

# Observation of excited $\Lambda_b^0$ baryons

The LHCb collaboration <sup>†</sup>

## Abstract

Using  $pp$  collision data corresponding to  $1.0 \text{ fb}^{-1}$  integrated luminosity collected by the LHCb detector, two narrow states are observed in the  $\Lambda_b^0 \pi^+ \pi^-$  spectrum with masses  $5911.97 \pm 0.12(\text{stat}) \pm 0.02(\text{syst}) \pm 0.66(\Lambda_b^0 \text{ mass}) \text{ MeV}/c^2$  and  $5919.77 \pm 0.08(\text{stat}) \pm 0.02(\text{syst}) \pm 0.66(\Lambda_b^0 \text{ mass}) \text{ MeV}/c^2$ . The significances of the observations are 5.2 and 10.2 standard deviations, respectively. These states are interpreted as the orbitally excited  $\Lambda_b^0$  baryons,  $\Lambda_b^{*0}(5912)$  and  $\Lambda_b^{*0}(5920)$ .

To be submitted to Phys. Rev. Lett.

1 The system of baryons containing a  $b$  quark (beauty baryons) remains largely unex-  
 2 plored, despite recent progress made at the experiments at the Tevatron. In addition to  
 3 the ground state,  $\Lambda_b^0$ , the  $\Xi_b^-$  baryon with the quark content  $bsd$  has been observed by  
 4 the D0 [1] and CDF [2] collaborations, followed by the observation of the doubly-strange  
 5  $\Omega_b^-$  baryon ( $bsb$ ) [3, 4]. The last ground state of beauty-strange content,  $\Xi_b^0$  ( $bsu$ ), has  
 6 been observed by CDF [5]. Recently, the CMS collaboration has found the corresponding  
 7 excited state, most likely  $\Xi_b^{*0}$  with  $J^P = 3/2^+$  [6]. Beauty baryons with two light quarks  
 8 ( $bqq$ , where  $q = u, d$ ), other than the  $\Lambda_b^0$ , have been studied so far by CDF only. Of the  
 9 triplets  $\Sigma_b^{\pm,0}$  with spin  $J = 1/2$  and  $\Sigma_b^{*\pm,0}$  with  $J = 3/2$  predicted by theory, only the  
 10 charged states  $\Sigma_b^{(*)\pm}$  have so far been observed via their decay to  $\Lambda_b^0\pi^\pm$  final states [7, 8].  
 11 None of the quantum numbers of beauty baryons have been measured.

12 The quark model predicts the existence of two orbitally excited  $\Lambda_b^0$  states,  $\Lambda_b^{*0}$ , with  
 13 the quantum numbers  $J^P = 1/2^-$  and  $3/2^-$ , respectively, that should decay to  $\Lambda_b^0\pi^+\pi^-$  or  
 14  $\Lambda_b^0\gamma$ . These states have not previously been established experimentally. The properties of  
 15 excited  $\Lambda_b^0$  baryons are discussed in Refs. [9–15]. Most predictions give masses above the  
 16  $\Lambda_b^0\pi^+\pi^-$  threshold, but below the  $\Sigma_b\pi$  threshold. Observation of  $\Lambda_b^{*0}$  states and measure-  
 17 ment of their quantum numbers would provide a further confirmation of the validity of  
 18 the quark model, and the precise measurement of their masses would test the applicability  
 19 of various theoretical models used to describe the interaction of heavy quarks.

20 This Letter reports the first observation of the  $\Lambda_b^{*0}$  states decaying into  $\Lambda_b^0\pi^+\pi^-$ , and  
 21 the measurement of their masses and upper limits on their natural widths. The data  
 22 set of  $1.0 \text{ fb}^{-1}$  collected in  $pp$  collisions at the LHC collider at the center-of-mass energy  
 23  $\sqrt{s} = 7 \text{ TeV}$  in 2011 is used for the analysis.

