupyterLabAppSettings={CodeRepositories=[{RepositoryUrl="repository"}]}
```

### Attach to a user profile

The following command attaches a Git repo URL to an existing user profile:

```
aws sagemaker update-user-profile --domain-id domain-id --user-profile-name user-name \  
  --user-settings  
  JupyterLabAppSettings={CodeRepositories=[{RepositoryUrl="repository"}]}
```

## Clone a Git repo in Amazon SageMaker Studio

Amazon SageMaker Studio connects to a local Git repo only. To access the files in the repo, clone the Git repo from within Studio. To do so, Studio offers a Git extension for you to enter the URL of a Git repo, clone it into your environment, push changes, and view commit history.

If the repo is private and requires credentials to access, you receive a prompt to enter your user credentials. Your credentials include your username and personal access token. For more information about personal access tokens, see [Managing your personal access tokens](#).

Admins can also attach suggested Git repository URLs at the Amazon SageMaker AI domain or user profile level. Users can then select the repo URL from the list of suggestions and clone that into Studio. For more information about attaching suggested repos, see [Attach Suggested Git Repos to Studio Classic](#).

## Detach Git repo URLs

This section shows how to detach Git repository URLs from an Amazon SageMaker AI domain (domain) or a user profile. You can detach repo URLs by using the AWS Command Line Interface (AWS CLI) or the Amazon SageMaker AI console.

### Detach a Git repo using the AWS CLI

To detach all Git repo URLs from a domain or user profile, you must pass an empty list of code repositories. This list is passed as part of the `JupyterLabAppSettings` parameter in an `update-domain` or `update-user-profile` command. To detach only one Git repo URL, pass the code repositories list without the desired Git repo URL.

#### Detach from an Amazon SageMaker AI domain

The following command detaches all Git repo URLs from a domain:

```
aws sagemaker update-domain --region region --domain-name domain-name \  
  --domain-settings JupyterLabAppSettings={CodeRepositories=[]}
```

#### Detach from a user profile

The following command detaches all Git repo URLs from a user profile:

```
aws sagemaker update-user-profile --domain-name domain-name --user-profile-name user-  
name \  
  --user-settings JupyterLabAppSettings={CodeRepositories=[]}
```

## Customize environments using custom images

If you need functionality that is different than what's provided by SageMaker distribution, you can bring your own image with your custom extensions and packages. You can also use it to personalize the JupyterLab UI for your own branding or compliance needs.

For a tutorial that helps you create an image that your users can run in their JupyterLab environment, see [Provide users with access to custom images](#).

For requirements for your image, see [Dockerfile specifications](#).

## Topics

- [Provide users with access to custom images](#)
- [Dockerfile specifications](#)

### Provide users with access to custom images

This documentation provides step-by-step instructions to provide your users with access to custom images within their JupyterLab environments. You can use the information on this page to create custom environments for your user's workflows. The process involves utilizing:

- Docker
- AWS Command Line Interface
- Amazon Elastic Container Registry
- Amazon SageMaker AI AWS Management Console

After following the guidance on this page, JupyterLab users on the Amazon SageMaker AI domain will have access to the custom image and environment from their Jupyter spaces to empower their machine learning workflows.

#### Important

This page assumes that you have the AWS Command Line Interface and Docker installed on your local machine.

To have your users successfully run their image within JupyterLab, you must do the following:

#### To have your users successfully run the image

1. Create the Dockerfile
2. Build the image from the Dockerfile
3. Upload the image to Amazon Elastic Container Registry
4. Attach the image to your Amazon SageMaker AI domain
5. Have your users access the image from your JupyterLab space

## Step 1: Create the Dockerfile

Create a Dockerfile to define the steps needed to create the environment needed to run the application in your users' containers.

### Important

Your Dockerfile must meet the specifications provided in [Dockerfile specifications](#).

For Dockerfile templates, see [Health check and URL for applications](#).

## Step 2: Build the image

In the same directory as your Dockerfile, build your image using the following command:

```
docker build -t username/imagename:tag your-account-id.dkr.ecr.AWS  
Region.amazonaws.com/your-repository-name:tag
```

### Important

Your image must be tagged in the following format: *123456789012*.dkr.ecr.your-region.amazonaws.com/*your-repository-name*:tag

You won't be able to push it to an Amazon Elastic Container Registry repository otherwise.

## Step 3: Push the image to the Amazon Elastic Container Registry repository

After you've built your image, log in to your Amazon ECR repository using the following command:

```
aws ecr get-login-password --region AWS Region | docker login --username AWS --  
password-stdin 123456789012.dkr.ecr.AWS Region.amazonaws.com
```

After you've logged in, push your Dockerfile using the following command:

```
docker push 123456789012.dkr.ecr.AWS Region.amazonaws.com/your-repository-name:tag
```

## Step 4: Attach image to the Amazon SageMaker AI domain of your users

### Important

Custom IAM policies that allow Studio users to create spaces must also grant permissions to list images (`sagemaker: ListImage`) to view custom images. To add the permission, see [Add or remove identity permissions](#) in the *AWS Identity and Access Management User Guide*.

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker AI resources already include permissions to list images while creating those resources.

After you've pushed the image, you must access it from your Amazon SageMaker AI domain. Use the following procedure to attach the image to a SageMaker AI domain:

### Attach the image using the SageMaker AI console

1. Open the [SageMaker AI console](#).
2. Under **Admin configurations**, choose **domains**.
3. From the list of **domains**, select a domain.
4. Open the **Environment** tab.
5. For **Custom images for personal Studio apps**, choose **Attach image**.
6. Specify the image source.
7. Choose **Next**.
8. Choose **Submit**.

### Attach the image using the AWS CLI

Use the following procedure to attach the image to a SageMaker domain through the AWS CLI :

1. Create a SageMaker image. The `AmazonSageMakerFullAccess` policy must be attached to your role as you use the following AWS CLI commands.

```
aws sagemaker create-image \
```

```
--image-name custom-image \  
--role-arn arn:aws:iam::account-id:role/service-role/execution-role
```

2. Create a SageMaker image version from the image. Pass the unique tag value that you chose when you pushed the image to Amazon ECR.

```
aws sagemaker create-image-version \  
--image-name custom-image \  
--base-image repository-uri:tag
```

3. Create a configuration file called `app-image-config-input.json`. The application image configuration is used as configuration for running a SageMaker image as a Code Editor application. You may also specify your [ContainerConfig](#) arguments here.

```
{  
  "AppImageConfigName": "app-image-config",  
  "CodeEditorAppImageConfig":  
  {  
    "ContainerConfig":  
    {}  
  }  
}
```

4. Create the `AppImageConfig` using the application image configuration file that you created.

```
aws sagemaker create-app-image-config \  
--cli-input-json file://app-image-config-input.json
```

5. Create a configuration file, named `updateDomain.json`. Be sure to specify your domain ID.

```
{  
  "DomainId": "domain-id",  
  "DefaultUserSettings": {  
    "JupyterLabAppSettings": {  
      "CustomImages": [  
        {  
          "ImageName": "custom-image",  
          "AppImageConfigName": "app-image-config"  
        }  
      ]  
    }  
  }  
}
```

```
}
```

6. Call the `UpdateDomain` command with the configuration file as input.

### Note

You must delete all of the applications in your domain before updating the domain with the new image. Note that you only need to delete applications; you **do not** need to delete user profiles or shared spaces. For instructions on deleting applications, choose one of the following options.

- If you use the SageMaker AI console, run through Step 1 to 5d and Step 6 to 7d of the [Delete a domain \(Console\)](#) section.
- If you use the AWS CLI, run through Step 1 to 3 of the [Delete a domain \(AWS CLI\)](#) section.

```
aws sagemaker update-domain --cli-input-json file://updateDomain.json
```

Your users can now select the image that you've attached to their Domain from their JupyterLab space.

## Dockerfile specifications

The image that you specify in your Dockerfile must match the specifications in the following sections to create the image successfully.

### Running the image

- `Entrypoint` – We recommend embedding the entry point into the image using the Docker `CMD` or `Entrypoint` instructions. You can also configure `ContainerEntrypoint` and `ContainerArguments` that are passed to the container at runtime.
- `EnvVariables` – With Studio, you can configure `ContainerEnvironment` variables that are made available to a container. The environment variable is overwritten with the environment variables from SageMaker AI. To provide you with a better experience, the environment variables are usually `AWS_` and `SageMaker_AI_` namespaced to give priority to platform environments.

The following are the environment variables:

- `AWS_REGION`
- `AWS_DEFAULT_REGION`
- `AWS_CONTAINER_CREDENTIALS_RELATIVE_URI`
- `SageMaker AI_SPACE_NAME`

## Specifications for the user and file system

- **WorkingDirectory** – The Amazon EBS volume for your space is mounted on the path `/home/sagemaker-user`. You can't change the mount path. Use the `WORKDIR` instruction to set the working directory of your image to a folder within `/home/sagemaker-user`.
- **UID** – The user ID of the Docker container. `UID=1000` is a supported value. You can add `sudo` access to your users. The IDs are remapped to prevent a process running in the container from having more privileges than necessary.
- **GID** – The group ID of the Docker container. `GID=100` is a supported value. You can add `sudo` access to your users. The IDs are remapped to prevent a process running in the container from having more privileges than necessary.
- **Metadata directories** – The `/opt/.sagemakerinternal` and `/opt/ml` directories that are used by AWS. The metadata file in `/opt/ml` contains metadata about resources such as `DomainId`.

Use the following command to show the file system contents:

```
cat /opt/ml/metadata/resource-metadata.json
{"AppType":"JupyterLab","DomainId":"example-domain-id","UserProfileName":"example-user-profile-name","ResourceArn":"arn:aws:sagemaker:AWS Region:111122223333;:app/domain-ID/user-ID/JupyterLab/default","ResourceName":"default","AppImageVersion":"current"}
```

- **Logging directories** – `/var/log/studio` are reserved for the logging directories of JupyterLab and the extensions associated with it. We recommend that you don't use the folders in creating your image.

## Health check and URL for applications

- **Base URL** – The base URL for the BYOI application must be `jupyterlab/default`. You can only have one application and it must always be named `default`.
- **HealthCheck API** – The HostAgent uses the HealthCheckAPI at port 8888 to check the health of the JupyterLab application. `jupyterlab/default/api/status` is the endpoint for the health check.
- **Home/Default URL** – The `/opt/.sagemakerinternal` and `/opt/ml` directories that are used by AWS. The metadata file in `/opt/ml` contains metadata about resources such as `DomainId`.
- **Authentication** – To enable authentication for your users, turn off the Jupyter notebooks token or password based authentication and allow all origins.

The following is a sample Amazon Linux 2 Dockerfile that meets the preceding specifications:

```
FROM public.ecr.aws/amazonlinux/amazonlinux:2023

ARG NB_USER="sagemaker-user"
ARG NB_UID="1000"
ARG NB_GID="100"

# Install Python3, pip, and other dependencies
RUN yum install -y \
    python3 \
    python3-pip \
    python3-devel \
    gcc \
    shadow-utils && \
    useradd --create-home --shell /bin/bash --gid "${NB_GID}" --uid ${NB_UID} \
    ${NB_USER} && \
    yum clean all

RUN python3 -m pip install --no-cache-dir \
    'jupyterlab>=4.0.0,<5.0.0' \
    urllib3 \
    jupyter-activity-monitor-extension \
    --ignore-installed

# Verify versions
RUN python3 --version && \
```

```
jupyter lab --version

USER ${NB_UID}
CMD jupyter lab --ip 0.0.0.0 --port 8888 \
    --ServerApp.base_url="/jupyterlab/default" \
    --ServerApp.token='' \
    --ServerApp.allow_origin='*'
```

The following is a sample Amazon SageMaker Distribution Dockerfile that meets the preceding specifications:

```
FROM public.ecr.aws/sagemaker/sagemaker-distribution:latest-cpu
ARG NB_USER="sagemaker-user"
ARG NB_UID=1000
ARG NB_GID=100

ENV MAMBA_USER=$NB_USER

USER root

RUN apt-get update
RUN micromamba install sagemaker-inference --freeze-installed --yes --channel conda-
forge --name base

USER $MAMBA_USER

ENTRYPOINT ["jupyter-lab"]
CMD ["--ServerApp.ip=0.0.0.0", "--ServerApp.port=8888", "--ServerApp.allow_origin=*",
    "--ServerApp.token=''", "--ServerApp.base_url=/jupyterlab/default"]
```

## Update the SageMaker Distribution Image

### Important

This topic assumes that you've created a space and given the user access to it. For more information, see [Give your users access to spaces](#).

Update the JupyterLab spaces that you've already created to use the latest version of the SageMaker Distribution Image to access the latest features. You can use either the Studio UI or the AWS Command Line Interface (AWS CLI) to update the image.

The following sections provide information about updating an image.

### Update the image (UI)

Updating the image involves restarting the JupyterLab space of your user. Use the following procedure to update your user's JupyterLab space with the latest image.

#### To update the image (UI)

1. Open Studio. For information about opening Studio, see [Launch Amazon SageMaker Studio](#).
2. Choose **JupyterLab**.
3. Select the JupyterLab space of your user.
4. Choose **Stop space**.
5. For **Image**, select an updated version of the SageMaker AI Distribution Image. For the latest image, choose **Latest**.
6. Choose **Run space**.

### Update the image (AWS CLI)

This section assumes that you have the AWS Command Line Interface (AWS CLI) installed. For information about installing the AWS CLI, see [Install or update to the latest version of the AWS CLI](#).

To update the image, you must do the following for your user's space:

1. Delete the JupyterLab application
2. Update the space
3. Create the application

#### Important

You must have the following information ready before you start updating the image:

- domain ID – The ID of your user's Amazon SageMaker AI domain.

- Application type – JupyterLab.
- Application name – default.
- Space name – The name specified for the space.
- Instance type – The Amazon EC2 instance type that you're using to run the application. For example, `m1.t3.medium`.
- SageMaker Image ARN – The Amazon Resource Name (ARN) of the SageMaker AI Distribution Image. You can provide the latest version of the SageMaker AI Distribution Image by specifying either `sagemaker-distribution-cpu` or `sagemaker-distribution-gpu` as the resource identifier.

To delete the JupyterLab application, run the following command:

```
aws sagemaker delete-app \  
--domain-id your-user's-domain-id \  
--app-type JupyterLab \  
--app-name default \  
--space-name name-of-your-user's-space
```

To update your user's space, run the following command:

```
aws sagemaker update-space \  
--space-name name-of-your-user's-space \  
--domain-id your-user's-domain-id
```

If you've updated the space successfully, you'll see the space ARN in the response:

```
{  
"SpaceArn": "arn:aws:sagemaker:AWS Region:111122223333:space/your-user's-domain-id/  
name-of-your-user's-space"  
}
```

To create the application, run the following command:

```
aws sagemaker create-app \  
--domain-id your-user's-domain-id \  
--app-type JupyterLab \  
--app-name default \  
--space-name name-of-your-user's-space \  
--resource-spec "InstanceType=instance-type,SageMakerImageArn=arn:aws:sagemaker:AWS  
Region:555555555555:image/sagemaker-distribution-resource-identifier"
```

## Delete unused resources

To avoid incurring additional costs running JupyterLab, we recommend deleting unused resources in the following order:

1. JupyterLab applications
2. Spaces
3. User profiles
4. domains

Use the following AWS Command Line Interface (AWS CLI) commands to delete resources within a domain:

### Delete a JupyterLab application

```
aws --region AWS Region sagemaker delete-app --domain-id example-domain-id --app-  
name default --app-type JupyterLab --space-name example-space-name
```

## Delete a space

### Important

If you delete a space, you delete the Amazon EBS volume associated with it. We recommend backing up any valuable data before you delete your space.

```
aws --region AWS Region sagemaker delete-space --domain-id example-domain-id --  
space-name example-space-name
```

## Delete a user profile

```
aws --region AWS Region sagemaker delete-user-profile --domain-id example-domain-id  
--user-profile example-user-profile
```

## Quotas

JupyterLab, has quotas for the following:

- The sum of all Amazon EBS volumes within an AWS account.
- The instance types that are available for your users.
- The number of instances for a particular that your users can launch.

To get more storage and compute for your users, request an increase to your AWS quotas. For more information about requesting a quota increase, see [Amazon SageMaker AI endpoints and quotas](#).

## Amazon SageMaker Notebook Instances

An Amazon SageMaker notebook instance is a machine learning (ML) compute instance running the Jupyter Notebook application. One of the best ways for machine learning (ML) practitioners to use Amazon SageMaker AI is to train and deploy ML models using SageMaker notebook instances. The SageMaker notebook instances help create the environment by initiating Jupyter servers

on Amazon Elastic Compute Cloud (Amazon EC2) and providing preconfigured kernels with the following packages: the Amazon SageMaker Python SDK, AWS SDK for Python (Boto3), AWS Command Line Interface (AWS CLI), Conda, Pandas, deep learning framework libraries, and other libraries for data science and machine learning.

Use Jupyter notebooks in your notebook instance to:

- prepare and process data
- write code to train models
- deploy models to SageMaker hosting
- test or validate your models

SageMaker AI also provides sample notebooks that contain complete code examples. These examples show how to use SageMaker AI to do common ML tasks. For more information, see [Access example notebooks](#).

For information about pricing with Amazon SageMaker notebook instance, see [Amazon SageMaker Pricing](#).

## Maintenance

SageMaker AI updates the underlying software for Amazon SageMaker Notebook Instances at least once every 90 days. Some maintenance updates, such as operating system upgrades, may require your application to be taken offline for a short period of time. It is not possible to perform any operations during this period while the underlying software is being updated. We recommend that you restart your notebooks at least once every 30 days to automatically consume patches.

For more information, contact [AWS Support](#).

## Machine Learning with the SageMaker Python SDK

To train, validate, deploy, and evaluate an ML model in a SageMaker notebook instance, use the SageMaker Python SDK. The SageMaker Python SDK abstracts AWS SDK for Python (Boto3) and SageMaker API operations. It enables you to integrate with and orchestrate other AWS services, such as Amazon Simple Storage Service (Amazon S3) for saving data and model artifacts, Amazon Elastic Container Registry (ECR) for importing and servicing the ML models, Amazon Elastic Compute Cloud (Amazon EC2) for training and inference.

You can also take advantage of SageMaker AI features that help you deal with every stage of a complete ML cycle: data labeling, data preprocessing, model training, model deployment, evaluation on prediction performance, and monitoring the quality of model in production.

If you're a first-time SageMaker AI user, we recommend you to use the SageMaker Python SDK, following the end-to-end ML tutorial. To find the open source documentation, see the [Amazon SageMaker Python SDK](#).

## Tutorial for building models with Notebook Instances

This Get Started tutorial walks you through how to create a SageMaker notebook instance, open a Jupyter notebook with a preconfigured kernel with the Conda environment for machine learning, and start a SageMaker AI session to run an end-to-end ML cycle. You'll learn how to save a dataset to a default Amazon S3 bucket automatically paired with the SageMaker AI session, submit a training job of an ML model to Amazon EC2, and deploy the trained model for prediction by hosting or batch inferencing through Amazon EC2.

This tutorial explicitly shows a complete ML flow of training the XGBoost model from the SageMaker AI built-in model pool. You use the [US Adult Census dataset](#), and you evaluate the performance of the trained SageMaker AI XGBoost model on predicting individuals' income.

- [SageMaker AI XGBoost](#) – The [XGBoost](#) model is adapted to the SageMaker AI environment and preconfigured as Docker containers. SageMaker AI provides a suite of [built-in algorithms](#) that are prepared for using SageMaker AI features. To learn more about what ML algorithms are adapted to SageMaker AI, see [Choose an Algorithm](#) and [Use Amazon SageMaker Built-in Algorithms](#). For the SageMaker AI built-in algorithm API operations, see [First-Party Algorithms](#) in the [Amazon SageMaker Python SDK](#).
- [Adult Census dataset](#) – The dataset from the [1994 Census bureau database](#) by Ronny Kohavi and Barry Becker (Data Mining and Visualization, Silicon Graphics). The SageMaker AI XGBoost model is trained using this dataset to predict if an individual makes over \$50,000 a year or less.

## Create an Amazon SageMaker Notebook Instance for the tutorial

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

An Amazon SageMaker notebook instance is a fully-managed machine learning (ML) Amazon Elastic Compute Cloud (Amazon EC2) compute instance. An Amazon SageMaker notebook instance runs the Jupyter Notebook application. Use the notebook instance to create and manage Jupyter notebooks for preprocessing data, train ML models, and deploy ML models.

### To create a SageMaker notebook instance

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. Choose **Notebook instances**, and then choose **Create notebook instance**.
3. On the **Create notebook instance** page, provide the following information (if a field is not mentioned, leave the default values):
  - a. For **Notebook instance name**, type a name for your notebook instance.
  - b. For **Notebook Instance type**, choose `m1.t2.medium`. This is the least expensive instance type that notebook instances support, and is enough for this exercise. If a `m1.t2.medium` instance type isn't available in your current AWS Region, choose `m1.t3.medium`.
  - c. For **Platform Identifier**, choose a platform type to create the notebook instance on. This platform type defines the Operating System and the JupyterLab version that your notebook instance is created with. For information about platform identifier type, see [Amazon Linux 2 notebook instances](#). For information about JupyterLab versions, see [JupyterLab versioning](#).
  - d. For **IAM role**, choose **Create a new role**, and then choose **Create role**. This IAM role automatically gets permissions to access any S3 bucket that has `sagemaker` in the name. It gets these permissions through the `AmazonSageMakerFullAccess` policy, which SageMaker AI attaches to the role.

#### Note

If you want to grant the IAM role permission to access S3 buckets without `sagemaker` in the name, you need to attach the `S3FullAccess` policy. You can also limit the permissions to specific S3 buckets to the IAM role. For more information and examples of adding bucket policies to the IAM role, see [Bucket Policy Examples](#).

- e. Choose **Create notebook instance**.

In a few minutes, SageMaker AI launches a notebook instance and attaches a 5 GB of Amazon EBS storage volume to it. The notebook instance has a preconfigured Jupyter notebook server, SageMaker AI and AWS SDK libraries, and a set of Anaconda libraries.

For more information about creating a SageMaker notebook instance, see [Create a Notebook Instance](#).

### (Optional) Change SageMaker Notebook Instance Settings

To change the ML compute instance type or the size of the Amazon EBS storage of a SageMaker AI notebook instance, edit the notebook instance settings.

#### To change and update the SageMaker Notebook instance type and the EBS volume

1. On the **Notebook instances** page in the SageMaker AI console, choose your notebook instance.
2. Choose **Actions**, choose **Stop**, and then wait until the notebook instance fully stops.
3. After the notebook instance status changes to **Stopped**, choose **Actions**, and then choose **Update settings**.
  - a. For **Notebook instance type**, choose a different ML instance type.
  - b. For **Volume size in GB**, type a different integer to specify a new EBS volume size.

#### Note

EBS storage volumes are encrypted, so SageMaker AI can't determine the amount of available free space on the volume. Because of this, you can increase the volume size when you update a notebook instance, but you can't decrease the volume size. If you want to decrease the size of the ML storage volume in use, create a new notebook instance with the desired size.

4. At the bottom of the page, choose **Update notebook instance**.
5. When the update is complete, **Start** the notebook instance with the new settings.

For more information about updating SageMaker notebook instance settings, see [Update a Notebook Instance](#).

## (Optional) Advanced Settings for SageMaker Notebook Instances

The following tutorial video shows how to set up and use SageMaker notebook instances through the SageMaker AI console. It includes advanced options, such as SageMaker AI lifecycle configuration and importing GitHub repositories. (Length: 26:04)

For complete documentation about SageMaker notebook instance, see [Use Amazon SageMaker notebook Instances](#).

## Create a Jupyter notebook in the SageMaker notebook instance

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#). [AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

To start scripting for training and deploying your model, create a Jupyter notebook in the SageMaker notebook instance. Using the Jupyter notebook, you can run machine learning (ML) experiments for training and inference while using SageMaker AI features and the AWS infrastructure.

### To create a Jupyter notebook

1. Open the notebook instance as follows:
  - a. Sign in to the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
  - b. On the **Notebook instances** page, open your notebook instance by choosing either:
    - **Open JupyterLab** for the JupyterLab interface
    - **Open Jupyter** for the classic Jupyter view

**Note**

If the notebook instance status shows **Pending** in the **Status** column, your notebook instance is still being created. The status will change to **InService** when the notebook instance is ready to use.

**2. Create a notebook as follows:**

- If you opened the notebook in the JupyterLab view, on the **File** menu, choose **New**, and then choose **Notebook**. For **Select Kernel**, choose **conda\_python3**. This preinstalled environment includes the default Anaconda installation and Python 3.
- If you opened the notebook in the classic Jupyter view, on the **Files** tab, choose **New**, and then choose **conda\_python3**. This preinstalled environment includes the default Anaconda installation and Python 3.

**3. Save the notebooks as follows:**

- In the JupyterLab view, choose **File**, choose **Save Notebook As...**, and then rename the notebook.
- In the Jupyter classic view, choose **File**, choose **Save as...**, and then rename the notebook.

## Prepare a dataset

In this step, you load the [Adult Census dataset](#) to your notebook instance using the SHAP (SHapley Additive exPlanations) Library, review the dataset, transform it, and upload it to Amazon S3. SHAP is a game theoretic approach to explain the output of any machine learning model. For more information about SHAP, see [Welcome to the SHAP documentation](#).

To run the following example, paste the sample code into a cell in your notebook instance.

### Load Adult Census Dataset Using SHAP

Using the SHAP library, import the Adult Census dataset as shown following:

```
import shap
X, y = shap.datasets.adult()
X_display, y_display = shap.datasets.adult(display=True)
feature_names = list(X.columns)
```

```
feature_names
```

**Note**

If the current Jupyter kernel does not have the SHAP library, install it by running the following conda command:

```
%conda install -c conda-forge shap
```

If you're using JupyterLab, you must manually refresh the kernel after the installation and updates have completed. Run the following IPython script to shut down the kernel (the kernel will restart automatically):

```
import IPython
IPython.Application.instance().kernel.do_shutdown(True)
```

The `feature_names` list object should return the following list of features:

```
['Age',
 'Workclass',
 'Education-Num',
 'Marital Status',
 'Occupation',
 'Relationship',
 'Race',
 'Sex',
 'Capital Gain',
 'Capital Loss',
 'Hours per week',
 'Country']
```

**Tip**

If you're starting with unlabeled data, you can use Amazon SageMaker Ground Truth to create a data labeling workflow in minutes. To learn more, see [Label Data](#).

## Overview the Dataset

Run the following script to display the statistical overview of the dataset and histograms of the numeric features.

```
display(X.describe())
hist = X.hist(bins=30, sharey=True, figsize=(20, 10))
```

	Age	Workclass	Education-Num	Marital Status	Occupation	Relationship	Race	Sex	Capital Gain	Capital Loss	Hours per week	Country

<b>max</b>	90.000000	8.000000	16.000000	6.000000	14.000000	5.000000	4.000000	1.000000	99999.000000	4356.000000	99.000000	41.000000

### Tip

If you want to use a dataset that needs to be cleaned and transformed, you can simplify and streamline data preprocessing and feature engineering using Amazon SageMaker Data Wrangler. To learn more, see [Prepare ML Data with Amazon SageMaker Data Wrangler](#).

## Split the Dataset into Train, Validation, and Test Datasets

Using Sklearn, split the dataset into a training set and a test set. The training set is used to train the model, while the test set is used to evaluate the performance of the final trained model. The dataset is randomly sorted with the fixed random seed: 80 percent of the dataset for training set and 20 percent of it for a test set.

```
from sklearn.model_selection import train_test_split
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2,
    random_state=1)
X_train_display = X_display.loc[X_train.index]
```

Split the training set to separate out a validation set. The validation set is used to evaluate the performance of the trained model while tuning the model's hyperparameters. 75 percent of the training set becomes the final training set, and the rest is the validation set.

```
X_train, X_val, y_train, y_val = train_test_split(X_train, y_train, test_size=0.25,
    random_state=1)
X_train_display = X_display.loc[X_train.index]
X_val_display = X_display.loc[X_val.index]
```

Using the pandas package, explicitly align each dataset by concatenating the numeric features with the true labels.

```
import pandas as pd
train = pd.concat([pd.Series(y_train, index=X_train.index,
    name='Income>50K', dtype=int), X_train], axis=1)
validation = pd.concat([pd.Series(y_val, index=X_val.index,
    name='Income>50K', dtype=int), X_val], axis=1)
test = pd.concat([pd.Series(y_test, index=X_test.index,
    name='Income>50K', dtype=int), X_test], axis=1)
```

Check if the dataset is split and structured as expected:

```
train
```

	Income>50K	Age	Workclass	Education-Num	Marital Status	Occupation	Relationship	Race	Sex	Capital Gain	Capital Loss	Hours per week	Country

## Convert the Train and Validation Datasets to CSV Files

Convert the train and validation dataframe objects to CSV files to match the input file format for the XGBoost algorithm.

```
# Use 'csv' format to store the data
# The first column is expected to be the output column
train.to_csv('train.csv', index=False, header=False)
validation.to_csv('validation.csv', index=False, header=False)
```

## Upload the Datasets to Amazon S3

Using the SageMaker AI and Boto3, upload the training and validation datasets to the default Amazon S3 bucket. The datasets in the S3 bucket will be used by a compute-optimized SageMaker instance on Amazon EC2 for training.

The following code sets up the default S3 bucket URI for your current SageMaker AI session, creates a new demo-sagemaker-xgboost-adult-income-prediction folder, and uploads the training and validation datasets to the data subfolder.

```
import sagemaker, boto3, os
bucket = sagemaker.Session().default_bucket()
prefix = "demo-sagemaker-xgboost-adult-income-prediction"

boto3.Session().resource('s3').Bucket(bucket).Object(
    os.path.join(prefix, 'data/train.csv')).upload_file('train.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(
```

```
os.path.join(prefix, 'data/validation.csv')).upload_file('validation.csv')
```

Run the following AWS CLI to check if the CSV files are successfully uploaded to the S3 bucket.

```
! aws s3 ls {bucket}/{prefix}/data --recursive
```

This should return the following output:

```
2021-01-14 17:52:09      786285 demo-sagemaker-xgboost-adult-income-prediction/data/train.csv
2021-01-14 17:52:10      262122 demo-sagemaker-xgboost-adult-income-prediction/data/validation.csv
```

## Train a Model

In this step, you choose a training algorithm and run a training job for the model. The [Amazon SageMaker Python SDK](#) provides framework estimators and generic estimators to train your model while orchestrating the machine learning (ML) lifecycle accessing the SageMaker AI features for training and the AWS infrastructures, such as Amazon Elastic Container Registry (Amazon ECR), Amazon Elastic Compute Cloud (Amazon EC2), Amazon Simple Storage Service (Amazon S3). For more information about SageMaker AI built-in framework estimators, see [Frameworks](#) in the [Amazon SageMaker Python SDK](#) documentation. For more information about built-in algorithms, see [Built-in algorithms and pretrained models in Amazon SageMaker](#).

### Topics

- [Choose the Training Algorithm](#)
- [Create and Run a Training Job](#)

### Choose the Training Algorithm

To choose the right algorithm for your dataset, you typically need to evaluate different models to find the most suitable models to your data. For simplicity, the SageMaker AI [XGBoost algorithm with Amazon SageMaker AI](#) built-in algorithm is used throughout this tutorial without the pre-evaluation of models.

#### Tip

If you want SageMaker AI to find an appropriate model for your tabular dataset, use Amazon SageMaker Autopilot that automates a machine learning solution. For more information, see [SageMaker Autopilot](#).

## Create and Run a Training Job

After you figured out which model to use, start constructing a SageMaker AI estimator for training. This tutorial uses the XGBoost built-in algorithm for the SageMaker AI generic estimator.

### To run a model training job

1. Import the [Amazon SageMaker Python SDK](#) and start by retrieving the basic information from your current SageMaker AI session.

```
import sagemaker

region = sagemaker.Session().boto_region_name
print("AWS Region: {}".format(region))

role = sagemaker.get_execution_role()
print("RoleArn: {}".format(role))
```

This returns the following information:

- `region` – The current AWS Region where the SageMaker AI notebook instance is running.
- `role` – The IAM role used by the notebook instance.

#### Note

Check the SageMaker Python SDK version by running `sagemaker.__version__`. This tutorial is based on `sagemaker>=2.20`. If the SDK is outdated, install the latest version by running the following command:

```
! pip install -qU sagemaker
```

If you run this installation in your existing SageMaker Studio or notebook instances, you need to manually refresh the kernel to finish applying the version update.

2. Create an XGBoost estimator using the `sagemaker.estimator.Estimator` class. In the following example code, the XGBoost estimator is named `xgb_model`.

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs
from sagemaker.session import TrainingInput
```

```
s3_output_location='s3://{}/{}/{}'.format(bucket, prefix, 'xgboost_model')

container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")
print(container)

xgb_model=sagemaker.estimator.Estimator(
    image_uri=container,
    role=role,
    instance_count=1,
    instance_type='ml.m4.xlarge',
    volume_size=5,
    output_path=s3_output_location,
    sagemaker_session=sagemaker.Session(),
    rules=[
        Rule.sagemaker(rule_configs.create_xgboost_report()),
        ProfilerRule.sagemaker(rule_configs.ProfilerReport())
    ]
)
```

To construct the SageMaker AI estimator, specify the following parameters:

- `image_uri` – Specify the training container image URI. In this example, the SageMaker AI XGBoost training container URI is specified using `sagemaker.image_uris.retrieve`.
- `role` – The AWS Identity and Access Management (IAM) role that SageMaker AI uses to perform tasks on your behalf (for example, reading training results, call model artifacts from Amazon S3, and writing training results to Amazon S3).
- `instance_count` and `instance_type` – The type and number of Amazon EC2 ML compute instances to use for model training. For this training exercise, you use a single `ml.m4.xlarge` instance, which has 4 CPUs, 16 GB of memory, an Amazon Elastic Block Store (Amazon EBS) storage, and a high network performance. For more information about EC2 compute instance types, see [Amazon EC2 Instance Types](#). For more information about billing, see [Amazon SageMaker pricing](#).
- `volume_size` – The size, in GB, of the EBS storage volume to attach to the training instance. This must be large enough to store training data if you use File mode (File mode is on by default). If you don't specify this parameter, its value defaults to 30.
- `output_path` – The path to the S3 bucket where SageMaker AI stores the model artifact and training results.

- `sagemaker_session` – The session object that manages interactions with SageMaker API operations and other AWS service that the training job uses.
- `rules` – Specify a list of SageMaker Debugger built-in rules. In this example, the `create_xgboost_report()` rule creates an XGBoost report that provides insights into the training progress and results, and the `ProfilerReport()` rule creates a report regarding the EC2 compute resource utilization. For more information, see [SageMaker Debugger interactive report for XGBoost](#).

** Tip**

If you want to run distributed training of large sized deep learning models, such as convolutional neural networks (CNN) and natural language processing (NLP) models, use SageMaker AI Distributed for data parallelism or model parallelism. For more information, see [Distributed training in Amazon SageMaker AI](#).

3. Set the hyperparameters for the XGBoost algorithm by calling the `set_hyperparameters` method of the estimator. For a complete list of XGBoost hyperparameters, see [XGBoost hyperparameters](#).

```
xgb_model.set_hyperparameters(  
    max_depth = 5,  
    eta = 0.2,  
    gamma = 4,  
    min_child_weight = 6,  
    subsample = 0.7,  
    objective = "binary:logistic",  
    num_round = 1000  
)
```

** Tip**

You can also tune the hyperparameters using the SageMaker AI hyperparameter optimization feature. For more information, see [Automatic model tuning with SageMaker AI](#).

4. Use the `TrainingInput` class to configure a data input flow for training. The following example code shows how to configure `TrainingInput` objects to use the training and

validation datasets you uploaded to Amazon S3 in the [Split the Dataset into Train, Validation, and Test Datasets](#) section.

```
from sagemaker.session import TrainingInput

train_input = TrainingInput(
    "s3://{}/{}{}".format(bucket, prefix, "data/train.csv"), content_type="csv"
)
validation_input = TrainingInput(
    "s3://{}/{}{}".format(bucket, prefix, "data/validation.csv"),
    content_type="csv"
)
```

5. To start model training, call the estimator's `fit` method with the training and validation datasets. By setting `wait=True`, the `fit` method displays progress logs and waits until training is complete.

```
xgb_model.fit({"train": train_input, "validation": validation_input}, wait=True)
```

For more information about model training, see [Train a Model with Amazon SageMaker](#). This tutorial training job might take up to 10 minutes.

After the training job has done, you can download an XGBoost training report and a profiling report generated by SageMaker Debugger. The XGBoost training report offers you insights into the training progress and results, such as the loss function with respect to iteration, feature importance, confusion matrix, accuracy curves, and other statistical results of training. For example, you can find the following loss curve from the XGBoost training report which clearly indicates that there is an overfitting problem.

Run the following code to specify the S3 bucket URI where the Debugger training reports are generated and check if the reports exist.

```
rule_output_path = xgb_model.output_path + "/" +  
    xgb_model.latest_training_job.job_name + "/rule-output"  
! aws s3 ls {rule_output_path} --recursive
```

Download the Debugger XGBoost training and profiling reports to the current workspace:

```
! aws s3 cp {rule_output_path} ./ --recursive
```

Run the following IPython script to get the file link of the XGBoost training report:

```
from IPython.display import FileLink, FileLinks
display("Click link below to view the XGBoost Training report",
       FileLink("CreateXgboostReport/xgboost_report.html"))
```

The following IPython script returns the file link of the Debugger profiling report that shows summaries and details of the EC2 instance resource utilization, system bottleneck detection results, and python operation profiling results:

```
profiler_report_name = [rule["RuleConfigurationName"]
                        for rule in
                        xgb_model.latest_training_job.rule_job_summary()
                        if "Profiler" in rule["RuleConfigurationName"]][0]
profiler_report_name
display("Click link below to view the profiler report",
       FileLink(profiler_report_name+"/profiler-output/profiler-report.html"))
```

### Tip

If the HTML reports do not render plots in the JupyterLab view, you must choose **Trust HTML** at the top of the reports.

To identify training issues, such as overfitting, vanishing gradients, and other problems that prevents your model from converging, use SageMaker Debugger and take automated actions while prototyping and training your ML models. For more information, see [Amazon SageMaker Debugger](#). To find a complete analysis of model parameters, see the [Explainability with Amazon SageMaker Debugger](#) example notebook.

You now have a trained XGBoost model. SageMaker AI stores the model artifact in your S3 bucket. To find the location of the model artifact, run the following code to print the `model_data` attribute of the `xgb_model` estimator:

```
xgb_model.model_data
```

**i Tip**

To measure biases that can occur during each stage of the ML lifecycle (data collection, model training and tuning, and monitoring of ML models deployed for prediction), use SageMaker Clarify. For more information, see [Model Explainability](#). For an end-to-end example, see the [Fairness and Explainability with SageMaker Clarify](#) example notebook.

## Deploy the model to Amazon EC2

To get predictions, deploy your model to Amazon EC2 using Amazon SageMaker AI.

### Topics

- [Deploy the Model to SageMaker AI Hosting Services](#)
- [\(Optional\) Use SageMaker AI Predictor to Reuse the Hosted Endpoint](#)
- [\(Optional\) Make Prediction with Batch Transform](#)

## Deploy the Model to SageMaker AI Hosting Services

To host a model through Amazon EC2 using Amazon SageMaker AI, deploy the model that you trained in [Create and Run a Training Job](#) by calling the `deploy` method of the `xgb_model` estimator. When you call the `deploy` method, you must specify the number and type of EC2 ML instances that you want to use for hosting an endpoint.

```
import sagemaker
from sagemaker.serializers import CSVSerializer
xgb_predictor=xgb_model.deploy(
    initial_instance_count=1,
    instance_type='ml.t2.medium',
    serializer=CSVSerializer()
)
```

- `initial_instance_count` (int) – The number of instances to deploy the model.
- `instance_type` (str) – The type of instances that you want to operate your deployed model.

- `serializer` (int) – Serialize input data of various formats (a NumPy array, list, file, or buffer) to a CSV-formatted string. We use this because the XGBoost algorithm accepts input files in CSV format.

The `deploy` method creates a deployable model, configures the SageMaker AI hosting services endpoint, and launches the endpoint to host the model. For more information, see the [SageMaker AI generic Estimator's `deploy` class method](#) in the [Amazon SageMaker Python SDK](#). To retrieve the name of endpoint that's generated by the `deploy` method, run the following code:

```
xgb_predictor.endpoint_name
```

This should return the endpoint name of the `xgb_predictor`. The format of the endpoint name is "sagemaker-xgboost-YYYY-MM-DD-HH-MM-SS-SSS". This endpoint stays active in the ML instance, and you can make instantaneous predictions at any time unless you shut it down later. Copy this endpoint name and save it to reuse and make real-time predictions elsewhere in SageMaker Studio or SageMaker AI notebook instances.

#### Tip

To learn more about compiling and optimizing your model for deployment to Amazon EC2 instances or edge devices, see [Compile and Deploy Models with Neo](#).

### (Optional) Use SageMaker AI Predictor to Reuse the Hosted Endpoint

After you deploy the model to an endpoint, you can set up a new SageMaker AI predictor by pairing the endpoint and continuously make real-time predictions in any other notebooks. The following example code shows how to use the SageMaker AI Predictor class to set up a new predictor object using the same endpoint. Re-use the endpoint name that you used for the `xgb_predictor`.

```
import sagemaker
xgb_predictor_reuse=sagemaker.predictor.Predictor(
    endpoint_name="sagemaker-xgboost-YYYY-MM-DD-HH-MM-SS-SSS",
    sagemaker_session=sagemaker.Session(),
    serializer=sagemaker.serializers.CSVSerializer()
)
```

The `xgb_predictor_reuse` Predictor behaves exactly the same as the original `xgb_predictor`. For more information, see the [SageMaker AI Predictor](#) class in the [Amazon SageMaker Python SDK](#).

### (Optional) Make Prediction with Batch Transform

Instead of hosting an endpoint in production, you can run a one-time batch inference job to make predictions on a test dataset using the SageMaker AI batch transform. After your model training has completed, you can extend the estimator to a `transformer` object, which is based on the [SageMaker AI Transformer](#) class. The batch transformer reads in input data from a specified S3 bucket and makes predictions.

#### To run a batch transform job

1. Run the following code to convert the feature columns of the test dataset to a CSV file and uploads to the S3 bucket:

```
X_test.to_csv('test.csv', index=False, header=False)

boto3.Session().resource('s3').Bucket(bucket).Object(
    os.path.join(prefix, 'test/test.csv')).upload_file('test.csv')
```

2. Specify S3 bucket URIs of input and output for the batch transform job as shown following:

```
# The location of the test dataset
batch_input = 's3://{}/{}'/test'.format(bucket, prefix)

# The location to store the results of the batch transform job
batch_output = 's3://{}/{}'/batch-prediction'.format(bucket, prefix)
```

3. Create a transformer object specifying the minimal number of parameters: the `instance_count` and `instance_type` parameters to run the batch transform job, and the `output_path` to save prediction data as shown following:

```
transformer = xgb_model.transformer(
    instance_count=1,
    instance_type='ml.m4.xlarge',
    output_path=batch_output
)
```

4. Initiate the batch transform job by executing the `transform()` method of the transformer object as shown following:

```
transformer.transform(  
    data=batch_input,  
    data_type='S3Prefix',  
    content_type='text/csv',  
    split_type='Line'  
)  
transformer.wait()
```

5. When the batch transform job is complete, SageMaker AI creates the `test.csv.out` prediction data saved in the `batch_output` path, which should be in the following format: `s3://sagemaker-<region>-111122223333/demo-sagemaker-xgboost-adult-income-prediction/batch-prediction`. Run the following AWS CLI to download the output data of the batch transform job:

```
! aws s3 cp {batch_output} ./ --recursive
```

This should create the `test.csv.out` file under the current working directory. You'll be able to see the float values that are predicted based on the logistic regression of the XGBoost training job.

## Evaluate the model

Now that you have trained and deployed a model using Amazon SageMaker AI, evaluate the model to ensure that it generates accurate predictions on new data. For model evaluation, use the test dataset that you created in [Prepare a dataset](#).

### Evaluate the Model Deployed to SageMaker AI Hosting Services

To evaluate the model and use it in production, invoke the endpoint with the test dataset and check whether the inferences you get returns a target accuracy you want to achieve.

#### To evaluate the model

1. Set up the following function to predict each line of the test set. In the following example code, the `rows` argument is to specify the number of lines to predict at a time. You can change the value of it to perform a batch inference that fully utilizes the instance's hardware resource.

```
import numpy as np  
def predict(data, rows=1000):
```

```
split_array = np.array_split(data, int(data.shape[0] / float(rows) + 1))
predictions = ''
for array in split_array:
    predictions = ','.join([predictions,
xgb_predictor.predict(array).decode('utf-8')])
return np.fromstring(predictions[1:], sep=',')
```

2. Run the following code to make predictions of the test dataset and plot a histogram. You need to take only the feature columns of the test dataset, excluding the 0th column for the actual values.

```
import matplotlib.pyplot as plt

predictions=predict(test.to_numpy()[:,1:])
plt.hist(predictions)
plt.show()
```

3. The predicted values are float type. To determine True or False based on the float values, you need to set a cutoff value. As shown in the following example code, use the Scikit-learn library to return the output confusion metrics and classification report with a cutoff of 0.5.

```
import sklearn

cutoff=0.5
```

```
print(sklearn.metrics.confusion_matrix(test.iloc[:, 0], np.where(predictions >
    cutoff, 1, 0)))
print(sklearn.metrics.classification_report(test.iloc[:, 0], np.where(predictions >
    cutoff, 1, 0)))
```

This should return the following confusion matrix:

```
[[4670  356]
 [ 480 1007]]
```

	precision	recall	f1-score	support
0	0.91	0.93	0.92	5026
1	0.74	0.68	0.71	1487
accuracy			0.87	6513
macro avg	0.82	0.80	0.81	6513
weighted avg	0.87	0.87	0.87	6513

- To find the best cutoff with the given test set, compute the log loss function of the logistic regression. The log loss function is defined as the negative log-likelihood of a logistic model that returns prediction probabilities for its ground truth labels. The following example code numerically and iteratively calculates the log loss values  $-(y \cdot \log(p) + (1-y) \cdot \log(1-p))$ , where  $y$  is the true label and  $p$  is a probability estimate of the corresponding test sample. It returns a log loss versus cutoff graph.

```
import matplotlib.pyplot as plt

cutoffs = np.arange(0.01, 1, 0.01)
log_loss = []
for c in cutoffs:
    log_loss.append(
        sklearn.metrics.log_loss(test.iloc[:, 0], np.where(predictions > c, 1, 0))
    )

plt.figure(figsize=(15,10))
plt.plot(cutoffs, log_loss)
plt.xlabel("Cutoff")
plt.ylabel("Log loss")
plt.show()
```

This should return the following log loss curve.

5. Find the minimum points of the error curve using the NumPy `argmin` and `min` functions:

```
print(
    'Log loss is minimized at a cutoff of ', cutoffs[np.argmin(log_loss)],
    ', and the log loss value at the minimum is ', np.min(log_loss)
)
```

This should return: Log loss is minimized at a cutoff of 0.53, and the log loss value at the minimum is 4.348539186773897.

Instead of computing and minimizing the log loss function, you can estimate a cost function as an alternative. For example, if you want to train a model to perform a binary classification for a business problem such as a customer churn prediction problem, you can set weights to the elements of confusion matrix and calculate the cost function accordingly.

You have now trained, deployed, and evaluated your first model in SageMaker AI.

**Tip**

To monitor model quality, data quality, and bias drift, use Amazon SageMaker Model Monitor and SageMaker AI Clarify. To learn more, see [Amazon SageMaker Model Monitor](#), [Monitor Data Quality](#), [Monitor Model Quality](#), [Monitor Bias Drift](#), and [Monitor Feature Attribution Drift](#).

**Tip**

To get human review of low confidence ML predictions or a random sample of predictions, use Amazon Augmented AI human review workflows. For more information, see [Using Amazon Augmented AI for Human Review](#).

## Clean up Amazon SageMaker notebook instance resources

To avoid incurring unnecessary charges, use the AWS Management Console to delete the endpoints and resources that you created while running the exercises.

**Note**

Training jobs and logs cannot be deleted and are retained indefinitely.

**Note**

If you plan to explore other exercises in this guide, you might want to keep some of these resources, such as your notebook instance, S3 bucket, and IAM role.

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/> and delete the following resources:
  - The endpoint. Deleting the endpoint also deletes the ML compute instance or instances that support it.
    1. Under **Inference**, choose **Endpoints**.

2. Choose the endpoint that you created in the example, choose **Actions**, and then choose **Delete**.
- The endpoint configuration.
  1. Under **Inference**, choose **Endpoint configurations**.
  2. Choose the endpoint configuration that you created in the example, choose **Actions**, and then choose **Delete**.
- The model.
  1. Under **Inference**, choose **Models**.
  2. Choose the model that you created in the example, choose **Actions**, and then choose **Delete**.
- The notebook instance. Before deleting the notebook instance, stop it.
  1. Under **Notebook**, choose **Notebook instances**.
  2. Choose the notebook instance that you created in the example, choose **Actions**, and then choose **Stop**. The notebook instance takes several minutes to stop. When the **Status** changes to **Stopped**, move on to the next step.
  3. Choose **Actions**, and then choose **Delete**.
2. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>, and then delete the bucket that you created for storing model artifacts and the training dataset.
3. Open the Amazon CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>, and then delete all of the log groups that have names starting with `/aws/sagemaker/`.

## Amazon Linux 2 notebook instances

### Important

Notebook instances running on the JupyterLab 1 and JupyterLab 3 platforms will reach end of support on June 30, 2025. We strongly recommend migrating your work to the new JupyterLab 4 notebook instances before this date to ensure you have a secure and supported environment. For more information, see [JupyterLab version maintenance](#).

Amazon SageMaker notebook instances currently support Amazon Linux 2 (AL2) operating systems. You can select the operating system that your notebook instance is based on when you create the notebook instance.

SageMaker AI supports notebook instances based on the following Amazon Linux 2 operating systems.

- **notebook-al2-v1**: These notebook instances support JupyterLab version 1. For information about JupyterLab versions, see [JupyterLab versioning](#).
- **notebook-al2-v2**: These notebook instances support JupyterLab version 3. For information about JupyterLab versions, see [JupyterLab versioning](#).
- **notebook-al2-v3**: These notebook instances support JupyterLab version 4. For information about JupyterLab versions, see [JupyterLab versioning](#).

Notebook instances created before 08/18/2021 automatically run on Amazon Linux (AL1). Notebook instances based on AL1 entered a maintenance phase as of 12/01/2022 and are no longer available for new notebook instance creation as of 02/01/2023. To replace AL1, you now have the option to create Amazon SageMaker notebook instances with AL2. For more information, see [AL1 Maintenance Phase Plan](#).

## Topics

- [Supported instance types](#)
- [Available Kernels](#)
- [AL1 Maintenance Phase Plan](#)

## Supported instance types

Amazon Linux 2 supports instance types listed under **Notebook Instances** in [Amazon SageMaker Pricing](#) with the exception that Amazon Linux 2 does not support m1 . p2 instances.

## Available Kernels

The following table gives information about the available kernels for SageMaker notebook instances. All of these images are supported on notebook instances based on the notebook-a12-v1, notebook-a12-v2, and notebook-a12-v3 operating systems.

SageMaker notebook instance kernels

Kernel name	Description
R	A kernel used to perform data analysis and visualization using R code from a Jupyter notebook.
Sparkmagic (PySpark)	A kernel used to do data science with remote Spark clusters from Jupyter notebooks using the Python programming language. This kernel comes with Python 3.10.
Sparkmagic (Spark)	A kernel used to do data science with remote Spark clusters from Jupyter notebooks using the Scala programming language. This kernel comes with Python 3.10.
Sparkmagic (SparkR)	A kernel used to do data science with remote Spark clusters from Jupyter notebooks using the R programming language. This kernel comes with Python 3.10.
conda_python3	A conda environment that comes pre-installed with popular packages for data science and machine learning. This kernel comes with Python 3.10.
conda_pytorch_p310	A conda environment that comes pre-installed with PyTorch version 2.2.0, as well as popular data science and machine learning packages. This kernel comes with Python 3.10.
conda_tensorflow2_p310	A conda environment that comes pre-installed with TensorFlow version 2.16.0, as well as popular data science and machine learning packages. This kernel comes with Python 3.10.

## AL1 Maintenance Phase Plan

The following table is a timeline for when AL1 entered its extended maintenance phase. The AL1 maintenance phase also coincides with the deprecation of Python 2 and Chainer. Notebooks based on AL2 do not have managed Python 2 and Chainer kernels.

Date	Description
08/18/2021	Notebook instances based on AL2 are launched. Newly launched notebook instances still default to AL1. AL1 is supported with security patches and updates, but no new features. You can choose between the two operating systems when launching a new notebook instance.
10/31/2022	The default platform identifier for SageMaker notebook instances changes from Amazon Linux (al1-v1) to Amazon Linux 2 (al2-v2). You can choose between the two operating systems when launching a new notebook instance.
12/01/2022	AL1 is no longer supported with non-critical security patches and updates. AL1 still receives fixes for <a href="#">critical</a> security-related issues. You can still launch instances on AL1, but assume the risks associated with using an unsupported operating system.
02/01/2023	AL1 is no longer an available option for new notebook instance creation. After this date, customers can create notebook instances with the AL2 platform identifiers. Existing notebooks with an <code>INSERVICE</code> status should be migrated to the latest platform since

Date	Description
	continuous availability of AL1 notebook instances cannot be guaranteed.
03/31/2024	<p>AL1 reaches its end of life on notebook instances on March 31, 2024. After this date, AL1 will no longer receive any security updates, bug fixes, or be available for new notebook instance creation.</p> <ul style="list-style-type: none"><li>Existing AL1 notebook instances with a STOPPED status cannot be restarted.</li><li>Existing notebooks with an INSERVICE status should be migrated to the latest platform since continuous availability of AL1 notebook instances cannot be guaranteed.</li></ul>

## Migrating to Amazon Linux 2

Your existing AL1 notebook instance is not automatically migrated to Amazon Linux 2. To upgrade your AL1 notebook instance to Amazon Linux 2, you must create a new notebook instance, replicate your code and environment, and delete your old notebook instance. For more information, see the [Amazon Linux 2 migration blog](#).

## JupyterLab versioning

### Important

Notebook instances running on the JupyterLab 1 and JupyterLab 3 platforms will reach end of support on June 30, 2025. We strongly recommend migrating your work to the new JupyterLab 4 notebook instances before this date to ensure you have a secure and supported environment. For more information, see [JupyterLab version maintenance](#).

The Amazon SageMaker notebook instance interface is based on JupyterLab, which is a web-based interactive development environment for notebooks, code, and data. Notebooks now support

using either JupyterLab 1, JupyterLab 3, or JupyterLab 4. A single notebook instance can run a single instance of JupyterLab (at most). You can have multiple notebook instances with different JupyterLab versions.

You can configure your notebook to run your preferred JupyterLab version by selecting the appropriate platform identifier. Use either the AWS CLI or the SageMaker AI console when creating your notebook instance. For more information about platform identifiers, see [Amazon Linux 2 vs Amazon Linux notebook instances](#). If you don't explicitly configure a platform identifier, your notebook instance defaults to running JupyterLab 1.

## Topics

- [JupyterLab version maintenance](#)
- [JupyterLab 4](#)
- [JupyterLab 3](#)
- [Create a notebook with your JupyterLab version](#)
- [View the JupyterLab version of a notebook from the console](#)

## JupyterLab version maintenance

Notebook instances running on the JupyterLab 1 and JupyterLab 3 platforms will reach its end of standard support on June 30, 2025. Effective on this date:

- You will no longer be able to create new, or restart stopped, JupyterLab 1 and JupyterLab 3 notebook instances.
- Existing in-service JupyterLab 1 and JupyterLab 3 notebook instances may continue to function, but will no longer receive SageMaker AI security updates or critical bug fixes.
- You will be responsible for managing the security of these instances on JupyterLab 1 and JupyterLab 3.
- If any issues arise with the existing JupyterLab 1 or JupyterLab 3 notebook instances, SageMaker AI cannot guarantee their continued availability without migrating the workload to a new JupyterLab 4 notebook instance.

We strongly recommend migrating your work to the new JupyterLab 4 notebook instances (platform identifier [notebook-al2-v3](#)) before June 30, 2025 to ensure you have a secure and supported environment. This will allow you to leverage the latest versions of Jupyter notebooks,

JupyterLab, and other ML libraries. For instructions, see [migrate your work to an SageMaker AI notebook instance with Amazon Linux 2](#).

## JupyterLab 4

JupyterLab 4 support is available only on the Amazon Linux 2 operating system platform. JupyterLab 4 includes the following features that are not available in JupyterLab 3:

- Optimized rendering for a faster experience
- Opt-in settings for faster tab switching and better performance with long notebooks. For more information, see the blog post [JupyterLab 4.0 is Here](#).
- Upgraded text editor
- New extension manager installing from pypi
- Added improvements to the UI, including document search and accessibility improvements

You can run JupyterLab 4 by specifying `notebook-a12-v3` as the platform identifier when creating your notebook instance.

### Note

If you attempt to migrate to a JupyterLab 4 Notebook Instance from another JupyterLab version, the package version changes between JupyterLab 3 and JupyterLab 4 might break any existing lifecycle configurations or Jupyter/JupyterLab extensions.

## Package version changes

JupyterLab 4 has the following package version changes from JupyterLab 3:

- JupyterLab has been upgraded from 3.x to 4.x.
- Jupyter notebook has been upgraded from 6.x to 7.x.
- `jupyterlab-git` has been updated to version 0.50.0.

## JupyterLab 3

### Important

Notebook instances running on the JupyterLab 1 and JupyterLab 3 platforms will reach end of support on June 30, 2025. We strongly recommend migrating your work to the new JupyterLab 4 notebook instances before this date to ensure you have a secure and supported environment. For more information, see [JupyterLab version maintenance](#).

JupyterLab 3 support is available only on the Amazon Linux 2 operating system platform. JupyterLab 3 includes the following features that are not available in JupyterLab 1. For more information about these features, see [JupyterLab 3.0 is released!](#).

- Visual debugger when using the following kernels:
  - conda\_pytorch\_p38
  - conda\_tensorflow2\_p38
  - conda\_amazonei\_pytorch\_latest\_p37
- File browser filter
- Table of Contents (TOC)
- Multi-language support
- Simple mode
- Single interface mode
- Live editing SVG files with updated rendering
- User interface for notebook cell tags

### Important changes to JupyterLab 3

For information about important changes when using JupyterLab 3, see the following JupyterLab change logs:

- [v2.0.0](#)
- [v3.0.0](#)

### Package version changes

JupyterLab 3 has the following package version changes from JupyterLab 1:

- JupyterLab has been upgraded from 1.x to 3.x.
- Jupyter notebook has been upgraded from 5.x to 6.x.
- jupyterlab-git has been updated to version 0.37.1.
- nbserverproxy 0.x (0.3.2) has been replaced with jupyter-server-proxy 3.x (3.2.1).

## Create a notebook with your JupyterLab version

### Important

Notebook instances running on the JupyterLab 1 and JupyterLab 3 platforms will reach end of support on June 30, 2025. We strongly recommend migrating your work to the new JupyterLab 4 notebook instances before this date to ensure you have a secure and supported environment. For more information, see [JupyterLab version maintenance](#).

You can select the JupyterLab version when creating your notebook instance from the console following the steps in [Create an Amazon SageMaker notebook instance](#).

You can also select the JupyterLab version by passing the `platform-identifier` parameter when creating your notebook instance using the AWS CLI as follows:

```
create-notebook-instance --notebook-instance-name <NEW_NOTEBOOK_NAME> \  
--instance-type <INSTANCE_TYPE> \  
--role-arn <YOUR_ROLE_ARN> \  
--platform-identifier <PLATFORM_TO_USE>
```

## View the JupyterLab version of a notebook from the console

### Important

Notebook instances running on the JupyterLab 1 and JupyterLab 3 platforms will reach end of support on June 30, 2025. We strongly recommend migrating your work to the new JupyterLab 4 notebook instances before this date to ensure you have a secure and supported environment. For more information, see [JupyterLab version maintenance](#).

You can view the JupyterLab version of a notebook using the following procedure:

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. From the left navigation, select **Notebook**.
3. From the dropdown menu, select **Notebook instances** to navigate to the **Notebook instances** page.
4. From the list of notebook instances, select your notebook instance name.
5. On the **Notebook instance settings** page, view the **Platform Identifier** to see the JupyterLab version of the notebook.

## Create an Amazon SageMaker notebook instance

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#). [AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

An Amazon SageMaker notebook instance is a ML compute instance running the Jupyter Notebook application. SageMaker AI manages creating the instance and related resources. Use Jupyter notebooks in your notebook instance to:

- prepare and process data
- write code to train models
- deploy models to SageMaker AI hosting
- test or validate your models

To create a notebook instance, use either the SageMaker AI console or the [CreateNotebookInstance](#) API.

The notebook instance type you choose depends on how you use your notebook instance. Ensure that your notebook instance is not bound by memory, CPU, or IO. To load a dataset into memory on the notebook instance for exploration or preprocessing, choose an instance type with enough RAM memory for your dataset. This requires an instance with at least 16 GB of memory (.xlarge or larger). If you plan to use the notebook for compute intensive preprocessing, we recommend you choose a compute-optimized instance such as a c4 or c5.

A best practice when using a SageMaker notebook is to use the notebook instance to orchestrate other AWS services. For example, you can use the notebook instance to manage large dataset processing. To do this, make calls to AWS Glue for ETL (extract, transform, and load) services or Amazon EMR for mapping and data reduction using Hadoop. You can use AWS services as temporary forms of computation or storage for your data.

You can store and retrieve your training and test data using an Amazon Simple Storage Service bucket. You can then use SageMaker AI to train and build your model. As a result, the instance type of your notebook would have no bearing on the speed of your model training and testing.

After receiving the request, SageMaker AI does the following:

- **Creates a network interface**—If you choose the optional VPC configuration, SageMaker AI creates the network interface in your VPC. It uses the subnet ID that you provide in the request to determine which Availability Zone to create the subnet in. SageMaker AI associates the security group that you provide in the request with the subnet. For more information, see [Connect a Notebook Instance in a VPC to External Resources](#).
- **Launches an ML compute instance**—SageMaker AI launches an ML compute instance in a SageMaker AI VPC. SageMaker AI performs the configuration tasks that allow it to manage your notebook instance. If you specified your VPC, SageMaker AI enables traffic between your VPC and the notebook instance.
- **Installs Anaconda packages and libraries for common deep learning platforms**—SageMaker AI installs all of the Anaconda packages that are included in the installer. For more information, see [Anaconda package list](#). SageMaker AI also installs the TensorFlow and Apache MXNet deep learning libraries.
- **Attaches an ML storage volume**—SageMaker AI attaches an ML storage volume to the ML compute instance. You can use the volume as a working area to clean up the training dataset or to temporarily store validation, test, or other data. Choose any size between 5 GB and 16384 GB,

in 1 GB increments, for the volume. The default is 5 GB. ML storage volumes are encrypted, so SageMaker AI can't determine the amount of available free space on the volume. Because of this, you can increase the volume size when you update a notebook instance, but you can't decrease the volume size. If you want to decrease the size of the ML storage volume in use, create a new notebook instance with the desired size.

Only files and data saved within the `/home/ec2-user/SageMaker` folder persist between notebook instance sessions. Files and data that are saved outside this directory are overwritten when the notebook instance stops and restarts. Each notebook instance's `/tmp` directory provides a minimum of 10 GB of storage in an instance store. An instance store is temporary, block-level storage that isn't persistent. When the instance is stopped or restarted, SageMaker AI deletes the directory's contents. This temporary storage is part of the root volume of the notebook instance.

If the instance type used by the notebook instance has NVMe support, customers can use the NVMe instance store volumes available for that instance type. For instances with NVMe store volumes, all instance store volumes are automatically attached to the instance at launch. For more information about instance types and their associated NVMe store volumes, see the [Amazon Elastic Compute Cloud Instance Type Details](#).

To make the attached NVMe store volume available for your notebook instance, complete the steps in [Make instance store volumes available on your instance](#). Complete the steps with root access or by using a lifecycle configuration script.

#### Note

NVMe instance store volumes are not persistent storage. This storage is short-lived with the instance and must be reconfigured every time an instance with this storage is launched.

- **Copies example Jupyter notebooks**— These Python code examples show model training and hosting exercises using different algorithms and training datasets.

### To create a SageMaker AI notebook instance:

1. Open the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. Choose **Notebook instances**, then choose **Create notebook instance**.
3. On the **Create notebook instance** page, provide the following information:

- a. For **Notebook instance name**, type a name for your notebook instance.
- b. For **Notebook instance type**, choose an instance size suitable for your use case. For a list of supported instance types and quotas, see [Amazon SageMaker AI Service Quotas](#).
- c. For **Platform Identifier**, choose a platform type to create the notebook instance on. This platform type dictates the Operating System and the JupyterLab version that your notebook instance is created with. For information about platform identifier type, see [Amazon Linux 2 notebook instances](#). For information about JupyterLab versions, see [JupyterLab versioning](#).

 **Important**

Notebook instances running on the JupyterLab 1 and JupyterLab 3 platforms will reach end of support on June 30, 2025. We strongly recommend migrating your work to the new JupyterLab 4 notebook instances before this date to ensure you have a secure and supported environment. For more information, see [JupyterLab version maintenance](#).

- d. (Optional) **Additional configuration** lets advanced users create a shell script that can run when you create or start the instance. This script, called a lifecycle configuration script, can be used to set the environment for the notebook or to perform other functions. For information, see [Customization of a SageMaker notebook instance using an LCC script](#).
- e. (Optional) **Additional configuration** also lets you specify the size, in GB, of the ML storage volume that is attached to the notebook instance. You can choose a size between 5 GB and 16,384 GB, in 1 GB increments. You can use the volume to clean up the training dataset or to temporarily store validation or other data.
- f. (Optional) For **Minimum IMDS Version**, select a version from the dropdown list. If this value is set to v1, both versions can be used with the notebook instance. If v2 is selected, then only IMDSv2 can be used with the notebook instance. For information about IMDSv2, see [Use IMDSv2](#).

 **Note**

Starting October 31, 2022, the default minimum IMDS Version for SageMaker notebook instances changes from IMDSv1 to IMDSv2.

Starting February 1, 2023, IMDSv1 is no longer be available for new notebook instance creation. After this date, you can create notebook instances with a minimum IMDS version of 2.

- g. For **IAM role**, choose either an existing IAM role in your account with the necessary permissions to access SageMaker AI resources or **Create a new role**. If you choose **Create a new role**, SageMaker AI creates an IAM role named `AmazonSageMaker-ExecutionRole-YYYYMMDDTHHmmSS`. The AWS managed policy `AmazonSageMakerFullAccess` is attached to the role. The role provides permissions that allow the notebook instance to call SageMaker AI and Amazon S3.
- h. For **Root access**, to give root access for all notebook instance users, choose **Enable**. To remove root access for users, choose **Disable**. If you give root access, all notebook instance users have administrator privileges and can access and edit all files on it.
- i. (Optional) **Encryption key** lets you encrypt data on the ML storage volume attached to the notebook instance using an AWS Key Management Service (AWS KMS) key. If you plan to store sensitive information on the ML storage volume, consider encrypting the information.
- j. (Optional) **Network** lets you put your notebook instance inside a Virtual Private Cloud (VPC). A VPC provides additional security and limits access to resources in the VPC from sources outside the VPC. For more information on VPCs, see [Amazon VPC User Guide](#).

#### To add your notebook instance to a VPC:

- i. Choose the **VPC** and a **SubnetId**.
- ii. For **Security Group**, choose your VPC's default security group.
- iii. If you need your notebook instance to have internet access, enable direct internet access. For **Direct internet access**, choose **Enable**. Internet access can make your notebook instance less secure. For more information, see [Connect a Notebook Instance in a VPC to External Resources](#).
- k. (Optional) To associate Git repositories with the notebook instance, choose a default repository and up to three additional repositories. For more information, see [Git repositories with SageMaker AI Notebook Instances](#).
- l. Choose **Create notebook instance**.

In a few minutes, Amazon SageMaker AI launches an ML compute instance—in this case, a notebook instance—and attaches an ML storage volume to it. The notebook instance

has a preconfigured Jupyter notebook server and a set of Anaconda libraries. For more information, see the [CreateNotebookInstance](#) API.

4. When the status of the notebook instance is `InService`, in the console, the notebook instance is ready to use. Choose **Open Jupyter** next to the notebook name to open the classic Jupyter dashboard.

#### Note

To augment the security of your Amazon SageMaker notebook instance, all regional `notebook.region.sagemaker.aws` domains are registered in the internet [Public Suffix List \(PSL\)](#). For further security, we recommend that you use cookies with a `__Host-` prefix to set sensitive cookies for the domains of your SageMaker notebook instances. This helps to defend your domain against cross-site request forgery attempts (CSRF). For more information, see the [Set-Cookie](#) page in the [mozilla.org](#) developer documentation website.

You can choose **Open JupyterLab** to open the JupyterLab dashboard. The dashboard provides access to your notebook instance and sample SageMaker AI notebooks that contain complete code walkthroughs. These walkthroughs show how to use SageMaker AI to perform common machine learning tasks. For more information, see [Access example notebooks](#). For more information, see [Control root access to a SageMaker notebook instance](#).

For more information about Jupyter notebooks, see [The Jupyter notebook](#).

## Access Notebook Instances

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

To access your Amazon SageMaker notebook instances, choose one of the following options:

- Use the console.

Choose **Notebook instances**. The console displays a list of notebook instances in your account. To open a notebook instance with a standard Jupyter interface, choose **Open Jupyter** for that instance. To open a notebook instance with a JupyterLab interface, choose **Open JupyterLab** for that instance.

The console uses your sign-in credentials to send a [CreatePresignedNotebookInstanceUrl](#) API request to SageMaker AI. SageMaker AI returns the URL for your notebook instance, and the console opens the URL in another browser tab and displays the Jupyter notebook dashboard.

#### Note

The URL that you get from a call to [CreatePresignedNotebookInstanceUrl](#) is valid only for 5 minutes. If you try to use the URL after the 5-minute limit expires, you are directed to the AWS Management Console sign-in page.

- Use the API.

To get the URL for the notebook instance, call the [CreatePresignedNotebookInstanceUrl](#) API and use the URL that the API returns to open the notebook instance.

Use the Jupyter notebook dashboard to create and manage notebooks and to write code. For more information about Jupyter notebooks, see <http://jupyter.org/documentation.html>.

## Update a Notebook Instance

After you create a notebook instance, you can update it using the SageMaker AI console and [UpdateNotebookInstance](#) API operation.

You can update the tags of a notebook instance that is InService. To update any other attribute of a notebook instance, its status must be Stopped.

### To update a notebook instance in the SageMaker AI console:

1. Open the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. Choose **Notebook instances**.
3. Choose the notebook instance that you want to update by selecting the notebook instance **Name** from the list.
4. If your notebook **Status** is not Stopped, select the **Stop** button to stop the notebook instance.

When you do this, the notebook instance status changes to Stopping. Wait until the status changes to Stopped to complete the following steps.

5. Select the **Edit** button to open the **Edit notebook instance** page. For information about the notebook properties you can update, see [Create an Amazon SageMaker notebook instance](#).
6. Update your notebook instance and select the **Update notebook instance** button at the bottom of the page when you are done to return to the notebook instances page. Your notebook instance status changes to **Updating**.

When the notebook instance update is complete, the status changes to Stopped.

## Customization of a SageMaker notebook instance using an LCC script

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio

and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).  
[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

A *lifecycle configuration* (LCC) provides shell scripts that run only when you create the notebook instance or whenever you start one. When you create a notebook instance, you can create a new LCC or attach an LCC that you already have. Lifecycle configuration scripts are useful for the following use cases:

- Installing packages or sample notebooks on a notebook instance
- Configuring networking and security for a notebook instance
- Using a shell script to customize a notebook instance

You can also use a lifecycle configuration script to access AWS services from your notebook. For example, you can create a script that lets you use your notebook to control other AWS resources, such as an Amazon EMR instance.

We maintain a public repository of notebook lifecycle configuration scripts that address common use cases for customizing notebook instances at <https://github.com/aws-samples/amazon-sagemaker-notebook-instance-lifecycle-config-samples>.

### Note

Each script has a limit of 16384 characters.

The value of the \$PATH environment variable that is available to both scripts is /usr/local/sbin:/usr/local/bin:/usr/bin:/usr/sbin:/sbin:/bin. The working directory, which is the value of the \$PWD environment variable, is /.

View CloudWatch Logs for notebook instance lifecycle configurations in log group /aws/sagemaker/NotebookInstances in log stream [notebook-instance-name]/[LifecycleConfigHook].

Scripts cannot run for longer than 5 minutes. If a script runs for longer than 5 minutes, it fails and the notebook instance is not created or started. To help decrease the run time of scripts, try the following:

- Cut down on necessary steps. For example, limit which conda environments in which to install large packages.
- Run tasks in parallel processes.
- Use the nohup command in your script.

You can see a list of notebook instance lifecycle configurations you previously created by choosing **Lifecycle configuration** in the SageMaker AI console. You can attach a notebook instance LCC when you create a new notebook instance. For more information about creating a notebook instance, see [Create an Amazon SageMaker notebook instance](#).

## Create a lifecycle configuration script

The following procedure shows how to create a lifecycle configuration script for use with an Amazon SageMaker notebook instance. For more information about creating a notebook instance, see [Create an Amazon SageMaker notebook instance](#).

### To create a lifecycle configuration

1. Open the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Lifecycle configurations**.
4. From the **Lifecycle configurations** page, choose the **Notebook Instance** tab.
5. Choose **Create configuration**.
6. For **Name**, type a name using alphanumeric characters and "-", but no spaces. The name can have a maximum of 63 characters.
7. (Optional) To create a script that runs when you create the notebook and every time you start it, choose **Start notebook**.
8. In the **Start notebook** editor, type the script.
9. (Optional) To create a script that runs only once, when you create the notebook, choose **Create notebook**.
10. In the **Create notebook** editor, type the script configure networking.
11. Choose **Create configuration**.

## Lifecycle Configuration Best Practices

The following are best practices for using lifecycle configurations:

### Important

We do not recommend storing sensitive information in your lifecycle configuration script.

- Lifecycle configurations run as the `root` user. If your script makes any changes within the `/home/ec2-user/SageMaker` directory, (for example, installing a package with `pip`), use the command `sudo -u ec2-user` to run as the `ec2-user` user. This is the same user that Amazon SageMaker AI runs as.
- SageMaker AI notebook instances use `conda` environments to implement different kernels for Jupyter notebooks. If you want to install packages that are available to one or more notebook kernels, enclose the commands to install the packages with `conda` environment commands that activate the `conda` environment that contains the kernel where you want to install the packages.

For example, if you want to install a package only for the `python3` environment, use the following code:

```
#!/bin/bash
sudo -u ec2-user -i <<EOF

# This will affect only the Jupyter kernel called "conda_python3".
source activate python3

# Replace myPackage with the name of the package you want to install.
pip install myPackage
# You can also perform "conda install" here as well.

source deactivate

EOF
```

If you want to install a package in all `conda` environments in the notebook instance, use the following code:

```
#!/bin/bash
sudo -u ec2-user -i <<EOF
```

```
# Note that "base" is special environment name, include it there as well.
for env in base /home/ec2-user/anaconda3/envs/*; do
    source /home/ec2-user/anaconda3/bin/activate $(basename "$env")

    # Installing packages in the Jupyter system environment can affect stability of
    your SageMaker
    # Notebook Instance. You can remove this check if you'd like to install Jupyter
    extensions, etc.
    if [ $env = 'JupyterSystemEnv' ]; then
        continue
    fi

    # Replace myPackage with the name of the package you want to install.
    pip install --upgrade --quiet myPackage
    # You can also perform "conda install" here as well.

    source /home/ec2-user/anaconda3/bin/deactivate
done

EOF
```

- You must store all conda environments in the default environments folder (/home/user/anaconda3/envs).

### Important

When you create or change a script, we recommend that you use a text editor that provides Unix-style line breaks, such as the text editor available in the console when you create a notebook. Copying text from a non-Linux operating system might introduce incompatible line breaks and result in an unexpected error.

## External library and kernel installation

### Important

Currently, all packages in notebook instance environments are licensed for use with Amazon SageMaker AI and do not require additional commercial licenses. However, this

might be subject to change in the future, and we recommend reviewing the licensing terms regularly for any updates.

Amazon SageMaker notebook instances come with multiple environments already installed. These environments contain Jupyter kernels and Python packages including: scikit, Pandas, NumPy, TensorFlow, and MXNet. These environments, along with all files in the `sample-notebooks` folder, are refreshed when you stop and start a notebook instance. You can also install your own environments that contain your choice of packages and kernels.

The different Jupyter kernels in Amazon SageMaker notebook instances are separate conda environments. For information about conda environments, see [Managing environments](#) in the *Conda* documentation.

Install custom environments and kernels on the notebook instance's Amazon EBS volume. This ensures that they persist when you stop and restart the notebook instance, and that any external libraries you install are not updated by SageMaker AI. To do that, use a lifecycle configuration that includes both a script that runs when you create the notebook instance (`on-create`) and a script that runs each time you restart the notebook instance (`on-start`). For more information about using notebook instance lifecycle configurations, see [Customization of a SageMaker notebook instance using an LCC script](#). There is a GitHub repository that contains sample lifecycle configuration scripts at [SageMaker AI Notebook Instance Lifecycle Config Samples](#).

The examples at <https://github.com/aws-samples/amazon-sagemaker-notebook-instance-lifecycle-config-samples/blob/master/scripts/persistent-conda-efs/on-create.sh> and <https://github.com/aws-samples/amazon-sagemaker-notebook-instance-lifecycle-config-samples/blob/master/scripts/persistent-conda-efs/on-start.sh> show the best practice for installing environments and kernels on a notebook instance. The `on-create` script installs the `ipykernel` library to create custom environments as Jupyter kernels, then uses `pip install` and `conda install` to install libraries. You can adapt the script to create custom environments and install libraries that you want. SageMaker AI does not update these libraries when you stop and restart the notebook instance, so you can ensure that your custom environment has specific versions of libraries that you want. The `on-start` script installs any custom environments that you create as Jupyter kernels, so that they appear in the dropdown list in the Jupyter **New** menu.

## Package installation tools

SageMaker notebooks support the following package installation tools:

- `conda install`
- `pip install`

You can install packages using the following methods:

- Lifecycle configuration scripts.

For example scripts, see [SageMaker AI Notebook Instance Lifecycle Config Samples](#). For more information on lifecycle configuration, see [Customize a Notebook Instance Using a Lifecycle Configuration Script](#).

- Notebooks – The following commands are supported.
  - `%conda install`
  - `%pip install`
- The Jupyter terminal – You can install packages using `pip` and `conda` directly.

From within a notebook you can use the system command syntax (lines starting with `!`) to install packages, for example, `!pip install` and `!conda install`. More recently, new commands have been added to IPython: `%pip` and `%conda`. These commands are the recommended way to install packages from a notebook as they correctly take into account the active environment or interpreter being used. For more information, see [Add %pip and %conda magic functions](#).

## Conda

Conda is an open source package management system and environment management system, which can install packages and their dependencies. SageMaker AI supports using Conda with either of the two main channels, the default channel, and the conda-forge channel. For more information, see [Conda channels](#). The conda-forge channel is a community channel where contributors can upload packages.

### Note

Due to how Conda resolves the dependency graph, installing packages from conda-forge can take significantly longer (in the worst cases, upwards of 10 minutes).

The Deep Learning AMI comes with many conda environments and many packages preinstalled. Due to the number of packages preinstalled, finding a set of packages that are guaranteed to

be compatible is difficult. You may see a warning "The environment is inconsistent, please check the package plan carefully". Despite this warning, SageMaker AI ensures that all the SageMaker AI provided environments are correct. SageMaker AI cannot guarantee that any user installed packages will function correctly.

### Note

Users of SageMaker AI, AWS Deep Learning AMIs and Amazon EMR can access the commercial Anaconda repository without taking a commercial license through February 1, 2024 when using Anaconda in those services. For any usage of the commercial Anaconda repository after February 1, 2024, customers are responsible for determining their own Anaconda license requirements.

Conda has two methods for activating environments: `conda activate/deactivate`, and `source activate/deactivate`. For more information, see [Should I use 'conda activate' or 'source activate' in Linux](#).

SageMaker AI supports moving Conda environments onto the Amazon EBS volume, which is persisted when the instance is stopped. The environments aren't persisted when the environments are installed to the root volume, which is the default behavior. For an example lifecycle script, see [persistent-conda-ebs](#).

### Supported conda operations (see note at the bottom of this topic)

- `conda install` of a package in a single environment
- `conda install` of a package in all environments
- `conda install` of a R package in the R environment
- Installing a package from the main conda repository
- Installing a package from conda-forge
- Changing the Conda install location to use EBS
- Supporting both `conda activate` and `source activate`

### Pip

Pip is the de facto tool for installing and managing Python packages. Pip searches for packages on the Python Package Index (PyPI) by default. Unlike Conda, pip doesn't have built in environment

support, and is not as thorough as Conda when it comes to packages with native/system library dependencies. Pip can be used to install packages in Conda environments.

You can use alternative package repositories with pip instead of the PyPI. For an example lifecycle script, see [on-start.sh](#).

### Supported pip operations (see note at the bottom of this topic)

- Using pip to install a package without an active conda environment (install packages system wide)
- Using pip to install a package in a conda environment
- Using pip to install a package in all conda environments
- Changing the pip install location to use EBS
- Using an alternative repository to install packages with pip

### Unsupported

SageMaker AI aims to support as many package installation operations as possible. However, if the packages were installed by SageMaker AI or DLAMI, and you use the following operations on these packages, it might make your notebook instance unstable:

- Uninstalling
- Downgrading
- Upgrading

We do not provide support for installing packages via yum install or installing R packages from CRAN.

Due to potential issues with network conditions or configurations, or the availability of Conda or PyPi, we cannot guarantee that packages will install in a fixed or deterministic amount of time.

#### Note

We cannot guarantee that a package installation will be successful. Attempting to install a package in an environment with incompatible dependencies can result in a failure. In such a case you should contact the library maintainer to see if it is possible to update the package dependencies. Alternatively you can attempt to modify the environment in such a way as

to allow the installation. This modification however will likely mean removing or updating existing packages, which means we can no longer guarantee stability of this environment.

## Notebook Instance Software Updates

Amazon SageMaker AI periodically tests and releases software that is installed on notebook instances. This includes:

- Kernel updates
- Security patches
- AWS SDK updates
- [Amazon SageMaker Python SDK](#) updates
- Open source software updates

To ensure that you have the most recent software updates, stop and restart your notebook instance, either in the SageMaker AI console or by calling [StopNotebookInstance](#).

You can also manually update software installed on your notebook instance while it is running by using update commands in a terminal or in a notebook.

### Note

Updating kernels and some packages might depend on whether root access is enabled for the notebook instance. For more information, see [Control root access to a SageMaker notebook instance](#).

You can check the [Personal Health Dashboard](#) or the security bulletin at [Security Bulletins](#) for updates.

