## Global Wealth Databook 2018

Thought leadership from Credit Suisse Research and the world's foremost experts

# Preface

Since 2010, the Credit Suisse Research Institute's Global Wealth Report has been the leading reference on global household wealth. It contains the most comprehensive and up-to-date findings on global wealth across the entire wealth spectrum – from the very base of the "wealth pyramid," capturing 3.2 billion adults with wealth below USD 10,000 to those at the apex of the wealth pyramid with USD 1 million or more who comprise less than 1% of the adult population, but own 45% of household wealth. During the 12 months to mid-2018, aggregate global wealth rose by USD 14.0 trillion (4.6%) to a total of USD 317 trillion, outpacing population growth. Wealth per adult grew by 3.2%, raising global mean wealth to a record high of USD 63,100 per adult.

While the Global Wealth Report highlights the main features of global wealth holdings in recent years, the Credit Suisse Research Institute's Global Wealth Databook provides a great deal more detail. It presents a considerable quantity of additional data on the level and distribution of household wealth across countries, as well as describing the data sources used in the project and the methodology used to obtain the published results. This level of detail sets it apart from other reports in this field.

Research for the Global Wealth Report and Global Wealth Databook has been undertaken on behalf of the Credit Suisse Research Institute by Professors Anthony Shorrocks and Jim Davies, recognized authorities on this topic, assisted by Dr. Rodrigo Lluberas. The Credit Suisse Research Institute is Credit Suisse's in-house think tank. The Institute was established in the aftermath of the 2008 financial crisis with the objective of studying long-term economic developments, which have – or promise to have – a global impact within and beyond the financial services industry.

The Global Wealth Databook provides estimates for the level and distribution of wealth for over 200 countries for the period 2000 to mid-2018. It covers the evolution of household wealth at both the regional and country levels. This year's Databook also presents findings on female wealth holdings, in particular on gender differences with males. Women nowadays account for an estimated 40% of global wealth overall, with most of the rise in their share of wealth having occurred in the 20th century.

# 1. Estimating the pattern of global household wealth

## 1.1 Introduction

We provide estimates of the wealth holdings of households around the world for each year since 2000. More specifically, we are interested in the distribution within and across nations of individual net worth, defined as the marketable value of financial assets plus non-financial assets (principally housing and land) less debts. No country in the world has a single comprehensive source of information on personal wealth, and many low- and middle-income countries have little direct evidence of any kind. However, a growing number of countries – including China and India as well many high-income countries – have relevant data from a variety of different sources which we are able to exploit in order to achieve our objective.

The procedure involves three main steps, the first two of which follow the structure first set out in Davies et al. (2008, 2011). (See also Davies et al., 2017.) The first step establishes the average level of wealth for each country. The best source of data for this purpose is household balance sheet (HBS) data, which are now provided by 49 countries, although 25 of these countries cover only financial assets and debts. For an additional three countries wealth levels can be calculated from household survey data. Together these countries cover 65% of the global population and 96% of total global wealth. The results are supplemented by econometric techniques, which generate estimates of the level of wealth in countries that lack direct information for one or more years.

The second step involves constructing the pattern of wealth holdings within nations. We use direct data on the distribution of wealth for 35 countries. Inspection of data for these countries suggests a relationship between wealth distribution and income distribution, which can be exploited in order to provide a rough estimate of wealth distribution for 133 other countries, which have data on income distribution but not on wealth ownership.

It is well known that the traditional sources of wealth distribution data are unlikely to provide an accurate picture of wealth ownership in the top tail of the distribution for most countries. To overcome this deficiency, the third step makes use of the information in the Forbes world list of billionaires to adjust the wealth distribution pattern in the highest wealth ranges.

Implementing these procedures leaves 37 countries for which it is difficult to estimate either the level of household wealth or the distribution of wealth, or both. Usually the countries concerned are small (e.g. Andorra, Bermuda, Guatemala, Monaco) or semi-detached from the global economy (e.g. Cuba, Somalia, North Korea). For our estimates of the pattern of global wealth, we assign these countries the average level and distribution of the region and income class to which they belong. This is done in preference to omitting the countries altogether, which would implicitly assume that their pattern of wealth holdings matches the world average. However, checks indicate that excluding these nations from the global picture would make little difference to the results.

Table 2-1 lists the 213 countries in the world along with some summary details. Note that China and India are treated as separate regions due to the size of their populations.

The following sections describe the estimation procedures in more detail. Two other general points should be mentioned at the outset. First, we use official exchange rates throughout to convert currencies to our standard measure of value, which is US dollars at the time in question. In international comparisons of consumption or income it is common to convert currencies using purchasing power parity (PPP) exchange rates, which take account of local prices, especially for non-traded services. However, in all countries a large share of personal wealth is owned by households in the top few percentiles of the distribution, who tend to be internationally mobile

and to move their assets across borders with significant frequency. For such people, the prevailing foreign currency rate is most relevant for international comparisons. So, there is a stronger case for using official exchange rates in studies of global wealth.

The second issue concerns the appropriate unit of analysis. A case can be made for basing the analysis on households or families. However, personal assets and debts are typically owned (or owed) by named individuals, and may be retained by those individuals if they leave the family. Furthermore, even though some household assets, such as housing, provide communal benefits, in households that include members other than a single individual or married couple, it is unusual for members to have an equal say in the management of assets, or to share equally in the proceeds if the asset is sold. Membership of households can be quite fluid (for example, with respect to older children living away from home) and the pattern of household structure varies markedly across countries. For all these reasons – plus the practical consideration that the number of households is unknown in most countries – we prefer to base our analysis on individuals rather than household or family units. More specifically, since children have little formal or actual wealth ownership, we focus on wealth ownership by adults, defined to be individuals aged 20 or above.

## 1.2 Household balance sheet data

The most reliable source of information on household wealth is household balance sheet (HBS) data. As shown in Table 1-1, “complete” financial and non-financial balance sheet data are available for 24 countries for at least one year. These are predominantly high-income countries, the exceptions being Mexico and South Africa, which fall within the upper middle income category according to the World Bank. The data are described as complete if financial assets, liabilities and non-financial assets are all adequately covered. Another 25 countries have financial balance sheets, but no details of real assets. This group contains nine upper middle income countries and six lower middle income countries, and hence is less biased towards the rich world than the group with complete household balance sheets. The sources of these data are recorded in Table 1-2.

Europe and North America, and OECD countries in particular, are well represented among countries with HBS data, and China joins this group this year. There has been considerable discussion of the household balance sheet in China of late. Li (2017) surveys the series that have been developed by different researchers. Piketty et al. (2017, 2018) provide the most comprehensive data and also the longest times series, so we use their estimates here. Li (2017) shows that his own independent estimates, which are for 2004–14 only, are similar to those of Piketty et al., (2017) if farmland is omitted from the latter. This provides support for the accuracy of the Piketty et al. estimates, but also a reason to prefer them in addition to the greater length of their time series, since farmland is a key household asset in rural China. Piketty et al. estimate the value of this land carefully, taking into account its increasingly private character over time.

HBS coverage is sparse in Africa, Asia and Latin America. Fortunately, survey evidence on wealth is available for the two largest developing countries without HBS data – India and Indonesia – which compensates to some extent for this deficiency. Although only financial HBS data are available for Russia, complete HBS data are available for the Czech Republic and financial data are recorded for nine other former socialist countries in Europe.

## 1.3 Household survey data

Information on assets and debts is collected in nationally representative surveys undertaken in an increasing number of countries (see Table 1-3 for our current list and sources). For three countries this is the only data we have, and we use it to estimate wealth levels (with a correction for financial assets explained in the next section) as well as distributions. Data on wealth obtained from household surveys vary in quality, due to the sampling and non-sampling problems faced by all sample surveys. The high skewness of wealth distributions makes sampling error important. Non-sampling error is also a problem due to differential response

rates – above some level wealthier households are less likely to participate – and under-reporting, especially of financial assets. Both of these problems make it difficult to obtain an accurate picture of the upper tail of the wealth distribution. To compensate, wealthier households are over-sampled in an increasing number of surveys, such as the US Survey of Consumer Finances and similar surveys in Canada, Germany, Spain, and several other EU countries. Over-sampling at the upper end is not routinely adopted by the developing countries which include asset information in their household surveys, but the reported response rates are much higher than in developed countries, and the sample sizes are large.

The US Survey of Consumer Finance is sufficiently well designed to capture most household wealth, but this is atypical. In particular, surveys usually yield lower totals for financial assets compared with HBS data. However, surveys generally do remarkably well for owner-occupied housing, which is the main component of non-financial assets (see Davies and Shorrocks, 2000, p. 630). Our methodology recognizes the general under-reporting of financial assets in surveys and attempts to correct this deficiency.

Other features of the survey evidence from developing countries capture important differences. Very high shares of non-financial wealth are found for India and Indonesia, reflecting both the importance of land and agricultural assets and the relative lack of access of the rural population to financial services. On the other hand, the share of non-financial assets in China is not much greater than in most high-income countries, in part because urban land is not privately owned. In addition, there has been rapid accumulation of financial assets by Chinese households for many years now. On average, debts are low in India and Indonesia, although debt problems of the poor are of course a concern in those countries.

For countries which have both HBS and survey data, we give priority to the HBS figures. The HBS estimates typically use a country's wealth survey results as one input, but also take account of other sources of information and should therefore dominate wealth survey estimates in quality. However, this does not ensure that HBS data are error-free.

## 1.4 Estimating the level and composition of wealth for other countries

For countries lacking direct data on wealth, we use standard econometric techniques to estimate per capita wealth levels from the 52 countries with HBS or survey data in at least one year. Data availability limits the number of countries that can be included in this procedure. However, we are able to employ a theoretically attractive model that yields observed or estimated wealth values for 176 countries, which collectively cover 97% of the world's population in 2018. There is a trade-off here between coverage and reliability. Alternative sets of explanatory variables could achieve greater country coverage, but not without compromising the quality of the regression estimates.