24 The LHCb detector [16] is a single-arm forward spectrometer covering the pseudo-  
 25 rapidity range  $2 < \eta < 5$ , designed for the study of particles containing  $b$  or  $c$  quarks.  
 26 The detector includes a high precision tracking system consisting of a silicon-strip vertex  
 27 detector surrounding the  $pp$  interaction region, a large-area silicon-strip detector located  
 28 upstream of a dipole magnet with a bending power of about 4 Tm, and three stations  
 29 of silicon-strip detectors and straw drift tubes placed downstream. The combined track-  
 30 ing system has a momentum resolution  $\Delta p/p$  that varies from 0.4% at 5 GeV/ $c$  to 0.6%  
 31 at 100 GeV/ $c$ , and an impact parameter (IP) resolution of 20  $\mu\text{m}$  for tracks with high  
 32 transverse momentum. Charged hadrons are identified using two ring-imaging Cherenkov  
 33 (RICH) detectors. Photon, electron and hadron candidates are identified by a calorime-  
 34 ter system consisting of scintillating-pad and preshower detectors, an electromagnetic  
 35 calorimeter and a hadronic calorimeter. Muons are identified by a muon system com-  
 36 posed of alternating layers of iron and multiwire proportional chambers.

37 The online event selection (trigger) consists of a hardware stage, based on information  
 38 from the calorimeter and muon systems, followed by a software stage which applies full  
 39 event reconstruction. The software trigger used in this analysis requires a two-, three- or  
 40 four-track secondary vertex with a high sum of the momenta transverse to the beam axis,  
 41  $p_T$ , of the tracks, and significant displacement from the primary interaction vertex (PV).  
 42 In addition, the secondary vertex should have at least one track with  $p_T > 1.7 \text{ GeV}/c$ , IP  
 43  $\chi^2$  with respect to any PV greater than 16 (where the IP  $\chi^2$  is defined as the difference

44 of the PV fit  $\chi^2$  with and without the track included), and a track fit  $\chi^2/\text{ndf} < 2$  where  
 45 ndf is the number of degrees of freedom in the fit. A multivariate algorithm is used for  
 46 the identification of the secondary vertices [17].

47 The  $\Lambda_b^0$  candidates are reconstructed in the  $\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-$ ,  $\Lambda_c^+ \rightarrow p K^- \pi^+$  decay chain  
 48 (addition of charge-conjugate states is implied throughout this Letter). The selection of  
 49  $\Lambda_b^0$  candidates is performed in two stages. First, a loose preselection of events containing  
 50 beauty hadron candidates decaying to charm hadron candidates is performed. It requires  
 51 that the tracks forming the candidate, as well as the beauty and charm vertices, have  
 52 good quality and are well separated from any PV, and the invariant masses of the beauty  
 53 and charm candidates are consistent with the masses of the corresponding particles.

54 The final selection requires that all the tracks forming the  $\Lambda_b^0$  candidate have an IP  
 55  $\chi^2$  with respect to any PV greater than 9, and the IP  $\chi^2$  of the  $\Lambda_b^0$  candidate to the  
 56 best PV (PV having the minimum IP  $\chi^2$  for the  $\Lambda_b^0$  candidate) is less than 16. Particle  
 57 identification (PID) information from the RICH detectors is used to identify kaons and  
 58 protons in the final state in the form of differences of logarithms of likelihoods between the  
 59 proton and pion ( $\text{DLL}_{p\pi}$ ) and kaon and pion ( $\text{DLL}_{K\pi}$ ) hypotheses. No PID requirements  
 60 are applied to the pions from  $\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-$  decays to increase the  $\Lambda_b^0$  yield: a significant  
 61 fraction of these pions have momenta above 100 GeV/c where the PID performance is  
 62 reduced. Finally, a kinematic fit is used which constrains the decay products of the  $\Lambda_b^0$   
 63 and  $\Lambda_c^+$  baryons to originate from common vertices, the  $\Lambda_b^0$  to originate from the PV and  
 64 the invariant mass of the  $\Lambda_c^+$  candidate to be equal to the established  $\Lambda_c^+$  mass [18].

