

10-301/601: Introduction to Machine Learning

Lecture 14 – Societal Impacts of ML

Geoff Gordon

with thanks to Matt Gormley & Henry Chai

System

- We never use an ML model in isolation — it is always part of a larger system or context
- System could include
 - many people in many roles — user, client, bystander
 - many other pieces of software — incl other models
 - the physical world — buildings, cars, roads
- with many kinds of interaction among these parts

System

- We never use an ML model in isolation — it is always part of a larger system or context
- System could include
 - many people in many roles — user, client, bystander
 - many other pieces of software — incl other models
 - the physical world — buildings, cars, roads
- with many kinds of interaction among these parts

We often don't know all parts of the system to start, and we often can't fully predict effects of changes to the system

8 WAYS MACHINE LEARNING WILL IMPROVE EDUCATION

By [Claire Cain Miller](#)

Possible systems

- E.g., suppose we learn a language model: for tokens x_t that represent words, parts of words, or phrases, predict $P(x_T \mid x_1, x_2, \dots, x_{T-1})$ — what systems could this model be part of?

To influence a system, we run through an ML pipeline

To influence a system, we run through an ML pipeline

Narrow views

- Because systems are complex, researchers sometimes take too narrow a view of impact of ML
 - e.g., ignore some aspects of the system — maybe measure only properties of model, not its effect on the system
 - e.g., restrict to a few stages of ML pipeline
- Leads to unintended consequences

Unintended consequences

- For one of these systems what might be unintended consequences of changes to model?

It's hard to

...and lots more

Harmful speech	<i>Hate speech</i>: suggestions that could be perceived as hateful or that intend to intimidate or promote violence, against a group or its members. <i>Intimidates & promotes violence</i>: suggestions that may steer users towards acting violently or that aim to intimidate certain individuals. <i>Offensive speech</i>: suggestions that dehumanize, insult, or ridicule, actively seeking to embarrass or harm reputation. <i>Discriminatory speech</i>: suggestions showing known or existing bias, prejudice, or intolerance, perpetuating, employing negative stereotypes, or encouraging feelings of fear or disgust towards a group or individual. <i>Defamation & derogatory speech</i>: suggestions that defame someone by suggesting negative associations, including suggestions of dishonesty or involvement in illicit activities. <i>Profane language</i>: suggestions including any sort of slurs, expletives, swear or curse words.
Potentially illicit	<i>Facilitates illicit activities</i>: suggestions condoning & constituting illicit speech, infringing on intellectual property, copyright rights or trademark agreements, or that facilitate or nudge users towards illicit activities. <i>Privacy breaching</i>: suggestions revealing unwanted details from someone's past or anything that may be construed as sensitive or personal information. <i>Terrorist or extremist propaganda</i>: suggestions that may steer or help users find extremist content related to terrorist or extremist activities like recruiting or sponsoring. <i>Defamation & derogatory speech</i>: See above. <i>Child abuse & pornography</i>: suggestions related to child abuse or child pornography.
Controversy, Misinformation, and Manipulation	<i>Controversial topics</i>: suggestions that seem to endorse one side of a known controversial debate. <i>Misinfo., disinfo. or misleading content</i>: suggestions that promote information that is factually incorrect, or that reinforce or nudge users towards conspiracy theories. <i>Coordinated attacks & suggestions manipulation</i>: suggestions that occur as a result of attempts to manipulate the search or suggestions results, such as by promoting certain businesses or by trying to affect someone's reputation.
Stereotypes & Bias	<i>Ideological bias</i>: suggestions that validate or endorse views that belong to certain ideological groups, or that promote stereotypical beliefs about an ideological group. <i>Systemically biased suggestions</i>: suggestions about certain topics that are systematically biased towards a group, reinforcing sensitive associations between the group & negative attributes or stereotypical beliefs. <i>Discriminatory speech</i>: See above. <i>Defamation & derogatory speech</i>: See above. <i>Offensive speech</i>: See above.
Adult queries	<i>Adult content</i>: suggestions that contain pornography-related terms or steer users towards pornographic/obscene content. <i>Child abuse</i>: See above.
Other types	<i>Animal cruelty</i>: suggestions that may steer users towards information about how to harm animals. <i>Self-harm and suicidal content</i>: suggestions that may steer someone towards hurting themselves. <i>Sensitive topics</i>: suggestions that may trigger memories of traumatic events or be considered sensitive or emotionally charged by certain groups due to historic or cultural reasons.