Separate regressions are run for financial assets, non-financial assets and liabilities. As errors in the three equations are likely to be correlated, the seemingly unrelated regressions (SUR) technique due to Zellner (1962) is applied, but only to financial assets and liabilities, since there are fewer observations for non-financial assets. The independent variables selected are as listed in Davies et al (2017). In particular, we include a dummy for cases where the data source is a survey rather than HBS data. This turns out to be negative and highly significant in the financial assets regression, indicating that the average level of financial assets tends to be much lower when the data derive from sample surveys. We use this result to adjust upwards the value of financial assets in the wealth level estimates for India, Indonesia, and Uruguay. We also include region-income dummies to capture any common fixed effects at the region-income level, and year dummies to control for shocks – like the recent financial crisis – or time trends that affect the world as a whole.

The resulting estimates of net worth per adult and the three components are reported in Table 2-4 for the years 2000 to 2018. HBS data are used where available (see Table 1-1); adjusted survey means are used for India, Indonesia, and Uruguay in specific years. Financial assets and liabilities are estimated for 119 countries, and non-financial assets for 143 countries in at least one year using the regressions described above.

There remain 37 countries containing 3% of the global adult population without an estimate of wealth per adult. In order to generate wealth figures for regions and for the world as a whole, we assigned to each of these countries the mean wealth per adult of the corresponding region (six categories) and income class (four categories). This imputation is admittedly crude, but better than simply disregarding the excluded countries, which would implicitly assume (incorrectly) that the countries concerned are representative of their region or the world.

For a few countries, including the United States, wealth levels are available for the most recent years, including the first quarter of 2018. In order to obtain estimates of net worth per adult and its components we update the most recent available figures using, where available, house price growth for non-financial assets, market capitalization for financial assets and GDP per capita growth for debts (see Table 1-4). Our projections are based on estimated relationships between these variables and the corresponding asset/debt totals in preceding years, rather than on proportionality. For countries without information on house prices and market capitalization, recent growth of GDP per capita is used to project net worth per adult forwards to mid-2018.

## 1.5 Wealth distribution within countries

An analysis of the global pattern of wealth holdings by individuals requires information on the distribution of wealth within countries. Direct observations on wealth distribution across households or individuals are available for 35 countries. The number of survey years we have varies across countries. Summary details are reported in Table 1-5 using a common template, which gives the shares of the top 10%, 5%, 1%, together with other distributional information in the form of cumulated shares of wealth (i.e. Lorenz curve ordinates).

The distributional data have certain fairly standard features. The unit of analysis is usually a household or family, but is in a few cases the (adult) individual. Household sample surveys are employed in almost all countries. The exceptions are the Nordic countries (Denmark, Finland, Norway and Sweden), which use data from tax and other registers covering the entire population. For all other countries, the wealth shares of the top groups are expected to be understated because wealthy households are less likely to respond, and because the financial assets that are of greater importance to the wealthy – for example, equities and bonds – are especially likely to be under-reported. Even in the U.S. Survey of Consumer Finance, where sophisticated measures are taken to counteract these problems, the sampling frame excludes the “Forbes 400” richest families, so that the extreme upper tail is not captured, by design. And in those countries using register data there can be difficulties due to valuation problems, for example in connection with pension assets and life insurance.

The summary details reported in Table 1-5 show a great deal of distributional information, but there are some empty cells. Estimates for the empty cells were generated by a revised version of the Shorrocks-Wan ungrouping program, which constructs a synthetic sample conforming exactly to any set of Lorenz values derived from a positive variable (Shorrocks and Wan, 2009). Where countries have some wealth distribution data, Lorenz curves for missing years are estimated by interpolation or by projection forwards or backwards.

For most countries lacking direct wealth distribution data, the pattern of wealth distribution was constructed from information on income distribution, based on the view that wealth inequality is likely to be highly correlated with income inequality across countries. Income distribution data was derived from the World Income Inequality Database, and the ungrouping program was used to generate all the Lorenz curve values required for the same template applied to wealth distribution.

For the 35 countries which have data on both wealth and income distribution, the Lorenz curves for wealth are everywhere lower than for income, indicating that wealth is more unequally distributed than income. We calculate the Gini coefficient values for both income and wealth and then estimate the missing Lorenz curves for wealth by scaling down the Lorenz curves for income by the median ratio of income to wealth Ginis.

To generate regional and global wealth patterns, to each country lacking income distribution data we assign the average (adult population weighted) wealth distribution pattern for the corresponding region and income class. This again was done in preference to simply disregarding the countries concerned.

## 1.6 Assembling the global distribution of wealth

To construct the global distribution of wealth, the level of wealth for each country was combined with details of its wealth pattern. Specifically, the ungrouping program was applied to each country to generate a set of synthetic sample values and sample weights consistent with the (estimated or imputed) wealth distribution, with the sample weights representing approximately 10,000 adults in the bottom 90% of the distribution, 1,000 adults in the top decile, and 100 adults in the top percentile. The wealth sample values were then scaled up to match the mean wealth of the respective country, and merged into a single world dataset comprising between 1.1 million and 1.4 million observations for each year. The complete global sample may be processed in a variety of ways, for example to obtain the minimum wealth and the wealth share of each percentile in the global distribution of wealth. The distribution within regions may also be calculated, along with the number of representatives of each country in any given global wealth percentile.

## 1.7 Adjusting the upper wealth tail

The survey data from which most of our wealth distribution estimates are derived tend to under-represent the wealthiest groups and to omit ultra-high net worth individuals. This deficiency does not affect our estimates of average wealth levels around the world, since these are determined by other methods. It does imply that the shares of the top percentile and top decile are likely to err on the low side unless adjustments are made to the upper tail. We would also not expect to generate accurate predictions of the number and value of holdings of high net worth individuals.

We tackle this problem by exploiting well-known statistical regularities in the top wealth tail and by making use of information on the wealth holdings of named individuals revealed in the rich list data reported by Forbes magazine and other publications. As described in more detail in Section 3, we use the number of billionaires reported by Forbes to fit a Pareto distribution to the upper tail of 56 countries. The revised top tail values in the synthetic sample were then replaced by the new estimates, and the resulting sample for each country was re-scaled to match the mean wealth value. This sequence was repeated until the process converged, typically after a few rounds. The overall global weighted sample still contains between 1.1 and 1.3 million observations, typically representing about 100, 1,000 or 10,000 adults. The adjusted sample can be used to produce improved estimates of the true wealth pattern within countries, regions and the world. The minimum sample size of 100 allows reliable estimates of the number and value of wealth holdings up to USD 100 million at the regional and global level. Estimates above USD 100 million are obtained by projecting the Pareto distribution forward.

## 1.8 Concluding remarks

While the study of global household wealth is still at an early stage, enormous progress has been achieved in recent years. Data on the level of wealth are improving in quality and are available for more countries. New household wealth surveys have begun in many countries, including a sizeable number within the Eurozone orchestrated by the ECB. More needs to be done to improve the quality and frequency of wealth data, and to make the data available for a greater number of countries. In the meantime, we will continue to try to fill the gaps in the estimates of wealth level by country and to improve the estimates of wealth distribution within countries. In future, some revisions to our estimates are inevitable. Nevertheless, we are confident that the broad trends revealed in the Credit Suisse Global Wealth Report for 2018 will remain substantially intact.

## 2. Household wealth levels, 2000–18

### 2.1 Introduction

As explained in the previous chapter, we aim to determine the level and distribution of household wealth across the world. The first stage in this process is to estimate the average level of household wealth and its core components for every country and every year since 2000.

Table 2-1 identifies 211 countries in 2018 and reports some core variables, including the classification by region, by income class according to the World Bank, and our assessment of the quality of wealth data. Population figures are available for all countries and years and are reported in Table 2-2. Figures for the number of adults, i.e. individuals aged 20 or above, are also available for most countries and years. Where the data are not reported elsewhere, we estimate the number of adults by assuming that the adult ratio is the (population weighted) average for the corresponding region and income class. The results are summarized in Table 2-3.

The procedure outlined in Chapter 1 describes the three ways in which wealth levels data are assembled: direct estimates via national household balance sheets (HBS) or household surveys; regression estimates using likely correlated variables; and imputations based on the region-income class average. In practice, the situation is slightly more complicated because some countries have direct observations for, say, financial wealth, but require non-financial wealth to be estimated. The timeliness of direct data is greatly improved nowadays. For financial wealth and debts at least, direct estimates for the first quarter of 2018 were available for 38 countries: Australia, Austria, Belgium, Bulgaria, Canada, Chile, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Italy, Japan, Korea, Latvia, Lithuania, Luxembourg, Malta, Netherlands, New Zealand, Norway, Poland, Portugal, Romania, Russia, Singapore, Slovakia, Slovenia, Spain, Sweden, Turkey, the United Kingdom and the United States. These countries account for 72% of global wealth in 2018. In contrast, regression-based estimates are impossible for many countries in recent years because data is missing on core regressors. In these situations, wealth estimates are obtained by taking the figure for the most recent year and updating using subsequent movements in stock market capitalization, house price indices, or – if nothing better is available – growth of GDP.

In Table 2-1, we do our best to summarize the quality of wealth data for each country on a five-point scale. A country gets five points, and a good rating if it has complete HBS data, and either wealth distribution data or a good basis for estimating the shape of the wealth distribution. A satisfactory rating and four points go to countries that would get a good rating except that their HBS data does not cover non-financial assets. These countries must have a full set of independent variables allowing regression-based estimates of non-financial assets. Countries without any HBS data but with a household wealth survey or other wealth distribution data (from estate tax or wealth tax sources) get a fair rating and three points. A poor rating (two points) goes to countries without HBS or wealth distribution data, but having a full set of independent variables allowing estimation of their wealth levels based on our cross-country regressions. If some independent variables are missing but the regression-based estimates can still be made, the rating is very poor (one point).

In Table 2-1, there are 37 countries for which wealth data quality is not assessed. These are the countries for which we have no sensible basis for estimating wealth. In calculating the regional and global wealth figures, we assign these countries the region-income class average; but the separate country data are not reported in the later tables.

## 2.2 Household wealth levels 2000–18

Table 2-4 summarizes information on household wealth this century for 174 countries, seven regions (including China and India), and the world as a whole. The data refer to end-year values during the period 2000–16 and to mid-year values for 2017 and 2018.