65 A momentum scale correction is applied to all invariant mass spectra in this analysis  
 66 to improve the mass measurement using the procedure similar to [19]. The momentum  
 67 scale has been calibrated using  $J/\psi \rightarrow \mu^+ \mu^-$  decays, and its accuracy has been quantified  
 68 with other two-body resonance decays ( $\Upsilon(1S) \rightarrow \mu^+ \mu^-$ ,  $K_s^0 \rightarrow \pi^+ \pi^-$ ,  $\phi \rightarrow K^+ K^-$ ).

69 Signal and background distributions are studied using simulation. Proton-proton collisions  
 70 are generated using PYTHIA 6.4 [20] with a specific LHCb configuration [21]. Decays  
 71 of hadronic particles are described by EVTGEN [22] in which final state radiation is gener-  
 72 ated using PHOTOS [23]. The interaction of the generated particles with the detector  
 73 and its response are implemented using the GEANT4 toolkit [24] as described in Ref. [25].

74 The distribution of the  $\Lambda_c^+ \pi^-$  invariant mass after the kinematic fit is shown in Fig. 1,  
 75 where a requirement of good quality of the kinematic fit is applied. In addition to the  $\Lambda_b^0 \rightarrow$   
 76  $\Lambda_c^+ \pi^-$  signal contribution, the spectrum contains backgrounds from random combinations  
 77 of tracks (random background), from partially-reconstructed decays where one or more  
 78 particles are not reconstructed, and from  $\Lambda_b^0 \rightarrow \Lambda_c^+ K^-$  decays with the kaon reconstructed  
 79 under the pion mass hypothesis. A fit of the spectrum yields  $70\,540 \pm 330$  signal events,  
 80 and the signal-to-background ratio in a  $\pm 25$  MeV/ $c^2$  interval around the nominal  $\Lambda_b^0$  mass  
 81 is  $S/B = 11$ . The fit to the  $\Lambda_c^+ \pi^-$  spectrum is only used to estimate the  $\Lambda_b^0$  yield and the  
 82  $\Lambda_b^0 \rightarrow \Lambda_c^+ K^-$  contribution, and is not used in the subsequent analysis.

83 The  $\Lambda_b^0$  candidates obtained with the above selection are combined with two tracks under  
 84 the pion mass hypothesis (referred to as slow pions from now on) to search for excited  
 85  $\Lambda_b^0$  states. The tracks are required to have transverse momentum  $p_T > 150$  MeV/ $c$ , and no  
 86 PID requirements are applied. A kinematic fit is applied that, in addition to all constraints

Figure 1: Invariant mass spectrum of  $\Lambda_c^+\pi^-$  combinations. The points with error bars are the data, and the fitted  $\Lambda_b^0 \rightarrow \Lambda_c^+\pi^-$  signal and three background components ( $\Lambda_b^0 \rightarrow \Lambda_c^+K^-$ , partially-reconstructed and random background) are shown with different fill styles.

87 described above for  $\Lambda_b^0$  candidates, constrains the two slow pion tracks to originate from  
 88 the PV and the invariant mass of the  $\Lambda_b^0$  candidate to a fixed value of  $5619.37 \text{ MeV}/c^2$ ,  
 89 which is a combination of the world average [18] and the LHCb measurement [26]. The  
 90 uncertainty on the combined  $\Lambda_b^0$  mass obtained in this way,  $0.69 \text{ MeV}/c^2$ , is treated as a  
 91 systematic effect. Combinations with a good quality of kinematic fit,  $\chi^2/\text{ndf} < 3.3$ , are  
 92 retained. From the simulation study, this requirement is optimal for the observation of a  
 93 narrow state near the kinematic threshold with signal-to-background ratio around one.