Worse yet, Goodhart's law

- When a measure becomes a target, it ceases to be a good measure [core idea is present in Goodhart, 1975]
 - We optimize our model for some performance measure P
 - Typically P isn't *quite* what we want
 - Interested parties exploit the difference — victim of our own success
- Another kind of unintended consequence

Worse yet, Goodhart's law

- When a measure becomes a target, it ceases to be a good measure [core idea is present in Goodhart, 1975]
- Ex: optimize ML model to predict length of hospital stay
- If medical professionals care about our predictions (maybe they influence insurance cost or hospital ratings)
 - they can game them: e.g., fudge a few features in medical record
 - or poison our data: transfer patients around, discharge and re-admit

What could
possibly go
wrong?

- Because it's so hard, *lots* of examples of problems

Echo chambers (ML systems reinforce beliefs or behaviors)

Racial bias is built into the design of pulse oximeters

Even if a system's predictions aren't directly biased, its *performance* might be biased

Gender and racial bias found in Amazon's facial recognition technology (again)

Research shows that Amazon's tech has a harder time identifying gender in darker-skinned and female faces

By **James Vincent** | Jan 25, 2019, 9:45am EST

Even if a system's predictions aren't directly biased, its *performance* might be biased

Gender and racial bias found in Amazon's facial recognition technology (again)

Research shows that Amazon's tech has a harder time identifying gender in darker-skinned and female faces

By **James Vincent** | Jan 25, 2019, 9:45am EST

“As facial recognition systems become more common, Amazon has emerged as a frontrunner in the field, courting customers around the US, including police departments and Immigration and Customs Enforcement (ICE).”

“And then the nightmare began,” says Guillermo Ibarrola, recalling his arrest at the crowded train station in the city center of Buenos Aires where we stand.

He points to the cameras at the end of the tracks, then his finger pans to a door at the edge of the large station hall of the heritage-listed building. “That’s where they kept me for six days.” He slept on bare concrete, in a small cell. The second night they gave him a blanket. “The facial recognition system identified me as a criminal,” he says. The crime he was alleged to have committed: “Armed robbery in a city where I had never been in my life. The possible sentence, they told me—up to 15 years.”

Source: <https://pulitzercenter.org/stories/twisted-eye-sky-over-buenos-aires>

Though the city’s facial recognition policy warns officers that the results of the technology are “nonscientific” and “should not be used as the sole basis for any decision,” Shute proceeded to build a case against one of the AI results: Christopher Gatlin, a 29-year-old father of four who had no apparent ties to the crime scene nor a history of violent offenses, as Shute would later acknowledge.

Arrested and jailed for a crime he says he didn’t commit, it would take Gatlin more than two years clear his name.

A Washington Post investigation into police use of facial recognition software found that law enforcement agencies across the nation are using the artificial intelligence tools in a way they were never intended to be used: as a shortcut to finding and charging suspects without other evidence.

FN rate: 37.40			FN rate: 27.99			FN rate: 47.72		

This is one possible definition of unfairness.

We'll explore a few others and see how they relate to one another.

Even without bias in the classifier, the system as a whole can be biased

“

However, when it came to race, judges appeared to misapply the AI guidance. Ho found judges generally sentenced Black and White defendants equally harshly based on their risk scores alone. But when the AI recommended probation for low-risk offenders, judges disproportionately declined to offer alternatives to incarceration for Black defendants.