Most of the column content is self-explanatory. The last column indicates the estimation method used for the wealth levels, grouped into five categories. Most figures up to 2008 are labeled as either (1) “Original data,” indicating data from official household balance sheets or (2) “Regression,” referring to estimated values based on wealth regressions. Two additional labels are reported for recent years where needed. “Original update” and “Regression update” mean original data (respectively, regression estimates) updated using market capitalization growth for financial assets, house prices for non-financial assets and GDP per capita growth for debts. The updating relies on country-specific estimates of the elasticity of each wealth component with respect to the indicated variable. For countries lacking information on house prices or market capitalization, GDP per capita growth was used to project net worth per adult forward to the years 2016–18.

Wealth estimates for recent years are subject to future revision as statistical agencies release more data. Wealth estimates for earlier periods should be less prone to change. As a rough guide, we expect that our wealth estimates prior to 2010 are not likely to change much in the future. However, statistical agencies occasionally make significant revisions to their historical data series – reflecting altered definitions of categories, or improved valuations, for example. When this happens, we are obliged to respect the new figures, and this can have repercussions for the wealth estimates of other countries, given the methods we employ. This year revisions to original data, especially for China and Spain, have led us to revise wealth per adult upwards in a number of countries. In addition, our methods are constantly being refined in response to new developments at the frontier of research, which can also affect the historical data, although mainly for countries with little hard evidence on wealth and hence more reliant on the methods used to derive our estimates.

## 2.3 Wealth trends 2000–18

From the data reported for individual years, time series can be assembled for a number of important wealth variables. Table 2-5 provides examples for the world and for each region. They show that wealth per adult has grown from USD 31,381 to 63,100 over the period 2000–18, an average growth rate of 4.1% per annum. Most of this growth occurred before the financial crisis. In the period since 2007 average wealth has stagnated in the world outside China and North America, although this is due in part to appreciation of the USD.

Table 2-5 provides similar details regarding the relative importance over time of the three main subcomponents of household wealth: financial assets, non-financial assets (principally housing and land) and debts. At the turn of the century, financial assets accounted for 56% of gross household assets. This share fell until 2008, when it briefly touched 50%. In the aftermath of the global financial crisis, non-financial assets showed little growth worldwide, in contrast to financial wealth, which grew robustly. As a consequence, the share of financial wealth recovered to 54% by 2015, almost the same division of the portfolio as in 2000. But non-financial assets have done relatively well since 2015, causing the share of financial assets to slip back to 52.5%. Expressed as a proportion of gross household wealth, debt has moved in a similar way to non-financial assets, and within a relatively narrow range. Globally, household debt rose from 14% of gross wealth in 2000 to 15% in 2008, and has since declined to 13%, below the level at the start of the century.

Finally, Table 2-7 extracts information on changes in household wealth in the 12 months to mid-2018. The United States continued its remarkable unbroken spell since the financial crisis with a gain of USD 6.3 trillion, while second place China gained USD 2.3 trillion. On the downside, Brazil was the biggest loser, shedding USD 378 billion due in large part to currency depreciation against the US dollar.

Country	Region	Income Group	GDP per adult	Wealth per adult	Wealth per adult	Total wealth	Share of world wealth	Wealth data quality

## 3. Estimating the distribution of global wealth

### 3.1 Comparison with data from rich lists

Our method of estimating global personal wealth is essentially a bottom-up approach. It begins by establishing the average level of wealth in different countries onto which we graft the pattern of wealth holding derived from household surveys and other sources. Although sample surveys do not formally exclude high net worth (HNW) individuals with net assets above USD 1 million, they tend to be under-represented, and their wealth holdings are likely to be undervalued. The same is true to a greater extent of ultra-high net worth (UHNW) individuals with net assets above USD 50 million. In fact, the US Survey of Consumer Finances – which otherwise does an excellent job in the upper tail of wealth distribution – explicitly omits the 400 wealthiest families from its sampling frame. Evidence suggests that other countries capture an even smaller fraction of individuals in high wealth categories. So further analysis and appropriate adjustments are required in order to construct plausible estimates of the number of wealthy individuals and the size of their holdings.

In order to proceed, we exploit the fact that the top tail of wealth distribution is usually well approximated by the Pareto distribution, which produces a straight-line graph when the logarithm of the number of persons above wealth level  $w$  is plotted against the logarithm of  $w$ . Our data yield a close fit to the Pareto distribution in the wealth range from USD 250,000 to USD 5 million. Above USD 5 million the relationship begins to break down, and the correspondence weakens further above USD 50 million, as expected given the limitations of the data sources. However, it still seems reasonable to use a fitted Pareto line to estimate the number of individuals in the highest echelons of the wealth distribution.

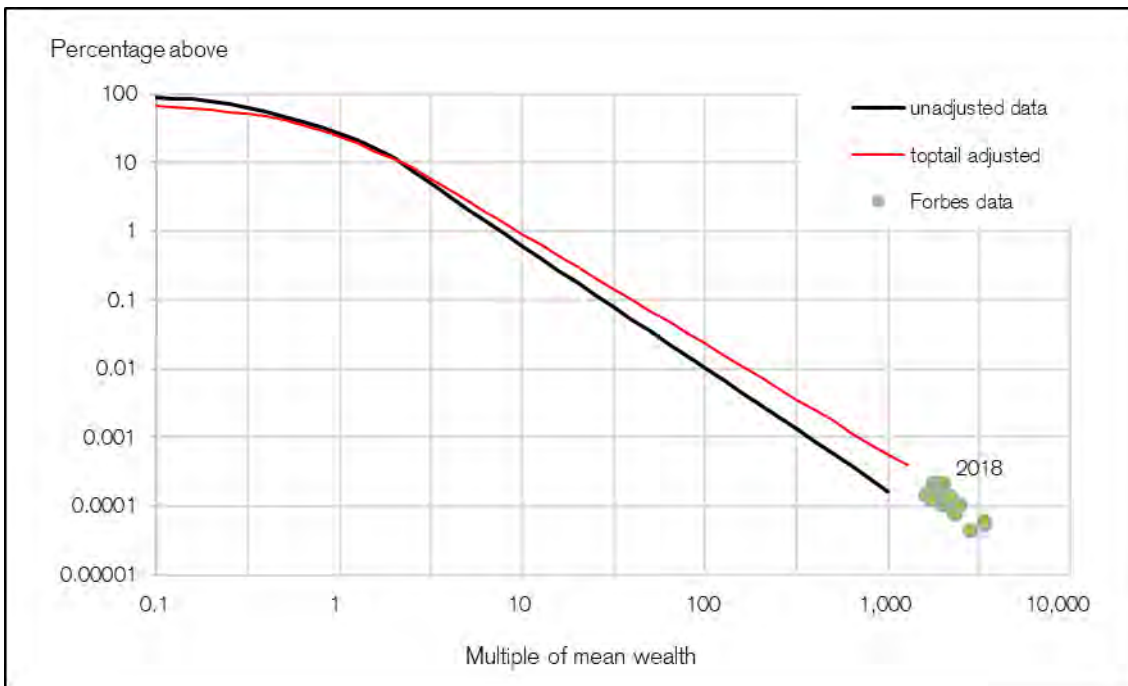

To determine the precise features of the top wealth tail, we rely heavily on the rich list data provided by Forbes and other sources. We make particular use of the number of billionaires reported by Forbes, since the data are available for many years and are broadly comparable across countries. We recognize that rich list data have limitations. The valuations of individual wealth holdings are dominated by financial assets, especially equity holdings in public companies traded in international markets. For practical reasons, less attention is given to non-financial assets apart from major real estate holdings and trophy assets, such as expensive yachts. Even less is known – and hence recorded – about personal debts. Some people cooperate enthusiastically with those compiling the lists; others jealously guard their privacy. There are also different country listings for nationals and residents, which is especially evident for India, for instance. The true legal ownership within families – as opposed to nominal ownership or control – adds further complications. Assigning the wealth recorded for Bill Gates, for example, to all family members might well result in several billionaire holdings, so the number of billionaires would increase in this instance. In other cases, reassigning the family wealth would reduce all the individual holdings below the billionaire threshold. For all these reasons, rich list data should be treated with caution. At the same time, the broad patterns and trends are informative, and they provide the best available source of information at the apex of global wealth distribution.

### 3.2 Adjusting the wealth pattern in the top tail

To mitigate some of the problems associated with small numbers of billionaires, we disregard countries that have recorded small numbers of billionaires in the Forbes list over the years. About 50 countries survive the cut. A further level of refinement involves converting the number of Forbes billionaires – which we assume refers to billionaire families – into the corresponding number of high wealth adults.

A small modification is made to the way that the Pareto curve is presented. The logarithm of the *fraction* of adults above a given wealth level  $w$  is plotted on the vertical axis, while the horizontal axis denotes wealth  $w$  expressed as a *multiple of mean wealth*, again on a logarithmic scale. This reformulation of the Pareto curve retains the core characteristic: a Pareto distribution still generates a straight-line, but the reformulation now has the advantage that the graph remains invariant if either the wealth sample weights or the wealth values are scaled up or down by the same factor, as might happen if the adult population rises or average wealth is growing. Any change in the reformulated graph for the unadjusted wealth sample, like that portrayed in Figure 1 based on United Kingdom data, must therefore indicate a change in the relative distribution of wealth, as represented by the Lorenz curve. In practice, the relative distribution of wealth tends to change slowly, so the graph is unlikely to change much from year to year, at least for wealth levels up to, say, ten times the mean.

**Figure 1: Fitted Pareto distribution to wealth top tail**

A Forbes data point for a single year can be constructed by computing the number of billionaires expressed as a percentage of the adult population (y-axis) and the minimum wealth of these billionaires (typically USD 1 billion exactly) expressed as a multiple of mean wealth (x-axis). Over time mean wealth and the number of billionaires both tend to increase, so the Forbes data points (the green dots in Figure 1) typically move towards the left and upwards.

