## 26 **Abstract**

### 27 Background

28

29 Enteral feeding will induce remission in as many as 80-90% of compliant patients with active Crohn's  
30 Disease (CD) but its method of action remains uncertain. This study was designed to examine its effects  
31 on the colonic microbiome.

32

### 33 Method

34

35 Healthy volunteers and patients with CD followed a regimen confined to enteral feeds alone for one or two  
36 weeks respectively. Chemicals excreted on breath or in faeces were characterised at the start and at the end  
37 of the feeding period by gas chromatography mass spectrometry (GC/MS).

38

### 39 Results

40 One week of feeding in healthy volunteers caused significant changes in stool colour and deterioration in  
41 breath odour, together with increased excretion of phenol and indoles on the breath. Feeding for two weeks  
42 in patients with CD produced significant improvements in symptoms and a decrease in the concentration  
43 of C-reactive protein. The faecal concentrations of microbial products including short chain fatty acids  
44 (SCFAs), and potentially toxic substances including 1-propanol, 1-butanol and the methyl and ethyl esters  
45 of SCFAs showed significant falls.

46

### 47 Conclusion

48 A significant change occurs in the production of microbial metabolites after enteral feeding in both healthy  
49 volunteers and patients with CD. Many of those detected in CD are toxic and may feasibly lead to the  
50 immunological attack on the gut microbiota, which is characteristic of IBD. The reduction in the production  
51 of such metabolites after enteral feeding may be the reason for its effectiveness in CD.

76 **Introduction**

77 Despite the increasing frequency of Crohn's disease, its treatment remains unsatisfactory. Many of the  
78 therapeutic agents used have unpleasant or even dangerous side effects and some are very expensive. The  
79 continuing perception of CD as a relapsing and remitting disorder emphasises the difficulty in maintaining  
80 long term control. A complete cure remains elusive.

81

82 Reports of a positive response to dietary manipulation in CD have emerged from several sources.<sup>1-8</sup> 2-4  
83 weeks of total enteral feeding has been reported to reduce remission in 85-90% of compliant patients  
84 suffering active CD.<sup>1-6</sup> Lack of understanding of the method of action of enteral feeds in CD has however,  
85 discouraged their use.<sup>2-8</sup>

86

87 Enteral feeds are nutritionally complete liquid mixtures of pre-digested foods presenting nitrogen as amino  
88 acids, oligopeptides or a single protein, carbohydrates as simple sugars, typically malto-dextrins, and fat as  
89 a single oil, (eg. Rapeseed oil), together with minerals and vitamins.

90 Suggestions as to the method of action of enteral feeding are many, but it is now known that bowel rest <sup>7</sup>  
91 and the reduction of potential food allergens <sup>2-4</sup> are incorrect. Enteral feeding is unlikely to have  
92 therapeutic benefit by producing immunosuppression as it is ineffective in the treatment of ulcerative  
93 colitis.<sup>3</sup> Reduction in inflammation can be detected before any improvement in nutritional state begins,<sup>8</sup>  
94 and the suggestion that dietary particles might be important was not supported by a controlled trial.<sup>9</sup>

95

96 The increasing evidence that inflammation in CD is provoked by an immune response targeted against the  
97 intestinal microbiome implies that manipulation of the metabolic activity of the microbiota might have a

98 role in the treatment of this disease<sup>10,12</sup> We and others have recently demonstrated an association between  
99 Crohn's disease and the profile volatile organic compounds obtained from breath and faecal headspace  
100 samples<sup>16,25</sup>. These measurements are a useful indication of changes in the gut microbiome, being simple,  
101 rapid and non-invasive. We have used this approach here in a study of the effects of enteral feeding. It has  
102 been suggested that food intolerance, as distinct from food allergy, might reflect an interaction between  
103 unabsorbed food residues and the intestinal microbiome.<sup>13</sup> As the nutrients contained in enteral feeds are  
104 absorbed high in the small intestine, they supply little in the way of energy substrates to micro-organisms  
105 in the lower bowel. This might lead to changes in microbial metabolism which in turn could lead to a  
106 reduction in inflammation. The present studies were designed to investigate this possibility.