As a result, similar Black offenders ended up with significantly fewer alternative punishments and longer average jail terms than their White counterparts — missing out on probation by 6% and receiving jail terms averaging a month longer.”

Source: <https://news.tulane.edu/pr/ai-sentencing-cut-jail-time-low-risk-offenders-study-finds-racial-bias-persisted>

Figure 1. Adoption of AI-Supported Risk Assessments in the U.S.

Source: https://papers.ssrn.com/sol3/papers.cfm?abstract_id=4533047

Deeper dive: measuring bias or fairness in a classifier

- A lot of interesting subtleties in this problem
- Easy to experiment with (only requires pre-collected datasets that exhibit biases)
- For this reason, very popular research focus (perhaps stealing attention from other important but harder to study problems)

Error rate

- So far we've tried to optimize error rate
 - or proxies such as log likelihood
- Can be problematic if
 - class imbalance
 - asymmetric costs
 - subpopulations with different behavior
 - ...

Different Types of Errors

confusion matrix

		Predicted Label	
		+1	-1
True label	+1	True positive (TP)	False negative (FN)
	-1	False positive (FP)	True negative (TN)

Different Types of Errors

confusion matrix

		Predicted Label		
		+1	-1	
True label	+1	True positive (TP)	False negative (FN)	Total positives (P) = TP + FN
	-1	False positive (FP)	True negative (TN)	Total negatives (N) = FP + TN

Different Types of Errors

confusion matrix

		Predicted Label		
		+1	-1	
True label	+1	True positive (TP)	False negative (FN)	Total positives (P) = TP + FN
	-1	False positive (FP)	True negative (TN)	Total negatives (N) = FP + TN
		Predicted positives (PP) = TP + FP	Predicted negatives (PN) = FN + TN	

Additional Performance Metrics

- Common ways to report more than just error rate
 - False positive rate (FPR) = $FP / N = FP / (FP + TN)$
 - False negative rate (FNR) = $FN / P = FN / (TP + FN)$
 - Positive predictive value (PPV) = $TP / PP = TP / (TP + FP)$
 - Negative predictive value (NPV) = $TN / PN = TN / (FN + TN)$
- And even more informative to report the above in chosen subsets of the data

Running Example

- Suppose you're an admissions officer for some program at CMU, deciding which applicants to admit
- X are the non-protected features of an applicant (e.g., standardized test scores, GPA, etc...)
- A is a protected feature (e.g. gender), usually categorical, i.e.,
 $A \in \{a_1, \dots, a_C\}$
- $h(X, A) \in \{+1, -1\}$ is your model's prediction, usually corresponding to some decision or action (e.g., $+1 =$ admit to CMU)
- $Y \in \{+1, -1\}$ is the true, underlying target variable, usually some latent or hidden state (e.g., $+1 =$ this applicant would be "successful" at CMU)

Asymmetric costs

- False positive: admit someone who won't succeed
- False negative: reject someone who would have succeeded
- Completely different consequences, no reason we would treat them the same

In subsets of data

- False positive:
 - admit a {female, male, latino, white, asian, ...} applicant who won't succeed
- False negative:
 - Reject a {female, male, latino, white, asian, ...} applicant who would have succeeded
- Societal and legal consequences are again different in different subpopulations

Attempt 0: Fairness through Unawareness

- Idea: build a model that only uses the non-protected features, X
- Achieves some notion of fairness:
 - “Similar” individuals will receive “similar” predictions
 - Two individuals who are identical except for their protected feature A would receive the same predictions

Attempt 0: Fairness through Unawareness

- Idea: build a model that only uses the non-protected features, X
- Achieves some notion of fairness:
 - “Similar” individuals will receive “similar” predictions
 - Two individuals who are identical except for their protected feature A would receive the same predictions
- Problem: the non-protected features X might give information about A
 - In general, X and A are *not* independent

Ex: statistical redlining

- Redlining: refusing loans based on address of applicant — end run around anti-discrimination laws
- Statistical redlining: letting a classifier learn that previous loan officers redlined — adds deniability

Healthcare risk algorithm had 'significant racial bias'

It reportedly underestimated health needs for black patients.