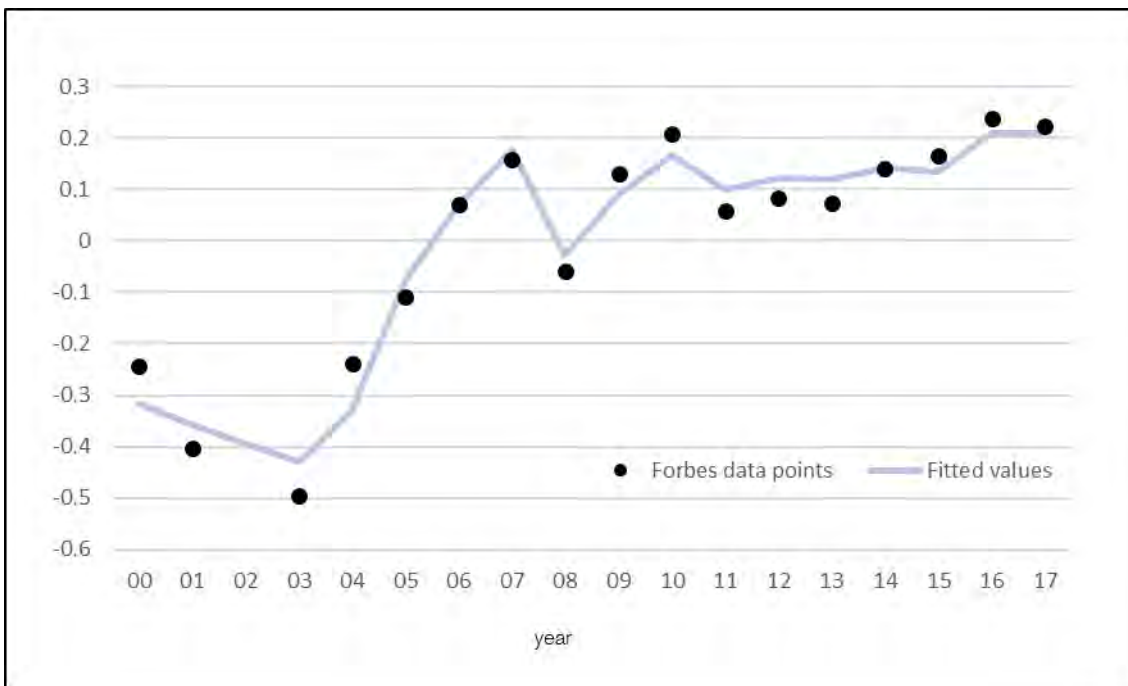

For any given year, our top-tail adjustment involves grafting onto the unadjusted curve a straight-line segment which is consistent with the Forbes observation, as captured by the red line in Figure 1. The unadjusted wealth sample values are then replaced by the fitted values in the top tail. However, this causes the sample mean to change, usually upwards. So the sample values must be scaled in order to restore consistency with the known and fixed value of mean wealth, and the procedure repeated until the process converges, which typically happens in a few rounds.

The greatest drawback with the Forbes data is the small sample size for many countries in many years. This impacts on the reliability of the top-tail adjustments and especially on the trends in inequality over time. To help mitigate this problem and increase confidence in the inequality trends, for any given country we combine the Forbes observations over years and try to smooth out the year-on-year variation. Specifically, we construct a reference top tail adjusted curve (like an extended version of the red line in Figure 1) and determine the deviation of each Forbes data point from this reference line. These deviations would be small if inequality changes little over the whole period – mainly just the result of sampling variability. But the evidence suggests that

changes over time are often significant and systematic. We attempt to identify the factors at work by regressing the deviations against the share of financial assets in total wealth and a time trend, with a possible structural break in 2007.

Figure 2 displays the outcome of this exercise for China. The fitted values are reassuringly close to the observations, suggesting that the share of financial assets and time trends account for much of the change in inequality over time. Figure 2 also highlights the upward time trend in the deviations from the reference curve, indicating a strong shift towards increasing inequality in China over the course of this century. For any country, when the number of billionaires is zero or small, we use the estimated deviations as the basis for making the top tail adjustment. But for countries and years with an adequate number of billionaires – which includes China for almost all years this century – we retain the value obtained directly from the Forbes data.

**Figure 2: Deviation of Forbes data points from reference Pareto curve: China, 2000-17**

### 3.3 Features of the global wealth distribution

Application of the top tail adjustment results in a synthetic sample containing nearly 1.5 million observations for the most recent years, with each observation representing approximately 10,000 adults at lower wealth levels and 100 adults at the top end. These samples are then processed to generate summary data on the wealth pattern within countries, regions and the world.

Table 3-1 reports figures for individual countries, and Table 3-2 provides more detail at the regional level. The results allow us to visualize the global wealth distribution in the form of a wealth pyramid which places adults in one of four wealth bands: under USD 10,000; between USD 10,000 and USD 100,000; between USD 100,000 and USD 1 million; and over USD 1 million. The base level of the pyramid contains 3.2 million adults, or 63% of the global population, but accounts for only 1.9% of global wealth. In contrast, dollar millionaires comprise 0.8% of all adults, but collectively own 45% of all assets. For adults with wealth exceeding USD 100,000 and USD 1 million, Table 3-3 provides further summary information for individual countries.

Combining the samples for all countries allows the features of the global distribution of wealth to be identified, including, for instance, the minimum wealth of each percentile (i.e. 1% group)

worldwide and the share of total wealth owned by this group. To be among the wealthiest half of the world in mid-2018, Table 3-4 shows that an adult needs only USD 4,210 in assets, once debts have been subtracted. However, a person needs at least USD 93,170 to belong to the top 10% of global wealth holders and USD 871,320 to be a member of the top 1%. Taken together, the bottom half of the global population own less than 1% of total wealth. In sharp contrast, the richest decile hold 85% of the world's wealth, and the top percentile alone account for 47% of global assets.

The decile breakdown by regions has a number of interesting features. China dominates the upper middle section of the global wealth distribution, accounting for 48% of members of deciles 7–9. In contrast, residents of India are heavily concentrated in the lower wealth strata, accounting for over a quarter of people in the bottom half of the distribution.

Table 3-4 shows that residents of Latin America are spread quite evenly across the global wealth spectrum. The Asia-Pacific region (excluding China and India) mimics the global pattern more closely still, although the apparent uniformity of the Asia-Pacific region masks a substantial degree of polarization between high-income countries, such as Hong Kong, Japan and Singapore, and lower income countries, such as Bangladesh, Indonesia, Pakistan and Vietnam. In fact, when high-income countries are excluded from the Asia-Pacific group, the wealth pattern within the remaining countries resembles that of India. Residents of Africa are even more heavily concentrated at the bottom end of the wealth spectrum: half of all African adults are found in the bottom two global wealth deciles. In sharp contrast, North America and Europe are heavily skewed toward the top tail, together accounting for 56% of adults in the top 10%, and 73% of those in the top percentile.

Table 3-5 lists the countries that have gained or lost most members of the global top decile and percentile during the year to mid-2018. It also reports changes in the number of millionaires during the past twelve months.

### 3.4 The number of high and ultra-high net worth individuals

Apart from the rich lists, which cover a relatively small number of named individuals, there is a scarcity of information on wealth holdings above USD 5-10 million. Survey details become patchy at best, and official statistics based on tax returns are often inadequate given the complexity of wealth ownership arrangements. Our method of adjusting the top tail using rich list data helps to bridge this gap. Smoothing and extrapolating the wealth distribution at the top then produces plausible estimates of the global pattern of asset holdings in the high net worth (HNW) category from USD 1 million to USD 50 million, and in the ultra-high net worth (UHNW) range from USD 50 million upwards.

Table 3-6 reports the numbers for mid-2018. While the base of the wealth pyramid is occupied by people from all countries at various stages of their lifecycles, HNW and UHNW individuals are heavily concentrated in particular regions and countries, and tend to share more similar lifestyles, participating in the same global markets for luxury goods, even when they reside in different continents. The wealth portfolios of these individuals are also likely to be more similar, with more of a focus on financial assets and, in particular, equity holdings in public companies traded in international markets.

For mid-2018, we estimate that 42.0 million HNW adults have wealth between USD 1 million and USD 50 million, of whom the vast majority (37.1 million) fall within the USD 1–5 million range. North America accounts for the greatest number, significantly above Europe, which in turn hosts nearly double the number in Asia-Pacific countries, excluding China and India. China now accounts for 8% of all HNW individuals, while Latin America, India and Africa together account for only 2% of the total.

UHNW individuals with net assets above USD 50 million now number 149,890 worldwide by our calculations. Among individual countries, the United States leads with 47% of UHNW adults. China occupies second place, but is a distant second with only 11% of the total membership.

Table 3-1: Wealth pattern within countries, 2018

Country	Adults	Mean wealth per adult	Median wealth per adult	Distribution of adults (%) by wealth range (USD)				Total	Gini %

## 4. Women and wealth

### 4.1 Introduction

This chapter reviews evidence on women's wealth from around the world. Evidence is more limited than might be expected given the interest in the topic. Household wealth surveys frequently fail to record which family member owns a particular household asset; and in any case, the legal ownership of a particular asset may differ from who controls that asset in practice. As we will see, however, there is enough evidence to allow us to justify some tentative conclusions. We piece together the evidence to "guesstimate" plausible ranges for women's share of total household wealth by region, and use that to generate a global estimate. Our conclusion is that women hold about 40% of global household wealth. Their share of wealth rose considerably during the 20<sup>th</sup> century, and women's wealth levels have risen along with all household wealth since the year 2000. However, it is not clear that women's overall *share* of wealth has continued to rise in this century. On the other hand, there is some evidence that the representation of women – particularly self-made women – has been rising in the last five to ten years at the very top of the wealth spectrum. In addition, women's share of wealth has almost certainly been rising in Asia, due to the rise of China, where women have a higher wealth share than in most other countries in the region.

We begin by looking at the share of women's wealth around the world and how it may have been changing. Attention then turns to the top of the wealth distribution, where women are often seen to be at a disadvantage, but where the handicaps may be lessening. Finally, we examine the kind of assets held by women, finding more non-financial assets and less risky financial portfolios compared with men.