107

## 108 **Methods**

### 109 **Study 1 Healthy volunteers**

110 Volunteers were recruited from students of either sex aged 18-65 years, at Cranfield University who were  
111 in good health and eating a normal diet. A total of 12 subjects was recruited aged 23-32, of which 8 were  
112 female. Subjects suffering conditions possibly requiring specific diets e.g. irritable bowel syndrome (IBS),  
113 or coeliac disease were excluded. Other exclusions were pregnancy or lactation, a course of antibiotics in  
114 the previous six weeks, bacterial products such as pro- or pre- biotics and any chronic medication other  
115 than oral contraceptives.

116

117 Subjects were randomly allocated to take either E028 extra (Nutricia UK Liverpool), or Modulen-IBD  
118 (Nestle Ltd, Croydon UK), for 7 days with all other foodstuffs excluded except water *ad libitum*..  
119 Nutritional requirements were calculated for each individual using Schofield's equation.<sup>14</sup>

120 After 7 days subjects returned to normal diets for 21 days before commencing the alternative enteral feed  
121 for a further 7 days. The two feeds were administered 4 weeks apart in order that they were taken at the

122 same stage of the menstrual cycles of female volunteers. During enteral feeding, subjects were asked to  
123 record how much feed they consumed and to complete symptom score sheets recording on a daily basis  
124 stool frequency, consistency and colour and any changes in breath odour. Weights were recorded and  
125 breath samples taken before the study and after each week of enteral feeding. This trial was an open,  
126 randomised controlled study performed at Cranfield University and approved by the ethics committee of  
127 Cranfield University and the NHS Cambridge local research ethics committee.

128 Volunteers were provided with a sheet depicting a range of faecal colours ranging from dark brown to  
129 bright green (copies supplied to the editor) and asked to assess the stool colour, consistency and frequency.  
130 They were asked to record daily changes in breath odour which was assessed subjectively on a scale from  
131 1 (odourless) to 4 (extremely unpleasant).

132 Bio-VOC samplers were used according to manufacturer's recommendations to obtain a one-litre end-tidal  
133 breath sample after breakfast on the first day of each feeding period. Samples were injected onto Thermal  
134 desorption tubes containing 1:1 Tenax TA and Carbotrap adsorbents (Markes International, Llantrisant,  
135 UK).

## 136 **Study 2 Patients with Crohn's disease**

137 Patients aged 18-65 years were recruited in the department of Gastroenterology, Addenbrooke's Hospital,  
138 Cambridge. A total of 17 patients each provided a faecal sample before treatment with enteral feed  
139 E028extra and again when they went into remission. At recruitment, all had symptoms of active disease.  
140 The diagnosis of CD was made by standard diagnostic criteria and the severity of symptoms was assessed  
141 using the Harvey and Bradshaw Index<sup>15</sup>. The concentration of C-reactive protein (CRP) in serum samples  
142 obtained at each visit was determined by the Biochemistry Department of Addenbrooke's Hospital to  
143 provide an objective measure of disease activity.

144

145 Any patients who had received antibiotics in the previous 6 weeks were excluded. Some were taking  
146 medication including 5-aminosalicylic acid compounds and/or azathioprine which had been insufficient to  
147 control their symptoms, but none had received previous dietary treatment. They were asked to continue  
148 such medication during the period of feeding with elemental diet. Non-fasting morning samples of faeces  
149 were obtained before starting two weeks treatment with E028 extra (Nutricia Liverpool UK) with amounts  
150 again being calculated by Schofield's equation. A further faecal sample was obtained at the end of this  
151 period. Samples were delivered to the hospital on the same day as passed with a maximum delay before  
152 freezing of 4 hours. They were stored at -40°C until transferred to the laboratory for analysis.

153 Ethical permission for this study was granted by the Leeds West LREC (Ref: 07/Q1205/39).

#### 154 **Laboratory analysis**

155 An internal standard solution comprising 50 ng deuterated (D8) toluene (Supelco Cat no 48,593) in  
156 methanol was added to each tube according to the manufacturer's instructions (Markes International Ltd,  
157 Llantrisant,UK). Head space samples were analysed by automated thermal desorption gas  
158 chromatography/mass spectrometry. A Perkin Elmer system was used for analysis combining a TurboMass  
159 MS 4.1 Autosystem XL GC and Automatic Thermal Desorption system (ATD 400 PerkinElmer, Wellesley  
160 MA). The gas carrier was CP-grade helium (BOC gases Guildford UK) passed through a combined trap  
161 for removal of hydrocarbons, oxygen and water vapour. A wall-coated Zebron ZB624 chromatographic  
162 column was used with dimensions 60 x .04 x 0.25mm (internal diameter), the liquid phase comprising a  
163 0.25 µm layer of 6% cyanopropylphenyl and 94% methylpolysiloxane.

