HL-LHC OPERATIONAL SCENARIOS

G. Arduini, D. Banfi, J. Barranco, N. Biancacci, O. Brüning, R. De Maria, M. Giovannozzi, W. Höfle, K. Li, E. Métral, J.E. Muller, Y. Papaphilippou, T. Pieloni, B. Salvant, E. Shaposhnikova, C. Tambasco, A. Valishev, D. Valuch, A. Wolski

The main aim of this document is to have a clearly identified set of beam and machine parameters to be used for numerical simulations.

Two scenarios are discussed [1]:

- i) Baseline scenario.
- ii) Ultimate scenario.

For both scenarios the main assumptions are [1]:

- i) New Mo-Gr collimators with a 5 μm Mo coating are installed, in LSS7 only.
- ii) Levelling with parallel separation in IP8.
- iii) Few non-colliding bunches for the experiments (for background studies).
- iv) Crab cavities are active providing full compensation of the crossing angle in IP1 and IP5. Reduction of the impedance of the Crab Cavities to the required level (and good control of the impedance of new equipment, in particular at large β values).
- v) All the existing circuits should operate at their nominal performance (e.g. non-conformities observed so far should be repaired by Run 4).

Parameters at SPS ¹ extraction [2]	HL-LHC (standard)	HL-LHC (BCMS)
Beam total energy [TeV]	0.45

¹ The Q20 optics is assumed, with a gamma transition of 17.951, 10 MV in the 200 MHz RF cavities and 1 MV in the 800 MHz RF cavities, in bunch shortening mode. The standard beam parameters are those requested by HL-LHC at injection and the BCMS beam emittance is extrapolated from Table 10 in Ref. [2] for the presently assumed acceptable space charge tune spread in the PS and SPS.

⁵ The crossing angle in IP2 and IP8 is the sum of an external crossing angle bump and an “internal” spectrometer compensation bump and it depends on the spectrometer polarity. The values quoted above correspond to the configuration with the spectrometer ON providing the minimum long-range beam-beam normalized separation. The external bump extends over the triplet and D1 and D2 magnets. The internal spectrometer compensation bump extends only over the long drift space between the two Q1 quadrupoles left and right from the IP. For IP2 the vertical external crossing angle sign can be changed and therefore the same sign of the internal and external angle can be chosen to be the same. This is not possible for IP8 as the sign of the external crossing angle must be compatible with the recombination scheme.

¹⁰ Assuming one batch less from the PS for machine protection (pilot injection, TL steering with 12 nominal bunches) and non-colliding bunches for experiments. Note that due to RF beam loading the abort gap length must not exceed the $3\mu\text{s}$ design value.

¹¹ The value of the luminosity at which levelling is performed is calculated assuming a visible cross-section of 85 mb for point 1/2/5 and 75 mb for IP8.

¹² This corresponds to the half-separation of $2.39/2.38\sigma$ to level the luminosity to 10^{31} cm⁻²s⁻¹ for the standard and BCMS beams respectively.

¹³ This corresponds to the half-separation of 1.35σ to level the pile-up to 4.5 events/crossing.