## Control an Amazon EMR Spark Instance Using a Notebook

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to

those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

You can use a notebook instance created with a custom lifecycle configuration script to access AWS services from your notebook. For example, you can create a script that lets you use your notebook with Sparkmagic to control other AWS resources, such as an Amazon EMR instance. You can then use the Amazon EMR instance to process your data instead of running the data analysis on your notebook. This allows you to create a smaller notebook instance because you won't use the instance to process data. This is helpful when you have large datasets that would require a large notebook instance to process the data.

The process requires three procedures using the Amazon SageMaker AI console:

- Create the Amazon EMR Spark instance
- Create the Jupyter Notebook
- Test the notebook-to-Amazon EMR connection

### To create an Amazon EMR Spark instance that can be controlled from a notebook using Sparkmagic

1. Open the Amazon EMR console at <https://console.aws.amazon.com/elasticmapreduce/>.
2. In the navigation pane, choose **Create cluster**.
3. On the **Create Cluster - Quick Options** page, under **Software configuration**, choose **Spark: Spark 2.4.4 on Hadoop 2.8.5 YARN with Ganglia 3.7.2 and Zeppelin 0.8.2**.
4. Set additional parameters on the page and then choose **Create cluster**.
5. On the **Cluster** page, choose the cluster name that you created. Note the **Master Public DNS**, the **EMR master's security group**, and the VPC name and subnet ID where the EMR cluster was created. You will use these values when you create a notebook.

## To create a notebook that uses Sparkmagic to control an Amazon EMR Spark instance

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. In the navigation pane, under **Notebook instances**, choose **Create notebook**.
3. Enter the notebook instance name and choose the instance type.
4. Choose **Additional configuration**, then, under **Lifecycle configuration**, choose **Create a new lifecycle configuration**.
5. Add the following code to the lifecycle configuration script:

```
# OVERVIEW
# This script connects an Amazon EMR cluster to an Amazon SageMaker notebook
  instance that uses Sparkmagic.
#
# Note that this script will fail if the Amazon EMR cluster's master node IP
  address is not reachable.
# 1. Ensure that the EMR master node IP is resolvable from the notebook instance.
#   One way to accomplish this is to have the notebook instance and the Amazon
  EMR cluster in the same subnet.
# 2. Ensure the EMR master node security group provides inbound access from the
  notebook instance security group.
#   Type          - Protocol - Port - Source
#   Custom TCP    - TCP      - 8998 - $NOTEBOOK_SECURITY_GROUP
# 3. Ensure the notebook instance has internet connectivity to fetch the
  SparkMagic example config.
#
# https://aws.amazon.com/blogs/machine-learning/build-amazon-sagemaker-notebooks-
  backed-by-spark-in-amazon-emr/

# PARAMETERS
EMR_MASTER_IP=your.emr.master.ip

cd /home/ec2-user/.sparkmagic

echo "Fetching Sparkmagic example config from GitHub..."
wget https://raw.githubusercontent.com/jupyter-incubator/sparkmagic/master/
  sparkmagic/example_config.json

echo "Replacing EMR master node IP in Sparkmagic config..."
sed -i -- "s/localhost/$EMR_MASTER_IP/g" example_config.json
```

```
mv example_config.json config.json

echo "Sending a sample request to Livy.."
curl "$EMR_MASTER_IP:8998/sessions"
```

6. In the **PARAMETERS** section of the script, replace your `.emr.master.ip` with the Master Public DNS name for the Amazon EMR instance.
7. Choose **Create configuration**.
8. On the **Create notebook** page, choose **Network - optional**.
9. Choose the VPC and subnet where the Amazon EMR instance is located.
10. Choose the security group used by the Amazon EMR master node.
11. Choose **Create notebook instance**.

While the notebook instance is being created, the status is **Pending**. After the instance has been created and the lifecycle configuration script has successfully run, the status is **InService**.

#### **Note**

If the notebook instance can't connect to the Amazon EMR instance, SageMaker AI can't create the notebook instance. The connection can fail if the Amazon EMR instance and notebook are not in the same VPC and subnet, if the Amazon EMR master security group is not used by the notebook, or if the Master Public DNS name in the script is incorrect.

### **To test the connection between the Amazon EMR instance and the notebook**

1. When the status of the notebook is **InService**, choose **Open Jupyter** to open the notebook.
2. Choose **New**, then choose **Sparkmagic (PySpark)**.
3. In the code cell, enter `%%info` and then run the cell.

The output should be similar to the following

```
Current session configs: {'driverMemory': '1000M', 'executorCores': 2, 'kind':
'pyspark'}

No active sessions.
```

## Access example notebooks

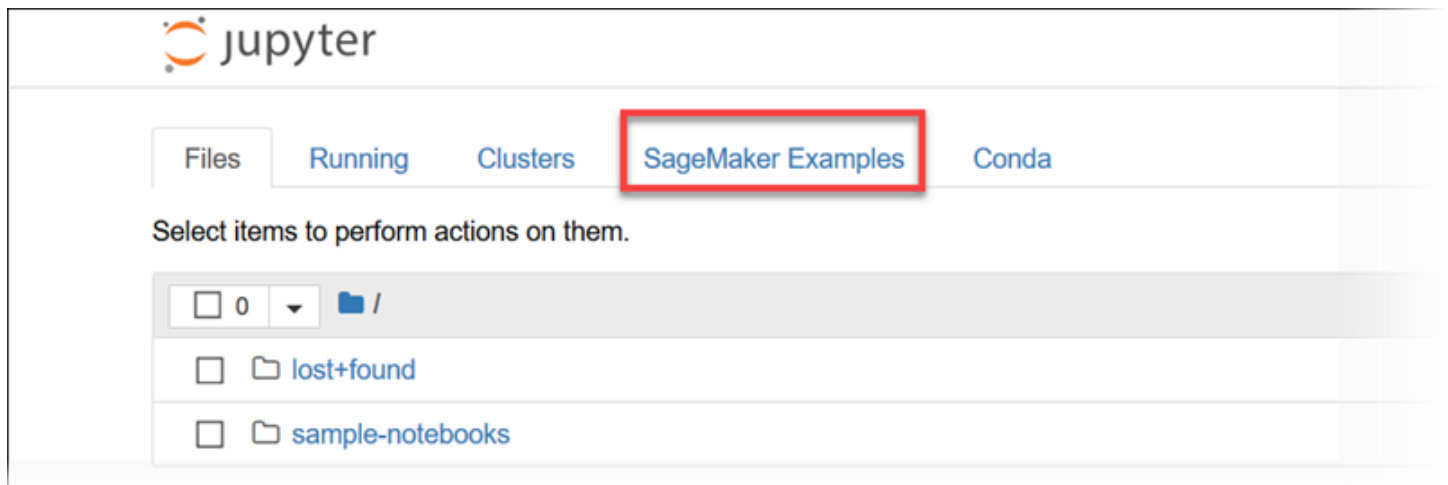

Your notebook instance contains example notebooks provided by Amazon SageMaker AI. The example notebooks contain code that shows how to apply machine learning solutions by using SageMaker AI. Notebook instances use the `nbexamples` Jupyter extension, which enables you to view a read-only version of an example notebook or create a copy of it that you can modify and run. For more information about the `nbexamples` extension, see <https://github.com/danielballan/nbexamples>. For information about example notebooks for SageMaker Studio, see [Use Amazon SageMaker Studio Classic Notebooks](#).

### Note

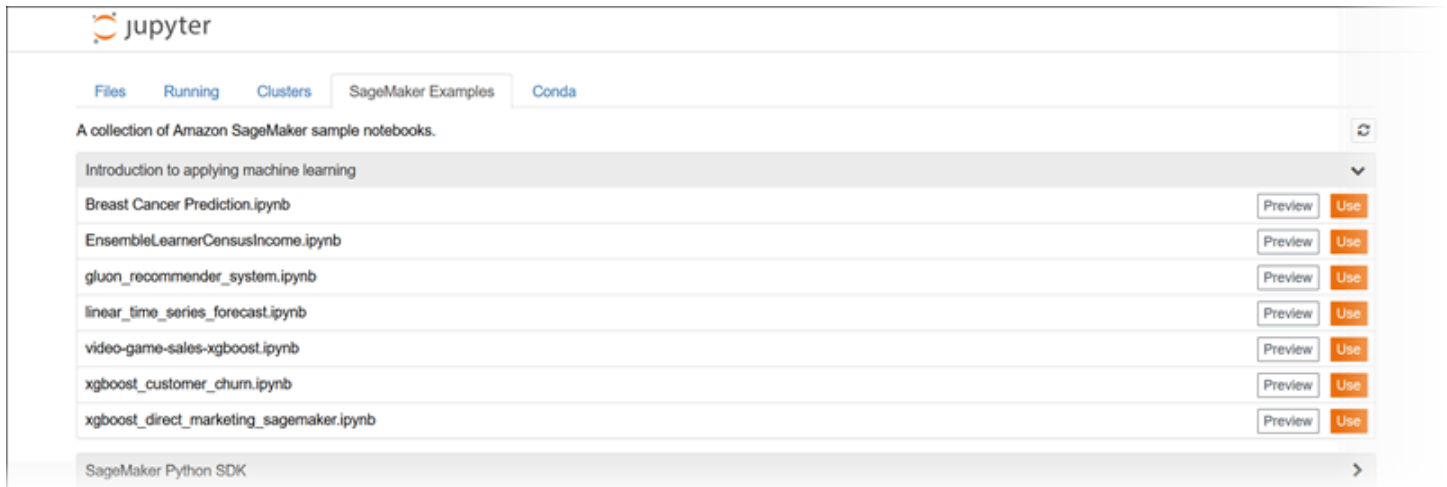

Example notebooks typically download datasets from the internet. If you disable SageMaker AI-provided internet access when you create your notebook instance, example notebooks might not work. For more information, see [Connect a Notebook Instance in a VPC to External Resources](#).

## Use or View Example Notebooks in Jupyter Classic

To view or use the example notebooks in the classic Jupyter view, choose the **SageMaker AI Examples** tab.

To view a read-only version of an example notebook in the Jupyter classic view, on the **SageMaker AI Examples** tab, choose **Preview** for that notebook. To create a copy of an example notebook in the home directory of your notebook instance, choose **Use**. In the dialog box, you can change the notebook's name before saving it.

## Use or View Example Notebooks in Jupyterlab

To view or use the example notebooks in the Jupyterlab view, choose the examples icon in the left navigation panel.

To view a read-only version of an example notebook, choose the name of the notebook. This opens the notebook as a tab in the main area. To create a copy of an example notebook in the home directory of your notebook instance, choose **Create a Copy** in the top banner. In the dialog box, type a name for the notebook and then choose **CREATE COPY**.

For more information about the example notebooks, see the [SageMaker AI examples GitHub repository](#).

## Set the Notebook Kernel

Amazon SageMaker AI provides several kernels for Jupyter that provide support for Python 2 and 3, Apache MXNet, TensorFlow, and PySpark. To set a kernel for a new notebook in the Jupyter notebook dashboard, choose **New**, and then choose the kernel from the list. For more information about the available kernels, see [Available Kernels](#).

You can also create a custom kernel that you can use in your notebook instance. For information, see [External library and kernel installation](#).

## Git repositories with SageMaker AI Notebook Instances

Associate Git repositories with your notebook instance to save your notebooks in a source control environment that persists even if you stop or delete your notebook instance. You can associate one default repository and up to three additional repositories with a notebook instance. The repositories can be hosted in AWS CodeCommit, GitHub, or on any other Git server. Associating Git repositories with your notebook instance can be useful for:

- **Persistence** - Notebooks in a notebook instance are stored on durable Amazon EBS volumes, but they do not persist beyond the life of your notebook instance. Storing notebooks in a Git repository enables you to store and use notebooks even if you stop or delete your notebook instance.
- **Collaboration** - Peers on a team often work on machine learning projects together. Storing your notebooks in Git repositories allows peers working in different notebook instances to share notebooks and collaborate on them in a source-control environment.
- **Learning** - Many Jupyter notebooks that demonstrate machine learning techniques are available in publicly hosted Git repositories, such as on GitHub. You can associate your notebook instance with a repository to easily load Jupyter notebooks contained in that repository.

There are two ways to associate a Git repository with a notebook instance:

- Add a Git repository as a resource in your Amazon SageMaker AI account. Then, to access the repository, you can specify an AWS Secrets Manager secret that contains credentials. That way, you can access repositories that require authentication.
- Associate a public Git repository that is not a resource in your account. If you do this, you cannot specify credentials to access the repository.

## Topics

- [Add a Git repository to your Amazon SageMaker AI account](#)
- [Create a Notebook Instance with an Associated Git Repository](#)
- [Associate a CodeCommit Repository in a Different AWS Account with a Notebook Instance](#)
- [Use Git Repositories in a Notebook Instance](#)

## Add a Git repository to your Amazon SageMaker AI account

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

To manage your GitHub repositories, easily associate them with your notebook instances, and associate credentials for repositories that require authentication, add the repositories as resources in your Amazon SageMaker AI account. You can view a list of repositories that are stored in your account and details about each repository in the SageMaker AI console and by using the API.

You can add Git repositories to your SageMaker AI account in the SageMaker AI console or by using the AWS CLI.

**Note**

You can use the SageMaker AI API [CreateCodeRepository](#) to add Git repositories to your SageMaker AI account, but step-by-step instructions are not provided here.

## Add a Git repository to your SageMaker AI account (Console)

### To add a Git repository as a resource in your SageMaker AI account

1. Open the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. Under **Notebook**, choose **Git repositories**, then choose **Add repository**.
3. To add an CodeCommit repository, choose **AWS CodeCommit**. To add a GitHub or other Git-based repository, choose **GitHub/Other Git-based repo**.

### To add an existing CodeCommit repository

1. Choose **Use existing repository**.
2. For **Repository**, choose a repository from the list.
3. Enter a name to use for the repository in SageMaker AI. The name must be 1 to 63 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
4. Choose **Add repository**.

### To create a new CodeCommit repository

1. Choose **Create new repository**.
2. Enter a name for the repository that you can use in both CodeCommit and SageMaker AI. The name must be 1 to 63 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
3. Choose **Create repository**.

### To add a Git repository hosted somewhere other than CodeCommit

1. Choose **GitHub/Other Git-based repo**.
2. Enter a name of up to 63 characters. Valid characters include alpha-numeric characters, a hyphen (-), and 0-9.

3. Enter the URL for the repository. Do not provide a username in the URL. Add the sign-in credentials in AWS Secrets Manager as described in the next step.
4. For **Git credentials**, choose the credentials to use to authenticate to the repository. This is necessary only if the Git repository is private.

 **Note**

If you have two-factor authentication enabled for your Git repository, enter a personal access token generated by your Git service provider in the password field.

- a. To use an existing AWS Secrets Manager secret, choose **Use existing secret**, and then choose a secret from the list. For information about creating and storing a secret, see [Creating a Basic Secret](#) in the *AWS Secrets Manager User Guide*. The name of the secret you use must contain the string `sagemaker`.

 **Note**

The secret must have a staging label of `AWSCURRENT` and must be in the following format:

```
{"username": UserName, "password": Password}
```

For GitHub repositories, we recommend using a personal access token in the password field. For information, see <https://help.github.com/articles/creating-a-personal-access-token-for-the-command-line/>.

- b. To create a new AWS Secrets Manager secret, choose **Create secret**, enter a name for the secret, and then enter the sign-in credentials to use to authenticate to the repository. The name for the secret must contain the string `sagemaker`.

 **Note**

The IAM role you use to create the secret must have the `secretsmanager:GetSecretValue` permission in its IAM policy.

The secret must have a staging label of `AWSCURRENT` and must be in the following format:

```
{"username": UserName, "password": Password}
```

For GitHub repositories, we recommend using a personal access token.

- c. To not use any credentials, choose **No secret**.
5. Choose **Create secret**.

## Add a Git repository to your Amazon SageMaker AI account (CLI)

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

Use the `create-code-repository` AWS CLI command to add a Git repository to Amazon SageMaker AI to give users access to external resources. Specify a name for the repository as the value of the `code-repository-name` argument. The name must be 1 to 63 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen). Also specify the following:

- The default branch
- The URL of the Git repository

### Note

Do not provide a username in the URL. Add the sign-in credentials in AWS Secrets Manager as described in the next step.

- The Amazon Resource Name (ARN) of an AWS Secrets Manager secret that contains the credentials to use to authenticate the repository as the value of the `git-config` argument

For information about creating and storing a secret, see [Creating a Basic Secret](#) in the *AWS Secrets Manager User Guide*. The following command creates a new repository named `MyRepository`

in your Amazon SageMaker AI account that points to a Git repository hosted at `https://github.com/myprofile/my-repo`".

For Linux, OS X, or Unix:

```
aws sagemaker create-code-repository \
    --code-repository-name "MyRepository" \
    --git-config Branch=branch,RepositoryUrl=https://github.com/
myprofile/my-repo,SecretArn=arn:aws:secretsmanager:us-east-2:012345678901:secret:my-
secret-ABc0DE
```

For Windows:

```
aws sagemaker create-code-repository ^
    --code-repository-name "MyRepository" ^
    --git-config "{\"Branch\":\"master\", \"RepositoryUrl\" :
    \"https://github.com/myprofile/my-repo\", \"SecretArn\" :
    \"arn:aws:secretsmanager:us-east-2:012345678901:secret:my-secret-ABc0DE\"}"
```

### Note

The secret must have a staging label of `AWSCURRENT` and must be in the following format:  
`{"username": UserName, "password": Password}`  
For GitHub repositories, we recommend using a personal access token.

## Create a Notebook Instance with an Associated Git Repository

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

You can associate Git repositories with a notebook instance when you create the notebook instance by using the AWS Management Console, or the AWS CLI. If you want to use a CodeCommit repository that is in a different AWS account than the notebook instance, set up cross-account access for the repository. For information, see [Associate a CodeCommit Repository in a Different AWS Account with a Notebook Instance](#).

## Topics

- [Create a Notebook Instance with an Associated Git Repository \(Console\)](#)
- [Create a Notebook Instance with an Associated Git Repository \(CLI\)](#)

## Create a Notebook Instance with an Associated Git Repository (Console)

To create a notebook instance and associate Git repositories in the Amazon SageMaker AI console

1. Follow the instructions at [Create an Amazon SageMaker Notebook Instance for the tutorial](#).
2. For **Git repositories**, choose Git repositories to associate with the notebook instance.
  - a. For **Default repository**, choose a repository that you want to use as your default repository. SageMaker AI clones this repository as a subdirectory in the Jupyter startup directory at `/home/ec2-user/SageMaker`. When you open your notebook instance, it opens in this repository. To choose a repository that is stored as a resource in your account, choose its name from the list. To add a new repository as a resource in your account, choose **Add a repository to SageMaker AI (opens the Add repository flow in a new window)** and then follow the instructions at [Create a Notebook Instance with an Associated Git Repository \(Console\)](#). To clone a public repository that is not stored in your account, choose **Clone a public Git repository to this notebook instance only**, and then specify the URL for that repository.
  - b. For **Additional repository 1**, choose a repository that you want to add as an additional directory. SageMaker AI clones this repository as a subdirectory in the Jupyter startup directory at `/home/ec2-user/SageMaker`. To choose a repository that is stored as a resource in your account, choose its name from the list. To add a new repository as

a resource in your account, choose **Add a repository to SageMaker AI (opens the Add repository flow in a new window)** and then follow the instructions at [Create a Notebook Instance with an Associated Git Repository \(Console\)](#). To clone a repository that is not stored in your account, choose **Clone a public Git repository to this notebook instance only**, and then specify the URL for that repository.

Repeat this step up to three times to add up to three additional repositories to your notebook instance.

## Create a Notebook Instance with an Associated Git Repository (CLI)

### Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#). [AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

To create a notebook instance and associate Git repositories by using the AWS CLI, use the `create-notebook-instance` command as follows:

- Specify the repository that you want to use as your default repository as the value of the `default-code-repository` argument. Amazon SageMaker AI clones this repository as a subdirectory in the Jupyter startup directory at `/home/ec2-user/SageMaker`. When you open your notebook instance, it opens in this repository. To use a repository that is stored as a resource in your SageMaker AI account, specify the name of the repository as the value of the `default-code-repository` argument. To use a repository that is not stored in your account, specify the URL of the repository as the value of the `default-code-repository` argument.
- Specify up to three additional repositories as the value of the `additional-code-repositories` argument. SageMaker AI clones this repository as a subdirectory in the Jupyter

startup directory at `/home/ec2-user/SageMaker`, and the repository is excluded from the default repository by adding it to the `.git/info/exclude` directory of the default repository. To use repositories that are stored as resources in your SageMaker AI account, specify the names of the repositories as the value of the `additional-code-repositories` argument. To use repositories that are not stored in your account, specify the URLs of the repositories as the value of the `additional-code-repositories` argument.

For example, the following command creates a notebook instance that has a repository named `MyGitRepo`, that is stored as a resource in your SageMaker AI account, as a default repository, and an additional repository that is hosted on GitHub:

```
aws sagemaker create-notebook-instance \
    --notebook-instance-name "MyNotebookInstance" \
    --instance-type "ml.t2.medium" \
    --role-arn "arn:aws:iam::012345678901:role/service-role/
AmazonSageMaker-ExecutionRole-20181129T121390" \
    --default-code-repository "MyGitRepo" \
    --additional-code-repositories "https://github.com/myprofile/my-
other-repo"
```

### Note

If you use an AWS CodeCommit repository that does not contain "SageMaker" in its name, add the `codecommit:GitPull` and `codecommit:GitPush` permissions to the role that you pass as the `role-arn` argument to the `create-notebook-instance` command. For information about how to add permissions to a role, see [Adding and Removing IAM Policies](#) in the *AWS Identity and Access Management User Guide*.

## Associate a CodeCommit Repository in a Different AWS Account with a Notebook Instance

To associate a CodeCommit repository in a different AWS account with your notebook instance, set up cross-account access for the CodeCommit repository.

## To set up cross-account access for a CodeCommit repository and associate it with a notebook instance:

1. In the AWS account that contains the CodeCommit repository, create an IAM policy that allows access to the repository from users in the account that contains your notebook instance. For information, see [Step 1: Create a Policy for Repository Access in AccountA](#) in the *CodeCommit User Guide*.
2. In the AWS account that contains the CodeCommit repository, create an IAM role, and attach the policy that you created in the previous step to that role. For information, see [Step 2: Create a Role for Repository Access in AccountA](#) in the *CodeCommit User Guide*.
3. Create a profile in the notebook instance that uses the role that you created in the previous step:
  - a. Open the notebook instance.
  - b. Open a terminal in the notebook instance.
  - c. Edit a new profile by typing the following in the terminal:

```
vi /home/ec2-user/.aws/config
```

- d. Edit the file with the following profile information:

```
[profile CrossAccountAccessProfile]  
region = us-west-2  
role_arn =  
  arn:aws:iam::CodeCommitAccount:role/CrossAccountRepositoryContributorRole  
credential_source=Ec2InstanceMetadata  
output = json
```

Where *CodeCommitAccount* is the account that contains the CodeCommit repository, *CrossAccountAccessProfile* is the name of the new profile, and *CrossAccountRepositoryContributorRole* is the name of the role you created in the previous step.

4. On the notebook instance, configure git to use the profile you created in the previous step:
  - a. Open the notebook instance.
  - b. Open a terminal in the notebook instance.
  - c. Edit the Git configuration file typing the following in the terminal:

```
vi /home/ec2-user/.gitconfig
```

- d. Edit the file with the following profile information:

```
[credential]
    helper = !aws codecommit credential-helper --
profile CrossAccountAccessProfile $@
    UseHttpPath = true
```

Where *CrossAccountAccessProfile* is the name of the profile that you created in the previous step.

## Use Git Repositories in a Notebook Instance

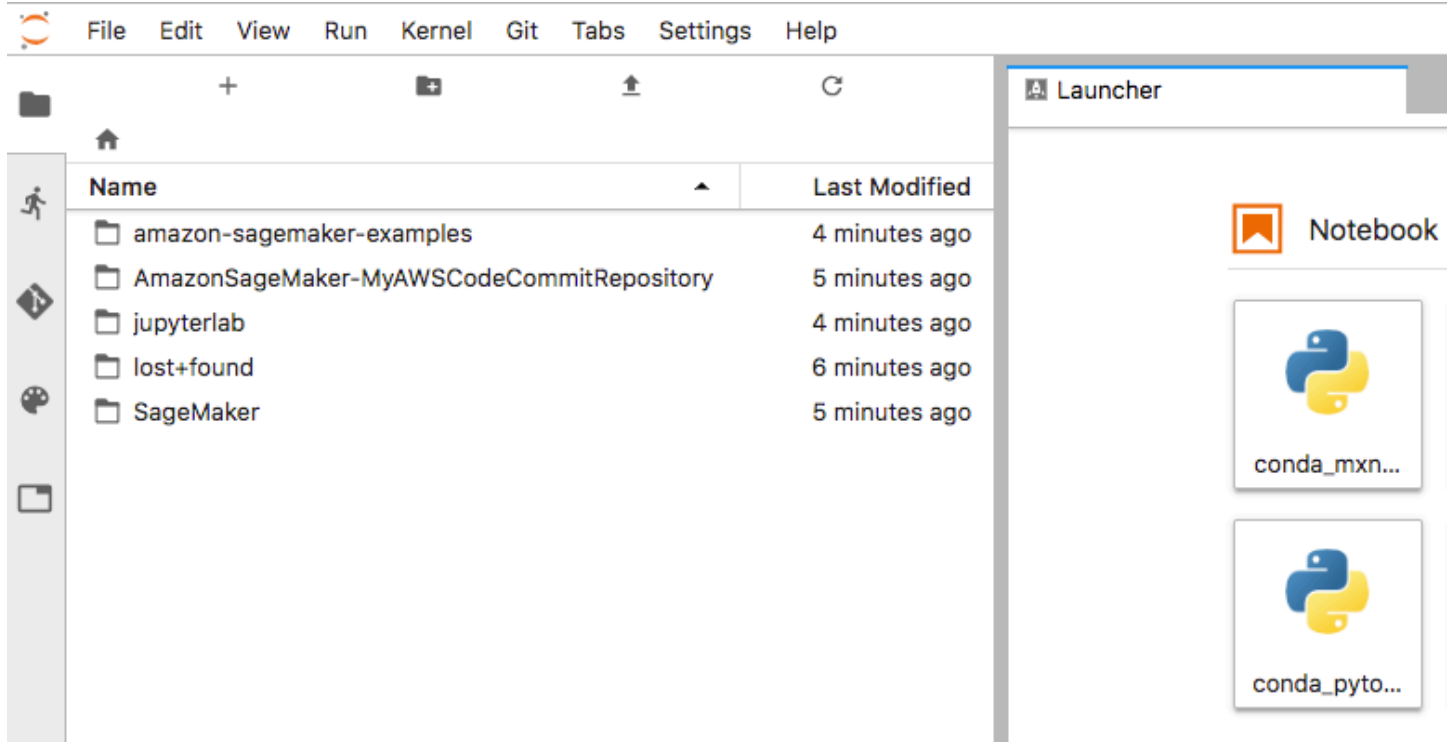

When you open a notebook instance that has Git repositories associated with it, it opens in the default repository, which is installed in your notebook instance directly under `/home/ec2-user/SageMaker`. You can open and create notebooks, and you can manually run Git commands in a notebook cell. For example:

```
!git pull origin master
```

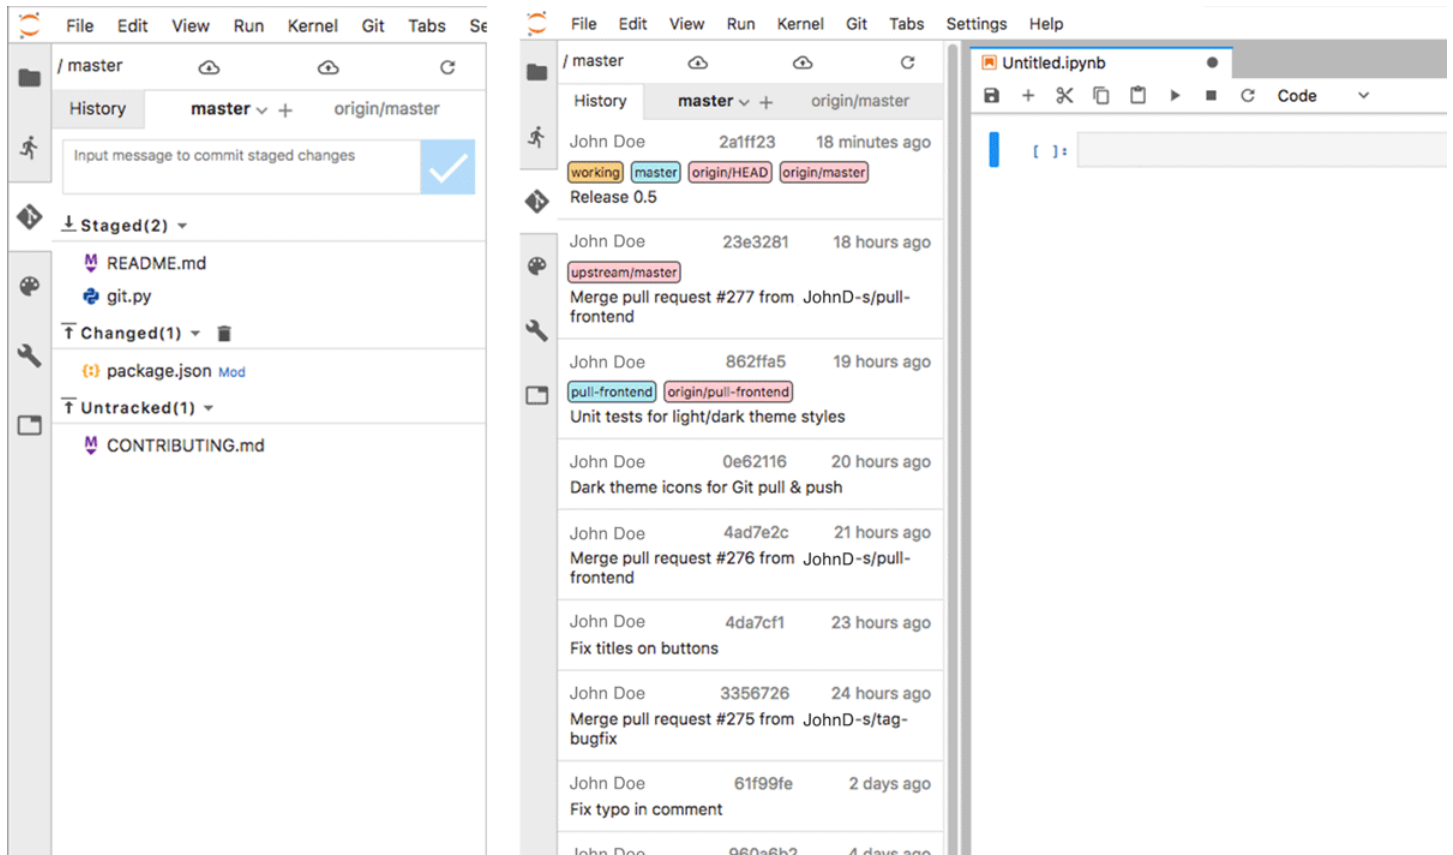

To open any of the additional repositories, navigate up one folder. The additional repositories are also installed as directories under `/home/ec2-user/SageMaker`.

If you open the notebook instance with a JupyterLab interface, the `jupyter-git` extension is installed and available to use. For information about the `jupyter-git` extension for JupyterLab, see <https://github.com/jupyterlab/jupyterlab-git>.

When you open a notebook instance in JupyterLab, you see the git repositories associated with it on the left menu:

You can use the jupyter-git extension to manage git visually, instead of using the command line:

## Notebook Instance Metadata

When you create a notebook instance, Amazon SageMaker AI creates a JSON file on the instance at the location `/opt/ml/metadata/resource-metadata.json` that contains the `ResourceName` and `ResourceArn` of the notebook instance. You can access this metadata from anywhere within the notebook instance, including in lifecycle configurations. For information about notebook instance lifecycle configurations, see [Customization of a SageMaker notebook instance using an LCC script](#).

### Note

The `resource-metadata.json` file can be modified with root access.

The `resource-metadata.json` file has the following structure:

```
{
  "ResourceArn": "NotebookInstanceArn",
  "ResourceName": "NotebookInstanceName"
}
```

You can use this metadata from within the notebook instance to get other information about the notebook instance. For example, the following commands get the tags associated with the notebook instance:

```
NOTEBOOK_ARN=$(jq '.ResourceArn'
                  /opt/ml/metadata/resource-metadata.json --raw-output)
aws sagemaker list-tags --resource-arn $NOTEBOOK_ARN
```

The output looks like the following:

```
{
  "Tags": [
    {
      "Key": "test",
      "Value": "true"
    }
  ]
}
```

## Monitor Jupyter Logs in Amazon CloudWatch Logs

Jupyter logs include important information such as events, metrics, and health information that provide actionable insights when running Amazon SageMaker notebooks. By importing Jupyter logs into CloudWatch Logs, customers can use CloudWatch Logs to detect anomalous behaviors, set alarms, and discover insights to keep the SageMaker AI notebooks running more smoothly. You can access the logs even when the Amazon EC2 instance that hosts the notebook is unresponsive, and use the logs to troubleshoot the unresponsive notebook. Sensitive information such as AWS account IDs, secret keys, and authentication tokens in presigned URLs are removed so that customers can share logs without leaking private information.

### To view Jupyter logs for a notebook instance:

1. Sign in to the AWS Management Console and open the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. Choose **Notebook instances**.
3. In the list of notebook instances, choose the notebook instance for which you want to view Jupyter logs by selecting the Notebook instance **Name**.

This will bring you to the details page for that notebook instance.

4. Under **Monitor** on the notebook instance details page, choose **View logs**.
5. In the CloudWatch console, choose the log stream for your notebook instance. Its name is in the form *NotebookInstanceName*/jupyter.log.

For more information about monitoring CloudWatch logs for SageMaker AI, see [Log groups and streams that Amazon SageMaker AI sends to Amazon CloudWatch Logs](#).

## Amazon SageMaker Studio Lab

Amazon SageMaker Studio Lab is a free service that gives customers access to AWS compute resources, in an environment based on open-source JupyterLab. It is based on the same architecture and user interface as Amazon SageMaker Studio Classic, but with a subset of Studio Classic capabilities.

With Studio Lab, you can use AWS compute resources to create and run your Jupyter notebooks without signing up for an AWS account. Because Studio Lab is based on open-source JupyterLab, you can take advantage of open-source Jupyter extensions to run your Jupyter notebooks.

## Studio Lab compared to Amazon SageMaker Studio Classic

While Studio Lab provides free access to AWS compute resources, Amazon SageMaker Studio Classic provides the following advanced machine learning capabilities that Studio Lab does not support.

- Continuous integration and continuous delivery (Pipelines)
- Real-time predictions
- Large-scale distributed training
- Data preparation (Amazon SageMaker Data Wrangler)
- Data labeling (Amazon SageMaker Ground Truth)
- Feature Store
- Bias analysis (Clarify)
- Model deployment
- Model monitoring

Studio Classic also supports fine-grained access control and security by using AWS Identity and Access Management (IAM), Amazon Virtual Private Cloud (Amazon VPC), and AWS Key Management Service (AWS KMS). Studio Lab does not support these Studio Classic features, nor does it support the use of estimators and built-in SageMaker AI algorithms.

To export your Studio Lab projects for use with Studio Classic, see [Export an Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio Classic](#).

The following topics give information about Studio Lab and how to use it

### Topics

- [Amazon SageMaker Studio Lab components overview](#)
- [Onboard to Amazon SageMaker Studio Lab](#)
- [Manage your account](#)
- [Launch your Amazon SageMaker Studio Lab project runtime](#)
- [Use Amazon SageMaker Studio Lab starter assets](#)
- [Studio Lab pre-installed environments](#)
- [Use the Amazon SageMaker Studio Lab project runtime](#)
- [Troubleshooting](#)

## Amazon SageMaker Studio Lab components overview

Amazon SageMaker Studio Lab consists of the following components. The following topics give more details about these components.

### Topics

- [Landing page](#)
- [Studio Lab account](#)
- [Project overview page](#)
- [Preview page](#)
- [Project](#)
- [Compute instance type](#)
- [Project runtime](#)
- [Session](#)

### Landing page

You can request an account and sign in to an existing account on your landing page. To navigate to the landing page, see the [Amazon SageMaker Studio Lab website](#). For more information about creating a Studio Lab account, see [Onboard to Amazon SageMaker Studio Lab](#).

The following screenshot shows the Studio Lab landing page interface for requesting a user account and signing in.

Sign in

# Learn and experiment with machine learning

Quickly create data analytics, scientific computing, and machine learning projects with notebooks in your browser.

Request free account

▶ Watch video

## Studio Lab account

Your Studio Lab account gives you access to Studio Lab. For more information about creating a user account, see [Onboard to Amazon SageMaker Studio Lab](#).

## Project overview page

You can launch a compute instance and view information about your project on this page. To navigate to this page, you must sign in from the [Amazon SageMaker Studio Lab website](#). The URL takes the following format.

```
https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>
```

The following screenshot shows a project overview in the Studio Lab user interface.

## My Project

Status  
Idle

Time remaining ⓘ  
—

Select compute type ⓘ  
 CPU  GPU

▶ Start runtime

Open  
project

## Preview page

On this page, you can access a read-only preview of a Jupyter notebook. You can not execute the notebook from preview, but you can copy that notebook into your project. For many customers, this may be the first Studio Lab page that customers see, as they may be opening a notebook from GitHub notebook. For more information on how to use GitHub resources, see [Use GitHub resources](#).

To copy the notebook preview to your Studio Lab project:

1. Sign in to your Studio Lab account. For more information about creating a Studio Lab account, see [Onboard to Amazon SageMaker Studio Lab](#).
2. Under **Notebook compute instance**, choose a compute instance type. For more information about compute instance types, see [Compute instance type](#).
3. Choose **Start runtime**. You might be asked to solve a CAPTCHA puzzle. For more information on CAPTCHA, see [What is a CAPTCHA puzzle?](#)
4. One time setup, for first time starting runtime using your Studio Lab account:
  - a. Enter a mobile phone number to associate with your Amazon SageMaker Studio Lab account and choose **Continue**.

For information on supported countries and regions, see [Supported countries and regions \(SMS channel\)](#).

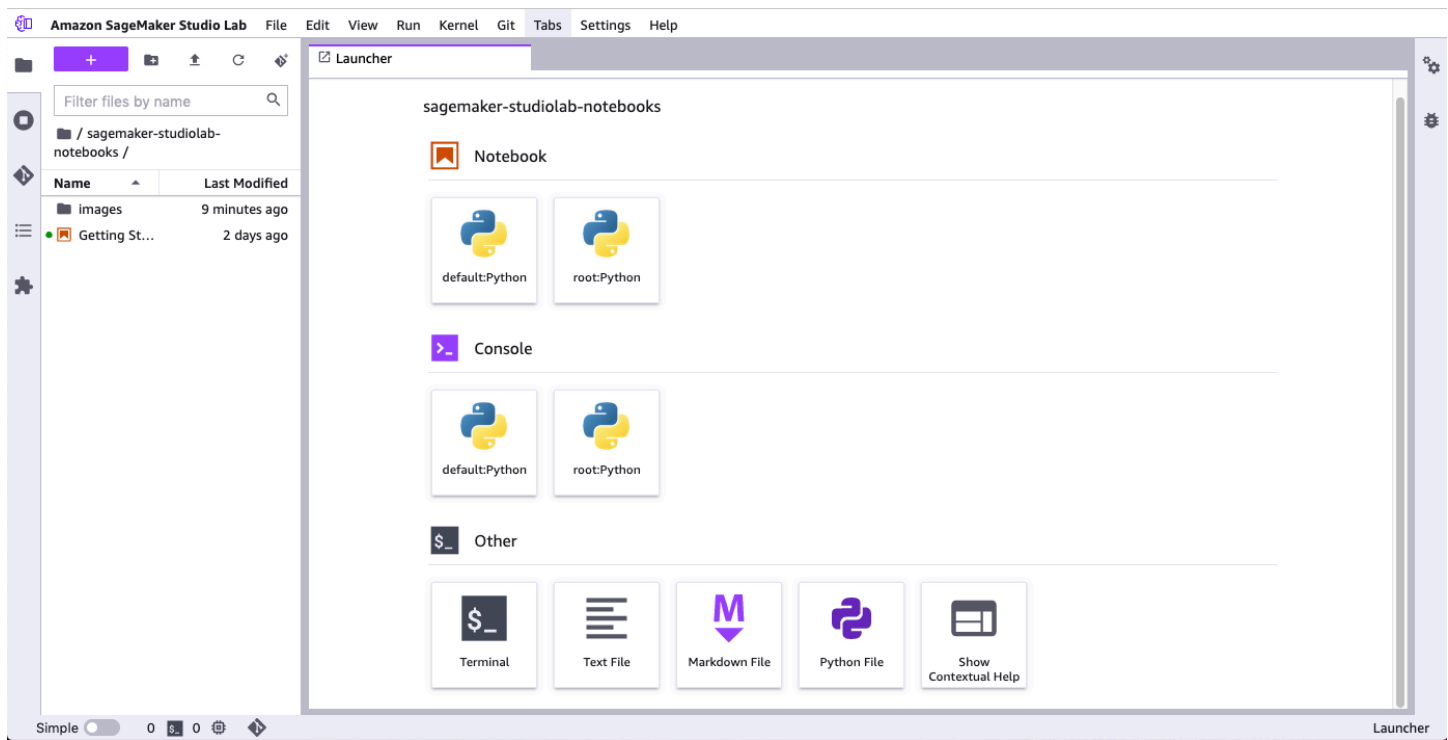

- b. Enter the 6-digit code sent to the associated mobile phone number and choose **Verify**.
5. Choose **Copy to project**.

## Project

Your project contains all of your files and folders, including your Jupyter notebooks. You have full control over the files in your project. Your project also includes the JupyterLab-based user interface. From this interface, you can interact with your Jupyter notebooks, edit your source code files, integrate with GitHub, and connect to Amazon S3. For more information, see [Use the Amazon SageMaker Studio Lab project runtime](#).

The following screenshot shows a Studio Lab project with the file browser open and the Studio Lab Launcher displayed.

## Compute instance type

Your Amazon SageMaker Studio Lab project runtime is based on an EC2 instance. You are allotted 15 GB of storage and 16 GB of RAM. Availability of compute instances is not guaranteed and is subject to demand. If you require additional storage or compute resources, consider switching to Studio.

Amazon SageMaker Studio Lab offers the choice of a CPU (Central Processing Unit) and a GPU (Graphical Processing Unit). The following sections give information about these two options, including selection guidance.

### CPU

A central processing unit (CPU) is designed to handle a wide range of tasks efficiently, but is limited in how many tasks it can run concurrently. For machine learning, a CPU is recommended for compute intensive algorithms, such as time series, forecasting, and tabular data.

The CPU compute type has up to 4 hours at a time with a limit of 8 hours in a 24-hour period.

## GPU

A graphics processing unit (GPU) is designed to render high-resolution images and video concurrently. A GPU is recommended for deep learning tasks, especially for transformers and computer vision.

The GPU compute type has up to 4 hours at a time with a limit of 4 hours in a 24-hour period.

## Compute time

When compute time for Studio Lab reaches its time limit, the instance stops all running computations. Studio Lab does not support time limit increases.

Studio Lab automatically saves your environment when you update your environment and every time you create a new file. Custom-installed extensions and packages persist even after your runtime has ended.

File edits are periodically saved, but are not saved when your runtime ends. To ensure that you do not lose your progress, save your work manually. If you have content in your Studio Lab project that you don't want to lose, we recommend that you back up your content elsewhere. For more information about exporting your environment and files, see [Export an Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio Classic](#).

During long computation, you do not need to keep your project open. For example, you can start training a model, then close your browser. The instance keeps running for up to the compute type limit in a 24-hour period. You can then sign in later to continue your work.

We recommend that you use checkpointing in your deep learning jobs. You can use saved checkpoints to restart a job from the previously saved checkpoint. For more information, see [File I/O](#).

## Project runtime

The project runtime is the period of time when your compute instance is running.

## Session

A user session begins every time you launch your project.

## Onboard to Amazon SageMaker Studio Lab

To onboard to Amazon SageMaker Studio Lab, follow the steps in this guide. In the following sections, you learn how to request a Studio Lab account, create your account, and sign in.

### Topics

- [Request a Studio Lab account](#)
- [Create a Studio Lab account](#)
- [Sign in to Studio Lab](#)

### Request a Studio Lab account

To use Studio Lab, you must first request approval to create a Studio Lab account. An AWS account cannot be used for onboarding to Studio Lab.

The following steps show how to request a Studio Lab account.

1. Navigate to the [Studio Lab landing page](#).
2. Select **Request account**.
3. Enter the required information into the form.
4. Select **Submit request**.
5. If you receive an email to verify your email address, follow the instructions in the email to complete this step.

Your account request must be approved before you can register for a Studio Lab account. Your request will be reviewed within five business days. When your account request is approved, you receive an email with a link to the Studio Lab account registration page. This link expires seven days after your request is approved. If the link expires, you must submit a new account request.

Note: Your account request is denied if your email has been associated with activity that violates our [Terms of Service](#) or other agreements.

## Referral codes

Studio Lab referral codes enable new account requests to be automatically approved to support machine learning events like workshops, hackathons, and classes. With a referral code, a trusted host can get their participants immediate access to Studio Lab. After an account has been created using a referral code, the account continues to exist after the expiration of the code.

To get a referral code, contact [Sales Support](#). To use a referral code, enter the code as part of the account request form.

## Create a Studio Lab account

After your request is approved, complete the following steps to create your Studio Lab account.

1. Select **Create account** in the account request approval email to open a new page.
2. From the new page, enter your **Email**, a **Password**, and a **Username**.
3. Select **Create account**.

You might be asked to solve a CAPTCHA puzzle. For more information on CAPTCHA, see [What is a CAPTCHA puzzle?](#)

## Sign in to Studio Lab

After you register for your account, you can sign in to Studio Lab.

1. Navigate to the [Studio Lab landing page](#).
2. Select **Sign in** to open a new page.
3. Enter your **Email** or **Username** and **Password**.
4. Select **Sign in** to open a new page to your project.

You might be asked to solve a CAPTCHA puzzle. For more information on CAPTCHA, see [What is a CAPTCHA puzzle?](#)

## Manage your account

The following topic gives information about managing your account, including changing your password, deleting your account, and getting information that we have collected. These topics

require that you sign in to your Amazon SageMaker Studio Lab account. For more information, see [Sign in to Studio Lab](#).

## Change your password

Follow these steps to change your Amazon SageMaker Studio Lab password.

1. Navigate to the Studio Lab project overview page. The URL takes the following format.

```
https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>
```

2. From the top-right corner, select your user name to open a dropdown menu.
3. From the dropdown menu, select **Change password** to open a new page.
4. Enter your current password into the **Enter your current password** field.
5. Enter your new password into the **Create a new password** and **Confirm your new password** fields.
6. Select **Submit**.

## Delete your account

Follow these steps to delete your Studio Lab account.

1. Navigate to the Studio Lab project overview page. The URL takes the following format.

```
https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>
```

2. From the top-right corner, select your user name to open a dropdown menu.
3. From the dropdown menu, select **Delete account** to open a new page.
4. Enter your password to confirm the deletion of your Studio Lab account.
5. Select **Delete**.

## Customer information

Studio Lab collects your email address, user name, encrypted password, project files, and metadata. When requesting an account, you can optionally choose to provide your first and last name, country, organization name, occupation, and the reason for your interest in this product.

We protect all customer personal data with encryption. For more information about how your personal information is handled, see the [Privacy Notice](#).

When you delete your account, all of your information is deleted immediately. If you have an inquiry about this, submit the [Amazon SageMaker Studio Lab Form](#). For information and support related to AWS compliance, see [Compliance support](#).

## Launch your Amazon SageMaker Studio Lab project runtime

The Amazon SageMaker Studio Lab project runtime lets you write and run code directly from your browser. It is based on JupyterLab and has an integrated terminal and console. For more information about JupyterLab, see the [JupyterLab Documentation](#).

The following topic gives information about how to manage your project runtime. These topics require that you sign in to your Amazon SageMaker Studio Lab account. For more information about signing in, see [Sign in to Studio Lab](#). For more information about your project, see [Amazon SageMaker Studio Lab components overview](#).

### Topics

- [Start your project runtime](#)
- [Stop your project runtime](#)
- [View remaining compute time](#)
- [Change your compute type](#)

### Start your project runtime

To use Studio Lab, you must start your project runtime. This runtime gives you access to the JupyterLab environment.

1. Navigate to the Studio Lab project overview page. The URL takes the following format.

```
https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>
```

2. Under **My Project**, select a compute type. For more information about compute types, see [Compute instance type](#).
3. Select **Start runtime**.

You might be asked to solve a CAPTCHA puzzle. For more information on CAPTCHA, see [What is a CAPTCHA puzzle?](#)

4. One time setup, for first time starting runtime using your Studio Lab account:
  - a. Enter a mobile phone number to associate with your Amazon SageMaker Studio Lab account and choose **Continue**.

For information on supported countries and regions, see [Supported countries and regions \(SMS channel\)](#).

- b. Enter the 6-digit code sent to the associated mobile phone number and choose **Verify**.
5. After the runtime is running, select **Open project** to open the project runtime environment in a new browser tab.

## Stop your project runtime

When you stop your project runtime, your files are not automatically saved. To ensure that you don't lose your work, save all of your changes before stopping your project runtime.

- Under **My Project**, select **Stop runtime**.

## View remaining compute time

Your project runtime has limited compute time based on the compute type that you select. For more information about compute time in Studio Lab, see [Compute instance type](#).

- Under **My Project**, view **Time remaining**.

## Change your compute type

You can switch your compute type based on your workflow. For more information about compute types, see [Compute instance type](#).

1. Save any project files before changing the compute type.
2. Navigate to the Studio Lab project overview page. The URL takes the following format.

```
https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>
```

3. Under **My Project**, select the desired compute type (CPU or GPU).
4. Confirm your choice by selecting **Restart** in the **Restart project runtime?** dialog box. Studio Lab stops your current project runtime, then starts a new project runtime with your updated compute type.
5. After your project runtime has started, select **Open project**. This opens your project runtime environment in a new browser tab. For information about using your project runtime environment, see [Use the Amazon SageMaker Studio Lab project runtime](#).

## Use Amazon SageMaker Studio Lab starter assets

Amazon SageMaker Studio Lab supports the following assets to help machine learning (ML) practitioners get started. This guide shows you how to clone notebooks for your project.

### Getting started notebook

Studio Lab comes with a starter notebook that gives general information and guides you through key workflows. When you launch your project runtime for the first time, this notebook automatically opens.

### Dive into Deep Learning

Dive into Deep Learning (D2L) is an interactive, open-source book that teaches the ideas, mathematical theory, and code that power machine learning. With over 150 Jupyter notebooks, D2L provides a comprehensive overview of deep learning principles. For more information about D2L, see the [D2L website](#).

The following procedure shows how to clone the D2L Jupyter notebooks to your instance.

1. Start and open the Studio Lab project runtime environment by following [Start your project runtime](#).
2. Once Studio Lab is open, choose the Git tab  on the left sidebar.
3. Choose **Clone a Repository**.

If you do not see the **Clone a Repository** option, this may be because you are currently in a Git repository. Instead, use the following substeps.

- a. Choose the Folder tab  
 on the left sidebar.
  - b. Beneath the file search bar, choose the folder icon to the left of the currently selected repository. When you hover over the folder icon, you will see the user directory (/home/studio-lab-user).
  - c. Once you are in the user directory, choose the Git tab on the left sidebar.
  - d. Choose **Clone a Repository**.
4. Under **Git repository URL (.git)** you will be asked to provide a URL.
  5. On a new browser tab, navigate to your Studio Lab project overview page. The URL takes the following format.

```
https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>
```

6. Under **New to machine learning?**, choose **Dive into Deep Learning**.
7. From the new **Dive into Deep Learning** browser tab, choose **GitHub** to open a new page with the example notebooks.
8. Choose **Code** and copy the GitHub repository's URL in the **HTTPS** tab.
9. Return to the Studio Lab open project browser tab, paste the D2L repository URL, and clone the repository.

## AWS Machine Learning University

The AWS Machine Learning University (MLU) provides access to the machine learning courses used to train Amazon's own developers. With AWS MLU, any developer can learn how to use machine learning with the learn-at-your-own-pace MLU Accelerator learning series. The MLU Accelerator series is designed to help developers begin their ML journey. It offers three-day foundational courses on these three subjects: Natural Language Processing, Tabular Data, and Computer Vision. For more information, see [Machine Learning University](#).

The following procedure shows how to clone the AWS MLU Jupyter notebooks to your instance.

1. Start and open the Studio Lab project runtime environment by following [Start your project runtime](#).

2. Once Studio Lab is open, choose the Git tab

on the left sidebar.

3. Choose **Clone a Repository**.

If you do not see the **Clone a Repository** option, this may be because you are currently in a Git repository. Instead, use the following substeps.

- a. Choose the Folder tab

on the left sidebar.

- b. Beneath the file search bar, choose the folder icon to the left of the currently selected repository. When you hover over the folder icon, you will see the user directory (/home/studio-lab-user).
- c. Once you are in the user directory, choose the Git tab on the left sidebar.
- d. Choose **Clone a Repository**.

4. Under **Git repository URL (.git)** you will be asked to provide a URL.

5. On a new browser tab, navigate to your Studio Lab project overview page. The URL takes the following format.

```
https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>
```

6. Under **New to machine learning?**, choose **AWS Machine Learning University**.
7. From the new **AWS Machine Learning University** browser tab, find a course that interests you by reading the **Course Summary** for each course.
8. Choose the corresponding GitHub repository of interest under **Course Content**, to open a new page with the example notebooks.
9. Choose **Code** and copy the GitHub repository's URL in the **HTTPS** tab.
10. Return to the Studio Lab open project browser tab, paste the MLU repository URL, and choose **Clone** to clone the repository.

## Roboflow

Roboflow gives you the tools to train, fine-tune, and label objects for computer vision applications. For more information, see <https://roboflow.com/>.

The following procedure shows how to clone the Roboflow Jupyter notebooks to your instance.

1. Navigate to the Studio Lab project overview page. The URL takes the following format.

```
https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>
```

2. Under **Resources and community**, find **Make AI Generated Images**.
3. Under **Make AI Generated Images** choose **Open notebook**.
4. Follow the tutorial under the Notebook preview.

## Studio Lab pre-installed environments

Amazon SageMaker Studio Lab uses conda environments to manage packages (or libraries) for your projects. This guide explains what conda environments are, how to interact with them, and the different pre-installed environments available in Studio Lab.

A conda environment is a directory that contains a collection of packages you have installed. It allows you to create isolated environments with specific package versions, preventing conflicts between projects with different dependencies.

You can interact with conda environments in Studio Lab in two ways:

- **Terminal:** Use the terminal to create, activate, and manage environments.
- **JupyterLab Notebook:** When opening a JupyterLab notebook, select the kernel with the environment name you wish to use, to use the packages installed in that environment.

For a walkthrough on managing environments, see [Manage your environment](#)

Studio Lab comes with several pre-installed environments that are either persistent or non-persistent memory environments. Any changes made to persistent memory environments will remain for your next session. Any changes to non-persistent memory environments will not remain for your next sessions, but the packages within will be updated and tested for compatibility by Amazon SageMaker AI. Here's an overview of each environment and its use case:

- **sagemaker-distribution:** A non-persistent environment managed by Amazon SageMaker AI. It contains popular packages for machine learning, data science, and visualization. This environment is regularly updated and tested for compatibility. Use this environment if you want a fully-managed setup with common packages pre-installed.

The `sagemaker-distribution` environment is closely related to the environment used in Amazon SageMaker Studio Classic, so after graduating from Studio Lab to Studio Classic the notebooks should run similarly. For information on exporting your environment from Studio Lab to Studio Classic, see [Export an Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio Classic](#).

- `default`: A persistent environment with minimal packages pre-installed. Use this environment if you want to customize it significantly by installing additional packages.
- `studiolab`: A persistent environment where JupyterLab and related packages installed. Use this environment for configuring the JupyterLab user interface and installing Jupyter server extensions.
- `studiolab-safemode`: A non-persistent environment activated automatically when there's an issue with your project runtime. Use this environment for troubleshooting purposes. For information on troubleshooting, see [Troubleshooting](#).
- `base`: A non-persistent environment used for system tooling. This environment is not intended for customer use.

To view the packages in an environment, run the command `conda list`.

For more information on installing packages within your environment, see [Customize your environment](#).

If you plan to graduate from Studio Lab to Amazon SageMaker Studio Classic, see [Export an Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio Classic](#).

For information on SageMaker images and their versions, see [Amazon SageMaker images available for use with Studio Classic](#).

## Use the Amazon SageMaker Studio Lab project runtime

The following topics give information about using the Amazon SageMaker Studio Lab project runtime. Before you can use the Studio Lab project runtime, you must onboard to Studio Lab by following the steps in [Onboard to Amazon SageMaker Studio Lab](#).

### Topics

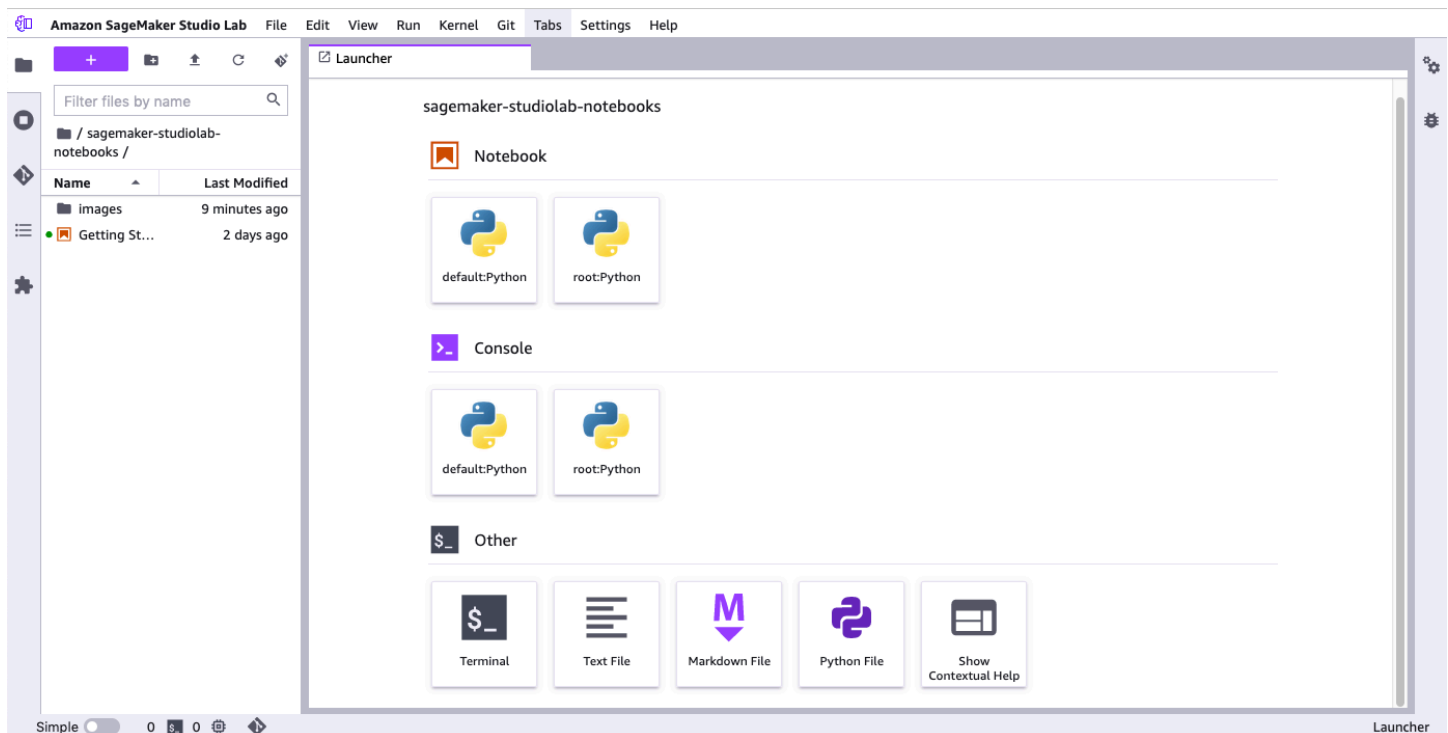

- [Amazon SageMaker Studio Lab UI overview](#)
- [Create or open an Amazon SageMaker Studio Lab notebook](#)

- [Use the Amazon SageMaker Studio Lab notebook toolbar](#)
- [Manage your environment](#)
- [Use external resources in Amazon SageMaker Studio Lab](#)
- [Get notebook differences](#)
- [Export an Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio Classic](#)
- [Shut down Studio Lab resources](#)

## Amazon SageMaker Studio Lab UI overview

Amazon SageMaker Studio Lab extends the JupyterLab interface. Previous users of JupyterLab will notice similarities between the JupyterLab and Studio Lab UI, including the workspace. For an overview of the basic JupyterLab interface, see [The JupyterLab Interface](#).

The following image shows Studio Lab with the file browser open and the Studio Lab Launcher displayed.

You will find the *menu bar* at the top of the screen. The *left sidebar* contains icons to open file browsers, resource browsers, and tools. The *status bar* is located at the bottom-left corner of Studio Lab.

The main work area is divided horizontally into two panes. The left pane is the *file and resource browser*. The right pane contains one or more tabs for resources, such as notebooks and terminals.

## Topics

- [Left sidebar](#)
- [File and resource browser](#)
- [Main work area](#)

## Left sidebar

The left sidebar includes the following icons. When you hover over an icon, a tooltip displays the icon name. When you choose an icon, the file and resource browser displays the described functionality. For hierarchical entries, a selectable breadcrumb at the top of the browser shows your location in the hierarchy.

Icon	Description
	<p><b>File Browser</b></p> <p>Choose the <b>Upload Files</b> icon  to add files to Studio Lab.</p> <p>Double-click a file to open the file in a new tab.</p> <p>To have adjacent files open, choose a tab that contains a notebook, Python, or text file, and then choose <b>New View for File</b>.</p> <p>Choose the plus (+) sign on the menu at the top of the file browser to open the Studio Lab Launcher.</p>
	<p><b>Running Terminals and Kernels</b></p> <p>You can see a list of all of the running terminals and kernels in your project. For more information, see <a href="#">Shut down Studio Lab resources</a>.</p>
	<p><b>Git</b></p>

Icon	Description
	You can connect to a Git repository and then access a full range of Git tools and operations. For more information, see <a href="#">Use external resources in Amazon SageMaker Studio Lab</a> .
	<b>Table of Contents</b> You can access the Table of Contents for your current Jupyter notebook.
	<b>Extension Manager</b> You can enable and manage third-party JupyterLab extensions.

## File and resource browser

The file and resource browser shows lists of your notebooks and files. On the menu at the top of the file browser, choose the plus (+) sign to open the Studio Lab Launcher. The Launcher allows you to create a notebook or open a terminal.

## Main work area

The main work area has multiple tabs that contain your open notebooks and terminals.

## Create or open an Amazon SageMaker Studio Lab notebook

When you create a notebook in Amazon SageMaker Studio Lab or open a notebook in Studio Lab, you must select a kernel for the notebook. The following topics describe how to create and open notebooks in Studio Lab.

For information about shutting down the notebook, see [Shut down Studio Lab resources](#).

## Topics

- [Open a Studio Lab notebook](#)
- [Create a notebook from the file menu](#)
- [Create a notebook from the Launcher](#)

## Open a Studio Lab notebook

Studio Lab can only open notebooks listed in the Studio Lab file browser. To clone a notebook into your file browser from an external repository, see [Use external resources in Amazon SageMaker Studio Lab](#).

### To open a notebook

1. In the left sidebar, choose the **File Browser** icon

to display the file browser.

2. Browse to a notebook file and double-click it to open the notebook in a new tab.

### Create a notebook from the file menu

#### To create a notebook from the File menu

1. From the Studio Lab menu, choose **File**, choose **New**, and then choose **Notebook**.
2. To use the default kernel, in the **Select Kernel** dialog box, choose **Select**. Otherwise, to select a different kernel, use the dropdown menu.

### Create a notebook from the Launcher

#### To create a notebook from the Launcher

1. Open the Launcher by using the keyboard shortcut `Ctrl + Shift + L`.

Alternatively, you can open Launcher from the left sidebar: Choose the **File Browser** icon, and then choose the plus (+) icon.

2. To use the default kernel from the Launcher, under **Notebook**, choose **default:Python**. Otherwise, select a different kernel.

After you choose the kernel, your notebook launches and opens in a new Studio Lab tab.

To view the notebook's kernel session, in the left sidebar, choose the **Running Terminals and Kernels** icon

You can stop the notebook's kernel session from this view.

## Use the Amazon SageMaker Studio Lab notebook toolbar

Amazon SageMaker Studio Lab notebooks extend the JupyterLab interface. For an overview of the basic JupyterLab interface, see [The JupyterLab Interface](#).

The following image shows the toolbar and an empty cell from a Studio Lab notebook.

When you hover over a toolbar icon, a tooltip displays the icon function. You can find additional notebook commands in the Studio Lab main menu. The toolbar includes the following icons:

Icon	Description
	<p><b>Save and checkpoint</b></p> <p>Saves the notebook and updates the checkpoint file.</p>
	<p><b>Insert cell</b></p> <p>Inserts a code cell below the current cell. The current cell is noted by the blue vertical marker in the left margin.</p>
	<p><b>Cut, copy, and paste cells</b></p> <p>Cuts, copies, and pastes the selected cells.</p>
	<p><b>Run cells</b></p> <p>Runs the selected cells. The cell that follows the last-selected cell becomes the new-selected cell.</p>
	<p><b>Interrupt kernel</b></p> <p>Interrupts the kernel, which cancels the currently-running operation. The kernel remains active.</p>
	<p><b>Restart kernel</b></p>

Icon	Description
	<p>Restarts the kernel. Variables are reset. Unsaved information is not affected.</p>
	<p><b>Restart kernel and re-run notebook</b></p> <p>Restarts the kernel. Variables are reset. Unsaved information is not affected. Then re-runs the entire notebook.</p>
	<p><b>Cell type</b></p> <p>Displays or changes the current cell type. The cell types are:</p> <ul style="list-style-type: none"> <li>• Code – Code that the kernel runs.</li> <li>• Markdown – Text rendered as markdown.</li> <li>• Raw – Content, including Markdown markup, that's displayed as text.</li> </ul>
	<p><b>Checkpoint diff</b></p> <p>Opens a new tab that displays the difference between the notebook and the checkpoint file. For more information, see <a href="#">Get notebook differences</a>.</p>
	<p><b>Git diff</b></p> <p>Only enabled if the notebook is opened from a Git repository. Opens a new tab that displays the difference between the notebook and the last Git commit. For more information, see <a href="#">Get notebook differences</a>.</p>
<p><b>default</b></p>	<p><b>Kernel</b></p> <p>Displays or changes the kernel that processes the cells in the notebook.</p> <p>No <code>Kernel</code> indicates that the notebook was opened without specifying a kernel. You can edit the notebook, but you can't run any cells.</p>

Icon	Description
	<p><b>Kernel busy status</b></p> <p>Displays a kernel's busy status by showing the circle's edge and its interior as the same color. The kernel is busy when it is starting and when it is processing cells. Additional kernel states are displayed in the status bar at the bottom-left corner of Studio Lab.</p>

## Manage your environment

Amazon SageMaker Studio Lab provides pre-installed environments for your Studio Lab notebook instances. Environments allow you to start up a Studio Lab notebook instance with the packages you want to use. This is done by installing packages in the environment and then selecting the environment as a Kernel.

Studio Lab has various environments pre-installed for you. You will typically want to use the `sagemaker-distribution` environment if you want to use a fully managed environment that already contains many popular packages used for machine learning (ML) engineers and data scientists. Otherwise you can use the default environment if you want persistent customization for your environment. For more information on the available pre-installed Studio Lab environments, see [Studio Lab pre-installed environments](#).

You can customize your environment by adding new packages (or libraries) to it. You can also create new environments from Studio Lab, import compatible environments, reset your environment to create space, and more.

The following commands are for running in a Studio Lab terminal. However, while installing packages it is highly recommended to install them within your Studio Lab Jupyter notebook. This ensures that the packages are installed in the intended environment. To run the commands in a Jupyter notebook, prefix the command with a `%` before running the cell. For example, the code snippet `pip list` in a terminal is the same as `%pip list` in a Jupyter notebook.

The following sections give information about your default conda environment, how to customize it, and how to add and remove conda environments. For a list of sample environments that you can install into Studio Lab, see [Creating Custom conda Environments](#). To use these sample environment YAML files with Studio Lab, see [Step 4: Install your Studio Lab conda environments in Studio Classic](#).

## Topics

- [Your default environment](#)
- [View environments](#)
- [Create, activate, and use new conda environments](#)
- [Using sample Studio Lab environments](#)
- [Customize your environment](#)
- [Refresh Studio Lab](#)

## Your default environment

Studio Lab uses conda environments to encapsulate the software packages that are needed to run notebooks. Your project contains a default conda environment, named `default`, with the [IPython kernel](#). This environment serves as the default kernel for your Jupyter notebooks.

## View environments

To view the environments in Studio Lab you can use a terminal or Jupyter notebook. The following command will be for a Studio Lab terminal. If you wish to run the corresponding commands in a Jupyter notebook, see [Manage your environment](#).

Open the Studio Lab terminal by opening the **File Browser** panel

choose the plus (+) sign on the menu at the top of the file browser to open the **Launcher**, then choose **Terminal**. From the Studio Lab terminal, list the conda environments by running the following.

```
conda env list
```

This command outputs a list of the conda environments and their locations in the file system. When you onboard to Studio Lab, you automatically activate the `studiolab` conda environment. The following is an example of listed environments after you onboard.

```
# conda environments:
#
default                /home/studio-lab-user/.conda/envs/default
studiolab              * /home/studio-lab-user/.conda/envs/studiolab
```

```
studiolab-safemode      /opt/amazon/sagemaker/safemode-home/.conda/envs/studiolab-  
safemode  
base                    /opt/conda  
sagemaker-distribution  /opt/conda/envs/sagemaker-distribution
```

The \* marks the activated environment.

## Create, activate, and use new conda environments

If you would like to maintain multiple environments for different use cases, you can create new conda environments in your project. The following sections show how to create and activate new conda environments. For a Jupyter notebook that shows how to create a custom environment, see [Setting up a Custom Environment in SageMaker Studio Lab](#).

### Note

Maintaining multiple environments counts against your available Studio Lab memory.

## Create conda environment

To create a conda environment, run the following conda command from your terminal. This example creates a new environment with Python 3.9.

```
conda create --name <ENVIRONMENT_NAME> python=3.9
```

Once the conda environment is created, you can view the environment in your environment list. For more information on how to view your environment list, see [View environments](#).

## Activate a conda environment

To activate any conda environment, run the following command in the terminal.

```
conda activate <ENVIRONMENT_NAME>
```

When you run this command, any packages installed using conda or pip are installed in the environment. For more information on installing packages, see [Customize your environment](#).

## Use a conda environment

1. To use your new conda environments with notebooks, make sure the `ipykernel` package is installed in the environment.

```
conda install ipykernel
```

2. Once the `ipykernel` package is installed in the environment, you can select the environment as the kernel for your notebook.

You may need to restart JupyterLab to see the environment available as a kernel. This can be done by choosing **Amazon SageMaker Studio Lab** in the top menu of your Studio Lab open project, and choosing **Restart JupyterLab....**

3. You can choose the kernel for an existing notebook or when you create a new one.
  - For an existing notebook: open the notebook and choose the current kernel from the right side of the top menu. You can choose the kernel you wish to use from the drop-down menu.
  - For a new notebook: open the Studio Lab launcher and choose the kernel under **Notebook**. This will open the notebook with the kernel you choose.

For an overview of the Studio Lab UI, see [Amazon SageMaker Studio Lab UI overview](#).

## Using sample Studio Lab environments

Studio Lab provides sample custom environments through the [SageMaker Studio Lab Examples](#) repository. The following shows how to clone and build these environments.

1. Clone the SageMaker Studio Lab Examples GitHub repository by following the instructions in [Use GitHub resources](#).
2. In Studio Lab choose the **File Browser** icon  on the left menu, so that the **File Browser** panel shows on the left.
3. Navigate to the `studio-lab-examples/custom-environments` directory in the File Browser.
4. Open the directory for the environment that you want to build.
5. Right click the `.yaml` file in the folder, then select **Build conda Environment**.
6. You can now use the environment as a kernel after your conda environment has finished building. For instructions on how to use an existing environment as a kernel, see [Create, activate, and use new conda environments](#)

## Customize your environment

You can customize your environment by installing and removing extensions and packages as needed. Studio Lab comes with environments with packages pre-installed and using an existing environment may save you time and memory, as pre-installed packages do not count against your available Studio Lab memory. For more information on the available pre-installed Studio Lab environments, see [Studio Lab pre-installed environments](#).

Any installed extensions and packages installed on your default environment will persist in your project. That is, you do not need to install your packages for every project runtime session. However, extensions and packages installed on your `sagemaker-distribution` environment will not persist, so you will need to install new packages during your next session. Thus, it is highly recommended to install packages within your notebook to ensure that the packages are installed in the intended environment.

To view your environments, run the command `conda env list`.

To activate your environment, run the command `conda activate <ENVIRONMENT_NAME>`.

To view the packages in an environment, run the command `conda list`.

## Install packages

It is highly recommended to install your packages within your Jupyter notebook to ensure that your packages are installed in the intended environment. To install additional packages to your environment from a Jupyter notebook, run one of the following commands in a cell within your Jupyter notebook. These commands install packages in the currently activated environment.

- `%conda install <PACKAGE>`
- `%pip install <PACKAGE>`

We don't recommend using the `!pip` or `!conda` commands because they can behave in unexpected ways when you have multiple environments.

After you install new packages to your environment, you may need to restart the kernel to ensure that the packages work in your notebook. This can be done by choosing **Amazon SageMaker Studio Lab** in the top menu of your Studio Lab open project and choosing **Restart JupyterLab...**

## Remove packages

To remove a package, run the command

```
%conda remove <PACKAGE_NAME>
```

This command will also remove any package that depends on `<PACKAGE_NAME>`, unless a replacement can be found without that dependency.

To remove all of the packages in an environment, run the command

```
conda deactivate  
&& conda env remove --name  
<ENVIRONMENT_NAME>
```

## Refresh Studio Lab

To refresh Studio Lab, remove all of your environments and files.

1. List all conda environments.

```
conda env list
```

2. Activate the base environment.

```
conda activate base
```

3. Remove each environment in the list of conda environments, besides base.

```
conda remove --name <ENVIRONMENT_NAME> --all
```

4. Delete all of the files on your Studio Lab.

```
rm -rf *.*
```

## Use external resources in Amazon SageMaker Studio Lab

With Amazon SageMaker Studio Lab, you can integrate external resources, such as Jupyter notebooks and data, from Git repositories and Amazon S3. You can also add an **Open in Studio Lab** button to your GitHub repo and notebooks. This button lets you clone your notebooks directly from Studio Lab.

The following topics show how to integrate external resources.

## Topics

- [Use GitHub resources](#)
- [Add an Open in Studio Lab button to your notebook](#)
- [Import files from your computer](#)
- [Connect to Amazon S3](#)

### Use GitHub resources

Studio Lab offers integration with GitHub. With this integration, you can clone notebooks and repositories directly to your Studio Lab project.

The following topics give information about how to use GitHub resources with Studio Lab.

### Studio Lab sample notebooks

To get started with a repository of sample notebooks tailored for Studio Lab, see [Studio Lab Sample Notebooks](#).

This repository provides notebooks for the following use cases and others.

- Computer vision
- Connecting to AWS
- Creating custom environments
- Geospatial data analysis
- Natural language processing
- Using R

### Clone a GitHub repo

To clone a GitHub repo to your Studio Lab project, follow these steps.

1. Start your Studio Lab project runtime. For more information on launching Studio Lab project runtime, see [Start your project runtime](#).

2. In Studio Lab, choose the **File Browser** icon

)

on the left menu, so that the **File Browser** panel shows on the left.

3. Navigate to your user directory by choosing the file icon beneath the file search bar.
4. Select the **Git** icon  from the left menu to open a new dropdown menu.
5. Choose **Clone a Repository**.
6. Paste the repository's URL under **Git repository URL (.git)**.
7. Select **Clone**.

## Clone individual notebooks from GitHub

To open a notebook in Studio Lab, you must have access to the repo that the notebook is in. The following examples describe Studio Lab permission-related behavior in various situations.

- If a repo is public, you can automatically clone the notebook into your project from the Studio Lab preview page.
- If a repo is private, you are prompted to sign in to GitHub from the Studio Lab preview page. If you have access to a private repo, you can clone the notebook into your project.
- If you don't have access to a private repo, you cannot clone the notebook from the Studio Lab preview page.

The following sections show two options for you to copy a GitHub notebook in your Studio Lab project. These options depend on whether the notebook has an **Open in Studio Lab** button.

### Option 1: Copy notebook with an Open in Studio Lab button

The following procedure shows how to copy a notebook that has an **Open in Studio Lab** button. If you want to add this button to your notebook, see [Add an Open in Studio Lab button to your notebook](#).

1. Sign in to Studio Lab following the steps in [Sign in to Studio Lab](#).
2. In a new browser tab, navigate to the GitHub notebook that you want to clone.
3. In the notebook, select the **Open in Studio Lab** button to open a new page in Studio Lab with a preview of the notebook.
4. If your project runtime is not already running, start it by choosing the **Start runtime** button at the top of the preview page. Wait for the runtime to start before proceeding to the next step.

5. After your project runtime has started, select **Copy to project** to open your project runtime in a new browser tab.
6. In the **Copy from GitHub?** dialog box, select **Copy notebook only**. This copies the notebook file to your project.

## Option 2: Clone any GitHub notebook

The following procedure shows how to copy any notebook from GitHub.

1. Navigate to the notebook in GitHub.
2. In the browser's address bar, modify the notebook URL, as follows.

```
# Original URL
https://github.com/<PATH_TO_NOTEBOOK>

# Modified URL
https://studiolab.sagemaker.aws/import/github/<PATH_TO_NOTEBOOK>
```

3. Navigate to the modified URL. This opens a preview of the notebook in Studio Lab.
4. If your project runtime is not already running, start it by choosing the **Start runtime** button at the top of the preview page. Wait for the runtime to start before proceeding to the next step.
5. After your project runtime has started, select **Copy to project** to open your project runtime in a new browser tab.
6. In the **Copy from GitHub?** dialog box, select **Copy notebook only** to copy the notebook file to your project.

## Add an Open in Studio Lab button to your notebook

When you add the **Open in Studio Lab** button to your notebooks, others can clone your notebooks or repositories directly to their Studio Lab projects. If you are sharing your notebook within a public GitHub repository, your content will be publicly readable. Do not share private content, such as AWS access keys or AWS Identity and Access Management credentials, in your notebook.

To add the functional **Open in Studio Lab** button to your Jupyter notebook or repository, add the following markdown to the top of your notebook or repository.

```
[![Open In SageMaker Studio Lab](https://studiolab.sagemaker.aws/studiolab.svg)]
(https://studiolab.sagemaker.aws/import/github/<PATH_TO_YOUR_NOTEBOOK_ON_GITHUB>)
```

## Import files from your computer

The following steps show how to import files from your computer to your Studio Lab project.

1. Open the Studio Lab project runtime.
2. Open the **File Browser** panel.
3. In the actions bar of the **File Browser** panel, select the **Upload Files** button.
4. Select the files that you want to upload from your local machine.
5. Select **Open**.

Alternatively, you can drag and drop files from your computer into the **File Browser** panel.

## Connect to Amazon S3

The AWS CLI enables AWS integration in your Studio Lab project. With this integration, you can pull resources from Amazon S3 to use with your Jupyter notebooks.

To use AWS CLI with Studio Lab, complete the following steps. For a notebook that outlines this integration, see [Using Studio Lab with AWS Resources](#).

1. Install the AWS CLI following the steps in [Installing or updating the latest version of the AWS CLI](#).
2. Configure your AWS credentials by following the steps in [Quick setup](#). The role for your AWS account must have permissions to access the Amazon S3 bucket that you are copying data from.
3. From your Jupyter notebook, clone resources from the Amazon S3 bucket, as needed. The following command shows how to clone all resources from an Amazon S3 path to your project. For more information, see the [AWS CLI Command Reference](#).

```
!aws s3 cp s3://<BUCKET_NAME>/<PATH_TO_RESOURCES>/ <PROJECT_DESTINATION_PATH>/ --recursive
```

## Get notebook differences

You can display the difference between the current notebook and the last checkpoint, or the last Git commit, using the Amazon SageMaker Studio Lab project UI.

## Topics

- [Get the difference between the last checkpoint](#)
- [Get the difference between the last commit](#)

### Get the difference between the last checkpoint

When you create a notebook, a hidden checkpoint file that matches the notebook is created. You can view changes between the notebook and the checkpoint file, or revert the notebook to match the checkpoint file.

To save the Studio Lab notebook and update the checkpoint file to match: Choose the **Save notebook and create checkpoint** icon

).

This is located on the Studio Lab menu's left side. The keyboard shortcut for **Save notebook and create checkpoint** is `Ctrl + s`.

To view changes between the Studio Lab notebook and the checkpoint file: Choose the **Checkpoint diff** icon

),

located in the center of the Studio Lab menu.

To revert the Studio Lab notebook to the checkpoint file: On the main Studio Lab menu, choose **File**, and then **Revert Notebook to Checkpoint**.

### Get the difference between the last commit

If a notebook is opened from a Git repository, you can view the difference between the notebook and the last Git commit.

To view the changes in the notebook from the last Git commit: Choose the **Git diff** icon

)

in the center of the notebook menu.

## Export an Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio Classic

Amazon SageMaker Studio Classic offers many features for machine learning and deep learning work flows that are unavailable in Amazon SageMaker Studio Lab. This page shows how to

migrate a Studio Lab environment to Studio Classic to take advantage of more compute capacity, storage, and features. However, you may want to familiarize yourself with Studio Classic's prebuilt containers, which are optimized for the full MLOP pipeline. For more information, see [Amazon SageMaker Studio Lab](#)

To migrate your Studio Lab environment to Studio Classic, you must first onboard to Studio Classic following the steps in [Amazon SageMaker AI domain overview](#).

## Topics

- [Step 1: Export your Studio Lab conda environment](#)
- [Step 2: Save your Studio Lab artifacts](#)
- [Step 3: Import your Studio Lab artifacts to Studio Classic](#)
- [Step 4: Install your Studio Lab conda environments in Studio Classic](#)

### Step 1: Export your Studio Lab conda environment

You can export a conda environment and add libraries or packages to the environment by following the steps in [Manage your environment](#). The following example demonstrates using the default environment to be exported to Studio Classic.