94 The fit of the  $\Lambda_c^+\pi^-$  mass spectrum (Fig. 1) indicates the presence of the background  
 95 from  $\Lambda_b^0 \rightarrow \Lambda_c^+K^-$  decays at a rate around 12%, relative to the  $\Lambda_b^0 \rightarrow \Lambda_c^+\pi^-$  signal.  
 96 Alternatively, its rate can be estimated from the ratio of  $B^+ \rightarrow \bar{D}^0K^+$  and  $B^+ \rightarrow \bar{D}^0\pi^+$   
 97 decays that equals to 8% [18]. Due to the  $\Lambda_b^0$  mass constraint in the kinematic fit, the  
 98  $\Lambda_b^0\pi^+\pi^-$  invariant mass distribution for this mode is biased by less than  $0.1 \text{ MeV}/c^2$  if  
 99 reconstructed under the  $\Lambda_c^+\pi^-$  mass hypothesis, and has a resolution only a factor of two  
 100 worse than that with the  $\Lambda_c^+\pi^-$  signal. After the kinematic fit quality requirement, the  
 101 fraction of  $\Lambda_b^0\pi^+\pi^-$  with  $\Lambda_b^0 \rightarrow \Lambda_c^+K^-$  decays compared to those with the  $\Lambda_c^+\pi^-$  is reduced  
 102 to 8%. This mode is thus not treated separately, and its effect is taken into account as a  
 103 part of the systematic uncertainty due to the signal shape.

104 Combinations of  $\Lambda_b^0$  candidates with both opposite-sign and same-sign slow pions are  
 105 selected in data. The latter are used to constrain the background shape coming from  
 106 random combinations of  $\Lambda_b^0$  baryon and two tracks. The assumption that the shape of the  
 107 background in  $\Lambda_b^0\pi^+\pi^-$  and  $\Lambda_b^0\pi^\pm\pi^\pm$  modes is the same is validated with simulation. The  
 108  $\Lambda_b^0\pi^+\pi^-$  and  $\Lambda_b^0\pi^\pm\pi^\pm$  invariant mass spectra are shown in Fig. 2; two narrow structures  
 109 with masses around  $5912$  and  $5920 \text{ MeV}/c^2$  are evident in the  $\Lambda_b^0\pi^+\pi^-$  spectrum. They

110 are interpreted as the orbitally excited  $A_b^0$  states, and are denoted hereafter as  $A_b^{*0}(5912)$   
 111 and  $A_b^{*0}(5920)$ .

112 A combined unbinned fit of the  $A_b^0\pi^+\pi^-$  and  $A_b^0\pi^\pm\pi^\pm$  samples is performed to ex-  
 113 tract the masses and event yields of the two states. The background is described with a  
 114 quadratic polynomial function with common parameters for both samples except for an  
 115 overall normalization. The probability density function (PDF) for each of the  $A_b^{*0}(5912)$   
 116 and  $A_b^{*0}(5920)$  signals is a sum of two Gaussian PDFs with the same mean. The rela-  
 117 tive normalization of the two Gaussian PDFs are fixed to the values obtained from the  
 118 simulation of states with masses 5912 and 5920 MeV/ $c^2$  and zero natural widths, while  
 119 the mean value and overall normalization for each signal are left free in the fit. The core  
 120 resolution (width of the narrower Gaussian PDF) obtained from simulation is 0.19 and  
 121 0.27 MeV/ $c^2$  for  $A_b^{*0}(5912)$  and  $A_b^{*0}(5920)$ , respectively. Study of several high-statistics  
 122 samples ( $A_b^0 \rightarrow A_c^+\pi^-$ ,  $\psi(2S) \rightarrow J/\psi\pi^+\pi^-$ ,  $D^{*+} \rightarrow D^0\pi^+$ ) shows that the invariant mass  
 123 resolution in data is typically worse by 20% than in the simulation. Thus the nominal data  
 124 fit uses the widths of Gaussian PDFs from the simulation multiplied by 1.2. The data  
 125 fit yields  $17.6 \pm 4.8$  events with mass  $M_{A_b^{*0}(5912)} = 5911.97 \pm 0.12$  MeV/ $c^2$  and  $52.5 \pm 8.1$   
 126 events with mass  $M_{A_b^{*0}(5920)} = 5919.77 \pm 0.08$  MeV/ $c^2$ .

