new row with modifications, allocated in the upper executor context, or NULL on error (see SPI_result for an error indication)

On error, SPI_result is set as follows:

SPI_ERROR_ARGUMENT

if *rel* is NULL, or if *row* is NULL, or if *ncols* is less than or equal to 0, or if *colnum* is NULL, or if *values* is NULL.

`SPI_ERROR_NOATTRIBUTE`

if *colnum* contains an invalid column number (less than or equal to 0 or greater than the number of columns in *row*)

`SPI_ERROR_UNCONNECTED`

if SPI is not active

SPI_freetuple

SPI_freetuple — free a row allocated in the upper executor context

Synopsis

```
void SPI_freetuple(HeapTuple row)
```

Description

SPI_freetuple frees a row previously allocated in the upper executor context.

This function is no longer different from plain heap_freetuple. It's kept just for backward compatibility of existing code.

Arguments

HeapTuple row
row to free

SPI_freetuptable

SPI_freetuptable — free a row set created by SPI_execute or a similar function

Synopsis

```
void SPI_freetuptable(SPITupleTable * tuptable)
```

Description

SPI_freetuptable frees a row set created by a prior SPI command execution function, such as SPI_execute. Therefore, this function is often called with the global variable SPI_tuptable as argument.

This function is useful if an SPI-using C function needs to execute multiple commands and does not want to keep the results of earlier commands around until it ends. Note that any unfreed row sets will be freed anyway at SPI_finish. Also, if a subtransaction is started and then aborted within execution of an SPI-using C function, SPI automatically frees any row sets created while the subtransaction was running.

Beginning in PostgreSQL 9.3, SPI_freetuptable contains guard logic to protect against duplicate deletion requests for the same row set. In previous releases, duplicate deletions would lead to crashes.

Arguments

```
SPITupleTable * tuptable
```

pointer to row set to free, or NULL to do nothing

SPI_freeplan

SPI_freeplan — free a previously saved prepared statement

Synopsis

```
int SPI_freeplan(SPIPlanPtr plan)
```

Description

SPI_freeplan releases a prepared statement previously returned by SPI_prepare or saved by SPI_keepplan or SPI_saveplan.

Arguments

SPIPlanPtr *plan*

pointer to statement to free

Return Value

0 on success; SPI_ERROR_ARGUMENT if *plan* is NULL or invalid

48.4. Transaction Management

It is not possible to run transaction control commands such as COMMIT and ROLLBACK through SPI functions such as SPI_execute. There are, however, separate interface functions that allow transaction control through SPI.

It is not generally safe and sensible to start and end transactions in arbitrary user-defined SQL-callable functions without taking into account the context in which they are called. For example, a transaction boundary in the middle of a function that is part of a complex SQL expression that is part of some SQL command will probably result in obscure internal errors or crashes. The interface functions presented here are primarily intended to be used by procedural language implementations to support transaction management in SQL-level procedures that are invoked by the CALL command, taking the context of the CALL invocation into account. SPI-using procedures implemented in C can implement the same logic, but the details of that are beyond the scope of this documentation.

SPI_commit

`SPI_commit`, `SPI_commit_and_chain` — commit the current transaction

Synopsis

```
void SPI_commit(void)
void SPI_commit_and_chain(void)
```

Description

`SPI_commit` commits the current transaction. It is approximately equivalent to running the SQL command `COMMIT`. After the transaction is committed, a new transaction is automatically started using default transaction characteristics, so that the caller can continue using SPI facilities. If there is a failure during commit, the current transaction is instead rolled back and a new transaction is started, after which the error is thrown in the usual way.

`SPI_commit_and_chain` is the same, but the new transaction is started with the same transaction characteristics as the just finished one, like with the SQL command `COMMIT AND CHAIN`.

These functions can only be executed if the SPI connection has been set as nonatomic in the call to `SPI_connect_ext`.