1. Open the Studio Lab terminal by opening the **File Browser** panel

),

choose the plus (+) sign on the menu at the top of the file browser to open the **Launcher**, then choose **Terminal**. From the Studio Lab terminal, list the conda environments by running the following.

```
conda env list
```

This command outputs a list of the conda environments and their locations in the file system. When you onboard to Studio Lab, you automatically activate the `studiolab` conda environment.

```
# conda environments: #
  default                /home/studio-lab-user/.conda/envs/default
  studiolab              * /home/studio-lab-user/.conda/envs/studiolab
  studiolab-safemode     /opt/amazon/sagemaker/safemode-home/.conda/
  envs/studiolab-safemode
```

base

/opt/conda

We recommend that you do not export the `studiolab`, `studiolab-safemode`, and `base` environments. These environments are not usable in Studio Classic for the following reasons:

- `studiolab`: This sets up the JupyterLab environment for Studio Lab. Studio Lab runs a different major version of JupyterLab than Studio Classic, so it is not usable in Studio Classic.
  - `studiolab-safemode`: This also sets up the JupyterLab environment for Studio Lab. Studio Lab runs a different major version of JupyterLab than Studio Classic, so it is not usable in Studio Classic.
  - `base`: This environment comes with conda by default. The base environment in Studio Lab and the base environment in Studio Classic have incompatible versions of many packages.
2. For the conda environment that you want to migrate to Studio Classic, first activate the conda environment. The default environment is then changed when new libraries are installed or removed from it. To get the exact state of the environment, export it into a YAML file using the command line. The following command lines export the default environment into a YAML file, creating a file called `myenv.yml`.

```
conda activate default
conda env export > ~/myenv.yml
```

## Step 2: Save your Studio Lab artifacts

Now that you have saved your environment to a YAML file, you can move the environment file to any platform.

Save to a local machine using Studio Lab GUI

### Note

Downloading a directory from the Studio Lab GUI by right-clicking on the directory is currently unavailable. If you wish to export a directory, please follow the steps using the **Save to Git repository** tab.

One option is to save the environment onto your local machine. To do this, use the following procedure.

1. In Studio Lab, choose the **File Browser** icon

on the left menu, so that the **File Browser** panel shows on the left.

2. Navigate to your user directory by choosing the file icon beneath the file search bar.
3. Choose (right-click) the `myenv.yml` file and then choose **Download**. You can repeat this process for other files you want to import to Studio Classic.

## Save to a Git repository

Another option is to save your environment to a Git repository. This option uses GitHub as an example. These steps require a GitHub account and repository. For more information, visit [GitHub](#). The following procedure shows how to synchronize your content with GitHub using the Studio Lab terminal.

1. From the Studio Lab terminal, navigate to your user directory and make a new directory to contain the files you want to export.

```
cd ~  
mkdir <NEW_DIRECTORY_NAME>
```

2. After you create a new directory, copy any file or directory you want to export to `<NEW_DIRECTORY_NAME>`.

Copy a file using the following code format:

```
cp <FILE_NAME> <NEW_DIRECTORY_NAME>
```

For example, replace `<FILE_NAME>` with `myenv.yml`.

Copy any directory using the following code format:

```
cp -r <DIRECTORY_NAME> <NEW_DIRECTORY_NAME>
```

For example, replace `<DIRECTORY_NAME>` with any directory name in your user directory.

3. Navigate to the new directory and initialize the directory as a Git repository using the following command. For more information, see the [git-init documentation](#).

```
cd <NEW_DIRECTORY_NAME>
git init
```

- Using Git, add all relevant files and then commit your changes.

```
git add .
git commit -m "<COMMIT_MESSAGE>"
```

For example, replace `<COMMIT_MESSAGE>` with Add Amazon SageMaker Studio Lab artifacts to GitHub repository to migrate to Amazon SageMaker Studio Classic .

- Push the commit to your remote repository. This repository has the format `https://github.com/<GITHUB_USERNAME>/<REPOSITORY_NAME>.git` where `<GITHUB_USERNAME>` is your GitHub user name and the `<REPOSITORY_NAME>` is your remote repository name. Create a branch `<BRANCH_NAME>` to push the content to the GitHub repository.

```
git branch -M <BRANCH_NAME>
git remote add origin https://github.com/<GITHUB_USERNAME>/<REPOSITORY_NAME>.git
git push -u origin <BRANCH_NAME>
```

### Step 3: Import your Studio Lab artifacts to Studio Classic

The following procedure shows how to import artifacts to Studio Classic. The instructions on using Feature Store through the console depends on if you have enabled Studio or Studio Classic as your default experience. For information on accessing Studio Classic through the console, see [Launch Studio Classic if Studio is your default experience](#).

From Studio Classic, you can import files from your local machine or from a Git repository. You can do this using the Studio Classic GUI or terminal. The following procedure uses the examples from [Step 2: Save your Studio Lab artifacts](#).

#### Import using the Studio Classic GUI

If you saved the files to your local machine, you can import the files to Studio Classic using the following steps.

1. Open the **File Browser** panel

at the top left of Studio Classic.

2. Choose the **Upload Files** icon

on the menu at the top of the **File Browser** panel.

3. Navigate to the file that you want to import, then choose **Open**.

### Note

To import a directory into Studio Classic, first compress the directory on your local machine to a file. On a Mac, right-click the directory and choose **Compress** "**<DIRECTORY\_NAME>**". In Windows, right-click the directory and choose **Send to**, and then choose **Compressed (zipped) folder**. After the directory is compressed, import the compressed file using the preceding steps. Unzip the compressed file by navigating to the Studio Classic terminal and running the command **<DIRECTORY\_NAME>.zip**.

## Import using a Git repository

This example provides two options for how to clone a GitHub repository into Studio Classic. You can use the Studio Classic GUI by choosing the **Git**

tab on the left side of Studio Classic. Choose **Clone a Repository**, then paste your GitHub repository URL from [Step 2: Save your Studio Lab artifacts](#). Another option is to use the Studio Classic terminal by using the following procedure.

1. Open the Studio Classic **Launcher**. For more information on opening the **Launcher**, see [Amazon SageMaker Studio Classic Launcher](#).
2. In the **Launcher**, in the **Notebooks and compute resources** section, choose **Change environment**.
3. In Studio Classic, open the **Launcher**. To open the **Launcher**, choose **Amazon SageMaker Studio Classic** at the top-left corner of Studio Classic.

To learn about all the available ways to open the **Launcher**, see [Use the Amazon SageMaker Studio Classic Launcher](#).

4. In the **Change environment** dialog, use the **Image** dropdown list to select the **Data Science** image and choose **Select**. This image comes with conda pre-installed.
5. In the Studio Classic **Launcher**, choose **Open image terminal**.
6. From the image terminal, run the following command to clone your repository. This command creates a directory named after <REPOSITORY\_NAME> in your Studio Classic instance and clones your artifacts in that repository.

```
git clone https://github.com/<GITHUB_USERNAME>/<REPOSITORY_NAME>.git
```

#### Step 4: Install your Studio Lab conda environments in Studio Classic

You can now recreate your conda environment by using your YAML file in your Studio Classic instance. Open the Studio Classic **Launcher**. For more information on opening the **Launcher**, see [Amazon SageMaker Studio Classic Launcher](#). From the **Launcher**, choose **Open image terminal**. In the terminal navigate to the directory that contains the YAML file, then run the following commands.

```
conda env create --file <ENVIRONMENT_NAME>.yaml  
conda activate <ENVIRONMENT_NAME>
```

After these commands are complete, you can select your environment as the kernel for your Studio Classic notebook instances. To view the available environment, run `conda env list`. To activate your environment, run `conda activate <ENVIRONMENT_NAME>`.

#### Shut down Studio Lab resources

You can view and shut down your running Amazon SageMaker Studio Lab resources from one location in your Studio Lab environment. The running resource types include terminals, and kernels. You can also shut down all resources of one resource type at the same time.

When you shut down all resources belonging to a resource type, the following occurs:

- **KERNELS** – All kernels, notebooks, and consoles are shut down.
- **TERMINALS** – All terminals are shut down.

## Shut down Studio Lab resources

1. Start your Studio Lab project runtime. For more information on launching Studio Lab project runtime, see [Start your project runtime](#).
2. Choose the **Running Terminals and Kernels** icon  on the left navigation pane.
3. Choose the **X** symbol to the right of the resource you wish to shut down. You can view the **X** symbol by hovering your cursor over a resource.
4. (Optional) You can shut down all the resources of a given resource type by choosing **Shut Down All** to the right of the resource type name.

## Troubleshooting

The guide shows common errors that might occur when using Amazon SageMaker Studio Lab. Each error contains a description, as well as a solution to the error.

### Note

You cannot share your password with multiple users or use Studio Lab to mine cryptocurrency. We don't recommend using Studio Lab for production tasks because of runtime limits.

### Can't access account

If you can't access your account, verify that you are using the correct email and password. If you have forgotten your password, use the following steps to reset your password. If you still cannot access your account, you must request and register for a new account using the instructions in [Onboard to Amazon SageMaker Studio Lab](#).

### Forgot password

If you forget your password, you must reset it using the following steps.

1. Navigate to the [Studio Lab landing page](#).
2. Select **Sign in**.

3. Select **Forgot password?** to open a new page.
4. Enter the email address that you used to sign up for an account.
5. Select **Send reset link** to send an email with a password reset link.
6. From the password reset email, select **Reset your password**.
7. Enter your new password.
8. Select **Submit**.

### Can't launch project runtime

If the Studio Lab project runtime does not launch, try launching it again. If this doesn't work, switch the instance type from CPU to GPU (or in reverse). For more information, see [Change your compute type](#).

### Runtime stopped running unexpectedly

If there is an issue with the environment used to run JupyterLab, then Studio Lab will automatically recreate the environment. Studio Lab does not support manual activation of this process.

### Conflicting versions

Because you can add packages and modify your environment as needed, you may run into conflicts between packages in your environment. If there are conflicts between packages in your environment, you must remove the conflicting package.

### Environment build fails

When you build an environment from a YAML file, a package-version conflict or file issue might cause a build to fail. To resolve this, remove the environment by running the following command. Do this before attempting to build it again.

```
conda remove --name <YOUR_ENVIRONMENT> --all
```

### Error message about allowing to download script from domain \*.aws.waf.com

Studio Classic uses the web application firewall service AWS WAF to protect your resources, which uses JavaScript. If you are using a browser security plugin that prevents JavaScript from downloading, this error may pop up. To use Studio Classic, allow the JavaScript download from \*.aws.waf.com as a trusted domain. For more information on AWS WAF, see [AWS WAF](#) from the AWS WAF, AWS Firewall Manager, and AWS Shield Advanced. Developer Guide.

## Disk space is full

If you run into a notification saying mentioning that your disk space is full or **File Load Error for <FILE\_NAME>** while attempting to open a file, you can remove files, directories, libraries, or environments to increase space. For more information on managing your libraries and environments, see [Manage your environment](#).

## Project runtime is in safe mode notification

If you run into a notification that **Project runtime is in safe mode**, you must free up some disk space to resume using the Studio Lab project runtime. Follow the instructions in the preceding troubleshoot item, **Disk space is full**. Once up to at least 500 MB of space has been cleared, you may restart the project runtime to use Studio Lab. This can be done by choosing **Amazon SageMaker Studio Lab** in the top menu of Studio Lab and choosing **Restart JupyterLab....**

## git Cannot import cv2

If you run into an error when importing cv2 after installing opencv-python, you must uninstall opencv-python and install opencv-python-headless as follows.

```
%pip uninstall opencv-python --yes
%pip install opencv-python-headless
```

You can then import cv2 as expected.

## Studio Lab becomes unresponsive when opening large files

The Studio Lab IDE may fail to render when large files are opened, resulting in blocked access to Studio Lab resources. To resolve this, reset the Studio Lab workspace using the following procedure.

1. After you open the IDE, copy the URL in your browser's address bar. This URL should be in the `https://xxxxxx.studio.us-east-2.sagemaker.aws/studiolab/default/jupyter/lab` format. Close the tab.
2. In a new tab, paste the URL and remove anything after `https://xxxxxx.studio.us-east-2.sagemaker.aws/studiolab/default/jupyter/lab`.
3. Add `?reset` to the end of the URL, so it is in the `https://xxxxxx.studio.us-east-2.sagemaker.aws/studiolab/default/jupyter/lab?reset` format.
4. Navigate to the updated URL. This resets the saved UI state and makes the Studio Lab IDE responsive.

# Amazon SageMaker Canvas

Amazon SageMaker Canvas gives you the ability to use machine learning to generate predictions without needing to write any code. The following are some use cases where you can use SageMaker Canvas:

- Predict customer churn
- Plan inventory efficiently
- Optimize price and revenue
- Improve on-time deliveries
- Classify text or images based on custom categories
- Identify objects and text in images
- Extract information from documents

With Canvas, you can chat with popular large language models (LLMs), access Ready-to-use models, or build a custom model trained on your data.

Canvas chat is a functionality that leverages open-source and Amazon LLMs to help you boost your productivity. You can prompt the models to get assistance with tasks such as generating content, summarizing or categorizing documents, and answering questions. To learn more, see [Generative AI foundation models in SageMaker Canvas](#).

The [Ready-to-use models](#) in Canvas can extract insights from your data for a variety of use cases. You don't have to build a model to use Ready-to-use models because they are powered by Amazon AI services, including [Amazon Rekognition](#), [Amazon Textract](#), and [Amazon Comprehend](#). You only have to import your data and start using a solution to generate predictions.

If you want a model that is customized to your use case and trained with your data, you can [build a model](#). You can get predictions customized to your data by doing the following:

1. Import your data from one or more data sources.
2. Build a predictive model.
3. Evaluate the model's performance.
4. Generate predictions with the model.

Canvas supports the following types of custom models:

- Numeric prediction (also known as *regression*)
- Categorical prediction for 2 and 3+ categories (also known as *binary* and *multi-class classification*)
- Time series forecasting
- Single-label image prediction (also known as *image classification*)
- Multi-category text prediction (also known as *multi-class text classification*)

To learn more about pricing, see the [SageMaker Canvas pricing page](#). You can also see [Billing and cost in SageMaker Canvas](#) for more information.

SageMaker Canvas is currently available in the following Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- South America (São Paulo)

## Topics

- [Are you a first-time SageMaker Canvas user?](#)
- [Getting started with using Amazon SageMaker Canvas](#)

- [Tutorial: Build an end-to-end machine learning workflow in SageMaker Canvas](#)
- [Amazon SageMaker Canvas setup and permissions management \(for IT administrators\)](#)
- [Generative AI assistance for solving ML problems in Canvas using Amazon Q Developer](#)
- [Data import](#)
- [Data preparation](#)
- [Generative AI foundation models in SageMaker Canvas](#)
- [Ready-to-use models](#)
- [Custom models](#)
- [Logging out of Amazon SageMaker Canvas](#)
- [Limitations and troubleshooting](#)
- [Billing and cost in SageMaker Canvas](#)

## Are you a first-time SageMaker Canvas user?

If you are a first-time user of SageMaker Canvas, we recommend that you begin by reading the following sections:

- For IT administrators – [Amazon SageMaker Canvas setup and permissions management \(for IT administrators\)](#)
- For analysts and individual users – [Getting started with using Amazon SageMaker Canvas](#)
- For an example of an end to end workflow – [Tutorial: Build an end-to-end machine learning workflow in SageMaker Canvas](#)

## Getting started with using Amazon SageMaker Canvas

This guide tells you how to get started with using SageMaker Canvas. If you're an IT administrator and would like more in-depth details, see [Amazon SageMaker Canvas setup and permissions management \(for IT administrators\)](#) to set up SageMaker Canvas for your users.

### Topics

- [Prerequisites for setting up Amazon SageMaker Canvas](#)
- [Step 1: Log in to SageMaker Canvas](#)
- [Step 2: Use SageMaker Canvas to get predictions](#)

## Prerequisites for setting up Amazon SageMaker Canvas

To set up a SageMaker Canvas application, onboard using one of the following setup methods:

- 1. Onboard with the AWS console.** To onboard through the AWS console, you first create an Amazon SageMaker AI domain. SageMaker AI domains support the various machine learning (ML) environments such as Canvas and [SageMaker Studio](#). For more information about domains, see [Amazon SageMaker AI domain overview](#).
  - a. (Quick) [Use quick setup for Amazon SageMaker AI](#)** – Choose this option if you'd like to quickly set up a domain. This grants your user all of the default Canvas permissions and basic functionality. Any additional features such as [document querying](#) can be enabled later by an admin. If you want to configure more granular permissions, we recommend that you choose the Advanced option instead.
  - b. (Standard) [Use custom setup for Amazon SageMaker AI](#)** – Choose this option if you'd like to complete a more advanced setup of your domain. Maintain granular control over user permissions such as access to data preparation features, generative AI functionality, and model deployments.
- 2. Onboard with AWS CloudFormation.** [AWS CloudFormation](#) automates the provisioning of resources and configurations so that you can set up Canvas for one or more user profiles at the same time. Use this option if you want to automate the onboarding process at scale and make sure that your applications are configured the same way every time. The following [CloudFormation template](#) provides a streamlined way to onboard to Canvas, ensuring that all required components are properly set up and allowing you to focus on building and deploying your machine learning models.

The following section describes how to onboard to Canvas by using the AWS console to create a domain.

### Important

For you to set up Amazon SageMaker Canvas, your version of Amazon SageMaker Studio must be 3.19.0 or later. For information about updating Amazon SageMaker Studio, see [Shut down and Update SageMaker Studio Classic](#).

## Onboard with the AWS console

If you're doing the quick domain setup, then you can follow the instructions in [Use quick setup for Amazon SageMaker AI](#), skip the rest of this section, and move on to [Step 1: Log in to SageMaker Canvas](#).

If you're doing the standard domain setup, then you can specify the Canvas features to which you'd like to grant your users access. Use the rest of this section as you complete the standard domain setup to help you configure the permissions that are specific to Canvas.

In the [Use custom setup for Amazon SageMaker AI](#) setup instructions, for **Step 2: Users and ML Activities**, you must select the Canvas permissions that you want to grant. In the **ML activities** section, you can select the following permissions policies to grant access to Canvas features. You can only select up to 8 **ML activities** total when setting up your domain. The first two permissions in the following list are required to use Canvas, while the rest are for additional features.

- **Run Studio Applications** – These permissions are necessary to start up the Canvas application.
- [Canvas Core Access](#) – These permissions grant you access to the Canvas application and the basic functionality of Canvas, such as creating datasets, using basic data transforms, and building and analyzing models.
- (Optional) [Canvas Data Preparation \(powered by Data Wrangler\)](#) – These permissions grant you access to create data flows and use advanced transforms to prepare your data in Canvas. These permissions are also necessary for creating data processing jobs and data preparation job schedules.
- (Optional) [Canvas AI Services](#) – These permissions grant you access to the Ready-to-use models, foundation models, and Chat with Data features in Canvas.
- (Optional) **Kendra access** – This permission grants you access to the [document querying](#) feature, where you can query documents stored in an Amazon Kendra index using foundation models in Canvas.

If you select this option, then in the **Canvas Kendra Access** section, enter the IDs for your Amazon Kendra indexes to which you want to grant access.

- (Optional) [Canvas MLOps](#) – This permission grants you access to the [model deployment](#) feature in Canvas, where you can deploy models for use in production.

In the domain setup's **Step 3: Applications** section, choose **Configure Canvas** and then do the following:

1. For the **Canvas storage configuration**, specify where you want Canvas to store the application data, such as model artifacts, batch predictions, datasets, and logs. SageMaker AI creates a Canvas/ folder inside this bucket to store the data. For more information, see [Configure your Amazon S3 storage](#). For this section, do the following:
  - a. Select **System managed** if you want to set the location to the default SageMaker AI-created bucket that follows the pattern `s3://sagemaker-{Region}-{your-account-id}`.
  - b. Select **Custom S3** to specify your own Amazon S3 bucket as the storage location. Then, enter the Amazon S3 URI.
  - c. (Optional) For **Encryption key**, specify a KMS key for encrypting Canvas artifacts stored at the specified location.
2. (Optional) For **Amazon Q Developer**, do the following:
  - a. Turn on **Enable Amazon Q Developer in SageMaker Canvas for natural language ML** to give your users permissions to leverage generative AI assistance during their ML workflow in Canvas. This option only grants permissions to query Amazon Q Developer for help with predetermined tasks that can be completed in the Canvas application.
  - b. Turn on **Enable Amazon Q Developer chat for general AWS questions** to give your users permissions to make generative AI queries related to AWS services.
3. (Optional) Configure the **Large data processing** section if your users plan to process datasets larger than 5 GB in Canvas. For more detailed information about how to configure these options, see [Grant Users Permissions to Use Large Data across the ML Lifecycle](#).
4. (Optional) For the **ML Ops permissions configuration** section, do the following:
  - a. Leave the **Enable direct deployment of Canvas models** option turned on to give your users permissions to deploy their models from Canvas to a SageMaker AI endpoint. For more information about model deployment in Canvas, see [Deploy your models to an endpoint](#).
  - b. Leave the **Enable Model Registry registration permissions for all users** option turned on to give your users permissions to register their model version to the SageMaker AI model registry (it is turned on by default). For more information, see [Register a model version in the SageMaker AI model registry](#).
  - c. If you left the **Enable Model Registry registration permissions for all users** option turned on, then select either **Register to Model Registry only** or **Register and approve model in Model Registry**.

5. (Optional) For the **Local file upload configuration** section, turn on the **Enable local file upload** option to give your users permissions to upload files to Canvas from their local machines. Turning this option on attaches a cross-origin resource sharing (CORS) policy to the Amazon S3 bucket specified in the **Canvas storage configuration** (and overrides any existing CORS policy). To learn more about local file upload permissions, see [Grant Your Users Permissions to Upload Local Files](#).
6. (Optional) For the **OAuth settings** section, do the following:
  - a. Choose **Add OAuth configuration**.
  - b. For **Data source**, select your data source.
  - c. For **Secret setup**, select **Create a new secret** and enter the information you have from your identity provider. If you haven't done the initial OAuth setup with your data source yet, see [Set up connections to data sources with OAuth](#).
7. (Optional) For the **Canvas Ready-to-use models configuration**, do the following:
  - a. Leave the **Enable Canvas Ready-to-use models** option turned on to give your users permissions to generate predictions with Ready-to-use models in Canvas (it is turned on by default). This option also gives you permissions to chat with generative-AI powered models. For more information, see [Generative AI foundation models in SageMaker Canvas](#).
  - b. Leave the **Enable document query using Amazon Kendra** option turned on to give your users permissions to use foundation models for querying documents stored in an Amazon Kendra index. Then, from the dropdown menu, select the existing indexes to which you want to grant access. For more information, see [Generative AI foundation models in SageMaker Canvas](#).
  - c. For **Amazon Bedrock role**, select **Create and use a new execution role** to create a new IAM execution role that has a trust relationship with Amazon Bedrock. This IAM role is assumed by Amazon Bedrock to fine-tune large language models (LLMs) in Canvas. If you already have an execution role with a trust relationship, then select **Use an existing execution role** and choose your role from the dropdown. For more information about manually configuring permissions for your own execution role, see [Grant Users Permissions to Use Amazon Bedrock and Generative AI Features in Canvas](#).
8. Finish configuring the rest of the domain settings using the [Use custom setup for Amazon SageMaker AI](#) procedures.

**Note**

If you encounter any issues with granting permissions through the console, such as permissions for Ready-to-use models, see the topic [Troubleshooting issues with granting permissions through the SageMaker AI console](#).

You should now have a SageMaker AI domain set up and all of the Canvas permissions configured.

You can edit the Canvas permissions for a domain or a specific user after the initial domain setup. Individual user settings override the domain settings. To learn how to edit your Canvas permissions in the domain settings, see [Edit domain settings](#).

**Give yourself permissions to use specific features in Canvas**

The following information outlines the various permissions that you can grant to a Canvas user to allow the use of various features and functionalities within Canvas. Some of these permissions can be granted during the domain setup, but some require additional permissions or configuration. Refer to the specific permissions information for each feature that you want to enable:

- **Local file upload.** The permissions for local file upload are turned on by default in the Canvas base permissions when setting up your domain. If you can't upload local files from your machine to SageMaker Canvas, you can attach a CORS policy to the Amazon S3 bucket that you specified in the Canvas storage configuration. If you allowed SageMaker AI to use the default bucket, the bucket follows the naming pattern `s3://sagemaker-{Region}-{your-account-id}`. For more information, see [Grant Your Users Permissions to Upload Local Files](#).
- **Custom image and text prediction models.** The permissions for building custom image and text prediction models are turned on by default in the Canvas base permissions when setting up your domain. However, if you have a custom IAM configuration and don't want to attach the [AmazonSageMakerCanvasFullAccess](#) policy to your user's IAM execution role, then you must explicitly grant your user the necessary permissions. For more information, see [Grant Your Users Permissions to Build Custom Image and Text Prediction Models](#).
- **Ready-to-use models and foundation models.** You might want to use the Canvas Ready-to-use models to make predictions for your data. With the Ready-to-use models permissions, you can also chat with generative AI-powered models. The permissions are turned on by default when setting up your domain, or you can edit the permissions for a domain that you've already created. The Canvas Ready-to-use models permissions option adds the

[AmazonSageMakerCanvasAIServiceAccess](#) policy to your execution role. For more information, see the [Get started](#) section of the Ready-to-use models documentation.

For more information about getting started with generative AI foundation models, see [Generative AI foundation models in SageMaker Canvas](#).

- **Fine-tune foundation models.** If you'd like to fine-tune foundation models in Canvas, you can either add the permissions when setting up your domain, or you can edit the permissions for the domain or user profile after creating your domain. You must add the [AmazonSageMakerCanvasAIServiceAccess](#) policy to the AWS IAM role you chose when setting up the user profile, and you must also add a trust relationship with Amazon Bedrock to the role. For instructions on how to add these permissions to your IAM role, see [Grant Users Permissions to Use Amazon Bedrock and Generative AI Features in Canvas](#).
- **Send batch predictions to Amazon QuickSight.** You might want to [send batch predictions](#), or datasets of predictions you generate from a custom model, to Amazon QuickSight for analysis. In [QuickSight](#), you can build and publish predictive dashboards with your prediction results. For instructions on how to add these permissions to your Canvas user's IAM role, see [Grant Your Users Permissions to Send Predictions to Amazon QuickSight](#).
- **Deploy Canvas models to a SageMaker AI endpoint.** SageMaker AI Hosting offers *endpoints* which you can use to deploy your model for use in production. You can deploy models built in Canvas to a SageMaker AI endpoint and then make predictions programmatically in a production environment. For more information, see [Deploy your models to an endpoint](#).
- **Register model versions to the model registry.** You might want to register *versions* of your model to the [SageMaker AI model registry](#), which is a repository for tracking the status of updated versions of your model. A data scientist or MLOps team working in the SageMaker Model Registry can view the versions of your model that you've built and approve or reject them. Then, they can deploy your model version to production or kick off an automated workflow. Model registration permissions are turned on by default for your domain. You can manage permissions at the user profile level and grant or remove permissions to specific users. For more information, see [Register a model version in the SageMaker AI model registry](#).
- **Import data from Amazon Redshift.** If you want to import data from Amazon Redshift, you must give yourself additional permissions. You must add the `AmazonRedshiftFullAccess` managed policy to the AWS IAM role you chose when setting up the user profile. For instructions on how to add the policy to the role, see [Grant Users Permissions to Import Amazon Redshift Data](#).

**Note**

The necessary permissions to import through other data sources, such as Amazon Athena and SaaS platforms, are included in the [AmazonSageMakerFullAccess](#) and [AmazonSageMakerCanvasFullAccess](#) policies. If you followed the standard setup instructions, these policies should already be attached to your execution role. For more information about these data sources and their permissions, see [Connect to data sources](#).

## Step 1: Log in to SageMaker Canvas

When the initial setup is complete, you can access SageMaker Canvas with any of the following methods, depending on your use case:

- In the [SageMaker AI console](#), choose the **Canvas** in the left navigation pane. Then, on the **Canvas** page, select your user from the dropdown and launch the Canvas application.
- Open [SageMaker Studio](#), and in the Studio interface, go to the Canvas page and launch the Canvas application.
- Use your organization's SAML 2.0-based SSO methods, such as Okta or the IAM Identity Center.

When you log into SageMaker Canvas for the first time, SageMaker AI creates the application and a SageMaker AI *space* for you. The Canvas application's data is stored in the space. To learn more about spaces, see [Collaboration with shared spaces](#). The space consists of your user profile's applications and a shared directory for all of your applications' data. If you don't want to use the default space created by SageMaker AI and would prefer to create your own space for storing application data, see the page [Store SageMaker Canvas application data in your own SageMaker AI space](#).

## Step 2: Use SageMaker Canvas to get predictions

After you've logged in to Canvas, you can start building models and generating predictions for your data.

You can either use Canvas Ready-to-use models to make predictions without building a model, or you can build a custom model for your specific business problem. Review the following information to decide whether Ready-to-use models or custom models are best for your use case.

- **Ready-to-use models.** With Ready-to-use models, you can use pre-built models to extract insights from your data. The Ready-to-use models cover a variety of use cases, such as language detection and document analysis. To get started making predictions with Ready-to-use models, see [Ready-to-use models](#).
- **Custom models.** With custom models, you can build a variety of model types that are customized to make predictions for your data. Use custom models if you'd like to build a model that is trained on your business-specific data and if you'd like to use features such as [evaluating your model's performance](#). To get started with building a custom model, see [Custom models](#).

## Tutorial: Build an end-to-end machine learning workflow in SageMaker Canvas

This tutorial guides you through an end-to-end machine learning (ML) workflow using Amazon SageMaker Canvas. SageMaker Canvas is a visual no-code interface that you can use to prepare data and to train and deploy ML models. For the tutorial, you use a NYC taxi dataset to train a model that predicts the fare amount for a given trip. You get hands-on experience with key ML tasks such as assessing data quality and addressing data issues, splitting data into training and test sets, model training and evaluation, making predictions, and deploying your trained model—all within the SageMaker Canvas application.

### Important

This tutorial assumes that you or your administrator have created an AWS account. For information about creating an AWS account, see [Getting started: Are you a first time AWS User?](#)

## Setting up

An Amazon SageMaker AI domain is a centralized place to manage all your Amazon SageMaker AI environments and resources. A domain acts as a virtual boundary for your work in SageMaker AI, providing isolation and access control for your machine learning (ML) resources.

To get started with Amazon SageMaker Canvas, you or your administrator must navigate to the SageMaker AI console and create a Amazon SageMaker AI domain. A domain has the storage and compute resources needed for you to run SageMaker Canvas. Within the domain, you configure

SageMaker Canvas to access your Amazon S3 buckets and deploy models. Use the following procedure to set up a quick domain and create a SageMaker Canvas application.

### To set up SageMaker Canvas

1. Navigate to the [SageMaker AI console](#).
2. On the left-hand navigation, choose SageMaker Canvas.
3. Choose **Create a SageMaker AI domain**.
4. Choose **Set up**. The domain can take a few minutes to set up.

The preceding procedure used a quick domain set up. You can perform an advanced set up to control all aspects of the account configuration, including permissions, integrations, and encryption. For more information about a custom set up, see [Use custom setup for Amazon SageMaker AI](#).

By default, doing the quick domain set up provides you with permissions to deploy models. If you have custom permissions set up through a standard domain and you need manually grant model deployment permissions, see [Permissions management](#).

### Flow creation

Amazon SageMaker Canvas is a machine learning platform that enables users to build, train, and deploy machine learning models without extensive coding or machine learning expertise. One of the powerful features of Amazon SageMaker Canvas is the ability to import and work with large datasets from various sources, such as Amazon S3.

For this tutorial, we're using the NYC taxi dataset to predict the fare amount for each trip using a Amazon SageMaker Canvas Data Wrangler data flow. The following procedure outlines the steps for importing a modified version of the NYC taxi dataset into a data flow.

#### Note

For improved processing, SageMaker Canvas imports a sample of your data. By default, it randomly samples 50,000 rows.

### To import the NYC taxi dataset

1. From the SageMaker Canvas home page, choose **Data Wrangler**.

2. Choose **Import data**.
3. Select **Tabular**.
4. Choose the toolbox next to data source.
5. Select **Amazon S3** from the dropdown.
6. For **Input S3 endpoint**, specify `s3://amazon-sagemaker-data-wrangler-documentation-artifacts/canvas-single-file-nyc-taxi-dataset.csv`.
7. Choose **Go**.
8. Select the checkbox next to the dataset.
9. Choose **Preview data**.
10. Choose **Save**.

## Data Quality and Insights Report 1 (sample)

After importing a dataset into Amazon SageMaker Canvas, you can generate a Data Quality and Insights report on a sample of the data. Use it to provide valuable insights into the dataset. The report does the following:

- Assesses the dataset's completeness
- Identifies missing values and outliers

It can identify other potential issues that may impact model performance. It also evaluates the predictive power of each feature concerning the target variable, allowing you to identify the most relevant features for problem you're trying to solve.

We can use the insights from the report to predict the fare amount. By specifying the **Fare amount** column as the target variable and selecting **Regression** as the problem type, the report will analyze the dataset's suitability for predicting continuous values like fare prices. The report should reveal that features like **year** and **hour\_of\_day** have low predictive power for the chosen target variable, providing you with valuable insights.

Use the following procedure to get a Data Quality and Insights report on a 50,000 row sample from the dataset.

### To get a report on a sample

1. Choose **Get data insights** from the pop up window next to the **Data types** node.

2. For **Analysis name**, specify a name for the report.
3. For **Problem type**, choose **Regression**.
4. For **Target column**, choose **Fare amount**.
5. Choose **Create**.

You can review the Data Quality and Insights report on a sample of your data. The report indicates that the **year** and **hour\_of\_day** features are not predictive of the target variable, **Fare amount**.

At the top of the navigation, choose the name of the data flow to navigate back to it.

## Drop year and hour of day

We're using insights from the report to drop the **year** and **hour\_of\_day** columns to streamline the feature space and potentially improve model performance.

Amazon SageMaker Canvas provides a user-friendly interface and tools to perform such data transformations.

Use the following procedure to drop the **year** and **hour\_of\_day** columns from the NYC taxi dataset using the Data Wrangler tool in Amazon SageMaker Canvas.

1. Choose the icon next to **Data types**.
2. Choose **Add step**.
3. In the search bar, write **Drop column**.
4. Choose **Manage columns**.
5. Choose **Drop column**.
6. For **Columns to drop**, select the **year** and **hour\_of\_day** columns.
7. Choose **Preview** to view how your transform changes your data.
8. Choose **Add**.

You can use the preceding procedure as the basis to add all of the other transforms in SageMaker Canvas.

## Data Quality and Insights Report 2 (full dataset)

For the previous insights report, we used a sample of the NYC taxi dataset. For our second report, we're running a comprehensive analysis on the entire dataset to identify potential issues impacting model performance.

Use the following procedure to create a Data Quality and Insights report on an entire dataset.

### To get a report on the entire dataset

1. Choose the icon next to the **Drop columns** node.
2. Choose **Get data insights**.
3. For **Analysis name**, specify a name for the report.
4. For **Problem type**, choose **Regression**.
5. For **Target column**, choose **Fare amount**.
6. For **Data size**, choose **Full dataset**.
7. Choose **Create**.

The following is an image from the insights report:

#### High Priority Warnings

3 high severity warnings were detected. See the list below.

##### Duplicate rows High

**i** We found that 91.8% of the data are duplicate. Some data sources could include valid duplicates and in other cases these duplicates could point to problems in data collection. Duplicate samples resulting from faulty data collection, could derail machine learning processes that rely on splitting to independent training and validation folds. For example quick model scores, prediction power estimation and automatic hyper parameter tuning. Duplicate samples could be removed from the dataset using the **Drop duplicates** transform under **Manage rows**.

##### Skewed target High

**i** The target column is skewed and contains outliers. Because the outliers induce high errors during model training the machine learning algorithms tend to focus on them. Thus, you might get poor prediction quality for the non-outlier samples. In case you are interested in predicting extreme values well or plan to use a machine learning algorithm that has the ability to handle outlier values there is no need for further action. However, if extreme values are not the point of interest consider removing or clipping them using the **Robust standard deviation numeric outliers** transform under **Handle outliers**.

##### Very low quick-model score High

**i** The predictive quality of the quick model on the validation fold is lower than the quality of the trivial model. The trivial model predicts "the average" for regression and "the most common class" for classification. Either the features that you've provided aren't useful in predicting the target, or the automatic feature processing couldn't parse the data efficiently. For more information, see the **summary of features** section in the report. To make your model more accurate, we recommend cleaning your dataset and adding more predictive features.

It shows the following issues:

- Duplicate rows
- Skewed target

Duplicate rows can lead to data leakage, where the model is exposed to the same data during training and testing. They can lead to overly optimistic performance metrics. Removing duplicate rows ensures that the model is trained on unique instances, reducing the risk of data leakage and improving the model's ability to generalize.

A skewed target variable distribution, in this case, the **Fare amount** column, can cause imbalanced classes, where the model may become biased towards the majority class. This can lead to poor performance on minority classes, which is particularly problematic in scenarios where accurately predicting rare or underrepresented instances is important.

## Addressing data quality issues

To address these issues and prepare the dataset for modeling, you can search for the following transformations and apply them:

1. Drop duplicates using the **Manage rows** transform.
2. **Handle outliers** in the **Fare amount** column using the **Robust standard deviation numeric outliers**.
3. **Handle outliers** in the **Trip distance** and **Trip duration** columns using the **Standard deviation numeric outliers**.
4. Use the **Encode categorical** to encode the **Rate code id**, **Payment type**, **Extra flag**, and **Toll flag** columns as floats.

If you're not sure about how to apply a transform, see [Drop year and hour of day](#)

By addressing these data quality issues and applying appropriate transformations, you can improve the dataset's suitability for modeling.

## Verifying data quality and quick model accuracy

After applying the transforms to address data quality issues, such as removing duplicate rows, we create our final Data Quality and Insights report. This report helps verify that the applied transformations resolved the issues and that the dataset is now in a suitable state for modeling.

When reviewing the final Data Quality and Insights report, you should expect to see no major data quality issues flagged. The report should indicate that:

- The target variable is no longer skewed

- There are no outliers or duplicate rows

Additionally, the report should provide a quick model score based on a baseline model trained on the transformed dataset. This score serves as an initial indicator of the model's potential accuracy and performance.

Use the following procedure to create the Data Quality and Insights report.

### To create the Data Quality and Insights report

1. Choose the icon next to the **Drop columns** node.
2. Choose **Get data insights**.
3. For **Analysis name**, specify a name for the report.
4. For **Problem type**, choose **Regression**.
5. For **Target column**, choose **Fare amount**.
6. For **Data size**, choose **Full dataset**.
7. Choose **Create**.

### Split the data into training and test sets

To train a model and evaluate its performance, we use the **Split data** transform to split the data into training and test sets.

By default, SageMaker Canvas uses a Randomized split, but you can also use the following types of splits:

- Ordered
- Stratified
- Split by key

You can change the **Split percentage** or add splits.

For this tutorial, use all of the default settings in the split. You need to double click on the dataset to view its name. The training dataset has the name **Dataset (Train)**.

Next to the **Ordinal encode** node apply the **Split data** transform.

## Train model

After you split your data, you can train a model. This model learns from patterns in your data. You can use it to make predictions or uncover insights.

SageMaker Canvas has both quick builds and standard builds. Use a standard build to train best performing model on your data.

Before you start training a model, you must first export the training dataset as a SageMaker Canvas dataset.

### To export your dataset

1. Next to the node for the training dataset, choose the icon and select **Export**.
2. Select **SageMaker Canvas dataset**.
3. Choose **Export** to export the dataset.

After you've created a dataset, you can train a model on the SageMaker Canvas dataset that you've created. For information about training a model, see [Build a custom numeric or categorical prediction model](#).

## Evaluate model and make predictions

After training your machine learning model, it's crucial to evaluate its performance to ensure it meets your requirements and performs well on unseen data. Amazon SageMaker Canvas provides a user-friendly interface to assess your model's accuracy, review its predictions, and gain insights into its strengths and weaknesses. You can use the insights to make informed decisions about its deployment and potential areas for improvement.

Use the following procedure to evaluate a model before you deploy it.

### To evaluate a model

1. Choose **My Models**.
2. Choose the model you've created.
3. Under **Versions**, select the version corresponding to the model.

You can now view the model evaluation metrics.

After you evaluate the model, you can make predictions on new data. We're using the test dataset that we've created.

To use the test dataset for predictions we need to convert it into a SageMaker Canvas dataset. The SageMaker Canvas dataset is in a format that the model can interpret.

Use the following procedure to create a SageMaker Canvas dataset from the test dataset.

### To create a SageMaker Canvas dataset

1. Next to the **Dataset (Test)** dataset, choose the radio icon.
2. Select **Export**.
3. Select **SageMaker Canvas dataset**.
4. For **Dataset name**, specify a name for the dataset.
5. Choose **Export**.

Use the following procedure to make predictions. It assumes that you're still on the **Analyze** page.

### To make predictions on test dataset

1. Choose **Predict**.
2. Choose **Manual**.
3. Select the dataset that you've exported.
4. Choose **Generate predictions**.
5. When SageMaker Canvas has finished generating predictions, select the icon to the right of the dataset.
6. Choose **Preview** to view the predictions.

## Deploy a model

After you've evaluated your model, you can deploy it to an endpoint. You can submit requests to the endpoint to get predictions.

Use the following procedure to deploy a model. It assumes that you're still on the **Predict** page.

### To deploy a model

1. Choose **Deploy**.

2. Choose **Create deployment**.
3. Choose **Deploy**.

## Cleaning up

You've successfully completed the tutorial. To avoid incurring additional charges, delete the resources that you're not using.

Use the following procedure to delete the endpoint that you created. It assumes that you're still on the **Deploy** page.

### To delete an endpoint

1. Choose the radio button to the right of your deployment.
2. Select **Delete deployment**.
3. Choose **Delete**.

After deleting the deployment, delete the datasets that you've created within SageMaker Canvas. Use the following procedure to delete the datasets.

### To delete the datasets

1. Choose **Datasets** on the left-hand navigation.
2. Select the dataset that you've analyzed and the synthetic dataset used for predictions.
3. Choose **Delete**.

To avoid incurring additional charges, you must log out of SageMaker Canvas. For more information, see [Logging out of Amazon SageMaker Canvas](#).

## Amazon SageMaker Canvas setup and permissions management (for IT administrators)

The following pages explain how IT administrators can configure Amazon SageMaker Canvas and grant permissions to users within their organizations. You learn how to set up the storage configuration, manage data encryption and VPCs, control access to specific capabilities like generative AI foundation models, integrate with other AWS services like Amazon Redshift, and

more. By following these steps, you can tailor SageMaker Canvas for your users based on your organization's specific requirements.

You can also set up SageMaker Canvas for your users with AWS CloudFormation. For more information, see [AWS::SageMaker AI::App](#) in the *AWS CloudFormation User Guide*.

## Grant Your Users Permissions to Upload Local Files

If your users are uploading files from their local machines to SageMaker Canvas, you must attach a CORS (cross-origin resource sharing) configuration to the Amazon S3 bucket that they're using. When setting up or editing the SageMaker AI domain or user profile, you can specify either a custom Amazon S3 location or the default location, which is a SageMaker AI created Amazon S3 bucket with a name that uses the following pattern: `s3://sagemaker-{Region}-{your-account-id}`. SageMaker Canvas adds your users' data to the bucket whenever they upload a file.

To grant users permissions to upload local files to the bucket, you can attach a CORS configuration to it using either of the following procedures. You can use the first method when editing the settings of your domain, where you opt in to allow SageMaker AI to attach the CORS configuration to the bucket for you. You can also use the first method for editing a user profile within a domain. The second method is the manual method, where you can attach the CORS configuration to the bucket yourself.

### SageMaker AI domain settings method

To grant your users permissions to upload local files, you can edit the Canvas application configuration in the domain settings. This attaches a Cross-Origin Resource Sharing (CORS) configuration to the Canvas storage configuration's Amazon S3 bucket and grants all users in the domain permission to upload local files into SageMaker Canvas. By default, the permissions option is turned on when you set up a new domain, but you can turn this option on and off as needed.

#### Note

If you have an existing CORS configuration on the storage configuration Amazon S3 bucket, turning on the local file upload option overwrites the existing configuration with the new configuration.

The following procedure shows how you can turn on this option by editing the domain settings in the SageMaker AI console.

1. Go to the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. In the left navigation pane, choose **Domains**.
3. From the list of domains, choose your domain.
4. On the domain details page, select the **App Configurations** tab.
5. Go to the **Canvas** section and choose **Edit**.
6. Turn on the **Enable local file upload** toggle. This attaches the CORS configuration and grants local file upload permissions.
7. Choose **Submit**.

Users in the specified domain should now have local file upload permissions.

You can also grant permissions to specific user profiles in a domain by following the preceding procedure and going into the user profile settings instead of the overall domain settings.

### Amazon S3 bucket method

If you want to manually attach the CORS configuration to the SageMaker AI Amazon S3 bucket, use the following procedure.

1. Sign in to <https://console.aws.amazon.com/s3/>.
2. Choose your bucket. If your domain uses the default SageMaker AI created bucket, the bucket's name uses the following pattern: `s3://sagemaker-{Region}-{your-account-id}`.
3. Choose **Permissions**.
4. Navigate to **Cross-origins resource sharing (CORS)**.
5. Choose **Edit**.
6. Add the following CORS policy:

```
[
  {
    "AllowedHeaders": [
      "*"
    ],
    "AllowedMethods": [
      "POST"
    ],
    "AllowedOrigins": [
      "*"
    ],
    "ExposeHeaders": []
  }
]
```

7. Choose **Save changes**.

In the preceding procedure, the CORS policy must have "POST" listed under AllowedMethods.

After you've gone through the procedure, you should have:

- An IAM role assigned to each of your users.

- Amazon SageMaker Studio Classic runtime permissions for each of your users. SageMaker Canvas uses Studio Classic to run the commands from your users.
- If the users are uploading files from their local machines, a CORS policy attached to their Amazon S3 bucket.

If your users still can't upload the local files after you update the CORS policy, the browser might be caching the CORS settings from a previous upload attempt. If they're running into issues, instruct them to clear their browser cache and try again.

## Set Up SageMaker Canvas for Your Users

To set up Amazon SageMaker Canvas, do the following:

- Create an Amazon SageMaker AI domain.
- Create user profiles for the domain
- Set up Okta Single Sign On (Okta SSO) for your users.
- Activate link sharing for models.

Use Okta Single-Sign On (Okta SSO) to grant your users access to Amazon SageMaker Canvas. SageMaker Canvas supports SAML 2.0 SSO methods. The following sections guide you through procedures to set up Okta SSO.

To set up a domain, see [Use custom setup for Amazon SageMaker AI](#) and follow the instructions for setting up your domain using IAM authentication. You can use the following information to help you complete the procedure in the section:

- You can ignore the step about creating projects.
- You don't need to provide access to additional Amazon S3 buckets. Your users can use the default bucket that we provide when we create a role.
- To grant your users access to share their notebooks with data scientists, turn on **Notebook Sharing Configuration**.
- Use Amazon SageMaker Studio Classic version 3.19.0 or later. For information about updating Amazon SageMaker Studio Classic, see [Shut down and Update SageMaker Studio Classic](#).

Use the following procedure to set up Okta. For all of the following procedures, you specify the same IAM role for *IAM-role* .

## Add the SageMaker Canvas application to Okta

Set up the sign-on method for Okta.

1. Sign in to the Okta Admin dashboard.
2. Choose **Add application**. Search for **AWS Account Federation**.
3. Choose **Add**.
4. Optional: Change the name to **Amazon SageMaker Canvas**.
5. Choose **Next**.
6. Choose **SAML 2.0** as the **Sign-On** method.
7. Choose **Identity Provider Metadata** to open the metadata XML file. Save the file locally.
8. Choose **Done**.

## Set up ID federation in IAM

AWS Identity and Access Management (IAM) is the AWS service that you use to gain access to your AWS account. You gain access to AWS through an IAM account.

1. Sign in to the AWS console.
2. Choose **AWS Identity and Access Management (IAM)**.
3. Choose **Identity Providers**.
4. Choose **Create Provider**.
5. For **Configure Provider**, specify the following:
  - **Provider Type** – From the dropdown list, choose **SAML**.
  - **Provider Name** – Specify **Okta**.
  - **Metadata Document** – Upload the XML document that you've saved locally from step 7 of [Add the SageMaker Canvas application to Okta](#).
6. Find your identity provider under **Identity Providers**. Copy its **Provider ARN** value.
7. For **Roles**, choose the IAM role that you're using for Okta SSO access.
8. Under **Trust Relationship** for the IAM role, choose **Edit Trust Relationship**.
9. Modify the IAM trust relationship policy by specifying the **Provider ARN** value that you've copied and add the following policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::123456789012:saml-provider/Okta"
      },
      "Action": [
        "sts:AssumeRoleWithSAML",
        "sts:SetSourceIdentity",
        "sts:TagSession"
      ],
      "Condition": {
        "StringEquals": {
          "SAML:aud": "https://signin.aws.amazon.com/saml"
        }
      }
    }
  ]
}
```

10. For **Permissions**, add the following policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AmazonSageMakerPresignedUrlPolicy",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedDomainUrl",
        "sagemaker:CreatePresignedDomainUrlWithPrincipalTag"
      ],
      "Resource": "*"
    }
  ]
}
```

## Configure SageMaker Canvas in Okta

Configure Amazon SageMaker Canvas in Okta using the following procedure.

To configure Amazon SageMaker Canvas to use Okta, follow the steps in this section. You must specify unique user names for each **SageMakerStudioProfileName** field. For example, you can use `user.login` as a value. If the username is different from the SageMaker Canvas profile name, choose a different uniquely identifying attribute. For example, you can use an employee's ID number for the profile name.

For an example of values that you can set for **Attributes**, see the code following the procedure.

1. Under **Directory**, choose **Groups**.
2. Add a group with the following pattern: `sagemaker#canvas#IAM-role#AWS-account-id`.
3. In Okta, open the **AWS Account Federation** application integration configuration.
4. Select **Sign On** for the AWS Account Federation application.
5. Choose **Edit** and specify the following:
  - SAML 2.0
  - **Default Relay State** – `https://Region.console.aws.amazon.com/sagemaker/home?region=Region#/studio/canvas/open/StudioId`. You can find the Studio Classic ID in the console: <https://console.aws.amazon.com/sagemaker/>
6. Choose **Attributes**.
7. In the **SageMakerStudioProfileName** fields, specify unique values for each username. The usernames must match the usernames that you've created in the AWS console.

```
Attribute 1:  
Name: https://aws.amazon.com/SAML/Attributes/  
PrincipalTag:SageMakerStudioUserProfileName  
Value: ${user.login}  
  
Attribute 2:  
Name: https://aws.amazon.com/SAML/Attributes/TransitiveTagKeys  
Value: {"SageMakerStudioUserProfileName"}
```

8. Select **Environment Type**. Choose **Regular AWS**.

- If your environment type isn't listed, you can set your ACS URL in the **ACS URL** field. If your environment type is listed, you don't need to enter your ACS URL
9. For **Identity Provider ARN**, specify the ARN you used in step 6 of the preceding procedure.
  10. Specify a **Session Duration**.
  11. Choose **Join all roles**.
  12. Turn on **Use Group Mapping** by specifying the following fields:
    - **App Filter** – okta
    - **Group Filter** – `^aws\#\S+\#(?IAM-role[\w\-\-]+)\#(?accountid\d+)$`
    - **Role Value Pattern** – `arn:aws:iam::${accountid}:saml-provider/Okta,arn:aws:iam::${accountid}:role/IAM-role`
  13. Choose **Save/Next**.
  14. Under **Assignments**, assign the application to the group that you've created.

### Add optional policies on access control in IAM

In IAM, you can apply the following policy to the administrator user who creates the user profiles.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateSageMakerStudioUserProfilePolicy",
      "Effect": "Allow",
      "Action": "sagemaker:CreateUserProfile",
      "Resource": "*",
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:TagKeys": [
            "studiouserid"
          ]
        }
      }
    }
  ]
}
```

If you choose to add the preceding policy to the admin user, you must use the following permissions from [Set up ID federation in IAM](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AmazonSageMakerPresignedUrlPolicy",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedDomainUrl",
        "sagemaker:CreatePresignedDomainUrlWithPrincipalTag"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "sagemaker:ResourceTag/studiouserid": "${aws:PrincipalTag/
SageMakerStudioUserProfileName}"
        }
      }
    }
  ]
}
```

## Configure your Amazon S3 storage

When you set up your SageMaker Canvas application, the default storage location for model artifacts, datasets, and other application data is an Amazon S3 bucket that Canvas creates. This default Amazon S3 bucket follows the naming pattern `s3://sagemaker-{Region}-{your-account-id}` and exists in the same Region as your Canvas application. However, you can customize the storage location and specify your own Amazon S3 bucket for storing Canvas application data. You might want to use your own Amazon S3 bucket for storing application data for any of the following reasons:

- Your organization has internal naming conventions for Amazon S3 buckets.
- You want to enable cross-account access to model artifacts or other Canvas data.
- You want to be compliant with internal security guidelines, such as restricting users to specific Amazon S3 buckets or model artifacts.

- You want enhanced visibility and access to logs produced by Canvas, independent of the AWS console or SageMaker Studio Classic.

By specifying your own Amazon S3 bucket, you can have increased control over your own storage and be compliant with your organization.

To get started, you can either create a new SageMaker AI domain or user profile, or you can update an existing domain or user profile. Note that the user profile settings override the domain-level settings. For example, you can use the default bucket configuration at the domain level, but you can specify a custom Amazon S3 bucket for an individual user. After specifying your own Amazon S3 bucket for the domain or user profile, Canvas creates a subfolder called `Canvas/<UserProfileName>` under the input Amazon S3 URI and saves all artifacts generated in the Canvas application under this subfolder.

### Important

If you update an existing domain or user profile, you no longer have access to your Canvas artifacts from the previous location. Your files are still in the old Amazon S3 location, but you can no longer view them from Canvas. The new configuration takes effect the next time you log into the application.

For more information about granting cross-account access to your Amazon S3 bucket, see [Granting cross-account object permissions](#) in the *Amazon S3 User Guide*.

The following sections describe how to specify a custom Amazon S3 bucket for your Canvas storage configuration. If you're setting up a new SageMaker AI domain (or a new user in a domain), then use the [New domain setup method](#) or the [New user profile setup method](#). If you have an existing Canvas user profile and would like to update the profile's storage configuration, use the [Existing user method](#).

## Before you begin

If you're specifying an Amazon S3 URI from a different AWS account, or if you're using a bucket that is encrypted with AWS KMS, then you must configure permissions before proceeding. You must grant AWS IAM permissions to ensure that Canvas can download and upload objects to and from your bucket. For detailed information on how to grant the required permissions, see [Grant permissions for cross-account Amazon S3 storage](#).

Additionally, the final Amazon S3 URI for the training folder in your Canvas storage location must be 128 characters or less. The final Amazon S3 URI consists of your bucket path `s3://<your-bucket-name>/<folder-name>/` plus the path that Canvas adds to your bucket: `Canvas/<user-profile-name>/Training`. For example, an acceptable path that is less than 128 characters is `s3://<amzn-s3-demo-bucket>/<machine-learning>/Canvas/<user-1>/Training`.

## New domain setup method

If you're setting up a new domain and Canvas application, use this section to configure the storage location at the domain level. This configuration applies to all new users you create in the domain, unless you specify a different storage location for individual user profiles.

When doing a **Standard setup** for your domain, on the **Step 3: Configure Applications - Optional** page, use the following procedure for the **Canvas** section:

1. For the **Canvas storage configuration**, do the following:
  - a. Select **System managed** if you want to set the location to the default SageMaker AI bucket that follows the pattern `s3://sagemaker-{Region}-{your-account-id}`.
  - b. Select **Custom S3** to specify your own Amazon S3 bucket as the storage location. Then, enter the Amazon S3 URI.
  - c. (Optional) For **Encryption key**, specify a KMS key for encrypting Canvas artifacts stored at the specified location.
2. Finish setting up the domain and choose **Submit**.

Your domain is now configured to use the Amazon S3 location you specified for SageMaker Canvas application storage.

## New user profile setup method

If you're setting up a new user profile in your domain, use this section to configure the storage location for the user. This configuration overrides the domain-level configuration.

When adding a user profile to your domain, for **Step 2: Configure Applications**, use the following procedure for the **Canvas** section:

1. For the **Canvas storage configuration**, do the following:

- a. Select **System managed** if you want to set the location to the default SageMaker AI created bucket that follows the pattern `s3://sagemaker-{Region}-{your-account-id}`.
  - b. Select **Custom S3** to specify your own Amazon S3 bucket as the storage location. Then, enter the Amazon S3 URI.
  - c. (Optional) For **Encryption key**, specify a KMS key for encrypting Canvas artifacts stored at the specified location.
2. Finish setting up the user profile and choose **Submit**.

Your user profile is now configured to use the Amazon S3 location you specified for SageMaker Canvas application storage.

### Existing user method

If you have an existing Canvas user profile and would like to update the Amazon S3 storage location, you can edit the SageMaker AI domain or user profile settings. The change takes effect the next time you log into the Canvas application.

#### Note

When you change the storage location for an existing Canvas application, you lose access to your Canvas artifacts from the previous storage location. The artifacts are still stored in the old Amazon S3 location, but you can no longer view them from Canvas.

Remember that the user profile settings override the general domain settings, so you can update the Amazon S3 storage location for specific user profiles without changing it for all of the users. You can update the storage configuration for an existing domain or user by using the following procedures.

#### Update an existing domain

Use the following procedure to update the storage configuration for a domain.

1. Open the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Domains**.

4. From the list of domains, choose your domain.
5. On the **Domain details** page, choose the **App Configurations** tab.
6. Scroll down to the **Canvas** section and choose **Edit**.
7. The **Edit Canvas settings** page opens. For the **Canvas storage configuration** section, do the following:
  - a. Select **System managed** if you want to set the location to the default SageMaker AI created bucket that follows the pattern `s3://sagemaker-{Region}-{your-account-id}`.
  - b. Select **Custom S3** to specify your own Amazon S3 bucket as the storage location. Then, enter the Amazon S3 URI.
  - c. (Optional) For **Encryption key**, specify a KMS key for encrypting Canvas artifacts stored at the specified location.
8. Finish any other modifications you want to make to the domain, and then choose **Submit** to save your changes.

## Update an existing user profile

Use the following procedure to update the storage configuration for a user profile.

1. Open the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of **domains**, choose your domain.
5. From the list of users in the domain, choose the user whose configuration you want to edit.
6. On the **User Details** page, choose **Edit**.
7. In the navigation pane, choose **Canvas settings**.
8. For the **Canvas storage configuration**, do the following:
  - a. Select **System managed** if you want to set the location to the default SageMaker AI bucket that follows the pattern `s3://sagemaker-{Region}-{your-account-id}`.
  - b. Select **Custom S3** to specify your own Amazon S3 bucket as the storage location. Then, enter the Amazon S3 URI.
  - c. (Optional) For **Encryption key**, specify a KMS key for encrypting Canvas artifacts stored at the specified location.

9. Finish any other modifications you want to make to the user profile, and then choose **Submit** to save your changes.

The storage location for your Canvas user profile should now be updated. The next time you log into the Canvas application, you receive a notification that the storage location has been updated. You lose access to any previous artifacts that you created in Canvas. You can still access the files in Amazon S3, but you can no longer view them in Canvas.

## Grant permissions for cross-account Amazon S3 storage

When setting up your SageMaker AI domain or user profile for users to access SageMaker Canvas, you specify an Amazon S3 storage location for Canvas artifacts. These artifacts include saved copies of your input datasets, model artifacts, predictions, and other application data. You can either use the default SageMaker AI created Amazon S3 bucket, or you can customize the storage location and specify your own bucket for storing Canvas application data.

You can specify an Amazon S3 bucket in another AWS account for storing your Canvas data, but first you must grant cross-account permissions so that Canvas can access the bucket.

The following sections describe how to grant permissions to Canvas for uploading and downloading objects to and from an Amazon S3 bucket in another account. There are additional permissions for when your bucket is encrypted with AWS KMS.

### Requirements

Before you begin, review the following requirements:

- Cross-account Amazon S3 buckets (and any associated AWS KMS keys) must be in the same AWS Region as the Canvas user domain or user profile.
- The final Amazon S3 URI for the training folder in your Canvas storage location must be 128 characters or less. The final S3 URI consists of your bucket path `s3://<your-bucket-name>/<folder-name>/` plus the path that Canvas adds to your bucket: `Canvas/<user-profile-name>/Training`. For example, an acceptable path that is less than 128 characters is `s3://<amzn-s3-demo-bucket>/<machine-learning>/Canvas/<user-1>/Training`.

## Permissions for cross-account Amazon S3 buckets

The following section outlines the basic steps for granting the necessary permissions so that Canvas can access your Amazon S3 bucket in another account. For more detailed instructions, see [Example 2: Bucket owner granting cross-account bucket permissions](#) in the *Amazon S3 User Guide*.

1. Create an Amazon S3 bucket, `bucketA`, in Account A.
2. The Canvas user exists in another account called Account B. In the following steps, we refer to the Canvas user's IAM role as `roleB` in Account B.

Give the IAM role `roleB` in Account B permission to download (`GetObject`) and upload (`PutObject`) objects to and from `bucketA` in Account A by attaching an IAM policy.

To limit access to a specific bucket folder, define the folder name in the resource element, such as `arn:aws:s3:::<bucketA>/FolderName/*`. For more information, see [How can I use IAM policies to grant user-specific access to specific folders?](#)

### Note

Bucket-level actions, such as `GetBucketCors` and `GetBucketLocation`, should be added on bucket-level resources, not folders.

The following example IAM policy grants the required permissions for `roleB` to access objects in `bucketA`:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:DeleteObject"
      ],
      "Resource": [
        "arn:aws:s3:::bucketA/FolderName/*",
      ]
    }
  ],
}
```

```

    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketCors",
        "s3:GetBucketLocation"
      ],
      "Resource": [
        "arn:aws:s3:::bucketA",
      ]
    }
  ]
}

```

3. Configure the bucket policy for bucketA in Account A to grant permissions to the IAM role roleB in Account B.

 **Note**

Admins must also turn off **Block all public access** under the bucket **Permissions** section.

The following is an example bucket policy for bucketA to grant the necessary permissions to roleB:

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::accountB:role/roleB"
      },
      "Action": [
        "s3:DeleteObject",
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": "arn:aws:s3:::bucketA/FolderName/*"
    },
    {

```

```
    "Effect": "Allow",
    "Principal": {
      "AWS": "arn:aws:iam::accountB:role/roleB"
    },
    "Action": [
      "s3:ListBucket",
      "s3:GetBucketCors",
      "s3:GetBucketLocation"
    ],
    "Resource": "arn:aws:s3:::bucketA"
  }
]
```

After configuring the preceding permissions, your Canvas user profile in Account B can now use the Amazon S3 bucket in Account A as the storage location for Canvas artifacts.

### Permissions for cross-account Amazon S3 buckets encrypted with AWS KMS

The following procedure shows you how to grant the necessary permissions so that Canvas can access your Amazon S3 bucket in another account that is encrypted with AWS KMS. The steps are similar to the procedure above, but with additional permissions. For more information about granting cross-account KMS key access, see [Allowing users in other accounts to use a KMS key](#) in the *AWS KMS Developer Guide*.

1. Create an Amazon S3 bucket, `bucketA`, and an Amazon S3 KMS key `s3KmsInAccountA` in Account A.
2. The Canvas user exists in another account called Account B. In the following steps, we refer to the Canvas user's IAM role as `roleB` in Account B.

Give the IAM role `roleB` in Account B permission to do the following:

- Download (`GetObject`) and upload (`PutObject`) objects to and from `bucketA` in Account A.
- Access the AWS KMS key `s3KmsInAccountA` in Account A.

The following example IAM policy grants the required permissions for `roleB` to access objects in `bucketA` and use the KMS key `s3KmsInAccountA`:

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:DeleteObject"
      ],
      "Resource": [
        "arn:aws:s3:::bucketA/FolderName/*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetBucketCors",
        "s3:GetBucketLocation"
      ],
      "Resource": [
        "arn:aws:s3:::bucketA"
      ]
    },
    {
      "Action": [
        "kms:DescribeKey",
        "kms:CreateGrant",
        "kms:RetireGrant",
        "kms:GenerateDataKey",
        "kms:GenerateDataKeyWithoutPlainText",
        "kms:Decrypt"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:kms:{region}:accountA:key/s3KmsInAccountA"
    }
  ]
}

```

3. Configure the bucket policy for bucketA and the key policy for s3KmsInAccountA in Account A to grant permissions to the IAM role roleB in Account B.

The following is an example bucket policy for bucketA to grant the necessary permissions to roleB:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::accountB:role/roleB"
      },
      "Action": [
        "s3:DeleteObject",
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": "arn:aws:s3:::bucketA/FolderName/*"
    },
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::accountB:role/roleB"
      },
      "Action": [
        "s3:GetBucketCors",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::bucketA"
    }
  ]
}
```

The following example is a key policy that you attach to the KMS key s3KmsInAccountA in Account A to grant roleB access. For more information about how to create and attach a key policy statement, see [Creating a key policy](#) in the *AWS KMS Developer Guide*.

```
{
  "Sid": "Allow use of the key",
  "Effect": "Allow",
  "Principal": {
    "AWS": [
```

```
    "arn:aws:iam::accountB:role/roleB"
  ]
},
"Action": [
  "kms:DescribeKey",
  "kms:CreateGrant",
  "kms:RetireGrant",
  "kms:GenerateDataKey",
  "kms:GenerateDataKeyWithoutPlainText",
  "kms:Decrypt"
],
"Resource": "*"
}
```

After configuring the preceding permissions, your Canvas user profile in Account B can now use the encrypted Amazon S3 bucket in Account A as the storage location for Canvas artifacts.

## Grant Users Permissions to Use Large Data across the ML Lifecycle

Amazon SageMaker Canvas users working with datasets larger than 10 GB in CSV format or 2.5 GB in Parquet format require specific permissions for large data processing. These permissions are essential for managing large-scale data throughout the machine learning lifecycle. When datasets exceed the stated thresholds, or the application's local memory capacity, SageMaker Canvas uses Amazon EMR Serverless for efficient processing. This applies to:

- **Data Import:** Importing large datasets with random or stratified sampling.
- **Data Preparation:** Exporting processed data from Data Wrangler in Canvas to Amazon S3, to a new Canvas dataset, or to a Canvas model.
- **Model Building:** Training models on large datasets.
- **Inference:** Making predictions on large datasets.

By default, SageMaker Canvas uses EMR Serverless to run these remote jobs with the following app settings:

- **Pre-Initialized capacity:** Not configured
- **Application limits:** Maximum capacity of 400 vCPUs, max concurrent 16 vCPUs per account, 3000 GB memory, 20000 GB disk
- **Metastore configuration:** AWS Glue Data Catalog

- Application logs: AWS managed storage (enabled), using an AWS owned encryption key
- Application behavior: Auto-starts on job submission and auto-stops after the application is idle for 15 minutes

To enable these large data processing capabilities, users need the necessary permissions, which can be granted through the Amazon SageMaker AI domain settings. The method for granting these permissions depends on how your Amazon SageMaker AI domain was set up initially. We'll cover three main scenarios:

- Quick domain setup
- Custom domain setup (with public internet access/without VPC)
- Custom domain setup (with VPC and without public internet access)

Each scenario requires specific steps to ensure that users have the required permissions to leverage EMR Serverless for large data processing across the entire machine learning lifecycle in SageMaker Canvas.

### Scenario 1: Quick domain setup

If you used the **Quick setup** option when creating your SageMaker AI domain, follow these steps:

1. Navigate to the Amazon SageMaker AI domain settings:
  - a. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
  - b. In the left navigation pane, choose **Domains**.
  - c. Select your domain.
  - d. Choose the **App Configurations** tab.
  - e. Scroll to the **Canvas** section and choose **Edit**.
2. Enable large data processing:
  - a. In the **Large data processing configuration** section, turn on **Enable EMR Serverless for large data processing**.
  - b. Create or select an EMR Serverless role:
    - i. Choose **Create and use a new execution role** to create a new IAM role that has a trust relationship with EMR Serverless and the [AWS managed policy](#):

[AmazonSageMakerCanvasEMRServerlessExecutionRolePolicy](#) policy attached. This IAM role is assumed by Canvas to create EMR Serverless jobs.

- ii. Alternatively, if you already have an execution role with a trust relationship for EMR Serverless, then select **Use an existing execution role** and choose your role from the dropdown.
  - The existing role must have a name that begins with the prefix `AmazonSageMakerCanvasEMRSExecutionAccess-`.
  - The role you select should also have at least the permissions described in the [AWS managed policy: AmazonSageMakerCanvasEMRServerlessExecutionRolePolicy](#) policy.
  - The role should have an EMR Serverless trust policy, as shown below:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EMRServerlessTrustPolicy",
      "Effect": "Allow",
      "Principal": {
        "Service": "emr-serverless.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "<your-account-id>"
        }
      }
    }
  ]
}
```

### 3. (Optional) Add Amazon S3 permissions for custom Amazon S3 buckets:

- a. The Canvas managed policy automatically grants read and write permissions for Amazon S3 buckets with `sagemaker` or `SageMaker AI` in their names. It also grants read permissions for objects in custom Amazon S3 buckets with the tag `"SageMaker": "true"`.
- b. For custom Amazon S3 buckets without the required tag, add the following policy to your EMR Serverless role:

c.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:DeleteObject"
      ],
      "Resource": [
        "arn:aws:s3::*"
      ]
    }
  ]
}
```

d. We recommend that you scope down the permissions to specific Amazon S3 buckets that you want Canvas to access.

4. Save your changes and restart your SageMaker Canvas application.

## Scenario 2: Custom domain setup (with public internet access/without VPC)

If you created or use a custom domain, follow steps 1-3 from Scenario 1, and then do these additional steps:

1. Add permissions for the Amazon ECR `DescribeImages` operation to your Amazon SageMaker AI execution role, as Canvas utilizes public Amazon ECR Docker images for data preparation and model training:
  - a. Sign in to the AWS console and open the IAM console at <https://console.aws.amazon.com/iam/>.
  - b. Choose **Roles**.
  - c. In the search box, search for your SageMaker AI execution role by name and select it.
  - d. Add the following policy to your SageMaker AI execution role. This can be done either by adding it as a new inline policy or by appending the policy statement to an existing one. Note that an IAM role can have a maximum of 10 policies attached.

```
{
```

```

    "Version": "2012-10-17",
    "Statement": [{
      "Sid": "ECRDescribeImagesOperation",
      "Effect": "Allow",
      "Action": "ecr:DescribeImages",
      "Resource": [
        "arn:aws:ecr:*:*:repository/sagemaker-data-wrangler-emr-container",
        "arn:aws:ecr:*:*:repository/ap-dataprep-emr"
      ]
    }]
  }

```

2. Save your changes and restart your SageMaker Canvas application.

### Scenario 3: Custom domain setup (with VPC and without public internet access)

If you created or use a custom domain, follow all steps from Scenario 2, then follow these additional steps:

1. Ensure your VPC subnets are private:
  - Verify that the route table for your subnets doesn't have an entry mapping `0.0.0.0/0` to an Internet Gateway.
2. Add permissions for creating network interfaces:
  - a. When using SageMaker Canvas with EMR Serverless for large-scale data processing, EMR Serverless requires the ability to create Amazon EC2 ENIs to enable network communication between EMR Serverless applications and your VPC resources.
  - b. Add the following policy to your Amazon SageMaker AI execution role. This can be done either by adding it as a new inline policy or by appending the policy statement to an existing one. Note that an IAM role can have a maximum of 10 policies attached.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowEC2ENICreation",
      "Effect": "Allow",
      "Action": [
        "ec2:CreateNetworkInterface"
      ],
    }
  ],
}

```

```

        "Resource": [
            "arn:aws:ec2:*:*:network-interface/*"
        ],
        "Condition": {
            "StringEquals": {
                "aws:CalledViaLast": "ops.emr-serverless.amazonaws.com"
            }
        }
    }
]
}

```

### 3. (Optional) Restrict ENI creation to specific subnets:

- a. To further secure your setup by restricting the creation of ENIs to certain subnets within your VPC, you can tag each subnet with specific conditions.
- b. Use the following IAM policy to ensure that EMR Serverless applications can only create Amazon EC2 ENIs within the allowed subnets and security groups:

```

{
    "Sid": "AllowEC2ENICreationInSubnetAndSecurityGroupWithEMRTags",
    "Effect": "Allow",
    "Action": [
        "ec2:CreateNetworkInterface"
    ],
    "Resource": [
        "arn:aws:ec2:*:*:subnet/*",
        "arn:aws:ec2:*:*:security-group/*"
    ],
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/KEY": "VALUE"
        }
    }
}

```

4. Follow the steps on the page [Configure Amazon SageMaker Canvas in a VPC without internet access](#) to set the VPC endpoint for Amazon S3, which is required by EMR Serverless and other AWS services that are used by SageMaker Canvas.
5. Save your changes and restart your SageMaker Canvas application.

By following these steps, you can enable large data processing in SageMaker Canvas for various domain setups, including those with custom VPC configurations. Remember to restart your SageMaker Canvas application after making these changes to apply the new permissions.

## Encrypt Your SageMaker Canvas Data with AWS KMS

You might have data that you want to encrypt while using Amazon SageMaker Canvas, such as your private company information or customer data. SageMaker Canvas uses AWS Key Management Service to protect your data. AWS KMS is a service that you can use to create and manage cryptographic keys for encrypting your data. For more information about AWS KMS, see [AWS Key Management Service](#) in the *AWS KMS Developer Guide*.

Amazon SageMaker Canvas provides you with several options for encrypting your data. SageMaker Canvas provides default encryption within the application for tasks such as building your model and generating insights. You can also choose to encrypt data stored in Amazon S3 to protect your data at rest. SageMaker Canvas supports importing encrypted datasets, so you can establish an encrypted workflow. The following sections describe how you can use AWS KMS encryption to protect your data while building models with SageMaker Canvas.

### Encrypt your data in SageMaker Canvas

With SageMaker Canvas, you can use two different AWS KMS encryption keys to encrypt your data in SageMaker Canvas, which you can specify when [setting up your domain](#) using the standard domain setup. These keys are specified in the following domain setup steps:

- **Step 3: Configure Applications - (Optional)** – When configuring the **Canvas storage configuration** section, you can specify an **Encryption key**. This is a KMS key that SageMaker Canvas uses for long-term storage of model objects and datasets, which are stored in the provided Amazon S3 bucket for your domain. If creating a Canvas application with the [CreateApp](#) API, use the `S3KMSKeyId` field to specify this key.
- **Step 6: Configure storage** – SageMaker Canvas uses one key for encrypting the Amazon SageMaker Studio private space that is created for your Canvas application, which includes temporary application storage, visualizations, and compute jobs (such as building models). You can use either the default AWS managed key or specify your own. If you specify your AWS KMS key, the data stored in the `/home/sagemaker-user` directory is encrypted with your key. If you don't specify an AWS KMS key, the data inside `/home/sagemaker-user` is encrypted with an AWS managed key. Regardless of whether you specify an AWS KMS key, all of the data outside of the working directory is encrypted with an AWS Managed Key. To learn more about the Studio space and your Canvas application storage, see [Store SageMaker Canvas application data in](#)

[your own SageMaker AI space](#). If creating a Canvas application with the [CreateApp](#) API, use the `KmsKeyID` field to specify this key.

The preceding keys can be the same or different KMS keys.

## Prerequisites

To use your own KMS key for either of the previously described purposes, you must first grant your user's IAM role permission to use the key. Then, you can specify the KMS key when setting up your domain.

The simplest way to grant your role permission to use the key is to modify the key policy. Use the following procedure to grant your role the necessary permissions.

1. Open the [AWS KMS console](#).
2. In the **Key Policy** section, choose **Switch to policy view**.
3. Modify the key's policy to grant permissions for the `kms:GenerateDataKey` and `kms:Decrypt` actions to the IAM role. Additionally, if you're modifying the key policy that encrypts your Canvas application storage in the Studio space, grant the `kms:CreateGrant` action. You can add a statement that's similar to the following:

```
{
  "Sid": "ExampleStmt",
  "Action": [
    "kms:CreateGrant", #this permission is only required for the key that encrypts
    your SageMaker Canvas application storage
    "kms:Decrypt",
    "kms:GenerateDataKey"
  ],
  "Effect": "Allow",
  "Principal": {
    "AWS": "<arn:aws:iam::111122223333:role/Jane>"
  },
  "Resource": "*"
}
```

4. Choose **Save changes**.

The less preferred method is to modify the user's IAM role to grant the user permissions to use or manage the KMS key. If you use this method, the KMS key policy must also allow access

management through IAM. To learn how to grant permission to a KMS key through the user's IAM role, see [Specifying KMS keys in IAM policy statements](#) in the *AWS KMS Developer Guide*.

## Encrypt your data in the SageMaker Canvas application

The first KMS key you can use in SageMaker Canvas is used for encrypting application data stored on Amazon Elastic Block Store (Amazon EBS) volumes and in the Amazon Elastic File System that SageMaker AI creates in your domain. SageMaker Canvas encrypts your data with this key in the underlying application and temporary storage systems created when using compute instances for building models and generating insights. SageMaker Canvas passes the key to other AWS services, such as Autopilot, whenever SageMaker Canvas initiates jobs with them to process your data.

You can specify this key by setting the `KmsKeyId` in the `CreateDomain` API call or while doing the standard domain setup in the console. If you don't specify your own KMS key, SageMaker AI uses a default AWS managed KMS key to encrypt your data in the SageMaker Canvas application.

To specify your own KMS key for use in the SageMaker Canvas application through the console, first set up your Amazon SageMaker AI domain using the **Standard setup**. Use the following procedure to complete the **Network and Storage Section** for the domain.

1. Fill out your desired Amazon VPC settings.
2. For **Encryption key**, choose **Enter a KMS key ARN**.
3. For **KMS ARN**, enter the ARN for your KMS key, which should have a format similar to the following: `arn:aws:kms:example-region-1:123456789098:key/111aa2bb-333c-4d44-5555-a111bb2c33dd`

## Encrypt your SageMaker Canvas data saved in Amazon S3

The second KMS key you can specify is used for data that SageMaker Canvas stores to Amazon S3. This KMS key is specified in the `S3KMSKeyId` field in the `CreateDomain` API call, or while doing the standard domain setup in the SageMaker AI console. SageMaker Canvas saves duplicates of your input datasets, application and model data, and output data to the Region's default SageMaker AI S3 bucket for your account. The naming pattern for this bucket is `s3://sagemaker-{Region}-{your-account-id}`, and SageMaker Canvas stores data in the `Canvas/` folder.

1. Turn on **Enable notebook resource sharing**.

2. For **S3 location for shareable notebook resources**, leave the default Amazon S3 path. Note that SageMaker Canvas does not use this Amazon S3 path; this Amazon S3 path is used for Studio Classic notebooks.
3. For **Encryption key**, choose **Enter a KMS key ARN**.
4. For **KMS ARN**, enter the ARN for your KMS key, which should have a format similar to the following: `arn:aws:kms:us-east-1:111122223333:key/111aa2bb-333c-4d44-5555-a111bb2c33dd`

## Import encrypted datasets from Amazon S3

Your users might have datasets that have been encrypted with a KMS key. While the preceding section shows you how to encrypt data in SageMaker Canvas and data stored to Amazon S3, you must grant your user's IAM role additional permissions if you want to import data from Amazon S3 that is already encrypted with AWS KMS.

To grant your user permissions to import encrypted datasets from Amazon S3 into SageMaker Canvas, add the following permissions to the IAM execution role that you've used for the user profile.

```
"kms:Decrypt",  
"kms:GenerateDataKey"
```

To learn how to edit the IAM permissions for a role, see [Adding and removing IAM identity permissions](#) in the *IAM User Guide*. For more information about KMS keys, see [Key policies in AWS Key Management Service](#) in the *AWS KMS Developer Guide*.

## FAQs

Refer to the following FAQ items for answers to commonly asked questions about SageMaker Canvas AWS KMS support.

### Q: Does SageMaker Canvas retain my KMS key?

A: No. SageMaker Canvas may temporarily cache your key or pass it on to other AWS services (such as Autopilot), but SageMaker Canvas does not retain your KMS key.

**Q: I specified a KMS key when setting up my domain. Why did my dataset fail to import in SageMaker Canvas?**

A: Your user's IAM role may not have permissions to use that KMS key. To grant your user permissions, see the [Prerequisites](#). Another possible error is that you have a bucket policy on your Amazon S3 bucket that requires the use of a specific KMS key that doesn't match the KMS key you specified in your domain. Make sure that you specify the same KMS key for your Amazon S3 bucket and your domain.

**Q: How do I find the Region's default SageMaker AI Amazon S3 bucket for my account?**

A: The default Amazon S3 bucket follows the naming pattern `s3://sagemaker-{Region}-{your-account-id}`. The `Canvas/` folder in this bucket stores your SageMaker Canvas application data.

**Q: Can I change the default SageMaker AI Amazon S3 bucket used to store SageMaker Canvas data?**

A: No, SageMaker AI creates this bucket for you.

**Q: What does SageMaker Canvas store in the default SageMaker AI Amazon S3 bucket?**

A: SageMaker Canvas uses the default SageMaker AI Amazon S3 bucket to store duplicates of your input datasets, model artifacts, and model outputs.

**Q: What use cases are supported for using KMS keys with SageMaker Canvas?**

A: With SageMaker Canvas, you can use your own encryption keys with AWS KMS for building regression, binary and multi-class classification, and time series forecasting models, as well as for batch inference with your model.

**Store SageMaker Canvas application data in your own SageMaker AI space**

Your Amazon SageMaker Canvas application data, such as datasets that you import and your model artifacts, is stored in a *Amazon SageMaker Studio private space*. The space consists of a storage volume for your application data with 100 GB of storage per user profile, the type of the space (in this case, a Canvas application), and the image for your application's container. When you set up Canvas and launch your application for the first time, SageMaker AI creates a default private space that is assigned to your user profile and stores your Canvas data. You don't have to do any additional configuration to set up the space because SageMaker AI automatically creates the space

on your behalf. However, if you don't want to use the default space, you have the option to specify a space that you created yourself. This can be useful if you want to isolate your data. The following page shows you how to create and configure your own Studio space for storing Canvas application data.

### Note

You can only configure a custom Studio space for new Canvas applications. You can't modify the space configuration for existing Canvas applications.

## Before you begin

Your Amazon SageMaker AI domain or user profile must have at least 100 GB of storage in order to create and use the SageMaker Canvas application.

If you created your domain through the SageMaker AI console, enough storage is provisioned by default and you don't need to take any additional action. If you created your domain or user profile with the [CreateDomain](#) or [CreateUserProfile](#) APIs, then make sure that you set the `MaximumEbsVolumeSizeInGb` value to 100 GB or greater. To set a greater storage value, you can either create a new domain or user profile, or you can update an existing domain or user profile using the [UpdateDomain](#) or [UpdateUserProfile](#) APIs.

## Create a new space

First, create a new Studio space that is configured to store Canvas application data. This is the space that you specify when creating a new Canvas application in the next step.

To create a space, you can use the AWS SDK for Python (Boto3) or the AWS CLI.

### SDK for Python (Boto3)

The following example shows you how to use the AWS SDK for Python (Boto3) `create_space` method to create a space that you can use for Canvas applications. Make sure to specify these parameters:

- `DomainId`: Specify the ID for your SageMaker AI domain. To find your ID, you can go to the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/> and locate your domain in the **Domains** section.
- `SpaceName`: Specify a name for the new space.

- `EbsVolumeSizeInGb`: Specify the storage volume size for your space (in GB). The minimum value is 5 and the maximum is 16384.
- `SharingType`: Specify this field as `Private`. For more information, see [Amazon SageMaker Studio spaces](#).
- `OwnerUserProfileName`: Specify the user profile name. To find user profile names associated with a domain, you can go to the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/> and locate your domain in the **Domains** section. In the domain's settings, you can view the user profiles.
- `AppType`: Specify this field as `Canvas`.