164

165 Thermal desorption tubes were initially purged for 2 minutes to remove air and water vapour and then  
166 desorbed for 5 minutes at 300°C. The automatic thermal desorption valve temperature was set at 180°C  
167 and TD tubes were desorbed onto the secondary cold trap, which was initially maintained at 30°C. Once  
168 desorption was complete, the secondary trap was heated to 320°C using the fastest available heating rate  
169 and then maintained for 5 minutes. The effluent was transferred to the gas chromatograph through a transfer

170 line heated to 210°C. The gas chromatograph oven was maintained at 50°C for 4 minutes after injection  
171 and then raised at a rate of 10°C/min to 220°C and then held for 9 minutes. Eluted products were transferred  
172 to the mass spectrometer via a line heated to 240°C. Electron ionisation (70eV) was used. Full scan mode  
173 was selected with mass-to-charge ratios from 33 to 350 m/z with a scan time of 0.3 second and 0.1 second  
174 interscan delay to produce a total ion count (TIC) chromatogram.

## 175 **Study 2**

176 Samples were transferred to the laboratory packed in dry ice inside insulated containers and on arrival were  
177 stored at -80°C until analysis.

178 Aliquots (5ml) of the defrosted samples were placed in gas sampling bags which were then sealed and filled  
179 with hydrocarbon-free air and incubated for 10 minutes at body temperature. A portable air pump was then  
180 used to draw 500ml of headspace through TD tubes packed with 50% Carbotrap and 50% Tenax. Full  
181 details have been published elsewhere <sup>16</sup>

182

## 183 **Data and statistical analysis**

### 184 **Study 1**

185 Compound identification was achieved using Automated Mass Spectral Deconvolution and Identification  
186 (AMDIS version 2.62) software and the National Institute of Standards and Technology mass spectral  
187 library. Quantification was achieved by comparing the area of each compound peak with the peak area  
188 associated with the known amount of d8 toluene.

189

190 Concentration data proved to be heavily right-skewed, therefore a non-parametric approach was adopted.  
191 A McNemar test was used to determine whether the probability of a compound to be present before or after  
192 the diet was significant. When present a Wilcoxon Rank Test was used to see if the compound was present  
193 in different quantities. Raw TIC data (i.e. a matrix of time vs. ion abundance) were also subjected to

194 Principal Components Analysis (PCA)<sup>27</sup> using Matlab (version 6/5 Mathworks Inc USA incorporating  
195 functions from the PLS Toolbox version 2.0 Eigenvector Research Inc USA).

## 196 **Study 2**

197 Compound identification and quantification were carried out as for study 1. In any given faecal headspace  
198 sample, automated mass spectral deconvolution and identification (AMDIS) would identify between 100-  
199 300 different compounds and it was therefore found necessary to select a subset of those we observed to  
200 render statistical analysis tractable. Three approaches were followed to provide a list of what we have  
201 termed ‘candidate compounds’. The list comprised first compounds that appeared to be most abundant  
202 from inspection of the results obtained using AMDIS; second compounds that appeared to discriminate  
203 between patient groups by visual inspection of a subset of pre-treatment sample chromatograms and third  
204 compounds selected on the basis of a search of the relevant literature. An initial generic list was made  
205 including short-chain fatty acids (SCFAs) and their derivatives, phenolic compounds and indoles and  
206 sulfides. This list was then refined according to publications dealing more explicitly with VOC profiles in  
207 disease. A final list of compounds was obtained in this way.

208

## 209 **Results**

### 210 **Study 1**

211

212 Of the 12 volunteers recruited, two females withdrew before the feeding commenced. During the first  
213 feeding period 2 withdrew after 2 days feeding, one (female having E028) because of persistent hunger and  
214 the other (male having Modulen-IBD) because of insomnia attributed to an empty stomach. Eight subjects  
215 completed the first phase. A further subject (male Modulen-IBD) withdrew after 4 days in the second phase  
216 because of malaise and headaches.

