Abstract

The beauty hadron decays is unique laboratory to study charmonium and charmonium-like states, such as the $\chi_{c1}(3872)$ meson, other exotic states and the tensor D-wave $\psi_2(3823)$ states. However the nature of many exotic charmonium-like candidates are still unknown. The most recent LHCb results related to b-hadron decays to charmonium states and obtained using large data samples collected during the Run 1 and Run 2 periods are presented. This includes the most precise determination of the mass and width of the $\chi_{c1}(3872)$ state using the $B^+ \to J/\psi\, \pi^+\pi^- K^+$ decays, observation of a resonant structure denoted as X(4740) in the $J/\psi\,\phi$ mass spectrum from $B^0_s \to J/\psi\, \pi^+\pi^- K^+ K^-$ decays and the precise measurement of the B^0_s meson mass.

Presented at XXVII Cracow EPIPHANY Conference on future of particle physics

1 Introduction

In the last two decades a plethora of new results in the charmonium spectra have been obtained in the beauty decays studies. A lot of the conventional and exotic charmonium resonances are observed such as $\chi_{c1}(3872)$, $\chi_{c1}(4700)$ and $P_c(4312)^+$ and conventional $\psi_2(3823)$ state. The LHCb experiment has collected high statistics during Run 1 and Run 2 periods that allows us to perform many precise measurements of the branching fractions of B- and B_s^0-meson decays and searches for new decays and states. The results described below are based on the data samples collected by the LHCb experiment in proton-proton (pp) collisions at the Large Hadron Collider from 2011 to 2018 with centre-of-mass energies of $\sqrt{s} = 7, 8$ and 13 TeV.

2 Study of the $B^+ \to J/\psi\,\pi^+\pi^- K^+K^-$ decays

Candidates of the $B_s^0 \to J/\psi\,\pi^+\pi^- K^+K^-$ decays are reconstructed via $J/\psi \to \mu^-\mu^+$ and selected using based on kinematics, particle identification and topology [1]. The yields of $B_s^0 \to J/\psi\,\pi^+\pi^- K^+K^-$ decays via the $B_s^0 \to \psi(2S)\phi$ and $B_s^0 \to \chi_{c1}(3872)\phi$ and $B_s^0 \to J/\psi\,K^{*0}\overline{K}^{*0}$ chains are determined using three-dimensional unbinned extended maximum-likelihood fits. The observed signal yield for the $B_s^0 \to \chi_{c1}(3872)\phi$ decays is 154 ± 15 which corresponds to a statistical significance more than 10 standard deviations. The fit to the mass distribution for the signal channel is shown in figure 1.

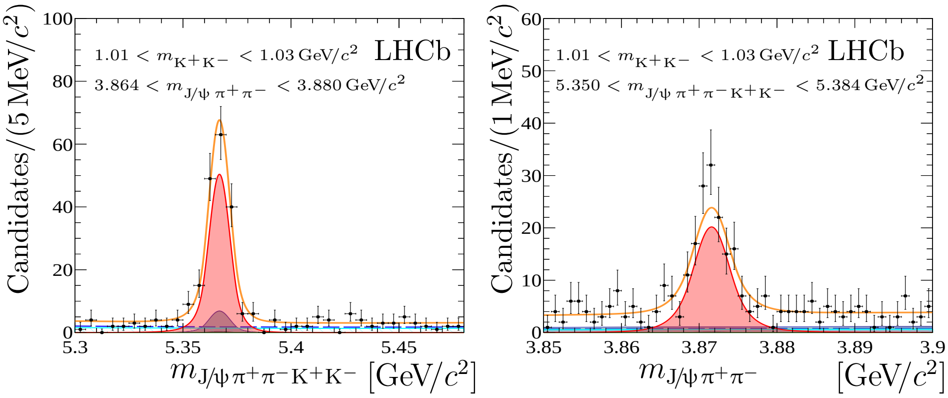

Figure 1: Distributions of the (left) $J/\psi\,\pi^+\pi^- K^+K^-$ and (right) $J/\psi\,\pi^+\pi^-$ mass for selected $B_s^0 \to \chi_{c1}(3872)\phi$ candidates (points with error bars) [1]. The red filled area corresponds to the $B_s^0 \to \chi_{c1}(3872)\phi$ signal. The orange line is the total fit.