127 Limits on natural widths  $\Gamma$  of the two states are obtained by performing an alternative  
 128 fit where the signal PDFs are convolved with relativistic Breit-Wigner distributions. The  
 129 dependence of Breit-Wigner width  $\Gamma$  on the  $A_b^0\pi^+\pi^-$  invariant mass  $M$  is taken into  
 130 account as  $\Gamma_{A_b^{*0}}(M) = \Gamma_{A_b^{*0}} \times (q/q_0)^2 \times (M_{A_b^{*0}}/M)$ . Here  $M_{A_b^{*0}}$  is the mass of the  $A_b^{*0}$   
 131 state, and  $q_{(0)}$  is the kinematic energy for the decay of the state with mass  $M_{(A_b^{*0})}$ :  $q_{(0)} =$   
 132  $M_{(A_b^{*0})} - M_{A_b^0} - 2M_\pi$ , where  $M_{A_b^0}$  and  $M_\pi$  are the masses of  $A_b^0$  and  $\pi^+$ , respectively.  
 133 Scans of Breit-Wigner widths  $\Gamma_{A_b^{*0}(5912)}$  and  $\Gamma_{A_b^{*0}(5920)}$  are performed with all the other  
 134 parameters free to vary in the fit. The upper limits are obtained without applying the  
 135 mass resolution scaling factor of 1.2 as in the nominal fit to account for the uncertainty  
 136 of this quantity: this gives a more conservative value for the upper limit. The 90%  
 137 (95%) confidence level (CL) upper limit on  $\Gamma$ , which corresponds to 1.28 (1.64) standard  
 138 deviations, is obtained as the value of  $\Gamma$  where the negative logarithm of the likelihood  
 139 is  $1.28^2/2 = 0.82$  ( $1.64^2/2 = 1.34$ ) greater than at its minimum. The 90% (95%) CL  
 140 upper limit is  $\Gamma_{A_b^{*0}(5912)} < 0.66$  MeV (0.83 MeV) for the  $A_b^{*0}(5912)$  state, and  $\Gamma_{A_b^{*0}(5920)} <$   
 141  $0.63$  MeV (0.75 MeV) for the  $A_b^{*0}(5920)$  state.

142 The invariant mass of the two pions,  $M(\pi^+\pi^-)$ , in the  $A_b^{*0}(5920) \rightarrow A_b^0\pi^+\pi^-$  decay  
 143 is shown in Fig. 3. The background is subtracted using the *sWeights* procedure [27].  
 144 The weights are calculated from the fit to  $A_b^0\pi^+\pi^-$  invariant mass distribution, which is  
 145 practically uncorrelated with  $M(\pi^+\pi^-)$ . The  $M(\pi^+\pi^-)$  distribution is consistent with  
 146 the result of phase-space decay simulation, with  $\chi^2/\text{ndf} = 1.6$  for  $\text{ndf} = 9$ . No peaking  
 147 structures are evident.

148 Systematic uncertainties on the mass measurement are shown in Table 1. The  
 149 dominant uncertainty in the absolute  $A_b^{*0}$  mass measurement comes from the uncer-  
 150 tainty on the  $A_b^0$  mass  $\delta M_{A_b^0} = 0.69$  MeV/ $c^2$ ; it is propagated to the  $A_b^{*0}$  mass un-  
 151 certainty as  $\delta M_{A_b^{*0}} = \delta M_{A_b^0} \times (M_{A_b^0}/M_{A_b^{*0}}) \simeq 0.66$  MeV/ $c^2$ . This uncertainty mostly

Figure 2: Invariant mass spectrum of (a)  $\Lambda_b^0 \pi^+ \pi^-$  and (b)  $\Lambda_b^0 \pi^\pm \pi^\pm$  combinations. The points with error bars are the data, the solid line is the fit result, the dashed line is the background contribution.