217

218 Stool consistency and frequency showed no change. There was a consistent change in stool colour from  
219 browns towards green on E028 extra ( $r=0.639$ ,  $p<0.05$  Spearman test), and a similar but less marked effect  
220 was seen after Modulen-IBD ( $r=0.598$ ,  $p<0.05$ ). Faecal colour had returned to normal by the start of the  
221 second feeding period.

222

223 All subjects showed deterioration in odour on E028 extra and 5 out of 6 on Modulen-IBD. One volunteer  
224 did not record his breath changes on a daily basis. A Spearman test showed a significant difference between  
225 the odour of the breaths of the volunteers before they started and the last day of the diet (E028 extra  $r=0.575$   
226  $p<0.05$ , Modulen-IBD  $r=0.574$   $p<0.05$ ). Subjects' breath odour had returned to normal at the start of the  
227 second feeding period. Numerical results were presented as mean with upper and lower quartiles. The  
228 frequency distributions for all compounds were found to be highly skewed with a proportion of nondetects;  
229 therefore, a nonparametric statistical approach was adopted.

230

231 Over 140 compounds were seen in the breath analysis including aldehydes, ketones, saturated and non-  
232 saturated hydrocarbons, organic acids, alkenes, alcohols and furans. The compounds also varied between  
233 volunteers. As at least one third of compounds were known to be environmental contaminants, e.g. benzene,  
234 toluene, xylene, we concentrated on two marker compounds known to be bacterial metabolites, phenol and  
235 indole.

236

237 The mean alveolar gradient for indole on a normal diet was  $0.034 \pm$  SD  $0.029$ . There was little change  
238 following Modulen-IBD  $0.041 \pm$  SD  $0.028$  (NS). After E028 it rose to  $0.149 \pm$  SD  $0.099$  (NS) The  
239 differences between the values after diet did not differ significantly from those before, but the aveolar  
240 gradient after E028 was significantly higher than that after Modulen-IBD ( $P<0.03$ ).

241

242 The mean level of alveolar gradient for phenol on the breath on a normal diet was  $0.024 \pm \text{SD } 0.017$ . After  
243 Modulen-IBD it rose to  $0.055 \pm \text{SD } 0.025$  (NS). After E028 the levels were  $0.229 \pm \text{SD } 0.152$  ( $p < 0.05$ ).  
244 The increase after E028 was significantly greater to that after Modulen-IBD  $P = 0.035$ . After 3 weeks of  
245 normal eating, breath chemicals had in every case returned to levels indistinguishable from those present  
246 at the start of the first period of enteral feeding.

247

## 248 **Results**

### 249 **Study 2:**

250

251 At the start of treatment all 17 patients had active disease as confirmed by a Harvey and Bradshaw index  
252 of  $>6$  and raised concentration of C-reactive protein (CRP) in the blood. 9 patients were receiving no  
253 medication, 4 were taking 5ASA compounds, 2 were taking 5ASA with Azathioprine, 1 taking  
254 Azathioprine alone and 1 taking Azathioprine and Prednisolone. Patients were asked to continue the same  
255 medication throughout the study and this was not changed in any way, remission being achieved in all cases  
256 by the addition of enteral feed. The mean Harvey & Bradshaw (H&B) before treatment was  $6.88 \pm \text{SD}$   
257  $2.93$  falling to  $4 \pm \text{SD } 5.50$  after treatment, ( $p < 0.05$ ). The initial mean CRP was  $36.0 \pm \text{SD } 41.3\text{mg/L}$   
258 falling to  $8.11 \pm \text{SD } 3.59$  after treatment ( $p < 0.05$ ).

259

260 The results of GC/MS faecal analysis are summarised in Table 1. Many compounds of known bacterial  
261 origin were present in the initial sample. These included propanoic and butanoic acids, para-cresol, indole,  
262 dimethyl disulphide and phenol. The concentrations of the SCFAs fell dramatically after enteral feeding.  
263 No difference was discerned in the fall of concentrations of bacterial metabolites in those subjects receiving  
264 enteral feeds alone, and those who continued their previous medication. Thus the results of all the patients  
265 were analysed together.

266

267 There were also however, a number of potentially toxic compounds present. These included the alcohols,  
268 1-propanol and 1-butanol as well as the methyl and ethyl esters of propanoic acid and butanoic acid. After  
269 treatment, the amounts of these compounds also fell significantly. The SCFA-esters disappeared virtually  
270 completely and there was a significant fall in the concentration of 1-propanol and 1-butanol. However,  
271 other chemicals including those derived by bacterial breakdown of amino acids, phenol and indole did not  
272 change significantly (table 1).