In addition, the decays $B_s^0 \to \chi_{c1}(3872)K^+K^-$ where the K^+K^- pair does not originate from a ϕ meson, is studied using a two-dimensional unbinned extended maximum-likelihood fit which is performed to corresponding mass distributions. The observed yield of signal decays is 378 ± 33, that is significantly larger than the yield of the $B_s^0 \to \chi_{c1}(3872)\phi$ decays, indicating a significant $B_s^0 \to \chi_{c1}(3872)K^+K^-$ contribution. A narrow ϕ component can be separated from the non-ϕ components using an unbinned maximum-likelihood fit to the background-subtracted and efficiency-corrected K^+K^- mass distribution. The fraction of the $B_s^0 \to \chi_{c1}(3872)K^+K^-$ signal component is found to be $(38.9 \pm 4.9)\%$. Using the obtained signal yields and fractions for described channels and corresponding efficiency

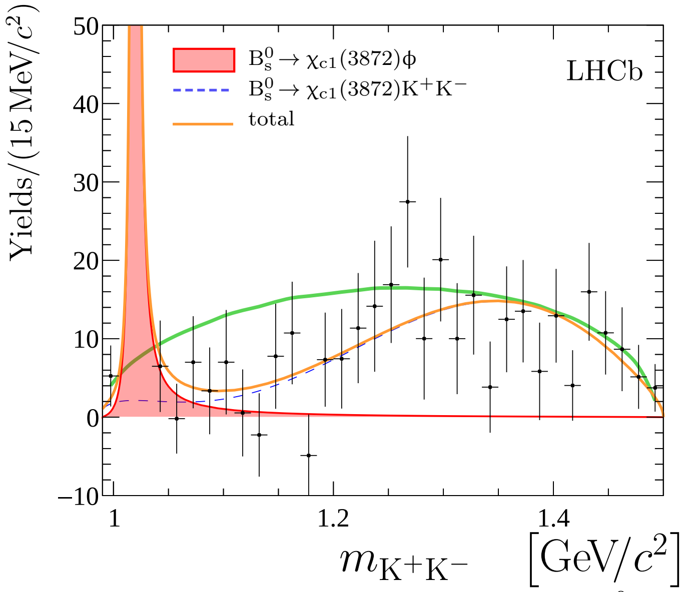

Figure 2: Background-subtracted K^+K^- mass distribution for selected $B_s^0 \to \chi_{c1}(3872)K^+K^-$ candidates (points with error bars) [1]. The orange line is the total fit.

ratios the following branching fractions are calculated:

$$\frac{\mathcal{B}_{B_s^0\to\chi_{c1}(3872)\phi} \times \mathcal{B}_{\chi_{c1}(3872)\to J/\psi\pi^+\pi^-}}{\mathcal{B}_{B_s^0\to\psi(2S)\phi} \times \mathcal{B}_{\psi(2S)\to J/\psi\pi^+\pi^-}} = (2.42 \pm 0.23 \pm 0.07) \times 10^{-2},$$

$$\frac{\mathcal{B}_{B_s^0\to J/\psi K^{*0}\overline{K}^{*0}} \times \mathcal{B}^2_{K^{*0}\to K^+\pi^-}}{\mathcal{B}_{B_s^0\to\psi(2S)\phi} \times \mathcal{B}_{\psi(2S)\to J/\psi\pi^+\pi^-} \times \mathcal{B}_{\phi\to K^+K^-}} = 1.22 \pm 0.03 \pm 0.04,$$

$$\frac{\mathcal{B}_{B_s^0\to\chi_{c1}(3872)(K^+K^-)_{\text{non-}\phi}}}{\mathcal{B}_{B_s^0\to\chi_{c1}(3872)\phi} \times \mathcal{B}_{\phi\to K^+K^-}} = 1.57 \pm 0.32 \pm 0.12,$$

where the first uncertainty is statistical and the second is systematic. The result for $B_s^0 \to \chi_{c1}(3872)\phi$ decay is found to be in a good agreement with the result by the CMS collaboration [2] but is more precise.

Four tetraquark candidates have been observed by the LHCb collaboration using an amplitude analysis of the $B^+ \to J/\psi\,\phi K^+$ decays [3, 4]. A search of the exotic states in the $J/\psi\,\phi$ spectrum is performed using the $B_s^0 \to J/\psi\,\pi^+\pi^-\phi$ decays. The $B_s^0 \to J/\psi\,\pi^+\pi^-\phi$ candidates are determined with two-dimensional unbinned extended maximum-likelihood fit to the $J/\psi\,\pi^+\pi^-K^+K^-$ and K^+K^- mass distributions.