### 4.2 Women's share of global wealth

Studies in several European countries have been able to examine the division of wealth ownership within married or cohabiting couples. Evidence for France, Germany, Spain and the United Kingdom for the period 1996 to 2013 indicates that, on average, women held 43% of total wealth (Table 4-1). A study for Sweden from 1979 to 1992 found a rapidly rising female share that would likely have reached a similar level had the study continued (Bolin and Pålsson, 2001). And for Italian couples it has recently been found that the wife held an average of 40% of their real estate wealth over the period 1995-2012 (Bayot and Voena, 2015).

In recent years many Eurozone countries have conducted Household Finance and Consumption Surveys (HFCS) under the auspices of the ECB, using comparable methods. Although the division of assets within households is not identified in the data, making certain assumptions, Sierminska (2017) used the first wave of these surveys, conducted in 2010/11, to estimate the gender wealth gap. She estimated that the ratio of mean female wealth to mean male wealth was 0.73. Assuming an equal number of men and women, that would imply women had a wealth share of 42%, consistent with the other studies mentioned above.

We have used the second wave of the HFCS, conducted in 2014, to look at gender wealth differences across the full distribution of wealth, assuming that married couples have an equal division of wealth between partners and attributing 20% of the wealth in a household consisting of a married couple and additional adults to those extra adults. The latter assumptions are necessary to overcome the absence of a recorded wealth division within households. Figure 4-2 shows the results. In the lowest wealth deciles (1 to 3), single people dominate, with single women slightly more numerous than single men. Many of these low-wealth singles have not been married; others are widowed or divorced. Single mothers are concentrated at this lower level. In the middle deciles married people dominate, but in the highest deciles they fall a little as a fraction of the population.

This is largely due to the presence of older high-wealth singles, including some people who never had children and were able to accumulate more without that expense, and some who inherited from their spouses on being widowed.

Compared to Europe, less is known about women's overall wealth share in the United States, because very few studies for the United States record the division of wealth between husbands and wives. However, the wealth ratio for single women and men is available (Wolff, 2017), and is similar to that in Europe. Another source is a large sample from the 1957 cohort of Wisconsin high school graduates whose wealth was recorded on an individual basis at ages 64-65 in 2004 (Ruel and Hauser, 2013). If the female:male wealth ratio observed at that point in their life cycle held for the population as a whole, women's share of wealth would have been 42%. This leads us to conclude that women's share of wealth in both Europe and North America is probably in the 40-45% range as we record in Table 4-3. This figure is a strong indication of the share of women globally: Europe and North America host only 17% of world adults, but together they account for 61% of global wealth.

As regards the rest of the world, recent studies for Africa and India indicate a significantly lower women's share than in the advanced countries, ranging between 20% and 30% (Table 4-1). The wealth share in China is higher than in Africa or India, but below the level in Europe or North America. According to Forbes women account for 8.0% of the many billionaires in China – a proportion that is lower than in most high-income countries, but higher than in most emerging market countries. Hurun finds that two-thirds of the world's self-made billionaire women are Chinese (Block, 2018). We guess that the wealth share of women in China is between 30% and 40%.

The Asia-Pacific region (excluding China and India), is very heterogeneous. It contains countries where the wealth situation of women is similar to that in India (e.g. Pakistan and Bangladesh), but other countries are more similar to China, and at least one country where the gender wealth gap is quite small – e.g. Australia (Ravazzin and Chesters, 2018). We guess that women's share in the region is between 25% and 35%. Finally, studies in some Latin American countries indicate a small gender wealth gap (Doss et al., 2014), but for the region as a whole women's share is below that in Europe and North America (Deere and Doss, 2008). We think it may be in the same 30-40% range as China.

Adding up our estimates for the different regions, as indicated in Table 4-2, places the share of women in global wealth in the range 35%-42%, or about 40% in round numbers. This is higher than the 30% estimate by the Boston Consulting Group (Beardsley et al., 2016). We think the difference in results might be partly due to our inclusion of non-financial assets, which make up about half of global household wealth and are more equally shared between women and men than financial assets. It appears that non-academic work in this area tends to focus on financial assets. The difference in results may also partly reflect that we base our estimate on an overview of empirical evidence rather than a modeling exercise. The latter approach is sensitive to the modeling assumptions and can generate somewhat surprising results, such as the estimate by EYGM Ltd. (2017) that women control 51% of wealth in the United States.

### 4.3 Is there a trend in women's share?

In high income countries the last several decades have seen a revolution in the work and family lives of women. Rather than having less education than men, in many of these countries they now acquire more. Instead of marrying young and having children soon after, they are marrying later and waiting longer to have children. They are employed and earning more, and saving more as a result. Further, they have greater financial independence, a rising share of wealth within marriage, and generally get a more equal share on divorce than years ago.

These developments have fueled the rise of women's wealth, and dominated in the 20<sup>th</sup> century. However, opposing forces have stalled or reversed progress at times. For example, the wealth of divorced women typically falls over time compared with their partners. The rise in divorce rates may therefore tend to reduce women's share of wealth. And with continued gender pay inequality, young single women, whose numbers have been increasing, may accumulate less wealth than their male peers. Finally, there is much evidence that women are more risk averse than men and tend to invest in less risky assets (see sections 4.7 and 4.8 below). When the prices of risky assets have been rising, as in recent years, this tends to reduce the relative wealth of women.

Only data can cast light on whether women's share of wealth has been rising or falling. The evidence is clear in high income countries during the last century: women's share of wealth was rising (Harbury and Hitchens, 1977; Bolin and Pålsson, 2001). From 2000 onwards, estimates made using comparable methods that can be compared over time are available over various intervals up to the year 2013. Women's share of wealth rose a little in France, showed no trend in the UK, and fell in Germany and Spain. In the United States, the wealth of single women rose in both relative and absolute terms from 2001 to 2007, but then fell sharply from 2007 to 2010 and from 2010 to 2013 (Wolff, 2017). It remained roughly constant in relative terms from 2013 to 2016 (data received in private communication). Estate tax-based evidence for the United Kingdom and the United States gives a mixed picture regarding changes in the representation of women in the highest wealth ranges.

For the world as a whole, the increase in China's wealth suggests a rise in the global share of women, since their share in China appears to be higher than in many other emerging markets or developing countries, as noted earlier. But the rise in China's share of wealth this century is almost perfectly offset by a decline in the wealth share of high-income countries, where women have an even higher share of wealth. That said, the rise of wealth in China has almost certainly increased women's share of wealth in Asia.

#### 4.4 The top end

Estate tax records have some advantages as a wealth data source, compared with household surveys, in the upper tail of wealth distribution. Response is not voluntary and it is against the law to under-report assets. While there are loopholes, certain assets legitimately not covered (pensions and annuities for example) and tax evasion is a problem, as usual, these records still provide a valuable window on the upper tail. Using the estate multiplier approach the records can provide an estimate of the distribution of wealth over the range of wealth that would necessitate estate tax filing.

The most recent official estate multiplier data for the United States are for 2013, when the tax threshold was USD 5.25 million, corresponding approximately to the top 0.25% of adults, who held an estimated 9% of total household wealth. Women accounted for 39% of this group and their mean net worth was 98% of that of men. Female representation declined slightly with wealth level, from 42% in the range USD 5.25–10 million to 39% above USD 50 million.

Estate tax estimates for the United Kingdom during 2011–13 show that 42% of those with wealth over GBP 2 million were female, similar to the proportion in the United States. The mean wealth of women in this range was 85% of that of the men, putting their share of total wealth in this top group at 38%, the same as in the United States.

On the basis of the estate tax-based estimates, we see that women's share of wealth at the top end in the United States and the United Kingdom is slightly less than the 40–45% share that we estimated for the population as a whole in Europe and North America. This supports the frequent claim that there is more of a gender wealth gap at the extremes of the wealth distribution, and in particular at the top.

More countries can be included by looking at global billionaire lists, although these cover the super-rich rather than just wealthy individuals. Also, there is little effort to separate the wealth of husbands and wives – if a wife does not play an active role in running a business, she is unlikely to be recognized and the couple's entire wealth is regarded as the husband's. This practice results in a much smaller fraction of women compared to estate tax or survey data. The rich lists might be said to reflect better women's control of wealth rather than their legal ownership. Of the 2208 billionaires on the 2018 Forbes list, just 244 (11.1%) were female (Table 4–4). Among the top 500 billionaires the fraction is 12.0%, similar to the 12.8% fraction of women recorded in the Hurun list of the top 500 global billionaires (Hurun Report, 2018). While these numbers might appear to challenge the view that representation of women declines with wealth at the top end, there could be another explanation if the very richest women are less likely to be overlooked, relative to men, than those just below them.

Regional differences in female representation among the billionaires are marked (Table 4–4). Reflecting their relatively high global share of women's wealth, Europe and North America have

the highest fractions of female billionaires. Latin America, Africa, Asia-Pacific and China come next, in the 8–10% range, although the figure for Africa may be misleading due to the small sample size: there are only 21 billionaires, of which just two are female. And if Australia is omitted from Asia-Pacific the fraction of billionaires in that region falls to 7.3%. India brings up the rear among regions, with only 6.3% female billionaires. However, there are quite a few individual countries that fall below India in terms of the % of billionaires who are female – Canada and Japan to name two perhaps surprising examples. Germany has the largest female fraction among its billionaires (26.0%), followed by Sweden (25.0%), Switzerland (23.8%), and Australia (18.6%). Among countries with at least 20 billionaires, Indonesia, Singapore and Taiwan stand out with zero who are female.

## 4.5 Changes at the top end

The Global Wealth Report 2010 examined the most recent estate tax-based evidence on gender differences in the upper tail of the wealth distributions in the United Kingdom and the United States, which related to 2004-05. These can be compared with the most recent estate tax data, which refer to 2013 for the US and 2011-13 for the UK. Trends in the two countries have been in opposite directions. For the United Kingdom, 35% of those with wealth over GBP 1 million were female in 2005, but that number rose to 45% in 2011-13. The female share of wealth above GBP 1 million also rose substantially, from 31% to 41%. In the United States, however, the fraction of women above the 2013 estate tax threshold in real terms (USD 5.25 million) fell from 42% in 2004 to 39% in 2013, and the wealth share fell from 41% to 38%. The contrast in trends between the two countries could be due partly to the greater fall in real estate values in the United States during the financial crisis of 2007/08, because women own relatively more housing, and less of stocks & shares, than men.