152 cancels in the mass difference  $\Delta M_{\Lambda_b^{*0}} = M_{\Lambda_b^{*0}} - M_{\Lambda_b^0}$ , where the residual uncertainty is  
 153  $\delta \Delta M_{\Lambda_b^{*0}} = \delta M_{\Lambda_b^0} \times (\Delta M_{\Lambda_b^0} / M_{\Lambda_b^{*0}})$ . The uncertainty of the signal parameterization is es-  
 154 timated by using the simulated signal parameterization without applying the resolution  
 155 scaling factor, by using the natural width for both states when left free in the fit, and by  
 156 conservatively including the  $\Lambda_b^0 \rightarrow \Lambda_c^+ K^-$  contribution with the rate 12% parameterized  
 157 from simulation. The uncertainty due to the background parameterization is estimated  
 158 by:

- 159
- using an alternative fit model for background description,

160

  - using the fit without the  $\Lambda_b^0 \pi^\pm \pi^\pm$  constraint,

161

  - using the fit with the background obtained from the simulation,

Figure 3: Invariant mass of the two pions from  $\Lambda_b^{*0}(5920) \rightarrow \Lambda_b^0 \pi^+ \pi^-$  decay. The points with the error bars are background-subtracted data, the solid histogram is the result of phase-space decay simulation.

Table 1: Systematic uncertainties on the mass difference  $\Delta M_{\Lambda_b^{*0}}$  between  $\Lambda_b^{*0}$  and  $\Lambda_b^0$ .

Source of uncertainty	Systematic bias, $\text{MeV}/c^2$	
	$\Delta M_{\Lambda_b^{*0}(5912)}$	$\Delta M_{\Lambda_b^{*0}(5920)}$
$\Lambda_b^0$ mass	0.034	0.035
Signal PDF	0.021	0.011
Background PDF	0.002	0.002
Momentum scale	0.008	0.013
Total	0.041	0.039

162 • fitting in the reduced invariant mass range 5910–5930  $\text{MeV}/c^2$ ,

163 and taking the largest difference from the nominal fit result as systematic uncertainty.  
 164 The effect of the momentum scale correction is evaluated by varying the scale coefficient  
 165 by its relative uncertainty  $5 \times 10^{-4}$  in simulated signal samples.

166 The significance of the observation of the two states is evaluated with simulated  
 167 pseudo-experiments. A large number of background-only invariant mass distributions  
 168 are simulated with parameters equal to the fit result, and each distribution is fitted with  
 169 models that include background only, as well as background and signal. The mean mass  
 170 value of the signal PDF is not constrained in the fit to account for a trial factor in the  
 171 range 5900–5950  $\text{MeV}/c^2$ . The significance is calculated as the fraction of samples where

172 the difference of the logarithms of fit likelihoods  $\Delta \log \mathcal{L}$  with and without the signal  
 173 is larger than in data. The fraction is obtained by an exponential extrapolation of the  
 174  $\Delta \log \mathcal{L}$  distribution [28] that allows a limited number of pseudo-experiments to be used  
 175 for a signal with high significance. The significance is then expressed in terms of the  
 176 number of standard deviations ( $\sigma$ ). The significance of the  $\Lambda_b^{*0}(5912)$  state obtained in  
 177 this way is  $5.4\sigma$  for the  $\Delta \log \mathcal{L}$  obtained from the nominal fit. To account for systematic  
 178 effects, the minimum  $\Delta \log \mathcal{L}$  among all systematic variations is taken; in that case the  
 179 significance reduces to  $5.2\sigma$ . Similarly, the statistical significance of the  $\Lambda_b^{*0}(5920)$  state  
 180 is  $11.7\sigma$ , and the significance including systematic uncertainties is  $10.2\sigma$ .

181 The fit biases and the validity of the statistical uncertainties are checked with pseudo-  
 182 experiments where the PDF contains both signal and background components. The fit  
 183 does not introduce any noticeable bias on the measurement of the masses. The mass  
 184 uncertainty for  $\Lambda_b^{*0}(5920)$  state is estimated correctly within 1% precision; however, the  
 185 mass uncertainty for the  $\Lambda_b^{*0}(5912)$  is underestimated by 4%. This factor is taken into  
 186 account in the final result.