The background-subtracted $J/\psi\,\phi$ mass spectrum of $B_s^0 \to J/\psi\,\pi^+\pi^-\phi$ candidates are shown in figure 3. It shows a prominent structure at a mass around 4.74 GeV/c^2. Since the regions of $\psi(2S)$ and $\chi_{c1}(3872)$ resonance masses are vetoed and no sizeable contributions from decays via other narrow charmonium states are observed in the background-subtracted $J/\psi\,\pi^+\pi^-$ mass spectrum, this structure cannot be explained by cross-feed from the $J/\psi\,\pi^+\pi^-$ mass spectrum. Moreover no such structure is seen in non-ϕ region of the K^+K^- mass. However the $\phi\pi^+\pi^-$ spectrum exhibits significant deviations from the phase-space distribution, indicating possible presence of excited ϕ states, referred to as ϕ^* states hereafter. The decays $B_s^0 \to J/\psi\,\phi^*$ via intermediate $\phi(1680)$, $\phi(1850)$ or $\phi(2170)$ states [5] are studied using simulated samples and no peaking structures are observed. Under the assumption that the observed structure, referred to as X(4740)

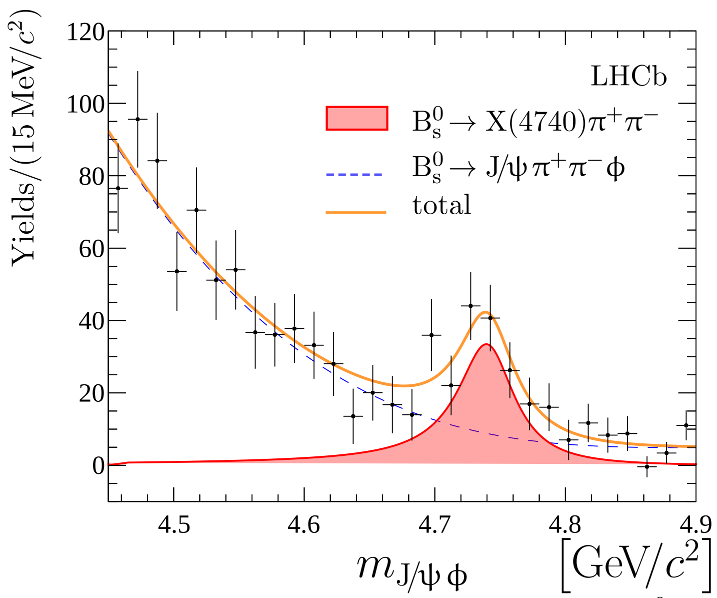

Figure 3: Background-subtracted $J/\psi\,\phi$ mass distribution for the selected $B_s^0 \to J/\psi\,\pi^+\pi^-\phi$ signal candidates (points with error bars) [1]. The red filled area corresponds to the $B_s^0 \to X(4740)\pi^+\pi^-$ signal. The orange line is the total fit.

hereafter, has a resonant nature, its mass and width are determined through an unbinned extended maximum-likelihood fit. The fit result is superimposed in figure 3. The obtained signal yield is 175 ± 39 and corresponds to a statistical significance above 5.3 standard deviations. The mass and width for the X(4740) state are found to be

$$\begin{aligned} m_{X(4740)} &= 4741 \pm 6 \pm 6\,\mathrm{GeV}/c^2\,, \\ \Gamma_{X(4740)} &= 53 \pm 15 \pm 11\,\mathrm{MeV}. \end{aligned}$$

The observed parameters qualitatively agree with those of the $\chi_{c1}(4700)$ state observed by the LHCb collaboration in references [3,4]. The obtained mass also agrees with the one expected for the 2^{++} $cs\overline{cs}$ tetraquark state [6].

The B_s^0 decays to the $\psi(2S)K^+K^-$ final states characterize the relatively small energy release allowing precise measurement of the B_s^0 meson mass. The mass of the B_s^0 meson is determined from an unbinned extended maximum-likelihood fit to the $\psi(2S)K^+K^-$ mass distribution. The improvement in the B_s^0 mass resolution and significant decrease of the systematic uncertainties is achieved by imposing a constraint on the reconstructed mass of the $J/\psi\,\pi^+\pi^-$ system to the known $\psi(2S)$ meson mass [5]. The measured value of the B_s^0 meson mass is found to be

$$m_{B_s^0} = 5366.98 \pm 0.07 \pm 0.13\,\mathrm{MeV}/c^2\,,$$

that is the most precise single measurement of this quantity.