Gender trends in wealth-holding can also be tracked at the top end using the Forbes 400 list, which covers the 400 wealthiest residents of the United States each year. There were 70 women on the list in 1990 and 74 in 1995, but their numbers fell sharply to 48 between 1995 and 2000 (Table 4–5). The number of women on the list fell further to 41 in 2010, but has since rebounded to 52. This pattern is consistent with a picture in which women's share of wealth did not rise in the early years of this century, but also points to the possibility that the situation is now changing.

Most women on the Forbes 400 list have always been inheritors, although there has also always been a minority of self-made women on the list. A key factor in the collapse in the number of women during 1995-2000 was the drop in the number who had inherited (Table 4–5). In the early and mid-1990s there was still a relatively large number of heiresses who had inherited from the “robber barons” of the late 19<sup>th</sup> and early 20<sup>th</sup> centuries. The 1990 list included 13 women who had inherited from the du Pont fortune, for example. Their median age was 79. By 1995 only 8 of them were left, and by the year 2000 only one remained.

The fall in the number of Forbes 400 women from the mid-1990s to the early 2000s, and the fact that most women at this wealth level are inheritors, suggest that, to an extent, trends in female representation in the top wealth tail could reflect earlier changes in male wealth distribution. The drop in the number of women on the Forbes list after 1995 may be an “echo” of the fall in wealth inequality in the United States from its pre-World War II highs to its low point in the 1960s and 70s. Lower male wealth at the top end for a decade or two could well result in fewer widows and daughters being launched into the Forbes 400 via inheritance in the following years, particularly if self-made wealth was rising among men in that later period – consistent with the argument of Edlund and Kopczuk (2009). Although the extent of the increase is a matter of debate, overall wealth inequality has clearly risen in the United States over the last two decades. This suggests that there could be an increase in the number of female inheritors on the Forbes 400 in the future as an echo of the burgeoning male wealth of these decades.

The drop in the number of female inheritors in the Forbes 400 over the period 1995-2000 was reinforced after 2000 by a fall in the number of women that we categorize as “self-made.” (The self-made category includes women who prospered as a result of actively working and leading joint businesses with their husbands, as well as those who succeeded alone.) That number fell from 13 in the year 2000 to 6 in 2005, partly due to mortality. Conversely, the rebound in the number of women in the Forbes 400 after 2010 is due to a doubling in the number of self-made women on

the list, from 7 in 2010 to 14 in 2017. An upsurge of self-made women is also evident in the Hurun global self-made women billionaires list, which saw 14 new names on the list in 2017 alone, bringing the total to 102 (Block, 2018; Hurun Report, 2018), as well as in Forbes' survey of the most successful self-made businesswomen in the United States (Forbes, 2018).

There have also been significant changes over time in the relative age and wealth of women versus men in the Forbes 400. In the 1990s the women were on average a little older than the men, and had about 20% less wealth. From 2005 onwards they have been a little younger than the men and have caught up in wealth terms: their median wealth was equal to that of men in 2010 and higher in 2017. These trends may be partly due to the rising number of self-made women on the list.

## 4.6 Female millennials

Last year the Credit Suisse Global Wealth Report and Databook examined the wealth of the millennials. This generation, consisting of those who came of age after the year 2000, had a more difficult time than previous generations due to a range of factors, including the global financial crisis, the economic slump that followed, technological change, and high house prices. As a result, its rate of wealth accumulation has been slower than earlier generations at the same age. There is also a gender dimension to the millennials' problems. Millennial women and men have both had difficulties but, overall, the women have been less severely affected than the men.

Female millennials have done better than their male counterparts because the industries most affected by the financial crisis and the global recession that followed tended to be male dominated – finance and construction, for example – while the more stable parts of the economy were not – education, health care and public administration, for example. The outcome shows up most dramatically in unemployment rates. In the United States average unemployment rates for men and women in their 20s were almost identical in the 1990s. This changed even before the financial crisis, with the female unemployment rate in this age group averaging 6.8% compared to the male rate of 7.4%. The male rate then rose rapidly after the crisis, peaking at 17.8% in April 2010, when the female rate also peaked, but at a much lower level of 10.8%. A greater rise in male unemployment rates after the financial crisis was also seen in the European Union.

Gender differences in the millennials' experience show up in comparisons of how the wealth of male and female millennials evolved in their youth versus the experience of previous generations. Evidence can be gleaned from the Survey of Consumer Finance (SCF) microdata for the United States regarding the experience of the youngest millennials to be affected by the financial crisis: single adults aged 20-24 in 2007. The average wealth of women in this group was 61% of the men's in the 2010 and 2013 surveys, much higher than the ratio of 43% found at the same age for those aged 20-24 in 1997, the generation immediately before the millennials.

## 4.7 Portfolio composition

The nature of gender differences in the portfolio composition of wealth was recently addressed in a major study for the European Commission using data from the first wave of the Household Finance and Consumption Survey (HFCS) covering 15 Eurozone countries around 2010/11 (Sierminska, 2017). The main results are as follows:

- Women had more of their assets in non-financial form (e.g. houses) than men: 75% versus 73% (see also Rossi and Sierminska, 2018).
- Women had a smaller fraction of their financial assets in risky form (stocks and mutual funds) – 13% versus 19% – and fewer women than men owned such assets: 16% versus 22%.
- Single women had more of their assets in non-financial form than married women: 80% versus 72%.
- Women and men had similar debt ratios: 10% of gross assets for both.

Evidence for other countries echoes these conclusions. Estate tax multiplier estimates for the United Kingdom are helpful here as they record wealth on an individual basis and cover about the top third of the population, who own most of the wealth in the country. These data do not distinguish between married and single persons, but the broad pattern of differences between female and male portfolios are similar to those in Europe. The women hold more of their assets in non-financial form – 57.5% in 2011/13 versus 53.1% for men. They are also less likely than men to hold risky assets, and dedicate a smaller proportion of their portfolios to them – 25% versus 31% (HMRC, 2016).

The United States Survey of Consumer Finance also casts some light on gender differences in portfolios. While it does not divide household wealth between spouses, single women and men can be compared with each other and with married couples. The evidence shows that single women in the United States have a much higher home ownership rate than single men or married couples – 75% versus 59% and 65% in 2013. Consequently, it is not surprising to find that, as in Europe, they also hold a higher fraction of their wealth in non-financial assets – 36% versus about 20% for both single men and couples (Wolff, 2017).

Pension coverage is another aspect of gender disparity that has attracted attention. In countries with compulsory superannuation schemes, like Australia and much of Europe, this is less of an issue, although since women still earn less over the lifetime, they must also have lower equity in earnings-related pension schemes. Bigger concerns develop in countries where “second pillar” pension coverage depends on whether or not one’s employer has a pension plan. People without such coverage can compensate to some extent through their own retirement saving (the “third pillar” of retirement income). However, in practice those without employer-based pensions have less retirement-related assets. In the past there were very marked gender difference in both participation in such pensions and in the amounts held. This difference has tended to decline in recent decades as more women have strong lifetime attachment to the labor force.

The improvement in pension coverage for women may be illustrated by the case of the United Kingdom. The pension analysis from the 1995 Family Resources Survey showed that British women of working age had pension wealth (both state and occupational) equal to just 14% of men at the median and 30% in terms of means. The differences in pension coverage appear to have been much larger for married than for single women. Recent trends are revealed by the Wealth and Assets Survey (WAS), which has emphasized pension wealth since its onset in 2006 (Office for National Statistics, 2018). Between the third wave (2010-2012) and the fifth (2014-16) the proportion of women currently contributing to a private pension scheme rose from 39% to 47%. In the fifth wave the median amount of non-state pension wealth for women with defined contribution pension plans was 65% of that for men, and 61% for defined benefit plans. This indicates a sizeable reduction in the gender gap in pension wealth compared with 1995.

Estate tax evidence also illuminates gender differences in portfolio composition at the top end. In the United States in 2013, 75.9% of women in the very high wealth group covered by estate data held publicly traded stock, slightly more than the 74.0% of men who did so. Public stock made up 22.0% of the women’s portfolios on average, compared with 16.4% for men. It may well be that women are more likely to hold less risky varieties of stock, in keeping with their well-established greater risk aversion. Women were much less likely to have closely held stock or to participate in non-corporate business. Other gender differences reflect factors such as the lower average age of the men and the greater likelihood that they are, or were, in paid employment or had a pension plan. These differences show up in the greater importance of life insurance and retirement assets for men. It is also worth noting that the women had about half as much debt as the men, relative to their total assets. Estate tax evidence for the United Kingdom over 2011/13 reveal a lower incidence and portfolio share of securities for women than for men. Other gender differences in portfolio composition for the United Kingdom are broadly similar to those in the United States.

Work coordinated by the international Gender Asset Gap Project provides a window on differences in the portfolios of women and men in Ecuador, Ghana and India (Doss et al., 2014). The sexes are remarkably similar in their ownership of different asset types in Ecuador, except for businesses. While women owned 54% of the businesses owned by the couples surveyed, their businesses were smaller. Women held only 28% of the business wealth in the sample, by value. The situation in Ghana and India is very different. In Ghana men are about twice as likely – and in India more than twice as likely – to own agricultural land or a principal residence. Except for jewelry, women are also much less likely to own consumer durables, including vehicles and mobile

phones. Given their increasing importance in business and financial activities, lower ownership of mobile phones is both indicative of women's lower opportunities to take part in those activities and a barrier to greater participation in them.

Barriers to female wealth accumulation in sub-Saharan Africa and South Asia have been partly responsible for the development of alternative savings and credit institutions that affect both the composition of women's portfolios and their wealth accumulation prospects. The most well-known is microcredit, which has been helpful in allowing groups of women to build up micro businesses in part by freeing them from dependence on money lenders. Another is the rotating saving and credit association (rosca) seen in various forms in many countries. Anderson (2002) studied rosca's in Kenya and found that they were particularly helpful for married women, allowing them to save for a significant expenditure, often taking the form of a consumer or producer durable, without their husbands being able to appropriate their savings.