```
response = client.create_space(  
    DomainId='<your-domain-id>',  
    SpaceName='<your-new-space-name>',  
    SpaceSettings={  
        'AppType': 'Canvas',  
        'SpaceStorageSettings': {  
            'EbsStorageSettings': {  
                'EbsVolumeSizeInGb': <storage-volume-size>  
            }  
        },  
    },  
    OwnershipSettings={  
        'OwnerUserProfileName': '<your-user-profile>'  
    },  
    SpaceSharingSettings={  
        'SharingType': 'Private'  
    }  
)
```

## AWS CLI

The following example shows you how to use the AWS CLI `create-space` method to create a space that you can use for Canvas applications. Make sure to specify these parameters:

- `domain-id`: Specify the ID for your domain. To find your ID, you can go to the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/> and locate your domain in the **Domains** section.
- `space-name`: Specify a name for the new space.

- `EbsVolumeSizeInGb`: Specify the storage volume size for your space (in GB). The minimum value is 5 and the maximum is 16384.
- `SharingType`: Specify this field as `Private`. For more information, see [Amazon SageMaker Studio spaces](#).
- `OwnerUserProfileName`: Specify the user profile name. To find user profile names associated with a domain, you can go to the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/> and locate your domain in the **Domains** section. In the domain's settings, you can view the user profiles.
- `AppType`: Specify this field as `Canvas`.

```
create-space
--domain-id <your-domain-id>
--space-name <your-new-space-name>
--space-settings '{
    "AppType": "Canvas",
    "SpaceStorageSettings": {
        "EbsStorageSettings": {"EbsVolumeSizeInGb": <storage-volume-size>}
    },
}'
--ownership-settings '{"OwnerUserProfileName": "<your-user-profile>"}'
--space-sharing-settings '{"SharingType": "Private"}'
```

You should now have a space. Keep track of your space's name for the next step.

## Create a new Canvas application

After creating a space, create a new Canvas application that specifies the space as its storage location.

To create a new Canvas application, you can use the AWS SDK for Python (Boto3) or the AWS CLI.

### Important

You must use the AWS SDK for Python (Boto3) or the AWS CLI to create your Canvas application. Specifying a custom space when creating Canvas applications through the SageMaker AI console isn't supported.

## SDK for Python (Boto3)

The following example shows you how to use the AWS SDK for Python (Boto3) `create_app` method to create a new Canvas application. Make sure to specify these parameters:

- `DomainId`: Specify the ID for your SageMaker AI domain.
- `SpaceName`: Specify the name of the space that you created in the previous step.
- `AppType`: Specify this field as `Canvas`.
- `AppName`: Specify `default` as the app name.

```
response = client.create_app(  
    DomainId='<your-domain-id>',  
    SpaceName='<your-space-name>',  
    AppType='Canvas',  
    AppName='default'  
)
```

## AWS CLI

The following example shows you how to use the AWS CLI `create-app` method to create a new Canvas application. Make sure to specify these parameters:

- `DomainId`: Specify the ID for your SageMaker AI domain.
- `SpaceName`: Specify the name of the space that you created in the previous step.
- `AppType`: Specify this field as `Canvas`.
- `AppName`: Specify `default` as the app name.

```
create-app  
--domain-id <your-domain-id>  
--space-name <your-space-name>  
--app-type Canvas  
--app-name default
```

You should now have a new Canvas application that uses a custom Studio space as the storage location for application data.

**⚠ Important**

Any time you delete the Canvas application (or log out) and have to re-create the application, you must provide your space in the SpaceName field to make sure that Canvas uses your space.

The space is attached to the user profile you specified in the space configuration. You can delete your Canvas application without deleting the space, and the data stored in the space remains. The data stored in your space is only deleted if you delete your user profile, or if you directly delete the space.

## Grant Your Users Permissions to Build Custom Image and Text Prediction Models

**⚠ Important**

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see [Provide permissions for tagging SageMaker AI resources](#).

[AWS managed policies for Amazon SageMaker AI](#) that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

In Amazon SageMaker Canvas, you can build [custom models](#) to meet your specific business need. Two of these custom model types are single-label image prediction and multi-category text prediction. The permissions to build these model types are included in the AWS Identity and Access Management (IAM) policy called [AmazonSageMakerCanvasFullAccess](#), which SageMaker AI attaches by default to your user's IAM execution role if you leave the [Canvas base permissions turned on](#). If you are using a custom IAM configuration, then you must explicitly add permissions to your user's IAM execution role so that they can build custom image and text prediction model types. To grant the necessary permissions to build image and text prediction models, read the following section to learn how to attach a least-permissions policy to your role.

To add the permissions to the user's IAM role, do the following:

1. Go to the [IAM console](#).
2. Choose **Roles**.
3. In the search box, search for the user's IAM role by name and select it.
4. On the page for the user's role, under **Permissions**, choose **Add permissions**.
5. Choose **Create inline policy**.
6. Select the JSON tab, and then paste the following least-permissions policy into the editor.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateAutoMLJobV2",
        "sagemaker:DescribeAutoMLJobV2"
      ],
      "Resource": "*"
    }
  ]
}
```

7. Choose **Review policy**.
8. Enter a **Name** for the policy.
9. Choose **Create policy**.

For more information about AWS managed policies, see [Managed policies and inline policies](#) in the *IAM User Guide*.

## Grant Users Permissions to Use Amazon Bedrock and Generative AI Features in Canvas

Generative AI features in Amazon SageMaker Canvas are powered by Amazon Bedrock foundation models, which are large language models (LLMs) that have the capability to understand and generate human-like text. This page describes how to grant the permissions necessary for the following features in SageMaker Canvas:

- [Chat with and compare Amazon Bedrock models](#): Access and start conversational chats with Amazon Bedrock models through SageMaker Canvas.
- [Use the Chat for data prep feature in Data Wrangler](#) : Use natural language to explore, visualize, and transform your data. This feature is powered by Anthropic Claude 2.
- [Fine-tune Amazon Bedrock foundation models](#): Fine-tune an Amazon Bedrock foundation model on your own data to receive customized responses.

In order to use these features, you must first request access to the specific Amazon Bedrock model that you want to use. Then, add the necessary AWS IAM permissions and a trust relationship with Amazon Bedrock to the user's execution role. To grant the permissions to the role, you can choose one of the following methods:

- Create a new Amazon SageMaker AI domain or user profile and turn on Amazon Bedrock permissions. For more information, see [Getting started with using Amazon SageMaker Canvas](#).
- Edit the settings for an existing Amazon SageMaker AI domain or user profile.
- Manually add permissions and a trust relationship to a domain's or user's IAM role.

### Step 1: Add Amazon Bedrock model access

Access to Amazon Bedrock models isn't granted by default, so you must go to the Amazon Bedrock console to request access to models for your AWS account.

To learn how to request access to a specific Amazon Bedrock model, following the procedure to **Add model access** on the page [Manage access to Amazon Bedrock foundation models](#) in the *Amazon Bedrock User Guide*.

### Step 2: Grant permissions to the user's IAM role

When setting up your Amazon SageMaker AI domain or user profile, the user's IAM execution role must have the [AmazonSageMakerCanvasBedrockAccess](#) policy attached, as well as a trust relationship with Amazon Bedrock, so that your user can access Amazon Bedrock models from SageMaker Canvas.

You can modify the domain settings and either create a new execution role (to which SageMaker AI attaches the required permissions for you) or specify an existing role.

Alternatively, you can manually modify the permissions for an existing IAM role through the IAM console.

Both methods are described in the following sections.

## Grant permissions through the domain settings

You can edit your domain or user profile settings to turn on the **Canvas Ready-to-use models configuration** setting and specify an Amazon Bedrock role.

To edit your domain settings and grant access to Amazon Bedrock models for Canvas users in the domain, do the following:

1. Go to the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. In the left navigation pane, choose **Domains**.
3. From the list of domains, choose your domain.
4. Choose the **App Configurations** tab.
5. In the **Canvas** section, choose **Edit**.
6. The **Edit Canvas settings** page opens. For the **Canvas Ready-to-use models configuration** section, do the following:
  - a. Turn on the **Enable Canvas Ready-to-use models option**.
  - b. For **Amazon Bedrock role**, select **Create and use a new execution role** to create a new IAM execution role that has the [AmazonSageMakerCanvasBedrockAccess](#) policy attached and a trust relationship with Amazon Bedrock. This IAM role is assumed by Amazon Bedrock when you access Amazon Bedrock models, use the chat for data prep feature, or fine-tune Amazon Bedrock models in Canvas. If you already have an execution role with a trust relationship, then select **Use an existing execution role** and choose your role from the dropdown.
7. Choose **Submit** to save your changes.

Your users should now have the necessary permissions to access Amazon Bedrock models, use the chat for data prep feature, and fine-tune Amazon Bedrock models in Canvas.

You can use the same procedure above for editing an individual user's settings, except go into the individual user's profile from the domain page and edit the user settings instead. Permissions granted to an individual user don't apply to other users in the domain, while permissions granted through the domain settings apply to all user profiles in the domain.

For more information on editing your domain settings, see [View and Edit domains](#).

## Grant permissions manually through IAM

You can manually grant users permissions to access and fine-tune Amazon Bedrock models in Canvas by adding permissions to the IAM role specified for the domain or user's profile. The IAM role must have the [AmazonSageMakerCanvasBedrockAccess](#) policy attached and a trust relationship with Amazon Bedrock.

The following section shows you how to attach the policy to your IAM role and create the trust relationship with Amazon Bedrock.

First, take note of your domain or user profile's IAM role. Note that permissions granted to an individual user don't apply to other users in the domain, while permissions granted through the domain apply to all user profiles in the domain.

To configure the IAM role and grant permissions to fine-tune foundation models in Canvas, do the following:

1. Go to the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Roles**.
3. Search for the user's IAM role by name from the list of roles and select it.
4. On the **Permissions** tab, choose **Add permissions**. From the dropdown menu, choose **Attach policies**.
5. Search for the `AmazonSageMakerCanvasBedrockAccess` policy and select it.
6. Choose **Add permissions**.
7. Back on the IAM role's page, choose the **Trust relationships** tab.
8. Choose **Edit trust policy**.
9. In the policy editor, find the **Add a principal option** in the right panel and choose **Add**.
10. In the dialog box, for **Principal type**, select **AWS services**.
11. For **ARN**, enter `bedrock.amazonaws.com`.
12. Choose **Add principal**.
13. Choose **Update policy**.

You should now have an IAM role that has the [AmazonSageMakerCanvasBedrockAccess](#) policy attached and a trust relationship with Amazon Bedrock. For information about AWS managed policies, see [Managed policies and inline policies](#) in the *IAM User Guide*.

## Update SageMaker Canvas for Your Users

You can update to the latest version of Amazon SageMaker Canvas as either a user or an IT administrator. You can update Amazon SageMaker Canvas for a single user at a time.

To update the Amazon SageMaker Canvas application, you must delete the previous version.

### Important

Deleting the previous version of Amazon SageMaker Canvas doesn't delete the data or models that the users have created.

Use the following procedure to log in to AWS, open Amazon SageMaker AI domain, and update Amazon SageMaker Canvas. The users can start using the SageMaker Canvas application when they log back in.

1. Sign in to the Amazon SageMaker AI console at [Amazon SageMaker Runtime](#).
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. On the **Domains** page, choose your domain.
5. From the list of **User profiles**, choose a user profile.
6. For the list of **Apps**, find the Canvas application (the **App type** says **Canvas**) and choose **Delete app**.
7. Complete the dialog box and choose **Confirm action**.

The following image shows the user profile page and highlights the **Delete app** action from the preceding procedure.

Amazon SageMaker > Control Panel

## User Details

General details about this user profile. Launch app ▾

## Request a Quota Increase

Your users might use AWS resources in amounts that exceed those specified by their quotas. If your users are resource constrained and encounter errors in SageMaker Canvas, you can request a quota increase for them.

For more details about SageMaker AI quotas and how to request a quota increase, see [Quotas](#).

Amazon SageMaker Canvas uses the following services to process the requests of your users:

- Amazon SageMaker Autopilot
- Amazon SageMaker Studio Classic domain

For a list of the available quotas for SageMaker Canvas operations, see [Amazon SageMaker AI endpoints and quotas](#).

## Request an increase for instances to build custom models

When building a custom model, if you encounter an error during post-building analysis that tells you to increase your quota for `m1.m5.2xlarge` instances, use the following information to resolve the issue.

You must increase the SageMaker AI Hosting endpoint quota for the `m1.m5.2xlarge` instance type to a non-zero value in your AWS account. After building a model, SageMaker Canvas hosts the model on a SageMaker AI Hosting endpoint and uses the endpoint to generate the post-building analysis. If you don't increase the default account quota of 0 for `m1.m5.2xlarge` instances, SageMaker Canvas cannot complete this step and generates an error during post-building analysis.

For the procedure to increase the quota, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

## Grant Users Permissions to Import Amazon Redshift Data

Your users might have datasets stored in Amazon Redshift. Before users can import data from Amazon Redshift into SageMaker Canvas, you must add the `AmazonRedshiftFullAccess` managed policy to the IAM execution role that you've used for the user profile and add Amazon Redshift as a service principal to the role's trust policy. You must also associate the IAM execution role with your Amazon Redshift cluster. Complete the procedures in the following sections to give your users the required permissions to import Amazon Redshift data.

### Add Amazon Redshift permissions to your IAM role

You must grant Amazon Redshift permissions to the IAM role specified in your user profile.

To add the `AmazonRedshiftFullAccess` policy to the user's IAM role, do the following.

1. Sign in to the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Roles**.
3. In the search box, search for the user's IAM role by name and select it.
4. On the page for the user's role, under **Permissions**, choose **Add permissions**.
5. Choose **Attach policies**.
6. Search for the `AmazonRedshiftFullAccess` managed policy and select it.
7. Choose **Attach policies** to attach the policy to the role.

After attaching the policy, the role's **Permissions** section should now include `AmazonRedshiftFullAccess`.

To add Amazon Redshift as a service principal to the IAM role, do the following.

1. On the same page for the IAM role, under **Trust relationships**, choose **Edit trust policy**.

2. In the **Edit trust policy** editor, update the trust policy to add Amazon Redshift as a service principal. An IAM role that allows Amazon Redshift to access other AWS services on your behalf has a trust relationship as follows:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "redshift.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

3. After editing the trust policy, choose **Update policy**.

You should now have an IAM role that has the policy `AmazonRedshiftFullAccess` attached to it and a trust relationship established with Amazon Redshift, giving users permission to import Amazon Redshift data into SageMaker Canvas. For more information about AWS managed policies, see [Managed policies and inline policies](#) in the *IAM User Guide*.

### Associate the IAM role with your Amazon Redshift cluster

In the settings for your Amazon Redshift cluster, you must associate the IAM role that you granted permissions to in the preceding section.

To associate an IAM role with your cluster, do the following.

1. Sign in to the Amazon Redshift console at <https://console.aws.amazon.com/redshiftv2/>.
2. On the navigation menu, choose **Clusters**, and then choose the name of the cluster that you want to update.
3. In the **Actions** dropdown menu, choose **Manage IAM roles**. The **Cluster permissions** page appears.
4. For **Available IAM roles**, enter either the ARN or the name of the IAM role, or choose the IAM role from the list.
5. Choose **Associate IAM role** to add it to the list of **Associated IAM roles**.

6. Choose **Save changes** to associate the IAM role with the cluster.

Amazon Redshift modifies the cluster to complete the change, and the IAM role to which you previously granted Amazon Redshift permissions is now associated with your Amazon Redshift cluster. Your users now have the required permissions to import Amazon Redshift data into SageMaker Canvas.

## Grant Your Users Permissions to Send Predictions to Amazon QuickSight

You must grant your SageMaker Canvas users permissions to send batch predictions to Amazon QuickSight. In Amazon QuickSight, users can create analyses and reports with a dataset and prepare dashboards to share their results. For more information about sending prediction to QuickSight for analysis, see [Send predictions to Amazon QuickSight](#).

To grant the necessary permissions to share batch predictions with users in QuickSight, you must add a permissions policy to the AWS Identity and Access Management (IAM) execution role that you've used for the user profile. The following section shows you how to attach a least-permissions policy to your role.

### Add the permissions policy to your IAM role

To add the permissions policy, use the following procedure:

1. Sign in to the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Roles**.
3. In the search box, search for the user's IAM role by name and select it.
4. On the page for the user's role, under **Permissions**, choose **Add permissions**.
5. Choose **Create inline policy**.
6. Select the JSON tab, and then paste the following least-permissions policy into the editor. Replace the placeholders *<your-account-number>* with your own AWS account number.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "quicksight:CreateDataSet",
        "quicksight:ListUsers",
```

```

        "quicksight:ListNamespaces",
        "quicksight:CreateDataSource",
        "quicksight:PassDataSet",
        "quicksight:PassDataSource"
    ],
    "Resource": [
        "arn:aws:quicksight:*:<your-account-number>:datasource/*",
        "arn:aws:quicksight:*:<your-account-number>:user/*",
        "arn:aws:quicksight:*:<your-account-number>:namespace/*",
        "arn:aws:quicksight:*:<your-account-number>:dataset/*"
    ]
}
]
}

```

7. Choose **Review policy**.
8. Enter a **Name** for the policy.
9. Choose **Create policy**.

You should now have a customer-managed IAM policy attached to your execution role that grants your Canvas users the necessary permissions to send batch predictions to users in QuickSight.

## Applications management

The following sections describe how you can manage your SageMaker Canvas applications. You can view, delete, or relaunch your applications from the **Domains** section of the SageMaker AI console.

### Topics

- [Check for active applications](#)
- [Delete an application](#)
- [Relaunch an application](#)

### Check for active applications

To check if you have any actively running SageMaker Canvas applications, use the following procedure.

1. Open the [SageMaker AI console](#).
2. On the left navigation pane, choose **Admin configurations**.

3. Under **Admin configurations**, choose **domains**.
4. On the **Domains** page, choose your domain.
5. On the **Domain details** page, under **User profiles**, select the user profile name for the Canvas application that you want to view.
6. Under **Apps**, find the application that says **Canvas** in the **App type** column.

The **Status** column displays the status of the application, such as **Ready**, **Pending**, or **Deleted**. If the application is **Ready**, then your SageMaker Canvas workspace instance is active. You can delete the application from the console or log out from the SageMaker Canvas interface.

### Delete an application

If you want to terminate your SageMaker Canvas workspace instance, you can either log out from the SageMaker Canvas application or delete your application from the SageMaker AI console. A *workspace instance* is dedicated for your use from when you start using SageMaker Canvas to the point when you stop using it. Deleting the application only terminates the workspace instance and stops workspace instance charges. Models and datasets aren't affected, but Quick build tasks automatically restart when you relaunch the application.

To delete your Canvas application through the AWS console, first close the browser tab in which your Canvas application was open. Then, use the following procedure to delete your SageMaker Canvas application.

1. Open the [SageMaker AI console](#).
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. On the **Domains** page, choose your domain.
5. On the **Domain details** page, under **User profiles**, select the user profile name for the Canvas application you want to view.
6. Under **Apps**, find the application that says **Canvas** in the **App type** column.
7. In the **Action** column, choose **Delete app**.
8. In the **Delete app** dialog box, select the **Yes, delete app** prompt, confirm the deletion by typing **delete** in the text field, and then choose **Delete**.

After you've successfully deleted the application, the **Status** column says **Deleted**. Otherwise, your application is still active.

You can also terminate the workspace instance by [logging out](#) from within the SageMaker Canvas application.

## Relaunch an application

If you delete or log out of your SageMaker Canvas application and want to relaunch the application, use the following procedure.

1. Navigate to the [SageMaker AI console](#).
2. In the navigation pane, choose **Canvas**.
3. On the SageMaker Canvas landing page, in the **Get Started** box, select your user profile from the dropdown.
4. Choose **Open Canvas** to open the application.

SageMaker Canvas begins launching the application.

You can also use the following secondary procedure if you encounter any issues with the previous procedure.

1. Open the [SageMaker AI console](#).
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. On the **Domains** page, choose your domain.
5. On the **Domain details** page, under **User profiles**, select the user profile name for the SageMaker Canvas application you want to view.
6. Choose **Launch** and select **Canvas** from the dropdown list.

SageMaker Canvas begins launching the application.

## Configure Amazon SageMaker Canvas in a VPC without internet access

The Amazon SageMaker Canvas application runs in a container in an AWS managed Amazon Virtual Private Cloud (VPC). If you want to further control access to your resources or run SageMaker Canvas without public internet access, you can configure your Amazon SageMaker AI domain and VPC settings. Within your own VPC, you can configure settings such as security groups (virtual firewalls that control inbound and outbound traffic from Amazon EC2 instances) and subnets (ranges of IP addresses in your VPC). To learn more about VPCs, see [How Amazon VPC works](#).

When the SageMaker Canvas application is running in the AWS managed VPC, it can interact with other AWS services using either an internet connection or through VPC endpoints created in a customer-managed VPC (without public internet access). SageMaker Canvas applications can access these VPC endpoints through a Studio Classic-created network interface that provides connectivity to the customer-managed VPC. The default behavior of the SageMaker Canvas application is to have internet access. When using an internet connection, the containers for the preceding jobs access AWS resources over the internet, such as the Amazon S3 buckets where you store training data and model artifacts.

However, if you have security requirements to control access to your data and job containers, we recommend that you configure SageMaker Canvas and your VPC so that your data and containers aren't accessible over the internet. SageMaker AI uses the VPC configuration settings you specify when setting up your domain for SageMaker Canvas.

If you want to configure your SageMaker Canvas application without internet access, you must configure your VPC settings when you onboard to [Amazon SageMaker AI domain](#), set up VPC endpoints, and grant the necessary AWS Identity and Access Management permissions. For information about configuring a VPC in Amazon SageMaker AI, see [Choose an Amazon VPC](#). The following sections describe how to run SageMaker Canvas in a VPC without public internet access.

### Configure Amazon SageMaker Canvas in a VPC without internet access

You can send traffic from SageMaker Canvas to other AWS services through your own VPC. If your own VPC doesn't have public internet access and you've set up your domain in **VPC only** mode, then SageMaker Canvas won't have public internet access as well. This includes all requests, such as accessing datasets in Amazon S3 or training jobs for standard builds, and the requests go through VPC endpoints in your VPC instead of the public internet. When you onboard to domain and [Choose an Amazon VPC](#), you can specify your own VPC as the default VPC for the domain, along with your desired security group and subnet settings. Then, SageMaker AI creates a network interface in your VPC that SageMaker Canvas uses to access VPC endpoints in your VPC.

Make sure that you set up one or more security groups in your VPC with inbound and outbound rules that allow [TCP traffic within the security group](#). This is required for connectivity between the Jupyter Server application and the Kernel Gateway applications. You must allow access to at least ports in the range 8192-65535. Also, make sure to create a distinct security group for each user profile and add inbound access from that same security group. We do not recommend reusing a domain level security group for user profiles. If the domain level security group allows inbound access to itself, all applications in the domain have access to all other applications in the domain. Note that the security group and subnet settings are set after you finish onboarding to domain.

When onboarding to domain, if you choose **Public internet only** as the network access type, the VPC is SageMaker AI managed and allows internet access.

You can change this behavior by choosing **VPC only** so that SageMaker AI sends all traffic to a network interface that SageMaker AI creates in your specified VPC. When you choose this option, you must provide the subnets, security groups, and VPC endpoints that are necessary to communicate with the SageMaker API and SageMaker AI Runtime, and various AWS services, such as Amazon S3 and Amazon CloudWatch, that are used by SageMaker Canvas. Note that you can only import data from Amazon S3 buckets located in the same Region as your VPC.

The following procedures show how you can configure these settings to use SageMaker Canvas without the internet.

### Step 1: Onboard to Amazon SageMaker AI domain

To send SageMaker Canvas traffic to a network interface in your own VPC instead of over the internet, specify the VPC you want to use when onboarding to [Amazon SageMaker AI domain](#). You must also specify at least two subnets in your VPC that SageMaker AI can use. Choose **Standard setup** and do the following procedure when configuring the **Network and Storage Section** for the domain.

1. Select your desired **VPC**.
2. Choose two or more **Subnets**. If you don't specify the subnets, SageMaker AI uses all of the subnets in the VPC.
3. Choose one or more **Security group(s)**.
4. Choose **VPC Only** to turn off direct internet access in the AWS managed VPC where SageMaker Canvas is hosted.

After disabling internet access, finish the onboarding process to set up your domain. For more information about the VPC settings for Amazon SageMaker AI domain, see [Choose an Amazon VPC](#).

### Step 2: Configure VPC endpoints and access

#### Note

In order to configure Canvas in your own VPC, you must enable private DNS hostnames for your VPC endpoints. For more information, see [Connect to SageMaker AI Through a VPC Interface Endpoint](#).

SageMaker Canvas only accesses other AWS services to manage and store data for its functionality. For example, it connects to Amazon Redshift if your users access an Amazon Redshift database. It can connect to an AWS service such as Amazon Redshift using an internet connection or a VPC endpoint. Use VPC endpoints if you want to set up connections from your VPC to AWS services that don't use the public internet.

A VPC endpoint creates a private connection to an AWS service that uses a networking path that is isolated from the public internet. For example, if you set up access to Amazon S3 using a VPC endpoint from your own VPC, then the SageMaker Canvas application can access Amazon S3 by going through the network interface in your VPC and then through the VPC endpoint that connects to Amazon S3. The communication between SageMaker Canvas and Amazon S3 is private.

For more information about configuring VPC endpoints for your VPC, see [AWS PrivateLink](#). If you are using Amazon Bedrock models in Canvas with a VPC, for more information about controlling access to your data, see [Protect jobs using a VPC](#) in the *Amazon Bedrock User Guide*.

The following are the VPC endpoints for each service you can use with SageMaker Canvas:

Service	Endpoint	Endpoint type
AWS Application Auto Scaling	com.amazonaws. <i>Region</i> .application-autoscaling	Interface
Amazon Athena	com.amazonaws. <i>Region</i> .athena	Interface
Amazon SageMaker AI	com.amazonaws. <i>Region</i> .sagemaker.api  com.amazonaws. <i>Region</i> .sagemaker.runtime  com.amazonaws. <i>Region</i> .notebook	Interface

Service	Endpoint	Endpoint type
Amazon SageMaker AI Data Science Assistant	com.amazonaws. <i>Region</i> .sagemaker-data-science-assistant	Interface
AWS Security Token Service	com.amazonaws. <i>Region</i> .sts	Interface
Amazon Elastic Container Registry (Amazon ECR)	com.amazonaws. <i>Region</i> .ecr.api  com.amazonaws. <i>Region</i> .ecr.dkr	Interface
Amazon Elastic Compute Cloud (Amazon EC2)	com.amazonaws. <i>Region</i> .ec2	Interface
Amazon Simple Storage Service (Amazon S3)	com.amazonaws. <i>Region</i> .s3	Gateway
Amazon Redshift	com.amazonaws. <i>Region</i> .redshift-data	Interface
AWS Secrets Manager	com.amazonaws. <i>Region</i> .secretsmanager	Interface
AWS Systems Manager	com.amazonaws. <i>Region</i> .ssm	Interface
Amazon CloudWatch	com.amazonaws. <i>Region</i> .monitoring	Interface
Amazon CloudWatch Logs	com.amazonaws. <i>Region</i> .logs	Interface
Amazon Forecast	com.amazonaws. <i>Region</i> .forecast  com.amazonaws. <i>Region</i> .forecastquery	Interface

Service	Endpoint	Endpoint type
Amazon Textract	com.amazonaws. <i>Region</i> .textract	Interface
Amazon Comprehend	com.amazonaws. <i>Region</i> .comprehend	Interface
Amazon Rekognition	com.amazonaws. <i>Region</i> .rekognition	Interface
AWS Glue	com.amazonaws. <i>Region</i> .glue	Interface
AWS Application Auto Scaling	com.amazonaws. <i>Region</i> .application-autoscaling	Interface
Amazon Relational Database Service (Amazon RDS)	com.amazonaws. <i>Region</i> .rds	Interface
Amazon Bedrock (see note after table)	com.amazonaws. <i>Region</i> .bedrock-runtime	Interface
Amazon Kendra	com.amazonaws. <i>Region</i> .kendra	Interface
Amazon EMR Serverless	com.amazonaws. <i>Region</i> .emr-serverless	Interface
Amazon Q Developer (see note after table)	com.amazonaws. <i>Region</i> .q	Interface

### Note

The Amazon Q Developer VPC endpoint is currently available only in the US East (N. Virginia) region. To connect to it from other regions, you can choose one of the following options based on your security and infrastructure preferences:

- **Set up a NAT Gateway.** Configure a NAT Gateway in your VPC's private subnet to enable internet connectivity for the Q Developer endpoint. For more information, see [Setting up a NAT Gateway in a VPC Private Subnet](#).
- **Enable cross-region VPC endpoint access.** Set up cross-region VPC endpoint access for Q Developer. Use this option to connect securely without requiring internet access. For more information, see [Configuring Cross-Region VPC Endpoint Access](#).

### Note

For Amazon Bedrock, the interface endpoint service name `com.amazonaws.Region.bedrock` has been deprecated. Create a new VPC endpoint with the service name listed in the preceding table.

Additionally, you can't fine-tune foundation models from Canvas VPCs with no internet access. This is because Amazon Bedrock doesn't support VPC endpoints for model customization APIs. To learn more about fine-tuning foundation models in Canvas, see [Fine-tune foundation models](#).

You must also add an endpoint policy for Amazon S3 to control AWS principal access to your VPC endpoint. For information about how to update your VPC endpoint policy, see [Control access to VPC endpoints using endpoint policies](#).

The following are two VPC endpoint policies that you can use. Use the first policy if you only want to grant access to the basic functionality of Canvas, such as importing data and creating models. Use the second policy if you want to grant access to the additional [generative AI features](#) in Canvas.

#### Basic VPC endpoint policy

The following policy grants the necessary access to your VPC endpoint for basic operations in Canvas.

```
{
  "Effect": "Allow",
  "Action": [
    "s3:GetObject",
    "s3:PutObject",
```

```

        "s3:DeleteObject",
        "s3:CreateBucket",
        "s3:GetBucketCors",
        "s3:GetBucketLocation"
    ],
    "Resource": [
        "arn:aws:s3::*SageMaker*",
        "arn:aws:s3::*Sagemaker*",
        "arn:aws:s3::*sagemaker*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:ListBucket",
        "s3:ListAllMyBuckets"
    ],
    "Resource": "*"
}

```

## Generative AI VPC endpoint policy

The following policy grants the necessary access to your VPC endpoint for basic operations in Canvas, as well as using generative AI foundation models.

```

{
    "Effect": "Allow",
    "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:DeleteObject",
        "s3:CreateBucket",
        "s3:GetBucketCors",
        "s3:GetBucketLocation"
    ],
    "Resource": [
        "arn:aws:s3::*SageMaker*",
        "arn:aws:s3::*Sagemaker*",
        "arn:aws:s3::*sagemaker*",
        "arn:aws:s3::*fmeval/datasets*",
        "arn:aws:s3::*jumpstart-cache-prod*"
    ]
},

```

```
{
  "Effect": "Allow",
  "Action": [
    "s3:ListBucket",
    "s3:ListAllMyBuckets"
  ],
  "Resource": "*"
}
```

### Step 3: Grant IAM permissions

The SageMaker Canvas user must have the necessary AWS Identity and Access Management permissions to allow connection to the VPC endpoints. The IAM role to which you give permissions must be the same one you used when onboarding to Amazon SageMaker AI domain. You can attach the SageMaker AI managed `AmazonSageMakerFullAccess` policy to the IAM role for the user to give the user the required permissions. If you require more restrictive IAM permissions and use custom policies instead, then give the user's role the `ec2:DescribeVpcEndpointServices` permission. SageMaker Canvas requires these permissions to verify the existence of the required VPC endpoints for standard build jobs. If it detects these VPC endpoints, then standard build jobs run by default in your VPC. Otherwise, they will run in the default AWS managed VPC.

For instructions on how to attach the `AmazonSageMakerFullAccess` IAM policy to your user's IAM role, see [Adding and removing IAM identity permissions](#).

To grant your user's IAM role the granular `ec2:DescribeVpcEndpointServices` permission, use the following procedure.

1. Sign in to the AWS Management Console and open the [IAM console](#).
2. In the navigation pane, choose **Roles**.
3. In the list, choose the name of the role to which you want to grant permissions.
4. Choose the **Permissions** tab.
5. Choose **Add permissions** and then choose **Create inline policy**.
6. Choose the **JSON** tab and enter the following policy, which grants the `ec2:DescribeVpcEndpointServices` permission:

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "ec2:DescribeVpcEndpointServices",
      "Resource": "*"
    }
  ]
}
```

7. Choose **Review policy**, and then enter a **Name** for the policy (for example, `VPCEndpointPermissions`).
8. Choose **Create policy**.

The user's IAM role should now have permissions to access the VPC endpoints configured in your VPC.

#### (Optional) Step 4: Override security group settings for specific users

If you are an administrator, you might want different users to have different VPC settings, or user-specific VPC settings. When you override the default VPC's security group settings for a specific user, these settings are passed on to the SageMaker Canvas application for that user.

You can override the security groups that a specific user has access to in your VPC when you set up a new user profile in Studio Classic. You can use the [CreateUserProfile](#) SageMaker API call (or [create\\_user\\_profile](#) with the [AWS CLI](#)), and then in the `UserSettings`, you can specify the `SecurityGroups` for the user.

## Set up connections to data sources with OAuth

The following section describes the steps you must take to set up OAuth connections to data sources from SageMaker Canvas. [OAuth](#) is a common authentication platform for granting access to resources without sharing passwords. With OAuth, you can quickly connect to your data from Canvas and import it for building models. Canvas currently supports OAuth for Snowflake and Salesforce Data Cloud.

### Note

You can only establish one OAuth connection for each data source.

## Set up OAuth for Salesforce Data Cloud

To set up OAuth for Salesforce Data Cloud, follow these general steps:

1. Sign in to Salesforce Data Cloud.
2. In Salesforce Data Cloud, create a new app connection and do the following:
  - a. Enable OAuth settings.
  - b. When prompted for a callback URL (or the URL of the resource accessing your data), specify the URL for your Canvas application. The Canvas application URL follows this format: `https://<domain-id>.studio.<region>.sagemaker.aws/canvas/default`
  - c. Copy the consumer key and secret.
  - d. Copy your authorization URL and token URL.

For more detailed instructions about performing the preceding tasks in Salesforce Data Cloud, see [Import data from Salesforce Data Cloud](#) in the Data Wrangler documentation for importing data from Salesforce Data Cloud.

After enabling access from Salesforce Data Cloud and getting your connection information, you must create an [AWS Secrets Manager](#) secret to store the information and add it to your Amazon SageMaker AI domain or user profile. Note that you can add a secret to both a domain and user profile, but Canvas looks for secrets in the user profile first.

To add a secret to your domain or user profile, do the following:

1. Go to the [Amazon SageMaker AI console](#).
2. Choose **domains** in the navigation pane.
3. From the list of **domains**, choose your domain.
  - a. If adding your secret to your domain, do the following:
    - i. Choose the domain.
    - ii. On the **domain settings** page, choose the **domain settings** tab.
    - iii. Choose **Edit**.
  - b. If adding the secret to your user profile, do the following:
    - i. Choose the user's domain.

- ii. On the **domain settings** page, choose the user profile.
  - iii. On the **User Details** page, choose **Edit**.
4. In the navigation pane, choose **Canvas settings**.
5. For **OAuth settings**, choose **Add OAuth configuration**.
6. For **Data source**, select **Salesforce Data Cloud**.
7. For **Secret Setup**, select **Create a new secret**. Alternatively, if you already created an AWS Secrets Manager secret with your credentials, enter the ARN for the secret. If creating a new secret, do the following:
  - a. For **Identity Provider**, select **SALESFORCE**.
  - b. For **Client ID**, **Client Secret**, **Authorization URL**, and **Token URL**, enter all of the information you gathered from Salesforce Data Cloud in the previous procedure.
8. Save your domain or user profile settings.

You should now be able to create a connection to your data in Salesforce Data Cloud from Canvas.

## Set up OAuth for Snowflake

To set up authentication for Snowflake, Canvas supports identity providers that you can use instead of having users directly enter their credentials into Canvas.

The following are links to the Snowflake documentation for the identity providers that Canvas supports:

- [Azure AD](#)
- [Okta](#)
- [Ping Federate](#)

The following process describes the general steps you must take. For more detailed instructions about performing these steps, you can refer to the [Setting up Snowflake OAuth Access](#) section in the Data Wrangler documentation for importing data from Snowflake.

To set up OAuth for Snowflake, do the following:

1. Register Canvas as an application with the identity provider. This requires specifying a redirect URL to Canvas, which should follow this format: `https://<domain-id>.studio.<region>.sagemaker.aws/canvas/default`

2. Within the identity provider, create a server or API that sends OAuth tokens to Canvas so that Canvas can access Snowflake. When setting up the server, use the authorization code and refresh token grant types, specify the access token lifetime, and set a refresh token policy. Additionally, within the External OAuth Security Integration for Snowflake, enable `external_oauth_any_role_mode`.
3. Get the following information from the identity provider: token URL, authorization URL, client ID, client secret. For Azure AD, also retrieve the OAuth scope credentials.
4. Store the information retrieved in the previous step in an AWS Secrets Manager secret.
  - a. For Okta and Ping Federate, the secret should look like the following format:

```
{"token_url":"https://identityprovider.com/oauth2/example-portion-of-URL-path/v2/token",
"client_id":"example-client-id", "client_secret":"example-client-secret",
"identity_provider":"OKTA|"PING_FEDERATE",
"authorization_url":"https://identityprovider.com/oauth2/example-portion-of-URL-path/v2/authorize"}
```

- b. For Azure AD, the secret should also include the OAuth scope credentials as the `datasource_oauth_scope` field.

After configuring the identity provider and the secret, you must create an [AWS Secrets Manager](#) secret to store the information and add it to your Amazon SageMaker AI domain or user profile. Note that you can add a secret to both a domain and user profile, but Canvas looks for secrets in the user profile first.

To add a secret to your domain or user profile, do the following:

1. Go to the [Amazon SageMaker AI console](#).
2. Choose **domains** in the navigation pane.
3. From the list of **domains**, choose your domain.
  - a. If adding your secret to your domain, do the following:
    - i. Choose the domain.
    - ii. On the **domain settings** page, choose the **domain settings** tab.
    - iii. Choose **Edit**.
  - b. If adding the secret to your user profile, do the following:

- i. Choose the user's domain.
  - ii. On the **domain settings** page, choose the user profile.
  - iii. On the **User Details** page, choose **Edit**.
4. In the navigation pane, choose **Canvas settings**.
5. For **OAuth settings**, choose **Add OAuth configuration**.
6. For **Data source**, select **Snowflake**.
7. For **Secret Setup**, select **Create a new secret**. Alternatively, if you already created an AWS Secrets Manager secret with your credentials, enter the ARN for the secret. If creating a new secret, do the following:
  - a. For **Identity Provider**, select **SNOWFLAKE**.
  - b. For **Client ID**, **Client Secret**, **Authorization URL**, and **Token URL**, enter all of the information you gathered from the identity provider in the previous procedure.
8. Save your domain or user profile settings.

You should now be able to create a connection to your data in Snowflake from Canvas.

## Generative AI assistance for solving ML problems in Canvas using Amazon Q Developer

While using Amazon SageMaker Canvas, you can chat with Amazon Q Developer in natural language to leverage generative AI and solve problems. Q Developer is an assistant that helps you translate your goals into machine learning (ML) tasks and describes each step of the ML workflow. Q Developer helps Canvas users reduce the amount of time, effort, and data science expertise required to leverage ML and make data-driven decisions for their organizations.

Through a conversation with Q Developer, you can initiate actions in Canvas such as preparing data, building an ML model, making predictions, and deploying a model. Q Developer makes suggestions for next steps and provides you with context as you complete each step. It also informs you of results; for example, Canvas can transform your dataset according to best practices, and Q Developer can list the transforms that were used and why.

Amazon Q Developer is available in SageMaker Canvas at no additional cost to both Amazon Q Developer Pro Tier and Free Tier users. However, standard charges apply for resources such as the

SageMaker Canvas workspace instance and any resources used for building or deploying models. For more information about pricing, see [Amazon SageMaker Canvas pricing](#).

Use of Amazon Q is licensed to you under [MIT's 0 License](#) and subject to the [AWS Responsible AI Policy](#). When you use Q Developer from outside the US, Q Developer processes data across US regions. For more information, see [Cross region inference in Amazon Q Developer](#).

## How it works

Amazon Q Developer is a generative AI powered assistant available in SageMaker Canvas that you can query using natural language. Q Developer makes suggestions for each step of the machine learning workflow, explaining concepts and providing you with options and more details as needed. You can use Q Developer for help with regression, binary classification, and multi-class classification use cases.

For example, to predict customer churn, upload a dataset of historical customer churn information to Canvas through Q Developer. Q Developer suggests an appropriate ML model type and steps to fix dataset issues, build a model, and make predictions.

### Important

Amazon Q Developer is intended for conversations about machine learning problems within SageMaker Canvas. It guides users through Canvas actions and optionally answers questions about AWS services. Q Developer processes model inputs only in English. For more information about how you can use Q Developer, see [Amazon Q Developer features](#) in the *Amazon Q Developer User Guide*.

## Supported regions

Amazon Q Developer is available within SageMaker Canvas in the following AWS Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)

- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (Paris)

## Amazon Q Developer capabilities available in Canvas

The following list summarizes the Canvas tasks with which Q Developer can provide assistance:

- **Describe your objective** – Q Developer can suggest an ML model type and general approach to solve your problem.
- **Import and analyze datasets** – Tell Q Developer where your dataset is stored or upload a file to save it as a Canvas dataset. Prompt Q Developer to identify any issues in your dataset, such as outliers or missing values. Q Developer provides summary statistics about your dataset and lists any identified issues.

Q Developer supports queries about the following statistics for individual columns:

- **Numeric columns** – number of valid values, feature type, mean, median, minimum, maximum, standard deviation, 25th percentile, 75th percentile, number of outliers
- **Categorical columns** – number of missing values, number of valid values, feature type, most frequent, most frequent category, most frequent category count, least frequent, least frequent category, least frequent category count, categories
- **Fix dataset issues** – Prompt Q Developer to use Canvas's data transformation capabilities to create a revised version of your dataset. Canvas creates a Data Wrangler data flow and applies transforms according to data science best practices. For more information, see [Data preparation](#).

If you want to do more advanced data analysis or data preparation tasks than you can accomplish with Q Developer, then we recommend that you go to the Data Wrangler data flow interface.

- **Train a model** – Q Developer tells you the recommended ML model type for your problem and a proposed model building configuration. You can use the suggested default settings to do a quick build, or you can modify the configuration and do a standard build. When ready, prompt Q Developer to build your Canvas model.

All of the custom model types are supported. For more information about model types and quick versus standard builds, see [How custom models work](#).

- **Evaluate model accuracy** – After building a model, Q Developer provides a summary of how the model scores across various metrics. These metrics help you determine the usefulness and accuracy of your model. Q Developer can explain any concept or metric in detail.

To view full details and visualizations, open the model from the chat or the **My Models** page of Canvas. For more information, see [Model evaluation](#).

- **Get predictions for new data** – You can upload a new dataset and prompt Q Developer to help you open the prediction feature of Canvas.

Q Developer opens a new window in the application where you can either make a single prediction or make batch predictions with a new dataset. For more information, see [Predictions with custom models](#).

- **Deploy a model** – To deploy your model for production, ask Q Developer to help you deploy your model through Canvas. Q Developer opens a new window in which you can configure your deployment.

After deploying, view your deployment details either 1) on the **My Models** page of Canvas in the model's **Deploy** tab, or 2) on the **ML Ops** page in the **Deployments** tab. For more information, see [Deploy your models to an endpoint](#).

## Prerequisites

To use Amazon Q Developer to build ML models in SageMaker Canvas, complete the following prerequisites:

### Set up a Canvas application

Make sure that you have a Canvas application set up. For information about how to set up a Canvas application, see [Getting started with using Amazon SageMaker Canvas](#).

### Grant Q Developer permissions

To access Q Developer while using Canvas, you must attach the necessary permissions to the AWS IAM role used for your SageMaker AI domain or user profile. You can do this through the console or by manually attaching an AWS managed policy.

Permissions attached at the domain level apply to all user profiles in the domain, unless individual permissions are granted or revoked at the user profile level.

### SageMaker AI console method

You can grant permissions by editing the SageMaker AI domain or user profile settings.

To grant permissions through the domain settings in the SageMaker AI console, do the following:

1. Open the Amazon SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Domains**.
4. From the list of domains, select your domain.
5. On the **Domain details** page, select the **App configurations** tab.
6. In the **Canvas** section, choose **Edit**.
7. On the **Edit Canvas settings** page, go to the **Amazon Q Developer** section and do the following:
  - a. Turn on **Enable Amazon Q Developer in SageMaker Canvas for natural language ML** to add the permissions to chat with Q Developer in Canvas to your domain's execution role.
  - b. (Optional) Turn on **Enable Amazon Q Developer chat for general AWS questions** if you want to ask Q Developer questions about various AWS services (for example: Describe how Athena works).

#### **Note**

When making general AWS queries to Q Developer, your requests route through the US East (N. Virginia) AWS Region. To prevent your data from routing through US East (N. Virginia), turn off the **Enable Amazon Q Developer chat for general AWS questions** toggle.

## Manual method

Attach the [AmazonSageMakerCanvasSMDDataScienceAssistantAccess](#) policy to the AWS IAM role used for your domain or user profile. For more information about how to do this, see [Adding and removing IAM identity permissions](#) in the *AWS IAM User Guide*.

### (Optional) Configure access to Q Developer from your VPC

If you have a VPC that is configured without public internet access, you can add a VPC endpoint for Q Developer. For more information, see [Configure Amazon SageMaker Canvas in a VPC without internet access](#).

## Getting started

To use Amazon Q Developer to build ML models in SageMaker Canvas, do the following:

1. Open your SageMaker Canvas application.
2. In the left navigation pane, choose **Amazon Q**.
3. Choose **Start a new conversation** to open a new chat.

When you start a new chat, Q Developer prompts you to state your problem or provide a dataset.

# Amazon Q

## Your generative AI assistant

👋 Hello,

I'm Amazon Q, your generative AI assistant. I can help you explore your data, and help you build ML models. Please tell me about yourself and the problem you are looking to solve today. Feel free to get started with a few examples below.

I am a customer service director for an e-commerce platform and want to predict which customers are at risk of churning so we can proactively address their concerns

I am a credit risk analyst at a bank and want to classify loan applicants into multiple risk categories (low risk, moderate risk, high risk) based on their financial characteristics and current economic indicators

I am a healthcare administrator at a hospital and want to predict patient readmission rates to improve post-discharge care and reduce unplanned return visits

I am a consumer electronics sales analyst and want to forecast product sales for the next 3 months.

[Learn more about what the assistant can do for you](#)

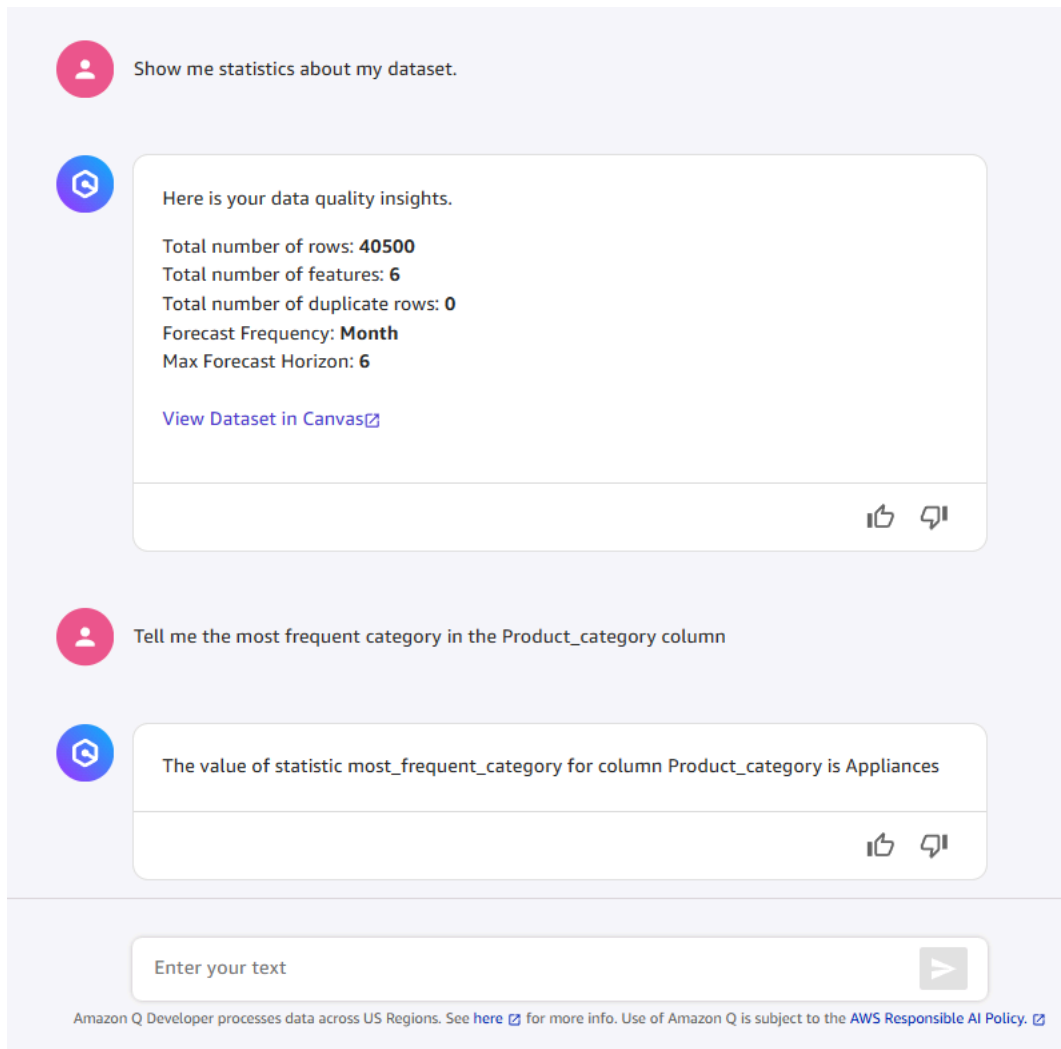

Tell me about a business problem you have

Amazon Q Developer processes data across US Regions. See [here](#) for more info. Use of Amazon Q is subject to the [AWS Responsible AI Policy](#).

After importing your data, you can ask Q Developer to provide you with summary statistics about your dataset, or you can ask questions about specific columns. For a list of the different statistics that Q Developer supports, see the preceding section [Amazon Q Developer capabilities available in](#)

[Canvas](#). The following screenshot shows an example of asking for dataset statistics and the most frequent category in a product category column.

Q Developer tracks any Canvas artifacts you import or create during the conversation, such as transformed datasets and models. You can access them from the chat or other Canvas application tabs. For example, if Q Developer fixes issues in your dataset, you can access the new, transformed dataset from the following places:

- The artifacts sidebar in the Q Developer chat interface
- The **Datasets** page of Canvas, where you can view both your original and transformed datasets. The transformed dataset has the **Built by Amazon Q** label added to it.
- The **Data Wrangler** page of Canvas, where Q Developer creates a new data flow for your dataset

The following screenshot shows the original dataset and the transformed dataset in the sidebar of a chat.

When your data is ready, ask Q Developer to help build a Canvas model. Q Developer might prompt you to confirm a few fields and review the build configuration. If you use the default build configuration, then your model is built using a quick build. If you want to customize any part of your build configuration, such as selecting the algorithms used or changing the objective metric, then your model is built with a standard build.

The following screenshot shows how you can prompt Q Developer to initiate a Canvas model build with only a few prompts. This example uses the default configuration to start a quick build.

Here are the configurations that will be used to build the model. Let me know if this looks good to you, or feel free to ask me to change any of the parameters you see here.

**Model Type**

Time series forecasting

*Your model will forecast demand by using past values to predict future data values*

**Target Column**

demand

**Item ID Column**

item\_id

**Time stamp column**

time\_stamp

**Objective metric**

AverageWeightedQuantileLoss

*The Weighted Quantile Loss (WQL) score measures the performance of models that predict quantiles. It assesses how well the predicted quantiles match the actual quantiles of a target variable.*

**Training method**

Quick Build

*Canvas builds a custom model using a single algorithm in about 15 minutes or less, balancing speed over accuracy.*

**Forecast quantiles**

0.1, 0.5, 0.9

**Forecast length**

1

Your training job has been successfully launched!

We are now processing your request, and the job is in progress. This may take a while depending on the size of the data and complexity of the model.

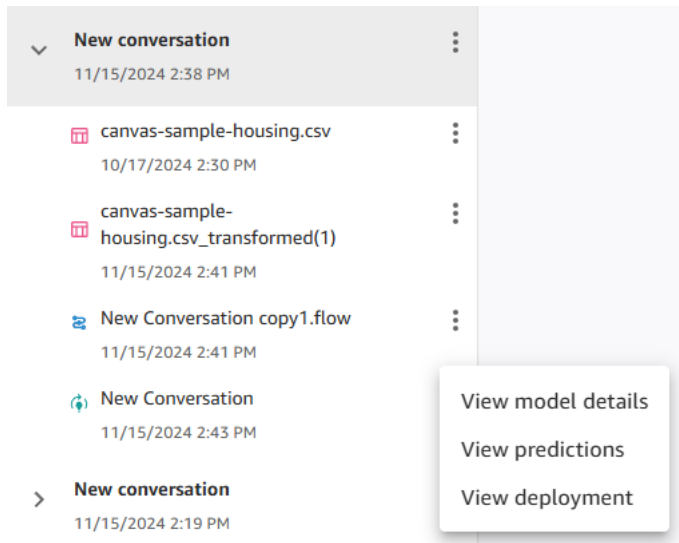

You will receive updates in the My Models tab as the job progresses. In the meantime, feel free to continue exploring or ask any questions.

Enter your text

Amazon Q Developer processes data across US Regions. See [here](#) for more info. Use of Amazon Q is subject to the [AWS Responsible AI Policy](#).

After building your model, you can perform additional actions using either natural language in the chat or the artifacts sidebar menu. For example, you can view model details and metrics, make predictions, or deploy the model. The following screenshot shows the sidebar where you can choose these additional options.

You can also perform any of these actions by going to the **My Models** page of Canvas and selecting your model. From your model's page, you can navigate to the **Analyze**, **Predict**, and **Deploy** tabs to view model metrics and visualizations, make predictions, and manage deployments, respectively.

## Logging Q Developer conversations with AWS CloudTrail

AWS CloudTrail is a service that records actions taken by users, roles, or AWS services in Amazon SageMaker AI. CloudTrail captures API calls resulting from your interactions with Amazon Q Developer (a conversational AI assistant) while using SageMaker Canvas (a no-code ML interface). CloudTrail data shows request details, the IP address of the requester, who made the request, and when.

Your interactions with Q Developer are sent as `SendConversation` API calls to the SageMaker AI Data Science Assistant service, which is an internal service that Canvas leverages on the backend. The event source for `SendConversation` API calls is `sagemaker-data-science-assistant.amazonaws.com`.

**Note**

For privacy and security reasons, the content of your conversations is hidden in the logs, appearing as `HIDDEN_DUE_TO_SECURITY_REASONS` in the request and response elements.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](#). To learn more about CloudTrail in SageMaker AI, see [Logging Amazon SageMaker AI API calls using AWS CloudTrail](#).

The following is an example log file entry for the `SendConversation` API:

```
{
  "eventVersion": "1.10",

}

```

## Data import

Amazon SageMaker Canvas supports importing tabular, image, and document data. You can import datasets from your local machine, Amazon services such as Amazon S3 and Amazon Redshift, and external data sources. When importing datasets from Amazon S3, you can bring a dataset of any size. Use the datasets that you import to build models and make predictions for other datasets.

Each use case for which you can build a custom model accepts different types of input. For example, if you want to build a single-label image classification model, then you should import image data. For more information about the different model types and the data they accept, see [How custom models work](#). You can import data and build custom models in SageMaker Canvas for the following data types:

- **Tabular** (CSV, Parquet, or tables)
  - Categorical – Use categorical data to build custom categorical prediction models for 2 and 3+ category prediction.
  - Numeric – Use numeric data to build custom numeric prediction models.
  - Text – Use text data to build custom multi-category text prediction models.
  - Timeseries – Use timeseries data to build custom time series forecasting models.
- **Image** (JPG or PNG) – Use image data to build custom single-label image prediction models.
- **Document** (PDF, JPG, PNG, TIFF) – Document data is only supported for SageMaker Canvas Ready-to-use models. To learn more about Ready-to-use models that can make predictions for document data, see [Ready-to-use models](#).

You can import data into Canvas from the following data sources:

- Local files on your computer
- Amazon S3 buckets
- Amazon Redshift provisioned clusters (not Amazon Redshift Serverless)
- AWS Glue Data Catalog through Amazon Athena
- Amazon Aurora
- Amazon Relational Database Service (Amazon RDS)
- Salesforce Data Cloud
- Snowflake
- Databricks, SQLServer, MariaDB, and other popular databases through JDBC connectors
- Over 40 external SaaS platforms, such as SAP OData

For a full list of data sources from which you can import, see the following table:

Source	Type	Supported data types
Local file upload	Local	Tabular, Image, Document
Amazon Aurora	Amazon internal	Tabular
Amazon S3 bucket	Amazon internal	Tabular, Image, Document
Amazon RDS	Amazon internal	Tabular
Amazon Redshift provisioned clusters (not Redshift Serverless)	Amazon internal	Tabular

For instructions on how to import data and information regarding input data requirements, such as the maximum file size for images, see [Create a dataset](#).

Canvas also provides several sample datasets in your application to help you get started. To learn more about the SageMaker AI-provided sample datasets you can experiment with, see [Use sample datasets](#).

After you import a dataset into Canvas, you can update the dataset at any time. You can do a manual update or you can set up a schedule for automatic dataset updates. For more information, see [Update a dataset](#).

For more information specific to each dataset type, see the following sections:

## Tabular

To import data from an external data source (such as a Snowflake database or a SaaS platform), you must authenticate and connect to the data source in the Canvas application. For more information, see [Connect to data sources](#).

If you want to import datasets larger than 5 GB from Amazon S3 into Canvas, you can achieve faster sampling by using Amazon Athena to query and sample the data from Amazon S3.

After creating datasets in Canvas, you can prepare and transform your data using the data preparation functionality of Data Wrangler. You can use Data Wrangler to handle missing values, transform your features, join multiple datasets into a single dataset, and more. For more information, see [Data preparation](#).

### Tip

As long as your data is arranged into tables, you can join datasets from various sources, such as Amazon Redshift, Amazon Athena, or Snowflake.

## Image

For information about how to edit an image dataset and perform tasks such as assigning or reassigning labels, adding images, or deleting images, see [Edit an image dataset](#).

## Create a dataset

### Note

If you're importing datasets larger than 5 GB into Amazon SageMaker Canvas, we recommend that you use the [Data Wrangler feature](#) in Canvas to create a data flow. Data Wrangler supports advanced data preparation features such as [joining](#) and [concatenating](#) data. After you create a data flow, you can export your data flow as a Canvas dataset and begin building a model. For more information, see [Export to create a model](#).

The following sections describe how to create a dataset in Amazon SageMaker Canvas. For custom models, you can create datasets for tabular and image data. For Ready-to-use models, you can use tabular and image datasets as well as document datasets. Choose your workflow based on the following information:

- For categorical, numeric, text, and timeseries data, see [Import tabular data](#).
- For image data, see [Import image data](#).
- For document data, see [Import document data](#).

A dataset can consist of multiple files. For example, you might have multiple files of inventory data in CSV format. You can upload these files together as a dataset as long as the schema (or column names and data types) of the files match.

Canvas also supports managing multiple versions of your dataset. When you create a dataset, the first version is labeled as V1. You can create a new version of your dataset by updating your dataset. You can do a manual update, or you can set up an automated schedule for updating your dataset with new data. For more information, see [Update a dataset](#).

When you import your data into Canvas, make sure that it meets the requirements in the following table. The limitations are specific to the type of model you're building.

Limit	2 category, 3+ category, numeric, and time series models	Text prediction models	Image prediction models	*Document data for Ready-to-use models
Supported file types	CSV and Parquet (local upload, Amazon S3, or databases)	CSV and Parquet (local upload, Amazon S3, or databases)	JPG, PNG	PDF, JPG, PNG, TIFF
	JSON (databases)	JSON (databases)		
Maximum file size	Local upload: 5 GB	Local upload: 5 GB	30 MB per image	5 MB per document

Limit	2 category, 3+ category, numeric, and time series models	Text prediction models	Image prediction models	*Document data for Ready-to- use models
	Data sources: PBs	Data sources: PBs		
Maximum number of files you can upload at a time	30	30	N/A	N/A
Maximum number of columns	1,000	1,000	N/A	N/A
Maximum number of entries (rows, images, or documents) for <b>Quick builds</b>	N/A	7500 rows	5000 images	N/A
Maximum number of entries (rows, images, or documents) for <b>Standard builds</b>	N/A	150,000 rows	180,000 images	N/A
Minimum number of entries (rows) for <b>Quick builds</b>	2 category: 500 rows  3+ category, numeric, time series: N/A	N/A	N/A	N/A
Minimum number of entries (rows, images, or documents) for <b>Standard builds</b>	250 rows	50 rows	50 images	N/A
Minimum number of entries (rows or images) per label	N/A	25 rows	25 rows	N/A

Limit	2 category, 3+ category, numeric, and time series models	Text prediction models	Image prediction models	*Document data for Ready-to- use models
Minimum number of labels	2 category: 2  3+ category: 3  Numeric, time series: N/A	2	2	N/A
Minimum sample size for random sampling	500	N/A	N/A	N/A
Maximum sample size for random sampling	200,000	N/A	N/A	N/A
Maximum number of labels	2 category: 2  3+ category, numeric, time series: N/A	1000	1000	N/A

\*Document data is currently only supported for [Ready-to-use models](#) that accept document data. You can't build a custom model with document data.

Also note the following restrictions:

- When importing data from an Amazon S3 bucket, make sure that your Amazon S3 bucket name doesn't contain a .. If your bucket name contains a ., you might experience errors when trying to import data into Canvas.
- For tabular data, Canvas disallows selecting any file with extensions other than .csv, .parquet, .parq, and .pqt for both local upload and Amazon S3 import. CSV files can

use any common or custom delimiter, and they must not have newline characters except when denoting a new row.

- For tabular data using Parquet files, note the following:
  - Parquet files can't include complex types like maps and lists.
  - The column names of Parquet files can't contain spaces.
  - If using compression, Parquet files must use either gzip or snappy compression types. For more information about the preceding compression types, see the [gzip documentation](#) and the [snappy documentation](#).
- For image data, if you have any unlabeled images, you must label them before building your model. For information about how to assign labels to images within the Canvas application, see [Edit an image dataset](#).
- If you set up automatic dataset updates or automatic batch prediction configurations, you can only create a total of 20 configurations in your Canvas application. For more information, see [How to manage automations](#).

After you import a dataset, you can view your datasets on the **Datasets** page at any time.

## Import tabular data

With tabular datasets, you can build categorical, numeric, time series forecasting, and text prediction models. Review the limitations table in the preceding **Import a dataset** section to ensure that your data meets the requirements for tabular data.

Use the following procedure to import a tabular dataset into Canvas:

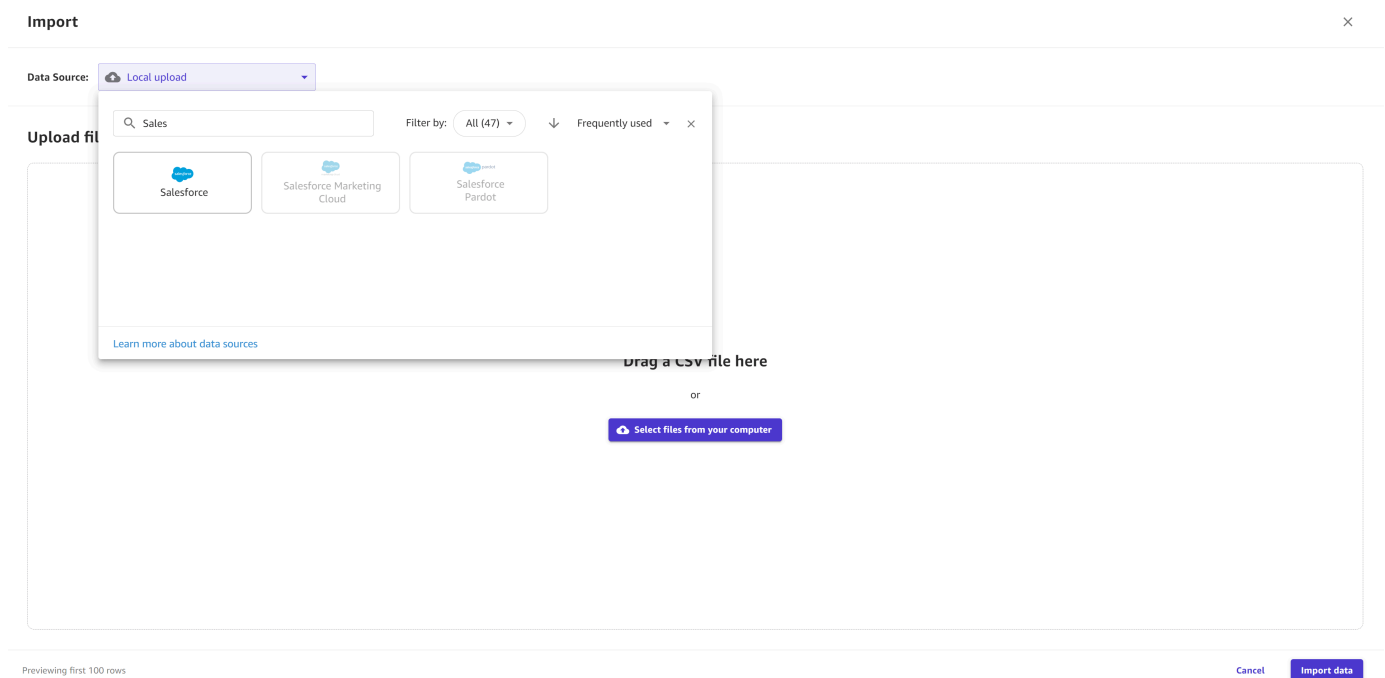

1. Open your SageMaker Canvas application.
2. In the left navigation pane, choose **Datasets**.
3. Choose **Import data**.
4. From the dropdown menu, choose **Tabular**.
5. In the popup dialog box, in the **Dataset name** field, enter a name for the dataset and choose **Create**.
6. On the **Create tabular dataset** page, open the **Data Source** dropdown menu.
7. Choose your data source:
  - To upload files from your computer, choose **Local upload**.

- To import data from another source, such as an Amazon S3 bucket or a Snowflake database, search for your data source in the **Search data source bar**. Then, choose the tile for your desired data source.

### Note

You can only import data from the tiles that have an active connection. If you want to connect to a data source that is unavailable to you, contact your administrator. If you're an administrator, see [Connect to data sources](#).

The following screenshot shows the **Data Source** dropdown menu.

8. (Optional) If you're connecting to an Amazon Redshift or Snowflake database for the first time, a dialog box appears to create a connection. Fill out the dialog box with your credentials and choose **Create connection**. If you already have a connection, choose your connection.
9. From your data source, select your files to import. For local upload and importing from Amazon S3, you can select files. For Amazon S3 only, you also have the option to directly enter the S3 URI, alias, or ARN of your bucket or S3 access point in the **Input S3 endpoint** field, and then choose files to import. For database sources, you can drag-and-drop data tables from the left navigation pane.

10. (Optional) For tabular data sources that support SQL querying (such as Amazon Redshift, Amazon Athena, or Snowflake), you can choose **Edit in SQL** to make SQL queries before importing them.

The following screenshot shows the **Edit SQL** view for an Amazon Athena data source.

The screenshot shows the 'Import' interface for an Athena data source. The 'Edit SQL' view is active, displaying a SQL query: `SELECT "passengerid", "survived", "pclass", "name", "sex", "age", "sibsp", "parch", "ticket", "fare", "cabin", "embarked" FROM "AwsDataCatalog"."titanic"."titanic";`. Below the SQL editor is an 'Import preview' table showing the first 100 rows of data.

<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
passengerid	survived	pclass	name	sex	age	sibsp	parch	ticket	
1	0	3	Braund, Mr. Owen Harris	male	22	1	0	A/5 21171	
2	1	1	Cummings, Mrs. John Bradley (Florence)	female	38	1	0	PC 17599	
3	1	3	Heikkinen, Miss. Laina	female	26	0	0	STON/O2. 3101282	
4	1	1	Futrelle, Mrs. Jacques Heath (Lily May)	female	35	1	0	113805	
5	0	3	Allen, Mr. William Henry	male	35	0	0	373450	
6	0	3	Moran, Mr. James	male		0	0	330877	
7	0	1	McCarthy, Mr. Timothy J	male	54	0	0	17463	
8	0	3	Palsson, Master. Gosta Leonard	male	2	3	1	349909	

11. Choose **Preview dataset** to preview your data before importing it.
12. In the **Import settings**, enter a **Dataset name** or use the default dataset name.
13. (Optional) For data that you import from Amazon S3, you are shown the **Advanced** settings and can fill out the following fields:
- Toggle the **Use first row as header** option on if you want to use the first row of your dataset as the column names. If you selected multiple files, this applies to each file.
  - If you're importing a CSV file, for the **File encoding (CSV)** dropdown, select your dataset file's encoding. UTF-8 is the default.
  - For the **Delimiter** dropdown, select the delimiter that separates each cell in your data. The default delimiter is `,`. You can also specify a custom delimiter.
  - Select **Multi-line detection** if you'd like Canvas to manually parse your entire dataset for multi-line cells. By default, this option is not selected and Canvas determines whether or not to use multi-line support by taking a sample of your data. However, Canvas might not detect any multi-line cells in the sample. If you have multi-line cells, we recommend that

you select the **Multi-line detection** option to force Canvas to check your entire dataset for multi-line cells.

14. When you're ready to import your data, choose **Create dataset**.

While your dataset is importing into Canvas, you can see your datasets listed on the **Datasets** page. From this page, you can [View your dataset details](#).

When the **Status** of your dataset shows as Ready, Canvas successfully imported your data and you can proceed with [building a model](#).

If you have a connection to a data source, such as an Amazon Redshift database or a SaaS connector, you can return to that connection. For Amazon Redshift and Snowflake, you can add another connection by creating another dataset, returning to the **Import data** page, and choosing the **Data Source** tile for that connection. From the dropdown menu, you can open the previous connection or choose **Add connection**.

#### **Note**

For SaaS platforms, you can only have one connection per data source.

## Import image data

With image datasets, you can build single-label image prediction custom models, which predict a label for an image. Review the limitations in the preceding **Import a dataset** section to ensure that your image dataset meets the requirements for image data.

#### **Note**

You can only import image datasets from local file upload or an Amazon S3 bucket. Also, for image datasets, you must have at least 25 images per label.

Use the following procedure to import an image dataset into Canvas:

1. Open your SageMaker Canvas application.
2. In the left navigation pane, choose **Datasets**.
3. Choose **Import data**.

4. From the dropdown menu, choose **Image**.
5. In the popup dialog box, in the **Dataset name** field, enter a name for the dataset and choose **Create**.
6. On the **Import** page, open the **Data Source** dropdown menu.
7. Choose your data source. To upload files from your computer, choose **Local upload**. To import files from Amazon S3, choose **Amazon S3**.
8. From your computer or Amazon S3 bucket, select the images or folders of images that you want to upload.
9. When you're ready to import your data, choose **Import data**.

While your dataset is importing into Canvas, you can see your datasets listed on the **Datasets** page. From this page, you can [View your dataset details](#).

When the **Status** of your dataset shows as Ready, Canvas successfully imported your data and you can proceed with [building a model](#).

When you are building your model, you can edit your image dataset, and you can assign or re-assign labels, add images, or delete images from your dataset. For more information about how to edit your image dataset, see [Edit an image dataset](#).

### Import document data

The Ready-to-use models for expense analysis, identity document analysis, document analysis, and document queries support document data. You can't build a custom model with document data.

With document datasets, you can generate predictions for expense analysis, identity document analysis, document analysis, and document queries Ready-to-use models. Review the limitations table in the [Create a dataset](#) section to ensure that your document dataset meets the requirements for document data.

#### Note

You can only import document datasets from local file upload or an Amazon S3 bucket.

Use the following procedure to import a document dataset into Canvas:

1. Open your SageMaker Canvas application.

2. In the left navigation pane, choose **Datasets**.
3. Choose **Import data**.
4. From the dropdown menu, choose **Document**.
5. In the popup dialog box, in the **Dataset name** field, enter a name for the dataset and choose **Create**.
6. On the **Import** page, open the **Data Source** dropdown menu.
7. Choose your data source. To upload files from your computer, choose **Local upload**. To import files from Amazon S3, choose **Amazon S3**.
8. From your computer or Amazon S3 bucket, select the document files that you want to upload.
9. When you're ready to import your data, choose **Import data**.

While your dataset is importing into Canvas, you can see your datasets listed on the **Datasets** page. From this page, you can [View your dataset details](#).

When the **Status** of your dataset shows as Ready, Canvas has successfully imported your data.

On the **Datasets** page, you can choose your dataset to preview it, which shows you up to the first 100 documents of your dataset.

## View your dataset details

For each of your datasets, you can view all of the files in a dataset, the dataset's version history, and any auto update configurations for the dataset. From the **Datasets** page, you can also initiate actions such as [Update a dataset](#) or [How custom models work](#).

To view the details for a dataset, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **Datasets**.
3. From the list of datasets, choose your dataset.

On the **Data** tab, you can see a preview of your data. If you choose **Dataset details**, you can see all of the files that are part of your dataset. Choose a file to see only the data from that file in the preview. For image datasets, the preview only shows you the first 100 images of your dataset.

On the **Version history** tab, you can see a list of all of the versions of your dataset. A new version is made whenever you update a dataset. To learn more about updating a dataset, see [Update a dataset](#). The following screenshot shows the **Version history** tab in the Canvas application.

Datasets / Sales\_dataset v1 Update dataset ▾ + Create a model ⋮

Data Version history Auto updates Dataset details

Version	Created ↓	Type	Files	Cells (Columns x Rows)	Status	
V6	03/11/2021 12:13 PM	Automatic update	2	20,000 (12 x 1,250)	Ready

Rows per page: 25 ▾ 1-6 of 6 < >

On the **Auto updates** tab, you can enable auto updates for the dataset and set up a configuration to update your dataset on a regular schedule. To learn more about setting up auto updates for a dataset, see [Configure automatic updates for a dataset](#). The following screenshot shows the **Auto updates** tab with auto updates turned on and a list of auto update jobs that have been performed on the dataset.

Datasets / Sales\_dataset V1 Update dataset + Create a model ⋮

## Update a dataset

After importing your initial dataset into Amazon SageMaker Canvas, you might have additional data that you want to add to your dataset. For example, you might get inventory data at the end of every week that you want to add to your dataset. Instead of importing your data multiple times, you can update your existing dataset and add or remove files from it.

### Note

You can only update datasets that you have imported through local upload or Amazon S3.

You can update your dataset either manually or automatically. For more information about automatic dataset updates, see [Configure automatic updates for a dataset](#).

Every time you update your dataset, Canvas creates a new version of your dataset. You can only use the latest version of your dataset to build a model or generate predictions. For more information about viewing the version history of your dataset, see [View your dataset details](#).

You can also use dataset updates with automated batch predictions, which starts a batch prediction job whenever you update your dataset. For more information, see [Batch predictions in SageMaker Canvas](#).

The following section describes how to do manual updates to your dataset.

## Manually update a dataset

To do a manual update, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **Datasets**.
3. From the list of datasets, choose the dataset you want to update.
4. Choose the **Update dataset** dropdown menu and choose **Manual update**. You are taken to the import data workflow.
5. From the **Data source** dropdown menu, choose either **Local upload** or **Amazon S3**.
6. The page shows you a preview of your data. From here, you can add or remove files from the dataset. If you're importing tabular data, the schema of the new files (column names and data types) must match the schema of the existing files. Additionally, your new files must not exceed the maximum dataset size or file size. For more information about these limitations, see [Import a dataset](#).

### Note

If you add a file with the same name as an existing file in your dataset, the new file overwrites the old version of the file.

7. When you're ready to save your changes, choose **Update dataset**.

You should now have a new version of your dataset.

On the **Datasets** page, you can choose the **Version history** tab to see all of the versions of your dataset and the history of both manual and automatic updates you've made.

## Configure automatic updates for a dataset

After importing your initial dataset into Amazon SageMaker Canvas, you might have additional data that you want to add to your dataset. For example, you might get inventory data at the end of every week that you want to add to your dataset. Instead of importing your data multiple times, you can update your existing dataset and add or remove files from it.

### Note

You can only update datasets that you have imported through local upload or Amazon S3.

With automatic dataset updates, you specify a location where Canvas checks for files at a frequency you specify. If you import new files during the update, the schema of the files must match the existing dataset exactly.

Every time you update your dataset, Canvas creates a new version of your dataset. You can only use the latest version of your dataset to build a model or generate predictions. For more information about viewing the version history of your dataset, see [View your dataset details](#).

You can also use dataset updates with automated batch predictions, which starts a batch prediction job whenever you update your dataset. For more information, see [Batch predictions in SageMaker Canvas](#).

The following section describes how to do automatic updates to your dataset.

An automatic update is when you set up a configuration for Canvas to update your dataset at a given frequency. We recommend that you use this option if you regularly receive new files of data that you want to add to your dataset.

When you set up the auto update configuration, you specify an Amazon S3 location where you upload your files and a frequency at which Canvas checks the location and imports files. Each instance of Canvas updating your dataset is referred to as a *job*. For each job, Canvas imports all of the files in the Amazon S3 location. If you have new files with the same names as existing files in your dataset, Canvas overwrites the old files with the new files.

For automatic dataset updates, Canvas doesn't perform schema validation. If the schema of files imported during an automatic update don't match the schema of the existing files or exceed the size limitations (see [Import a dataset](#) for a table of file size limitations), then you get errors when your jobs run.

**Note**

You can only set up a maximum of 20 automatic configurations in your Canvas application. Additionally, Canvas only does automatic updates while you're logged in to your Canvas application. If you log out of your Canvas application, automatic updates pause until you log back in.

To configure automatic updates for your dataset, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **Datasets**.
3. From the list of datasets, choose the dataset you want to update.
4. Choose the **Update dataset** dropdown menu and choose **Automatic update**. You are taken to the **Auto update** tab for the dataset.
5. Turn on the **Auto update enabled** toggle.
6. For **Specify a data source**, enter the Amazon S3 path to a folder where you plan to regularly upload files.
7. For **Choose a frequency**, select **Hourly**, **Weekly**, or **Daily**.
8. For **Specify a starting time**, use the calendar and time picker to select when you want the first auto update job to start.
9. When you're ready to create the auto update configuration, choose **Save**.

Canvas begins the first job of your auto update cadence at the specified starting time.

## View your automatic dataset update jobs

To view the job history for your automatic dataset updates in Amazon SageMaker Canvas, on your dataset details page, choose the **Auto updates** tab.

Each automatic update to a dataset shows as a job in the **Auto updates** tab under the **Job history** section. For each job, you can see the following:

- **Job created** – The timestamp for when Canvas started updating the dataset.
- **Files** – The number of files in the dataset.
- **Cells (Columns x Rows)** – The number of columns and rows in the dataset.

- **Status** – The status of the dataset after the update. If the job was successful, the status is **Ready**. If the job failed for any reason, the status is **Failed**, and you can hover over the status for more details.

## Edit your automatic dataset update configuration

You might want to make changes to your auto update configuration for a dataset, such as changing the frequency of the updates. You might also want to turn off your automatic update configuration to pause the updates to your dataset.

To make changes to your auto update configuration for a dataset, go to the **Auto updates** tab of your dataset and choose **Edit** to make changes to the configuration.

To pause your dataset updates, turn off your automatic configuration. You can turn off auto updates by going to the **Auto updates** tab of your dataset and turning the **Enable auto updates** toggle off. You can turn this toggle back on at any time to resume the update schedule.

To learn how to delete your configuration, see [Delete an automatic configuration](#).

## Connect to data sources

In Amazon SageMaker Canvas, you can import data from a location outside of your local file system through an AWS service, a SaaS platform, or other databases using JDBC connectors. For example, you might want to import tables from a data warehouse in Amazon Redshift, or you might want to import Google Analytics data.

When you go through the **Import** workflow to import data in the Canvas application, you can choose your data source and then select the data that you want to import. For certain data sources, like Snowflake and Amazon Redshift, you must specify your credentials and add a connection to the data source.

The following screenshot shows the data sources toolbar in the **Import** workflow, with all of the available data sources highlighted. You can only import data from the data sources that are available to you. Contact your administrator if your desired data source isn't available.

[How to connect to data sources](#)

The following sections provide information about establishing connections to external data sources and importing data from them. Review the following section first to determine what permissions you need to import data from your data source.

## Permissions

Review the following information to ensure that you have the necessary permissions to import data from your data source:

- **Amazon S3:** You can import data from any Amazon S3 bucket as long as your user has permissions to access the bucket. For more information about using AWS IAM to control access to Amazon S3 buckets, see [Identity and access management in Amazon S3](#) in the *Amazon S3 User Guide*.
- **Amazon Athena:** If you have the [AmazonSageMakerFullAccess](#) policy and the [AmazonSageMakerCanvasFullAccess](#) policy attached to your user's execution role, then you can query your AWS Glue Data Catalog with Amazon Athena. If you're part of an Athena workgroup, make sure that the Canvas user has permissions to run Athena queries on the data. For more information, see [Using workgroups for running queries](#) in the *Amazon Athena User Guide*.
- **Amazon DocumentDB:** You can import data from any Amazon DocumentDB database as long as you have the credentials (username and password) to connect to the database and have the minimum base Canvas permissions attached to your user's execution role. For more information about Canvas permissions, see the [Prerequisites for setting up Amazon SageMaker Canvas](#).