Jon Fingas, @jonfingas
10.26.19 in [Medicine](#)

“While it [the algorithm] didn't directly consider ethnicity, its emphasis on medical costs as bellwethers for health led to the code routinely underestimating the needs of black patients. A sicker black person would receive the same risk score as a healthier white person simply because of how much they could spend.”

Trying to achieve fairness

1. Pre-processing data
2. Additional constraints during training
3. Post-processing predictions

Premise for 1 and 2:
If your definition of fairness is satisfied in your training data, then most models will preserve that relationship.

Trying to achieve fairness

1. Pre-processing data
2. Additional constraints during training
3. Post-processing predictions

Premise for 1 and 2:
If your definition of fairness is satisfied in your training data, then most models will preserve that relationship.

All of these will **reduce accuracy** on the **training** set — why might this be OK?

Three Definitions of Fairness

- **Independence:**

- **Separation:**

- **Sufficiency:**

Three Definitions of Fairness

- Independence (selection rate parity): $h(X, A) \perp A$
- Separation:
- Sufficiency:

Independence

- Proportion of accepted applicants is the same for all genders

$$P(h(X, A) = +1 \mid A = a_i) = P(h(X, A) = +1 \mid A = a_j) \quad \forall a_i, a_j$$

or more generally,

$$P(h(X, A) = +1 \mid A = a_i) \approx P(h(X, A) = +1 \mid A = a_j) \quad \forall a_i, a_j$$

$$\frac{P(h(X, A) = +1 \mid A = a_i)}{P(h(X, A) = +1 \mid A = a_j)} \geq 1 - \epsilon \quad \forall a_i, a_j \text{ for some } \epsilon$$

Achieving Independence

- Massaging the dataset: strategically flip labels so that $Y \perp A$ in the training data

X	A	Y	Score	Y'
...	+1	+1	0.98	+1
	+1	+1	0.89	+1
	+1	+1	0.61	-1
	+1	-1	0.30	-1
	-1	+1	0.96	+1
	-1	-1	0.42	+1
	-1	-1	0.31	-1
	-1	-1	0.02	-1

Achieving Independence

- Reweighting the dataset: weight the training data points so that under the implied distribution, $Y \perp A$

X	A	Y	Score	Ω
...	+1	+1	0.98	1/12
	+1	+1	0.89	1/12
	+1	+1	0.61	1/12
	+1	-1	0.30	1/4
	-1	+1	0.96	1/4
	-1	-1	0.42	1/12
	-1	-1	0.31	1/12
	-1	-1	0.02	1/12

Achieving independence

- Constrain the training process:
 - if we predict too many positives in one class, add a penalty for predicting positive in that class
 - adjust penalty until we get parity

Achieving independence

- Post-process the classifier
 - Many classifiers work by testing $\text{score}_\theta(X, A) \geq \tau$
 - Use different thresholds τ_a for different subgroups
 - E.g., accept top X% of applicants in each subgroup

Independence

- Proportion of accepted applicants is the same for all genders

$$P(h(X, A) = +1 \mid A = a_i) = P(h(X, A) = +1 \mid A = a_j) \quad \forall a_i, a_j$$

or more generally,

$$P(h(X, A) = +1 \mid A = a_i) \approx P(h(X, A) = +1 \mid A = a_j) \quad \forall a_i, a_j$$

$$\frac{P(h(X, A) = +1 \mid A = a_i)}{P(h(X, A) = +1 \mid A = a_j)} \geq 1 - \epsilon \quad \forall a_i, a_j \text{ for some } \epsilon$$