273

## 274 **Discussion**

275

276 The present study demonstrates changes in chemicals of microbial origin in both healthy controls and in  
277 patients with CD after administration of enteral feeds. Our first study confirms reports of stool colour  
278 change during treatment with the development of breath odour. It is probable that this was the result of the  
279 cessation of the normal microbial breakdown of biliverdin (green) to stercobilin (brown).

280

281 We also attempted to assess bacterial activity by determination on the breath of known bacterial metabolites  
282 that might be absorbed into the blood stream from the colon. Many chemicals are present in breath and  
283 urine and we detected 140. Their origins of many are poorly understood. We therefore concentrated on  
284 changes in the excretion of two chemicals whose synthesis by the microbiota is well understood, namely  
285 phenol and indole.<sup>14,15</sup>

286

287 Phenol and indole are produced by the microbial conversion of tyrosine and tryptophan respectively. Much  
288 less is produced when carbohydrate fermentation is continuing in the colon. Conversely, when  
289 carbohydrate was withdrawn from the diet, phenol production from endogenous protein sources such as  
290 intestinal secretions and exfoliated cells was increased<sup>17,18</sup>

291

292 In the present study, phenol and indole identified on the breath showed a significant increase in  
293 concentration after feeding with Modulen-IBD and an even greater increase after E028extra, which rapidly  
294 returned to base line on resumption of a normal diet. This is consistent with a switch in colonic  
295 fermentation to a protein-based pattern, as an effect of ingesting carbohydrate in the form of maltodextrins  
296 - simple sugars that are absorbed high in the small intestine - rather than complex carbohydrates that may  
297 pass down to be fermented by the colonic flora. Indole is malodorous and may contribute to the unpleasant  
298 breath odour reported by our volunteers.

299

300 The effect of E028 on phenol and indole was greater than that of Modulen IBD. This may be related to the  
301 content of long chain triglyceride in the feeds which we and others have shown to be an important factor  
302 influencing their effectiveness.<sup>2,28</sup> The LCT content of Modulen IBD is greater than that of E028 extra.

303

304 The term 'enterometabolic disease' has been suggested for non-infective conditions arising from abnormal  
305 fermentation by the colonic microbiota<sup>13</sup>. Patients with IBS have a similar abnormal gut flora to that seen  
306 in CD.<sup>11,20,23</sup> and have a markedly increased excretion of a bacterial product, hydrogen. This was  
307 dramatically reduced, with highly significant reduction in symptoms, when patients were switched from a  
308 standard diet to an exclusion diet, suggesting that the diet reduced microbial activity<sup>24</sup>. Support for this  
309 concept was provided by the demonstration of reduced hydrogen excretion in patients with IBS, again with  
310 significant improvement in symptoms, when microbial activity was reduced by administration of  
311 antibiotics or by enteral feeding.<sup>25</sup>

312 Is it possible that CD like IBS may be an 'entero-metabolic disorder',<sup>13</sup> and that enteral feeding is effective  
313 because it reduces the metabolic activity of an abnormal colonic flora?

314

315 There is strong evidence that the host microflora provokes an immunological response in CD. Duchmann  
316 and his colleagues showed that monocytes from the peripheral blood and the lamina propria were activated  
317 when incubated with preparations of faecal bacteria from other subjects, but not by such preparations  
318 derived from the faeces of the host. Monocyte activation occurred only when host faeces was incubated  
319 with cells obtained from the lamina propria from sites of active CD. No activation was seen in monocytes  
320 obtained from areas where no active CD was present, suggesting that monocytes in areas of active CD were  
321 specifically targeted against the host microflora.<sup>10</sup>

322

323 This finding has been supported by later studies that demonstrated that the great majority of microorganisms  
324 found in the faeces of patients with IBD were coated with immunoglobulin, including IgA, IgG and IgM,  
325 whereas in normal subjects or those with IBS, less than 20% were so affected<sup>12</sup>.