- **Amazon Redshift:** To give yourself the necessary permissions to import data from Amazon Redshift, see [Grant Users Permissions to Import Amazon Redshift Data](#).
- **Amazon RDS:** If you have the [AmazonSageMakerCanvasFullAccess](#) policy attached to your user's execution role, then you'll be able to access your Amazon RDS databases from Canvas.
- **SaaS platforms:** If you have the [AmazonSageMakerFullAccess](#) policy and the [AmazonSageMakerCanvasFullAccess](#) policy attached to your user's execution role, then you have the necessary permissions to import data from SaaS platforms. See [Use SaaS connectors with Canvas](#) for more information about connecting to a specific SaaS connector.
- **JDBC connectors:** For database sources such as Databricks, MySQL or MariaDB, you must enable username and password authentication on the source database before attempting to connect from Canvas. If you're connecting to a Databricks database, you must have the JDBC URL that contains the necessary credentials.

## Connect to a database stored in AWS

You might want to import data that you've stored in AWS. You can import data from Amazon S3, use Amazon Athena to query a database in the AWS Glue Data Catalog, import data from [Amazon RDS](#), or make a connection to a provisioned Amazon Redshift database (not Redshift Serverless).

You can create multiple connections to Amazon Redshift. For Amazon Athena, you can access any databases that you have in your [AWS Glue Data Catalog](#). For Amazon S3, you can import data from a bucket as long as you have the necessary permissions.

Review the following sections for more detailed information.

## Connect to data in Amazon S3, Amazon Athena, or Amazon RDS

For Amazon S3, you can import data from an Amazon S3 bucket as long as you have permissions to access the bucket.

For Amazon Athena, you can access databases in your AWS Glue Data Catalog as long as you have permissions through your [Amazon Athena workgroup](#).

For Amazon RDS, if you have the [AmazonSageMakerCanvasFullAccess](#) policy attached to your user's role, then you'll be able to import data from your Amazon RDS databases into Canvas.

To import data from an Amazon S3 bucket, or to run queries and import data tables with Amazon Athena, see [Create a dataset](#). You can only import tabular data from Amazon Athena, and you can import tabular and image data from Amazon S3.

## Connect to an Amazon DocumentDB database

Amazon DocumentDB is a fully managed, serverless, document database service. You can import unstructured document data stored in an Amazon DocumentDB database into SageMaker Canvas as a tabular dataset, and then you can build machine learning models with the data.

### Important

Your SageMaker AI domain must be configured in **VPC only** mode to add connections to Amazon DocumentDB. You can only access Amazon DocumentDB clusters in the same Amazon VPC as your Canvas application. Additionally, Canvas can only connect to TLS-enabled Amazon DocumentDB clusters. For more information about how to set up Canvas in **VPC only** mode, see [Configure Amazon SageMaker Canvas in a VPC without internet access](#).

To import data from Amazon DocumentDB databases, you must have credentials to access the Amazon DocumentDB database and specify the username and password when creating a database connection. You can configure more granular permissions and restrict access by modifying the Amazon DocumentDB user permissions. To learn more about access control in Amazon DocumentDB, see [Database Access Using Role-Based Access Control](#) in the *Amazon DocumentDB Developer Guide*.

When you import from Amazon DocumentDB, Canvas converts your unstructured data into a tabular dataset by mapping the fields to columns in a table. Additional tables are created for each complex field (or nested structure) in the data, where the columns correspond to the sub-fields of the complex field. For more detailed information about this process and examples of schema conversion, see the [Amazon DocumentDB JDBC Driver Schema Discovery](#) GitHub page.

Canvas can only make a connection to a single database in Amazon DocumentDB. To import data from a different database, you must create a new connection.

You can import data from Amazon DocumentDB into Canvas by using the following methods:

- [Create a dataset](#). You can import your Amazon DocumentDB data and create a tabular dataset in Canvas. If you choose this method, make sure that you follow the [Import tabular data](#) procedure.
- [Create a data flow](#). You can create a data preparation pipeline in Canvas and add your Amazon DocumentDB database as a data source.

To proceed with importing your data, follow the procedure for one of the methods linked in the preceding list.

When you reach the step in either workflow to choose a data source (Step 6 for creating a dataset, or Step 8 for creating a data flow), do the following:

1. For **Data Source**, open the dropdown menu and choose **DocumentDB**.
2. Choose **Add connection**.
3. In the dialog box, specify your Amazon DocumentDB credentials:
  - a. Enter a **Connection name**. This is a name used by Canvas to identify this connection.
  - b. For **Cluster**, select the cluster in Amazon DocumentDB that stores your data. Canvas automatically populates the dropdown menu with Amazon DocumentDB clusters in the same VPC as your Canvas application.
  - c. Enter the **Username** for your Amazon DocumentDB cluster.
  - d. Enter the **Password** for your Amazon DocumentDB cluster.
  - e. Enter the name of the **Database** to which you want to connect.
  - f. The **Read preference** option determines which types of instances on your cluster Canvas reads the data from. Select one of the following:
    - **Secondary preferred** – Canvas defaults to reading from the cluster's secondary instances, but if a secondary instance isn't available, then Canvas reads from a primary instance.
    - **Secondary** – Canvas only reads from the cluster's secondary instances, which prevents the read operations from interfering with the cluster's regular read and write operations.
  - g. Choose **Add connection**. The following image shows the dialog box with the preceding fields for an Amazon DocumentDB connection.

### Add a new DocumentDB connection ✕

---

Create a name to identify your connection

Cluster

First part of the cluster endpoint used to construct the URI for connecting your database.

Read preference 

Secondary preferred

Secondary

Cancel Add connection

You should now have an Amazon DocumentDB connection, and you can use your Amazon DocumentDB data in Canvas to create either a dataset or a data flow.

## Connect to an Amazon Redshift database

You can import data from Amazon Redshift, a data warehouse where your organization keeps its data. Before you can import data from Amazon Redshift, the AWS IAM role you use must have the `AmazonRedshiftFullAccess` managed policy attached. For instructions on how to attach this policy, see [Grant Users Permissions to Import Amazon Redshift Data](#).

To import data from Amazon Redshift, you do the following:

1. Create a connection to an Amazon Redshift database.
2. Choose the data that you're importing.
3. Import the data.

You can use the Amazon Redshift editor to drag datasets onto the import pane and import them into SageMaker Canvas. For more control over the values returned in the dataset, you can use the following:

- SQL queries
- Joins

With SQL queries, you can customize how you import the values in the dataset. For example, you can specify the columns returned in the dataset or the range of values for a column.

You can use joins to combine multiple datasets from Amazon Redshift into a single dataset. You can drag your datasets from Amazon Redshift into the panel that gives you the ability to join the datasets.

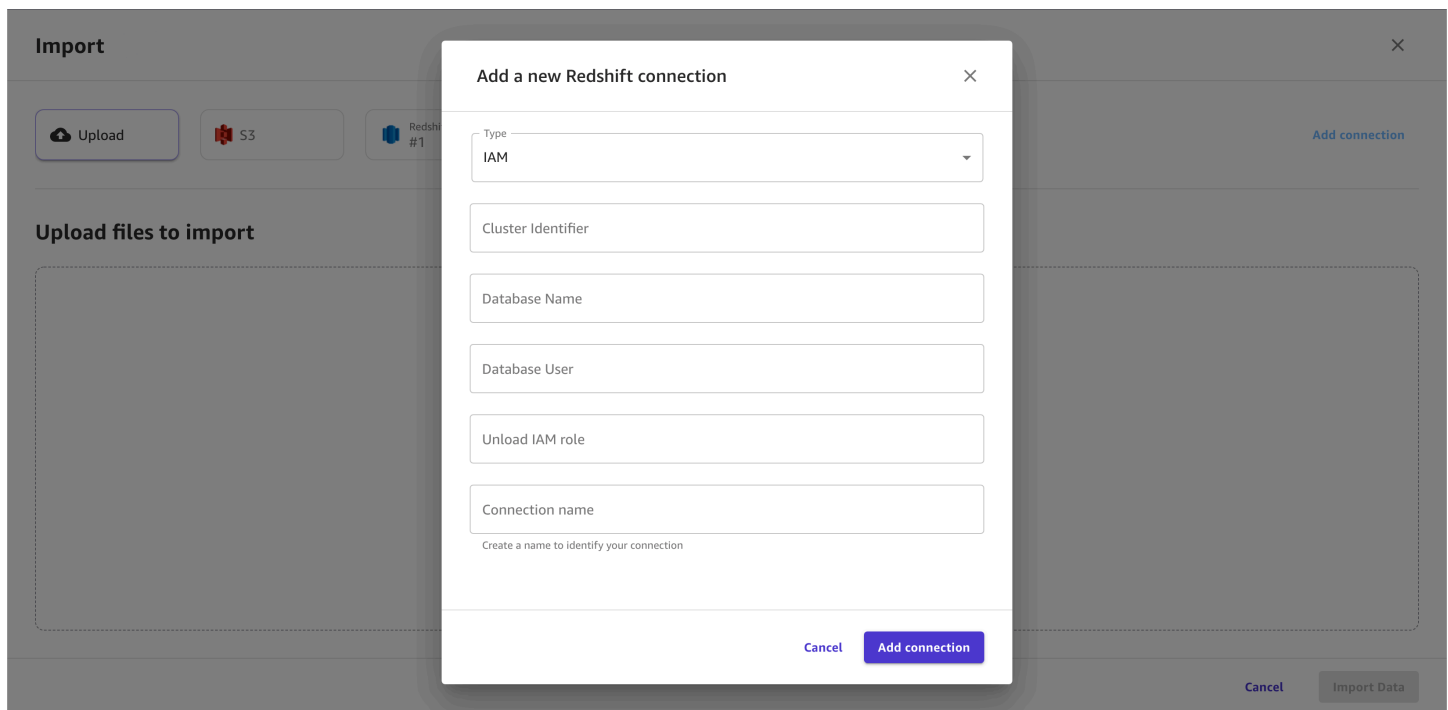

You can use the SQL editor to edit the dataset that you've joined and convert the joined dataset into a single node. You can join another dataset to the node. You can import the data that you've selected into SageMaker Canvas.

Use the following procedure to import data from Amazon Redshift.

1. In the SageMaker Canvas application, go to the **Datasets** page.
2. Choose **Import data**, and from the dropdown menu, choose **Tabular**.
3. Enter a name for the dataset and choose **Create**.
4. For **Data Source**, open the dropdown menu and choose **Redshift**.
5. Choose **Add connection**.
6. In the dialog box, specify your Amazon Redshift credentials:
  - a. For **Authentication method**, choose **IAM**.
  - b. Enter the **Cluster identifier** to specify to which cluster you want to connect. Enter only the cluster identifier and not the full endpoint of the Amazon Redshift cluster.
  - c. Enter the **Database name** of the database to which you want to connect.
  - d. Enter a **Database user** to identify the user you want to use to connect to the database.
  - e. For **ARN**, enter the IAM role ARN of the role that the Amazon Redshift cluster should assume to move and write data to Amazon S3. For more information about this role, see [Authorizing Amazon Redshift to access other AWS services on your behalf](#) in the *Amazon Redshift Management Guide*.

- f. Enter a **Connection name**. This is a name used by Canvas to identify this connection.
7. From the tab that has the name of your connection, drag the .csv file that you're importing to the **Drag and drop table to import** pane.
8. Optional: Drag additional tables to the import pane. You can use the GUI to join the tables. For more specificity in your joins, choose **Edit in SQL**.
9. Optional: If you're using SQL to query the data, you can choose **Context** to add context to the connection by specifying values for the following:
  - **Warehouse**
  - **Database**
  - **Schema**
10. Choose **Import data**.

Import Data

## Connect to your data with JDBC connectors

With JDBC, you can connect to your databases from sources such as Databricks, SQLServer, MySQL, PostgreSQL, MariaDB, Amazon RDS, and Amazon Aurora.

You must make sure that you have the necessary credentials and permissions to create the connection from Canvas.

- For Databricks, you must provide a JDBC URL. The URL formatting can vary between Databricks instances. For information about finding the URL and the specifying the parameters within it, see [JDBC configuration and connection parameters](#) in the Databricks documentation. The following is an example of how a URL can be formatted:  
`jdbc:spark://aws-sagemaker-datawrangler.cloud.databricks.com:443/default;transportMode=http;ssl=1;httpPath=sql/protocolv1/o/3122619508517275/0909-200301-cut318;AuthMech=3;UID=token;PWD=personal-access-token`
- For other database sources, you must set up username and password authentication, and then specify those credentials when connecting to the database from Canvas.

Additionally, your data source must either be accessible through the public internet, or if your Canvas application is running in **VPC only** mode, then the data source must run in the same VPC. For more information about configuring an Amazon RDS database in a VPC, see [Amazon VPC VPCs and Amazon RDS](#) in the *Amazon RDS User Guide*.

After you've configured your data source credentials, you can sign in to the Canvas application and create a connection to the data source. Specify your credentials (or, for Databricks, the URL) when creating the connection.

## Connect to data sources with OAuth

Canvas supports using OAuth as an authentication method for connecting to your data in Snowflake and Salesforce Data Cloud. [OAuth](#) is a common authentication platform for granting access to resources without sharing passwords.

### Note

You can only establish one OAuth connection for each data source.

To authorize the connection, you must following the initial setup described in [Set up connections to data sources with OAuth](#).

After setting up the OAuth credentials, you can do the following to add a Snowflake or Salesforce Data Cloud connection with OAuth:

1. Sign in to the Canvas application.
2. Create a tabular dataset. When prompted to upload data, choose Snowflake or Salesforce Data Cloud as your data source.
3. Create a new connection to your Snowflake or Salesforce Data Cloud data source. Specify OAuth as the authentication method and enter your connection details.

You should now be able to import data from your databases in Snowflake or Salesforce Data Cloud.

### Connect to a SaaS platform

You can import data from Snowflake and over 40 other external SaaS platforms. For a full list of the connectors, see the table on [Data import](#).

#### Note

You can only import tabular data, such as data tables, from SaaS platforms.

### Use Snowflake with Canvas

Snowflake is a data storage and analytics service, and you can import your data from Snowflake into SageMaker Canvas. For more information about Snowflake, see the [Snowflake documentation](#).

You can import data from your Snowflake account by doing the following:

1. Create a connection to the Snowflake database.
2. Choose the data that you're importing by dragging and dropping the table from the left navigation menu into the editor.
3. Import the data.

You can use the Snowflake editor to drag datasets onto the import pane and import them into SageMaker Canvas. For more control over the values returned in the dataset, you can use the following:

- SQL queries
- Joins

With SQL queries, you can customize how you import the values in the dataset. For example, you can specify the columns returned in the dataset or the range of values for a column.

You can join multiple Snowflake datasets into a single dataset before you import into Canvas using SQL or the Canvas interface. You can drag your datasets from Snowflake into the panel that gives you the ability to join the datasets, or you can edit the joins in SQL and convert the SQL into a single node. You can join other nodes to the node that you've converted. You can then combine the datasets that you've joined into a single node and join the nodes to a different Snowflake dataset. Finally, you can import the data that you've selected into Canvas.

Use the following procedure to import data from Snowflake to Amazon SageMaker Canvas.

1. In the SageMaker Canvas application, go to the **Datasets** page.
2. Choose **Import data**, and from the dropdown menu, choose **Tabular**.
3. Enter a name for the dataset and choose **Create**.
4. For **Data Source**, open the dropdown menu and choose **Snowflake**.
5. Choose **Add connection**.
6. In the **Add a new Snowflake connection** dialog box, specify your Snowflake credentials. For the **Authentication method**, choose one of the following:
  - **Basic - username password** – Provide your Snowflake account ID, username, and password.
  - **ARN** – For improved protection of your Snowflake credentials, provide the ARN of an AWS Secrets Manager secret that contains your credentials. For more information, see [Create an AWS Secrets Manager secret](#) in the *AWS Secrets Manager User Guide*.

Your secret should have your Snowflake credentials stored in the following JSON format:

```
{"accountid": "ID",  
  "username": "username",  
  "password": "password"}
```

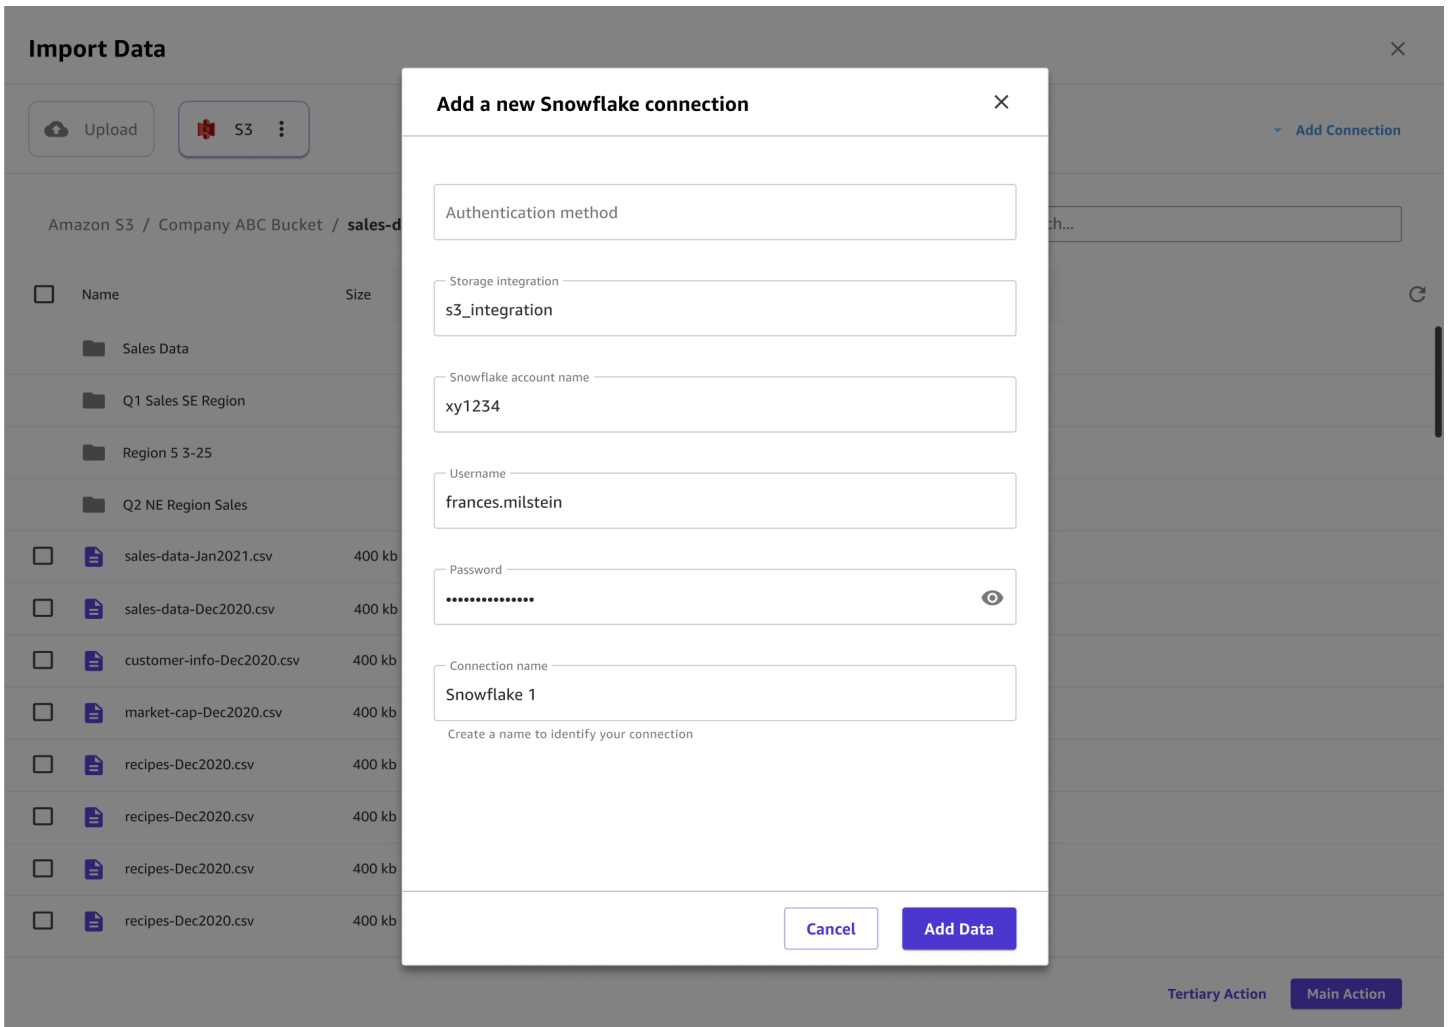

- **OAuth** – OAuth lets you authenticate without providing a password but requires additional setup. For more information about setting up OAuth credentials for Snowflake, see [Set up connections to data sources with OAuth](#).

7. Choose **Add connection**.
8. From the tab that has the name of your connection, drag the .csv file that you're importing to the **Drag and drop table to import** pane.
9. Optional: Drag additional tables to the import pane. You can use the user interface to join the tables. For more specificity in your joins, choose **Edit in SQL**.
10. Optional: If you're using SQL to query the data, you can choose **Context** to add context to the connection by specifying values for the following:
  - **Warehouse**
  - **Database**
  - **Schema**

Adding context to a connection makes it easier to specify future queries.

11. Choose **Import data**.

The following image shows an example of fields specified for a Snowflake connection.

The following image shows the page used to add context to a connection.

## Use SaaS connectors with Canvas

### i Note

For SaaS platforms besides Snowflake, you can only have one connection per data source.

Before you can import data from a SaaS platform, your administrator must authenticate and create a connection to the data source. For more information about how administrators can create a connection with a SaaS platform, see [Managing Amazon AppFlow connections](#) in the *Amazon AppFlow User Guide*.

If you're an administrator getting started with Amazon AppFlow for the first time, see [Getting started](#) in the *Amazon AppFlow User Guide*.

To import data from a SaaS platform, you can follow the standard [Import tabular data](#) procedure, which shows you how to import tabular datasets into Canvas.

## Sample datasets in Canvas

SageMaker Canvas provides sample datasets addressing unique use cases so you can start building, training, and validating models quickly without writing any code. The use cases associated with these datasets highlight the capabilities of SageMaker Canvas, and you can leverage these datasets to get started with building models. You can find the sample datasets in the **Datasets** page of your SageMaker Canvas application.

The following datasets are the samples that SageMaker Canvas provides by default. These datasets cover use cases such as predicting house prices, loan defaults, and readmission for diabetic patients; forecasting sales; predicting machine failures to streamline predictive maintenance in manufacturing units; and generating supply chain predictions for transportation and logistics. The datasets are stored in the `sample_dataset` folder in the default Amazon S3 bucket that SageMaker AI creates for your account in a Region.

- **canvas-sample-diabetic-readmission.csv:** This dataset contains historical data including over fifteen features with patient and hospital outcomes. You can use this dataset to predict whether high-risk diabetic patients are likely to get readmitted to the hospital within 30 days of discharge, after 30 days, or not at all. Use the **redadmitted** column as the target column, and use the 3+ category prediction model type with this dataset. To learn more about how to build a model with this dataset, see the [SageMaker Canvas workshop page](#). This dataset was obtained from the [UCI Machine Learning Repository](#).
- **canvas-sample-housing.csv:** This dataset contains data on the characteristics tied to a given housing price. You can use this dataset to predict housing prices. Use the **median\_house\_value** column as the target column, and use the numeric prediction model type with this dataset. To learn more about building a model with this dataset, see the [SageMaker Canvas workshop page](#). This is the California housing dataset obtained from the [StatLib repository](#).
- **canvas-sample-loans.csv:** This dataset contains complete loan data for all loans issued from 2007–2011, including the current loan status and latest payment information. You can use this dataset to predict whether a customer will repay a loan. Use the **loan\_status** column as the target column, and use the 3+ category prediction model type with this dataset. To learn more about how to build a model with this dataset, see the [SageMaker Canvas workshop page](#). This data uses the LendingClub data obtained from [Kaggle](#).

- **canvas-sample-maintenance.csv:** This dataset contains data on the characteristics tied to a given maintenance failure type. You can use this dataset to predict which failure will occur in the future. Use the **Failure Type** column as the target column, and use the 3+ category prediction model type with this dataset. To learn more about how to build a model with this dataset, see the [SageMaker Canvas workshop page](#). This dataset was obtained from the [UCI Machine Learning Repository](#).
- **canvas-sample-shipping-logs.csv:** This dataset contains complete shipping data for all products delivered, including estimated time shipping priority, carrier, and origin. You can use this dataset to predict the estimated time of arrival of the shipment in number of days. Use the **ActualShippingDays** column as the target column, and use the numeric prediction model type with this dataset. To learn more about how to build a model with this data, see the [SageMaker Canvas workshop page](#). This is a synthetic dataset created by Amazon.
- **canvas-sample-sales-forecasting.csv:** This dataset contains historical time series sales data for retail stores. You can use this dataset to forecast sales for a particular retail store. Use the **sales** column as the target column, and use the time series forecasting model type with this dataset. To learn more about how to build a model with this dataset, see the [SageMaker Canvas workshop page](#). This is a synthetic dataset created by Amazon.

## Re-import a deleted sample dataset

Amazon SageMaker Canvas provides you with sample datasets for various use cases that highlight the capabilities of Canvas. To learn more about the sample datasets that are available, see [Sample datasets in Canvas](#). If you no longer wish to use the sample datasets, you can delete them from the **Datasets** page of your SageMaker Canvas application. However, these datasets are still stored in the Amazon S3 bucket that you specified as the [Canvas storage location](#), so you can always access them later.

If you used the default Amazon S3 bucket, the bucket name follows the pattern `sagemaker-{region}-{account ID}`. You can find the sample datasets in the directory path `Canvas/sample_dataset`.

If you delete a sample dataset from your SageMaker Canvas application and want to access the sample dataset again, use the following procedure.

1. Navigate to the **Datasets** page in your SageMaker Canvas application.
2. Choose **Import data**.

3. From the list of Amazon S3 buckets, select the bucket that is your Canvas storage location. If using the default SageMaker AI-created Amazon S3 bucket, it follows the naming pattern `sagemaker-{region}-{account ID}`.
4. Select the **Canvas** folder.
5. Select the **sample\_dataset** folder, which contains all of the sample datasets for SageMaker Canvas.
6. Select the dataset you want to import, and then choose **Import data**.

## Data preparation

### Note

Previously, Amazon SageMaker Data Wrangler was part of the SageMaker Studio Classic experience. Now, if you update to using the new Studio experience, you must use SageMaker Canvas to access Data Wrangler and receive the latest feature updates. If you have been using Data Wrangler in Studio Classic until now and want to migrate to Data Wrangler in Canvas, you might have to grant additional permissions so that you can create and use a Canvas application. For more information, see [\(Optional\) Migrate from Data Wrangler in Studio Classic to SageMaker Canvas](#).

To learn how to migrate your data flows from Data Wrangler in Studio Classic, see [\(Optional\) Migrate data from Studio Classic to Studio](#).

Use Amazon SageMaker Data Wrangler in Amazon SageMaker Canvas to prepare, featurize and analyze your data. You can integrate a Data Wrangler data preparation flow into your machine learning (ML) workflows to simplify and streamline data pre-processing and feature engineering using little to no coding. You can also add your own Python scripts and transformations to customize workflows.

- **Data Flow** – Create a data flow to define a series of ML data prep steps. You can use a flow to combine datasets from different data sources, identify the number and types of transformations you want to apply to datasets, and define a data prep workflow that can be integrated into an ML pipeline.
- **Transform** – Clean and transform your dataset using standard *transforms* like string, vector, and numeric data formatting tools. Featurize your data using transforms like text and date/time embedding and categorical encoding.

- **Generate Data Insights** – Automatically verify data quality and detect abnormalities in your data with Data Wrangler Data Quality and Insights Report.
- **Analyze** – Analyze features in your dataset at any point in your flow. Data Wrangler includes built-in data visualization tools like scatter plots and histograms, as well as data analysis tools like target leakage analysis and quick modeling to understand feature correlation.
- **Export** – Export your data preparation workflow to a different location. The following are example locations:
  - Amazon Simple Storage Service (Amazon S3) bucket
  - Amazon SageMaker Feature Store – Store the features and their data in a centralized store.
- **Automate data preparation** – Create machine learning workflows from your data flow.
  - Amazon SageMaker Pipelines – Build workflows that manage your SageMaker AI data preparation, model training, and model deployment jobs.
  - Serial inference pipeline – Create a serial inference pipeline from your data flow. Use it to make predictions on new data.
  - Python script – Store the data and their transformations in a Python script for your custom workflows.

## Create a data flow

Use a Data Wrangler flow in SageMaker Canvas, or *data flow*, to create and modify a data preparation pipeline. We recommend that you use Data Wrangler for datasets larger than 5 GB.

To get started, use the following procedure to import your data into a data flow.

1. Open SageMaker Canvas.
2. In the left-hand navigation, choose **Data Wrangler**.
3. Choose **Import and prepare**.
4. From the dropdown menu, choose either **Tabular** or **Image**.
5. For **Select a data source**, choose your data source and select the data that you want to import. You have the option to select up to 30 files or one folder. If you have a dataset already imported into Canvas, choose **Canvas dataset** as your source. Otherwise, connect to a data source such as Amazon S3 or Snowflake and browse through your data. For information about connecting to a data source or importing data, see the following pages:

- [Data import](#)

- [Connect to data sources](#)
6. After selecting the data that you want to import, choose **Next**.
  7. (Optional) For the **Import settings** section when importing a tabular dataset, expand the **Advanced** dropdown menu. You can specify the following advanced settings for data flow imports:
    - **Sampling method** – Select the sampling method and sample size you'd like to use. For more information about how to change your sample, see the section [Edit the data flow sampling configuration](#).
    - **File encoding (CSV)** – Select your dataset file's encoding. UTF-8 is the default.
    - **Skip first rows** – Enter the number of rows you'd like to skip importing if you have redundant rows at the beginning of your dataset.
    - **Delimiter** – Select the delimiter that separates each item in your data. You can also specify a custom delimiter.
    - **Multi-line detection** – Select this option if you'd like Canvas to manually parse your entire dataset for multi-line cells. Canvas determines whether or not to use multi-line support by taking a sample of your data, but Canvas might not detect any multi-line cells in the sample. In this case, we recommend that you select the **Multi-line detection** option to force Canvas to check your entire dataset for multi-line cells.
  8. Choose **Import**.

You should now have a new data flow, and you can begin adding transform steps and analyses.

## How the data flow UI works

To help you navigate your data flow, Data Wrangler has the following tabs in the top navigation pane:

- **Data flow** – This tab provides you with a visual view of your data flow step where you can add or remove transforms, and export data.
- **Data** – This tab gives you a preview of your data so that you can check the results of your transforms. You can also see an ordered list of your data flow steps and edit or reorder the steps.

**Note**

In this tab, you can only preview data visualizations (such as the distribution of values per column) for Amazon S3 data sources. Visualizations for other data sources, such as Amazon Athena, aren't supported.

- **Analyses** – In this tab, you can see separate sub-tabs for each analysis you create. For example, if you create a histogram and a Data Quality and Insights (DQI) report, Canvas creates a tab for each.

When you import a dataset, the original dataset appears on the data flow and is named **Source**. SageMaker Canvas automatically infers the types of each column in your dataset and creates a new dataframe named **Data types**. You can select this frame to update the inferred data types.

The datasets, transformations, and analyses that you use in the data flow are represented as *steps*. Each time you add a transform step, you create a new dataframe. When multiple transform steps (other than **Join** or **Concatenate**) are added to the same dataset, they are stacked.

Under the **Combine data** option, **Join** and **Concatenate** create standalone steps that contain the new joined or concatenated dataset.

## Edit the data flow sampling configuration

When importing tabular data into a Data Wrangler data flow, you can opt to take a sample of your dataset to speed up the data exploration and cleaning process. Running exploratory transforms on a sample of your dataset is often faster than running transforms on your entire dataset, and when you're ready to export your dataset and build a model, you can apply the transforms to the full dataset.

Canvas supports the following sampling methods:

- **FirstK** – Canvas selects the first  $K$  items from your dataset, where  $K$  is a number you specify. This sampling method is simple but can introduce bias if your dataset isn't randomly ordered.
- **Random** – Canvas selects items from the dataset at random, with each item having an equal probability of being chosen. This sampling method helps ensure that the sample is representative of the entire dataset.
- **Stratified** – Canvas divides the dataset into groups (or *strata*) based on one or more attributes (for example, age and income level). Then, a proportional number of items are randomly selected

from each group. This method ensures that all relevant subgroups are adequately represented in the sample.

You can edit your sampling configuration at any time to change the size of the sample used for data exploration.

To make changes to your sampling configuration, do the following:

1. In your data flow graph, select your data source node.
2. Choose **Sampling** on the bottom navigation bar.
3. The **Sampling** dialog box opens. For the **Sampling method** dropdown, select your desired sampling method.
4. For **Maximum sample size**, enter the number of rows you want to sample.
5. Choose **Update** to save your changes.

The changes to your sampling configuration should now be applied.

## Add a step to your data flow

In your Data Wrangler data flows, you can add steps that represent data transformations and analyses.

To add a step to your data flow, select **+** next to any dataset node or previously added step. Then, select one of the following options:

- **Edit data types** (For a **Data types** step only): If you have not added any transforms to a **Data types** step, you can double-click on the **Data types** step in your flow to open the **Data** tab and edit the data types that Data Wrangler inferred when importing your dataset.
- **Add transform**: Adds a new transform step. See [Transform data](#) to learn more about the data transformations you can add.
- **Get data insights**: Add analyses, such as histograms or custom visualizations. You can use this option to analyze your data at any point in the data flow. See [Perform exploratory data analysis \(EDA\)](#) to learn more about the analyses you can add.
- **Join**: Find this option under **Combine data** to join two datasets and add the resulting dataset to the data flow. To learn more, see [Join Datasets](#).
- **Concatenate**: Find this option under **Combine data** to concatenate two datasets and add the resulting dataset to the data flow. To learn more, see [Concatenate Datasets](#).

## Edit data flow steps

In Amazon SageMaker Canvas, you can edit individual steps in your data flows to transform your dataset without having to create a new data flow. The following page covers how to edit join and concatenate steps, as well as data source steps.

### Edit join and concatenate steps

Within your data flows, you have the flexibility to edit your join and concatenate steps. You can make necessary adjustments to your data processing workflow, ensuring that your data is properly combined and transformed without having to redo your entire data flow.

To edit a join or concatenate step in your data flow, do the following:

1. Open your data flow.
2. Choose the plus icon (+) next to the join or concatenate node that you want to edit.
3. From the context menu, choose **Edit**.
4. A side panel opens where you can edit the details of your join or concatenation. Modify your step fields, such as the type of join. To swap out a data node and select a different one to join or concatenate, choose the delete icon next to the node and then, in the data flow view, select the new node that you want to include in your transformation.

#### Note

When swapping out a node during the editing process, you can only select steps that occur before the join or concatenate operation. You can swap either the left or right node, but you can only swap one node at a time. Additionally, you cannot select a source node as a replacement.

5. Choose **Preview** to view the result of the combining operation.
6. Choose **Update** to save your changes.

Your data flow should now be updated.

### Edit or replace a data source step

You might need to make changes to your data source or dataset without deleting the transforms and data flow steps applied to your original data. Within Data Wrangler, you can edit or replace

your data source configuration while keeping the steps of your data flow. When editing a data source, you can change the import settings, such as the sampling size or method and any advanced settings. You can also add more files with the same schema, or for query-based data sources such as Amazon Athena, you can edit the query. When replacing a data source, you have the option to select a different dataset, or even import the data from a different data source altogether, as long as the schema of the new data matches the original data.

To edit a data source configuration, do the following:

1. In the Canvas application, go to the **Data Wrangler** page.
2. Choose your data flow to view it.
3. In the **Data flow** tab that shows your data flow steps, find the **Source** node that you want to edit.
4. Choose the ellipsis icon next to the **Source** node.
5. From the context menu, choose **Edit**.
6. For Amazon S3 data sources and local upload, you have the option to select or upload more files with the same schema as your original data. For query-based data sources such as Amazon Athena, you can remove and select different tables in the visual query builder, or you can edit the SQL query directly. When you're done, choose **Next**.
7. For the **Import settings**, make any desired changes.
8. When you're done, choose **Save changes**.

Your data source should now be updated.

To replace a data source, do the following:

1. In the Canvas application, go to the **Data Wrangler** page.
2. Choose your data flow to view it.
3. In the **Data flow** tab that shows your data flow steps, find the **Source** node that you want to edit.
4. Choose the ellipsis icon next to the **Source** node.
5. From the context menu, choose **Replace**.
6. Go through the [create a data flow experience](#) to select another data source and data.
7. When you've selected your data and are ready to update the source node, choose **Save**.

You should now see the **Source** node updated in your data flow.

## Reorder steps in your data flow

After adding steps to your data flow, you have the option to reorder steps instead of deleting and re-adding them in the correct order. For example, you might decide to move a transform to impute missing values before a step to format strings.

### Note

You can't change the order of certain step types, such as defining your data source, changing data types, joining, concatenating, or splitting. Steps that can't be reordered are grayed out in the Canvas application UI.

To reorder your data flow steps, do the following:

1. While editing a data flow in Data Wrangler, choose the **Data** tab. A side panel called **Steps** lists your data flow steps in order.
2. Hover over a transform step and choose the **More options** icon (  ) next to that step.
3. From the context menu, choose **Reorder**.
4. Drag and drop your data flow steps into your desired order.
5. When you've finished, choose **Save**.

Your data flow steps and graph should now reflect the changes you've made.

## Delete a step from your data flow

Within your data flows, you have the flexibility to delete your join and concatenate steps and choose whether or not to still apply any subsequent transforms to your data.

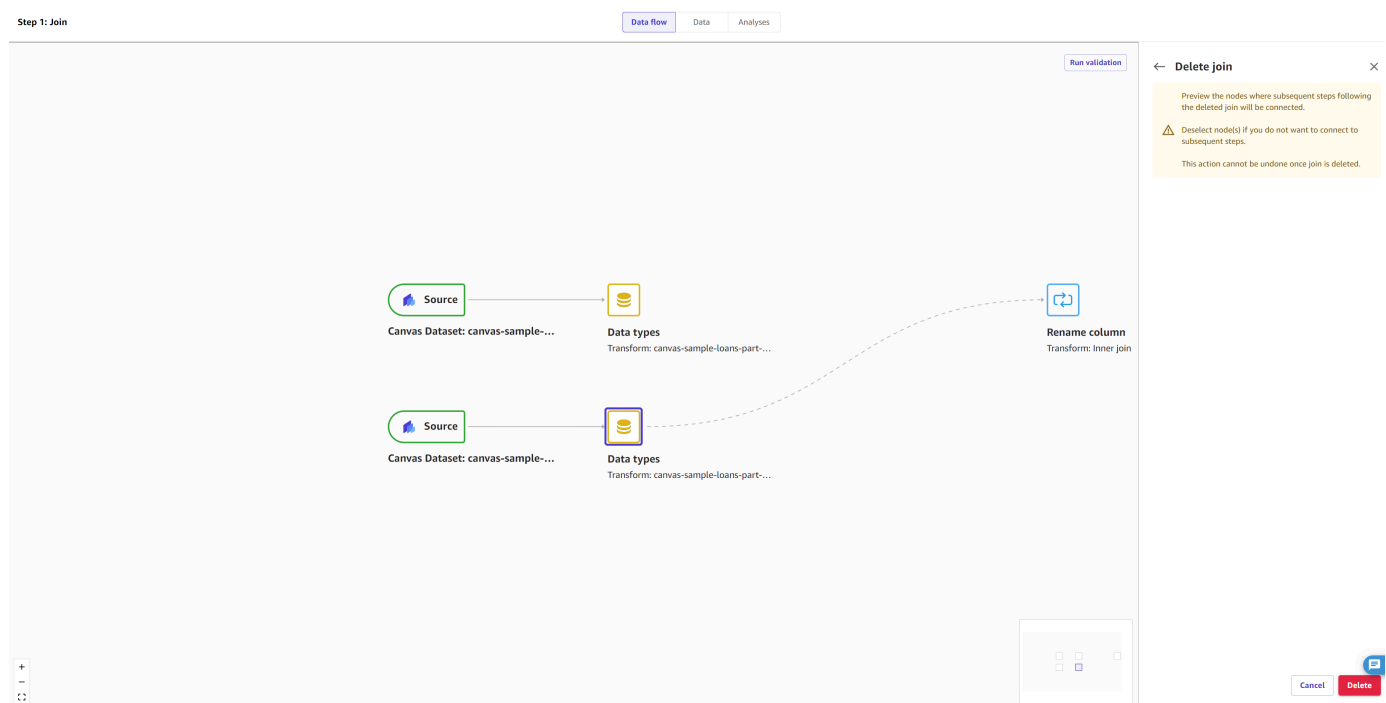

To delete a join or concatenate step from your data flow, do the following:

1. Open your data flow.
2. Choose the plus icon (+) next to the join or concatenate node that you want to delete.

3. In the context menu, choose **Delete**.
4. (Optional) If you have transformation steps following the join or concatenate step, then you can choose whether or not to keep the subsequent transformation steps and add them separately to each data node. In the **Delete join** side panel, choose a node to deselect it and remove any subsequent transformation steps. You can leave both nodes selected to keep all transformation steps, or you can deselect both nodes to discard all transformation steps.

The following screenshot shows this step with only the second of two data nodes selected. When the join is successfully deleted, then the subsequent **Rename column** transform is only kept by the second data node.

5. Choose **Delete**.

The join or concatenate step should now be removed from your data flow.

## Perform exploratory data analysis (EDA)

Data Wrangler includes built-in analyses that help you generate visualizations and data analyses in a few clicks. You can also create custom analyses using your own code.

You add an analysis to a dataframe by selecting a step in your data flow, and then choosing **Add analysis**. To access an analysis you've created, select the step that contains the analysis, and select the analysis.

Analyses are generated using a sample of up to 200,000 rows of your dataset, and you can configure the sample size. For more information about changing the sample size of your data flow, see [Edit the data flow sampling configuration](#).

 **Note**

Analyses are optimized for data with 1000 or fewer columns. You may experience some latency when generating analyses for data with additional columns.

You can add the following analysis to a dataframe:

- Data visualizations, including histograms and scatter plots.
- A quick summary of your dataset, including number of entries, minimum and maximum values (for numeric data), and most and least frequent categories (for categorical data).
- A quick model of the dataset, which can be used to generate an importance score for each feature.
- A target leakage report, which you can use to determine if one or more features are strongly correlated with your target feature.
- A custom visualization using your own code.

Use the following sections to learn more about these options.

### Get insights on data and data quality

Use the **Data Quality and Insights Report** to perform an analysis of the data that you've imported into Data Wrangler. We recommend that you create the report after you import your dataset. You can use the report to help you clean and process your data. It gives you information such as the number of missing values and the number of outliers. If you have issues with your data, such as target leakage or imbalance, the insights report can bring those issues to your attention.

Use the following procedure to create a Data Quality and Insights report. It assumes that you've already imported a dataset into your Data Wrangler flow.

#### To create a Data Quality and Insights report

1. Choose the ellipsis icon next to a node in your Data Wrangler flow.

2. Select **Get data insights**.
3. For **Analysis type**, select **Data Quality and Insights Report**.
4. For **Analysis name**, specify a name for the insights report.
5. For **Problem type**, specify **Regression** or **Classification**.
6. For **Target column**, specify the target column.
7. For **Data size**, specify one of the following:
  - **Sampled dataset** – Uses the interactive sample from your data flow, which can contain up to 200,000 rows of your dataset. For information about how to edit the size of your sample, see [Edit the data flow sampling configuration](#).
  - **Full dataset** – Uses the full dataset from your data source to create the report.

 **Note**

Creating a Data Quality and Insights report on the full dataset uses an Amazon SageMaker processing job. A SageMaker Processing job provisions the additional compute resources required to get insights for all of your data. For more information about SageMaker Processing jobs, see [Data transformation workloads with SageMaker Processing](#).

8. Choose **Create**.

The following topics show the sections of the report:

### Topics

- [Summary](#)
- [Target column](#)
- [Quick model](#)
- [Feature summary](#)
- [Samples](#)
- [Definitions](#)

You can either download the report or view it online. To download the report, choose the download button at the top right corner of the screen.

## Summary

The insights report has a brief summary of the data that includes general information such as missing values, invalid values, feature types, outlier counts, and more. It can also include high severity warnings that point to probable issues with the data. We recommend that you investigate the warnings.

## Target column

When you create the Data Quality and Insights Report, Data Wrangler gives you the option to select a target column. A target column is a column that you're trying to predict. When you choose a target column, Data Wrangler automatically creates a target column analysis. It also ranks the features in the order of their predictive power. When you select a target column, you must specify whether you're trying to solve a regression or a classification problem.

For classification, Data Wrangler shows a table and a histogram of the most common classes. A class is a category. It also presents observations, or rows, with a missing or invalid target value.

For regression, Data Wrangler shows a histogram of all the values in the target column. It also presents observations, or rows, with a missing, invalid, or outlier target value.

## Quick model

The **Quick model** provides an estimate of the expected predicted quality of a model that you train on your data.

Data Wrangler splits your data into training and validation folds. It uses 80% of the samples for training and 20% of the values for validation. For classification, the sample is stratified split. For a stratified split, each data partition has the same ratio of labels. For classification problems, it's important to have the same ratio of labels between the training and classification folds. Data Wrangler trains the XGBoost model with the default hyperparameters. It applies early stopping on the validation data and performs minimal feature preprocessing.

For classification models, Data Wrangler returns both a model summary and a confusion matrix.

To learn more about the information that the classification model summary returns, see [Definitions](#).

A confusion matrix gives you the following information:

- The number of times the predicted label matches the true label.

- The number of times the predicted label doesn't match the true label.

The true label represents an actual observation in your data. For example, if you're using a model to detect fraudulent transactions, the true label represents a transaction that is actually fraudulent or non-fraudulent. The predicted label represents the label that your model assigns to the data.

You can use the confusion matrix to see how well the model predicts the presence or the absence of a condition. If you're predicting fraudulent transactions, you can use the confusion matrix to get a sense of both the sensitivity and the specificity of the model. The sensitivity refers to the model's ability to detect fraudulent transactions. The specificity refers to the model's ability to avoid detecting non-fraudulent transactions as fraudulent.

## Feature summary

When you specify a target column, Data Wrangler orders the features by their prediction power. Prediction power is measured on the data after it is split into 80% training and 20% validation folds. Data Wrangler fits a model for each feature separately on the training fold. It applies minimal feature preprocessing and measures prediction performance on the validation data.

It normalizes the scores to the range [0,1]. Higher prediction scores indicate columns that are more useful for predicting the target on their own. Lower scores point to columns that aren't predictive of the target column.

It's uncommon for a column that isn't predictive on its own to be predictive when it's used in tandem with other columns. You can confidently use the prediction scores to determine whether a feature in your dataset is predictive.

A low score usually indicates the feature is redundant. A score of 1 implies perfect predictive abilities, which often indicates target leakage. Target leakage usually happens when the dataset contains a column that isn't available at the prediction time. For example, it could be a duplicate of the target column.

## Samples

Data Wrangler provides information about whether your samples are anomalous or if there are duplicates in your dataset.

Data Wrangler detects anomalous samples using the *isolation forest algorithm*. The isolation forest associates an anomaly score with each sample (row) of the dataset. Low anomaly scores indicate

anomalous samples. High scores are associated with non-anomalous samples. Samples with a negative anomaly score are usually considered anomalous and samples with positive anomaly score are considered non-anomalous.

When you look at a sample that might be anomalous, we recommend that you pay attention to unusual values. For example, you might have anomalous values that result from errors in gathering and processing the data. The following is an example of the most anomalous samples according to the Data Wrangler's implementation of the isolation forest algorithm. We recommend using domain knowledge and business logic when you examine the anomalous samples.

Data Wrangler detects duplicate rows and calculates the ratio of duplicate rows in your data. Some data sources could include valid duplicates. Other data sources could have duplicates that point to problems in data collection. Duplicate samples that result from faulty data collection could interfere with machine learning processes that rely on splitting the data into independent training and validation folds.

The following are elements of the insights report that can be impacted by duplicated samples:

- Quick model
- Prediction power estimation
- Automatic hyperparameter tuning

You can remove duplicate samples from the dataset using the **Drop duplicates** transform under **Manage rows**. Data Wrangler shows you the most frequently duplicated rows.

## Definitions

The following are definitions for the technical terms that are used in the data insights report.

### Feature types

The following are the definitions for each of the feature types:

- **Numeric** – Numeric values can be either floats or integers, such as age or income. The machine learning models assume that numeric values are ordered and a distance is defined over them. For example, 3 is closer to 4 than to 10 and  $3 < 4 < 10$ .
- **Categorical** – The column entries belong to a set of unique values, which is usually much smaller than the number of entries in the column. For example, a column of length 100 could contain the unique values Dog, Cat, and Mouse. The values could be numeric, text, or a

combination of both. Horse, House, 8, Love, and 3.1 would all be valid values and could be found in the same categorical column. The machine learning model does not assume order or distance on the values of categorical features, as opposed to numeric features, even when all the values are numbers.

- **Binary** – Binary features are a special categorical feature type in which the cardinality of the set of unique values is 2.
- **Text** – A text column contains many non-numeric unique values. In extreme cases, all the elements of the column are unique. In an extreme case, no two entries are the same.
- **Datetime** – A datetime column contains information about the date or time. It can have information about both the date and time.

## Feature statistics

The following are definitions for each of the feature statistics:

- **Prediction power** – Prediction power measures how useful the column is in predicting the target.
- **Outliers** (in numeric columns) – Data Wrangler detects outliers using two statistics that are robust to outliers: median and robust standard deviation (RSTD). RSTD is derived by clipping the feature values to the range [5 percentile, 95 percentile] and calculating the standard deviation of the clipped vector. All values larger than  $\text{median} + 5 * \text{RSTD}$  or smaller than  $\text{median} - 5 * \text{RSTD}$  are considered to be outliers.
- **Skew** (in numeric columns) – Skew measures the symmetry of the distribution and is defined as the third moment of the distribution divided by the third power of the standard deviation. The skewness of the normal distribution or any other symmetric distribution is zero. Positive values imply that the right tail of the distribution is longer than the left tail. Negative values imply that the left tail of the distribution is longer than the right tail. As a rule of thumb, a distribution is considered skewed when the absolute value of the skew is larger than 3.
- **Kurtosis** (in numeric columns) – Pearson's kurtosis measures the heaviness of the tail of the distribution. It's defined as the fourth moment of the distribution divided by the square of the second moment. The kurtosis of the normal distribution is 3. Kurtosis values lower than 3 imply that the distribution is concentrated around the mean and the tails are lighter than the tails of the normal distribution. Kurtosis values higher than 3 imply heavier tails or outliers.
- **Missing values** – Null-like objects, empty strings and strings composed of only white spaces are considered missing.

- **Valid values for numeric features or regression target** – All values that you can cast to finite floats are valid. Missing values are not valid.
- **Valid values for categorical, binary, or text features, or for classification target** – All values that are not missing are valid.
- **Datetime features** – All values that you can cast to a datetime object are valid. Missing values are not valid.
- **Invalid values** – Values that are either missing or you can't properly cast. For example, in a numeric column, you can't cast the string "six" or a null value.

## Quick model metrics for regression

The following are the definitions for the quick model metrics:

- **R2 or coefficient of determination** – R2 is the proportion of the variation in the target that is predicted by the model. R2 is in the range of  $[-\infty, 1]$ . 1 is the score of the model that predicts the target perfectly and 0 is the score of the trivial model that always predicts the target mean.
- **MSE or mean squared error** – MSE is in the range  $[0, \infty]$ . 0 is the score of the model that predicts the target perfectly.
- **MAE or mean absolute error** – MAE is in the range  $[0, \infty]$  where 0 is the score of the model that predicts the target perfectly.
- **RMSE or root mean square error** – RMSE is in the range  $[0, \infty]$  where 0 is the score of the model that predicts the target perfectly.
- **Max error** – The maximum absolute value of the error over the dataset. Max error is in the range  $[0, \infty]$ . 0 is the score of the model that predicts the target perfectly.
- **Median absolute error** – Median absolute error is in the range  $[0, \infty]$ . 0 is the score of the model that predicts the target perfectly.

## Quick model metrics for classification

The following are the definitions for the quick model metrics:

- **Accuracy** – Accuracy is the ratio of samples that are predicted accurately. Accuracy is in the range  $[0, 1]$ . 0 is the score of the model that predicts all samples incorrectly and 1 is the score of the perfect model.

- **Balanced accuracy** – Balanced accuracy is the ratio of samples that are predicted accurately when the class weights are adjusted to balance the data. All classes are given the same importance, regardless of their frequency. Balanced accuracy is in the range [0, 1]. 0 is the score of the model that predicts all samples wrong. 1 is the score of the perfect model.
- **AUC (binary classification)** – This is the area under the receiver operating characteristic curve. AUC is in the range [0, 1] where a random model returns a score of 0.5 and the perfect model returns a score of 1.
- **AUC (OVR)** – For multiclass classification, this is the area under the receiver operating characteristic curve calculated separately for each label using one versus rest. Data Wrangler reports the average of the areas. AUC is in the range [0, 1] where a random model returns a score of 0.5 and the perfect model returns a score of 1.
- **Precision** – Precision is defined for a specific class. Precision is the fraction of true positives out of all the instances that the model classified as that class. Precision is in the range [0, 1]. 1 is the score of the model that has no false positives for the class. For binary classification, Data Wrangler reports the precision of the positive class.
- **Recall** – Recall is defined for a specific class. Recall is the fraction of the relevant class instances that are successfully retrieved. Recall is in the range [0, 1]. 1 is the score of the model that classifies all the instances of the class correctly. For binary classification, Data Wrangler reports the recall of the positive class.
- **F1** – F1 is defined for a specific class. It's the harmonic mean of the precision and recall. F1 is in the range [0, 1]. 1 is the score of the perfect model. For binary classification, Data Wrangler reports the F1 for classes with positive values.

## Textual patterns

**Patterns** describe the textual format of a string using an easy to read format. The following are examples of textual patterns:

- "{digits:4-7}" describes a sequence of digits that have a length between 4 and 7.
- "{alnum:5}" describes an alpha-numeric string with a length of exactly 5.

Data Wrangler infers the patterns by looking at samples of non-empty strings from your data. It can describe many of the commonly used patterns. The **confidence** expressed as a percentage indicates how much of the data is estimated to match the pattern. Using the textual pattern, you can see which rows in your data you need to correct or drop.

The following describes the patterns that Data Wrangler can recognize:

Pattern	Textual Format
{alnum}	Alphanumeric strings
{any}	Any string of word characters
{digits}	A sequence of digits
{lower}	A lowercase word
{mixed}	A mixed-case word
{name}	A word beginning with a capital letter
{upper}	An uppercase word
{whitespace}	Whitespace characters

A word character is either an underscore or a character that might appear in a word in any language. For example, the strings 'Hello\_word' and 'écoute' both consist of word characters. 'H' and 'é' are both examples of word characters.

## Bias report

SageMaker Canvas provides the bias report in Data Wrangler to help uncover potential biases in your data. The bias report analyzes the relationship between the target column (label) and a column that you believe might contain bias (facet variable). For example, if you are trying to predict customer conversion, the facet variable may be the age of the customer. The bias report can help you determine whether or not your data is biased toward a certain age group.

To generate a bias report in Canvas, do the following:

1. In your data flow in Data Wrangler, choose the **More options** icon (  ) next to a node in the flow.
2. From the context menu, choose **Get data insights**.

3. The **Create analysis** side panel opens. For the **Analysis type** dropdown menu, select **Bias Report**.
4. In the **Analysis name** field, enter a name for the bias report.
5. For the **Select the column your model predicts (target)** dropdown menu, select your target column.
6. For **Is your predicted column a value or threshold?**, select **Value** if your target column has categorical values or **Threshold** if it has numerical values.
7. For **Predicted value** (or **Predicted threshold**, depending on your selection in the previous step), enter the target column value or values that correspond to a positive outcome. For example, if predicting customer conversion, your value might be yes to indicate that a customer was converted.
8. For the **Select the column to analyze for bias** dropdown menu, select the column that you believe might contain bias, also known as the facet variable.
9. For **Is your column a value or threshold?**, select **Value** if the facet variable has categorical values or **Threshold** if it has numerical values.
10. For **Column value(s) to analyze for bias** (or **Column threshold to analyze for bias**, depending on your selection in the previous step), enter the value or values that you want to analyze for potential bias. For example, if you're checking for bias against customers over a certain age, use the beginning of that age range as your threshold.
11. For **Choose bias metrics**, select the bias metrics you'd like to include in your bias report. Hover over the info icons for more information about each metric.
12. (Optional) When prompted with the option **Would you like to analyze additional metrics?**, select **Yes** to view and include more bias metrics.
13. When you're ready to create the bias report, choose **Add**.

Once generated, the report gives you an overview of the bias metrics you selected. You can view the bias report at any time from the **Analyses** tab of your data flow.

## Histogram

Use histograms to see the counts of feature values for a specific feature. You can inspect the relationships between features using the **Color by** option.

You can use the **Facet by** feature to create histograms of one column, for each value in another column.

## Scatter plot

Use the **Scatter Plot** feature to inspect the relationship between features. To create a scatter plot, select a feature to plot on the **X axis** and the **Y axis**. Both of these columns must be numeric typed columns.

You can color scatter plots by an additional column.

Additionally, you can facet scatter plots by features.

## Table summary

Use the **Table Summary** analysis to quickly summarize your data.

For columns with numerical data, including log and float data, a table summary reports the number of entries (count), minimum (min), maximum (max), mean, and standard deviation (stddev) for each column.

For columns with non-numerical data, including columns with string, Boolean, or date/time data, a table summary reports the number of entries (count), least frequent value (min), and most frequent value (max).

## Quick model

Use the **Quick Model** visualization to quickly evaluate your data and produce importance scores for each feature. A [feature importance score](#) score indicates how useful a feature is at predicting a target label. The feature importance score is between [0, 1] and a higher number indicates that the feature is more important to the whole dataset. On the top of the quick model chart, there is a model score. A classification problem shows an F1 score. A regression problem has a mean squared error (MSE) score.

When you create a quick model chart, you select a dataset you want evaluated, and a target label against which you want feature importance to be compared. Data Wrangler does the following:

- Infers the data types for the target label and each feature in the dataset selected.
- Determines the problem type. Based on the number of distinct values in the label column, Data Wrangler determines if this is a regression or classification problem type. Data Wrangler sets a categorical threshold to 100. If there are more than 100 distinct values in the label column, Data Wrangler classifies it as a regression problem; otherwise, it is classified as a classification problem.

- Pre-processes features and label data for training. The algorithm used requires encoding features to vector type and encoding labels to double type.
- Trains a random forest algorithm with 70% of data. Spark's [RandomForestRegressor](#) is used to train a model for regression problems. The [RandomForestClassifier](#) is used to train a model for classification problems.
- Evaluates a random forest model with the remaining 30% of data. Data Wrangler evaluates classification models using an F1 score and evaluates regression models using an MSE score.
- Calculates feature importance for each feature using the Gini importance method.

## Target leakage

Target leakage occurs when there is data in a machine learning training dataset that is strongly correlated with the target label, but is not available in real-world data. For example, you may have a column in your dataset that serves as a proxy for the column you want to predict with your model.

When you use the **Target Leakage** analysis, you specify the following:

- **Target:** This is the feature about which you want your ML model to be able to make predictions.
- **Problem type:** This is the ML problem type on which you are working. Problem type can either be **classification** or **regression**.
- (Optional) **Max features:** This is the maximum number of features to present in the visualization, which shows features ranked by their risk of being target leakage.

For classification, the target leakage analysis uses the area under the receiver operating characteristic, or AUC - ROC curve for each column, up to **Max features**. For regression, it uses a coefficient of determination, or R2 metric.

The AUC - ROC curve provides a predictive metric, computed individually for each column using cross-validation, on a sample of up to around 1000 rows. A score of 1 indicates perfect predictive abilities, which often indicates target leakage. A score of 0.5 or lower indicates that the information on the column could not provide, on its own, any useful information towards predicting the target. Although it can happen that a column is uninformative on its own but is useful in predicting the target when used in tandem with other features, a low score could indicate the feature is redundant.

## Multicollinearity

Multicollinearity is a circumstance where two or more predictor variables are related to each other. The predictor variables are the features in your dataset that you're using to predict a target variable. When you have multicollinearity, the predictor variables are not only predictive of the target variable, but also predictive of each other.

You can use the **Variance Inflation Factor (VIF)**, **Principal Component Analysis (PCA)**, or **Lasso feature selection** as measures for the multicollinearity in your data. For more information, see the following.

### Variance Inflation Factor (VIF)

The Variance Inflation Factor (VIF) is a measure of collinearity among variable pairs. Data Wrangler returns a VIF score as a measure of how closely the variables are related to each other. A VIF score is a positive number that is greater than or equal to 1.

A score of 1 means that the variable is uncorrelated with the other variables. Scores greater than 1 indicate higher correlation.

Theoretically, you can have a VIF score with a value of infinity. Data Wrangler clips high scores to 50. If you have a VIF score greater than 50, Data Wrangler sets the score to 50.

You can use the following guidelines to interpret your VIF scores:

- A VIF score less than or equal to 5 indicates that the variables are moderately correlated with the other variables.
- A VIF score greater than or equal to 5 indicates that the variables are highly correlated with the other variables.

### Principle Component Analysis (PCA)

Principal Component Analysis (PCA) measures the variance of the data along different directions in the feature space. The feature space consists of all the predictor variables that you use to predict the target variable in your dataset.

For example, if you're trying to predict who survived on the *RMS Titanic* after it hit an iceberg, your feature space can include the passengers' age, gender, and the fare that they paid.

From the feature space, PCA generates an ordered list of variances. These variances are also known as singular values. The values in the list of variances are greater than or equal to 0. We can use them to determine how much multicollinearity there is in our data.

When the numbers are roughly uniform, the data has very few instances of multicollinearity. When there is a lot of variability among the values, we have many instances of multicollinearity. Before it performs PCA, Data Wrangler normalizes each feature to have a mean of 0 and a standard deviation of 1.

 **Note**

PCA in this circumstance can also be referred to as Singular Value Decomposition (SVD).

## Lasso feature selection

Lasso feature selection uses the L1 regularization technique to only include the most predictive features in your dataset.

For both classification and regression, the regularization technique generates a coefficient for each feature. The absolute value of the coefficient provides an importance score for the feature. A higher importance score indicates that it is more predictive of the target variable. A common feature selection method is to use all the features that have a non-zero lasso coefficient.

## Detect anomalies in time series data

You can use the anomaly detection visualization to see outliers in your time series data. To understand what determines an anomaly, you need to understand that we decompose the time series into a predicted term and an error term. We treat the seasonality and trend of the time series as the predicted term. We treat the residuals as the error term.

For the error term, you specify a threshold as the number of standard of deviations the residual can be away from the mean for it to be considered an anomaly. For example, you can specify a threshold as being 3 standard deviations. Any residual greater than 3 standard deviations away from the mean is an anomaly.

You can use the following procedure to perform an **Anomaly detection** analysis.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add analysis**.

3. For **Analysis type**, choose **Time Series**.
4. For **Visualization**, choose **Anomaly detection**.
5. For **Anomaly threshold**, choose the threshold that a value is considered an anomaly.
6. Choose **Preview** to generate a preview of the analysis.
7. Choose **Add** to add the transform to the Data Wrangler data flow.

### Seasonal trend decomposition in time series data

You can determine whether there's seasonality in your time series data by using the Seasonal Trend Decomposition visualization. We use the STL (Seasonal Trend decomposition using LOESS) method to perform the decomposition. We decompose the time series into its seasonal, trend, and residual components. The trend reflects the long term progression of the series. The seasonal component is a signal that recurs in a time period. After removing the trend and the seasonal components from the time series, you have the residual.

You can use the following procedure to perform a **Seasonal-Trend decomposition** analysis.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add analysis**.
3. For **Analysis type**, choose **Time Series**.
4. For **Visualization**, choose **Seasonal-Trend decomposition**.
5. For **Anomaly threshold**, choose the threshold that a value is considered an anomaly.
6. Choose **Preview** to generate a preview of the analysis.
7. Choose **Add** to add the transform to the Data Wrangler data flow.

### Create custom visualizations

You can add an analysis to your Data Wrangler flow to create a custom visualization. Your dataset, with all the transformations you've applied, is available as a [Pandas DataFrame](#). Data Wrangler uses the `df` variable to store the dataframe. You access the dataframe by calling the variable.

You must provide the output variable, `chart`, to store an [Altair](#) output chart. For example, you can use the following code block to create a custom histogram using the Titanic dataset.

```
import altair as alt
df = df.iloc[:30]
```

```
df = df.rename(columns={"Age": "value"})
df = df.assign(count=df.groupby('value').value.transform('count'))
df = df[["value", "count"]]
base = alt.Chart(df)
bar = base.mark_bar().encode(x=alt.X('value', bin=True, axis=None), y=alt.Y('count'))
rule = base.mark_rule(color='red').encode(
    x='mean(value):Q',
    size=alt.value(5))
chart = bar + rule
```

### To create a custom visualization:

1. Next to the node containing the transformation that you'd like to visualize, choose the **+**.
2. Choose **Add analysis**.
3. For **Analysis type**, choose **Custom Visualization**.
4. For **Analysis name**, specify a name.
5. Enter your code in the code box.
6. Choose **Preview** to preview your visualization.
7. Choose **Save** to add your visualization.

If you don't know how to use the Altair visualization package in Python, you can use custom code snippets to help you get started.

Data Wrangler has a searchable collection of visualization snippets. To use a visualization snippet, choose **Search example snippets** and specify a query in the search bar.

The following example uses the **Binned scatterplot** code snippet. It plots a histogram for 2 dimensions.

The snippets have comments to help you understand the changes that you need to make to the code. You usually need to specify the column names of your dataset in the code.

```
import altair as alt

# Specify the number of top rows for plotting
rows_number = 1000
df = df.head(rows_number)
# You can also choose bottom rows or randomly sampled rows
```

```
# df = df.tail(rows_number)
# df = df.sample(rows_number)

chart = (
  alt.Chart(df)
  .mark_circle()
  .encode(
    # Specify the column names for binning and number of bins for X and Y axis
    x=alt.X("col1:Q", bin=alt.Bin(maxbins=20)),
    y=alt.Y("col2:Q", bin=alt.Bin(maxbins=20)),
    size="count()",
  )
)

# :Q specifies that label column has quantitative type.
# For more details on Altair typing refer to
# https://altair-viz.github.io/user_guide/encoding.html#encoding-data-types
```

## Transform data

Amazon SageMaker Data Wrangler provides numerous ML data transforms to streamline cleaning and featurizing your data. Using the interactive data preparation tools in Data Wrangler, you can sample datasets of any size with a variety of sampling techniques and start exploring your data in a matter of minutes. After finalizing your data transforms on the sampled data, you can then scale the data flow to apply those transformations to the entire dataset.

When you add a transform, it adds a step to the data flow. Each transform you add modifies your dataset and produces a new dataframe. All subsequent transforms apply to the resulting dataframe.

Data Wrangler includes built-in transforms, which you can use to transform columns without any code. If you know how you want to prepare your data but don't know how to get started or which transforms to use, you can use the chat for data prep feature to interact conversationally with Data Wrangler and apply transforms using natural language. For more information, see [Chat for data prep](#).

You can also add custom transformations using PySpark, Python (User-Defined Function), pandas, and PySpark SQL. Some transforms operate in place, while others create a new output column in your dataset.

You can apply transforms to multiple columns at once. For example, you can delete multiple columns in a single step.

You can apply the **Process numeric** and **Handle missing** transforms only to a single column.

Use this page to learn more about the built-in and custom transforms offered by Data Wrangler.

## Join Datasets

You can join datasets directly in your data flow. When you join two datasets, the resulting joined dataset appears in your flow. The following join types are supported by Data Wrangler.

- **Left outer** – Include all rows from the left table. If the value for the column joined on a left table row does not match any right table row values, that row contains null values for all right table columns in the joined table.
- **Left anti** – Include rows from the left table that do not contain values in the right table for the joined column.
- **Left semi** – Include a single row from the left table for all identical rows that satisfy the criteria in the join statement. This excludes duplicate rows from the left table that match the criteria of the join.
- **Right outer** – Include all rows from the right table. If the value for the joined column in a right table row does not match any left table row values, that row contains null values for all left table columns in the joined table.
- **Inner** – Include rows from left and right tables that contain matching values in the joined column.
- **Full outer** – Include all rows from the left and right tables. If the row value for the joined column in either table does not match, separate rows are created in the joined table. If a row doesn't contain a value for a column in the joined table, null is inserted for that column.
- **Cartesian cross** – Include rows which combine each row from the first table with each row from the second table. This is a [Cartesian product](#) of rows from tables in the join. The result of this product is the size of the left table times the size of the right table. Therefore, we recommend caution in using this join between very large datasets.

Use the following procedure to join two datasets. You should have already imported two data sources into your data flow.

1. Select the **More options** icon (  ) next to the left node that you want to join. The first node you select is always the left table in your join.
2. Hover over **Combine data**, and then choose **Join**.
3. Select the right node. The second node you select is always the right table in your join.
4. The **Join type** field is set to **Inner join** by default. Select the dropdown menu to change the join type.
5. For **Join keys**, verify the columns from the left and right tables that you want to use to join the data. You can add or remove additional join keys.
6. For **Name of join**, enter a name for the joined data, or use the default name.
7. (Optional) Choose **Preview** to preview the joined data.
8. Choose **Add** to complete the join.

#### Note

If you receive a notice that Canvas didn't identify any matching rows when joining your data, we recommend that you either verify that you've selected the correct columns, or update your sample to try to find matching rows. You can choose a different sampling strategy or change the size of the sample. For information about how to edit the sample, see [Edit the data flow sampling configuration](#).

You should now see a join node added to your data flow.

## Concatenate Datasets

Concatenating combines two datasets by appending the rows from one dataset to another.

Use the following procedure to concatenate two datasets. You should have already imported two data sources into your data flow.

### To concatenate two datasets:

1. Select the **More options** icon (  )

next to the left node that you want to concatenate. The first node you select is always the left table in your concatenate operation.

2. Hover over **Combine data**, and then choose **Concatenate**.
3. Select the right node. The second node you select is always the right table in your concatenate.
4. (Optional) Select the checkbox next to **Remove duplicates after concatenation** to remove duplicate columns.
5. (Optional) Select the checkbox next to **Add column to indicate source dataframe** to add a column to the resulting dataframe that lists the source dataset for each record.
  - a. For **Indicator column name**, enter a name for the added column.
  - b. For **First dataset indicating string**, enter the value you want to use to mark records from the first dataset (or the left node).
  - c. For **Second dataset indicating string**, enter the value you want to use to mark records from the second dataset (or the right node).
6. For **Name of concatenate**, enter a name for the concatenation.
7. (Optional) Choose **Preview** to preview the concatenated data.
8. Choose **Add** to add the new dataset to your data flow.

You should now see a concatenate node added to your data flow.

## Balance Data

You can balance the data for datasets with an underrepresented category. Balancing a dataset can help you create better models for binary classification.

### Note

You can't balance datasets containing column vectors.

You can use the **Balance data** operation to balance your data using one of the following operators:

- *Random oversampling* – Randomly duplicates samples in the minority category. For example, if you're trying to detect fraud, you might only have cases of fraud in 10% of your data. For an equal proportion of fraudulent and non-fraudulent cases, this operator randomly duplicates fraud cases within the dataset 8 times.

- *Random undersampling* – Roughly equivalent to random oversampling. Randomly removes samples from the overrepresented category to get the proportion of samples that you desire.
- *Synthetic Minority Oversampling Technique (SMOTE)* – Uses samples from the underrepresented category to interpolate new synthetic minority samples. For more information about SMOTE, see the following description.

You can use all transforms for datasets containing both numeric and non-numeric features. SMOTE interpolates values by using neighboring samples. Data Wrangler uses the R-squared distance to determine the neighborhood to interpolate the additional samples. Data Wrangler only uses numeric features to calculate the distances between samples in the underrepresented group.

For two real samples in the underrepresented group, Data Wrangler interpolates the numeric features by using a weighted average. It randomly assigns weights to those samples in the range of [0, 1]. For numeric features, Data Wrangler interpolates samples using a weighted average of the samples. For samples A and B, Data Wrangler could randomly assign a weight of 0.7 to A and 0.3 to B. The interpolated sample has a value of  $0.7A + 0.3B$ .

Data Wrangler interpolates non-numeric features by copying from either of the interpolated real samples. It copies the samples with a probability that it randomly assigns to each sample. For samples A and B, it can assign probabilities 0.8 to A and 0.2 to B. For the probabilities it assigned, it copies A 80% of the time.

## Custom Transforms

The **Custom Transforms** group allows you to use Python (User-Defined Function), PySpark, pandas, or PySpark (SQL) to define custom transformations. For all three options, you use the variable `df` to access the dataframe to which you want to apply the transform. To apply your custom code to your dataframe, assign the dataframe with the transformations that you've made to the `df` variable. If you're not using Python (User-Defined Function), you don't need to include a return statement. Choose **Preview** to preview the result of the custom transform. Choose **Add** to add the custom transform to your list of **Previous steps**.

You can import the popular libraries with an `import` statement in the custom transform code block, such as the following:

- NumPy version 1.19.0
- scikit-learn version 0.23.2
- SciPy version 1.5.4

- pandas version 1.0.3
- PySpark version 3.0.0

### Important

**Custom transform** doesn't support columns with spaces or special characters in the name. We recommend that you specify column names that only have alphanumeric characters and underscores. You can use the **Rename column** transform in the **Manage columns** transform group to remove spaces from a column's name. You can also add a **Python (Pandas) Custom transform** similar to the following to remove spaces from multiple columns in a single step. This example changes columns named `A column` and `B column` to `A_column` and `B_column` respectively.

```
df.rename(columns={"A column": "A_column", "B column": "B_column"})
```

If you include print statements in the code block, the result appears when you select **Preview**. You can resize the custom code transformer panel. Resizing the panel provides more space to write code.

The following sections provide additional context and examples for writing custom transform code.

### Python (User-Defined Function)

The Python function gives you the ability to write custom transformations without needing to know Apache Spark or pandas. Data Wrangler is optimized to run your custom code quickly. You get similar performance using custom Python code and an Apache Spark plugin.

To use the Python (User-Defined Function) code block, you specify the following:

- **Input column** – The input column where you're applying the transform.
- **Mode** – The scripting mode, either pandas or Python.
- **Return type** – The data type of the value that you're returning.

Using the pandas mode gives better performance. The Python mode makes it easier for you to write transformations by using pure Python functions.

## PySpark

The following example extracts date and time from a timestamp.

```
from pyspark.sql.functions import from_unixtime, to_date, date_format
df = df.withColumn('DATE_TIME', from_unixtime('TIMESTAMP'))
df = df.withColumn('EVENT_DATE', to_date('DATE_TIME')).withColumn(
    'EVENT_TIME', date_format('DATE_TIME', 'HH:mm:ss'))
```

## pandas

The following example provides an overview of the dataframe to which you are adding transforms.

```
df.info()
```

## PySpark (SQL)

The following example creates a new dataframe with four columns: *name*, *fare*, *pclass*, *survived*.

```
SELECT name, fare, pclass, survived FROM df
```

If you don't know how to use PySpark, you can use custom code snippets to help you get started.

Data Wrangler has a searchable collection of code snippets. You can use to code snippets to perform tasks such as dropping columns, grouping by columns, or modelling.

To use a code snippet, choose **Search example snippets** and specify a query in the search bar. The text you specify in the query doesn't have to match the name of the code snippet exactly.

The following example shows a **Drop duplicate rows** code snippet that can delete rows with similar data in your dataset. You can find the code snippet by searching for one of the following:

- Duplicates
- Identical
- Remove

The following snippet has comments to help you understand the changes that you need to make. For most snippets, you must specify the column names of your dataset in the code.

```
# Specify the subset of columns
# all rows having identical values in these columns will be dropped

subset = ["col1", "col2", "col3"]
df = df.dropDuplicates(subset)

# to drop the full-duplicate rows run
# df = df.dropDuplicates()
```

To use a snippet, copy and paste its content into the **Custom transform** field. You can copy and paste multiple code snippets into the custom transform field.

### Custom Formula

Use **Custom formula** to define a new column using a Spark SQL expression to query data in the current dataframe. The query must use the conventions of Spark SQL expressions.

#### Important

**Custom formula** doesn't support columns with spaces or special characters in the name. We recommend that you specify column names that only have alphanumeric characters and underscores. You can use the **Rename column** transform in the **Manage columns** transform group to remove spaces from a column's name. You can also add a **Python (Pandas) Custom transform** similar to the following to remove spaces from multiple columns in a single step. This example changes columns named `A column` and `B column` to `A_column` and `B_column` respectively.

```
df.rename(columns={"A column": "A_column", "B column": "B_column"})
```

You can use this transform to perform operations on columns, referencing the columns by name. For example, assuming the current dataframe contains columns named `col_a` and `col_b`, you can use the following operation to produce an **Output column** that is the product of these two columns with the following code:

```
col_a * col_b
```

Other common operations include the following, assuming a dataframe contains `col_a` and `col_b` columns:

- Concatenate two columns: `concat(col_a, col_b)`
- Add two columns: `col_a + col_b`
- Subtract two columns: `col_a - col_b`
- Divide two columns: `col_a / col_b`
- Take the absolute value of a column: `abs(col_a)`

For more information, see the [Spark documentation](#) on selecting data.

## Reduce Dimensionality within a Dataset

Reduce the dimensionality in your data by using Principal Component Analysis (PCA). The dimensionality of your dataset corresponds to the number of features. When you use dimensionality reduction in Data Wrangler, you get a new set of features called components. Each component accounts for some variability in the data.

The first component accounts for the largest amount of variation in the data. The second component accounts for the second largest amount of variation in the data, and so on.

You can use dimensionality reduction to reduce the size of the data sets that you use to train models. Instead of using the features in your dataset, you can use the principal components instead.

To perform PCA, Data Wrangler creates axes for your data. An axis is an affine combination of columns in your dataset. The first principal component is the value on the axis that has the largest amount of variance. The second principal component is the value on the axis that has the second largest amount of variance. The *n*th principal component is the value on the axis that has the *n*th largest amount of variance.

You can configure the number of principal components that Data Wrangler returns. You can either specify the number of principal components directly or you can specify the variance threshold percentage. Each principal component explains an amount of variance in the data. For example, you might have a principal component with a value of 0.5. The component would explain 50% of the variation in the data. When you specify a variance threshold percentage, Data Wrangler returns the smallest number of components that meet the percentage that you specify.

The following are example principal components with the amount of variance that they explain in the data.

- Component 1 – 0.5
- Component 2 – 0.45
- Component 3 – 0.05

If you specify a variance threshold percentage of 94 or 95, Data Wrangler returns Component 1 and Component 2. If you specify a variance threshold percentage of 96, Data Wrangler returns all three principal components.

You can use the following procedure to run PCA on your dataset.

To run PCA on your dataset, do the following.

1. Open your Data Wrangler data flow.
2. Choose the **+**, and select **Add transform**.
3. Choose **Add step**.
4. Choose **Dimensionality Reduction**.
5. For **Input Columns**, choose the features that you're reducing into the principal components.
6. (Optional) For **Number of principal components**, choose the number of principal components that Data Wrangler returns in your dataset. If you specify a value for the field, you can't specify a value for **Variance threshold percentage**.
7. (Optional) For **Variance threshold percentage**, specify the percentage of variation in the data that you want explained by the principal components. Data Wrangler uses the default value of 95 if you don't specify a value for the variance threshold. You can't specify a variance threshold percentage if you've specified a value for **Number of principal components**.
8. (Optional) Deselect **Center** to not use the mean of the columns as the center of the data. By default, Data Wrangler centers the data with the mean before scaling.
9. (Optional) Deselect **Scale** to not scale the data with the unit standard deviation.
10. (Optional) Choose **Columns** to output the components to separate columns. Choose **Vector** to output the components as a single vector.
11. (Optional) For **Output column**, specify a name for an output column. If you're outputting the components to separate columns, the name that you specify is a prefix. If you're outputting the components to a vector, the name that you specify is the name of the vector column.

12. (Optional) Select **Keep input columns**. We don't recommend selecting this option if you plan on only using the principal components to train your model.
13. Choose **Preview**.
14. Choose **Add**.

## Encode Categorical

Categorical data is usually composed of a finite number of categories, where each category is represented with a string. For example, if you have a table of customer data, a column that indicates the country a person lives in is categorical. The categories would be *Afghanistan*, *Albania*, *Algeria*, and so on. Categorical data can be *nominal* or *ordinal*. Ordinal categories have an inherent order, and nominal categories do not. The highest degree obtained (*High school*, *Bachelors*, *Masters*, and so on) is an example of ordinal categories.

Encoding categorical data is the process of creating a numerical representation for categories. For example, if your categories are *Dog* and *Cat*, you may encode this information into two vectors,  $[1, 0]$  to represent *Dog*, and  $[0, 1]$  to represent *Cat*.

When you encode ordinal categories, you may need to translate the natural order of categories into your encoding. For example, you can represent the highest degree obtained with the following map: `{"High school": 1, "Bachelors": 2, "Masters":3}`.

Use categorical encoding to encode categorical data that is in string format into arrays of integers.

The Data Wrangler categorical encoders create encodings for all categories that exist in a column at the time the step is defined. If new categories have been added to a column when you start a Data Wrangler job to process your dataset at time  $t$ , and this column was the input for a Data Wrangler categorical encoding transform at time  $t-1$ , these new categories are considered *missing* in the Data Wrangler job. The option you select for **Invalid handling strategy** is applied to these missing values. Examples of when this can occur are:

- When you use a .flow file to create a Data Wrangler job to process a dataset that was updated after the creation of the data flow. For example, you may use a data flow to regularly process sales data each month. If that sales data is updated weekly, new categories may be introduced into columns for which an encode categorical step is defined.
- When you select **Sampling** when you import your dataset, some categories may be left out of the sample.

In these situations, these new categories are considered missing values in the Data Wrangler job.

You can choose from and configure an *ordinal* and a *one-hot encode*. Use the following sections to learn more about these options.

Both transforms create a new column named **Output column name**. You specify the output format of this column with **Output style**:

- Select **Vector** to produce a single column with a sparse vector.
- Select **Columns** to create a column for every category with an indicator variable for whether the text in the original column contains a value that is equal to that category.

## Ordinal Encode

Select **Ordinal encode** to encode categories into an integer between 0 and the total number of categories in the **Input column** you select.

**Invalid handing strategy:** Select a method to handle invalid or missing values.

- Choose **Skip** if you want to omit the rows with missing values.
- Choose **Keep** to retain missing values as the last category.
- Choose **Error** if you want Data Wrangler to throw an error if missing values are encountered in the **Input column**.
- Choose **Replace with NaN** to replace missing with NaN. This option is recommended if your ML algorithm can handle missing values. Otherwise, the first three options in this list may produce better results.

## One-Hot Encode

Select **One-hot encode** for **Transform** to use one-hot encoding. Configure this transform using the following:

- **Drop last category:** If `True`, the last category does not have a corresponding index in the one-hot encoding. When missing values are possible, a missing category is always the last one and setting this to `True` means that a missing value results in an all zero vector.
- **Invalid handing strategy:** Select a method to handle invalid or missing values.
  - Choose **Skip** if you want to omit the rows with missing values.

- Choose **Keep** to retain missing values as the last category.
- Choose **Error** if you want Data Wrangler to throw an error if missing values are encountered in the **Input column**.
- **Is input ordinal encoded:** Select this option if the input vector contains ordinal encoded data. This option requires that input data contain non-negative integers. If **True**, input  $i$  is encoded as a vector with a non-zero in the  $i$ th location.