## 4.8 Saving, investment and risk aversion

It has been established through a number of studies that women tend to be more risk averse than men (Jianakopulos and Bernasek, 1998; Croson and Gneezy, 2009). This shows up in their choice of less risky portfolios, as noted above. It is sometimes thought that women also tend to save more than men, which would seem to be in line with greater risk aversion. However, research does not support the idea that they are higher savers (Woolley et al., 2013). From a life-cycle saving perspective, women would be expected to have a higher saving rate, since they live longer. However, women also spend more on their children than do men, which tends to reduce their saving. More generally, there is a complex behavioral interaction between wives and husbands in making saving decisions whose results are hard to predict. Evidence concerning the saving behavior of single women and men may tell us little about the likely saving behavior of married couples.

Much recent attention has been given to differences between men and women in investment styles (Silverstein et al., 2009; Beardsley, 2016; EYGM Limited, 2017). Financial advisors have been told that they need to understand those differences in order to serve female clients well. Surveys have shown that women tend to save for particular purposes rather than simply to accumulate greater wealth. Their greater risk aversion shows up as well in their interest in sustainable investments, and in their avoidance of risky activities like day trading and speculation – found to be a significant advantage compared with male investors in the famous study of Barber and Odean (2001). But there are other important gender differences. For example, it has been found that women on average have less investment knowledge and are less confident about investing than men (Lusardi and Mitchell, 2008). This does not necessarily handicap them relative to men, however. It has also been found that men tend to be overconfident about their investing ability. Caution and patience can yield dividends in the world of investment.

## 4.9 Conclusion

Women's wealth rose as a share of global wealth in the 20<sup>th</sup> century. Since the year 2000, their wealth has generally risen alongside men's, but the ratio of women's to men's wealth has not always and everywhere increased. The drop in the wealth of single women relative to male singles in the United States after 2010, for example, provides a warning that changes in the gender wealth gap are not always in the direction hoped for. However, women's share of wealth has almost certainly risen in Asia in the last two decades, due to the rise of China's wealth, which is more equally distributed between the sexes than in the bulk of the region. And there are signs that more self-made women are succeeding in business and entering the highest wealth ranks around the world. Women are also making progress in terms of pension coverage in some countries. If the goal is complete gender equality, however, more needs to be done. There are some regions where gender wealth gaps remain large, and around the world there are groups of women, such as single mothers, with very low average wealth.

Country	Study	Data source	Year(s)	Family units	Women's share of wealth <sup>1</sup> (%)
Ecuador	Doss et al. (2014)	Gender Asset Gap Project survey	2010	All	52.0

## 5. Composition of wealth portfolios

### 5.1 Financial versus non-financial assets

We look first at the relative importance of financial versus non-financial assets in the average household portfolio. Expressed as a percentage of gross household assets, the pattern clearly differs markedly between poorer and richer countries and regions, as can be seen in Table 5-1, which shows the breakdown for the countries with the best data. In developing countries, for example India and Indonesia, it is not unusual for 80% or more of total assets to be held in the form of non-financial assets, including housing, farms and small business assets. This pattern is also associated with the relative under-development of financial institutions in many lower income countries.

As countries develop – and make the transition to a market economy – the importance of non-financial assets tends to decline. An interesting example is provided by China, where the share of financial assets in gross wealth is 38% in 2018. Another example is provided by Singapore, a country further along the development path, but still nevertheless seeing the share of financial assets in household portfolios continuing to rise – from 46% in 2000 to 55% in 2018. In the richest countries, financial assets typically account for more than half of household wealth. An important example is the United States, where 72-73% of household assets have been held in financial form in each year since 2010 (although the share is somewhat inflated by the US practice of classifying all business equity as a financial asset).

There are interesting exceptions to this general pattern. Robust house price rises drove the share of non-financial assets above 60% in France and Italy by 2010 before drifting down in those countries. The share of non-financial assets also rose in the United Kingdom, from 36% in 2000 to 50% in 2007, although it has since fallen back to 47%. In the developing world, South Africa is a strong outlier, having an exceptionally high share of financial assets: the share of 66% in 2018 exceeds that found in all G7 countries except the United States. This high share reflects, on the one hand, the advanced development of South Africa's financial institutions including its private pensions, and on the other hand, relatively low house prices.

### 5.2 Composition of financial assets

Table 5-2 provides some detail on the composition of financial assets, for a greater number of countries. It shows the breakdown into three categories: currency and deposits (liquid assets); equities (all shares and other equities held directly by households); and other financial assets. In most countries, the reserves of life insurance companies and pension funds form the largest component of "other financial assets" – these reserves comprise equities and other financial assets that are in effect being held on behalf of the household sector.

The composition of financial assets differs considerably across countries. One interesting aspect is that equities held directly are not always a large component of household financial wealth, even in countries with very active financial markets. In the United Kingdom and Japan, for example, equities account for 10-15% of total financial assets. In contrast, they make up around 30% of financial assets in the United States, and over 40% in Bulgaria, Estonia, Finland, Hungary, New Zealand and Sweden. To calculate the overall percentage of the household portfolio held in equities, equities held indirectly via insurance policies and pension plans would need to be added to the total of those held directly. However, this is not possible since the household balance sheet data available in most countries do not show the composition of assets held in insurance and pension reserves. If the purpose were to find out the total exposure of the household sector to stock market risk, it is also not clear that this exercise would provide the answer. Households have explicit or implicit guarantees on their rights to

many insurance and pension benefits, so that the risk characteristics of the latter may differ from those of the assets held in the reserves.

Where equities account for more of the portfolio, there is less room for liquid assets or other financial assets. The strongest negative association is between equities and other financial assets, perhaps because other financial assets are larger where private pension systems are more highly developed and may tend to crowd out privately held equities. A good example of this phenomenon is found in Australia, where only 19% of the average portfolio is in equities vs. an average of 28% for the countries in Table 5-2 showing 2017 data, but other financial assets have a share of 60%, well above the average figure of 35%. A similar pairing of below-average equities and above-average other financial assets is seen, in most years, in eleven countries in Table 5-2, including Belgium, Germany, Ireland, Norway, Singapore and the United Kingdom. The opposite scenario, of above average equities and below average other financial assets is found in eight countries, which include some transition economies as well as Austria, Finland, Luxembourg, New Zealand, and Spain. The negative association between equities and liquid assets is weaker, but shows up in countries like Japan where liquid assets are 53% of the portfolio versus 14% for equities, and at the opposite end of the scale the United States, with only 14% in liquid form versus 32% in equities.

There are also interesting differences across country types. The typical portfolio in the well-established high-income market economies has less liquid assets than average, equities at about the average level, and other financial assets somewhat above average. Emerging market countries tend to have less in both equities and other financial assets than the established high-income countries, and therefore a higher share in liquid assets than seen in the typical rich country. On average, the transition countries have more in liquid assets than either the high-income countries or emerging market economies, perhaps reflecting the fact that their financial systems have had less time to develop.

### 5.3 Changes over time

While the financial crisis of 2007-2008 is becoming a distant memory, it was a landmark event for household wealth, bringing an abrupt decline in most personal fortunes and a change in household behavior and wealth performance in most countries. In light of these aspects, it is interesting to examine how the overall composition of personal wealth and, in particular, the proportion of financial assets to total gross household assets has changed over the past decade. A decline in the relative importance of financial assets was seen in a number of countries in 2008, for example in Italy, Singapore and Switzerland. In other countries, the credit crisis depressed both property prices and share values, so the share of financial assets was more stable.

Longer term, the share of financial assets does not often appear to change dramatically. In France, a relative increase in property prices in the period since 2000 has reduced the share from 46% to 39%, and a similar effect is seen in Italy, where the share fell from 48% to 42%. Elsewhere, however, effects generally seem to be mostly short term. The United States showed a relative decline in financial assets from 2000 to 2005, for example, but then with a booming stock market the share rebounded. Its rise was only halted temporarily by the financial crisis. The share peaked at 73% in 2014 and has now fallen back a little, to 72%, which is not much greater than its year 2000 level of 69%. Japan showed a rise in the proportion of financial assets during 2000-05, a decline during the financial crisis, and a small subsequent increase, finishing at 61%, significantly above the 53% seen in 2000. The importance of debt has also changed over the years since 2000. For many countries, including the United Kingdom and the United States, there was a significant rise in the period leading up to the financial crisis and a decline thereafter. However, this experience is not universal. In Japan and Germany, for example, it has been trending downward over the entire period. What is common to most OECD countries, however, is that the debt ratio fell after the financial crisis. So where debt had not risen before the crisis, it nonetheless tended to fall afterwards – from 12% to 11% in Japan, for example, and from 17% to 13% in Germany. Contrasting post-crisis results are seen in a few high-income countries where the debt ratio held steady, as in France, or even rose a little, as in Australia. Trends also differed in rapidly developing countries like China, India and Indonesia,

which have seen their debt ratios rise throughout the early year of the century, seemingly unaffected by volatility in the global economy. Since 2014, debt has fallen as a fraction of gross assets in most developed countries.

## 5.4 Conclusion

The composition of household balance sheets is an important determinant of trends in consumption and investment, and in many ways reflects the financial development of individual countries. For instance, debt as a proportion of total household assets tends to be low in developing countries and some transition countries because financial intermediation and property rights are underdeveloped, while debt levels in OECD countries are relatively high, reflecting a more developed financial system.

Our analysis of household balance sheets examines financial and non-financial assets and debt from a global perspective. In general, non-financial assets like housing, land and small business assets make up a relatively large proportion of household wealth in the developing world and in transition countries. While their relative importance is smaller in the high-income countries, there is variation. Non-financial assets are still quantitatively more important than financial assets in Australia, France, Germany, and Italy. In contrast, financial assets form a larger proportion of the household balance sheets in countries such as the United States, Japan and the Netherlands.

## 6. Region and country focus

### 6.1 Introduction

Countries differ greatly in terms of their level and pattern of wealth holdings. There are also distinct differences at the regional level. It is therefore interesting to compare regional variations and trends since the year 2000, and to document the variety of country circumstances and experiences.

The quality of wealth data is good in the high-income countries that are home to most of the world's wealth and is improving elsewhere. The countries discussed in this section are all interesting in their own right. But another reason for their selection is that they all have a credible way to estimate both the mean level of household wealth and the distribution of wealth across the population.