Independence

- Proportion of accepted applicants is the same for all genders

$$P(h(X, A) = +1 \mid A = a_i) = P(h(X, A) = +1 \mid A = a_j) \quad \forall a_i, a_j$$

or more generally,

$$P(h(X, A) = +1 \mid A = a_i) \approx P(h(X, A) = +1 \mid A = a_j) \quad \forall a_i, a_j$$

$$\frac{P(h(X, A) = +1 \mid A = a_i)}{P(h(X, A) = +1 \mid A = a_j)} \geq 1 - \epsilon \quad \forall a_i, a_j \text{ for some } \epsilon$$

- Problem: permits laziness, i.e., a classifier that always predicts **+1** will achieve independence

Independence

- Proportion of accepted applicants is the same for all genders

$$P(h(X, A) = +1 \mid A = a_i) = P(h(X, A) = +1 \mid A = a_j) \quad \forall a_i, a_j$$

or more generally,

$$P(h(X, A) = +1 \mid A = a_i) \approx P(h(X, A) = +1 \mid A = a_j) \quad \forall a_i, a_j$$

$$\frac{P(h(X, A) = +1 \mid A = a_i)}{P(h(X, A) = +1 \mid A = a_j)} \geq 1 - \epsilon \quad \forall a_i, a_j \text{ for some } \epsilon$$

- Problem: permits laziness, i.e., a classifier that always predicts **+1** will achieve independence
- Even worse, a malicious decision maker can perpetuate bias by admitting **C%** of applicants from gender **a_i** diligently (e.g., according to a model) and admitting **C%** of applicants from all other genders at random

Three Definitions of Fairness

- **Independence (selection rate parity):** $h(X, A) \perp A$
 - Proportion of accepted applicants is the same for all genders
 - Permits laziness/is susceptible to adversarial decisions
- **Separation:**
- **Sufficiency:**

Three Definitions of Fairness

- **Independence (selection rate parity):** $h(X, A) \perp A$
 - Proportion of accepted applicants is the same for all genders
 - Permits laziness/is susceptible to adversarial decisions
- **Separation (equality of FPR and FNR):** $h(X, A) \perp A \mid Y$
- **Sufficiency:**

Separation

- Predictions and protected features can be correlated to the extent justified by the (latent) target variable

$$P(h(X, A) = +1 \mid Y = +1, A = a_i) = P(h(X, A) = +1 \mid Y = +1, A = a_j)$$

$$P(h(X, A) = +1 \mid Y = -1, A = a_i) = P(h(X, A) = +1 \mid Y = -1, A = a_j) \quad \forall a_i, a_j$$

Separation

- Predictions and protected features can be correlated to the extent justified by the (latent) target variable

$$P(h(X, A) = +1 \mid Y = +1, A = a_i) = P(h(X, A) = +1 \mid Y = +1, A = a_j)$$

$$P(h(X, A) = +1 \mid Y = -1, A = a_i) = P(h(X, A) = +1 \mid Y = -1, A = a_j) \quad \forall a_i, a_j$$

or equivalently, the model's true positive rate (TPR),

$P(h(X, A) = +1 \mid Y = +1)$, and false positive rate (FPR),

$P(h(X, A) = +1 \mid Y = -1)$, must be equal across groups

- Natural relaxations care about only one of these two

Achieving Separation

Definition: ROC curve

- For a score-based classifier, ROC curve plots $\text{TPR} = 1 - \text{FNR}$ against FPR at different thresholds τ

$$h(X, A) = \mathbb{I}(\text{score}_\theta(X, A) \geq \tau)$$

Achieving Separation

Definition: ROC curve

- Can achieve separation by using different thresholds for different groups, corresponding to where their ROC curves intersect

$$h(X, A) = \mathbb{I}(\text{score}_\theta(X, A) \geq \tau)$$

Separation

- Predictions and protected features can be correlated to the extent justified by the ~~(latent)~~ target variable training data