## Similarity encode

Use similarity encoding when you have the following:

- A large number of categorical variables
- Noisy data

The similarity encoder creates embeddings for columns with categorical data. An embedding is a mapping of discrete objects, such as words, to vectors of real numbers. It encodes similar strings to vectors containing similar values. For example, it creates very similar encodings for "California" and "California".

Data Wrangler converts each category in your dataset into a set of tokens using a 3-gram tokenizer. It converts the tokens into an embedding using min-hash encoding.

The similarity encodings that Data Wrangler creates:

- Have low dimensionality
- Are scalable to a large number of categories
- Are robust and resistant to noise

For the preceding reasons, similarity encoding is more versatile than one-hot encoding.

To add the similarity encoding transform to your dataset, use the following procedure.

To use similarity encoding, do the following.

1. Sign in to the [Amazon SageMaker AI Console](#).
2. Choose **Open Studio Classic**.
3. Choose **Launch app**.

4. Choose **Studio**.
5. Specify your data flow.
6. Choose a step with a transformation.
7. Choose **Add step**.
8. Choose **Encode categorical**.
9. Specify the following:
  - **Transform – Similarity encode**
  - **Input column** – The column containing the categorical data that you're encoding.
  - **Target dimension** – (Optional) The dimension of the categorical embedding vector. The default value is 30. We recommend using a larger target dimension if you have a large dataset with many categories.
  - **Output style** – Choose **Vector** for a single vector with all of the encoded values. Choose **Column** to have the encoded values in separate columns.
  - **Output column** – (Optional) The name of the output column for a vector encoded output. For a column-encoded output, this is the prefix of the column names followed by listed number.

## Featurize Text

Use the **Featurize Text** transform group to inspect string-typed columns and use text embedding to featurize these columns.

This feature group contains two features, *Character statistics* and *Vectorize*. Use the following sections to learn more about these transforms. For both options, the **Input column** must contain text data (string type).

### Character Statistics

Use **Character statistics** to generate statistics for each row in a column containing text data.

This transform computes the following ratios and counts for each row, and creates a new column to report the result. The new column is named using the input column name as a prefix and a suffix that is specific to the ratio or count.

- **Number of words:** The total number of words in that row. The suffix for this output column is - stats\_word\_count.

- **Number of characters:** The total number of characters in that row. The suffix for this output column is `-stats_char_count`.
- **Ratio of upper:** The number of uppercase characters, from A to Z, divided by all characters in the column. The suffix for this output column is `-stats_capital_ratio`.
- **Ratio of lower:** The number of lowercase characters, from a to z, divided by all characters in the column. The suffix for this output column is `-stats_lower_ratio`.
- **Ratio of digits:** The ratio of digits in a single row over the sum of digits in the input column. The suffix for this output column is `-stats_digit_ratio`.
- **Special characters ratio:** The ratio of non-alphanumeric (characters like `#$%:@`) characters to over the sum of all characters in the input column. The suffix for this output column is `-stats_special_ratio`.

## Vectorize

Text embedding involves mapping words or phrases from a vocabulary to vectors of real numbers. Use the Data Wrangler text embedding transform to tokenize and vectorize text data into term frequency–inverse document frequency (TF-IDF) vectors.

When TF-IDF is calculated for a column of text data, each word in each sentence is converted to a real number that represents its semantic importance. Higher numbers are associated with less frequent words, which tend to be more meaningful.

When you define a **Vectorize** transform step, Data Wrangler uses the data in your dataset to define the count vectorizer and TF-IDF methods . Running a Data Wrangler job uses these same methods.

You configure this transform using the following:

- **Output column name:** This transform creates a new column with the text embedding. Use this field to specify a name for this output column.
- **Tokenizer:** A tokenizer converts the sentence into a list of words, or *tokens*.

Choose **Standard** to use a tokenizer that splits by white space and converts each word to lowercase. For example, "Good dog" is tokenized to ["good", "dog"].

Choose **Custom** to use a customized tokenizer. If you choose **Custom**, you can use the following fields to configure the tokenizer:

- **Minimum token length:** The minimum length, in characters, for a token to be valid. Defaults to 1. For example, if you specify 3 for minimum token length, words like `a`, `at`, `in` are dropped from the tokenized sentence.
- **Should regex split on gaps:** If selected, `regex` splits on gaps. Otherwise, it matches tokens. Defaults to `True`.
- **Regex pattern:** Regex pattern that defines the tokenization process. Defaults to `' \\s+'`.
- **To lowercase:** If chosen, Data Wrangler converts all characters to lowercase before tokenization. Defaults to `True`.

To learn more, see the Spark documentation on [Tokenizer](#).

- **Vectorizer:** The vectorizer converts the list of tokens into a sparse numeric vector. Each token corresponds to an index in the vector and a non-zero indicates the existence of the token in the input sentence. You can choose from two vectorizer options, *Count* and *Hashing*.
- **Count vectorize** allows customizations that filter infrequent or too common tokens. **Count vectorize parameters** include the following:
  - **Minimum term frequency:** In each row, terms (tokens) with smaller frequency are filtered. If you specify an integer, this is an absolute threshold (inclusive). If you specify a fraction between 0 (inclusive) and 1, the threshold is relative to the total term count. Defaults to 1.
  - **Minimum document frequency:** Minimum number of rows in which a term (token) must appear to be included. If you specify an integer, this is an absolute threshold (inclusive). If you specify a fraction between 0 (inclusive) and 1, the threshold is relative to the total term count. Defaults to 1.
  - **Maximum document frequency:** Maximum number of documents (rows) in which a term (token) can appear to be included. If you specify an integer, this is an absolute threshold (inclusive). If you specify a fraction between 0 (inclusive) and 1, the threshold is relative to the total term count. Defaults to `0.999`.
  - **Maximum vocabulary size:** Maximum size of the vocabulary. The vocabulary is made up of all terms (tokens) in all rows of the column. Defaults to 262144.
  - **Binary outputs:** If selected, the vector outputs do not include the number of appearances of a term in a document, but rather are a binary indicator of its appearance. Defaults to `False`.

To learn more about this option, see the Spark documentation on [CountVectorizer](#).

- **Hashing** is computationally faster. **Hash vectorize parameters** includes the following:

- **Number of features during hashing:** A hash vectorizer maps tokens to a vector index according to their hash value. This feature determines the number of possible hash values. Large values result in fewer collisions between hash values but a higher dimension output vector.

To learn more about this option, see the Spark documentation on [FeatureHasher](#)

- **Apply IDF** applies an IDF transformation, which multiplies the term frequency with the standard inverse document frequency used for TF-IDF embedding. **IDF parameters** include the following:
  - **Minimum document frequency** : Minimum number of documents (rows) in which a term (token) must appear to be included. If **count\_vectorize** is the chosen vectorizer, we recommend that you keep the default value and only modify the **min\_doc\_freq** field in **Count vectorize parameters**. Defaults to 5.
- **Output format:**The output format of each row.
  - Select **Vector** to produce a single column with a sparse vector.
  - Select **Flattened** to create a column for every category with an indicator variable for whether the text in the original column contains a value that is equal to that category. You can only choose flattened when **Vectorizer** is set as **Count vectorizer**.

## Transform Time Series

In Data Wrangler, you can transform time series data. The values in a time series dataset are indexed to specific time. For example, a dataset that shows the number of customers in a store for each hour in a day is a time series dataset. The following table shows an example of a time series dataset.

Hourly number of customers in a store

Number of customers	Time (hour)
4	09:00
10	10:00
14	11:00
25	12:00

Number of customers	Time (hour)
20	13:00
18	14:00

For the preceding table, the **Number of Customers** column contains the time series data. The time series data is indexed on the hourly data in the **Time (hour)** column.

You might need to perform a series of transformations on your data to get it in a format that you can use for your analysis. Use the **Time series** transform group to transform your time series data. For more information about the transformations that you can perform, see the following sections.

## Topics

## Group by a Time Series

You can use the group by operation to group time series data for specific values in a column.

For example, you have the following table that tracks the average daily electricity usage in a household.

Average daily household electricity usage

Household ID	Daily timestamp	Electricity usage (kWh)	Number of household occupants
household_0	1/1/2020	30	2
household_0	1/2/2020	40	2
household_0	1/4/2020	35	3
household_1	1/2/2020	45	3
household_1	1/3/2020	55	4

If you choose to group by ID, you get the following table.

Electricity usage grouped by household ID

Household ID	Electricity usage series (kWh)	Number of household occupants series
household_0	[30, 40, 35]	[2, 2, 3]
household_1	[45, 55]	[3, 4]

Each entry in the time series sequence is ordered by the corresponding timestamp. The first element of the sequence corresponds to the first timestamp of the series. For `household_0`, 30 is the first value of the **Electricity Usage Series**. The value of 30 corresponds to the first timestamp of 1/1/2020.

You can include the starting timestamp and ending timestamp. The following table shows how that information appears.

Electricity usage grouped by household ID

Household ID	Electricity usage series (kWh)	Number of household occupants series	Start_time	End_time
household_0	[30, 40, 35]	[2, 2, 3]	1/1/2020	1/4/2020
household_1	[45, 55]	[3, 4]	1/2/2020	1/3/2020

You can use the following procedure to group by a time series column.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
3. Choose **Add step**.
4. Choose **Time Series**.
5. Under **Transform**, choose **Group by**.
6. Specify a column in **Group by this column**.
7. For **Apply to columns**, specify a value.
8. Choose **Preview** to generate a preview of the transform.
9. Choose **Add** to add the transform to the Data Wrangler data flow.

## Resample Time Series Data

Time series data usually has observations that aren't taken at regular intervals. For example, a dataset could have some observations that are recorded hourly and other observations that are recorded every two hours.

Many analyses, such as forecasting algorithms, require the observations to be taken at regular intervals. Resampling gives you the ability to establish regular intervals for the observations in your dataset.

You can either upsample or downsample a time series. Downsampling increases the interval between observations in the dataset. For example, if you downsample observations that are taken either every hour or every two hours, each observation in your dataset is taken every two hours. The hourly observations are aggregated into a single value using an aggregation method such as the mean or median.

Upsampling reduces the interval between observations in the dataset. For example, if you upsample observations that are taken every two hours into hourly observations, you can use an interpolation method to infer hourly observations from the ones that have been taken every two hours. For information on interpolation methods, see [pandas.DataFrame.interpolate](#).

You can resample both numeric and non-numeric data.

Use the **Resample** operation to resample your time series data. If you have multiple time series in your dataset, Data Wrangler standardizes the time interval for each time series.

The following table shows an example of downsampling time series data by using the mean as the aggregation method. The data is downsampled from every two hours to every hour.

Hourly temperature readings over a day before downsampling

Timestamp	Temperature (Celsius)
12:00	30
1:00	32
2:00	35
3:00	32
4:00	30

Temperature readings downsampled to every two hours

Timestamp	Temperature (Celsius)
12:00	30
2:00	33.5
4:00	35

You can use the following procedure to resample time series data.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
3. Choose **Add step**.
4. Choose **Resample**.
5. For **Timestamp**, choose the timestamp column.
6. For **Frequency unit**, specify the frequency that you're resampling.
7. (Optional) Specify a value for **Frequency quantity**.
8. Configure the transform by specifying the remaining fields.
9. Choose **Preview** to generate a preview of the transform.
10. Choose **Add** to add the transform to the Data Wrangler data flow.

## Handle Missing Time Series Data

If you have missing values in your dataset, you can do one of the following:

- For datasets that have multiple time series, drop the time series that have missing values that are greater than a threshold that you specify.
- Impute the missing values in a time series by using other values in the time series.

Imputing a missing value involves replacing the data by either specifying a value or by using an inferential method. The following are the methods that you can use for imputation:

- Constant value – Replace all the missing data in your dataset with a value that you specify.
- Most common value – Replace all the missing data with the value that has the highest frequency in the dataset.
- Forward fill – Use a forward fill to replace the missing values with the non-missing value that precedes the missing values. For the sequence: [2, 4, 7, NaN, NaN, NaN, 8], all of the missing values are replaced with 7. The sequence that results from using a forward fill is [2, 4, 7, 7, 7, 7, 8].
- Backward fill – Use a backward fill to replace the missing values with the non-missing value that follows the missing values. For the sequence: [2, 4, 7, NaN, NaN, NaN, 8], all of the missing values are replaced with 8. The sequence that results from using a backward fill is [2, 4, 7, 8, 8, 8, 8].
- Interpolate – Uses an interpolation function to impute the missing values. For more information on the functions that you can use for interpolation, see [pandas.DataFrame.interpolate](#).

Some of the imputation methods might not be able to impute all the missing values in your dataset. For example, a **Forward fill** can't impute a missing value that appears at the beginning of the time series. You can impute the values by using either a forward fill or a backward fill.

You can either impute missing values within a cell or within a column.

The following example shows how values are imputed within a cell.

Electricity usage with missing values

Household ID	Electricity usage series (kWh)
household_0	[30, 40, 35, NaN, NaN]
household_1	[45, NaN, 55]

Electricity usage with values imputed using a forward fill

Household ID	Electricity usage series (kWh)
household_0	[30, 40, 35, 35, 35]
household_1	[45, 45, 55]

The following example shows how values are imputed within a column.

Average daily household electricity usage with missing values

Household ID	Electricity usage (kWh)
household_0	30
household_0	40
household_0	NaN
household_1	NaN
household_1	NaN

## Average daily household electricity usage with values imputed using a forward fill

Household ID	Electricity usage (kWh)
household_0	30
household_0	40
household_0	40
household_1	40
household_1	40

You can use the following procedure to handle missing values.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
3. Choose **Add step**.
4. Choose **Handle missing**.
5. For **Time series input type**, choose whether you want to handle missing values inside of a cell or along a column.
6. For **Impute missing values for this column**, specify the column that has the missing values.
7. For **Method for imputing values**, select a method.
8. Configure the transform by specifying the remaining fields.
9. Choose **Preview** to generate a preview of the transform.
10. If you have missing values, you can specify a method for imputing them under **Method for imputing values**.
11. Choose **Add** to add the transform to the Data Wrangler data flow.

### Validate the Timestamp of Your Time Series Data

You might have time stamp data that is invalid. You can use the **Validate time stamp** function to determine whether the timestamps in your dataset are valid. Your timestamp can be invalid for one or more of the following reasons:

- Your timestamp column has missing values.
- The values in your timestamp column are not formatted correctly.

If you have invalid timestamps in your dataset, you can't perform your analysis successfully. You can use Data Wrangler to identify invalid timestamps and understand where you need to clean your data.

The time series validation works in one of the two ways:

You can configure Data Wrangler to do one of the following if it encounters missing values in your dataset:

- Drop the rows that have the missing or invalid values.
- Identify the rows that have the missing or invalid values.
- Throw an error if it finds any missing or invalid values in your dataset.

You can validate the timestamps on columns that either have the `timestamp` type or the `string` type. If the column has the `string` type, Data Wrangler converts the type of the column to `timestamp` and performs the validation.

You can use the following procedure to validate the timestamps in your dataset.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
3. Choose **Add step**.
4. Choose **Validate timestamps**.
5. For **Timestamp Column**, choose the timestamp column.
6. For **Policy**, choose whether you want to handle missing timestamps.
7. (Optional) For **Output column**, specify a name for the output column.
8. If the date time column is formatted for the string type, choose **Cast to datetime**.
9. Choose **Preview** to generate a preview of the transform.
10. Choose **Add** to add the transform to the Data Wrangler data flow.

## Standardizing the Length of the Time Series

If you have time series data stored as arrays, you can standardize each time series to the same length. Standardizing the length of the time series array might make it easier for you to perform your analysis on the data.

You can standardize your time series for data transformations that require the length of your data to be fixed.

Many ML algorithms require you to flatten your time series data before you use them. Flattening time series data is separating each value of the time series into its own column in a dataset. The number of columns in a dataset can't change, so the lengths of the time series need to be standardized between you flatten each array into a set of features.

Each time series is set to the length that you specify as a quantile or percentile of the time series set. For example, you can have three sequences that have the following lengths:

- 3
- 4
- 5

You can set the length of all of the sequences as the length of the sequence that has the 50th percentile length.

Time series arrays that are shorter than the length you've specified have missing values added. The following is an example format of standardizing the time series to a longer length: [2, 4, 5, NaN, NaN, NaN].

You can use different approaches to handle the missing values. For information on those approaches, see [Handle Missing Time Series Data](#).

The time series arrays that are longer than the length that you specify are truncated.

You can use the following procedure to standardize the length of the time series.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
3. Choose **Add step**.

4. Choose **Standardize length**.
5. For **Standardize the time series length for the column**, choose a column.
6. (Optional) For **Output column**, specify a name for the output column. If you don't specify a name, the transform is done in place.
7. If the datetime column is formatted for the string type, choose **Cast to datetime**.
8. Choose **Cutoff quantile** and specify a quantile to set the length of the sequence.
9. Choose **Flatten the output** to output the values of the time series into separate columns.
10. Choose **Preview** to generate a preview of the transform.
11. Choose **Add** to add the transform to the Data Wrangler data flow.

### Extract Features from Your Time Series Data

If you're running a classification or a regression algorithm on your time series data, we recommend extracting features from the time series before running the algorithm. Extracting features might improve the performance of your algorithm.

Use the following options to choose how you want to extract features from your data:

- Use **Minimal subset** to specify extracting 8 features that you know are useful in downstream analyses. You can use a minimal subset when you need to perform computations quickly. You can also use it when your ML algorithm has a high risk of overfitting and you want to provide it with fewer features.
- Use **Efficient subset** to specify extracting the most features possible without extracting features that are computationally intensive in your analyses.
- Use **All features** to specify extracting all features from the time series.
- Use **Manual subset** to choose a list of features that you think explain the variation in your data well.

Use the following the procedure to extract features from your time series data.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
3. Choose **Add step**.
4. Choose **Extract features**.

5. For **Extract features for this column**, choose a column.
6. (Optional) Select **Flatten** to output the features into separate columns.
7. For **Strategy**, choose a strategy to extract the features.
8. Choose **Preview** to generate a preview of the transform.
9. Choose **Add** to add the transform to the Data Wrangler data flow.

## Use Lagged Features from Your Time Series Data

For many use cases, the best way to predict the future behavior of your time series is to use its most recent behavior.

The most common uses of lagged features are the following:

- Collecting a handful of past values. For example, for time,  $t + 1$ , you collect  $t$ ,  $t - 1$ ,  $t - 2$ , and  $t - 3$ .
- Collecting values that correspond to seasonal behavior in the data. For example, to predict the occupancy in a restaurant at 1:00 PM, you might want to use the features from 1:00 PM on the previous day. Using the features from 12:00 PM or 11:00 AM on the same day might not be as predictive as using the features from previous days.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
3. Choose **Add step**.
4. Choose **Lag features**.
5. For **Generate lag features for this column**, choose a column.
6. For **Timestamp Column**, choose the column containing the timestamps.
7. For **Lag**, specify the duration of the lag.
8. (Optional) Configure the output using one of the following options:
  - **Include the entire lag window**
  - **Flatten the output**
  - **Drop rows without history**
9. Choose **Preview** to generate a preview of the transform.
10. Choose **Add** to add the transform to the Data Wrangler data flow.

## Create a Datetime Range In Your Time Series

You might have time series data that don't have timestamps. If you know that the observations were taken at regular intervals, you can generate timestamps for the time series in a separate column. To generate timestamps, you specify the value for the start timestamp and the frequency of the timestamps.

For example, you might have the following time series data for the number of customers at a restaurant.

Time series data on the number of customers at a restaurant

Number of customers
10
14
24
40
30
20

If you know that the restaurant opened at 5:00 PM and that the observations are taken hourly, you can add a timestamp column that corresponds to the time series data. You can see the timestamp column in the following table.

Time series data on the number of customers at a restaurant

Number of customers	Timestamp
10	1:00 PM
14	2:00 PM
24	3:00 PM

Number of customers	Timestamp
40	4:00 PM
30	5:00 PM
20	6:00 PM

Use the following procedure to add a datetime range to your data.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
3. Choose **Add step**.
4. Choose **Datetime range**.
5. For **Frequency type**, choose the unit used to measure the frequency of the timestamps.
6. For **Starting timestamp**, specify the start timestamp.
7. For **Output column**, specify a name for the output column.
8. (Optional) Configure the output using the remaining fields.
9. Choose **Preview** to generate a preview of the transform.
10. Choose **Add** to add the transform to the Data Wrangler data flow.

## Use a Rolling Window In Your Time Series

You can extract features over a time period. For example, for time,  $t$ , and a time window length of 3, and for the row that indicates the  $t$ th timestamp, we append the features that are extracted from the time series at times  $t - 3$ ,  $t - 2$ , and  $t - 1$ . For information on extracting features, see [Extract Features from Your Time Series Data](#).

You can use the following procedure to extract features over a time period.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the **+**, and select **Add transform**.
3. Choose **Add step**.
4. Choose **Rolling window features**.
5. For **Generate rolling window features for this column**, choose a column.

6. For **Timestamp Column**, choose the column containing the timestamps.
7. (Optional) For **Output Column**, specify the name of the output column.
8. For **Window size**, specify the window size.
9. For **Strategy**, choose the extraction strategy.
10. Choose **Preview** to generate a preview of the transform.
11. Choose **Add** to add the transform to the Data Wrangler data flow.

## Featurize Datetime

Use **Featurize date/time** to create a vector embedding representing a datetime field. To use this transform, your datetime data must be in one of the following formats:

- Strings describing datetime: For example, "January 1st, 2020, 12:44pm".
- A Unix timestamp: A Unix timestamp describes the number of seconds, milliseconds, microseconds, or nanoseconds from 1/1/1970.

You can choose to **Infer datetime format** and provide a **Datetime format**. If you provide a datetime format, you must use the codes described in the [Python documentation](#). The options you select for these two configurations have implications for the speed of the operation and the final results.

- The most manual and computationally fastest option is to specify a **Datetime format** and select **No** for **Infer datetime format**.
- To reduce manual labor, you can choose **Infer datetime format** and not specify a datetime format. It is also a computationally fast operation; however, the first datetime format encountered in the input column is assumed to be the format for the entire column. If there are other formats in the column, these values are NaN in the final output. Inferring the datetime format can give you unparsed strings.
- If you don't specify a format and select **No** for **Infer datetime format**, you get the most robust results. All the valid datetime strings are parsed. However, this operation can be an order of magnitude slower than the first two options in this list.

When you use this transform, you specify an **Input column** which contains datetime data in one of the formats listed above. The transform creates an output column named **Output column name**. The format of the output column depends on your configuration using the following:

- **Vector:** Outputs a single column as a vector.
- **Columns:** Creates a new column for every feature. For example, if the output contains a year, month, and day, three separate columns are created for year, month, and day.

Additionally, you must choose an **Embedding mode**. For linear models and deep networks, we recommend choosing **cyclic**. For tree-based algorithms, we recommend choosing **ordinal**.

## Format String

The **Format string** transforms contain standard string formatting operations. For example, you can use these operations to remove special characters, normalize string lengths, and update string casing.

This feature group contains the following transforms. All transforms return copies of the strings in the **Input column** and add the result to a new, output column.

Name	Function
Left pad	Left-pad the string with a given <b>Fill character</b> to the given <b>width</b> . If the string is longer than <b>width</b> , the return value is shortened to <b>width</b> characters.
Right pad	Right-pad the string with a given <b>Fill character</b> to the given <b>width</b> . If the string is longer than <b>width</b> , the return value is shortened to <b>width</b> characters.
Center (pad on either side)	Center-pad the string (add padding on both sides of the string) with a given <b>Fill character</b> to the given <b>width</b> . If the string is longer than <b>width</b> , the return value is shortened to <b>width</b> characters.
Prepend zeros	Left-fill a numeric string with zeros, up to a given <b>width</b> . If the string is longer than <b>width</b> , the return value is shortened to <b>width</b> characters.

Name	Function
Strip left and right	Returns a copy of the string with the leading and trailing characters removed.
Strip characters from left	Returns a copy of the string with leading characters removed.
Strip characters from right	Returns a copy of the string with trailing characters removed.
Lower case	Convert all letters in text to lowercase.
Upper case	Convert all letters in text to uppercase.
Capitalize	Capitalize the first letter in each sentence.
Swap case	Converts all uppercase characters to lowercase and all lowercase characters to uppercase characters of the given string, and returns it.
Add prefix or suffix	Adds a prefix and a suffix the string column. You must specify at least one of <b>Prefix</b> and <b>Suffix</b> .
Remove symbols	Removes given symbols from a string. All listed characters are removed. Defaults to white space.

## Handle Outliers

Machine learning models are sensitive to the distribution and range of your feature values. Outliers, or rare values, can negatively impact model accuracy and lead to longer training times. Use this feature group to detect and update outliers in your dataset.

When you define a **Handle outliers** transform step, the statistics used to detect outliers are generated on the data available in Data Wrangler when defining this step. These same statistics are used when running a Data Wrangler job.

Use the following sections to learn more about the transforms this group contains. You specify an **Output name** and each of these transforms produces an output column with the resulting data.

### Robust standard deviation numeric outliers

This transform detects and fixes outliers in numeric features using statistics that are robust to outliers.

You must define an **Upper quantile** and a **Lower quantile** for the statistics used to calculate outliers. You must also specify the number of **Standard deviations** from which a value must vary from the mean to be considered an outlier. For example, if you specify 3 for **Standard deviations**, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip:** Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove:** Use this option to remove rows with outliers from the dataframe.
- **Invalidate:** Use this option to replace outliers with invalid values.

### Standard Deviation Numeric Outliers

This transform detects and fixes outliers in numeric features using the mean and standard deviation.

You specify the number of **Standard deviations** a value must vary from the mean to be considered an outlier. For example, if you specify 3 for **Standard deviations**, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip:** Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove:** Use this option to remove rows with outliers from the dataframe.
- **Invalidate:** Use this option to replace outliers with invalid values.

## Quantile Numeric Outliers

Use this transform to detect and fix outliers in numeric features using quantiles. You can define an **Upper quantile** and a **Lower quantile**. All values that fall above the upper quantile or below the lower quantile are considered outliers.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip:** Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove:** Use this option to remove rows with outliers from the dataframe.
- **Invalidate:** Use this option to replace outliers with invalid values.

## Min-Max Numeric Outliers

This transform detects and fixes outliers in numeric features using upper and lower thresholds. Use this method if you know threshold values that demark outliers.

You specify a **Upper threshold** and a **Lower threshold**, and if values fall above or below those thresholds respectively, they are considered outliers.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip:** Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove:** Use this option to remove rows with outliers from the dataframe.
- **Invalidate:** Use this option to replace outliers with invalid values.

## Replace Rare

When you use the **Replace rare** transform, you specify a threshold and Data Wrangler finds all values that meet that threshold and replaces them with a string that you specify. For example, you may want to use this transform to categorize all outliers in a column into an "Others" category.

- **Replacement string:** The string with which to replace outliers.
- **Absolute threshold:** A category is rare if the number of instances is less than or equal to this absolute threshold.

- **Fraction threshold:** A category is rare if the number of instances is less than or equal to this fraction threshold multiplied by the number of rows.
- **Max common categories:** Maximum not-rare categories that remain after the operation. If the threshold does not filter enough categories, those with the top number of appearances are classified as not rare. If set to 0 (default), there is no hard limit to the number of categories.

## Handle Missing Values

Missing values are a common occurrence in machine learning datasets. In some situations, it is appropriate to impute missing data with a calculated value, such as an average or categorically common value. You can process missing values using the **Handle missing values** transform group. This group contains the following transforms.

### Fill Missing

Use the **Fill missing** transform to replace missing values with a **Fill value** you define.

### Impute Missing

Use the **Impute missing** transform to create a new column that contains imputed values where missing values were found in input categorical and numerical data. The configuration depends on your data type.

For numeric data, choose an imputing strategy, the strategy used to determine the new value to impute. You can choose to impute the mean or the median over the values that are present in your dataset. Data Wrangler uses the value that it computes to impute the missing values.

For categorical data, Data Wrangler imputes missing values using the most frequent value in the column. To impute a custom string, use the **Fill missing** transform instead.

### Add Indicator for Missing

Use the **Add indicator for missing** transform to create a new indicator column, which contains a Boolean "false" if a row contains a value, and "true" if a row contains a missing value.

### Drop Missing

Use the **Drop missing** option to drop rows that contain missing values from the **Input column**.

### Manage Columns

You can use the following transforms to quickly update and manage columns in your dataset:

Name	Function
Drop Column	Delete a column.
Duplicate Column	Duplicate a column.
Rename Column	Rename a column.
Move Column	Move a column's location in the dataset. Choose to move your column to the start or end of the dataset, before or after a reference column, or to a specific index.

## Manage Rows

Use this transform group to quickly perform sort and shuffle operations on rows. This group contains the following:

- **Sort:** Sort the entire dataframe by a given column. Select the check box next to **Ascending order** for this option; otherwise, deselect the check box and descending order is used for the sort.
- **Shuffle:** Randomly shuffle all rows in the dataset.

## Manage Vectors

Use this transform group to combine or flatten vector columns. This group contains the following transforms.

- **Assemble:** Use this transform to combine Spark vectors and numeric data into a single column. For example, you can combine three columns: two containing numeric data and one containing vectors. Add all the columns you want to combine in **Input columns** and specify a **Output column name** for the combined data.
- **Flatten:** Use this transform to flatten a single column containing vector data. The input column must contain PySpark vectors or array-like objects. You can control the number of columns created by specifying a **Method to detect number of outputs**. For example, if you select **Length of first vector**, the number of elements in the first valid vector or array found in the column determines the number of output columns that are created. All other input vectors with too many items are truncated. Inputs with too few items are filled with NaNs.

You also specify an **Output prefix**, which is used as the prefix for each output column.

## Process Numeric

Use the **Process Numeric** feature group to process numeric data. Each scalar in this group is defined using the Spark library. The following scalars are supported:

- **Standard Scaler:** Standardize the input column by subtracting the mean from each value and scaling to unit variance. To learn more, see the Spark documentation for [StandardScaler](#).
- **Robust Scaler:** Scale the input column using statistics that are robust to outliers. To learn more, see the Spark documentation for [RobustScaler](#).
- **Min Max Scaler:** Transform the input column by scaling each feature to a given range. To learn more, see the Spark documentation for [MinMaxScaler](#).
- **Max Absolute Scaler:** Scale the input column by dividing each value by the maximum absolute value. To learn more, see the Spark documentation for [MaxAbsScaler](#).

## Sampling

After you've imported your data, you can use the **Sampling** transformer to take one or more samples of it. When you use the sampling transformer, Data Wrangler samples your original dataset.

You can choose one of the following sample methods:

- **Limit:** Samples the dataset starting from the first row up to the limit that you specify.
- **Randomized:** Takes a random sample of a size that you specify.
- **Stratified:** Takes a stratified random sample.

You can stratify a randomized sample to make sure that it represents the original distribution of the dataset.

You might be performing data preparation for multiple use cases. For each use case, you can take a different sample and apply a different set of transformations.

The following procedure describes the process of creating a random sample.

To take a random sample from your data.

1. Choose the **+** to the right of the dataset that you've imported. The name of your dataset is located below the **+**.
2. Choose **Add transform**.
3. Choose **Sampling**.
4. For **Sampling method**, choose the sampling method.
5. For **Approximate sample size**, choose the approximate number of observations that you want in your sample.
6. (Optional) Specify an integer for **Random seed** to create a reproducible sample.

The following procedure describes the process of creating a stratified sample.

To take a stratified sample from your data.

1. Choose the **+** to the right of the dataset that you've imported. The name of your dataset is located below the **+**.
2. Choose **Add transform**.
3. Choose **Sampling**.
4. For **Sampling method**, choose the sampling method.
5. For **Approximate sample size**, choose the approximate number of observations that you want in your sample.
6. For **Stratify column**, specify the name of the column that you want to stratify on.
7. (Optional) Specify an integer for **Random seed** to create a reproducible sample.

## Search and Edit

Use this section to search for and edit specific patterns within strings. For example, you can find and update strings within sentences or documents, split strings by delimiters, and find occurrences of specific strings.

The following transforms are supported under **Search and edit**. All transforms return copies of the strings in the **Input column** and add the result to a new output column.

Name	Function
Find substring	Returns the index of the first occurrence of the <b>Substring</b> for which you searched , You can start and end the search at <b>Start</b> and <b>End</b> respectively.
Find substring (from right)	Returns the index of the last occurrence of the <b>Substring</b> for which you searched. You can start and end the search at <b>Start</b> and <b>End</b> respectively.
Matches prefix	Returns a Boolean value if the string contains a given <b>Pattern</b> . A pattern can be a character sequence or regular expression. Optionally, you can make the pattern case sensitive.
Find all occurrences	Returns an array with all occurrences of a given pattern. A pattern can be a character sequence or regular expression.
Extract using regex	Returns a string that matches a given Regex pattern.
Extract between delimiters	Returns a string with all characters found between <b>Left delimiter</b> and <b>Right delimiter</b> .
Extract from position	Returns a string, starting from <b>Start position</b> in the input string, that contains all characters up to the start position plus <b>Length</b> .
Find and replace substring	Returns a string with all matches of a given <b>Pattern</b> (regular expression) replaced by <b>Replacement string</b> .
Replace between delimiters	Returns a string with the substring found between the first appearance of a <b>Left delimiter</b> and the last appearance of a <b>Right</b>

Name	Function
	<b>delimiter</b> replaced by <b>Replacement string</b> . If no match is found, nothing is replaced.
Replace from position	Returns a string with the substring between <b>Start position</b> and <b>Start position plus Length</b> replaced by <b>Replacement string</b> . If <b>Start position plus Length</b> is greater than the length of the replacement string, the output contains ....
Convert regex to missing	Converts a string to None if invalid and returns the result. Validity is defined with a regular expression in <b>Pattern</b> .
Split string by delimiter	Returns an array of strings from the input string, split by <b>Delimiter</b> , with up to <b>Max number of splits</b> (optional). The delimiter defaults to white space.

## Split data

Use the **Split data** transform to split your dataset into two or three datasets. For example, you can split your dataset into a dataset used to train your model and a dataset used to test it. You can determine the proportion of the dataset that goes into each split. For example, if you're splitting one dataset into two datasets, the training dataset can have 80% of the data while the testing dataset has 20%.

Splitting your data into three datasets gives you the ability to create training, validation, and test datasets. You can see how well the model performs on the test dataset by dropping the target column.

Your use case determines how much of the original dataset each of your datasets get and the method you use to split the data. For example, you might want to use a stratified split to make sure that the distribution of the observations in the target column are the same across datasets. You can use the following split transforms:

- **Randomized split** — Each split is a random, non-overlapping sample of the original dataset. For larger datasets, using a randomized split might be computationally expensive and take longer than an ordered split.
- **Ordered split** – Splits the dataset based on the sequential order of the observations. For example, for an 80/20 train-test split, the first observations that make up 80% of the dataset go to the training dataset. The last 20% of the observations go to the testing dataset. Ordered splits are effective in keeping the existing order of the data between splits.
- **Stratified split** – Splits the dataset to make sure that the number of observations in the input column have proportional representation. For an input column that has the observations 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 3, 3, 3, an 80/20 split on the column would mean that approximately 80% of the 1s, 80% of the 2s, and 80% of the 3s go to the training set. About 20% of each type of observation go to the testing set.
- **Split by key** – Avoids data with the same key occurring in more than one split. For example, if you have a dataset with the column 'customer\_id' and you're using it as a key, no customer id is in more than one split.

After you split the data, you can apply additional transformations to each dataset. For most use cases, they aren't necessary.

Data Wrangler calculates the proportions of the splits for performance. You can choose an error threshold to set the accuracy of the splits. Lower error thresholds more accurately reflect the proportions that you specify for the splits. If you set a higher error threshold, you get better performance, but lower accuracy.

For perfectly split data, set the error threshold to 0. You can specify a threshold between 0 and 1 for better performance. If you specify a value greater than 1, Data Wrangler interprets that value as 1.

If you have 10000 rows in your dataset and you specify an 80/20 split with an error of 0.001, you would get observations approximating one of the following results:

- 8010 observations in the training set and 1990 in the testing set
- 7990 observations in the training set and 2010 in the testing set

The number of observations for the testing set in the preceding example is in the interval between 8010 and 7990.

By default, Data Wrangler uses a random seed to make the splits reproducible. You can specify a different value for the seed to create a different reproducible split.

### Randomized split

Use the following procedure to perform a randomized split on your dataset.

To split your dataset randomly, do the following

1. Choose the **+** next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. Choose **Split data**.
4. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
5. (Optional) Choose the **+** to create an additional split.
  - Specify the names and proportions of all the splits. The proportions must sum to 1.
6. (Optional) Specify a value for **Error threshold** other than the default value.
7. (Optional) Specify a value for **Random seed**.
8. Choose **Preview**.
9. Choose **Add**.

### Ordered split

Use the following procedure to perform an ordered split on your dataset.

To make an ordered split in your dataset, do the following.

1. Choose the **+** next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. For **Transform**, choose **Ordered split**.
4. Choose **Split data**.
5. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the **+** to create an additional split.

- Specify the names and proportions of all the splits. The proportions must sum to 1.
7. (Optional) Specify a value for **Error threshold** other than the default value.
  8. (Optional) For **Input column**, specify a column with numeric values. Uses the values of the columns to infer which records are in each split. The smaller values are in one split with the larger values in the other splits.
  9. (Optional) Select **Handle duplicates** to add noise to duplicate values and create a dataset of entirely unique values.
  10. (Optional) Specify a value for **Random seed**.
  11. Choose **Preview**.
  12. Choose **Add**.

## Stratified split

Use the following procedure to perform a stratified split on your dataset.

To make a stratified split in your dataset, do the following.

1. Choose the **+** next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. Choose **Split data**.
4. For **Transform**, choose **Stratified split**.
5. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the **+** to create an additional split.
  - Specify the names and proportions of all the splits. The proportions must sum to 1.
7. For **Input column**, specify a column with up to 100 unique values. Data Wrangler can't stratify a column with more than 100 unique values.
8. (Optional) Specify a value for **Error threshold** other than the default value.
9. (Optional) Specify a value for **Random seed** to specify a different seed.
10. Choose **Preview**.
11. Choose **Add**.

## Split by column keys

Use the following procedure to split by the column keys in your dataset.

To split by the column keys in your dataset, do the following.

1. Choose the **+** next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. Choose **Split data**.
4. For **Transform**, choose **Split by key**.
5. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the **+** to create an additional split.
  - Specify the names and proportions of all the splits. The proportions must sum to 1.
7. For **Key columns**, specify the columns with values that you don't want to appear in both datasets.
8. (Optional) Specify a value for **Error threshold** other than the default value.
9. Choose **Preview**.
10. Choose **Add**.

## Parse Value as Type

Use this transform to cast a column to a new type. The supported Data Wrangler data types are:

- Long
- Float
- Boolean
- Date, in the format dd-MM-yyyy, representing day, month, and year respectively.
- String

## Validate String

Use the **Validate string** transforms to create a new column that indicates that a row of text data meets a specified condition. For example, you can use a **Validate string** transform to verify that a

string only contains lowercase characters. The following transforms are supported under **Validate string**.

The following transforms are included in this transform group. If a transform outputs a Boolean value, `True` is represented with a 1 and `False` is represented with a 0.

Name	Function
String length	Returns <code>True</code> if a string length equals specified length. Otherwise, returns <code>False</code> .
Starts with	Returns <code>True</code> if a string starts with a specified prefix. Otherwise, returns <code>False</code> .
Ends with	Returns <code>True</code> if a string length equals specified length. Otherwise, returns <code>False</code> .
Is alphanumeric	Returns <code>True</code> if a string only contains numbers and letters. Otherwise, returns <code>False</code> .
Is alpha (letters)	Returns <code>True</code> if a string only contains letters. Otherwise, returns <code>False</code> .
Is digit	Returns <code>True</code> if a string only contains digits. Otherwise, returns <code>False</code> .
Is space	Returns <code>True</code> if a string only contains numbers and letters. Otherwise, returns <code>False</code> .
Is title	Returns <code>True</code> if a string contains any white spaces. Otherwise, returns <code>False</code> .
Is lowercase	Returns <code>True</code> if a string only contains lower case letters. Otherwise, returns <code>False</code> .
Is uppercase	Returns <code>True</code> if a string only contains upper case letters. Otherwise, returns <code>False</code> .

Name	Function
Is numeric	Returns <code>True</code> if a string only contains numbers. Otherwise, returns <code>False</code> .
Is decimal	Returns <code>True</code> if a string only contains decimal numbers. Otherwise, returns <code>False</code> .

## Unnest JSON Data

If you have a .csv file, you might have values in your dataset that are JSON strings. Similarly, you might have nested data in columns of either a Parquet file or a JSON document.

Use the **Flatten structured** operator to separate the first level keys into separate columns. A first level key is a key that isn't nested within a value.

For example, you might have a dataset that has a *person* column with demographic information on each person stored as JSON strings. A JSON string might look like the following.

```
{"seq": 1, "name": {"first": "Nathaniel", "last": "Ferguson"}, "age": 59, "city": "Posbotno", "state": "WV"}
```

The **Flatten structured** operator converts the following first level keys into additional columns in your dataset:

- seq
- name
- age
- city
- state

Data Wrangler puts the values of the keys as values under the columns. The following shows the column names and values of the JSON.

```
seq, name,                age, city, state
1, {"first": "Nathaniel", "last": "Ferguson"}, 59, Posbotno, WV
```

For each value in your dataset containing JSON, the **Flatten structured** operator creates columns for the first-level keys. To create columns for nested keys, call the operator again. For the preceding example, calling the operator creates the columns:

- name\_first
- name\_last

The following example shows the dataset that results from calling the operation again.

```
seq, name,                age, city, state, name_first, name_last
1, {"first": "Nathaniel", "last": "Ferguson"}, 59, Posbotno, WV, Nathaniel, Ferguson
```

Choose **Keys to flatten on** to specify the first-level keys that want to extract as separate columns. If you don't specify any keys, Data Wrangler extracts all the keys by default.

## Explode Array

Use **Explode array** to expand the values of the array into separate output rows. For example, the operation can take each value in the array, `[[1, 2, 3], [4, 5, 6], [7, 8, 9]]` and create a new column with the following rows:

```
[1, 2, 3]
[4, 5, 6]
[7, 8, 9]
```

Data Wrangler names the new column, `input_column_name_flatten`.

You can call the **Explode array** operation multiple times to get the nested values of the array into separate output columns. The following example shows the result of calling the operation multiple times on a dataset with a nested array.

Putting the values of a nested array into separate columns

id	array	id	array_items	id	array_items
1	[ [cat, dog], [bat, frog] ]	1	[cat, dog]	1	cat
2	[[rose, petunia], [lily, daisy]]	1	[bat, frog]	1	dog
		2	[rose, petunia]	1	bat
		2	[lily, daisy]	1	frog
			2	2	rose
			2	2	petunia
			2	2	lily
			2	2	daisy

## Transform Image Data

Use Data Wrangler to import and transform the images that you're using for your machine learning (ML) pipelines. After you've prepared your image data, you can export it from your Data Wrangler flow to your ML pipeline.

You can use the information provided here to familiarize yourself with importing and transforming image data in Data Wrangler. Data Wrangler uses OpenCV to import images. For more information about supported image formats, see [Image file reading and writing](#).

After you've familiarized yourself with the concepts of transforming your image data, go through the following tutorial, [Prepare image data with Amazon SageMaker Data Wrangler](#).

The following industries and use cases are examples where applying machine learning to transformed image data can be useful:

- Manufacturing – Identifying defects in items from the assembly line

- Food – Identifying spoiled or rotten food
- Medicine – Identifying lesions in tissues

When you work with image data in Data Wrangler, you go through the following process:

1. Import – Select the images by choosing the directory containing them in your Amazon S3 bucket.
2. Transform – Use the built-in transformations to prepare the images for your machine learning pipeline.
3. Export – Export the images that you've transformed to a location that can be accessed from the pipeline.

Use the following procedure to import your image data.

### To import your image data

1. Navigate to the **Create connection** page.
2. Choose **Amazon S3**.
3. Specify the Amazon S3 file path that contains the image data.
4. For **File type**, choose **Image**.
5. (Optional) Choose **Import nested directories** to import images from multiple Amazon S3 paths.
6. Choose **Import**.

Data Wrangler uses the open-source [imgaug](#) library for its built-in image transformations. You can use the following built-in transformations:

- **ResizeImage**
- **EnhanceImage**
- **CorruptImage**
- **SplitImage**
- **DropCorruptedImages**
- **DropImageDuplicates**

- **Brightness**
- **ColorChannels**
- **Grayscale**
- **Rotate**

Use the following procedure to transform your images without writing code.

### To transform the image data without writing code

1. From your Data Wrangler flow, choose the **+** next to the node representing the images that you've imported.
2. Choose **Add transform**.
3. Choose **Add step**.
4. Choose the transform and configure it.
5. Choose **Preview**.
6. Choose **Add**.

In addition to using the transformations that Data Wrangler provides, you can also use your own custom code snippets. For more information about using custom code snippets, see [Custom Transforms](#). You can import the OpenCV and imgaug libraries within your code snippets and use the transforms associated with them. The following is an example of a code snippet that detects edges within the images.

```
# A table with your image data is stored in the `df` variable
import cv2
import numpy as np
from pyspark.sql.functions import column

from sagemaker_dataprep.compute.operators.transforms.image.constants import
    DEFAULT_IMAGE_COLUMN, IMAGE_COLUMN_TYPE
from sagemaker_dataprep.compute.operators.transforms.image.decorators import
    BasicImageOperationDecorator, PandasUDF0operationDecorator

@BasicImageOperationDecorator
def my_transform(image: np.ndarray) -> np.ndarray:
```

```
# To use the code snippet on your image data, modify the following lines within the
function
    HYST_THRLD_1, HYST_THRLD_2 = 100, 200
    edges = cv2.Canny(image, HYST_THRLD_1, HYST_THRLD_2)
    return edges

@PandasUDFOperationDecorator(IMAGE_COLUMN_TYPE)
def custom_image_udf(image_row):
    return my_transform(image_row)

df = df.withColumn(DEFAULT_IMAGE_COLUMN,
    custom_image_udf(column(DEFAULT_IMAGE_COLUMN)))
```

When apply transformations in your Data Wrangler flow, Data Wrangler only applies them to a sample of the images in your dataset. To optimize your experience with the application, Data Wrangler doesn't apply the transforms to all of your images.

## Filter data

Use Data Wrangler to filter the data in your columns. When you filter the data in a column, you specify the following fields:

- **Column name** – The name of the column that you're using to filter the data.
- **Condition** – The type of filter that you're applying to values in the column.
- **Value** – The value or category in the column to which you're applying the filter.

You can filter on the following conditions:

- **=** – Returns values that match the value or category that you specify.
- **!=** – Returns values that don't match the value or category that you specify.
- **>=** – For **Long** or **Float** data, filters for values that are greater than or equal to the value that you specify.
- **<=** – For **Long** or **Float** data, filters for values that are less than or equal to the value that you specify.
- **>** – For **Long** or **Float** data, filters for values that are greater than the value that you specify.

- **<** – For **Long** or **Float** data, filters for values that are less than the value that you specify.

For a column that has the categories, male and female, you can filter out all the male values. You could also filter for all the female values. Because there are only male and female values in the column, the filter returns a column that only has female values.

You can also add multiple filters. The filters can be applied across multiple columns or the same column. For example, if you're creating a column that only has values within a certain range, you add two different filters. One filter specifies that the column must have values greater than the value that you provide. The other filter specifies that the column must have values less than the value that you provide.

Use the following procedure to add the filter transform to your data.

### To filter your data

1. From your Data Wrangler flow, choose the **+** next to the node with the data that you're filtering.
2. Choose **Add transform**.
3. Choose **Add step**.
4. Choose **Filter data**.
5. Specify the following fields:
  - **Column name** – The column that you're filtering.
  - **Condition** – The condition of the filter.
  - **Value** – The value or category in the column to which you're applying the filter.
6. (Optional) Choose **+** following the filter that you've created.
7. Configure the filter.
8. Choose **Preview**.
9. Choose **Add**.

### Chat for data prep

#### **Important**

For administrators:

- Chat for data prep requires the `AmazonSageMakerCanvasAIServiceAccess` policy. For more information, see [AWS managed policy: AmazonSageMakerCanvasAIServiceAccess](#)
- Chat for data prep requires access to Amazon Bedrock and the **Anthropic Claude** model within it. For more information, see [Add model access](#).
- You must run SageMaker Canvas data prep in the same AWS Region as the Region where you're running your model. Chat for data prep is available in the US East (N. Virginia), US West (Oregon), and Europe (Frankfurt) AWS Regions.

In addition to using the built-in transforms and analyses, you can use natural language to explore, visualize, and transform your data in a conversational interface. Within the conversational interface, you can use natural language queries to understand and prepare your data to build ML models.

The following are examples of some prompts that you can use:

- Summarize my data
- Drop column *example-column-name*
- Replace missing values with median
- Plot histogram of prices
- What is the most expensive item sold?
- How many distinct items were sold?
- Sort data by region

When you're transforming your data using your prompts, you can view a preview that shows how data is being transformed. You can choose to add it as step in your Data Wrangler flow based on what you see in the preview.

The responses to your prompts generate code for your transformations and analyses. You can modify the code to update the output from the prompt. For example, you can modify the code for an analysis to change the values of the axes of a graph.

Use the following procedure to start chatting with your data:

## To chat with your data

1. Open the SageMaker Canvas data flow.
2. Choose the speech bubble.

The screenshot shows the SageMaker Canvas interface for a data flow. The current step is 'Step 2. Data types'. The interface includes a 'Data' tab and a 'Chat for data prep' button. The main area displays three histograms for 'ActualShippingDays', 'ExpectedShippingDays', and 'Carrier'. A chat input field contains the prompt 'e.g. Help me understand my data with a summary'. The 'Steps' panel on the right shows the current step and a table of column names and types.

Column name	Type
ActualShippingDays	long
ExpectedShippingDays	long
Carrier	string
YShippingDistance	long

3. Specify a prompt.
4. (Optional) If an analysis has been generated by your query, choose **Add to analyses** to reference it for later.

The screenshot shows the SageMaker Canvas interface for a data flow. The current step is 'Step 2. Data types'. The interface includes a 'Data' tab and a 'Chat for data prep' button. The main area displays a scatter plot of 'total\_rooms' vs 'median\_income'. A chat input field contains the prompt 'e.g. Help me understand my data with a summary'. The 'Steps' panel on the right shows the current step and a table of column names and types.

Column name	Type
longitude	float
latitude	float
housing_median_age	float
total_rooms	float
total_bedrooms	float

5. (Optional) If you've transformed your data using a prompt, do the following.
  - a. Choose **Preview** to view the results.
  - b. (Optional) Modify the code in the transform and choose **Update**.
  - c. (Optional) If you're happy with the results of the transform, choose **Add to steps** to add it to the steps panel on the right-hand navigation.

The screenshot shows the Amazon SageMaker Data Wrangler interface. The main panel displays a chat-based transformation step titled "Step 3. Chat Transform: Remove population < 100". The chat history shows a user prompt: "remove rows where population is less than 100" and an AI response: "The code filters out rows where the population column is less than 100, keeping only rows with population greater than or equal to 100." A green checkmark indicates the transformation has been added to the steps panel.

Below the chat, there are five histograms for the columns: longitude (float), latitude (float), housing\_median\_age (float), total\_rooms (float), and total\_bedrooms (float). Below the histograms is a table of data rows:

longitude (float)	latitude (float)	housing_median_age (float)	total_rooms (float)	total_bedrooms (float)
-122.23	37.88	41	880	129
-122.22	37.86	21	7099	1106
-122.24	37.85	52	1467	190
-122.25	37.85	52	1274	235
-122.25	37.85	52	1627	280
-122.25	37.85	52	919	213
-122.25	37.84	52	2535	489

The right-hand navigation panel shows the "Steps" section with a list of steps: 1. S3 Source, 2. Data types, and 3. Chat Transform: Remove population < 100. The selected step is expanded, showing the name "Chat Transform: Remove population < 100", the language "Python (PySpark)", and the example code snippet:

```
1 import pyspark.sql.functions as F
2
3 df = df.filter(F.col('population') >= 100
```

Buttons for "Clear", "Preview", and "Update" are visible at the bottom of the step configuration panel.

After you've prepared your data using natural language, you can create a model using your transformed data. For more information about creating a model, see [How custom models work](#).

## How data processing works in Data Wrangler

While working with data interactively in an Amazon SageMaker Data Wrangler data flow, Amazon SageMaker Canvas only applies the transformations to a sample dataset for you to preview. After finishing your data flow in SageMaker Canvas, you can process all of your data and save it in a location that is suitable for your machine learning workflows.

There are several options for how to proceed after you've finished transforming your data in Data Wrangler:

- [Create a model](#). You can create a Canvas model, where you directly start creating a model with your prepared data. You can create a model either after processing your entire dataset, or by exporting just the sample data you worked with in Data Wrangler. Canvas saves your processed data (either the entire dataset or the sample data) as a Canvas dataset.

We recommend that you use your sample data for quick iterations, but that you use your entire data when you want to train your final model. When building tabular models, datasets larger than 5 GB are automatically downsampled to 5 GB, and for time series forecasting models, datasets larger than 30 GB are downsampled to 30 GB.

To learn more about creating a model, see [How custom models work](#).

- [Export the data](#). You can export your data for use in machine learning workflows. When you choose to export your data, you have several options:
  - You can save your data in the Canvas application as a dataset. For more information about the supported file types for Canvas datasets and additional requirements when importing data into Canvas, see [Create a dataset](#).
  - You can save your data to Amazon S3. Depending on the Canvas memory availability, your data is processed in the application and then exported to Amazon S3. If the size of your dataset exceeds what Canvas can process, then by default, Canvas uses an EMR Serverless job to scale to multiple compute instances, process your full dataset, and export it to Amazon S3. You can also manually configure a SageMaker Processing job to have more granular control over the compute resources used to process your data.
- [Export a data flow](#). You might want to save the code for your data flow so that you can modify or run your transformations outside of Canvas. Canvas provides you with the option to save your data flow transformations as Python code in a Jupyter notebook, which you can then export to Amazon S3 for use elsewhere in your machine learning workflows.

When you export your data from a data flow and save it either as a Canvas dataset or to Amazon S3, Canvas creates a new destination node in your data flow, which is a final node that shows you where your processed data is stored. You can add additional destination nodes to your flow if you'd like to perform multiple export operations. For example, you can export the data from different points in your data flow to only apply some of the transformations, or you can export transformed data to different Amazon S3 locations. For more information about how to add or edit a destination node, see [Add destination nodes](#) and [Edit a destination node](#).

For more information about setting up a schedule with Amazon EventBridge to automatically process and export your data on a schedule, see [Create a schedule to automatically process new data](#).

## Export to create a model

In just a few clicks from your data flow, you can export your transformed data and start creating an ML model in Canvas. Canvas saves your data as a Canvas dataset, and you're taken to the model build configuration page for a new model.

To create a Canvas model with your transformed data:

1. Navigate to your data flow.
2. Choose the ellipsis icon next to the node that you're exporting.
3. From the context menu, choose **Create model**.
4. In the **Export to create a model** side panel, enter a **Dataset name** for the new dataset.
5. Leave the **Process entire dataset** option selected to process and export your entire dataset before proceeding with building a model. Turn this option off to train your model using the interactive sample data you are working with in your data flow.
6. Enter a **Model name** to name the new model.
7. Select a **Problem type**, or the type of model that you want to build. For more information about the supported model types in SageMaker Canvas, see [How custom models work](#).
8. Select the **Target column**, or the value that you want the model to predict.
9. Choose **Export and create model**.

The **Build** tab for a new Canvas model should open, and you can finish configuring and training your model. For more information about how to build a model, see [Build a model](#).

## Export data

Export data to apply the transforms from your data flow to the full imported dataset. You can export any node in your data flow to the following locations:

- SageMaker Canvas dataset
- Amazon S3

If you want to train models in Canvas, you can export your full, transformed dataset as a Canvas dataset. If you want to use your transformed data in machine learning workflows external to SageMaker Canvas, you can export your dataset to Amazon S3.

## Export to a Canvas dataset

Use the following procedure to export a SageMaker Canvas dataset from a node in your data flow.

### To export a node in your flow as a SageMaker Canvas dataset

1. Navigate to your data flow.
2. Choose the ellipsis icon next to the node that you're exporting.
3. In the context menu, hover over **Export**, and then select **Export data to Canvas dataset**.
4. In the **Export to Canvas dataset** side panel, enter a **Dataset name** for the new dataset.
5. Leave the **Process entire dataset** option selected if you want SageMaker Canvas to process and save your full dataset. Turn this option off to only apply the transforms to the sample data you are working with in your data flow.
6. Choose **Export**.

You should now be able to go to the **Datasets** page of the Canvas application and see your new dataset.

## Export to Amazon S3

When exporting your data to Amazon S3, you can scale to transform and process data of any size. Canvas automatically processes your data locally if the application's memory can handle the size of your dataset. If your dataset size exceeds the local memory capacity of 5 GB, then Canvas initiates a remote job on your behalf to provision additional compute resources and process the data more quickly. By default, Canvas uses Amazon EMR Serverless to run these remote jobs. However, you can manually configure Canvas to use either EMR Serverless or a SageMaker Processing job with your own settings.

### Note

When running an EMR Serverless job, by default the job inherits the IAM role, KMS key settings, and tags of your Canvas application.

The following summarizes the options for remote jobs in Canvas:

- **EMR Serverless:** This is the default option that Canvas uses for remote jobs. EMR Serverless automatically provisions and scales compute resources to process your data so that you don't have to worry about choosing the right compute resources for your workload. For more information about EMR Serverless, see the [EMR Serverless User Guide](#).
- **SageMaker Processing:** SageMaker Processing jobs offer more advanced options and granular control over the compute resources used to process your data. For example, you can specify the type and count of the compute instances, configure the job in your own VPC and control network access, automate processing jobs, and more. For more information about automating processing jobs see [Create a schedule to automatically process new data](#). For more general information about SageMaker Processing jobs, see [Data transformation workloads with SageMaker Processing](#).

The following file types are supported when exporting to Amazon S3:

- CSV
- Parquet

To get started, review the following prerequisites.

### Prerequisites for EMR Serverless jobs

To create a remote job that uses EMR Serverless resources, you must have the necessary permissions. You can grant permissions either through the Amazon SageMaker AI domain or user profile settings, or you can manually configure your user's AWS IAM role. For instructions on how to grant users permissions to perform large data processing, see [Grant Users Permissions to Use Large Data across the ML Lifecycle](#).

If you don't want to configure these policies but still need to process large datasets through Data Wrangler, you can alternatively use a SageMaker Processing job.

Use the following procedures to export your data to Amazon S3. To configure a remote job, follow the optional advanced steps.

### To export a node in your flow to Amazon S3

1. Navigate to your data flow.

2. Choose the ellipsis icon next to the node that you're exporting.
3. In the context menu, hover over **Export**, and then select **Export data to Amazon S3**.
4. In the **Export to Amazon S3** side panel, you can change the **Dataset name** for the new dataset.
5. For the **S3 location**, enter the Amazon S3 location to which you want to export the dataset. You can enter the S3 URI, alias, or ARN of the S3 location or S3 access point. For more information access points, see [Managing data access with Amazon S3 access points](#) in the *Amazon S3 User Guide*.
6. (Optional) For the **Advanced settings**, specify values for the following fields:
  - a. **File type** – The file format of your exported data.
  - b. **Delimiter** – The delimiter used to separate values in the file.
  - c. **Compression** – The compression method used to reduce the file size.
  - d. **Number of partitions** – The number of dataset files that Canvas writes as the output of the job.
  - e. **Choose columns** – You can choose a subset of columns from the data to include in the partitions.
7. Leave the **Process entire dataset** option selected if you want Canvas to apply your data flow transforms to your entire dataset and export the result. If you deselect this option, Canvas only applies the transforms to the sample of your dataset used in the interactive Data Wrangler data flow.

**Note**

If you only export a sample of your data, Canvas processes your data in the application and doesn't create a remote job for you.
8. Leave the **Auto job configuration** option selected if you want Canvas to automatically determine whether to run the job using Canvas application memory or an EMR Serverless job. If you deselect this option and manually configure your job, then you can choose to use either an EMR Serverless or a SageMaker Processing job. For instructions on how to configure an EMR Serverless or a SageMaker Processing job, see the section after this procedure before you export your data.
9. Choose **Export**.

The following procedures show how to manually configure the remote job settings for either EMR Serverless or SageMaker Processing when exporting your full dataset to Amazon S3.

## EMR Serverless

To configure an EMR Serverless job while exporting to Amazon S3, do the following:

1. In the Export to Amazon S3 side panel, turn off the **Auto job configuration** option.
2. Select **EMR Serverless**.
3. For **Job name**, enter a name for your EMR Serverless job. The name can contain letters, numbers, hyphens, and underscores.
4. For **IAM role**, enter the user's IAM execution role. This role should have the required permissions to run EMR Serverless applications. For more information, see [Grant Users Permissions to Use Large Data across the ML Lifecycle](#).
5. (Optional) For **KMS key**, specify the key ID or ARN of an AWS KMS key to encrypt the job logs. If you don't enter a key, Canvas uses a default key for EMR Serverless.
6. (Optional) For **Monitoring configuration**, enter the name of an Amazon CloudWatch Logs log group to which you want to publish your logs.
7. (Optional) For **Tags**, add metadata tags to the EMR Serverless job consisting of key-value pairs. These tags can be used to categorize and search for jobs.
8. Choose **Export** to start the job.

## SageMaker Processing

To configure a SageMaker Processing job while exporting to Amazon S3, do the following:

1. In the **Export to Amazon S3** side panel, turn off the **Auto job configuration** option.
2. Select **SageMaker Processing**.
3. For **Job name**, enter a name for your SageMaker AI Processing job.
4. For **Instance type**, select the type of compute instance to run the processing job.
5. For **Instance count**, specify the number of compute instances to launch.
6. For **IAM role**, enter the user's IAM execution role. This role should have the required permissions for SageMaker AI to create and run processing jobs on your behalf. These permissions are granted if you have the [AmazonSageMakerFullAccess](#) policy attached to your IAM role.

7. For **Volume size**, enter the storage size in GB for the ML storage volume that is attached to each processing instance. Choose the size based on your expected input and output data size.
8. (Optional) For **Volume KMS key**, specify a KMS key to encrypt the storage volume. If you don't specify a key, the default Amazon EBS encryption key is used.
9. (Optional) For **KMS key**, specify a KMS key to encrypt input and output Amazon S3 data sources used by the processing job.
10. (Optional) For **Spark memory configuration**, do the following:
  - a. Enter **Driver memory in MB** for the Spark driver node that handles job coordination and scheduling.
  - b. Enter **Executor memory in MB** for the Spark executor nodes that run individual tasks in the job.
11. (Optional) For **Network configuration**, do the following:
  - a. For **Subnet configuration**, enter the IDs of the VPC subnets for the processing instances to be launched in. By default, the job uses the settings of your default VPC.
  - b. For **Security group configuration**, enter the IDs of the security groups to control inbound and outbound connectivity rules.
  - c. Turn on the **Enable inter-container traffic encryption** option to encrypt network communication between processing containers during the job.
12. (Optional) For **Associate schedules**, you can choose create an Amazon EventBridge schedule to have the processing job run on recurring intervals. Choose **Create new schedule** and fill out the dialog box. For more information about filling out this section and running processing jobs on a schedule, see [Create a schedule to automatically process new data](#).
13. (Optional) Add **Tags** as key-value pairs so that you can categorize and search for processing jobs.
14. Choose **Export** to start the processing job.

After exporting your data, you should find the fully processed dataset in the specified Amazon S3 location.

## Export a data flow

Exporting your data flow translates the operations that you've made in Data Wrangler and exports it into a Jupyter notebook of Python code that you can modify and run. This can be helpful for integrating the code for your data transformations into your machine learning pipelines.

You can choose any data node in your data flow and export it. Exporting the data node exports the transformation that the node represents and the transformations that precede it.

### To export a data flow as a Jupyter notebook

1. Navigate to your data flow.
2. Choose the ellipsis icon next to the node that you want to export.
3. In the context menu, hover over **Export**, and then hover over **Export via Jupyter notebook**.
4. Choose one of the following:
  - **SageMaker Pipelines**
  - **Amazon S3**
  - **SageMaker AI Inference Pipeline**
  - **SageMaker AI Feature Store**
  - **Python Code**
5. The **Export data flow as notebook** dialog box opens. Select one of the following:
  - **Download a local copy**
  - **Export to S3 location**
6. If you selected **Export to S3 location**, enter the Amazon S3 location to which you want to export the notebook.
7. Choose **Export**.

Your Jupyter notebook should either download to your local machine, or you can find it saved in the Amazon S3 location you specified.

### Add destination nodes

A destination node in SageMaker Canvas specifies where to store your processed and transformed data. When you choose to export your transformed data to Amazon S3, Canvas uses the specified

destination node location, applying all the transformations you've configured in your data flow. For more information about export jobs to Amazon S3, see the preceding section [Export to Amazon S3](#).

By default, choosing to export your data to Amazon S3 adds a destination node to your data flow. However, you can add multiple destination nodes to your flow, allowing you to simultaneously export different sets of transformations or variations of your data to different Amazon S3 locations. For example, you can create one destination node that exports the data after applying all transformations, and another destination node that exports the data after only certain initial transformations, such as a join operation. This flexibility enables you to export and store different versions or subsets of your transformed data in separate S3 locations for various use cases.

Use the following procedure to add a destination node to your data flow.

### To add a destination node

1. Navigate to your data flow.
2. Choose the ellipsis icon next to the node where you want to place the destination node.
3. In the context menu, hover over **Export**, and then select **Add destination**.
4. In the **Export destination** side panel, enter a **Dataset name** to name the output.
5. For **Amazon S3 location**, enter the Amazon S3 location to which you want to export the output. You can enter the S3 URI, alias, or ARN of the S3 location or S3 access point. For more information access points, see [Managing data access with Amazon S3 access points](#) in the *Amazon S3 User Guide*.
6. For **Export settings**, specify the following fields:
  - a. **File type** – The file format of the exported data.
  - b. **Delimiter** – The delimiter used to separate values in the file.
  - c. **Compression** – The compression method used to reduce the file size.
7. For **Partitioning**, specify the following fields:
  - a. **Number of partitions** – The number of dataset files that SageMaker Canvas writes as the output of the job.
  - b. **Choose columns** – You can choose a subset of columns from the data to include in the partitions.
8. Choose **Add** if you want to simply add a destination node to your data flow, or choose **Add** and then choose **Export** if you want to add the node and initiate an export job.

You should now see a new destination node in your flow.

## Edit a destination node

A *destination node* in a Amazon SageMaker Canvas data flow specifies the Amazon S3 location where your processed and transformed data is stored, applying all the configured transformations in your data flow. You can edit the configuration of an existing destination node and then choose to re-run the job to overwrite the data in the specified Amazon S3 location. For more information about adding a new destination node, see [Add destination nodes](#).

Use the following procedure to edit a destination node in your data flow and initiate an export job.

### To edit a destination node

1. Navigate to your data flow.
2. Choose the ellipsis icon next to the destination node that you want to edit.
3. In the context menu, choose **Edit**.
4. The **Edit destination** side panel opens. From this panel, you can edit details such as the dataset name, the Amazon S3 location, and the export and partitioning settings.
5. (Optional) In **Additional nodes to export**, you can select more destination nodes to process when you run the export job.
6. Leave the **Process entire dataset** option selected if you want Canvas to apply your data flow transforms to your entire dataset and export the result. If you deselect this option, Canvas only applies the transforms to the sample of your dataset used in the interactive Data Wrangler data flow.
7. Leave the **Auto job configuration** option selected if you want Canvas to automatically determine whether to run the job using Canvas application memory or an EMR Serverless job. If you deselect this option and manually configure your job, then you can choose to use either an EMR Serverless or a SageMaker Processing job. For instructions on how to configure an EMR Serverless or a SageMaker Processing job, see the preceding section [Export to Amazon S3](#).
8. When you're done making changes, choose **Update**.

Saving changes to your destination node configuration doesn't automatically re-run a job or overwrite data that has already been processed and exported. Export your data again to run a job with the new configuration. If you decide to export your data again with a job, Canvas uses the updated destination node configuration to transform and output the data to the specified location, overwriting any existing data.

## Create a schedule to automatically process new data

### Note

The following section only applies to SageMaker Processing jobs. If you used the default Canvas settings or EMR Serverless to create a remote job to apply transforms to your full dataset, this section doesn't apply.

If you're processing data periodically, you can create a schedule to run the processing job automatically. For example, you can create a schedule that runs a processing job automatically when you get new data. For more information about processing jobs, see [Export to Amazon S3](#).

When you create a job, you must specify an IAM role that has permissions to create the job. You can use the [AmazonSageMakerCanvasDataPrepFullAccess](#) policy to add permissions.

Add the following trust policy to the role to allow EventBridge to assume it.

```
{
  "Effect": "Allow",
  "Principal": {
    "Service": "events.amazonaws.com"
  },
  "Action": "sts:AssumeRole"
}
```

### Important

When you create a schedule, Data Wrangler creates an eventRule in EventBridge. You incur charges for both the event rules that you create and the instances used to run the processing job.

For information about EventBridge pricing, see [Amazon EventBridge pricing](#). For information about processing job pricing, see [Amazon SageMaker Pricing](#).

You can set a schedule using one of the following methods:

- [CRON expressions](#)

**Note**

Data Wrangler doesn't support the following expressions:

- LW#
- Abbreviations for days
- Abbreviations for months

- [RATE expressions](#)
- Recurring – Set an hourly or daily interval to run the job.
- Specific time – Set specific days and times to run the job.

The following sections provide procedures on scheduling jobs when filling out the SageMaker AI Processing job settings while [exporting your data to Amazon S3](#). All of the following instructions begin in the **Associate schedules** section of the SageMaker Processing job settings.

## CRON

Use the following procedure to create a schedule with a CRON expression.

1. In the **Export to Amazon S3** side panel, make sure you've turned off the **Auto job configuration** toggle and have the **SageMaker Processing** option selected.
2. In the **SageMaker Processing** job settings, open the **Associate schedules** section and choose **Create new schedule**.
3. The **Create new schedule** dialog box opens. For **Schedule Name**, specify the name of the schedule.
4. For **Run Frequency**, choose **CRON**.
5. For each of the **Minutes**, **Hours**, **Days of month**, **Month**, and **Day of week** fields, enter valid CRON expression values.
6. Choose **Create**.
7. (Optional) Choose **Add another schedule** to run the job on an additional schedule.

**Note**

You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

8. Choose one of the following:
  - **Schedule and run now** – The job runs immediately and subsequently runs on the schedules.
  - **Schedule only** – The job only runs on the schedules that you specify.
9. Choose **Export** after you've filled out the rest of the export job settings.

**RATE**

Use the following procedure to create a schedule with a RATE expression.

1. In the **Export to Amazon S3** side panel, make sure you've turned off the **Auto job configuration** toggle and have the **SageMaker Processing** option selected.
2. In the **SageMaker Processing** job settings, open the **Associate schedules** section and choose **Create new schedule**.
3. The **Create new schedule** dialog box opens. For **Schedule Name**, specify the name of the schedule.
4. For **Run Frequency**, choose **Rate**.
5. For **Value**, specify an integer.
6. For **Unit**, select one of the following:
  - **Minutes**
  - **Hours**
  - **Days**
7. Choose **Create**.
8. (Optional) Choose **Add another schedule** to run the job on an additional schedule.

**Note**

You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

9. Choose one of the following:
  - **Schedule and run now** – The job runs immediately and subsequently runs on the schedules.
  - **Schedule only** – The job only runs on the schedules that you specify.
10. Choose **Export** after you've filled out the rest of the export job settings.

## Recurring

Use the following procedure to create a schedule that runs a job on a recurring basis.

1. In the **Export to Amazon S3** side panel, make sure you've turned off the **Auto job configuration** toggle and have the **SageMaker Processing** option selected.
2. In the **SageMaker Processing** job settings, open the **Associate schedules** section and choose **Create new schedule**.
3. The **Create new schedule** dialog box opens. For **Schedule Name**, specify the name of the schedule.
4. For **Run Frequency**, choose **Recurring**.
5. For **Every x hours**, specify the hourly frequency that the job runs during the day. Valid values are integers in the inclusive range of **1** and **23**.
6. For **On days**, select one of the following options:
  - **Every Day**
  - **Weekends**
  - **Weekdays**
  - **Select Days**
  - (Optional) If you've selected **Select Days**, choose the days of the week to run the job.

**Note**

The schedule resets every day. If you schedule a job to run every five hours, it runs at the following times during the day:

- 00:00
- 05:00
- 10:00
- 15:00
- 20:00

7. Choose **Create**.
8. (Optional) Choose **Add another schedule** to run the job on an additional schedule.

**Note**

You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

9. Choose one of the following:
  - **Schedule and run now** – The job runs immediately and subsequently runs on the schedules.
  - **Schedule only** – The job only runs on the schedules that you specify.
10. Choose **Export** after you've filled out the rest of the export job settings.

## Specific time

Use the following procedure to create a schedule that runs a job at specific times.

1. In the **Export to Amazon S3** side panel, make sure you've turned off the **Auto job configuration** toggle and have the **SageMaker Processing** option selected.
2. In the **SageMaker Processing** job settings, open the **Associate schedules** section and choose **Create new schedule**.

3. The **Create new schedule** dialog box opens. For **Schedule Name**, specify the name of the schedule.
4. For **Run Frequency**, choose **Start time**.
5. For **Start time**, enter a time in UTC format (for example, **09:00**). The start time defaults to the time zone where you are located.
6. For **On days**, select one of the following options:
  - **Every Day**
  - **Weekends**
  - **Weekdays**
  - **Select Days**
  - (Optional) If you've selected **Select Days**, choose the days of the week to run the job.
7. Choose **Create**.
8. (Optional) Choose **Add another schedule** to run the job on an additional schedule.

 **Note**

You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

9. Choose one of the following:
  - **Schedule and run now** – The job runs immediately and subsequently runs on the schedules.
  - **Schedule only** – The job only runs on the schedules that you specify.
10. Choose **Export** after you've filled out the rest of the export job settings.

You can use the SageMaker AI AWS Management Console to view the jobs that are scheduled to run. Your processing jobs run within Pipelines. Each processing job has its own pipeline. It runs as a processing step within the pipeline. You can view the schedules that you've created within a pipeline. For information about viewing a pipeline, see [View the details of a pipeline](#).

Use the following procedure to view the jobs that you've scheduled.

To view the jobs you've scheduled, do the following.

1. Open Amazon SageMaker Studio Classic.
2. Open Pipelines
3. View the pipelines for the jobs that you've created.

The pipeline running the job uses the job name as a prefix. For example, if you've created a job named `housing-data-feature-engineering`, the name of the pipeline is `canvas-data-prep-housing-data-feature-engineering`.

4. Choose the pipeline containing your job.
5. View the status of the pipelines. Pipelines with a **Status** of **Succeeded** have run the processing job successfully.

To stop the processing job from running, do the following:

To stop a processing job from running, delete the event rule that specifies the schedule. Deleting an event rule stops all the jobs associated with the schedule from running. For information about deleting a rule, see [Disabling or deleting an Amazon EventBridge rule](#).

You can stop and delete the pipelines associated with the schedules as well. For information about stopping a pipeline, see [StopPipelineExecution](#). For information about deleting a pipeline, see [DeletePipeline](#).

## Automate data preparation in SageMaker Canvas

After you transform your data in data flow, you can export the transforms to your machine learning workflows. When you export your transforms, SageMaker Canvas creates a Jupyter notebook. You must run the notebook within Amazon SageMaker Studio Classic. For information about getting started with Studio Classic, contact your administrator.

### Automate data preparation using Pipelines

When you want to build and deploy large-scale machine learning (ML) workflows, you can use Pipelines to create workflows that manage and deploy SageMaker AI jobs. With Pipelines, you can build workflows that manage your SageMaker AI data preparation, model training, and model deployment jobs. You can use the first-party algorithms that SageMaker AI offers by using Pipelines. For more information on Pipelines, see [SageMaker Pipelines](#).

When you export one or more steps from your data flow to Pipelines, Data Wrangler creates a Jupyter notebook that you can use to define, instantiate, run, and manage a pipeline.

## Use a Jupyter Notebook to Create a Pipeline

Use the following procedure to create a Jupyter notebook to export your Data Wrangler flow to Pipelines.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to Pipelines.

1. Choose the **+** next to the node that you want to export.
2. Choose **Export data flow**.
3. Choose **Pipelines (via Jupyter Notebook)**.
4. Download the Jupyter notebook or copy it to an Amazon S3 location. We recommend copying it to an Amazon S3 location that you can access within Studio Classic. Contact your administrator if you need guidance on a suitable location.
5. Run the Jupyter notebook.

You can use the Jupyter notebook that Data Wrangler produces to define a pipeline. The pipeline includes the data processing steps that are defined by your Data Wrangler flow.

You can add additional steps to your pipeline by adding steps to the steps list in the following code in the notebook:

```
pipeline = Pipeline(  
    name=pipeline_name,  
    parameters=[instance_type, instance_count],  
    steps=[step_process], #Add more steps to this list to run in your Pipeline  
)
```

For more information on defining pipelines, see [Define SageMaker AI Pipeline](#).

## Automate data preparation using an inference endpoint

Use your Data Wrangler flow to process data at the time of inference by creating a SageMaker AI serial inference pipeline from your Data Wrangler flow. An inference pipeline is a series of steps that results in a trained model making predictions on new data. A serial inference pipeline within Data Wrangler transforms the raw data and provides it to the machine learning model for a prediction. You create, run, and manage the inference pipeline from a Jupyter notebook within Studio Classic. For more information about accessing the notebook, see [Use a Jupyter notebook to create an inference endpoint](#).

Within the notebook, you can either train a machine learning model or specify one that you've already trained. You can either use Amazon SageMaker Autopilot or XGBoost to train the model using the data that you've transformed in your Data Wrangler flow.

The pipeline provides the ability to perform either batch or real-time inference. You can also add the Data Wrangler flow to SageMaker Model Registry. For more information about hosting models, see [Multi-model endpoints](#).

### Important

You can't export your Data Wrangler flow to an inference endpoint if it has the following transformations:

- Join
- Concatenate
- Group by

If you must use the preceding transforms to prepare your data, use the following procedure.

#### **To prepare your data for inference with unsupported transforms**

1. Create a Data Wrangler flow.
2. Apply the preceding transforms that aren't supported.
3. Export the data to an Amazon S3 bucket.
4. Create a separate Data Wrangler flow.
5. Import the data that you've exported from the preceding flow.
6. Apply the remaining transforms.
7. Create a serial inference pipeline using the Jupyter notebook that we provide.

For information about exporting your data to an Amazon S3 bucket see [Export data](#). For information about opening the Jupyter notebook used to create the serial inference pipeline, see [Use a Jupyter notebook to create an inference endpoint](#).

Data Wrangler ignores transforms that remove data at the time of inference. For example, Data Wrangler ignores the [Handle Missing Values](#) transform if you use the **Drop missing** configuration.

If you've refit transforms to your entire dataset, the transforms carry over to your inference pipeline. For example, if you used the median value to impute missing values, the median value from refitting the transform is applied to your inference requests. You can either refit the transforms from your Data Wrangler flow when you're using the Jupyter notebook or when you're exporting your data to an inference pipeline. .

The serial inference pipeline supports the following data types for the input and output strings. Each data type has a set of requirements.

### Supported datatypes

- `text/csv` – the datatype for CSV strings
  - The string can't have a header.
  - Features used for the inference pipeline must be in the same order as features in the training dataset.
  - There must be a comma delimiter between features.
  - Records must be delimited by a newline character.

The following is an example of a validly formatted CSV string that you can provide in an inference request.

```
abc,0.0,"Doe, John",12345\ndef,1.1,"Doe, Jane",67890
```

- `application/json` – the datatype for JSON strings
  - The features used in the dataset for the inference pipeline must be in the same order as the features in the training dataset.
  - The data must have a specific schema. You define schema as a single `instances` object that has a set of features. Each features object represents an observation.

The following is an example of a validly formatted JSON string that you can provide in an inference request.

```
{
  "instances": [
```

```
{
  "features": ["abc", 0.0, "Doe, John", 12345]
},
{
  "features": ["def", 1.1, "Doe, Jane", 67890]
}
]
```

## Use a Jupyter notebook to create an inference endpoint

Use the following procedure to export your Data Wrangler flow to create an inference pipeline.

To create an inference pipeline using a Jupyter notebook, do the following.

1. Choose the **+** next to the node that you want to export.
2. Choose **Export data flow**.
3. Choose **SageMaker AI Inference Pipeline (via Jupyter Notebook)**.
4. Download the Jupyter notebook or copy it to an Amazon S3 location. We recommend copying it to an Amazon S3 location that you can access within Studio Classic. Contact your administrator if you need guidance on a suitable location.
5. Run the Jupyter notebook.

When you run the Jupyter notebook, it creates an inference flow artifact. An inference flow artifact is a Data Wrangler flow file with additional metadata used to create the serial inference pipeline. The node that you're exporting encompasses all of the transforms from the preceding nodes.

### Important

Data Wrangler needs the inference flow artifact to run the inference pipeline. You can't use your own flow file as the artifact. You must create it by using the preceding procedure.

## Automate data preparation using Python Code

To export all steps in your data flow to a Python file that you can manually integrate into any data processing workflow, use the following procedure.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to Python code.

1. Choose the **+** next to the node that you want to export.
2. Choose **Export data flow**.
3. Choose **Python Code**.
4. Download the Jupyter notebook or copy it to an Amazon S3 location. We recommend copying it to an Amazon S3 location that you can access within Studio Classic. Contact your administrator if you need guidance on a suitable location.
5. Run the Jupyter notebook.

You might need to configure the Python script to make it run in your pipeline. For example, if you're running a Spark environment, make sure that you are running the script from an environment that has permission to access AWS resources.

## Generative AI foundation models in SageMaker Canvas

Amazon SageMaker Canvas provides generative AI foundation models that you can use to start conversational chats. These content generation models are trained on large amounts of text data to learn the statistical patterns and relationships between words, and they can produce coherent text that is statistically similar to the text on which they were trained. You can use this capability to increase your productivity by doing the following:

- Generate content, such as document outlines, reports, and blogs
- Summarize text from large corpuses of text, such as earnings call transcripts, annual reports, or chapters of user manuals
- Extract insights and key takeaways from large passages of text, such as meeting notes or narratives
- Improve text and catch grammatical errors or typos

The foundation models are a combination of Amazon SageMaker JumpStart and [Amazon Bedrock](#) large language models (LLMs). Canvas offers the following models:

Model	Type	Description
Amazon Titan	Amazon Bedrock model	<p>Amazon Titan is a powerful, general-purpose language model that you can use for tasks such as summarization, text generation (such as creating a blog post), classification, open-ended Q&amp;A, and information extraction. It is pretrained on large datasets, making it suitable for complex tasks and reasoning. To continue supporting best practices in the responsible use of AI, Amazon Titan foundation models are built to detect and remove harmful content in the data, reject inappropriate content in the user input, and filter model outputs that contain inappropriate content (such as hate speech, profanity, and violence).</p>
Anthropic Claude Instant	Amazon Bedrock model	<p>Anthropic's Claude Instant is a faster and more cost-effective yet still very capable model. This model can handle a range of tasks including casual dialogue, text analysis, summarization, and document question answering. Just like Claude-2, Claude Instant can support</p>

Model	Type	Description
		up to 100,000 tokens in each prompt, equivalent to about 200 pages of information.
Anthropic Claude-2	Amazon Bedrock model	Claude-2 is Anthropic's most powerful model, which excels at a wide range of tasks from sophisticated dialogue and creative content generation to detailed instruction following. Claude-2 can take up to 100,000 tokens in each prompt, equivalent to about 200 pages of information. It can generate longer responses compared to its prior version. It supports use cases such as question answering, information extraction, removing PII, content generation, multiple-choice classification, roleplay, comparing text, summarization, and document Q&A with citation.

