

Conditional VAE in Healthcare

Author: Sara Zoccheddu

Supervisor(s): Nicola Serra, Olivia Jullian Parra

Summary

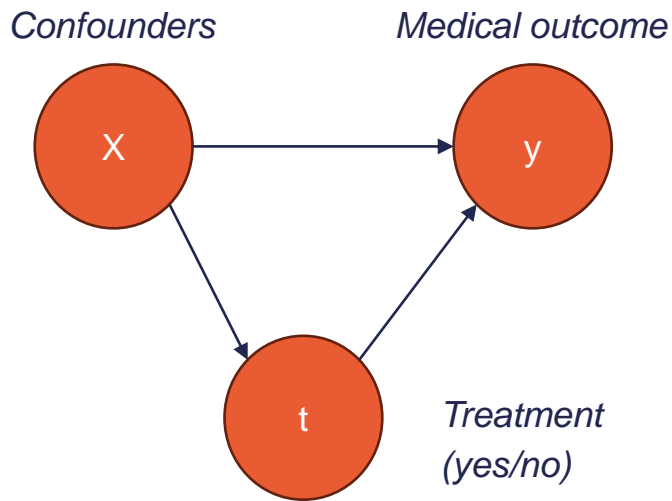

- General context: Machine Learning for Causal Inference in Multimorbidity
- Conditional Variational Autoencoder
- Task: Reconstruction of two gaussian distributions using CVAE
- Conditional VAE applied to the IST dataset
- Results

Machine Learning for Causal Inference in Multimorbidity

Multimorbidity: coexistence of two or more chronic conditions in the same individual

Conceptual model

- **X:** patient's personal information (age, BMI, blood pressure, other previous treatments, etc...)
- **t:** if the treatment (i.e., aspirin) was taken or not
- **y:** outcome (i.e., dead, not recovered, recovered...)

We cannot ignore the link between X and t: patient's confounders affect the treatment.

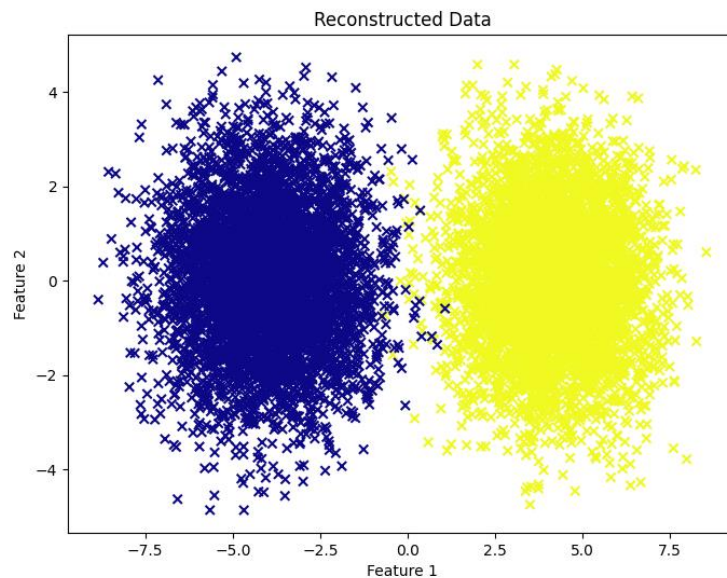

Conditional Variational Autoencoder (CVAE)

- A **variational autoencoder** (VAE) is a **generative model**: it should be able to generate fake samples that look like original samples from our data.
- Data is passed to the **encoder**.
- The encoder returns a **probability distribution** in the latent space.
- One point is sampled from the distribution and it is passed to the **decoder**.
- In a **Conditional VAE**, also **labels** are passed both to the encoder and the decoder.

Task: Reconstruction of two gaussian distributions using CVAE

Goal: Learn how to hard-code a CVAE and apply it to a bidimensional dataset.

Conditional VAE applied to the IST dataset

- The International Stroke Trial (IST) was conducted between 1991 and 1996.
- RCT (Randomized Controlled Trial): very low bias.
- **Goal:** understand whether early administration of aspirin, heparin, both or neither influenced the clinical course of acute ischemic stroke.
- **Idea:** apply the previous CVAE model to the IST dataset and see whether results are consistent with the ones obtained with the RCT.

“The International Stroke Trial database” - Peter AG Sandercock, Maciej Niewada, Anna Członkowska and for the International Stroke Trial Collaborative Group

Conditional VAE applied to the IST dataset

Step 1: Reconstruct the original data with the CVAE model

Step 2: Study the effect of administration of Heparin

Conditional VAE applied to the IST dataset

Step 2: Study the effect of administration of Heparin

- **ITE** (Individual Treatment Effect):
 - Difference between probability of dying or not recovering by taking Heparin or not taking Heparin
 - If $ITE > 0$: Treatment is **harmful**
 - If $ITE < 0$: Treatment is **beneficial**
- Conclusion: The effect of Heparin is meaningless on a large scale.

Comparison of results between RCT and CVAE

- The original data was well reconstructed by the CVAE model.
- The analysis of data from the RCT and the analysis of data generated by the CVAE gave similar results.

Why would you use a CVAE instead of a RCT in Healthcare?

- To have good results in RCT you would need a huge number of patients, therefore RCTs are not always feasible.
- CVAE allows to generate new data.
- CVAE allows to model causality taking into consideration all the variables representing a patient.
- Useful for studying multimorbidity and cases in which more than one treatment is involved.

Thank you!