$$P(h(X, A) = -1 \mid Y = +1, A = a_i) = P(h(X, A) = -1 \mid Y = +1, A = a_j)$$

$$P(h(X, A) = +1 \mid Y = -1, A = a_i) = P(h(X, A) = +1 \mid Y = -1, A = a_j) \quad \forall a_i, a_j$$

or equivalently, the model's true positive rate (FNR),

$P(h(X, A) = -1 \mid Y = +1)$, and false positive rate (FPR),

$P(h(X, A) = +1 \mid Y = -1)$, must be equal across groups

Separation

- Predictions and protected features can be correlated to the extent justified by the ~~(latent) target variable~~ training data

$$P(h(X, A) = -1 \mid Y = +1, A = a_i) = P(h(X, A) = -1 \mid Y = +1, A = a_j)$$

$$P(h(X, A) = +1 \mid Y = -1, A = a_i) = P(h(X, A) = +1 \mid Y = -1, A = a_j) \quad \forall a_i, a_j$$

or equivalently, the model's true positive rate (FNR),

$P(h(X, A) = -1 \mid Y = +1)$, and false positive rate (FPR),

$P(h(X, A) = +1 \mid Y = -1)$, must be equal across groups

- Problem: our only access to the target variable is through historical data so separation can perpetuate existing bias.

Three Definitions of Fairness

- **Independence (selection rate parity):** $h(X, A) \perp A$
 - Proportion of accepted applicants is the same for all genders
 - Permits laziness/is susceptible to adversarial decisions
- **Separation (equality of FPR and FNR):** $h(X, A) \perp A \mid Y$
 - All “good” applicants are accepted with the same probability, regardless of gender
 - Perpetuates existing biases in the training data
- **Sufficiency:**

Three Definitions of Fairness

- **Independence (selection rate parity):** $h(X, A) \perp A$
 - Proportion of accepted applicants is the same for all genders
 - Permits laziness/is susceptible to adversarial decisions
- **Separation (equality of FPR and FNR):** $h(X, A) \perp A \mid Y$
 - All “good” applicants are accepted with the same probability, regardless of gender
 - Perpetuates existing biases in the training data
- **Sufficiency (equality of PPV and NPV):** $Y \perp A \mid h(X, A)$

Sufficiency

- Knowing the prediction is *sufficient* for decorrelating the (latent) target variable and the protected feature

$$P(Y = +1 \mid h(X, A) = +1, A = a_i) = P(Y = +1 \mid h(X, A) = +1, A = a_j)$$

$$P(Y = +1 \mid h(X, A) = -1, A = a_i) = P(Y = +1 \mid h(X, A) = -1, A = a_j) \quad \forall a_i, a_j$$

Sufficiency

- Knowing the prediction is *sufficient* for decorrelating the (latent) target variable and the protected feature

$$P(Y = +1 \mid h(X, A) = +1, A = a_i) = P(Y = +1 \mid h(X, A) = +1, A = a_j)$$

$$P(Y = +1 \mid h(X, A) = -1, A = a_i) = P(Y = +1 \mid h(X, A) = -1, A = a_j) \quad \forall a_i, a_j$$

If a model uses some score to make predictions, then that score is *calibrated across groups* if

$$P(Y = +1 \mid \text{SCORE}, A = a_i) = \text{SCORE} \quad \forall a_i$$

Sufficiency

- Knowing the prediction is *sufficient* for decorrelating the (latent) target variable and the protected feature

$$P(Y = +1 \mid h(X, A) = +1, A = a_i) = P(Y = +1 \mid h(X, A) = +1, A = a_j)$$

$$P(Y = +1 \mid h(X, A) = -1, A = a_i) = P(Y = +1 \mid h(X, A) = -1, A = a_j) \quad \forall a_i, a_j$$