Model	Type	Description
Falcon-7B-Instruct	JumpStart model	<p>Falcon-7B-Instruct has 7 billion parameters and was fine-tuned on a mixture of chat and instruct datasets. It is suitable as a virtual assistant and performs best when following instructions or engaging in conversation. Since the model was trained on large amounts of English-language web data, it carries the stereotypes and biases commonly found online and is not suitable for languages other than English. Compared to Falcon-40B-Instruct, Falcon-7B-Instruct is a slightly smaller and more compact model.</p>

Model	Type	Description
Falcon-40B-Instruct	JumpStart model	<p>Falcon-40B-Instruct has 40 billion parameters and was fine-tuned on a mixture of chat and instruct datasets. It is suitable as a virtual assistant and performs best when following instructions or engaging in conversation. Since the model was trained on large amounts of English-language web data, it carries the stereotypes and biases commonly found online and is not suitable for languages other than English. Compared to Falcon-7B-Instruct, Falcon-40B-Instruct is a slightly larger and more powerful model.</p>

Model	Type	Description
Jurassic-2 Mid	Amazon Bedrock model	<p>Jurassic-2 Mid is a high-performance text generation model trained on a massive corpus of text (current up to mid 2022). It is highly versatile, general-purpose, and capable of composing human-like text and solving complex tasks such as question answering, text classification, and many others. This model offers zero-shot instruction capabilities, allowing it to be directed with only natural language and without the use of examples. It performs up to 30% faster than its predecessor, the Jurassic-1 model.</p> <p>Jurassic-2 Mid is AI21's mid-sized model, carefully designed to strike the right balance between exceptional quality and affordability.</p>

Model	Type	Description
Jurassic-2 Ultra	Amazon Bedrock model	<p>Jurassic-2 Ultra is a high-performance text generation model trained on a massive corpus of text (current up to mid 2022). It is highly versatile, general-purpose, and capable of composing human-like text and solving complex tasks such as question answering, text classification, and many others. This model offers zero-shot instruction capabilities, allowing it to be directed with only natural language and without the use of examples. It performs up to 30% faster than its predecessor, the Jurassic-1 model.</p> <p>Compared to Jurassic-2 Mid, Jurassic-2 Ultra is a slightly larger and more powerful model.</p>

Model	Type	Description
Llama-2-7b-Chat	JumpStart model	Llama-2-7b-Chat is a foundation model by Meta that is suitable for engaging in meaningful and coherent conversations, generating new content, and extracting answers from existing notes. Since the model was trained on large amounts of English-language internet data, it carries the biases and limitations commonly found online and is best-suited for tasks in English.

Model	Type	Description
Llama-2-13B-Chat	Amazon Bedrock model	<p>Llama-2-13B-Chat by Meta was fine-tuned on conversational data after initial training on internet data. It is optimized for natural dialog and engaging chat abilities, making it well-suited as a conversational agent. Compared to the smaller Llama-2-7b-Chat, Llama-2-13B-Chat has nearly twice as many parameters, allowing it to remember more context and produce more nuanced conversational responses. Like Llama-2-7b-Chat, Llama-2-13B-Chat was trained on English-language data and is best-suited for tasks in English.</p>

Model	Type	Description
Llama-2-70B-Chat	Amazon Bedrock model	<p>Like Llama-2-7b-Chat and Llama-2-13B-Chat, the Llama-2-70B-Chat model by Meta is optimized for engaging in natural and meaningful dialog. With 70 billion parameters, this large conversational model can remember more extensive context and produce highly coherent responses when compared to the more compact model versions. However, this comes at the cost of slower responses and higher resource requirements. Llama-2-70B-Chat was trained on large amounts of English-language internet data and is best-suited for tasks in English.</p>

Model	Type	Description
Mistral-7B	JumpStart model	<p>Mistral-7B by Mistral.AI is an excellent general purpose language model suitable for a wide range of natural language (NLP) tasks like text generation, summarization, and question answering . It utilizes grouped-query attention (GQA) which allows for faster inference speeds, making it perform comparably to models with twice or three times as many parameters. It was trained on a mixture of text data including books, websites, and scientific papers in the English language, so it is best-suited for tasks in English.</p>

Model	Type	Description
Mistral-7B-Chat	JumpStart model	<p>Mistral-7B-Chat is a conversational model by Mistral.AI based on Mistral-7B. While Mistral-7B is best for general NLP tasks, Mistral-7B-Chat has been further fine-tuned on conversational data to optimize its abilities for natural, engaging chat. As a result, Mistral-7B-Chat generates more human-like responses and remembers the context of previous responses. Like Mistral-7B, this model is best-suited for English language tasks.</p>
MPT-7B-Instruct	JumpStart model	<p>MPT-7B-Instruct is a model for long-form instruction following tasks and can assist you with writing tasks including text summarization and question-answering to save you time and effort. This model was trained on large amounts of fine-tuned data and can handle larger inputs, such as complex documents. Use this model when you want to process large bodies of text or want the model to generate long responses.</p>

The foundation models from Amazon Bedrock are currently only available in the US East (N. Virginia) and US West (Oregon) Regions. Additionally, when using foundation models from Amazon Bedrock, you are charged based on the volume of input tokens and output tokens, as specified by each model provider. For more information, see the [Amazon Bedrock pricing page](#). The JumpStart foundation models are deployed on SageMaker AI Hosting instances, and you are charged for the duration of usage based on the instance type used. For more information about the cost of different instance types, see the Amazon SageMaker AI Hosting: Real-Time Inference section on the [SageMaker pricing page](#).

Document querying is an additional feature that you can use to query and get insights from documents stored in indexes using Amazon Kendra. With this functionality, you can generate content from the context of those documents and receive responses that are specific to your business use case, as opposed to responses that are generic to the large amounts of data on which the foundation models were trained. For more information about indexes in Amazon Kendra, see the [Amazon Kendra Developer Guide](#).

If you would like to get responses from any of the foundation models that are customized to your data and use case, you can fine-tune foundation models. To learn more, see [Fine-tune foundation models](#).

If you'd like to get predictions from an Amazon SageMaker JumpStart foundation model through an application or website, you can deploy the model to a SageMaker AI *endpoint*. SageMaker AI endpoints host your model, and you can send requests to the endpoint through your application code to receive predictions from the model. For more information, see [Deploy your models to an endpoint](#).

## Complete the prerequisites for foundation models in SageMaker Canvas

The following sections outline the prerequisites for interacting with foundation models and using the document query feature in Canvas. The rest of the content on this page assumes that you've met the prerequisites for foundation models. The document query feature requires additional permissions.

### Prerequisites for foundation models

The permissions you need for interacting with models are included in the Canvas Ready-to-use models permissions. To use the generative AI-powered models in Canvas, you must turn on the **Canvas Ready-to-use models configuration** permissions when setting up your Amazon SageMaker AI domain. For more information, see [Prerequisites for setting up Amazon SageMaker Canvas](#). The **Canvas Ready-to-use models configuration** attaches the

[AmazonSageMakerCanvasAIServiceAccess](#) policy to your Canvas user's AWS Identity and Access Management (IAM) execution role. If you encounter any issues with granting permissions, see the topic [Troubleshooting issues with granting permissions through the SageMaker AI console](#).

If you've already set up your domain, you can edit your domain settings and turn on the permissions. For instructions on how to edit your domain settings, see [Edit domain settings](#). When editing the settings for your domain, go to the **Canvas settings** and turn on the **Enable Canvas Ready-to-use models** option.

Certain JumpStart foundation models also require that you request a SageMaker AI instance quota increase. Canvas hosts the models that you're currently interacting with on these instances, but the default quota for your account may be insufficient. If you run into an error while running any of the following models, request a quota increase for the associated instance types:

- Falcon-40B – m1.g5.12xlarge, m1.g5.24xlarge
- Falcon-13B – m1.g5.2xlarge, m1.g5.4xlarge, m1.g5.8xlarge
- MPT-7B-Instruct – m1.g5.2xlarge, m1.g5.4xlarge, m1.g5.8xlarge

For the preceding instances types, request an increase from 0 to 1 for the endpoint usage quota. For more information about how to increase an instance quota for your account, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

## Prerequisites for document querying

### Note

Document querying is supported in the following AWS Regions: US East (N. Virginia), US East (Ohio), US West (Oregon), Europe (Ireland), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Asia Pacific (Mumbai).

The document querying feature requires that you already have an Amazon Kendra index that stores your documents and document metadata. For more information about Amazon Kendra, see the [Amazon Kendra Developer Guide](#). To learn more about the quotas for querying indexes, see [Quotas](#) in the *Amazon Kendra Developer Guide*.

You must also make sure that your Canvas user profile has the necessary permissions for document querying. The [AmazonSageMakerCanvasFullAccess](#) policy must be attached to the AWS IAM

execution role for the SageMaker AI domain that hosts your Canvas application (this policy is attached by default to all new and existing Canvas user profiles). You must also specifically grant document querying permissions and specify access to one or more Amazon Kendra indexes.

If your Canvas administrator is setting up a new domain or user profile, have them set up the domain by following the instructions in [Prerequisites for setting up Amazon SageMaker Canvas](#). While setting up the domain, they can turn on the document querying permissions through the **Canvas Ready-to-use models configuration**.

The Canvas administrator can manage document querying permissions at the user profile level as well. For example, if the administrator wants to grant document querying permissions to some user profiles but remove permissions for others, they can edit the permissions for a specific user.

The following procedure shows how to turn on document querying permissions for a specific user profile:

1. Open the SageMaker AI console at <https://console.aws.amazon.com/sagemaker/>.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the user profile's domain.
5. On the **domain details** page, choose the **User profile** whose permissions you want to edit.
6. On the **User Details** page, choose **Edit**.
7. In the left navigation pane, choose **Canvas settings**.
8. In the **Canvas Ready-to-use models configuration** section, turn on the **Enable document query using Amazon Kendra** toggle.
9. In the dropdown, select one or more Amazon Kendra indexes to which you want to grant access.
10. Choose **Submit** to save the changes to your domain settings.

You should now be able to use Canvas foundation models to query documents in the specified Amazon Kendra indexes.

## Start a new conversation to generate, extract, or summarize content

To get started with generative AI foundation models in Canvas, you can initiate a new chat session with one of the models. For JumpStart models, you are charged while the model is active, so

you must start up models when you want to use them and shut them down when you are done interacting. If you do not shut down a JumpStart model, Canvas shuts it down after 2 hours of inactivity. For Amazon Bedrock models (such as Amazon Titan), you are charged by prompt; the models are already active and don't need to be started up or shut down. You are charged directly for use of these models by Amazon Bedrock.

To open a chat with a model, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **Ready-to-use models**.
3. Choose **Generate, extract and summarize content**.
4. On the welcome page, you'll receive a recommendation to start up the default model. You can start the recommended model, or you can choose **Select another model** from the dropdown to choose a different one.
5. If you selected a JumpStart foundation model, you have to start it up before it is available for use. Choose **Start up the model**, and then the model is deployed to a SageMaker AI instance. It might take several minutes for this to complete. When the model is ready, you can enter prompts and ask the model questions.

If you selected a foundation model from Amazon Bedrock, you can start using it instantly by entering a prompt and asking questions.

Depending on the model, you can perform various tasks. For example, you can enter a passage of text and ask the model to summarize it. Or, you can ask the model to come up with a short summary of the market trends in your domain.

The model's responses in a chat are based on the context of your previous prompts. If you want to ask a new question in the chat that is unrelated to the previous conversation topic, we recommend that you start a new chat with the model.

## Extract information from documents with document querying

### Note

This section assumes that you've completed the section above [Prerequisites for document querying](#).

Document querying is a feature that you can use while interacting with foundation models in Canvas. With document querying, you can access a corpus of documents stored in an Amazon Kendra *index*, which holds the contents of your documents and is structured in a way to make documents searchable. You can ask specific questions that are targeted to the data in your Amazon Kendra index, and the foundation model returns answers to your questions. For example, you can query an internal knowledge base of IT information and ask questions such as “How do I connect to my company’s network?” For more information about setting up an index, see the [Amazon Kendra Developer Guide](#).

When using the document query feature, the foundation models restrict their responses to the content of the documents in your index with a technique called Retrieval Augmented Generation (RAG). This technique bundles the most relevant information from the index along with the user's prompt and sends it to the foundation model to get a response. Responses are limited to what can be found in your index, preventing the model from giving you incorrect responses based on external data. For more information about this process, see the blog post [Quickly build high-accuracy Generative AI applications on enterprise data](#).

To get started, in a chat with a foundation model in Canvas, turn on the **Document query** toggle at the top of the page. From the dropdown, select the Amazon Kendra index that you want to query. Then, you can begin asking questions related to the documents in your index.

### Important

Document querying supports the [Compare model outputs](#) feature. Any existing chat history is overwritten when you start a new chat to compare model outputs.

## Start up models

### Note

The following section describe starting up models, which only applies to the JumpStart foundation models, such as Falcon-40B-Instruct. You can access Amazon Bedrock models, such as Amazon Titan, instantly at any time.

You can start up as many JumpStart models as you like. Each active JumpStart model incurs charges on your account, so we recommend that you don't start up more models than you are currently using.

To start up another model, you can do the following:

1. On the **Generate, extract and summarize content** page, choose **New chat**.
2. Choose the model from the dropdown menu. If you want to choose a model not displayed in the dropdown, choose **Start up another model**, and then select the model that you want to start up.
3. Choose **Start up model**.

The model should begin starting up, and within a few minutes you can chat with the model.

## Shut down models

We highly recommend that you shut down models that you aren't using. The models automatically shut down after 2 hours of inactivity. However, to manually shut down a model, you can do the following:

1. On the **Generate, extract and summarize content** page, open the chat for the model that you want to shut down.
2. On the chat page, choose the **More options** icon (⋮).
3. Choose **Shut down model**.
4. In the **Shut down model** confirmation box, choose **Shut down**.

The model begins shutting down. If your chat compares two or more models, you can shut down an individual model from the chat page by choosing the model's **More options** icon (⋮) and then choosing **Shut down model**.

## Compare model outputs

You might want to compare the output of different models side by side to see which model output you prefer. This can help you decide which model is best suited to your use case. You can compare up to three models in chats.

**Note**

Each individual model incurs charges on your account.

You must start a new chat to add models for comparison. To compare the output of models side by side in a chat, do the following:

1. In a chat, choose **New chat**.
2. Choose **Compare**, and use the dropdown menu to select the model that you want to add. To add a third model, choose **Compare** again to add another model.

**Note**

If you want to use a JumpStart model that isn't currently active, you are prompted to start up the model.

When the models are active, you see the two models side by side in the chat. You can submit your prompt, and each model responds in the same chat, as shown in the following screenshot.

Ready-to-use models / **Generate, extract and summarize content** Ready-to-use model

+ New chat

Write a report outlining the potential benefits and ROI of implementing a customer relationship management (CRM) system.

Here is a draft report on the potential benefits and ROI of implementing a CRM system:

Potential Benefits and ROI of Implementing a CRM System

Introduction

Customer relationship management (CRM) systems are software tools that help businesses manage relationships and interactions with customers and prospects. Implementing a CRM can provide numerous benefits that drive return on investment (ROI) through increased sales, improved customer retention and loyalty, and operational efficiencies. This report outlines the key benefits a business can realize from CRM implementation and how they translate to measurable ROI.

Increased Sales

One of the biggest potential benefits of CRM is increased sales revenue. By tracking every customer interaction in one centralized database, sales teams can better capitalize on cross-sell and upsell opportunities. The CRM provides insights into which customers are ready to buy more or upgrade their purchases. Sales reps can focus their efforts on these qualified leads to drive more sales.

According to research, businesses see an average 10% or more increase in annual revenue after implementing a CRM. For a company with \$10 million in yearly sales, a CRM could help generate an additional \$1 million or more.

Improved Customer Retention

It costs 5 times more to attract a new customer than to keep an existing one. A CRM helps retain more customers by tracking satisfaction levels, purchase history, and support needs. Sales and marketing teams can proactively reach out to at-risk customers and provide tailored promotions to encourage repeat purchases.

A customer relationship management (CRM) system can be a powerful tool for businesses of all sizes. It can help businesses to streamline their customer interactions, improve customer satisfaction, and increase their ROI. A CRM system can help businesses to better manage customer relationships by providing a centralized platform for customer data, including contact information and communication history. This can help businesses to better understand their customers and their needs, which can lead to improved customer service and increased customer loyalty.

A CRM system can also help businesses to improve their sales and marketing strategies. By tracking customer interactions and analyzing customer data, businesses can identify opportunities to increase sales and improve customer relationships.

Finally, a CRM system can help businesses to better understand their ROI. By tracking customer interactions and analyzing customer data, businesses can identify areas where they can save money and increase their ROI.

Overall, a CRM system can be a powerful tool for businesses of all sizes. It can help businesses to streamline their customer interactions, improve customer satisfaction, and increase their ROI.

Ask me anything...

When you're done interacting, make sure to shut down any JumpStart models individually to avoid incurring further charges.

## Fine-tune foundation models

The foundation models that you can access through Amazon SageMaker Canvas can help you with a range of general purpose tasks. However, if you have a specific use case and would like to customized responses based on your own data, you can *fine-tune* a foundation model.

To fine-tune a foundation model, you provide a dataset that consists of sample prompts and model responses. Then, you train the foundation model on the data. Finally, the fine-tuned foundation model is able to provide you with more specific responses.

The following list contains the foundation models that you can fine-tune in Canvas:

- Titan Express
- Falcon-7B
- Falcon-7B-Instruct
- Falcon-40B-Instruct

- Falcon-40B
- Flan-T5-Large
- Flan-T5-Xl
- Flan-T5-Xxl
- MPT-7B
- MPT-7B-Instruct

You can access more detailed information about each foundation model in the Canvas application while fine-tuning a model. For more information, see [Fine-tune the model](#).

This topic describes how to fine-tune foundation models in Canvas.

### Before you begin

Before fine-tuning a foundation model, make sure that you have the permissions for Ready-to-use models in Canvas and an AWS Identity and Access Management execution role that has a trust relationship with Amazon Bedrock, which allows Amazon Bedrock to assume your role while fine-tuning foundation models.

While setting up or editing your Amazon SageMaker AI domain, you must 1) turn on the Canvas Ready-to-use models configuration permissions, and 2) create or specify an Amazon Bedrock role, which is an IAM execution role to which SageMaker AI attaches a trust relationship with Amazon Bedrock. For more information about configuring these settings, see [Prerequisites for setting up Amazon SageMaker Canvas](#).

You can configure the Amazon Bedrock role manually if you would rather use your own IAM execution role (instead of letting SageMaker AI create one on your behalf). For more information about configuring your own IAM execution role's trust relationship with Amazon Bedrock, see [Grant Users Permissions to Use Amazon Bedrock and Generative AI Features in Canvas](#).

You must also have a dataset that is formatted for fine-tuning large language models (LLMs). The following is a list of requirements for your dataset:

- The dataset must be tabular and contain at least two columns of text data—one input column (which contains example prompts to the model) and one output column (which contains example responses from the model).

An example is the following:

Input	Output
What are your shipping terms?	We offer free shipping on all orders over \$50. Orders under \$50 have a shipping fee of \$5.99.
How can I return an item?	To return an item, please visit our returns center and follow the instructions. You must provide your order number and the reason for the return.
I'm having trouble with my product. What can I do?	Please contact our customer support team and we will be happy to help you troubleshoot the issue.

- We recommend that the dataset has at least 100 text pairs (rows of corresponding input and output items). This ensures that the foundation model has enough data for fine-tuning and increases the accuracy of its responses.
- Each input and output item should contain a maximum of 512 characters. Anything longer is reduced to 512 characters when fine-tuning the foundation model.

When fine-tuning an Amazon Bedrock model, you must adhere to the Amazon Bedrock quotas. For more information, see [Model customization quotas](#) in the *Amazon Bedrock User Guide*.

For more information about general dataset requirements and limitations in Canvas, see [Create a dataset](#).

### Fine-tune a foundation model

You can fine-tune a foundation model by using any of the following methods in the Canvas application:

- While in a **Generate, extract and summarize content** chat with a foundation model, choose the **Fine-tune model** icon

).

- While in a chat with a foundation model, if you've re-generated the response two or more times, then Canvas offers you the option to **Fine-tune model**. The following screenshot shows you what this looks like.

Not happy with the model's response? You can fine-tune it to get the responses you want.

 Fine-tune model

[Learn more about fine-tuning a model.](#)

- On the **My models** page, you can create a new model by choosing **New model**, and then select **Fine-tune foundation model**.
- On the **Ready-to-use models** home page, you can choose **Create your own model**, and then in the **Create new model** dialog box, choose **Fine-tune foundation model**.
- While browsing your datasets in the **Data Wrangler** tab, you can select a dataset and choose **Create a model**. Then, choose **Fine-tune foundation model**.

After you've begun to fine-tune a model, do the following:

### Select a dataset

On the **Select** tab of fine-tuning a model, you choose the data on which you'd like to train the foundation model.

Either select an existing dataset or create a new dataset that meets the requirements listed in the [Before you begin](#) section. For more information about how to create a dataset, see [Create a dataset](#).

When you've selected or created a dataset and you're ready to move on, choose **Select dataset**.

### Fine-tune the model

After selecting your data, you're now ready to begin training and fine-tune the model.

On the **Fine-tune** tab, do the following:

1. (Optional) Choose **Learn more about our foundation models** to access more information about each model and help you decide which foundation model or models to deploy.
2. For **Select up to 3 base models**, open the dropdown menu and check up to 3 foundation models (up to 2 JumpStart models and 1 Amazon Bedrock model) that you'd like to fine-tune during the training job. By fine-tuning multiple foundation models, you can compare

their performance and ultimately choose the one best suited to your use case as the default model. For more information about default models, see [View model candidates in the model leaderboard](#).

3. For **Select Input column**, select the column of text data in your dataset that contains the example model prompts.
4. For **Select Output column**, select the column of text data in your dataset that contains the example model responses.
5. (Optional) To configure advanced settings for the training job, choose **Configure model**. For more information about the advanced model building settings, see [Advanced model building configurations](#).

In the **Configure model** pop-up window, do the following:

- a. For **Hyperparameters**, you can adjust the **Epoch count**, **Batch size**, **Learning rate**, and **Learning rate warmup steps** for each model you selected. For more information about these parameters, see the [Hyperparameters section in the JumpStart documentation](#).
  - b. For **Data split**, you can specify percentages for how to divide your data between the **Training set** and **Validation set**.
  - c. For **Max job runtime**, you can set the maximum amount of time that Canvas runs the build job. This feature is only available for JumpStart foundation models.
  - d. After configuring the settings, choose **Save**.
6. Choose **Fine-tune** to begin training the foundation models you selected.

After the fine-tuning job begins, you can leave the page. When the model shows as **Ready** on the **My models** page, it's ready for use, and you can now analyze the performance of your fine-tuned foundation model.

### Analyze the fine-tuned foundation model

On the **Analyze** tab of your fine-tuned foundation model, you can see the model's performance.

The **Overview** tab on this page shows you the perplexity and loss scores, along with analyses that visualize the model's improvement over time during training. The following screenshot shows the **Overview** tab.

On this page, you can see the following visualizations:

- The **Perplexity Curve** measures how well the model predicts the next word in a sequence, or how grammatical the model's output is. Ideally, as the model improves during training, the score decreases and results in a curve that lowers and flattens over time.
- The **Loss Curve** quantifies the difference between the correct output and the model's predicted output. A loss curve that decreases and flattens over time indicates that the model is improving its ability to make accurate predictions.

The **Advanced metrics** tab shows you the hyperparameters and additional metrics for your model. It looks like the following screenshot:

My models > get\_cand\_delay > Version 1 Add version ↻ ⋮

Select Fine-tune **Analyze**

**Model status**

Training perplexity ⓘ	Validation perplexity ⓘ	Training loss ⓘ	Validation loss ⓘ	<a href="#">Test in Ready-to-use models</a>
208981.297	61340.328	11.157	11.024	

Overview **Advanced metrics** Model leaderboard

ROUGE ⓘ  
0.000

Explainability **Artifacts**

**Hyperparameters**

Hyperparameters ⓘ	
Name	Value
epochCount	10
batchSize	1
learningRate	0.0002
learningRateWarmupSteps	1

The **Advanced metrics** tab contains the following information:

- The **Explainability** section contains the **Hyperparameters**, which are the values set before the job to guide the model's fine-tuning. If you didn't specify custom hyperparameters in the model's advanced settings in the [Fine-tune the model](#) section, then Canvas selects default hyperparameters for you.

For JumpStart models, you can also see the advanced metric [ROUGE \(Recall-Oriented Understudy for Gisting Evaluation\)](#), which evaluates the quality of summaries generated by the model. It measures how well the model can summarize the main points of a passage.

- The **Artifacts** section provides you with links to artifacts generated during the fine-tuning job. You can access the training and validation data saved in Amazon S3, as well as the link to the model evaluation report (to learn more, see the following paragraph).

To get more model evaluation insights, you can download a report that is generated using [SageMaker Clarify](#), which is a feature that can help you detect bias in your model and data. First, generate the report by choosing **Generate evaluation report** at the bottom of the page. After the report has generated, you can download the full report by choosing **Download report** or by returning to the **Artifacts** section.

You can also access a Jupyter notebook that shows you how to replicate your fine-tuning job in Python code. You can use this to replicate or make programmatic changes to your fine-tuning job or get a deeper understanding of how Canvas fine-tunes your model. To learn more about model notebooks and how to access them, see [Download a model notebook](#).

For more information about how to interpret the information in the **Analyze** tab of your fine-tuned foundation model, see the topic [Model evaluation](#).

After analyzing the **Overview** and **Advanced metrics** tabs, you can also choose to open the **Model leaderboard**, which shows you the list of the base models trained during the build. The model with the lowest loss score is considered the best performing model and is selected as the **Default model**, which is the model whose analysis you see in the **Analyze** tab. You can only test and deploy the default model. For more information about the model leaderboard and how to change the default model, see [View model candidates in the model leaderboard](#).

### Test a fine-tuned foundation model in a chat

After analyzing the performance of a fine-tuned foundation model, you might want to test it out or compare its responses with the base model. You can test a fine-tuned foundation model in a chat in the **Generate, extract and summarize content** feature.

Start a chat with a fine-tuned model by choosing one of the following methods:

- On the fine-tuned model's **Analyze** tab, choose **Test in Ready-to-use foundation models**.
- On the Canvas **Ready-to-use models** page, choose **Generate, extract and summarize content**. Then, choose **New chat** and select the version of the model that you want to test.

The model starts up in a chat, and you can interact with it like any other foundation model. You can add more models to the chat and compare their outputs. For more information about the functionality of chats, see [Generative AI foundation models in SageMaker Canvas](#).

### Operationalize fine-tuned foundation models

After fine-tuning your model in Canvas, you can do the following:

- Register the model to the SageMaker Model Registry for integration into your organizations MLOps processes. For more information, see [Register a model version in the SageMaker AI model registry](#).

- Deploy the model to a SageMaker AI endpoint and send requests to the model from your application or website to get predictions (or *inference*). For more information, see [Deploy your models to an endpoint](#).

### Important

You can only register and deploy JumpStart based fine-tuned foundation models, not Amazon Bedrock based models.

## Ready-to-use models

With Amazon SageMaker Canvas Ready-to-use models, you can make predictions on your data without writing a single line of code or having to build a model—all you have to bring is your data. The Ready-to-use models use pre-built models to generate predictions without requiring you to spend the time, expertise, or cost required to build a model, and you can choose from a variety of use cases ranging from language detection to expense analysis.

Canvas integrates with existing AWS services, such as [Amazon Textract](#), [Amazon Rekognition](#), and [Amazon Comprehend](#), to analyze your data and make predictions or extract insights. You can use the predictive power of these services from within the Canvas application to get high quality predictions for your data.

Canvas supports the following Ready-to-use models types:

Ready-to-use model	Description	Supported data type
Sentiment analysis	Detect sentiment in lines of text, which can be positive, negative, neutral, or mixed. Currently, you can only do sentiment analysis for English language text.	Plain text or tabular (CSV, Parquet)
Entities extraction	Extract entities, which are real-world objects such as people, places, and commercial items, or units	Plain text or tabular (CSV, Parquet)

Ready-to-use model	Description	Supported data type
	such as dates and quantities, from text.	
Language detection	Determine the dominant language in text such as English, French, or German.	Plain text or tabular (CSV, Parquet)
Personal information detection	Detect personal information that could be used to identify an individual, such as addresses, bank account numbers, and phone numbers, from text.	Plain text or tabular (CSV, Parquet)
Object detection in images	Detect objects, concepts, scenes, and actions in your images.	Image (JPG, PNG)
Text detection in images	Detect text in your images.	Image (JPG, PNG)
Expense analysis	Extract information from invoices and receipts, such as date, number, item prices, total amount, and payment terms.	Document (PDF, JPG, PNG, TIFF)
Identity document analysis	Extract information from passports, driver licenses, and other identity documentation issued by the US Government.	Document (PDF, JPG, PNG, TIFF)
Document analysis	Analyze documents and forms for relationships among detected text.	Document (PDF, JPG, PNG, TIFF)

Ready-to-use model	Description	Supported data type
Document queries	Extract information from structured documents such as paystubs, bank statements, W-2s, and mortgage application forms by asking questions using natural language.	Document (PDF)

## Get started

To get started with Ready-to-use models, review the following information.

### Prerequisites

To use Ready-to-use models in Canvas, you must turn on the **Canvas Ready-to-use models configuration** permissions when [setting up your Amazon SageMaker AI domain](#). The **Canvas Ready-to-use models configuration** attaches the [AmazonSageMakerCanvasAIServicesAccess](#) policy to your Canvas user's AWS Identity and Access Management (IAM) execution role. If you encounter any issues with granting permissions, see the topic [Troubleshooting issues with granting permissions through the SageMaker AI console](#).

If you've already set up your domain, you can edit your domain settings and turn on the permissions. For instructions on how to edit your domain settings, see [Edit domain settings](#). When editing the settings for your domain, go to the **Canvas settings** and turn on the **Enable Canvas Ready-to-use models** option.

### (Optional) Opt out of AI services data storage

Certain AWS AI services store and use your data to make improvements to the service. You can opt out of having your data stored or used for service improvements. To learn more about how to opt out, see [AI services opt-out policies](#) in the *AWS Organizations User Guide*.

### How to use Ready-to-use models

To get started with Ready-to-use models, do the following:

1. **(Optional) Import your data.** You can import a tabular, image, or document dataset to generate batch predictions, or a dataset of predictions, with Ready-to-use models. To get started with importing a dataset, see [Create a data flow](#).

2. **Generate predictions.** You can generate single or batch predictions with your chosen Ready-to-use model. To get started with making predictions, see [Make predictions for text data](#).

## Make predictions for text data

The following procedures describe how to make both single and batch predictions for text datasets. Each Ready-to-use model supports both **Single predictions** and **Batch predictions** for your dataset. A **Single prediction** is when you only need to make one prediction. For example, you have one image from which you want to extract text, or one paragraph of text for which you want to detect the dominant language. A **Batch prediction** is when you'd like to make predictions for an entire dataset. For example, you might have a CSV file of customer reviews for which you'd like to analyze the customer sentiment, or you might have image files in which you'd like to detect objects.

You can use these procedures for the following Ready-to-use model types: sentiment analysis, entities extraction, language detection, and personal information detection.

### Note

For sentiment analysis, you can only use English language text.

## Single predictions

To make a single prediction for Ready-to-use models that accept text data, do the following:

1. In the left navigation pane of the Canvas application, choose **Ready-to-use models**.
2. On the **Ready-to-use models** page, choose the Ready-to-use model for your use case. For text data, it should be one of the following: **Sentiment analysis**, **Entities extraction**, **Language detection**, or **Personal information detection**.
3. On the **Run predictions** page for your chosen Ready-to-use model, choose **Single prediction**.
4. For **Text field**, enter the text for which you'd like to get a prediction.
5. Choose **Generate prediction results** to get your prediction.

In the right pane **Prediction results**, you receive an analysis of your text in addition to a **Confidence** score for each result or label. For example, if you chose language detection and

entered a passage of text in French, you might get French with a 95% confidence score and traces of other languages, like English, with a 5% confidence score.

The following screenshot shows the results for a single prediction using language detection where the model is 100% confident that the passage is English.

The screenshot displays the Amazon SageMaker AI Language detection interface. At the top, it says "Language detection (AI SOLUTION)" with a subtitle "Determine the dominant language in text such as English, French or German." Below this, there are two tabs: "Single prediction" (selected) and "Batch prediction". A "Pricing Information" link is visible in the top right. A note states: "Use single prediction to get real-time results on the text you enter. The results are the languages detected in the text. To generate prediction results from multiple CSV datasets, use batch prediction instead." The main area has a "Text field" with a "Supported languages" link and a "Generate prediction results" button. The text entered is: "I enjoyed visiting Mexico. It was very comfortable but also expensive. The amenities were ok but the service was better than I expected. Chichen Itza and Museo Nacional de Antropologia are my top favorites." Below the text is a button that says "Enter your own text to predict." The "Prediction results" panel on the right shows a search bar and a "Confidence" section with a blue bar representing 100% confidence for "English". At the bottom left, it indicates "206 out of 100,000 characters used."

## Batch predictions

To make batch predictions for Ready-to-use models that accept text data, do the following:

1. In the left navigation pane of the Canvas application, choose **Ready-to-use models**.
2. On the **Ready-to-use models** page, choose the Ready-to-use model for your use case. For text data, it should be one of the following: **Sentiment analysis**, **Entities extraction**, **Language detection**, or **Personal information detection**.
3. On the **Run predictions** page for your chosen Ready-to-use model, choose **Batch prediction**.
4. Choose **Select dataset** if you've already imported your dataset. If not, choose **Import new dataset**, and then you are directed through the import data workflow.
5. From the list of available datasets, select your dataset and choose **Generate predictions** to get your predictions.

After the prediction job finishes running, on the **Run predictions** page, you see an output dataset listed under **Predictions**. This dataset contains your results, and if you select the **More options** icon (⋮), you can **Preview** the output data. Then, you can choose **Download** to download the results.

## Make predictions for image data

The following procedures describe how to make both single and batch predictions for image datasets. Each Ready-to-use model supports both **Single predictions** and **Batch predictions** for your dataset. A **Single prediction** is when you only need to make one prediction. For example, you have one image from which you want to extract text, or one paragraph of text for which you want to detect the dominant language. A **Batch prediction** is when you'd like to make predictions for an entire dataset. For example, you might have a CSV file of customer reviews for which you'd like to analyze the customer sentiment, or you might have image files in which you'd like to detect objects.

You can use these procedures for the following Ready-to-use model types: object detection images and text detection in images.

### Single predictions

To make a single prediction for Ready-to-use models that accept image data, do the following:

1. In the left navigation pane of the Canvas application, choose **Ready-to-use models**.
2. On the **Ready-to-use models** page, choose the Ready-to-use model for your use case. For image data, it should be one of the following: **Object detection images** or **Text detection in images**.
3. On the **Run predictions** page for your chosen Ready-to-use model, choose **Single prediction**.
4. Choose **Upload image**.
5. You are prompted to select an image to upload from your local computer. Select the image from your local files, and then the prediction results generate.

In the right pane **Prediction results**, you receive an analysis of your image in addition to a **Confidence** score for each object or text detected. For example, if you chose object detection in images, you receive a list of objects in the image along with a confidence score of how certain the model is that each object was accurately detected, such as 93%.

The following screenshot shows the results for a single prediction using the object detection in images solution, where the model predicts objects such as a clock tower and bus with 100% confidence.

**Object detection in images** AI SOLUTION

Detect objects, concepts, scenes, and actions in your images.

● Clock Tower	100%
● Tower	100%
● Bus	100%
● Vehicle	100%
● Housing	95%
● Tour Bus	93%
● Double Decker Bus	92%
● House	88%
● Person	71%

## Batch predictions

To make batch predictions for Ready-to-use models that accept image data, do the following:

1. In the left navigation pane of the Canvas application, choose **Ready-to-use models**.
2. On the **Ready-to-use models** page, choose the Ready-to-use model for your use case. For image data, it should be one of the following: **Object detection images** or **Text detection in images**.
3. On the **Run predictions** page for your chosen Ready-to-use model, choose **Batch prediction**.
4. Choose **Select dataset** if you've already imported your dataset. If not, choose **Import new dataset**, and then you are directed through the import data workflow.
5. From the list of available datasets, select your dataset and choose **Generate predictions** to get your predictions.

After the prediction job finishes running, on the **Run predictions** page, you see an output dataset listed under **Predictions**. This dataset contains your results, and if you select the **More options** icon (⋮),

you can choose **View prediction results** to preview the output data. Then, you can choose **Download prediction** and download the results as a CSV or a ZIP file.

## Make predictions for document data

The following procedures describe how to make both single and batch predictions for document datasets. Each Ready-to-use model supports both **Single predictions** and **Batch predictions** for your dataset. A **Single prediction** is when you only need to make one prediction. For example, you have one image from which you want to extract text, or one paragraph of text for which you want to detect the dominant language. A **Batch prediction** is when you'd like to make predictions for an entire dataset. For example, you might have a CSV file of customer reviews for which you'd like to analyze the customer sentiment, or you might have image files in which you'd like to detect objects.

You can use these procedures for the following Ready-to-use model types: expense analysis, identity document analysis, and document analysis.

### Note

For document queries, only single predictions are currently supported.

## Single predictions

To make a single prediction for Ready-to-use models that accept document data, do the following:

1. In the left navigation pane of the Canvas application, choose **Ready-to-use models**.
2. On the **Ready-to-use models** page, choose the Ready-to-use model for your use case. For document data, it should be one of the following: **Expense analysis**, **Identity document analysis**, or **Document analysis**.
3. On the **Run predictions** page for your chosen Ready-to-use model, choose **Single prediction**.
4. If your Ready-to-use model is identity document analysis or document analysis, complete the following actions. If you're doing expense analysis or document queries, skip this step and go to Step 5 or Step 6, respectively.
  - a. Choose **Upload document**.
  - b. You are prompted to upload a PDF, JPG, or PNG file from your local computer. Select the document from your local files, and then the prediction results will generate.

5. If your Ready-to-use model is expense analysis, do the following:
  - a. Choose **Upload invoice or receipt**.
  - b. You are prompted to upload a PDF, JPG, PNG, or TIFF file from your local computer. Select the document from your local files, and then the prediction results will generate.
6. If your Ready-to-use model is document queries, do the following:
  - a. Choose **Upload document**.
  - b. You are prompted to upload a PDF file from your local computer. Select the document from your local files. Your PDF must be 1–100 pages long.

 **Note**

If you're in the Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), or Europe (Frankfurt) regions, then the maximum PDF size for document queries is 20 pages.

- c. In the right side pane, enter queries to search for information in the document. The number of characters you can have in a single query is from 1–200. You can add up to 15 queries at a time.
- d. Choose **Submit queries**, and then the results generate with answers to your queries. You are billed once for each submissions of queries you make.

In the right pane **Prediction results**, you'll receive an analysis of your document.

The following information describes the results for each type of solution:

- For expense analysis, the results are categorized into **Summary fields**, which include fields such as the total on a receipt, and **Line item fields**, which include fields such as individual items on a receipt. The identified fields are highlighted on the document image in the output.
- For identity document analysis, the output shows you the fields that the Ready-to-use model identified, such as first and last name, address, or date of birth. The identified fields are highlighted on the document image in the output.
- For document analysis, the results are categorized into **Raw text**, **Forms**, **Tables**, and **Signatures**. **Raw text** includes all of the extracted text, while **Forms**, **Tables**, and **Signatures** only include information on the form that falls into those categories. For example, **Tables** only includes

information extracted from tables in the document. The identified fields are highlighted on the document image in the output.

- For document queries, Canvas returns answers to each of your queries. You can open the collapsible query dropdown to view a result, along with a confidence score for the prediction. If Canvas finds multiple answers in the document, then you might have more than one result for each query.

The following screenshot shows the results for a single prediction using the document analysis solution.

**Document analysis** AI SOLUTION  
Analyze documents and forms for relationships among detected text.

Single prediction | Batch prediction Pricing Information

Use single prediction to get real-time results on the document you upload. The results are the raw text, forms, tables, and signatures detected from the document. To generate prediction results from multiple document datasets, use batch prediction instead.

## Batch predictions

To make batch predictions for Ready-to-use models that accept document data, do the following:

- In the left navigation pane of the Canvas application, choose **Ready-to-use models**.
- On the **Ready-to-use models** page, choose the Ready-to-use model for your use case. For image data, it should be one of the following: **Expense analysis**, **Identity document analysis**, or **Document analysis**.
- On the **Run predictions** page for your chosen Ready-to-use model, choose **Batch prediction**.

4. Choose **Select dataset** if you've already imported your dataset. If not, choose **Import new dataset**, and then you are directed through the import data workflow.
5. From the list of available datasets, select your dataset and choose **Generate predictions**. If your use case is document analysis, continue to Step 6.
6. (Optional) If your use case is Document analysis, another dialog box called **Select features to include in batch prediction** appears. You can select **Forms**, **Tables**, and **Signatures** to group the results by those features. Then, choose **Generate predictions**.

After the prediction job finishes running, on the **Run predictions** page, you see an output dataset listed under **Predictions**. This dataset contains your results, and if you select the **More options** icon (⋮), you can choose **View prediction results** to preview the analysis of your document data.

The following information describes the results for each type of solution:

- For expense analysis, the results are categorized into **Summary fields**, which include fields such as the total on a receipt, and **Line item fields**, which include fields such as individual items on a receipt. The identified fields are highlighted on the document image in the output.
- For identity document analysis, the output shows you the fields that the Ready-to-use model identified, such as first and last name, address, or date of birth. The identified fields are highlighted on the document image in the output.
- For document analysis, the results are categorized into **Raw text**, **Forms**, **Tables**, and **Signatures**. **Raw text** includes all of the extracted text, while **Forms**, **Tables**, and **Signatures** only include information on the form that falls into those categories. For example, **Tables** only includes information extracted from tables in the document. The identified fields are highlighted on the document image in the output.

After previewing your results, you can choose **Download prediction** and download the results as a ZIP file.

## Custom models

In Amazon SageMaker Canvas, you can train custom machine learning models tailored to your specific data and use case. By training a custom model on your data, you are able to capture characteristics and trends that are specific and most representative of your data. For example, you

might want to create a custom time series forecasting model that you train on inventory data from your warehouse to manage your logistics operations.

Canvas supports training a range of model types. After training a custom model, you can evaluate the model's performance and accuracy. Once satisfied with a model, you can make predictions on new data, and you also have the option to share the custom model with data scientists for further analysis or to deploy it to a SageMaker AI hosted endpoint for real-time inference, all from within the Canvas application.

You can train a Canvas custom model on the following types of datasets:

- Tabular (including numeric, categorical, timeseries, and text data)
- Image

The following table shows the types of custom models that you can build in Canvas, along with their supported data types and data sources.

Model type	Example use case	Supported data types	Supported data sources
Numeric prediction	Predicting house prices based on features like square footage	Numeric	Local upload, Amazon S3, SaaS connectors
2 category prediction	Predicting whether or not a customer is likely to churn	Binary or categorical	Local upload, Amazon S3, SaaS connectors
3+ category prediction	Predicting patient outcomes after being discharged from the hospital	Categorical	Local upload, Amazon S3, SaaS connectors
Time series forecasting	Predicting your inventory for the next quarter	Timeseries	Local upload, Amazon S3, SaaS connectors

Model type	Example use case	Supported data types	Supported data sources
Single-label image prediction	Predicting types of manufacturing defects in images	Image (JPG, PNG)	Local upload, Amazon S3
Multi-category text prediction	Predicting categories of products, such as clothing, electronics, or household goods, based on product descriptions	Source column: text Target column: binary or categorical	Local upload, Amazon S3

## Get started

To get started with building and generating predictions from a custom model, do the following:

- Determine your use case and type of model that you want to build. For more information about the custom model types, see [How custom models work](#). For more information about the data types and sources supported for custom models, see [Data import](#).
- [Import your data](#) into Canvas. You can build a custom model with any tabular or image dataset that meets the input requirements. For more information about the input requirements, see [Create a dataset](#).

To learn more about sample datasets provided by SageMaker AI with which you can experiment, see [Sample datasets in Canvas](#).

- [Build](#) your custom model. You can do a **Quick build** to get your model and start making predictions more quickly, or you can do a **Standard build** for greater accuracy.

For numeric, categorical, and time series forecasting model types, you can clean and prepare your data with the [Data Wrangler feature](#). In Data Wrangler, you can create a data flow and use various data preparation techniques, such as applying advanced transforms or joining datasets. For image prediction models, you can [Edit an image dataset](#) to update your labels or add and delete images. Note that you can't use these features for multi-category text prediction models.

- [Evaluate your model's performance](#) and determine how well it might perform on real-world data.
- [Make single or batch predictions](#) with your model.

## How custom models work

Use Amazon SageMaker Canvas to build a custom model on the dataset that you've imported. Use the model that you've built to make predictions on new data. SageMaker Canvas uses the information in the dataset to build up to 250 models and choose the one that performs the best.

When you begin building a model, Canvas automatically recommends one or more *model types*. Model types fall into one of the following categories:

- **Numeric prediction** – This is known as *regression* in machine learning. Use the numeric prediction model type when you want to make predictions for numeric data. For example, you might want to predict the price of houses based on features such as the house's square footage.
- **Categorical prediction** – This is known as *classification* in machine learning. When you want to categorize data into groups, use the categorical prediction model types:
  - **2 category prediction** – Use the 2 category prediction model type (also known as *binary classification* in machine learning) when you have two categories that you want to predict for your data. For example, you might want to determine whether a customer is likely to churn.
  - **3+ category prediction** – Use the 3+ category prediction model type (also known as *multi-class classification* in machine learning) when you have three or more categories that you want to predict for your data. For example, you might want to predict a customer's loan status based on features such as previous payments.
- **Time series forecasting** – Use time series forecasts when you want to make predictions over a period of time. For example, you might want to predict the number of items you'll sell in the next quarter. For information about time series forecasts, see [Time Series Forecasts in Amazon SageMaker Canvas](#).
- **Image prediction** – Use the single-label image prediction model type (also known as *single-label image classification* in machine learning) when you want to assign labels to images. For example, you might want to classify different types of manufacturing defects in images of your product.
- **Text prediction** – Use the multi-category text prediction model type (also known as *multi-class text classification* in machine learning) when you want to assign labels to passages of text. For example, you might have a dataset of customer reviews for a product, and you want to determine whether customers liked or disliked the product. You might have your model predict whether a given passage of text is Positive, Negative, or Neutral.

For a table of the supported input data types for each model type, see [Custom models](#).

For each tabular data model that you build (which includes numeric, categorical, time series forecasting, and text prediction models), you choose the **Target column**. The **Target column** is the column that contains the information that you want to predict. For example, if you're building a model to predict whether people have cancelled their subscriptions, the **Target column** contains data points that are either a yes or a no about someone's cancellation status.

For image prediction models, you build the model with a dataset of images that have been assigned labels. For the unlabeled images that you provide, the model predicts a label. For example, if you're building a model to predict whether an image is a cat or a dog, you provide images labeled as cats or dogs when building the model. Then, the model can accept unlabeled images and predict them as either cats or dogs.

### What happens when you build a model

To build your model, you can choose either a **Quick build** or a **Standard build**. The **Quick build** has a shorter build time, but the **Standard build** generally has a higher accuracy.

For tabular and time series forecasting models, Canvas uses *downsampling* to reduce the size of datasets larger than 5 GB or 30 GB, respectively. Canvas downsamples with the stratified sampling method. The table below lists the size of the downsample by model type. To control the sampling process, you can use Data Wrangler in Canvas to sample using your preferred sampling technique. For time series data, you can resample to aggregate data points. For more information about sampling, see [Sampling](#). For more information about resampling time series data, see [Resample Time Series Data](#).

If you choose to do a **Quick build** on a dataset with more than 50,000 rows, then Canvas samples your data down to 50,000 rows for a shorter model training time.

The following table summarizes key characteristics of the model building process, including average build times for each model and build type, the size of the downsample when building models with large datasets, and the minimum and maximum number of data points you should have for each build type.

Limit	Numeric and categorical prediction	Time series forecasting	Image prediction	Text prediction
<b>Quick build</b> time	2-20 minutes	2-20 minutes	15-30 minutes	15-30 minutes

Limit	Numeric and categorical prediction	Time series forecasting	Image prediction	Text prediction
<b>Standard build time</b>	2-4 hours	2-4 hours	2-5 hours	2-5 hours
Downsample size (the reduced size of a large dataset after Canvas downsamples)	5 GB	30 GB	N/A	N/A
Minimum number of entries (rows) for <b>Quick builds</b>	2 category: 500 rows  3+ category, numeric, time series: N/A	N/A	N/A	N/A
Minimum number of entries (rows, images, or documents) for <b>Standard builds</b>	250	50	50	N/A
Maximum number of entries (rows, images, or documents) for <b>Quick builds</b>	N/A	N/A	5000	7500
Maximum number of entries (rows, images, or documents) for <b>Standard builds</b>	N/A	150,000	180,000	N/A
Maximum number of columns	1,000	1,000	N/A	N/A

Canvas predicts values by using the information in the rest of the dataset, depending on the model type:

- For categorical prediction, Canvas puts each row into one of the categories listed in the **Target column**.

- For numeric prediction, Canvas uses the information in the dataset to predict the numeric values in the **Target column**.
- For time series forecasting, Canvas uses historical data to predict values for the **Target column** in the future.
- For image prediction, Canvas uses images that have been assigned labels to predict labels for unlabeled images.
- For text prediction, Canvas analyzes text data that has been assigned labels to predict labels for passages of unlabeled text.

### Additional features to help you build your model

Before building your model, you can use Data Wrangler in Canvas to prepare your data using 300+ built-in transforms and operators. Data Wrangler supports transforms for both tabular and image datasets. Additionally, you can connect to data sources outside of Canvas, create jobs to apply transforms to your entire dataset, and export your fully prepared and cleaned data for use in ML workflows outside of Canvas. For more information, see [Data preparation](#).

To see visualizations and analytics to explore your data and determine which features to include in your model, you can use Data Wrangler's built-in analyses. You can also access a **Data Quality and Insights Report** that highlights potential issues with your dataset and provides recommendations for how to fix them. For more information, see [Perform exploratory data analysis \(EDA\)](#).

In addition to the more advanced data preparation and exploration functionality provided through Data Wrangler, Canvas provides some basic features that you can use:

- To filter your data and access a set of basic data transforms, see [Prepare data for model building](#).
- To access simple visualizations and analytics for feature exploration, see [Data exploration and analysis](#).
- To learn more about additional features such as previewing your model, validating your dataset, and changing the size of the random sample used to build your model, see [Preview your model](#).

For tabular datasets with multiple columns (such as datasets for building categorical, numeric, or time series forecasting model types), you might have rows with missing data points. While Canvas builds the model, it automatically adds missing values. Canvas uses the values in your dataset to perform a mathematical approximation for the missing values. For the highest model accuracy, we recommend adding in the missing data if you can find it. Note that the missing data feature is not supported for text prediction or image prediction models.

## Get started

To get started with building a custom model, see [Build a model](#) and follow the procedure for the type of model that you want to build.

## Preview your model

### Note

The following functionality is only available for custom models built with tabular datasets. Multi-category text prediction models are also excluded.

SageMaker Canvas provides you with a tool to preview your model before you begin building. This gives you an estimated accuracy score and also gives you a preliminary idea of how each column might impact the model.

To preview the model score, when you're on the **Build** tab of your model, choose **Preview model**.

The model preview generates an **Estimated accuracy** prediction of how well the model might analyze your data. The accuracy of a **Quick build** or a **Standard build** represents how well the model can perform on real data and is generally higher than the **Estimated accuracy**.

The model preview also provides you with the **Column Impact** scores, which can indicate the importance of each column to the model's predictions.

The following screenshot shows a model preview in the Canvas application.

**New model 2021-11-16 6:27 PM**

Select | **Build** | Analyze | Predict

**Select a column to predict**  
Identify the target you want to predict. Your Machine Learning model will be built to predict this target column.

Target column: **ROLE\_FAMILY\_DESC**

Value distribution:

**Model type**  
Canvas detects and automatically recommends the appropriate model type.

**Numeric prediction**  
Estimate the target columns value based on the values of other columns.  
[Change model type](#)

**Quick build**  
[Preview model](#)

**Amazon\_employee\_access.csv**

target	ROLE_TITLE	ROLE_ROLLUP_2	ROLE_ROLLUP_1	ROLE_FAMILY_DE...	ROLE_FAMILY	ROLE_DEPTNAME	ROLE_CODE	RESOURCE
1	117905	118300	117961	117906	290919	123472	117908	39353
1	118536	118343	117961	118536	308574	123125	118539	17183
1	117879	118220	118219	267952	19721	117884	117880	36724

- ROLE\_ROLLUP\_1: 8521.76
- ROLE\_ROLLUP\_2: 4887.00

Total columns: 10 | Total rows: 32,769 | Sample: 100 rows | Visualizations: 20k rows

Amazon SageMaker Canvas automatically handles missing values in your dataset while it builds the model. It infers the missing values by using adjacent values that are present in the dataset.

If you're satisfied with your model preview and want to proceed with building a model, then see [Build a model](#).

## Data validation

Before you build your model, SageMaker Canvas checks your dataset for issues that might cause your build to fail. If SageMaker Canvas finds any issues, then it warns you on the **Build** page before you attempt to build a model.

You can choose **Validate data** to see a list of the issues with your dataset. You can then use the SageMaker Canvas [Data Wrangler data preparation features](#), or your own tools, to fix your dataset before starting a build. If you don't fix the issues with your dataset, then your build fails.

If you make changes to your dataset to fix the issues, you have the option to re-validate your dataset before attempting a build. We recommend that you re-validate your dataset before building.

The following table shows the issues that SageMaker Canvas checks for in your dataset and how to resolve them.

Issue	Resolution
Wrong model type for your data	Try another model type or use a different dataset.
Missing values in your target column	Replace the missing values, drop rows with missing values, or use a different dataset.
Too many unique labels in your target column	Verify that you've used the correct column for your target column, or use a different dataset.
Too many non-numeric values in your target column	Choose a different target column, select another model type, or use a different dataset.
One or more column names contain double underscores	Rename the columns to remove any double underscores, and try again.
None of the rows in your dataset are complete	Replace the missing values, or use a different dataset.
Too many unique labels for the number of rows in your data	Check that you're using the right target column, increase the number of rows in your dataset, consolidate similar labels, or use a different dataset.

## Random sample

SageMaker Canvas uses the random sampling method to sample your dataset. The random sample method means that each row has an equal chance of being picked for the sample. You can choose a column in the preview to get summary statistics for the random sample, such as the mean and the mode.

By default, SageMaker Canvas uses a random sample size of 20,000 rows from your dataset for datasets with more than 20,000 rows. For datasets smaller than 20,000 rows, the default sample size is the number of rows in your dataset. You can increase or decrease the sample size by choosing **Random sample** in the **Build** tab of the SageMaker Canvas application. You can use the slider to select your desired sample size, and then choose **Update** to change the sample size. The maximum sample size you can choose for a dataset is 40,000 rows, and the minimum sample size is

500 rows. If you choose a large sample size, the dataset preview and summary statistics might take a few moments to reload.

The **Build** page shows a preview of 100 rows from your dataset. If the sample size is the same size as your dataset, then the preview uses the first 100 rows of your dataset. Otherwise, the preview uses the first 100 rows of the random sample.

## Build a model

The following sections show you how to build a model for each of the main types of custom models.

- To build numeric prediction, 2 category prediction, or 3+ category prediction models, see [Build a custom numeric or categorical prediction model](#).
- To build single-label image prediction models, see [Build a custom image prediction model](#).
- To build multi-category text prediction models, see [Build a custom text prediction model](#).
- To build time series forecasting models, see [Build a time series forecasting model](#).

### Note

If you encounter an error during post-building analysis that tells you to increase your quota for `m1.m5.2xlarge` instances, see [Request a Quota Increase](#).

## Build a custom numeric or categorical prediction model

Numeric and categorical prediction models support both **Quick builds** and **Standard builds**.

To build a numeric or categorical prediction model, use the following procedure:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **My models**.
3. Choose **New model**.
4. In the **Create new model** dialog box, do the following:
  - a. Enter a name in the **Model name** field.
  - b. Select the **Predictive analysis** problem type.

- c. Choose **Create**.
5. For **Select dataset**, select your dataset from the list of datasets. If you haven't already imported your data, choose **Import** to be directed through the import data workflow.
6. When you're ready to begin building your model, choose **Select dataset**.
7. On the **Build** tab, for the **Target column** dropdown list, select the target for your model that you would like to predict.
8. For **Model type**, Canvas automatically detects the problem type for you. If you want to change the type or configure advanced model settings, choose **Configure model**.

When the **Configure model** dialog box opens, do the following:

- a. For **Model type**, choose the model type that you want to build.
- b. After you choose the model type, there are additional **Advanced settings**. For more information about each of the advanced settings, see [Advanced model building configurations](#). To configure the advanced settings, do the following:
  - i. (Optional) For the **Objective metric** dropdown menu, select the metric that you want Canvas to optimize while building your model. If you don't select a metric, Canvas chooses one for you by default. For descriptions of the available metrics, see [Metrics reference](#).
  - ii. For **Training method**, choose **Auto**, **Ensemble**, or **Hyperparameter optimization (HPO) mode**.
  - iii. For **Algorithms**, select the algorithms that you want to include for building model candidates.
  - iv. For **Data split**, specify in percentages how you want to split your data between the **Training set** and the **Validation set**. The training set is used for building the model, while the validation set is used for testing accuracy of model candidates.
  - v. For **Max candidates and runtime**, do the following:
    - A. Set the **Max candidates** value, or the maximum number of model candidates that Canvas can generate. Note that **Max candidates** is only available in HPO mode.
    - B. Set the hour and minute values for **Max job runtime**, or the maximum amount of time that Canvas can spend building your model. After the maximum time, Canvas stops building and selects the best model candidate.
- c. After configuring the advanced settings, choose **Save**.

## 9. Select or deselect columns in your data to include or drop them from your build.

### Note

If you make batch predictions with your model after building, Canvas adds dropped columns to your prediction results. However, Canvas does not add the dropped columns to your batch predictions for time series models.

10. (Optional) Use the visualization and analytics tools that Canvas provides to visualize your data and determine which features you might want to include in your model. For more information, see [Explore and analyze your data](#).
11. (Optional) Use data transformations to clean, transform, and prepare your data for model building. For more information, see [Prepare your data with advanced transformations](#). You can view and remove your transforms by choosing **Model recipe** to open the **Model recipe** side panel.
12. (Optional) For additional features such as previewing the accuracy of your model, validating your dataset, and changing the size of the random sample that Canvas takes from your dataset, see [Preview your model](#).
13. After reviewing your data and making any changes to your dataset, choose **Quick build** or **Standard build** to begin a build for your model. The following screenshot shows the **Build** page and the **Quick build** and **Standard build** options.

The screenshot displays the 'Build' interface for a model named 'titanic-model'. The 'Build' tab is active, and the target column is 'Survived'. The 'Model type' is '2 category prediction'. A modal window on the right shows 'Quick build' and 'Standard build' options. Below the modal, a data table for 'titanic.csv' is shown with columns for Column name, Data type, Missing, Mismatched, Unique, Mean / Mode, and Correlation to target.

Column name	Data type	Missing	Mismatched	Unique	Mean / Mode	Correlation to target
Survived	Binary	0.00% (0)	0.00% (0)	2	0	--
Siblings/Spouses Aboard	Numeric	0.00% (0)	0.00% (0)	7	0	-0.037
Sex	Categorical	0.00% (0)	0.00% (0)	3	male	N/A
Pclass	Numeric	0.00% (0)	0.00% (0)	3	3	-0.337
Parents/Children Aboard	Numeric	0.00% (0)	0.00% (0)	7	0	0.08
Name	Text	0.00% (0)	0.00% (0)	887	Capt. Edward Gifford ...	N/A
Fare	Numeric	0.00% (0)	0.00% (0)	248	8.05	0.256
Age	Numeric	0.45% (4)	0.00% (0)	72	22	-0.056

After your model begins building, you can leave the page. When the model shows as **Ready** on the **My models** page, it's ready for analysis and predictions.

## Build a custom image prediction model

Single-label image prediction models support both **Quick builds** and **Standard builds**.

To build a single-label image prediction model, use the following procedure:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **My models**.
3. Choose **New model**.
4. In the **Create new model** dialog box, do the following:
  - a. Enter a name in the **Model name** field.
  - b. Select the **Image analysis** problem type.
  - c. Choose **Create**.
5. For **Select dataset**, select your dataset from the list of datasets. If you haven't already imported your data, choose **Import** to be directed through the import data workflow.
6. When you're ready to begin building your model, choose **Select dataset**.
7. On the **Build** tab, you see the **Label distribution** for the images in your dataset. The **Model type** is set to **Single-label image prediction**.
8. On this page, you can preview your images and edit the dataset. If you have any unlabeled images, choose **Edit dataset** and [Assign labels to unlabeled images](#). You can also perform other tasks when you [Edit an image dataset](#), such as renaming labels and adding images to the dataset.
9. After reviewing your data and making any changes to your dataset, choose **Quick build** or **Standard build** to begin a build for your model. The following screenshot shows the **Build** page of an image prediction model that is ready to be built.

household-items-prediction V1 Draft Add version

Select **Build** Analyze Predict

**Label Distribution**

After your model begins building, you can leave the page. When the model shows as **Ready** on the **My models** page, it's ready for analysis and predictions.

## Build a custom text prediction model

Multi-category text prediction models support both **Quick builds** and **Standard builds**.

To build a text prediction model, use the following procedure:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **My models**.
3. Choose **New model**.
4. In the **Create new model** dialog box, do the following:
  - a. Enter a name in the **Model name** field.
  - b. Select the **Text analysis** problem type.
  - c. Choose **Create**.
5. For **Select dataset**, select your dataset from the list of datasets. If you haven't already imported your data, choose **Import** to be directed through the import data workflow.
6. When you're ready to begin building your model, choose **Select dataset**.

- On the **Build** tab, for the **Target column** dropdown list, select the target for your model that you would like to predict. The target column must have a binary or categorical data type, and there must be at least 25 entries (or rows of data) for each unique label in the target column.
- For **Model type**, confirm that the model type is automatically set to **Multi-category text prediction**.
- For the training column, select your source column of text data. This should be the column containing the text that you want to analyze.
- Choose **Quick build** or **Standard build** to begin building your model. The following screenshot shows the **Build** page of a text prediction model that is ready to be built.

The screenshot shows the SageMaker Canvas interface for building a model. The title is "multi-category-text-prediction-2". The "Build" tab is active. On the left, "Select a column to predict" shows the "target" column selected, with a value distribution bar chart showing categories: Negative, Positive, and Other (2 Categories). On the right, "Select model type" shows "Multi-category text prediction" selected, with a note: "Your model classifies your target column into 2 or more categories." A "Standard build" button is visible. Below this is a data table for "nlp-demo-twitter-sentiment\_train(2)...".

Summary statistics: Total columns: 4, Total rows: 64,683, Total cells: 258,732, Previewing first 100 rows.

After your model begins building, you can leave the page. When the model shows as **Ready** on the **My models** page, it's ready for analysis and predictions.

## Build a time series forecasting model

Time series forecasting models support both **Quick builds** and **Standard builds**.

To build a time series forecasting model, use the following procedure:

- Open the SageMaker Canvas application.
- In the left navigation pane, choose **My models**.

3. Choose **New model**.
4. In the **Create new model** dialog box, do the following:
  - a. Enter a name in the **Model name** field.
  - b. Select the **Time series forecasting** problem type.
  - c. Choose **Create**.
5. For **Select dataset**, select your dataset from the list of datasets. If you haven't already imported your data, choose **Import** to be directed through the import data workflow.
6. When you're ready to begin building your model, choose **Select dataset**.
7. On the **Build** tab, for the **Target column** dropdown list, select the target for your model that you would like to predict.
8. In the **Model type** section, choose **Configure model**.
9. The **Configure model** box opens. For the **Time series configuration** section, fill out the following fields:
  - a. For **Item ID column**, choose a column in your dataset that uniquely identifies each row.
  - b. (Optional) For **Group column**, choose one or more categorical columns that you want to use for grouping your forecasting values.
  - c. For **Time stamp column**, select the column with timestamps (in datetime format). For more information about the accepted datetime formats, see [Time Series Forecasts in Amazon SageMaker Canvas](#).
  - d. For the **Forecast length** field, enter the period of time for which you want to forecast values. Canvas automatically detects the units of time in your data.
  - e. (Optional) Turn on the **Use holiday schedule** toggle to select a holiday schedule from various countries and make your forecasts with holiday data more accurate.
10. In the **Configure model** box, there are additional settings in the **Advanced** section. For more information about each of the advanced settings, see [Advanced model building configurations](#). To configure the **Advanced** settings, do the following:
  - a. For the **Objective metric** dropdown menu, select the metric that you want Canvas to optimize while building your model. If you don't select a metric, Canvas chooses one for you by default. For descriptions of the available metrics, see [Metrics reference](#).
  - b. If you're running a standard build, you'll see the **Algorithms** section. This section is for selecting the time series forecasting algorithms that you'd like to use for building your

model. You can select a subset of the available algorithms, or you can select all of them if you aren't sure which ones to try.

When you run your standard build, Canvas builds an ensemble model that combines all of the algorithms together to optimize prediction accuracy.

 **Note**

If you're running a quick build, Canvas uses a single tree-based learning algorithm to train your model, and you don't have to select any algorithms.

- c. For **Forecast quantiles**, enter up to 5 comma-separated quantile values to specify the upper and lower bounds of your forecast.
  - d. After configuring the **Advanced** settings, choose **Save**.
11. Select or deselect columns in your data to include or drop them from your build.

 **Note**

If you make batch predictions with your model after building, Canvas adds dropped columns to your prediction results. However, Canvas does not add the dropped columns to your batch predictions for time series models.

12. (Optional) Use the visualization and analytics tools that Canvas provides to visualize your data and determine which features you might want to include in your model. For more information, see [Explore and analyze your data](#).
13. (Optional) Use data transformations to clean, transform, and prepare your data for model building. For more information, see [Prepare your data with advanced transformations](#). You can view and remove your transforms by choosing **Model recipe** to open the **Model recipe** side panel.
14. (Optional) For additional features such as previewing the accuracy of your model, validating your dataset, and changing the size of the random sample that Canvas takes from your dataset, see [Preview your model](#).
15. After reviewing your data and making any changes to your dataset, choose **Quick build** or **Standard build** to begin a build for your model.

After your model begins building, you can leave the page. When the model shows as **Ready** on the **My models** page, it's ready for analysis and predictions.

## Advanced model building configurations

Amazon SageMaker Canvas supports various advanced settings that you can configure when building a model. The following page lists all of the advanced settings along with additional information about their options and configurations.

### Note

The following advanced settings are currently only supported for numeric, categorical, and time series forecasting model types.

## Advanced numeric and categorical prediction model settings

Canvas supports the following advanced settings for numeric and categorical prediction model types.

### Objective metric

The objective metric is the metric that you want Canvas to optimize while building your model. If you don't select a metric, Canvas chooses one for you by default. For descriptions of the available metrics, see the [Metrics reference](#).

### Training method

Canvas can automatically select the training method based on the dataset size, or you can select it manually. The following training methods are available for you to choose from:

- **Ensembling** – SageMaker AI leverages the AutoGluon library to train several base models. To find the best combination for your dataset, ensemble mode runs 5–10 trials with different model and meta parameter settings. Then, these models are combined using a stacking ensemble method to create an optimal predictive model. For a list of algorithms supported by ensemble mode for tabular data, see the following [Algorithms](#) section.
- **Hyperparameter optimization (HPO)** – SageMaker AI finds the best version of a model by tuning hyperparameters using Bayesian optimization or multi-fidelity optimization while running training jobs on your dataset. HPO mode selects the algorithms that are most relevant to your dataset and selects the best range of hyperparameters to tune your models. To tune your

models, HPO mode runs up to 100 trials (default) to find the optimal hyperparameters settings within the selected range. If your dataset size is less than 100 MB, SageMaker AI uses Bayesian optimization. SageMaker AI chooses multi-fidelity optimization if your dataset is larger than 100 MB.

For a list of algorithms supported by HPO mode for tabular data, see the following [Algorithms](#) section.

- **Auto** – SageMaker AI automatically chooses either ensembling mode or HPO mode based on your dataset size. If your dataset is larger than 100 MB, SageMaker AI chooses HPO mode. Otherwise, it chooses ensembling mode.

## Algorithms

In **Ensembling** mode, Canvas supports the following machine learning algorithms:

- [LightGBM](#) – An optimized framework that uses tree-based algorithms with gradient boosting. This algorithm uses trees that grow in breadth, rather than depth, and is highly optimized for speed.
- [CatBoost](#) – A framework that uses tree-based algorithms with gradient boosting. Optimized for handling categorical variables.
- [XGBoost](#) – A framework that uses tree-based algorithms with gradient boosting that grows in depth, rather than breadth.
- [Random Forest](#) – A tree-based algorithm that uses several decision trees on random sub-samples of the data with replacement. The trees are split into optimal nodes at each level. The decisions of each tree are averaged together to prevent overfitting and improve predictions.
- [Extra Trees](#) – A tree-based algorithm that uses several decision trees on the entire dataset. The trees are split randomly at each level. The decisions of each tree are averaged to prevent overfitting and to improve predictions. Extra trees add a degree of randomization in comparison to the random forest algorithm.
- [Linear Models](#) – A framework that uses a linear equation to model the relationship between two variables in observed data.
- Neural network torch – A neural network model that's implemented using [Pytorch](#).
- Neural network fast.ai – A neural network model that's implemented using [fast.ai](#).

In **HPO mode**, Canvas supports the following machine learning algorithms:

- [XGBoost](#) – A supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models.
- Deep learning algorithm – A multilayer perceptron (MLP) and feedforward artificial neural network. This algorithm can handle data that is not linearly separable.

## Data split

You have the option to specify how you want to split your dataset between the training set (the portion of your dataset used for building the model) and the validation set, (the portion of your dataset used for verifying the model's accuracy). For example, a common split ratio is 80% training and 20% validation, where 80% of your data is used to build the model while 20% is saved for measuring model performance. If you don't specify a custom ratio, then Canvas splits your dataset automatically.

## Max candidates

### Note

This feature is only available in the HPO training mode.

You can specify the maximum number of model candidates that Canvas generates while building your model. We recommend that you use the default number of candidates, which is 100, to build the most accurate models. The maximum number you can specify is 250. Decreasing the number of model candidates may impact your model's accuracy.

## Max job runtime

You can specify the maximum job runtime, or the maximum amount of time that Canvas spends building your model. After the time limit, Canvas stops building and selects the best model candidate.

The maximum time that you can specify is 720 hours. We highly recommend that you keep the maximum job runtime greater than 30 minutes to ensure that Canvas has enough time to generate model candidates and finish building your model.

## Advanced time series forecasting model settings

For time series forecasting models, Canvas supports the Objective metric, which is listed in the previous section.

Time series forecasting models also support the following advanced setting:

### Algorithm selection

When you build a time series forecasting model, Canvas uses an *ensemble* (or a combination) of statistical and machine learning algorithms to deliver highly accurate time series forecasts. By default, Canvas selects the optimal combination of all the available algorithms based on the time series in your dataset. However, you have the option to specify one or more algorithms to use for your forecasting model. In this case, Canvas determines the best blend using only your selected algorithms. If you're uncertain about which algorithm to select for training your model, we recommend that you choose all of the available algorithms.

#### Note

Algorithm selection is only supported for standard builds. If you don't select any algorithms in the advanced settings, then by default SageMaker AI runs a quick build and trains model candidates using a single tree-based learning algorithm. For more information about the difference between quick builds and standard builds, see [How custom models work](#).

Canvas supports the following time series forecasting algorithms:

- [Autoregressive Integrated Moving Average \(ARIMA\)](#) – A simple stochastic time series model that uses statistical analysis to interpret the data and make future predictions. This algorithm is useful for simple datasets with fewer than 100 time series.
- [Convolutional Neural Network - Quantile Regression \(CNN-QR\)](#) – A proprietary, supervised learning algorithm that trains one global model from a large collection of time series and uses a quantile decoder to make predictions. CNN-QR works best with large datasets containing hundreds of time series.
- [DeepAR+](#) – A proprietary, supervised learning algorithm for forecasting scalar time series using recurrent neural networks (RNNs) to train a single model jointly over all of the time series. DeepAR+ works best with large datasets containing hundreds of feature time series.
- [Non-Parametric Time Series \(NPTS\)](#) – A scalable, probabilistic baseline forecaster that predicts the future value distribution of a given time series by sampling from past observations. NPTS is useful when working with sparse or intermittent time series (for example, forecasting demand for individual items where the time series has many 0s or low counts).
- [Exponential Smoothing \(ETS\)](#) – A forecasting method that produces forecasts which are weighted averages of past observations where the weights of older observations exponentially decrease.

The algorithm is useful for simple datasets with fewer than 100 time series and datasets with seasonality patterns.

- [Prophet](#) – An additive regression model that works best with time series that have strong seasonal effects and several seasons of historical data. The algorithm is useful for datasets with non-linear growth trends that approach a limit.

## Forecast quantiles

For time series forecasting, SageMaker AI trains 6 model candidates with your target time series. Then, SageMaker AI combines these models using a stacking ensemble method to create an optimal forecasting model for a given objective metric. Each forecasting model generates a probabilistic forecast by producing forecasts at quantiles between P1 and P99. These quantiles are used to account for forecast uncertainty. By default, forecasts are generated for 0.1 (p10), 0.5 (p50), and 0.9 (p90). You can choose to specify up to five of your own quantiles from 0.01 (p1) to 0.99 (p99), by increments of 0.01 or higher.

## Edit an image dataset

In Amazon SageMaker Canvas, you can edit your image datasets and review your labels before building a model. You might want to perform tasks such as assigning labels to unlabeled images or adding more images to the dataset. These tasks can all be done in the Canvas application, providing you with one place to modify your dataset and build a model.

### Note

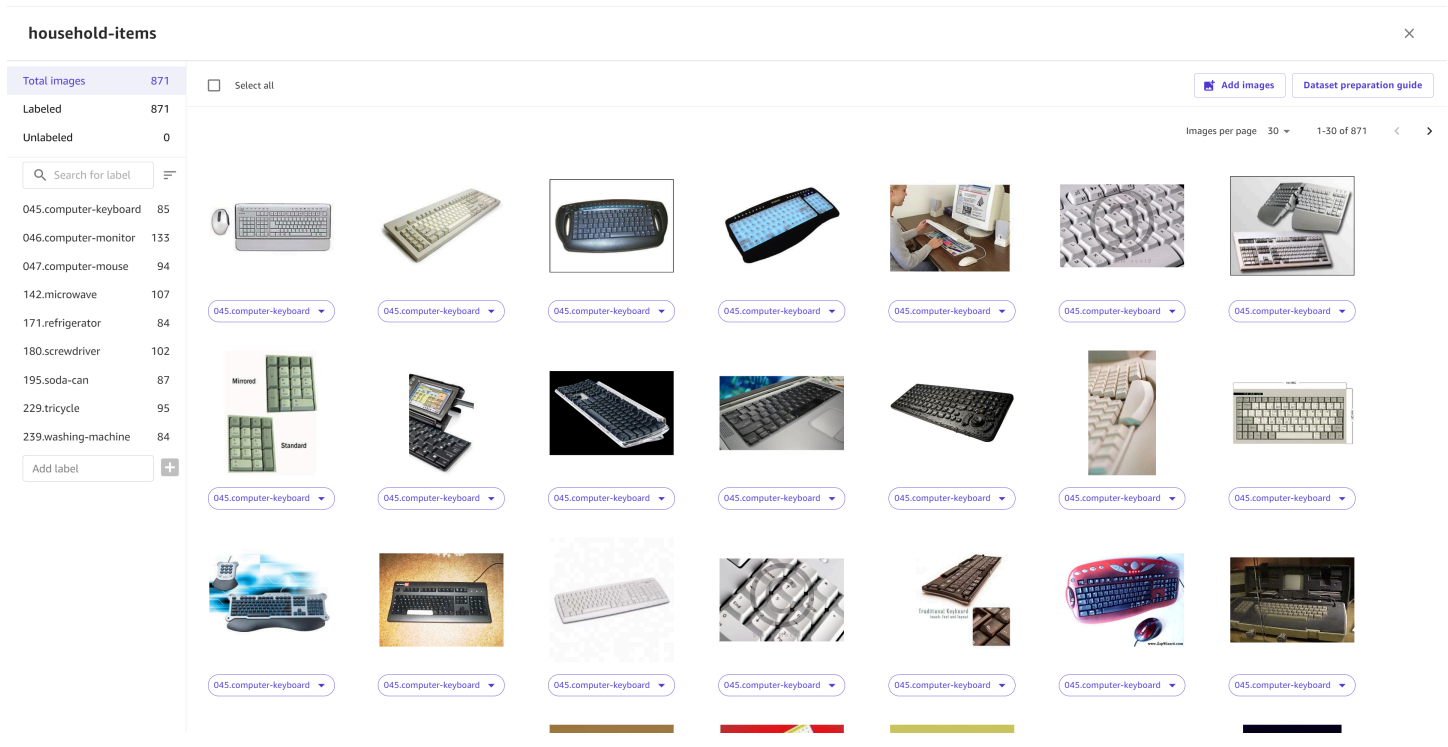

Before building a model, you must assign labels to all images in your dataset. Also, you must have at least 25 images per label and a minimum of two labels. For more information about assigning labels, see the section on this page called **Assign labels to unlabeled images**. If you can't determine a label for an image, you should delete it from your dataset. For more information about deleting images, see the section on this page [Add or delete images from the dataset](#).

To begin editing your image dataset, you should be on the **Build** tab while building your single-label image prediction model.

A new page opens that shows the images in your dataset along with their labels. This page categorizes your image dataset into **Total images**, **Labeled images**, and **Unlabeled images**. You

can also review the **Dataset preparation guide** for best practices on building a more accurate image prediction model.

The following screenshot shows the page for editing your image dataset.

From this page, you can do the following actions.

### View the properties for each image (label, size, dimensions)

To view an individual image, you can search for it by file name in the search bar. Then, choose the image to open the full view. You can view the image properties and reassign the image's label. Choose **Save** when you're doing viewing the image.

### Add, rename, or delete labels in the dataset

Canvas lists the labels for your dataset in the left navigation pane. You can add new labels to the dataset by entering a label in the **Add label** text field.

To rename or delete a label from your dataset, choose the **More options** icon

() next to the label and select either **Rename** or **Delete**. If you rename the label, you can enter the new label name and choose **Confirm**. If you delete the label, the label is removed from all images in your dataset that have that label. Any images with that label are left unlabeled.

## Assign labels to unlabeled images

To view the unlabeled images in your dataset, choose **Unlabeled** in the left navigation pane. For each image, select it and open the label titled **Unlabeled** and select a label to assign to the image from the dropdown list. You can also select more than one image and perform this action, and all selected images are assigned the label you chose.

## Reassign labels to images

You can reassign labels to images by selecting the image (or multiple images at a time) and opening the dropdown titled with the current label. Select your desired label, and the image or images are updated with the new label.

## Sort your images by label

You can view all the images for a given label by choosing the label in the left navigation pane.

## Add or delete images from the dataset

You can add more images to your dataset by choosing **Add images** in the top navigation pane. You'll be taken through the workflow to import more images. The images you import are added to your existing dataset.

You can delete images from your dataset by selecting them and then choosing **Delete** in the top navigation pane.

### Note

After making any changes to your dataset, choose **Save dataset** to make sure that you don't lose your changes.

## Data exploration and analysis

### Note

You can only use SageMaker Canvas visualizations and analytics for models built on tabular datasets. Multi-category text prediction models are also excluded.

In Amazon SageMaker Canvas, you can explore the variables in your dataset using visualizations and analytics and create in-application visualizations and analytics. You can use these explorations to uncover relationships between your variables before building your model.

For more information about visualization techniques in Canvas, see [Explore your data using visualization techniques](#).

For more information about analytics in Canvas, see [Explore your data using analytics](#).

## Explore your data using visualization techniques

### Note

You can only use SageMaker Canvas visualizations for models built on tabular datasets. Multi-category text prediction models are also excluded.

With Amazon SageMaker Canvas, you can explore and visualize your data to gain advanced insights into your data before building your ML models. You can visualize using scatter plots, bar charts, and box plots, which can help you understand your data and discover the relationships between features that could affect the model accuracy.

In the **Build** tab of the SageMaker Canvas application, choose **Data visualizer** to begin creating your visualizations.

You can change the visualization sample size to adjust the size of the random sample taken from your dataset. A sample size that is too large might affect the performance of your data visualizations, so we recommend that you choose an appropriate sample size. To change the sample size, use the following procedure.

1. Choose **Visualization sample**.
2. Use the slider to select your desired sample size.
3. Choose **Update** to confirm the change to your sample size.