SPI_rollback

SPI_rollback, SPI_rollback_and_chain — abort the current transaction

Synopsis

```
void SPI_rollback(void)
void SPI_rollback_and_chain(void)
```

Description

SPI_rollback rolls back the current transaction. It is approximately equivalent to running the SQL command `ROLLBACK`. After the transaction is rolled back, a new transaction is automatically started using default transaction characteristics, so that the caller can continue using SPI facilities.

SPI_rollback_and_chain is the same, but the new transaction is started with the same transaction characteristics as the just finished one, like with the SQL command `ROLLBACK AND CHAIN`.

These functions can only be executed if the SPI connection has been set as nonatomic in the call to SPI_connect_ext.

SPI_start_transaction

SPI_start_transaction — obsolete function

Synopsis

```
void SPI_start_transaction(void)
```

Description

SPI_start_transaction does nothing, and exists only for code compatibility with earlier PostgreSQL releases. It used to be required after calling SPI_commit or SPI_rollback, but now those functions start a new transaction automatically.

48.5. Visibility of Data Changes

The following rules govern the visibility of data changes in functions that use SPI (or any other C function):

- During the execution of an SQL command, any data changes made by the command are invisible to the command itself. For example, in:

```
INSERT INTO a SELECT * FROM a;
```

the inserted rows are invisible to the SELECT part.
- Changes made by a command C are visible to all commands that are started after C, no matter whether they are started inside C (during the execution of C) or after C is done.
- Commands executed via SPI inside a function called by an SQL command (either an ordinary function or a trigger) follow one or the other of the above rules depending on the read/write flag passed to SPI. Commands executed in read-only mode follow the first rule: they cannot see changes of the calling command. Commands executed in read-write mode follow the second rule: they can see all changes made so far.
- All standard procedural languages set the SPI read-write mode depending on the volatility attribute of the function. Commands of STABLE and IMMUTABLE functions are done in read-only mode, while commands of VOLATILE functions are done in read-write mode. While authors of C functions are able to violate this convention, it's unlikely to be a good idea to do so.

The next section contains an example that illustrates the application of these rules.

48.6. Examples

This section contains a very simple example of SPI usage. The C function `execq` takes an SQL command as its first argument and a row count as its second, executes the command using `SPI_exec` and returns the number of rows that were processed by the command.

```
#include "postgres.h"

#include "executor/spi.h"
#include "utils/builtins.h"

PG_MODULE_MAGIC;

PG_FUNCTION_INFO_V1(execq);

Datum
execq(PG_FUNCTION_ARGS)
{
    char *command;
    int cnt;
    int ret;
```

```
uint64 proc;

/* Convert given text object to a C string */
command = text_to_cstring(PG_GETARG_TEXT_PP(0));
cnt = PG_GETARG_INT32(1);

SPI_connect();

ret = SPI_exec(command, cnt);

proc = SPI_processed;

/*
 * If some rows were fetched, print them via elog(INFO).
 */
if (ret > 0 && SPI_tuptable != NULL)
{
    SPITupleTable *tuptable = SPI_tuptable;
    TupleDesc tupdesc = tuptable->tupdesc;
    char buf[8192];
    uint64 j;

    for (j = 0; j < tuptable->numvals; j++)
    {
        HeapTuple tuple = tuptable->vals[j];
        int i;

        for (i = 1, buf[0] = 0; i <= tupdesc->natts; i++)
            snprintf(buf + strlen(buf), sizeof(buf) - strlen(buf), " %s%s",
                     SPI_getvalue(tuple, tupdesc, i),
                     (i == tupdesc->natts) ? " " : " |");
        elog(INFO, "EXECQ: %s", buf);
    }
}

SPI_finish();
pfree(command);

PG_RETURN_INT64(proc);
}
```

This is how you declare the function after having compiled it into a shared library (details are in [Section 39.10.5](#)):

```
CREATE FUNCTION execq(text, integer) RETURNS int8
AS 'filename'
LANGUAGE C STRICT;
```