The accompanying tables collate information on wealth holdings for each of the regions and countries. Some of the core data is summarized in Table 6-1. Table 6-2 reports wealth per adult measured in US dollars at current and "smoothed exchanged rates," the latter referring to 5-year moving average exchange rates. Table 6-3 provides similar information for aggregate household wealth measured in trillion US dollars. Table 6-4 shows the composition of wealth for the most recent year for which figures are available. For each region and country, the wealth share of each decile and the top percentiles is recorded in Table 6-5, along with the minimum wealth needed to belong to a given regional wealth quantile. Finally, Table 6-6 shows the distribution of the adult population by wealth range.

### 6.2 Mean wealth 2000–18

Three charts are provided for each of the regions. Figure 1 plots two series for mean wealth over 2000–2018, one measured in current US dollars and the second calculated using smoothed exchange rates. The global level of wealth per adult – which amounted to USD 63,100 in 2018 – masks considerable regional variation. The average for North America in 2018 was USD 391,700 compared to USD 145,000 in Europe, USD 48,100 in the Asia-Pacific region (excluding China and India), USD 47,800 in China, USD 18,600 in Latin America, USD 7,000 in India, and USD 4,100 in Africa.

All regions have recorded an increase in wealth per adult since the start of the century. If wealth is measured in local currencies, growth has been sustained and generally continuous apart from the financial crisis period when all regions except Latin America suffered a setback. If wealth is valued in current USD, the picture is somewhat different. Between 2000 and 2007, dollar depreciation raised the regional growth rates; but dollar appreciation in more recent years has had the opposite effect. As a consequence, wealth per adult in 2018 remains below its 2007 level in Africa and Europe. In Latin America, wealth per adult initially moved up after 2007, but later fell back.

This in turn has implications for global wealth inequality. Although wealth levels in Europe and North America have always been far above those in other regions, particularly Africa and India, the regional imbalance eroded during the early years of the century. Africa, India, Latin America, and most notably China, all increased their share of world wealth between 2000 and 2007, hinting at the possibility that global wealth inequality was on a long-term downward trend. The shares of the top 1% and top 10% in world wealth fell significantly between 2000 and 2008: the share of the top percentile, for instance, declined from 47% to 43%. However, the trend reversed after the financial crisis, and inequality rose, particularly at the very top. Recent evidence suggests that this episode has now come to an end. For the moment, wealth inequality seems to have leveled out and may be edging downwards in some regions.

### 6.3 Components of personal wealth

Table 6-4 displays the breakdown of wealth per adult for each region into financial and real (non-financial) forms, as well as the average level of debt. On average internationally, financial assets now comprise 53% of gross assets, while non-financial assets account for 47% and debts amount to 13%. Financial assets are relatively more important in Japan where they represent 62% of gross assets and the United States, where they account for 72%. In developing regions, non-financial assets typically account for the bulk of household wealth: they form 65% of gross assets in Latin America and 91% of assets in India, for example.

A systematic link with the stage of development is also evident in the level of household debts expressed as a percentage of gross assets. The share is 11% in India, 9% in China and 10% in Africa, but averages 14% in the Asia-Pacific region, Europe and North America.

### 6.4 Wealth distribution

Table 6-5 shows wealth distribution for each region. Some interesting contrasts between regions are evident. More than 93% of adults in Africa own less than USD 10,000, and 91% of adults in India fall in this range. Meanwhile the fraction is 33% in China, 43% in Europe and 28% in North America. On the other hand, 26% of adults in Europe and 42% in North America have wealth above USD 100,000. The wealth distribution in both Latin America and the Asia-Pacific region closely resembles the pattern in the world as a whole, and Latin America shows 71% and Asia-Pacific 73% of all adults owning less than USD 10,000.

Among developed countries, there is substantial variation in the percentage of adults recorded in the lowest wealth ranges. Some countries report significant numbers of people in this category, while others show very few. This reflects such factors as availability of credit including student loans, as well as how many young adults live separately from their parents, making their low wealth more apparent in the survey returns.

## About the authors

**Professor Anthony Shorrocks** is an Honorary Professorial Research Fellow at the University of Manchester, a Senior Research Fellow at the World Institute for Development Economics Research (UNU-WIDER) in Helsinki, and Director of Global Economic Perspectives Ltd. After receiving his PhD from the London School of Economics (LSE), he taught at the LSE until 1983, when he became Professor of Economics at Essex University, serving also as Head of Department and Director of Economic Research for the British Household Panel Study. From 2001 to 2009, he was Director of UNU-WIDER in Helsinki. He has published widely on income and wealth distribution, inequality, poverty and mobility, and was elected a Fellow of the Econometric Society in 1996. Publications include "The age-wealth relationship: A cross section and cohort analysis" (Review of Economics and Statistics 1975), "The portfolio composition of asset holdings in the United Kingdom" (Economic Journal 1982), and, with Jim Davies and others, "Assessing the quantitative importance of inheritance in the distribution of wealth" (Oxford Economic Papers 1978), "The distribution of wealth" (Handbook of Income Distribution 2000), "The world distribution of household wealth" in Personal Wealth from a Global Perspective (Oxford University Press 2008), "The global pattern of household wealth" (Journal of International Development 2009), "The Level and Distribution of Global Household Wealth" (Economic Journal 2011) and "Estimating the Level and Distribution of Global Wealth, 2000-2014" (Review of Income and Wealth, 2017).

**Professor Jim Davies** has been a member of the Department of Economics at the University of Western Ontario in Canada since 1977 and served as chair of the department from 1992 to 2001. He received his PhD from the London School of Economics in 1979. Jim was the director of the Economic Policy Research Institute at UWO from 2001 to 2012. In 2010, he completed a five-year term as managing editor of the academic journal Canadian Public Policy. From 2006 to 2008, he directed an international research program on household wealth holdings at UNU-WIDER in Helsinki and edited the resulting volume, "Personal Wealth from a Global Perspective" (Oxford University Press 2008). He has authored two books and over 70 articles and chapters in books on topics ranging from tax policy to household saving and the distribution of wealth. Publications include "The Relative Impact of Inheritance and Other Factors on Economic Inequality" (Quarterly Journal of Economics 1982), "Wealth and Economic Inequality" (Oxford Handbook of Economic Inequality, Oxford University Press, 2009), and several publications on wealth authored jointly with Anthony Shorrocks and others. Jim is also the editor of "Personal Wealth From a Global Perspective" (Oxford University Press, 2008), and "The Economics of the Distribution of Wealth," published in 2013 by Edward Elgar.

**Dr. Rodrigo Lluberas** is an Analyst at the Research department of Uruguay Central Bank. He received his PhD in Economics from Royal Holloway College, University of London and his MSc in Economics from University College London. He has been a visiting scholar at the Institute for Fiscal Studies and an Economist at Towers Watson in London. Prior to undertaking his MSc, he worked for three years as an economic analyst at Watson Wyatt Global Research Services and more recently as a research assistant at NESTA. His main areas of expertise are pensions, consumption and wealth. Rodrigo is a co-author of "Estimating the Level and Distribution of Global Wealth, 2000-2014" (Review of Income and Wealth, 2017).

## Additional regional disclaimers

Hong Kong: Credit Suisse (Hong Kong) Limited ("CSHK") is licensed and regulated by the Securities and Futures Commission of Hong Kong under the laws of Hong Kong, which differ from Australian laws. CSHKL does not hold an Australian financial services license (AFSL) and is exempt from the requirement to hold an AFSL under the Corporations Act 2001 (the Act) under Class Order 03/1103 published by the ASIC in respect of financial services provided to Australian wholesale clients (within the meaning of section 761G of the Act). Research on Taiwanese securities produced by Credit Suisse AG, Taipei Securities Branch has been prepared by a registered Senior Business Person. Malaysia: Research provided to residents of Malaysia is authorized by the Head of Research for Credit Suisse Securities (Malaysia) Sdn Bhd, to whom they should direct any queries on +603 2723 2020. Singapore: This report has been prepared and issued for distribution in Singapore to institutional investors, accredited investors and expert investors (each as defined under the Financial Advisers Regulations) only, and is also distributed by Credit Suisse AG, Singapore branch to overseas investors (as defined

under the Financial Advisers Regulations). By virtue of your status as an institutional investor, accredited investor, expert investor or overseas investor, Credit Suisse AG, Singapore branch is exempted from complying with certain compliance requirements under the Financial Advisers Act, Chapter 110 of Singapore (the "FAA"), the Financial Advisers Regulations and the relevant Notices and Guidelines issued thereunder, in respect of any financial advisory service which Credit Suisse AG, Singapore branch may provide to you. UAE: This information is being distributed by Credit Suisse AG (DIFC Branch), duly licensed and regulated by the Dubai Financial Services Authority ("DFSA"). Related financial services or products are only made available to Professional Clients or Market Counterparties, as defined by the DFSA, and are not intended for any other persons. Credit Suisse AG (DIFC Branch) is located on Level 9 East, The Gate Building, DIFC, Dubai, United Arab Emirates. UK: The protections made available by the Financial Conduct Authority and/or the Prudential Regulation Authority for retail clients do not apply to investments or services provided by a person outside the UK, nor will the Financial Services Compensation Scheme be available if the issuer of the investment fails to meet its obligations. To the extent communicated in the United Kingdom ("UK") or capable of having an effect in the UK, this document constitutes a financial promotion which has been approved by Credit Suisse (UK) Limited which is authorized by the Prudential Regulation Authority and regulated by the Financial Conduct Authority and the Prudential Regulation Authority for the conduct of investment business in the UK. The registered address of Credit Suisse (UK) Limited is Five Cabot Square, London, E14 4QR. Please note that the rules under the UK's Financial Services and Markets Act 2000 relating to the protection of retail clients will not be applicable to you and that any potential compensation made available to "eligible claimants" under the UK's Financial Services Compensation Scheme will also not be available to you. Tax treatment depends on the individual circumstances of each client and may be subject to changes in future EU: This report has been produced by subsidiaries and affiliates of Credit Suisse operating under its Global Markets Division and/or International Wealth Management Division.

This document may not be reproduced either in whole, or in part, without the written permission of the authors and Credit Suisse.