If a model uses some score to make predictions, then that score is *calibrated across groups* if

$$P(Y = +1 \mid \text{SCORE}, A = a_i) = \text{SCORE} \quad \forall a_i$$

A model being calibrated across groups implies sufficiency

Sufficiency

- Knowing the prediction is *sufficient* for decorrelating the (latent) target variable and the protected feature

$$P(Y = +1 \mid h(X, A) = +1, A = a_i) = P(Y = +1 \mid h(X, A) = +1, A = a_j)$$

$$P(Y = +1 \mid h(X, A) = -1, A = a_i) = P(Y = +1 \mid h(X, A) = -1, A = a_j) \quad \forall a_i, a_j$$

If a model uses some score to make predictions, then that score is *calibrated across groups* if

$$P(Y = +1 \mid \text{SCORE}, A = a_i) = \text{SCORE} \quad \forall a_i$$

A model being calibrated across groups implies sufficiency

- In general, most off-the-shelf ML models can achieve sufficiency without intervention

Three Definitions of Fairness

- **Independence (selection rate parity):** $h(X, A) \perp A$
 - Proportion of accepted applicants is the same for all genders
 - Permits laziness/is susceptible to adversarial decisions
- **Separation (equality of FPR and FNR):** $h(X, A) \perp A \mid Y$
 - All “good”/”bad” applicants are accepted with the same probability, regardless of gender
 - Perpetuates existing biases in the training data
- **Sufficiency (equality of PPV and NPV):** $Y \perp A \mid h(X, A)$
 - For the purposes of predicting Y , the information contained in $h(X, A)$ is “sufficient”, A becomes irrelevant

Three Definitions of Fairness

- **Independence (selection rate parity):** $h(X, A) \perp A$
 - Proportion of accepted applicants is the same for all genders
 - Permits laziness/is susceptible to adversarial decisions
- **Separation (equality of FPR and FNR):** $h(X, A) \perp A \mid Y$
 - All “good”/”bad” applicants are accepted with the same probability, regardless of gender
 - Perpetuates existing biases in the training data
- **Sufficiency (equality of PPV and NPV):** $Y \perp A \mid h(X, A)$
 - For the purposes of predicting Y , the information contained in $h(X, A)$ is “sufficient”, A becomes irrelevant

Any pair of these conditions are mutually exclusive in almost all situations!

Many Definitions of Fairness (Barocas et al., 2019)

Name	Closest relative	Note
Statistical parity	Independence	Equivalent
Group fairness	Independence	Equivalent
Demographic parity	Independence	Equivalent
Conditional statistical parity	Independence	Relaxation
Darlington criterion (4)	Independence	Equivalent
Equal opportunity	Separation	Relaxation
Equalized odds	Separation	Equivalent
Conditional procedure accuracy	Separation	Equivalent
Avoiding disparate mistreatment	Separation	Equivalent
Balance for the negative class	Separation	Relaxation
Balance for the positive class	Separation	Relaxation
Predictive equality	Separation	Relaxation
Equalized correlations	Separation	Relaxation
Darlington criterion (3)	Separation	Relaxation
Cleary model	Sufficiency	Equivalent
Conditional use accuracy	Sufficiency	Equivalent
Predictive parity	Sufficiency	Relaxation
Calibration within groups	Sufficiency	Equivalent
Darlington criterion (1), (2)	Sufficiency	Relaxation

Key takeaways / learning objectives

- High-profile cases of algorithmic bias and unintended consequences are increasingly common as machine learning is applied more broadly in a variety of contexts
- To prevent or fix, need to look at entire system and entire training pipeline
- Various definitions of fairness [of just the inner classifier]
 - Selection rate parity (Independence): $h(X, A) \perp A$
 - Equality of FPR and FNR (Separation): $h(X, A) \perp A \mid Y$
 - Equality of PPV and NPV (Sufficiency): $Y \perp A \mid h(X, A)$
- In all but the simplest of cases, any two of these three are mutually exclusive