326 Furthermore, a significant reduction in the number of microorganisms coated with immunoglobulin was  
327 seen after 2 weeks treatment with corticosteroids in UC, and a similar response occurred in CD after a two  
328 week course of elemental feeding. This suggested that the immune response to the flora had been  
329 significantly reduced, an interpretation supported by the finding that patients with CD and UC in long term  
330 remission had similar numbers of coated bacteria to those seen in healthy controls.<sup>12</sup>

331 No specific pathogen has as yet been confirmed as being the cause of CD, but it has been demonstrated that  
332 the faecal flora is abnormal with an overgrowth of facultative anaerobes and reduction in the numbers of  
333 important beneficial species such as *Lactobacilli* and *Bifidobacter*.<sup>11,20</sup> Although previous studies of the  
334 effects of enteral feeding on the composition of the bacterial flora in CD, had been inconclusive,<sup>21,22</sup>

335 a recent study of the entire gut mucosal microbiome in a child with CD before and after nutritional therapy  
336 showed that the flora, initially markedly abnormal, returned after therapy, to a pattern very similar to that  
337 found in a healthy control<sup>26</sup>. Likewise, it has also been shown that enteral nutrition in CD may reduce the  
338 levels of certain bacteria within the *Firmicutes*. These bacteria are important producers of SCFAs and this  
339 report is in keeping with our discovery of reduced SCFA production.<sup>27</sup>

340

341 Unfortunately, it was not possible in the present study to perform complex studies of changes in the gut  
342 microbiome, but changes in bacterial metabolites serve as valuable markers of its metabolic activity. SCFAs  
343 have an important function in the colon especially butanoic acid which is a major source of nutrition for  
344 colonocytes.<sup>19</sup> They are produced by the microbial fermentation of undigested complex carbohydrates  
345 entering the caecum and the fall in faecal SCFA concentration found after enteral feeding in our patients  
346 with CD was consistent with reduction in colonic fermentation.

347

348 Such a reduction in fermentation might be beneficial if it resulted in less production of toxic metabolites.  
349 There were highly significant falls in the concentrations of number of chemicals including 1-propanol, p-  
350 cresol, phenol, 1-butanol, dimethyl disulphide and fatty acid ethyl esters (Table 1). These are known to be  
351 toxic chemicals which we have shown not to be present in the stools of healthy volunteers.<sup>16</sup> It seems  
352 possible that the production of such chemicals might be a factor initiating an immune attack on the  
353 microflora. This could lead to coating of microflora with immunoglobulin – a suggestion which has been  
354 supported by the significant reduction in bacterial coating seen after 2 weeks feeding with enteral feeds.<sup>12,16</sup>

355

356 Similar toxic chemicals also appear in UC, but in contrast to CD, **do not fall** after enteral feeding, but only  
357 after successful treatment by immunosuppression with prednisolone<sup>16</sup>. Although evidence on the role of  
358 diet in UC remains weak, this suggests that the microflora in UC differs from that in CD in that it derives  
359 its nutritional requirements, not from food residues, but from other substances present in the large intestine  
360 – possibly mucus or intestinal secretions. It is therefore feasible, that the production of toxic chemicals  
361 resulting from abnormal bacterial metabolism, may be an important factor in the initiation of an immune  
362 attack on the microflora in inflammatory bowel disease.

**Table 1 Changes in faecal chemicals before and after elemental feeding in patients with Crohn's disease**

<b>Compound</b>	<b>VOC concentration (ng/l)</b>		<b>p-value</b>
	<b>Pre-treatment</b>	<b>Post-treatment</b>	
acetone	57 (38, 128)	80 (50, 104)	0.435
propanoic acid	169 (0, 328)	12 (0, 84)	0.031*
butanoic acid	1110 (316, 1596))	24 (0, 104)	0.001*
1-propanol	229 (41, 892)	36 (0, 233)	0.025*
propanoic acid, ethyl ester	19 (0, 117)	0 (0, 15)	0.008*
butanoic acid, methyl ester	19 (7, 121)	0 (0, 1)	0.013*
butanoic acid, ethyl ester	46 (4, 255)	0 (0, 15)	0.008*
p-cresol	518 (118, 1160)	480 (144, 1051)	0.687
indole	118 (54, 146)	20 (0, 128)	0.125
dimethyl disulphide	83 (34, 683)	39 (0, 140)	0.113
1-butanol	99 (57, 256)	58 (0, 199)	0.030*
butanoic acid, 3-methyl	147 (48, 504)	0 (0, 45)	0.015*
phenol	64 (16, 102)	24 (10, 177)	0.332