### Note

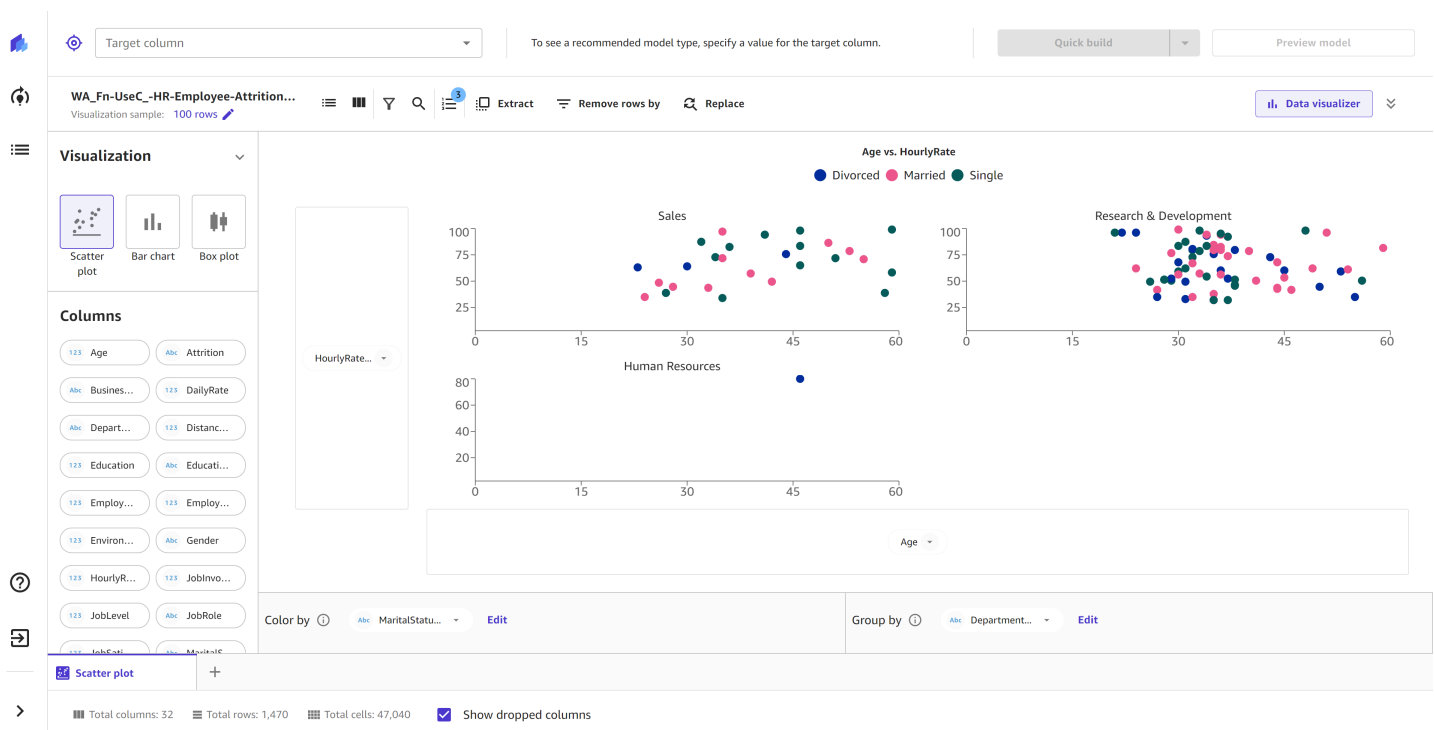

Certain visualization techniques require columns of a specific data type. For example, you can only use numeric columns for the x and y-axes of scatter plots.

## Scatter plot

To create a scatter plot with your dataset, choose **Scatter plot** in the **Visualization** panel. Choose the features you want to plot on the x and y-axes from the **Columns** section. You can drag and drop the columns onto the axes or, once an axis has been dropped, you can choose a column from the list of supported columns.

You can use **Color by** to color the data points on the plot with a third feature. You can also use **Group by** to group the data into separate plots based on a fourth feature.

The following image shows a scatter plot that uses **Color by** and **Group by**. In this example, each data point is colored by the `MaritalStatus` feature, and grouping by the `Department` feature results in a scatter plot for the data points of each department.

## Bar chart

To create a bar chart with your dataset, choose **Bar chart** in the **Visualization** panel. Choose the features you want to plot on the x and y-axes from the **Columns** section. You can drag and drop the columns onto the axes or, once an axis has been dropped, you can choose a column from the list of supported columns.

You can use **Group by** to group the bar chart by a third feature. You can use **Stack by** to vertically shade each bar based on the unique values of a fourth feature.

The following image shows a bar chart that uses **Group by** and **Stack by**. In this example, the bar chart is grouped by the `MaritalStatus` feature and stacked by the `JobLevel` feature. For each `JobRole` on the x axis, there is a separate bar for the unique categories in the `MaritalStatus` feature, and every bar is vertically stacked by the `JobLevel` feature.

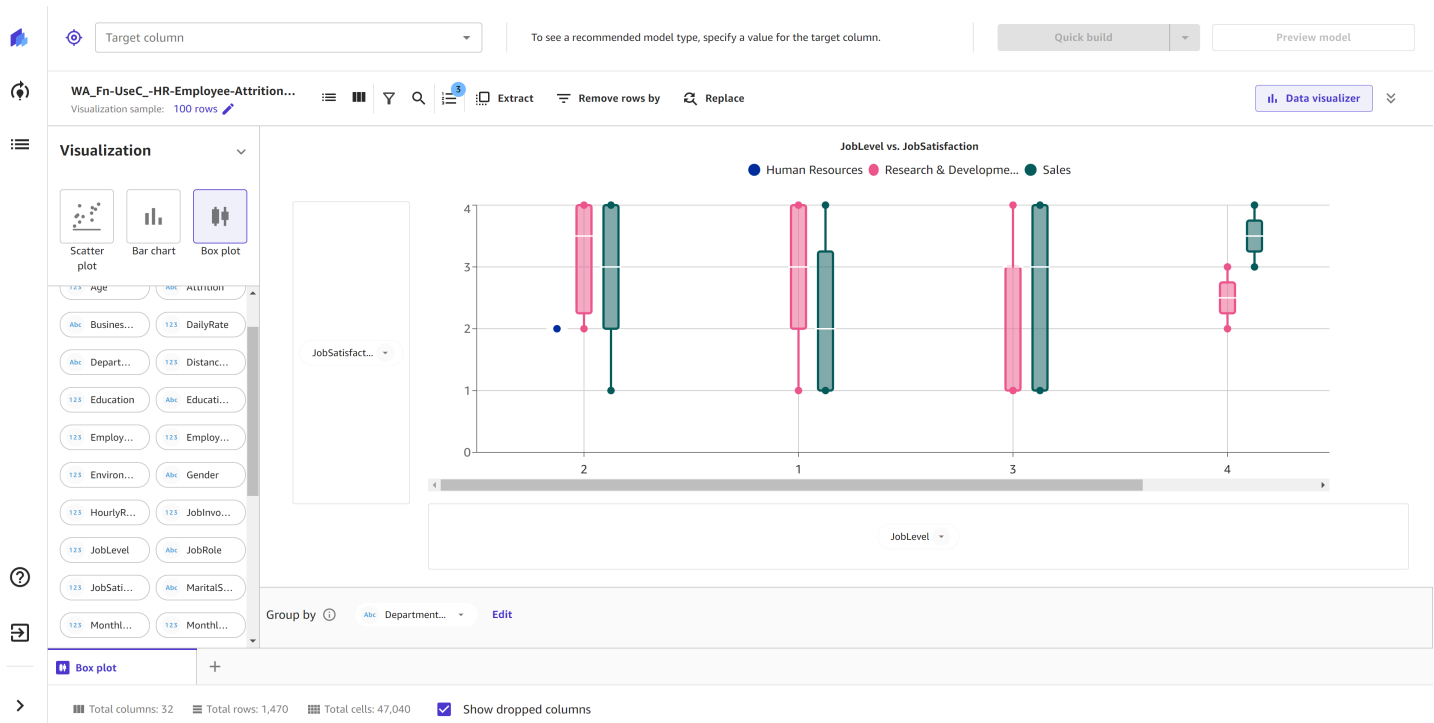

## Box plot

To create a box plot with your dataset, choose **Box plot** in the **Visualization** panel. Choose the features you want to plot on the x and y-axes from the **Columns** section. You can drag and drop the columns onto the axes or, once an axis has been dropped, you can choose a column from the list of supported columns.

You can use **Group by** to group the box plots by a third feature.

The following image shows a box plot that uses **Group by**. In this example, the x and y-axes show `JobLevel` and `JobSatisfaction`, respectively, and the colored box plots are grouped by the `Department` feature.

## Explore your data using analytics

### Note

You can only use SageMaker Canvas analytics for models built on tabular datasets. Multi-category text prediction models are also excluded.

With analytics in Amazon SageMaker Canvas, you can explore your dataset and gain insight on all of your variables before building a model. You can determine the relationships between features in your dataset using correlation matrices. You can use this technique to summarize your dataset into a matrix that shows the correlations between two or more values. This helps you identify and visualize patterns in a given dataset for advanced data analysis.

The matrix shows the correlation between each feature as positive, negative, or neutral. You might want to include features that have a high correlation with each other when building your model. Features that have little to no correlation might be irrelevant to your model, and you can drop those features when building your model.

To get started with correlation matrices in SageMaker Canvas, see the following section.

## Create a correlation matrix

You can create a correlation matrix when you are preparing to build a model in the **Build** tab of the SageMaker Canvas application.

For instructions on how to begin creating a model, see [Build a model](#).

After you've started preparing a model in the SageMaker Canvas application, do the following:

1. In the **Build** tab, choose **Data visualizer**.
2. Choose **Analytics**.
3. Choose **Correlation matrix**.

You should see a visualization similar to the following screenshot, which shows up to 15 columns of the dataset organized into a correlation matrix.

After you've created the correlation matrix, you can customize it by doing the following:

### 1. Choose your columns

For **Columns**, you can select the columns that you want to include in the matrix. You can compare up to 15 columns from your dataset.

**Note**

You can use numeric, categorical, or binary column types for a correlation matrix. The correlation matrix doesn't support datetime or text data column types.

To add or remove columns from the correlation matrix, select and deselect columns from the **Columns** panel. You can also drag and drop columns from the panel directly onto the matrix. If your dataset has a lot of columns, you can search for the columns you want in the **Search columns** bar.

To filter the columns by data type, choose the dropdown list and select **All**, **Numeric**, or **Categorical**. Selecting **All** shows you all of the columns from your dataset, whereas the **Numeric** and **Categorical** filters only show you the numeric or categorical columns in your dataset. Note that binary column types are included in the numeric or categorical filters.

For the best data insights, include your target column in the correlation matrix. When you include your target column in the correlation matrix, it appears as the last feature on the matrix with a target symbol.

## 2. Choose your correlation type

SageMaker Canvas supports different *correlation types*, or methods for calculating the correlation between your columns.

To change the correlation type, use the **Columns** filter mentioned in the preceding section to filter for your desired column type and columns. You should see the **Correlation type** in the side panel. For numeric comparisons, you have the option to select either **Pearson** or **Spearman**. For categorical comparisons, the correlation type is set as **MI**. For categorical and mixed comparisons, the correlation type is set as **Spearman & MI**.

For matrices that only compare numeric columns, the correlation type is either Pearson or Spearman. The Pearson measure evaluates the linear relationship between two continuous variables. The Spearman measure evaluates the monotonic relationship between two variables. For both Pearson and Spearman, the scale of correlation ranges from -1 to 1, with either end of the scale indicating a perfect correlation (a direct 1:1 relationship) and 0 indicating no correlation. You might want to select Pearson if your data has more linear relationships (as revealed by a [scatter plot visualization](#)). If your data is not linear, or contains a mixture of linear and monotonic relationships, then you might want to select Spearman.

For matrices that only compare categorical columns, the correlation type is set to Mutual Information Classification (MI). The MI value is a measure of the mutual dependence between two random variables. The MI measure is on a scale of 0 to 1, with 0 indicating no correlation and 1 indicating a perfect correlation.

For matrices that compare a mix of numeric and categorical columns, the correlation type **Spearman & MI** is a combination of the Spearman and MI correlation types. For correlations between two numeric columns, the matrix shows the Spearman value. For correlations between a numeric and categorical column or two categorical columns, the matrix shows the MI value.

Lastly, remember that correlation does not necessarily indicate causation. A strong correlation value only indicates that there is a relationship between two variables, but the variables might not have a causal relationship. Carefully review your columns of interest to avoid bias when building your model.

### 3. Filter your correlations

In the side panel, you can use the **Filter correlations** feature to filter for the range of correlation values that you want to include in the matrix. For example, if you want to filter for features that only have positive or neutral correlation, you can set the **Min** to 0 and the **Max** to 1 (valid values are -1 to 1).

For Spearman and Pearson comparisons, you can set the **Filter correlations** range anywhere from -1 to 1, with 0 meaning that there is no correlation. -1 and 1 mean that the variables have a strong negative or positive correlation, respectively.

For MI comparisons, the correlation range only goes from 0 to 1, with 0 meaning that there is no correlation and 1 meaning that the variables have a strong correlation, either positive or negative.

Each feature has a perfect correlation (1) with itself. Therefore, you might notice that the top row of the correlation matrix is always 1. If you want to exclude these values, you can use the filter to set the **Max** less than 1.

Keep in mind that if your matrix compares a mix of numeric and categorical columns and uses the **Spearman & MI** correlation type, then the *categorical x numeric* and *categorical x categorical* correlations (which use the MI measure) are on a scale of 0 to 1, whereas the *numeric x numeric* correlations (which use the Spearman measure) are on a scale of -1 to 1. Review your correlations of interest carefully to ensure that you know the correlation type being used to calculate each value.

## 4. Choose the visualization method

In the side panel, you can use **Visualize by** to change the visualization method of the matrix. Choose the **Numeric** visualization method to show the correlation (Pearson, Spearman, or MI) value, or choose the **Size** visualization method to visualize the correlation with differently sized and colored dots. If you choose **Size**, you can hover over a specific dot on the matrix to see the actual correlation value.

## 5. Choose a color palette

In the side panel, you can use **Color selection** to change the color palette used for the scale of negative to positive correlation in the matrix. Select one of the alternative color palettes to change the colors used in the matrix.

## Prepare data for model building

### Note

You can now do advanced data preparation in SageMaker Canvas with Data Wrangler, which provides you with a natural language interface and over 300 built-in transformations. For more information, see [Data preparation](#).

Your machine learning dataset might require data preparation before you build your model. You might want to clean your data due to various issues, which might include missing values or outliers, and perform feature engineering to improve the accuracy of your model. Amazon SageMaker Canvas provides ML data transforms with which you can clean, transform, and prepare your data for model building. You can use these transforms on your datasets without any code. SageMaker Canvas adds the transforms you use to the **Model recipe**, which is a record of the data preparation done on your data before building the model. Any data transforms you use only modify the input data for model building and do not modify your original data source.

The preview of your dataset shows the first 100 rows of the dataset. If your dataset has more than 20,000 rows, Canvas takes a random sample of 20,000 rows and previews the first 100 rows from that sample. You can only search for and specify values from the previewed rows, and the filter functionality only filters the previewed rows and not the entire dataset.

The following transforms are available in SageMaker Canvas for you to prepare your data for building.

**Note**

You can only use advanced transformations for models built on tabular datasets. Multi-category text prediction models are also excluded.

**Drop columns**

You can exclude a column from your model build by dropping it in the **Build** tab of the SageMaker Canvas application. Deselect the column you want to drop, and it isn't included when building the model.

**Note**

If you drop columns and then make [batch predictions](#) with your model, SageMaker Canvas adds the dropped columns back to the output dataset available for you to download. However, SageMaker Canvas does not add the dropped columns back for time series models.

**Filter rows**

The filter functionality filters the previewed rows (the first 100 rows of your dataset) according to conditions that you specify. Filtering rows creates a temporary preview of the data and does not impact the model building. You can filter to preview rows that have missing values, contain outliers, or meet custom conditions in a column you choose.

**Filter rows by missing values**

Missing values are a common occurrence in machine learning datasets. If you have rows with null or empty values in certain columns, you might want to filter for and preview those rows.

To filter missing values from your previewed data, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Filter by rows** (∇).
2. Choose the **Column** you want to check for missing values.
3. For the **Operation**, choose **Is missing**.

SageMaker Canvas filters for rows that contain missing values in the **Column** you selected and provides a preview of the filtered rows.

The screenshot displays the SageMaker Canvas interface. At the top, there's a navigation bar with 'My models / deployment 2.8.2 / Version 1' and a 'Target column' dropdown. Below this, a toolbar includes 'Manage columns', 'Manage rows', 'Time series', and 'View all'. The main area shows a data table with columns: demand, time\_stamp, Product\_c..., price, Location, and item\_id. Each column has a corresponding visualization: demand (histogram), time\_stamp (bar chart), Product\_c... (horizontal bar chart), price (histogram), Location (horizontal bar chart), and item\_id (vertical bar chart). A 'Filter by rows' dialog is open on the right, with 'demand' selected as the column and 'Is missing' as the operation. The table shows rows with various timestamps, product categories (Wearables, mobile\_devices), prices, and locations (Seattle, Tokyo, Mumbai, London, Jakarta).

time_stamp	Product_c...	price	Location	item_id
2019-10-01 00:00:00	Wearables	97.79892302	Seattle	sku - 001
2019-12-01 00:00:00	Wearables	97.79892302	Seattle	sku - 001
2019-10-01 00:00:00	Wearables	97.79892302	Tokyo	sku - 001
2019-11-01 00:00:00	Wearables	97.79892302	Tokyo	sku - 001
2019-11-01 00:00:00	Wearables	97.79892302	Mumbai	sku - 001
2019-12-01 00:00:00	Wearables	97.79892302	Mumbai	sku - 001
2019-10-01 00:00:00	Wearables	97.79892302	London	sku - 001
2019-11-01 00:00:00	Wearables	97.79892302	London	sku - 001
2019-11-01 00:00:00	Wearables	97.79892302	Jakarta	sku - 001
2019-10-01 00:00:00	mobile_devices	120.8227701	Seattle	sku - 002
2019-11-01 00:00:00	mobile_devices	120.8227701	Seattle	sku - 002

## Filter rows by outliers

Outliers, or rare values in the distribution and range of your data, can negatively impact model accuracy and lead to longer building times. SageMaker Canvas enables you to detect and filter rows that contain outliers in numeric columns. You can choose to define outliers with either standard deviations or a custom range.

To filter for outliers in your data, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Filter by rows** (🔍).
2. Choose the **Column** you want to check for outliers.
3. For the **Operation**, choose **Is outlier**.
4. Set the **Outlier range** to either **Standard deviation** or **Custom range**.
5. If you choose **Standard deviation**, specify a **SD** (standard deviation) value from 1–3. If you choose **Custom range**, select either **Percentile** or **Number**, and then specify the **Min** and **Max** values.

The **Standard deviation** option detects and filters for outliers in numeric columns using the mean and standard deviation. You specify the number of standard deviations a value must vary from the

mean to be considered an outlier. For example, if you specify 3 for **SD**, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The **Custom range** option detects and filters for outliers in numeric columns using minimum and maximum values. Use this method if you know your threshold values that delimit outliers. You can set the **Type** of the range to either **Percentile** or **Number**. If you choose **Percentile**, the **Min** and **Max** values should be the minimum and maximum of the percentile range (0-100) that you want to allow. If you choose **Number**, the **Min** and **Max** values should be the minimum and maximum numeric values that you want to filter in the data.

The screenshot displays the Amazon SageMaker Canvas interface for a dataset named 'titanic (1).csv'. The main area shows a data table with columns: Fare, Pclass, PassengerId, Survived, Name, Sex, and Age. Each column has a small histogram above it. The 'Fare' column has a histogram showing a distribution with a peak around 150 and a tail extending to 159.94. The 'Survived' column has a histogram showing two categories. The 'Age' column has a histogram showing a distribution with a peak around 20 and a tail extending to 76.0. The 'Filter by rows' panel is open on the right, showing the 'Fare' column selected, the operation 'Is outlier' chosen, and the 'Custom Range' type selected with a 'Number' type and 'Min' value of 10 and 'Max' value of 80. The panel also shows a 'Cancel' button.

Fare	Pclass	PassengerId	Survived	Name	Sex	Age
7.25	3	1	0	Braund, Mr. Owen Harris	male	22
7.925	3	3	1	Heikkinen, Miss. Laina	female	26
8.05	3	5	0	Allen, Mr. William Henry	male	35
8.4583	3	6	0	Moran, Mr. James	male	
8.05	3	13	0	Saunders, Mr. William Henry	male	20
7.8542	3	15	0	Vestrom, Miss. Hulda Amanda A...	female	14
7.225	3	20	1	Masselmani, Mrs. Fatima	female	
8.0292	3	23	1	McGowan, Miss. Anna "Annie"	female	15
7.225	3	27	0	Emir, Mr. Farred Chehab	male	
263	1	28	0	Fortune, Mr. Charles Alexander	male	19
7.8792	3	29	1	O'Dwyer, Miss. Ellen "Nellie"	female	
7.8958	3	30	0	Todoroff, Mr. Lalio	male	
146.5208	1	32	1	Spencer, Mrs. William Augustus (...)	female	
7.75	3	33	1	Glynn, Miss. Mary Agatha	female	
82.1708	1	35	0	Meyer, Mr. Edgar Joseph	male	28
7.2292	3	37	1	Mamee, Mr. Hanna	male	
8.05	3	38	0	Cann, Mr. Ernest Charles	male	21

## Filter rows by custom values

You can filter for rows with values that meet custom conditions. For example, you might want to preview rows that have a price value greater than 100 before removing them. With this functionality, you can filter rows that exceed the threshold you set and preview the filtered data.

To use the custom filter functionality, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Filter by rows** ( ).
2. Choose the **Column** you want to check.
3. Select the type of **Operation** you want to use, and then specify the values for the selected condition.

For the **Operation**, you can choose one of the following options. Note that the available operations depend on the data type of the column you choose. For example, you cannot create a `is greater than` operation for a column containing text values.

Operation	Supported data type	Supported feature type	Function
Is equal to	Numeric, Text	Binary, Categorical	Filters rows where the value in <b>Column</b> equals the values you specify.
Is not equal to	Numeric, Text	Binary, Categorical	Filters rows where the value in <b>Column</b> doesn't equal the values you specify.
Is less than	Numeric	N/A	Filters rows where the value in <b>Column</b> is less than the value you specify.
Is less than or equal to	Numeric	N/A	Filters rows where the value in <b>Column</b> is less than or equal to the value you specify.
Is greater than	Numeric	N/A	Filters rows where the value in <b>Column</b> is greater than the value you specify.
Is greater than or equal to	Numeric	N/A	Filters rows where the value in <b>Column</b> is greater than or equal to the value you specify.
Is between	Numeric	N/A	Filters rows where the value in <b>Column</b> is between or equal to two values you specify.
Contains	Text	Categorical	Filters rows where the value in <b>Column</b> contains a values you specify.

Operation	Supported data type	Supported feature type	Function
Starts with	Text	Categorical	Filters rows where the value in <b>Column</b> begins with a value you specify.
Ends with	Categorical	Categorical	Filters rows where the value in <b>Column</b> ends with a value you specify.

After you set the filter operation, SageMaker Canvas updates the preview of the dataset to show you the filtered data.

The screenshot shows the SageMaker Canvas interface. At the top, there's a navigation bar with 'My models / deployment 2.8.2 / Version 1' and a 'Target column' dropdown. Below that, a toolbar contains icons for 'Manage columns', 'Manage rows', 'Time series', and 'View all'. The main area displays a data preview with columns: Product\_category, demand, time\_stamp, price, Location, and item\_id. Each column has a corresponding chart (bar or histogram). A 'Filter by rows' dialog box is open on the right, showing the 'Product\_category' column selected with the operation 'Is equal to' and the value 'Wearables'. The dialog also includes a 'Value' field with 'Wearables' entered and a 'Specify a value' field. A 'Cancel' button is at the bottom right of the dialog. At the bottom of the interface, there are statistics: 'Total columns: 6', 'Total rows: 40,500', 'Total cells: 243,000', and 'Previewing first 100 rows'. A 'Show dropped columns' checkbox is also visible.

## Functions and operators

You can use mathematical functions and operators to explore and distribute your data. You can use the SageMaker Canvas supported functions or create your own formula with your existing data and create a new column with the result of the formula. For example, you can add the corresponding values of two columns and save the result to a new column.

You can nest statements to create more complex functions. The following are some examples of nested functions that you might use.

- To calculate BMI, you could use the function `weight / (height ^ 2)`.
- To classify ages, you could use the function `Case(age < 18, 'child', age < 65, 'adult', 'senior')`.

You can specify functions in the data preparation stage before you build your model. To use a function, do the following.

- In the **Build** tab of the SageMaker Canvas application, choose **View all** and then choose **Custom formula** to open the **Custom formula** panel.
- In the **Custom formula** panel, you can choose a **Formula** to add to your **Model Recipe**. Each formula is applied to all of the values in the columns you specify. For formulas that accept two or more columns as arguments, use columns with matching data types; otherwise, you get an error or null values in the new column.
- After you've specified a **Formula**, add a column name in the **New Column Name** field. SageMaker Canvas uses this name for the new column that is created.
- (Optional) Choose **Preview** to preview your transform.
- To add the function to your **Model Recipe**, choose **Add**.

SageMaker Canvas saves the result of your function to a new column using the name you specified in **New Column Name**. You can view or remove functions from the **Model Recipe** panel.

SageMaker Canvas supports the following operators for functions. You can use either the text format or the in-line format to specify your function.

Operator	Description	Supported data types	Text format	In-line format
Add	Returns the sum of the values	Numeric	Add(sales1, sales2)	sales1 + sales2
Subtract	Returns the difference between the values	Numeric	Subtract(sales1, sales2)	sales1 - sales2

Operator	Description	Supported data types	Text format	In-line format
Multiply	Returns the product of the values	Numeric	Multiply(sales1, sales2)	sales1 * sales2
Divide	Returns the quotient of the values	Numeric	Divide(sales1, sales2)	sales1 / sales2
Mod	Returns the result of the modulo operator (the remainder after dividing the two values)	Numeric	Mod(sales1, sales2)	sales1 % sales2
Abs	Returns the absolute value of the value	Numeric	Abs(sales1)	N/A
Negate	Returns the negative of the value	Numeric	Negate(c1)	-c1
Exp	Returns e (Euler's number) raised to the power of the value	Numeric	Exp(sales1)	N/A
Log	Returns the logarithm (base 10) of the value	Numeric	Log(sales1)	N/A
Ln	Returns the natural logarithm (base e) of the value	Numeric	Ln(sales1)	N/A
Pow	Returns the value raised to a power	Numeric	Pow(sales1, 2)	sales1 ^ 2
If	Returns a true or false label based on a condition you specify	Boolean, Numeric, Text	If(sales1 > 7000, 'true_label', 'false_label')	N/A

Operator	Description	Supported data types	Text format	In-line format
Or	Returns a Boolean value of whether one of the specified values or conditions is true or not	Boolean	Or(fullprice, discount)	fullprice    discount
And	Returns a Boolean value of whether two of the specified values or conditions are true or not	Boolean	And(sales 1,sales2)	sales1 && sales2
Not	Returns a Boolean value that is the opposite of the specified value or conditions	Boolean	Not(sales1)	!sales1
Case	Returns a Boolean value based on conditional statements (returns c1 if cond1 is true, returns c2 if cond2 is true, else returns c3)	Boolean, Numeric, Text	Case(cond1, c1, cond2, c2, c3)	N/A
Equal	Returns a Boolean value of whether two values are equal	Boolean, Numeric, Text	N/A	c1 = c2 c1 == c2
Not equal	Returns a Boolean value of whether two values are not equal	Boolean, Numeric, Text	N/A	c1 != c2
Less than	Returns a Boolean value of whether c1 is less than c2	Boolean, Numeric, Text	N/A	c1 < c2
Greater than	Returns a Boolean value of whether c1 is greater than c2	Boolean, Numeric, Text	N/A	c1 > c2

Operator	Description	Supported data types	Text format	In-line format
Less than or equal	Returns a Boolean value of whether c1 is less than or equal to c2	Boolean, Numeric, Text	N/A	c1 <= c2
Greater than or equal	Returns a Boolean value of whether c1 is greater than or equal to c2	Boolean, Numeric, Text	N/A	c1 >= c2

SageMaker Canvas also supports aggregate operators, which can perform operations such as calculating the sum of all the values or finding the minimum value in a column. You can use aggregate operators in combination with standard operators in your functions. For example, to calculate the difference of values from the mean, you could use the function `Abs(height - avg(height))`. SageMaker Canvas supports the following aggregate operators.

Aggregate operator	Description	Format	Example
sum	Returns the sum of all the values in a column	sum	sum(c1)
minimum	Returns the minimum value of a column	min	min(c2)
maximum	Returns the maximum value of a column	max	max(c3)
average	Returns the average value of a column	avg	avg(c4)
std	Returns the sample standard deviation of a column	std	std(c1)
stddev	Returns the standard deviation of the values in a column	stddev	stddev(c1)

Aggregate operator	Description	Format	Example
variance	Returns the unbiased variance of the values in a column	variance	variance(c1)
approx_count_distinct	Returns the approximate number of distinct items in a column	approx_count_distinct	approx_count_distinct(c1)
count	Returns the number of items in a column	count	count(c1)
first	Returns the first value of a column	first	first(c1)
last	Returns the last value of a column	last	last(c1)
stddev_pop	Returns the population standard deviation of a column	stddev_pop	stddev_pop(c1)
variance_pop	Returns the population variance of the values in a column	variance_pop	variance_pop(c1)

## Manage rows

With the Manage rows transform, you can perform sort, random shuffle, and remove rows of data from the dataset.

### Sort rows

To sort the rows in a dataset by a given column, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Manage rows** and then choose **Sort rows**.
2. For **Sort Column**, choose the column you want to sort by.
3. For **Sort Order**, choose either **Ascending** or **Descending**.
4. Choose **Add** to add the transform to the **Model recipe**.

## Shuffle rows

To randomly shuffle the rows in a dataset, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Manage rows** and then choose **Shuffle rows**.
2. Choose **Add** to add the transform to the **Model recipe**.

## Drop duplicate rows

To remove duplicate rows in a dataset, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Manage rows** and then choose **Drop duplicate rows**.
2. Choose **Add** to add the transform to the **Model recipe**.

## Remove rows by missing values

Missing values are a common occurrence in machine learning datasets and can impact model accuracy. Use this transform if you want to drop rows with null or empty values in certain columns.

To remove rows that contain missing values in a specified column, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Manage rows**.
2. Choose **Drop rows by missing values**.
3. Choose **Add** to add the transform to the **Model recipe**.

SageMaker Canvas drops rows that contain missing values in the **Column** you selected. After removing the rows from the dataset, SageMaker Canvas adds the transform in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the rows return to your dataset.

The screenshot shows the Amazon SageMaker Canvas interface. At the top, there's a navigation bar with 'My models / deployment 2.8.2 / Version 1' and a 'Target column' dropdown. Below that, a toolbar includes 'Manage columns', 'Manage rows', 'Time series', and 'View all'. The main area displays a data table with columns: demand, time\_stamp, Product\_c..., price, Location, and item\_id. The 'demand' column is highlighted. On the right, a 'Drop rows by missing values' dialog is open, showing a dropdown menu with 'demand' selected. The dialog also has 'Preview', 'Cancel', and 'Add' buttons.

267.9		2018-03-01 00:00:00	Wearables	110.7954801	Tokyo	sku - 001

At the bottom of the interface, there are statistics: Total columns: 6, Total rows: 40,500, Total cells: 243,000, and a 'Show dropped columns' checkbox.

## Remove rows by outliers

Outliers, or rare values in the distribution and range of your data, can negatively impact model accuracy and lead to longer building times. With SageMaker Canvas, you can detect and remove rows that contain outliers in numeric columns. You can choose to define outliers with either standard deviations or a custom range.

To remove outliers from your data, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Manage rows**.
2. Choose **Drop rows by outlier values**.
3. Choose the **Column** you want to check for outliers.
4. Set the **Operator** to **Standard deviation**, **Custom numeric range**, or **Custom quantile range**.
5. If you choose **Standard deviation**, specify a **Standard deviations** (standard deviation) value from 1–3. If you choose **Custom numeric range** or **Custom quantile range**, specify the **Min** and **Max** values (numbers for numeric ranges, or percentiles between 0–100% for quantile ranges).
6. Choose **Add** to add the transform to the **Model recipe**.

The **Standard deviation** option detects and removes outliers in numeric columns using the mean and standard deviation. You specify the number of standard deviations a value must vary from the

mean to be considered an outlier. For example, if you specify 3 for **Standard deviations**, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The **Custom numeric range** and **Custom quantile range** options detect and remove outliers in numeric columns using minimum and maximum values. Use this method if you know your threshold values that delimit outliers. If you choose a numeric range, the **Min** and **Max** values should be the minimum and maximum numeric values that you want to allow in the data. If you choose a quantile range, the **Min** and **Max** values should be the minimum and maximum of the percentile range (0–100) that you want to allow.

After removing the rows from the dataset, SageMaker Canvas adds the transform in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the rows return to your dataset.

The screenshot shows the SageMaker Canvas interface. At the top, there's a navigation bar with 'My models / deployment 2.8.2 / Version 1'. Below that, a search bar for 'Target column' and a 'Quick build' button are visible. The main area displays a data table with columns: price, time\_stamp, Product\_c..., Location, item\_id, and demand. The table contains 15 rows of data. On the right side, the 'Drop rows by outlier values' configuration panel is open. It includes a 'Column' dropdown set to 'price', an 'Operator' dropdown set to 'Standard deviation', and a 'Standard deviations' input field set to '1'. There are 'Preview', 'Cancel', and 'Add' buttons at the bottom of the panel.

## Remove rows by custom values

You can remove rows with values that meet custom conditions. For example, you might want to exclude all of the rows with a price value greater than 100 when building your model. With this transform, you can create a rule that removes all rows that exceed the threshold you set.

To use the custom remove transform, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Manage rows**.
2. Choose **Drop rows by formula**.

3. Choose the **Column** you want to check.
4. Select the type of **Operation** you want to use, and then specify the values for the selected condition.
5. Choose **Add** to add the transform to the **Model recipe**.

For the **Operation**, you can choose one of the following options. Note that the available operations depend on the data type of the column you choose. For example, you cannot create a `is greater than` operation for a column containing text values.

Operation	Supported data type	Supported feature type	Function
Is equal to	Numeric, Text	Binary, Categorical	Removes rows where the value in <b>Column</b> equals the values you specify.
Is not equal to	Numeric, Text	Binary, Categorical	Removes rows where the value in <b>Column</b> doesn't equal the values you specify.
Is less than	Numeric	N/A	Removes rows where the value in <b>Column</b> is less than the value you specify.
Is less than or equal to	Numeric	N/A	Removes rows where the value in <b>Column</b> is less than or equal to the value you specify.
Is greater than	Numeric	N/A	Removes rows where the value in <b>Column</b> is greater than the value you specify.
Is greater than or equal to	Numeric	N/A	Removes rows where the value in <b>Column</b> is greater than or equal to the value you specify.

Operation	Supported data type	Supported feature type	Function
Is between	Numeric	N/A	Removes rows where the value in <b>Column</b> is between or equal to two values you specify.
Contains	Text	Categorical	Removes rows where the value in <b>Column</b> contains a values you specify.
Starts with	Text	Categorical	Removes rows where the value in <b>Column</b> begins with a value you specify.
Ends with	Text	Categorical	Removes rows where the value in <b>Column</b> ends with a value you specify.

After removing the rows from the dataset, SageMaker Canvas adds the transform in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the rows return to your dataset.

The screenshot displays the Amazon SageMaker Canvas interface. At the top, there's a navigation bar with 'My models / deployment 2.8.2 / Version 1' and a 'Target column' dropdown. Below this is a toolbar with icons for source, filters, search, and management. The main area shows a data table with columns: Product\_category, time\_stamp, price, Location, item\_id, and demand. The table contains 15 rows of data for 'Wearables' products. On the right, the 'Drop rows by formula' configuration panel is open, showing a dropdown for 'Product\_category' and a configuration for the operation 'Is equal to' with a value dropdown set to 'Wearables'.

## Rename columns

With the rename columns transform, you can rename columns in your data. When you rename a column, SageMaker Canvas changes the column name in the model input.

You can rename a column in your dataset by double-clicking on the column name in the **Build** tab of the SageMaker Canvas application and entering a new name. Pressing the **Enter** key submits the change, and clicking anywhere outside the input cancels the change. You can also rename a column by clicking the **More options** icon (⋮), located at the end of the row in list view or at the end of the header cell in grid view, and choosing **Rename**.

Your column name can't be longer than 32 characters or have double underscores (\_\_), and you can't rename a column to the same name as another column. You also can't rename a dropped column.

The following screenshot shows how to rename a column by double-clicking the column name.

The screenshot displays the SageMaker Canvas interface for a new model. The top navigation bar includes 'Select', 'Build', 'Analyze', and 'Predict' tabs. The 'Build' tab is active, showing a 'Select a column to predict' section with a dropdown menu set to 'Target column'. The 'Model type' section shows 'Standard build' as the recommended type. Below this is a table of columns from the dataset 'store\_daily\_sales.csv'.

Column name ↓	Data type	Missing (0)	Mismatched (0)	Unique (0)	Mean / Mode
<input checked="" type="checkbox"/> store	Numeric	0.00% (0)	0.00% (0)	1,115	907
<input checked="" type="checkbox"/> schoolholiday	Binary	0.00% (0)	0.00% (0)	2	0
<input checked="" type="checkbox"/> date	Datetime	0.00% (0)	0.00% (0)	942	2015-07-11 00:00:00
<input checked="" type="checkbox"/> sales	Numeric	0.00% (0)	0.00% (0)	8,122	0
<input checked="" type="checkbox"/> promo	Binary	0.00% (0)	0.00% (0)	2	0

At the bottom of the interface, there is a checkbox labeled 'Show dropped columns' which is currently checked.

When you rename a column, SageMaker Canvas adds the transform in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the column reverts to its original name.

## Manage columns

With the following transforms, you can change the data type of columns and replace missing values or outliers for specific columns. SageMaker Canvas uses the updated data types or values when building your model but doesn't change your original dataset. Note that if you've dropped a column from your dataset using the [Drop columns](#) transform, you can't replace values in that column.

### Replace missing values

Missing values are a common occurrence in machine learning datasets and can impact model accuracy. You can choose to drop rows that have missing values, but your model is more accurate if you choose to replace the missing values instead. With this transform, you can replace missing values in numeric columns with the mean or median of the data in a column, or you can also specify a custom value with which to replace missing values. For non-numeric columns, you can replace missing values with the mode (most common value) of the column or a custom value.

Use this transform if you want to replace the null or empty values in certain columns. To replace missing values in a specified column, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Manage columns**.
2. Choose **Replace missing values**.
3. Choose the **Column** in which you want to replace missing values.
4. Set **Mode** to **Manual** to replace missing values with values that you specify. With the **Automatic (default)** setting, SageMaker Canvas replaces missing values with imputed values that best fit your data. This imputation method is done automatically for each model build, unless you specify the **Manual** mode.
5. Set the **Replace with** value:
  - If your column is numeric, then select **Mean**, **Median**, or **Custom**. **Mean** replaces missing values with the mean for the column, and **Median** replaces missing values with the median for the column. If you choose **Custom**, then you must specify a custom value that you want to use to replace missing values.
  - If your column is non-numeric, then select **Mode** or **Custom**. **Mode** replaces missing values with the mode, or the most common value, for the column. For **Custom**, specify a custom value that you want to use to replace missing values.
6. Choose **Add** to add the transform to the **Model recipe**.

After replacing the missing values in the dataset, SageMaker Canvas adds the transform in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the missing values return to the dataset.

The screenshot shows the Amazon SageMaker Canvas interface. At the top, there's a navigation bar with 'My models / deployment 2.8.2 / Version 1'. Below that, a search bar for 'Target column' and a 'Quick build' button are visible. The main area displays a data table with columns: demand, time\_stamp, Product\_c..., price, Location, and item\_id. The table contains 15 rows of data. On the right side, a dialog box titled 'Replace missing values' is open. It prompts the user to 'Replace missing values with a custom value. Learn more'. The dialog has fields for 'Column' (set to 'demand'), 'Mode' (set to 'Manual'), and 'Replace with' (set to 'Custom'). There are 'Preview', 'Cancel', and 'Add' buttons at the bottom of the dialog.

## Replace outliers

Outliers, or rare values in the distribution and range of your data, can negatively impact model accuracy and lead to longer building times. SageMaker Canvas enables you to detect outliers in numeric columns and replace the outliers with values that lie within an accepted range in your data. You can choose to define outliers with either standard deviations or a custom range, and you can replace outliers with the minimum and maximum values in the accepted range.

To replace outliers in your data, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Manage columns**.
2. Choose **Replace outlier values**.
3. Choose the **Column** in which you want to replace outliers.
4. For **Define outliers**, choose **Standard deviation**, **Custom numeric range**, or **Custom quantile range**.
5. If you choose **Standard deviation**, specify a **Standard deviations** (standard deviation) value from 1–3. If you choose **Custom numeric range** or **Custom quantile range**, specify the **Min** and **Max** values (numbers for numeric ranges, or percentiles between 0–100% for quantile ranges).

6. For **Replace with**, select **Min/max range**.
7. Choose **Add** to add the transform to the **Model recipe**.

The **Standard deviation** option detects outliers in numeric columns using the mean and standard deviation. You specify the number of standard deviations a value must vary from the mean to be considered an outlier. For example, if you specify 3 for **Standard deviations**, a value must fall more than 3 standard deviations from the mean to be considered an outlier. SageMaker Canvas replaces outliers with the minimum value or maximum value in the accepted range. For example, if you configure the standard deviations to only include values from 200–300, then SageMaker Canvas changes a value of 198 to 200 (the minimum).

The **Custom numeric range** and **Custom quantile range** options detect outliers in numeric columns using minimum and maximum values. Use this method if you know your threshold values that delimit outliers. If you choose a numeric range, the **Min** and **Max** values should be the minimum and maximum numeric values that you want to allow. SageMaker Canvas replaces any values that fall outside of the minimum and maximum to the minimum and maximum values. For example, if your range only allows values from 1–100, then SageMaker Canvas changes a value of 102 to 100 (the maximum). If you choose a quantile range, the **Min** and **Max** values should be the minimum and maximum of the percentile range (0–100) that you want to allow.

After replacing the values in the dataset, SageMaker Canvas adds the transform in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the original values return to the dataset.

## Change data type

SageMaker Canvas provides you with the ability to change the *data type* of your columns between numeric, text, and datetime, while also displaying the associated *feature type* for that data type. A *data type* refers to the format of the data and how it is stored, while the *feature type* refers to the characteristic of the data used in machine learning algorithms, such as binary or categorical. This gives you the flexibility to manually change the type of data in your columns based on the features. The ability to choose the right data type ensures data integrity and accuracy prior to building models. These data types are used when building models.

### Note

Currently, changing the feature type (for example, from binary to categorical) is not supported.

The following table lists all of the supported data types in Canvas.

Data type	Description	Example
Numeric	Numeric data represents numerical values	1, 2, 3 1.1, 1.2, 1.3
Text	Text data represents sequences of characters, like names or descriptions	A, B, C, D apple, banana, orange 1A!, 2A!, 3A!
Datetime	Datetime data represents dates and times in timestamp format	2019-07-01 01:00:00, 2019-07-01 02:00:00, 2019-07-01 03:00:00

The following table lists all of the supported feature types in Canvas.

Feature type	Description	Example
Binary	Binary features represent two possible values	0, 1, 0, 1, 0 (2 distinct values) true, false, true (2 distinct values)
Categorical	Categorical features represent distinct categories or groups	apple, banana, orange, apple (3 distinct values) A, B, C, D, E, A, D, C (5 distinct values)

To modify data type of a column in a dataset, do the following.

1. In the **Build** tab of the SageMaker Canvas application, go to the **Column view** or **Grid view** and select the **Data type** dropdown for the specific column.
2. In the **Data type** dropdown, choose the data type to convert to. The following screenshot shows the dropdown menu.

The screenshot shows the Amazon SageMaker AI interface for a dataset named 'canvas-sample-shipping-logs.csv'. The interface includes a navigation bar with 'My models / deployment 2.8.2 / Version 1', a 'Target column' dropdown, and buttons for 'Quick build' and 'Preview model'. Below the navigation bar, there are tabs for 'Manage columns', 'Manage rows', 'Time series', and 'View all'. A 'Data visualizer' button is also present. A light blue banner provides instructions on how to build a model with this dataset. The main area displays a table with columns and their properties:

Column name	Data type	Feature type	Missing	Mismatched	Unique	Mode
YShippingDistance	123 Numeric	-	0.00% (0)	0.00% (0)	424	8
XShippingDistance	123 Numeric	-	0.00% (0)	0.00% (0)	421	-8
ShippingPriority	123 Numeric	Categorical	0.00% (0)	0.00% (0)	4	Ground
ShippingOrigin	123 Numeric	Categorical	0.00% (0)	0.00% (0)	8	Seattle
Productid	Text	-	0.00% (0)	0.00% (0)	12	cf71718d-1851-44e4...
OrderID	Text	-	0.00% (0)	0.00% (0)	1,000	00572689-382d-46e...
OrderDate_year	123 Numeric	Binary	0.00% (0)	0.00% (0)	2	2,021
OrderDate_week_of_year	123 Numeric	-	0.00% (0)	0.00% (0)	53	5
OrderDate_month	123 Numeric	-	0.00% (0)	0.00% (0)	12	1
OrderDate_hour	123 Numeric	-	0.00% (0)	0.00% (0)	1	0
OrderDate_day_of_year	123 Numeric	-	0.00% (0)	0.00% (0)	346	292
OrderDate	Datetime	-	0.00% (0)	0.00% (0)	561	2020-08-01 00:00:00

At the bottom, there are summary statistics: Total columns: 17, Total rows: 1,000, Total cells: 17,000, and a checkbox for 'Show dropped columns'.

3. For **Column**, choose or verify the column you want to change the data type for.
4. For **New data type**, choose or verify the new data type you want to convert to.
5. If the **New data type** is **Datetime** or **Numeric**, choose one of the following options under **Handle invalid values**:
  - a. **Replace with empty value** – Invalid values are substituted with an empty value
  - b. **Delete rows** – Rows with an invalid value are removed from the dataset
  - c. **Replace with custom value** – Invalid values are substituted with the **Custom Value** that you specify.
6. Choose **Add** to add the transform to the **Model recipe**.

The data type for your column should now be updated.

## Prepare time series data

Use the following functionalities to prepare your time series data for building time series forecasting models.

## Resample time series data

By resampling time-series data, you can establish regular intervals for the observations in your time series dataset. This is particularly useful when working with time series data containing irregularly spaced observations. For instance, you can use resampling to transform a dataset with observations recorded every one hour, two hour and three hour intervals into a regular one hour

interval between observations. Forecasting algorithms require the observations to be taken at regular intervals.

To resample time series data, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Time series**.
2. Choose **Resample**.
3. For **Timestamp column**, choose the column you want to apply the transform to. You can only select columns of the **Datetime** type.
4. In the **Frequency settings** section, choose a **Frequency** and **Rate**. **Frequency** is the unit of frequency and **Rate** is the interval of the unit of frequency to be applied to the column. For example, choosing **Calendar Day** for **Frequency value** and 1 for **Rate** sets the interval to increase every 1 calendar day, such as 2023-03-26 00:00:00, 2023-03-27 00:00:00, 2023-03-28 00:00:00. See the table after this procedure for a complete list of **Frequency value**.
5. Choose **Add** to add the transform to the **Model recipe**.

The following table lists all of the **Frequency** types you can select when resampling time series data.

Frequency	Description	Example values (assuming Rate is 1)
Business Day	Resample observations in the datetime column to 5 business days of the week (Monday, Tuesday, Wednesday, Thursday, Friday)	2023-03-24 00:00:00 2023-03-27 00:00:00 2023-03-28 00:00:00 2023-03-29 00:00:00 2023-03-30 00:00:00 2023-03-31 00:00:00 2023-04-03 00:00:00
Calendar Day	Resample observations in the datetime column	2023-03-26 00:00:00

Frequency	Description	Example values (assuming Rate is 1)
	to all 7 days of the week (Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, Sunday)	2023-03-27 00:00:00 2023-03-28 00:00:00 2023-03-29 00:00:00 2023-03-30 00:00:00 2023-03-31 00:00:00 2023-04-01 00:00:00
Week	Resample observations in the datetime column to the first day of each week	2023-03-13 00:00:00 2023-03-20 00:00:00 2023-03-27 00:00:00 2023-04-03 00:00:00
Month	Resample observations in the datetime column to the first day of each month	2023-03-01 00:00:00 2023-04-01 00:00:00 2023-05-01 00:00:00 2023-06-01 00:00:00
Annual Quarter	Resample observations in the datetime column to the last day of each quarter	2023-03-31 00:00:00 2023-06-30 00:00:00 2023-09-30 00:00:00 2023-12-31 00:00:00

Frequency	Description	Example values (assuming Rate is 1)
Year	Resample observations in the datetime column to the last day of each year	2022-12-31 0:00:00 2023-12-31 00:00:00 2024-12-31 00:00:00
Hour	Resample observations in the datetime column to each hour of each day	2023-03-24 00:00:00 2023-03-24 01:00:00 2023-03-24 02:00:00 2023-03-24 03:00:00
Minute	Resample observations in the datetime column to each minute of each hour	2023-03-24 00:00:00 2023-03-24 00:01:00 2023-03-24 00:02:00 2023-03-24 00:03:00
Second	Resample observations in the datetime column to each second of each minute	2023-03-24 00:00:00 2023-03-24 00:00:01 2023-03-24 00:00:02 2023-03-24 00:00:03

When applying the resampling transform, you can use the **Advanced** option to specify how the resulting values of the rest of the columns (other than the timestamp column) in your dataset are modified. This can be achieved by specifying the resampling methodology, which can either be downsampling or upsampling for both numeric and non-numeric columns.

*Downsampling* increases the interval between observations in the dataset. For example, if you downsample observations that are taken either every hour or every two hours, each observation in your dataset is taken every two hours. The values of other columns of the hourly observations

are aggregated into a single value using a combination method. The following tables show an example of downsampling time series data by using mean as the combination method. The data is downsampled from every two hours to every hour.

The following table shows the hourly temperature readings over a day before downsampling.

Timestamp	Temperature (Celsius)
12:00 pm	30
1:00 am	32
2:00 am	35
3:00 am	32
4:00 am	30

The following table shows the temperature readings after downsampling to every two hours.

Timestamp	Temperature (Celsius)
12:00 pm	30
2:00 am	33.5
2:00 am	35
4:00 am	32.5

To downsample time series data, do the following:

1. Expand the **Advanced** section under the **Resample** transform.
2. Choose **Non-numeric combination** to specify the combination method for non-numeric columns. See the table below for a complete list of combination methods.
3. Choose **Numeric combination** to specify the combination method for numeric columns. See the table below for a complete list of combination methods.

If you don't specify combination methods, the default values are Most Common for **Non-numeric combination** and Mean for **Numeric combination**. The following table lists the methods for numeric and non-numeric combination.

Downsampling methodology	Combination method	Description
Non-numeric combination	Most Common	Aggregate values in the non-numeric column by the most commonly occurring value
Non-numeric combination	Last	Aggregate values in the non-numeric column by the last value in the column
Non-numeric combination	First	Aggregate values in the non-numeric column by the first value in the column
Numeric combination	Mean	Aggregate values in the numeric column by the taking the mean of all the values in the column
Numeric combination	Median	Aggregate values in the numeric column by the taking the median of all the values in the column
Numeric combination	Min	Aggregate values in the numeric column by the taking the minimum of all the values in the column
Numeric combination	Max	Aggregate values in the numeric column by the taking the maximum of all the values in the column

Downsampling methodology	Combination method	Description
Numeric combination	Sum	Aggregate values in the numeric column by adding all the values in the column
Numeric combination	Quantile	Aggregate values in the numeric column by the taking the quantile of all the values in the column

*Upsampling* reduces the interval between observations in the dataset. For example, if you upsample observations that are taken every two hours into hourly observations, the values of other columns of the hourly observations are interpolated from the ones that have been taken every two hours.

To upsample time series data, do the following:

1. Expand the **Advanced** section under the **Resample** transform.
2. Choose **Non-numeric estimation** to specify the estimation method for non-numeric columns. See the table after this procedure for a complete list of methods.
3. Choose **Numeric estimation** to specify the estimation method for numeric columns. See the table below for a complete list of methods.
4. (Optional) Choose **ID Column** to specify the column that has the IDs of the observations of the time series. Specify this option if your dataset has two time series. If you have a column representing only one time series, don't specify a value for this field. For example, you can have a dataset that has the columns `id` and `purchase`. The `id` column has the following values: `[1, 2, 2, 1]`. The `purchase` column has the following values `[$2, $3, $4, $1]`. Therefore, the dataset has two time series—one time series is: 1: `[$2, $1]`, and the other time series is 2: `[$3, $4]`.

If you don't specify estimation methods, the default values are `Forward Fill` for **Non-numeric estimation** and `Linear` for **Numeric estimation**. The following table lists the methods for estimation.

Upsampling methodology	Estimation method	Description
Non-numeric estimation	Forward Fill	Interpolate values in the non-numeric column by taking the consecutive values after all the values in the column
Non-numeric estimation	Backward Fill	Interpolate values in the non-numeric column by taking the consecutive values before all the values in the column
Non-numeric estimation	Keep Missing	Interpolate values in the non-numeric column by showing empty values
Numeric estimation	Linear, Time, Index, Zero, S-Linear, Nearest, Quadratic, Cubic, Barycentric, Polynomial, Krogh, Piecewise Polynomial, Spline, P-chip, Akima, Cubic Spline, From Derivatives	Interpolate values in the numeric column by using the specified interpolator. For information on interpolation methods, see <a href="#">pandas.DataFrame.interpolate</a> in the pandas documentation.

The following screenshot shows the **Advanced** settings with the fields for downsampling and upsampling filled out.

The screenshot displays the Amazon SageMaker Canvas interface. At the top, there's a navigation bar with 'My models / deployment 2.8.2 / Version 1' and a 'Target column' dropdown. Below this is a toolbar with icons for source, search, and management. The main area shows a data table with columns for time stamps, product categories, price, location, and item IDs. The table contains 20 rows of data. To the right, a 'Resample' panel is open, allowing users to adjust the frequency of the time series data. The panel includes options for 'Timestamp column', 'Frequency' (set to 'Month'), 'Advanced' settings, 'ID column', 'Downsample settings' (set to 'Most Common'), and 'Upsample settings' (set to 'Forward Fill').

time_stamp	time_stamp... 123	time_stamp... 123	time_stamp... 123	Product_C...	price	Location	Item_id
2017-12-01 00:00:00	3	11	334	Wearables	110.7954801	Seattle	sku - 001

2019-02-01 00:00:00	0	1	31	Wearables	82.97735656	Tokyo	sku - 001
2019-04-01 00:00:00	1	3	90	Wearables	92.56446737	Tokyo	sku - 001
2019-05-01 00:00:00	1	4	120	Wearables	97.79892302	Tokyo	sku - 001

## Use datetime extraction

With the datetime extraction transform, you can extract values from a datetime column to a separate column. For example, if you have a column containing dates of purchases, you can extract the month value to a separate column and use the new column when building your model. You can also extract multiple values to separate columns with a single transform.

Your datetime column must use a supported timestamp format. For a list of the formats that SageMaker Canvas supports, see [Time Series Forecasts in Amazon SageMaker Canvas](#). If your dataset does not use one of the supported formats, update your dataset to use a supported timestamp format and re-import it to Amazon SageMaker Canvas before building your model.

To perform a datetime extraction, do the following.

1. In the **Build** tab of the SageMaker Canvas application, on the transforms bar, choose **View all**.
2. Choose **Extract features**.
3. Choose the **Timestamp column** from which you want to extract values.

4. For **Values**, select one or more values to extract from the column. The values you can extract from a timestamp column are **Year, Month, Day, Hour, Week of year, Day of year, and Quarter**.
5. (Optional) Choose **Preview** to preview the transform results.
6. Choose **Add** to add the transform to the **Model recipe**.

SageMaker Canvas creates a new column in the dataset for each of the values you extract. Except for **Year** values, SageMaker Canvas uses a 0-based encoding for the extracted values. For example, if you extract the **Month** value, January is extracted as 0, and February is extracted as 1.

The screenshot shows the Amazon SageMaker Canvas interface. At the top, there's a navigation bar with 'My models / deployment 2.8.2 / Version 1' and a 'Target column' dropdown. Below that, the dataset 'canvas-sample-shipping-logs.csv' is displayed with a 'Full dataset: 1.0k rows' indicator. A 'Data visualizer' tab is active, showing a table of data with columns: OrderDate, OrderDate..., YShipping..., XShipping..., ShippingP..., and Shipping... Each column has a corresponding histogram. The table shows rows of data with columns for OrderDate, OrderDate..., YShipping..., XShipping..., ShippingP..., and Shipping... The 'Extract features' dialog box is open on the right, showing the 'OrderDate' column selected as the 'Timestamp column' and 'Month' selected as the 'Values' to extract. The dialog also has 'Preview', 'Cancel', and 'Add' buttons.

Source	Preview	YShipping...	XShipping...	ShippingP...	Shipping...
2020-09-11 00:00:00	8	100	-44	Express	Atlanta
2021-06-22 00:00:00	5	18	-154	Standard	Seattle
2020-12-25 00:00:00	11	-14	-389	Ground	Chicago
2021-07-06 00:00:00	6	301	-13	Ground	San Francisco
2021-04-03 00:00:00	3	118	89	Ground	San Francisco
2021-06-17 00:00:00	5	-290	-21	Standard	Chicago
2020-06-14 00:00:00	5	-190	7	Standard	Las Vegas
2020-08-17 00:00:00	7	-17	104	Air	Seattle

You can see the transform listed in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the new columns are removed from the dataset.

## Model evaluation

After you've built your model, you can evaluate how well your model performed on your data before using it to make predictions. You can use information, such as the model's accuracy when predicting labels and advanced metrics, to determine whether your model can make sufficiently accurate predictions for your data.

The section [Evaluate your model's performance](#) describes how to view and interpret the information on your model's **Analyze** page. The section [Use advanced metrics in your analyses](#)

contains more detailed information about the **Advanced metrics** used to quantify your model's accuracy.

You can also view more advanced information for specific *model candidates*, which are all of the model iterations that Canvas runs through while building your model. Based on the advanced metrics for a given model candidate, you can select a different candidate to be the default, or the version that is used for making predictions and deploying. For each model candidate, you can view the **Advanced metrics** information to help you decide which model candidate you'd like to select as the default. You can view this information by selecting the model candidate from the **Model leaderboard**. For more information, see [View model candidates in the model leaderboard](#).

Canvas also provides the option to download a Jupyter notebook so that you can view and run the code used to build your model. This is useful if you'd like to make adjustments to the code or learn more about how your model was built. For more information, see [Download a model notebook](#).

## Evaluate your model's performance

Amazon SageMaker Canvas provides overview and scoring information for the different types of model. Your model's score can help you determine how accurate your model is when it makes predictions. The additional scoring insights can help you quantify the differences between the actual and predicted values.

To view the analysis of your model, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **My models**.
3. Choose the model that you built.
4. In the top navigation pane, choose the **Analyze** tab.
5. Within the **Analyze** tab, you can view the overview and scoring information for your model.

The following sections describe how to interpret the scoring for each model type.

## Evaluate categorical prediction models

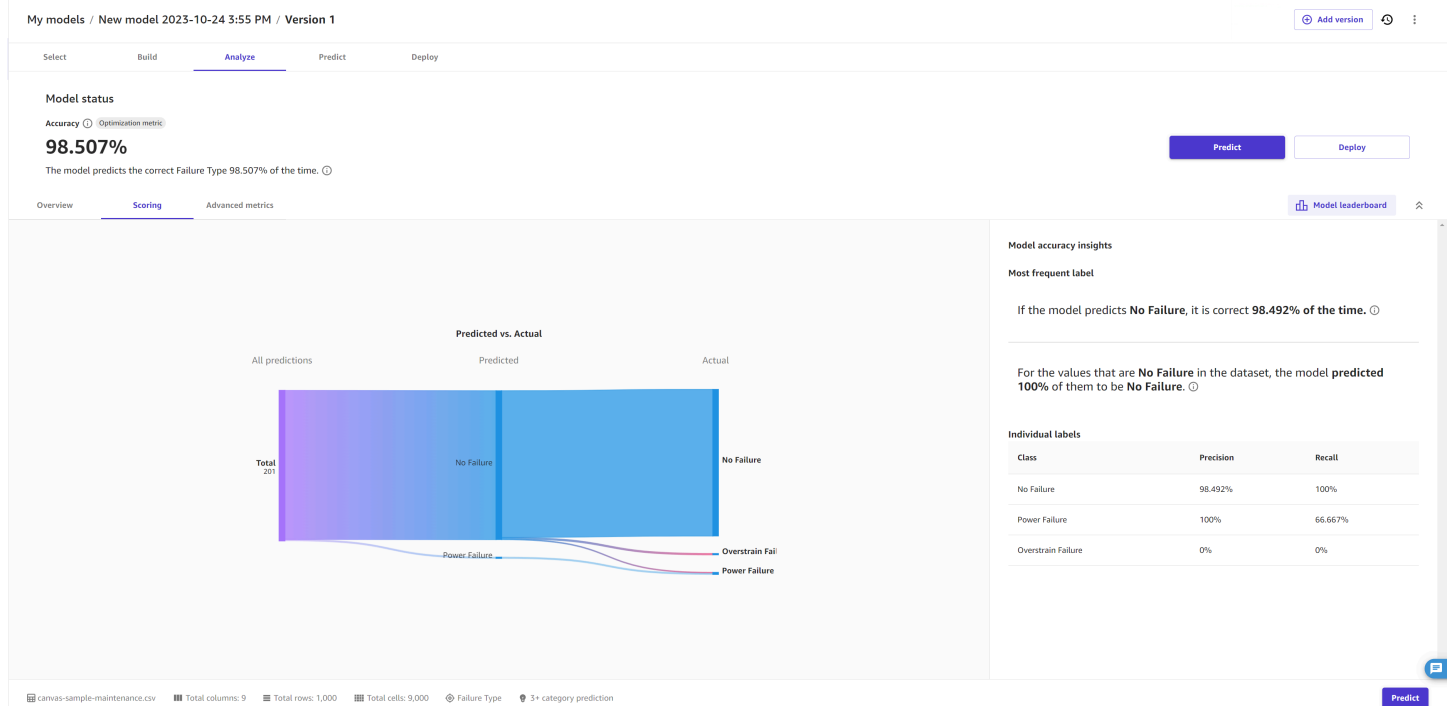

The **Overview** tab shows you the column impact for each column. **Column impact** is a percentage score that indicates how much weight a column has in making predictions in relation to the other columns. For a column impact of 25%, Canvas weighs the prediction as 25% for the column and 75% for the other columns.

The following screenshot shows the **Accuracy** score for the model, along with the **Optimization metric**, which is the metric that you choose to optimize when building the model. In this case, the **Optimization metric** is **Accuracy**. You can specify a different optimization metric if you build a new version of your model.

The **Scoring** tab for a categorical prediction model gives you the ability to visualize all the predictions. Line segments extend from the left of the page, indicating all the predictions the model has made. In the middle of the page, the line segments converge on a perpendicular segment to indicate the proportion of each prediction to a single category. From the predicted category, the segments branch out to the actual category. You can get a visual sense of how accurate the predictions were by following each line segment from the predicted category to the actual category.

The following image gives you an example **Scoring** section for a **3+ category prediction** model.

You can also view the **Advanced metrics** tab for more detailed information about your model's performance, such as the advanced metrics, error density plots, or confusion matrices. To learn more about the **Advanced metrics** tab, see [Use advanced metrics in your analyses](#).

## Evaluate numeric prediction models

The **Overview** tab shows you the column impact for each column. **Column impact** is a percentage score that indicates how much weight a column has in making predictions in relation to the other columns. For a column impact of 25%, Canvas weighs the prediction as 25% for the column and 75% for the other columns.

The following screenshot shows the **RMSE** score for the model on the **Overview** tab, which in this case is the **Optimization metric**. The **Optimization metric** is the metric that you choose to optimize when building the model. You can specify a different optimization metric if you build a new version of your model.

**Model status**

RMSE ⓘ Optimization metric

43344.19

The model often predicts a value that is within +/- 43344.19 of the actual value for median\_house\_value ⓘ

Predict

Overview Scoring

The **Scoring** tab for numeric prediction shows a line to indicate the model's predicted value in relation to the data used to make predictions. The values of the numeric prediction are often +/- the RMSE (root mean squared error) value. The value that the model predicts is often within the range of the RMSE. The width of the purple band around the line indicates the RMSE range. The predicted values often fall within the range.

The following image shows the **Scoring** section for numeric prediction.

You can also view the **Advanced metrics** tab for more detailed information about your model's performance, such as the advanced metrics, error density plots, or confusion matrices. To learn more about the **Advanced metrics** tab, see [Use advanced metrics in your analyses](#).

## Evaluate time series forecasting models

On the **Analyze** page for time series forecasting models, you can see an overview of the model's metrics. You can hover over each metric for more information, or you can see [Use advanced metrics in your analyses](#) for more information about each metric.

In the **Column impact** section, you can see the score for each column. **Column impact** is a percentage score that indicates how much weight a column has in making predictions in relation to the other columns. For a column impact of 25%, Canvas weighs the prediction as 25% for the column and 75% for the other columns.

The following screenshot shows the time series metrics scores for the model, along with the **Optimization metric**, which is the metric that you choose to optimize when building the model. In this case, the **Optimization metric** is **RMSE**. You can specify a different optimization metric if you build a new version of your model. These metrics scores are taken from your backtest results, which are available for download in the **Artifacts** tab.

The **Artifacts** tab provides access to several key resources that you can use to dive deeper into your model's performance and continue iterating upon it:

- **Shuffled training and validation splits** – This section includes links to the artifacts generated when your dataset was split into training and validation sets, enabling you to review the data distribution and potential biases.
- **Backtest results** – This section includes a link to the forecasted values for your validation dataset, which is used to generate accuracy metrics and evaluation data for your model.
- **Accuracy metrics** – This section lists the advanced metrics that evaluate your model's performance, such as Root Mean Squared Error (RMSE). For more information about each metric, see [Metrics for time series forecasts](#).
- **Explainability report** – This section provides a link to download the explainability report, which offers insights into the model's decision-making process and the relative importance of input columns. This report can help you identify potential areas for improvement.

On the **Analyze** page, you can also choose the **Download** button to directly download the backtest results, accuracy metrics, and explainability report artifacts to your local machine.

## Evaluate image prediction models

The **Overview** tab shows you the **Per label performance**, which gives you an overall accuracy score for the images predicted for each label. You can choose a label to see more specific details, such as the **Correctly predicted** and **Incorrectly predicted** images for the label.

You can turn on the **Heatmap** toggle to see a heatmap for each image. The heatmap shows you the areas of interest that have the most impact when your model is making predictions. For more information about heatmaps and how to use them to improve your model, choose the **More info** icon next to the **Heatmap** toggle.

The **Scoring** tab for single-label image prediction models shows you a comparison of what the model predicted as the label versus what the actual label was. You can select up to 10 labels at a time. You can change the labels in the visualization by choosing the labels dropdown menu and selecting or deselecting labels.

You can also view insights for individual labels or groups of labels, such as the three labels with the highest or lowest accuracy, by choosing the **View scores for** dropdown menu in the **Model accuracy insights** section.

The following screenshot shows the **Scoring** information for a single-label image prediction model.

## Evaluate text prediction models

The **Overview** tab shows you the **Per label performance**, which gives you an overall accuracy score for the passages of text predicted for each label. You can choose a label to see more specific details, such as the **Correctly predicted** and **Incorrectly predicted** passages for the label.

The **Scoring** tab for multi-category text prediction models shows you a comparison of what the model predicted as the label versus what the actual label was.

In the **Model accuracy insights** section, you can see the **Most frequent category**, which tells you the category that the model predicted most frequently and how accurate those predictions were. If you model predicts a label of **Positive** correctly 99% of the time, then you can be fairly confident that your model is good at predicting positive sentiment in text.

The following screenshot shows the **Scoring** information for a multi-category text prediction model.

## Use advanced metrics in your analyses

The following section describes how to find and interpret the advanced metrics for your model in Amazon SageMaker Canvas.

### i Note

Advanced metrics are only currently available for numeric and categorical prediction models.

To find the **Advanced metrics** tab, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **My models**.
3. Choose the model that you built.
4. In the top navigation pane, choose the **Analyze** tab.
5. Within the **Analyze** tab, choose the **Advanced metrics** tab.

In the **Advanced metrics** tab, you can find the **Performance** tab. The page looks like the following screenshot.

The screenshot shows the Amazon SageMaker AI interface for a model named 'New model 2023-10-24 3:55 PM / Version 1'. The 'Analyze' tab is active, and the 'Advanced metrics' sub-tab is selected. The model status shows an accuracy of 98.507%. Below this, a table provides an overview of key metrics:

Metric	Value
Average f1	59.747%
Average accuracy	98.507%
Average precision	66.164%
Average recall	55.556%
Average AUC	Not available

The 'Performance' section is expanded to show a 'Metrics table' with the following data:

Metric name	Value
accuracy	0.9850746593203735
balancedAccuracy	0.5555555820465008
f1Macro	0.597468376159668
precisionMacro	0.661641538143158
recallMacro	0.5555555820465008
logLoss	0.8182187676429749
inferenceLatency	0.09214318543672562

At the bottom of the interface, a status bar indicates: 'canvas-sample-maintenance.csv', 'Total columns: 9', 'Total rows: 1,000', 'Total cells: 9,000', 'Failure Type', and '3+ category prediction'. A 'Predict' button is visible in the bottom right corner.

At the top, you can see an overview of the metrics scores, including the **Optimization metric**, which is the metric that you selected (or that Canvas selected by default) to optimize when building the model.

The following sections describe more detailed information for the **Performance** tab within the **Advanced metrics**.

## Performance

In the **Performance** tab, you'll see a **Metrics table**, along with visualizations that Canvas creates based on your model type. For categorical prediction models, Canvas provides a *confusion matrix*, whereas for numeric prediction models, Canvas provides you with *residuals* and *error density* charts.

In the **Metrics table**, you are provided with a full list of your model's scores for each advanced metric, which is more comprehensive than the scores overview at the top of the page. The metrics shown here depend on your model type. For a reference to help you understand and interpret each metric, see [Metrics reference](#).

To understand the visualizations that might appear based on your model type, see the following options:

- **Confusion matrix** – Canvas uses confusion matrices to help you visualize when a model makes predictions correctly. In a confusion matrix, your results are arranged to compare the predicted values against the actual values. The following example explains how a confusion matrix works for a 2 category prediction model that predicts positive and negative labels:
  - True positive – The model correctly predicted positive when the true label was positive.
  - True negative – The model correctly predicted negative when the true label was negative.
  - False positive – The model incorrectly predicted positive when the true label was negative.
  - False negative – The model incorrectly predicted negative when the true label was positive.
- **Precision recall curve** – The precision recall curve is a visualization of the model's precision score plotted against the model's recall score. Generally, a model that can make perfect predictions would have precision and recall scores that are both 1. The precision recall curve for a decently accurate model is fairly high in both precision and recall.
- **Residuals** – Residuals are the difference between the actual values and the values predicted by the model. A residuals chart plots the residuals against the corresponding values to visualize their distribution and any patterns or outliers. A normal distribution of residuals around zero indicates that the model is a good fit for the data. However, if the residuals are significantly skewed or have outliers, it may indicate that the model is overfitting the data or that there are other issues that need to be addressed.
- **Error density** – An error density plot is a representation of the distribution of errors made by a model. It shows the probability density of the errors at each point, helping you to identify any areas where the model may be overfitting or making systematic errors.

## View model candidates in the model leaderboard

When you do a [Standard build](#) for tabular and time series forecasting models in Amazon SageMaker Canvas, SageMaker AI trains multiple *model candidates* (different iterations of the model) and by default selects the one with the highest value for the optimization metric. For tabular models, Canvas builds up to 250 different model candidates using various algorithms and hyperparameter settings. For time series forecasting models, Canvas builds 7 different models—one for each of the [supported forecasting algorithms](#) and one ensemble model that averages the predictions of the other models to try to optimize accuracy.

The default model candidate is the only version that you can use in Canvas for actions like making predictions, registering to the model registry, or deploying to an endpoint. However, you might want to review all of the model candidates and select a different candidate to be the default

model. You can view all of the model candidates and more details about each candidate on the **Model leaderboard** in Canvas.

To view the **Model leaderboard**, do the following:

1. Open the SageMaker Canvas application.
2. In the left navigation pane, choose **My models**.
3. Choose the model that you built.
4. In the top navigation pane, choose the **Analyze** tab.
5. Within the **Analyze** tab, choose **Model leaderboard**.

The **Model leaderboard** page opens, which for tabular models looks like the following screenshot.

The screenshot displays the 'Model leaderboard' for a 'Housing\_price\_predictor' model in 'Version 1'. The interface includes a search bar and a table of model candidates. The table has the following data:

Model name	Accuracy	F1 Optimization	Precision	Recall
XGBoost_01 (Default model)	98.232%	83.245%	79.653%	75.568%
XGBoost_02	98.212%	84.122%	78.375%	75.113%
ExtraTrees_01	97.127%	83.125%	78.122%	75.265%
ExtraTrees_02	97.115%	86.924%	78.156%	74.319%
LinearLearner_01	96.398%	85.356%	78.339%	74.319%
LinearLearner_02	96.113%	82.412%	78.107%	74.106%
LinearLearner_05	95.365%	83.122%	77.226%	73.513%
XGBoost_123	95.092%	82.056%	76.165%	73.615%
XGBoost_58	94.469%	82.035%	75.592%	74.365%
ExtraTrees_98	94.122%	81.122%	75.135%	74.293%
ExtraTrees_109	93.824%	80.357%	75.287%	74.106%
ExtraTrees_122	93.812%	80.323%	76.273%	74.102%
ExtraTrees_109	93.785%	80.185%	77.532%	74.098%

For time series forecasting models, you see 7 models, which include one for each of the time series forecasting algorithms supported by Canvas and one ensemble model. For more information about the algorithms, see [Advanced time series forecasting model settings](#).

In the preceding screenshot, you can see that the first model candidate listed is marked as the **Default model**. This is the model candidate with which you can make predictions or deploy to endpoints.

To view more detailed metrics information about the model candidates to compare them, you can choose the **More options** icon

(  )  
and choose **View model details**.

### **Important**

Loading the model details for non-default model candidates may take a few minutes (typically less than 10 minutes), and SageMaker AI Hosting charges apply. For more information, see [SageMaker AI Pricing](#).

The model candidate opens in the **Analyze** tab, and the metrics shown are specific to that model candidate. When you're done reviewing the model candidate's metrics, you can go back or exit the view to return to the **Model leaderboard**.

If you'd like to set the **Default model** to a different candidate, you can choose the **More options** icon

(  )  
and choose **Change to the default model**. Changing the default model for a model trained using HPO mode might take several minutes.

### **Note**

If your model is already deployed in production, [registered to the model registry](#), or has [automations](#) set up, you must delete your deployment, model registration, or automations before changing the default model.

## Metrics reference

The following sections describe the metrics that are available in Amazon SageMaker Canvas for each model type.

## Metrics for numeric prediction

The following list defines the metrics for numeric prediction in SageMaker Canvas and gives you information about how you can use them.

- **InferenceLatency** – The approximate amount of time between making a request for a model prediction to receiving it from a real-time endpoint to which the model is deployed. This metric is measured in seconds and is only available for models built with the **Ensembling** mode.
- **MAE** – Mean absolute error. On average, the prediction for the target column is +/- {MAE} from the actual value.

Measures how different the predicted and actual values are when they're averaged over all values. MAE is commonly used in numeric prediction to understand model prediction error. If the predictions are linear, MAE represents the average distance from a predicted line to the actual value. MAE is defined as the sum of absolute errors divided by the number of observations. Values range from 0 to infinity, with smaller numbers indicating a better model fit to the data.

- **MAPE** – Mean absolute percent error. On average, the prediction for the target column is +/- {MAPE} % from the actual value.

MAPE is the mean of the absolute differences between the actual values and the predicted or estimated values, divided by the actual values and expressed as a percentage. A lower MAPE indicates better performance, as it means that the predicted or estimated values are closer to the actual values.

- **MSE** – Mean squared error, or the average of the squared differences between the predicted and actual values.

MSE values are always positive. The better a model is at predicting the actual values, the smaller the MSE value is.

- **R2** – The percentage of the difference in the target column that can be explained by the input column.

Quantifies how much a model can explain the variance of a dependent variable. Values range from one (1) to negative one (-1). Higher numbers indicate a higher fraction of explained variability. Values close to zero (0) indicate that very little of the dependent variable can be explained by the model. Negative values indicate a poor fit and that the model is outperformed by a constant function (or a horizontal line).

- **RMSE** – Root mean squared error, or the standard deviation of the errors.

Measures the square root of the squared difference between predicted and actual values, and is averaged over all values. It is used to understand model prediction error, and it's an important metric to indicate the presence of large model errors and outliers. Values range from zero (0) to infinity, with smaller numbers indicating a better model fit to the data. RMSE is dependent on scale, and should not be used to compare datasets of different types.

## Metrics for categorical prediction

This section defines the metrics for categorical prediction in SageMaker Canvas and gives you information about how you can use them.

The following is a list of available metrics for 2-category prediction:

- Accuracy – The percentage of correct predictions.

Or, the ratio of the number of correctly predicted items to the total number of predictions. Accuracy measures how close the predicted class values are to the actual values. Values for accuracy metrics vary between zero (0) and one (1). A value of 1 indicates perfect accuracy, and 0 indicates complete inaccuracy.

- AUC – A value between 0 and 1 that indicates how well your model is able to separate the categories in your dataset. A value of 1 indicates that it was able to separate the categories perfectly.
- BalancedAccuracy – Measures the ratio of accurate predictions to all predictions.

This ratio is calculated after normalizing true positives (TP) and true negatives (TN) by the total number of positive (P) and negative (N) values. It is defined as follows:  $0.5 * ((TP/P) + (TN/N))$ , with values ranging from 0 to 1. The balanced accuracy metric gives a better measure of accuracy when the number of positives or negatives differ greatly from each other in an imbalanced dataset, such as when only 1% of email is spam.

- F1 – A balanced measure of accuracy that takes class balance into account.

It is the harmonic mean of the precision and recall scores, defined as follows:  $F1 = 2 * (\text{precision} * \text{recall}) / (\text{precision} + \text{recall})$ . F1 scores vary between 0 and 1. A score of 1 indicates the best possible performance, and 0 indicates the worst.

- InferenceLatency – The approximate amount of time between making a request for a model prediction to receiving it from a real-time endpoint to which the model is deployed. This metric is measured in seconds and is only available for models built with the **Ensembling** mode.

- **LogLoss** – Log loss, also known as cross-entropy loss, is a metric used to evaluate the quality of the probability outputs, rather than the outputs themselves. Log loss is an important metric to indicate when a model makes incorrect predictions with high probabilities. Values range from 0 to infinity. A value of 0 represents a model that perfectly predicts the data.
- **Precision** – Of all the times that {category x} was predicted, the prediction was correct {precision}% of the time.

Precision measures how well an algorithm predicts the true positives (TP) out of all of the positives that it identifies. It is defined as follows:  $\text{Precision} = \text{TP} / (\text{TP} + \text{FP})$ , with values ranging from zero (0) to one (1). Precision is an important metric when the cost of a false positive is high. For example, the cost of a false positive is very high if an airplane safety system is falsely deemed safe to fly. A false positive (FP) reflects a positive prediction that is actually negative in the data.

- **Recall** – The model correctly predicted {recall}% to be {category x} when {target\_column} was actually {category x}.

Recall measures how well an algorithm correctly predicts all of the true positives (TP) in a dataset. A true positive is a positive prediction that is also an actual positive value in the data. Recall is defined as follows:  $\text{Recall} = \text{TP} / (\text{TP} + \text{FN})$ , with values ranging from 0 to 1. Higher scores reflect a better ability of the model to predict true positives (TP) in the data. Note that it is often insufficient to measure only recall, because predicting every output as a true positive yields a perfect recall score.

The following is a list of available metrics for 3+ category prediction:

- **Accuracy** – The percentage of correct predictions.

Or, the ratio of the number of correctly predicted items to the total number of predictions. Accuracy measures how close the predicted class values are to the actual values. Values for accuracy metrics vary between zero (0) and one (1). A value of 1 indicates perfect accuracy, and 0 indicates complete inaccuracy.

- **BalancedAccuracy** – Measures the ratio of accurate predictions to all predictions.

This ratio is calculated after normalizing true positives (TP) and true negatives (TN) by the total number of positive (P) and negative (N) values. It is defined as follows:  $0.5 * ((\text{TP} / \text{P}) + (\text{TN} / \text{N}))$ , with values ranging from 0 to 1. The balanced accuracy metric gives a better measure of accuracy

when the number of positives or negatives differ greatly from each other in an imbalanced dataset, such as when only 1% of email is spam.

- **F1macro** – The F1macro score applies F1 scoring by calculating the precision and recall, and then taking their harmonic mean to calculate the F1 score for each class. Then, the F1macro averages the individual scores to obtain the F1macro score. F1macro scores vary between 0 and 1. A score of 1 indicates the best possible performance, and 0 indicates the worst.
- **InferenceLatency** – The approximate amount of time between making a request for a model prediction to receiving it from a real-time endpoint to which the model is deployed. This metric is measured in seconds and is only available for models built with the **Ensemblingmode**.
- **LogLoss** – Log loss, also known as cross-entropy loss, is a metric used to evaluate the quality of the probability outputs, rather than the outputs themselves. Log loss is an important metric to indicate when a model makes incorrect predictions with high probabilities. Values range from 0 to infinity. A value of 0 represents a model that perfectly predicts the data.
- **PrecisionMacro** – Measures precision by calculating precision for each class and averaging scores to obtain precision for several classes. Scores range from zero (0) to one (1). Higher scores reflect the model's ability to predict true positives (TP) out of all of the positives that it identifies, averaged across multiple classes.
- **RecallMacro** – Measures recall by calculating recall for each class and averaging scores to obtain recall for several classes. Scores range from 0 to 1. Higher scores reflect the model's ability to predict true positives (TP) in a dataset, whereas a true positive reflects a positive prediction that is also an actual positive value in the data. It is often insufficient to measure only recall, because predicting every output as a true positive will yield a perfect recall score.

Note that for 3+ category prediction, you also receive the average F1, Accuracy, Precision, and Recall metrics. The scores for these metrics are just the metric scores averaged for all categories.

### Metrics for image and text prediction

The following is a list of available metrics for image prediction and text prediction.

- **Accuracy** – The percentage of correct predictions.

Or, the ratio of the number of correctly predicted items to the total number of predictions. Accuracy measures how close the predicted class values are to the actual values. Values for accuracy metrics vary between zero (0) and one (1). A value of 1 indicates perfect accuracy, and 0 indicates complete inaccuracy.

- **F1** – A balanced measure of accuracy that takes class balance into account.

It is the harmonic mean of the precision and recall scores, defined as follows:  $F1 = 2 * (\text{precision} * \text{recall}) / (\text{precision} + \text{recall})$ . F1 scores vary between 0 and 1. A score of 1 indicates the best possible performance, and 0 indicates the worst.

- Precision – Of all the times that {category x} was predicted, the prediction was correct {precision}% of the time.

Precision measures how well an algorithm predicts the true positives (TP) out of all of the positives that it identifies. It is defined as follows:  $\text{Precision} = TP / (TP + FP)$ , with values ranging from zero (0) to one (1). Precision is an important metric when the cost of a false positive is high. For example, the cost of a false positive is very high if an airplane safety system is falsely deemed safe to fly. A false positive (FP) reflects a positive prediction that is actually negative in the data.

- Recall – The model correctly predicted {recall}% to be {category x} when {target\_column} was actually {category x}.

Recall measures how well an algorithm correctly predicts all of the true positives (TP) in a dataset. A true positive is a positive prediction that is also an actual positive value in the data. Recall is defined as follows:  $\text{Recall} = TP / (TP + FN)$ , with values ranging from 0 to 1. Higher scores reflect a better ability of the model to predict true positives (TP) in the data. Note that it is often insufficient to measure only recall, because predicting every output as a true positive yields a perfect recall score.