3 Study of the $B^+ \to J/\psi\,\pi^+\pi^-K^+$ decays

The search of the spin-2 component of the *D*-wave charmonium triplet, the $\psi_2(3823)$ state, is performed with $B^+ \to J/\psi\,\pi^+\pi^-K^+$ decays [7,8]. To extract the B^+ candidates, a multivariate classifier algorithm based on a decision tree with gradient boosting is applied. For signal yield determinations of the $B^+ \to (\psi(2S) \to J/\psi\,\pi^+\pi^-)K^+$, $B^+ \to (\chi_{c1}(3872) \to J/\psi\,\pi^+\pi^-)K^+$ and $B^+ \to (\psi_2(3823) \to J/\psi\,\pi^+\pi^-)K^+$, a simultaneous unbinned extended maximum-likelihood fit to the $m_{J/\psi\pi^+\pi^-K^+}$ and $m_{J/\psi\pi^+\pi^-}$ variables is performed. The signal yield for the $B^+ \to \psi_2(3823)K^+$ decays is determined to be 137 ± 26 which correspond to statistical significance above 5.1 standard deviations. Large signal yield for the $B^+ \to \psi(2S)K^+$ signal, 4230 ± 70, allows for the precise measurement of the mass and width of the $\chi_{c1}(3872)$ state. For the first time the non-zero Breit–Wigner width is observed for the $\chi_{c1}(3872)$ state with significance more than 5 standard deviations and its measured value is:

$$\Gamma_{\chi_{c1}(3872)} = 0.96^{+0.19}_{-0.18} \pm 0.21\,\text{MeV}\,.$$

The upper limit for the Breit–Wigner width of $\psi_2(3823)$ is improved and its value is set to be $\Gamma_{\psi_2(3823)} < 5.2\,(6.6)\,\text{MeV}$, for 90 (95)% C.L. The mass splitting between the states are found to be

$$\begin{aligned}
\delta m^{\chi_{c1}(3872)}_{\psi_2(3823)} &= 47.50 \pm 0.53 \pm 0.13\,\text{MeV}/c^2\,,\\
\delta m^{\psi_2(3823)}_{\psi(2S)} &= 137.98 \pm 0.53 \pm 0.14\,\text{MeV}/c^2\,,\\
\delta m^{\psi_2(3823)}_{\psi(2S)} &= 185.49 \pm 0.06 \pm 0.03\,\text{MeV}/c^2\,,
\end{aligned}$$

The results Breit–Wigner mass of the $\chi_{c1}(3872)$ state are in good agreement with an independent analysis of inclusive $b \to \chi_{c1}(3872)X$ decays [9]. The binding energy of the $\chi_{c1}(3872)$ state is derived from the mass splitting and its value is found to be $\delta E = 0.12 \pm 0.13\,\text{MeV}$. It is consistent with zero within uncertainties, that are currently dominated by the uncertainty for the neutral and charged kaon mass measurements [10,11].

The measured yields of the $B^+ \to \chi_{c1}(3872)K^+$, $B^+ \to \psi_2(3823)K^+$ and $B^+ \to \psi(2S)K^+$ signal decays allow for a precise determination of the ratios of the branching fractions:

$$\begin{aligned}
\frac{\mathcal{B}_{B^+\to\psi_2(3823)K^+} \times \mathcal{B}_{\psi_2(3823)\to J/\psi\pi^+\pi^-}}{\mathcal{B}_{B^+\to\chi_{c1}(3872)K^+} \times \mathcal{B}_{\chi_{c1}(3872)\to J/\psi\pi^+\pi^-}} &= (3.56 \pm 0.67 \pm 0.11) \times 10^{-2}\,,\\
\frac{\mathcal{B}_{B^+\to\psi_2(3823)K^+} \times \mathcal{B}_{\psi_2(3823)\to J/\psi\pi^+\pi^-}}{\mathcal{B}_{B^+\to\psi(2S)K^+} \times \mathcal{B}_{\psi(2S)\to J/\psi\pi^+\pi^-}} &= (1.31 \pm 0.25 \pm 0.04) \times 10^{-3}\,,\\
\frac{\mathcal{B}_{B^+\to\chi_{c1}(3872)K^+} \times \mathcal{B}_{\chi_{c1}(3872)\to J/\psi\pi^+\pi^-}}{\mathcal{B}_{B^+\to\psi(2S)K^+} \times \mathcal{B}_{\psi(2S)\to J/\psi\pi^+\pi^-}} &= (3.69 \pm 0.07 \pm 0.06) \times 10^{-2}\,.
\end{aligned}$$

4 Conclusion

A study of b-meson decays $B^+ \to J/\psi\,\pi^+\pi^-K^+$ and $B^0_s \to J/\psi\,\pi^+\pi^-K^+K^-$ is made using the Run 1 and Run 2 data, collected with the LHCb detector [1, 7]. The reported results include the observation of the non-zero width of the $\chi_{c1}(3872)$ state; the most precise measurement of the masses of the $\chi_{c1}(3872)$ and $\psi_2(3823)$ states; the most precise measurement of several ratios of branching fractions of the B^+ and B^0_s mesons decays; the most precise single measurement of the B^0_s meson mass and the observation of a new structure, denoted as the X(4740) state, in the $J/\psi\,\phi$ mass spectrum.