187 In summary, we report the observation of two narrow states in the  $\Lambda_b^0 \pi^+ \pi^-$  mass  
 188 spectrum,  $\Lambda_b^{*0}(5912)$  and  $\Lambda_b^{*0}(5920)$ , with masses

$$M_{\Lambda_b^{*0}(5912)} = 5911.97 \pm 0.12 \pm 0.02 \pm 0.66 \text{ MeV}/c^2,$$

$$M_{\Lambda_b^{*0}(5920)} = 5919.77 \pm 0.08 \pm 0.02 \pm 0.66 \text{ MeV}/c^2,$$

189 where the first uncertainty is statistical, the second is systematic, and the third is the  
 190 uncertainty due to knowledge of the  $\Lambda_b^0$  mass. The values of the mass differences with  
 191 respect to the  $\Lambda_b^0$  mass, where most of the last uncertainty cancels, and the remaining  
 192 part is included in the systematic uncertainty, are

$$\Delta M_{\Lambda_b^{*0}(5912)} = 292.60 \pm 0.12(\text{stat}) \pm 0.04(\text{syst}) \text{ MeV}/c^2,$$

$$\Delta M_{\Lambda_b^{*0}(5920)} = 300.40 \pm 0.08(\text{stat}) \pm 0.04(\text{syst}) \text{ MeV}/c^2.$$

193 The signal yield for the  $\Lambda_b^{*0}(5912)$  state is  $17.6 \pm 4.8$  events, and the significance of  
 194 the signal (including systematic uncertainty and trial factor in the mass range 5900–  
 195 5950  $\text{MeV}/c^2$ ) is 5.2 standard deviations. For the  $\Lambda_b^{*0}(5920)$  state, the yield is  $52.5 \pm 8.1$   
 196 events and the significance is 10.2 standard deviations. The limits on the natural widths of  
 197 these states are  $\Gamma_{\Lambda_b^{*0}(5912)} < 0.66 \text{ MeV}$  ( $< 0.83 \text{ MeV}$ ) and  $\Gamma_{\Lambda_b^{*0}(5920)} < 0.63 \text{ MeV}$  ( $< 0.75$ )  
 198 at the 90% (95%) CL.

199 The masses of  $\Lambda_b^{*0}$  states obtained in our analysis are 30–40  $\text{MeV}/c^2$  higher than in  
 200 the prediction using the constituent quark model [12], and 20–30  $\text{MeV}/c^2$  lower than the  
 201 predictions based on the relativistic quark model [11], modeling the color hyperfine inter-  
 202 action [14] and an approach based on the heavy quark effective theory [15]. Calculation  
 203 involving a combined heavy quark and large number of colors expansion [9, 10] gives a  
 204 value roughly in agreement, although only the spin-averaged prediction is available. The  
 205 earlier prediction based on the relativized quark potential model [13] matches well the  
 206 absolute mass values for both states, but the  $\Lambda_b^0$  mass prediction using this model is  
 207 35  $\text{MeV}/c^2$  lower than the measured value.

208 We express our gratitude to our colleagues in the CERN accelerator departments for  
 209 the excellent performance of the LHC. We thank the technical and administrative staff at  
 210 CERN and at the LHCb institutes, and acknowledge support from the National Agencies:  
 211 CAPES, CNPq, FAPERJ and FINEP (Brazil); CERN; NSFC (China); CNRS/IN2P3  
 212 (France); BMBF, DFG, HGF and MPG (Germany); SFI (Ireland); INFN (Italy); FOM  
 213 and NWO (The Netherlands); SCSR (Poland); ANCS (Romania); MinES of Russia and  
 214 Rosatom (Russia); MICINN, XuntaGal and GENCAT (Spain); SNSF and SER (Switzer-  
 215 land); NAS Ukraine (Ukraine); STFC (United Kingdom); NSF (USA). We also acknowl-  
 216 edge the support received from the ERC under FP7 and the Region Auvergne.