Here is a sample session:

```
=> SELECT execq('CREATE TABLE a (x integer)', 0);
 execq
-----
      0
(1 row)

=> INSERT INTO a VALUES (execq('INSERT INTO a VALUES (0)', 0));
INSERT 0 1
=> SELECT execq('SELECT * FROM a', 0);
INFO:  EXECQ:  0      -- inserted by execq
```

```

INFO: EXECQ: 1      -- returned by execq and inserted by upper INSERT

  execq
-----
      2
(1 row)

=> SELECT execq('INSERT INTO a SELECT x + 2 FROM a RETURNING *', 1);
INFO: EXECQ: 2      -- 0 + 2, then execution was stopped by count
  execq
-----
      1
(1 row)

=> SELECT execq('SELECT * FROM a', 10);
INFO: EXECQ: 0
INFO: EXECQ: 1
INFO: EXECQ: 2

  execq
-----
      3      -- 10 is the max value only, 3 is the real number of rows
(1 row)

=> SELECT execq('INSERT INTO a SELECT x + 10 FROM a', 1);
  execq
-----
      3      -- all rows processed; count does not stop it, because nothing is
returned
(1 row)

=> SELECT * FROM a;
  x
----
  0
  1
  2
10
11
12
(6 rows)

=> DELETE FROM a;
DELETE 6
=> INSERT INTO a VALUES (execq('SELECT * FROM a', 0) + 1);
INSERT 0 1
=> SELECT * FROM a;
  x
---
  1      -- 0 (no rows in a) + 1
(1 row)

=> INSERT INTO a VALUES (execq('SELECT * FROM a', 0) + 1);
INFO: EXECQ: 1
INSERT 0 1
=> SELECT * FROM a;
  x
---
```

```

1
2          -- 1 (there was one row in a) + 1
(2 rows)

-- This demonstrates the data changes visibility rule.
-- execq is called twice and sees different numbers of rows each time:

=> INSERT INTO a SELECT execq('SELECT * FROM a', 0) * x FROM a;
INFO: EXECQ: 1      -- results from first execq
INFO: EXECQ: 2
INFO: EXECQ: 1      -- results from second execq
INFO: EXECQ: 2
INFO: EXECQ: 2
INSERT 0 2
=> SELECT * FROM a;
 x
---
1
2
2          -- 2 rows * 1 (x in first row)
6          -- 3 rows (2 + 1 just inserted) * 2 (x in second row)
(4 rows)

```

Chapter 49. Background Worker Processes

Postgres Pro can be extended to run user-supplied code in separate processes. Such processes are started, stopped and monitored by `postgres`, which permits them to have a lifetime closely linked to the server's status. These processes are attached to Postgres Pro's shared memory area and have the option to connect to databases internally; they can also run multiple transactions serially, just like a regular client-connected server process. Also, by linking to `libpq` they can connect to the server and behave like a regular client application.

Warning

There are considerable robustness and security risks in using background worker processes because, being written in the `C` language, they have unrestricted access to data. Administrators wishing to enable modules that include background worker processes should exercise extreme caution. Only carefully audited modules should be permitted to run background worker processes.

Background workers can be initialized at the time that Postgres Pro is started by including the module name in `shared_preload_libraries`. A module wishing to run a background worker can register it by calling `RegisterBackgroundWorker (BackgroundWorker *worker)` from its `_PG_init()` function. Background workers can also be started after the system is up and running by calling `RegisterDynamicBackgroundWorker (BackgroundWorker *worker, BackgroundWorkerHandle **handle)`. Unlike `RegisterBackgroundWorker`, which can only be called from within the postmaster process, `RegisterDynamicBackgroundWorker` must be called from a regular backend or another background worker.

The structure `BackgroundWorker` is defined thus:

```
typedef void (*bgworker_main_type) (Datum main_arg);
typedef struct BackgroundWorker
{
    char          bgw_name[BGW_MAXLEN];
    char          bgw_type[BGW_MAXLEN];
    int           bgw_flags;
    BgWorkerStartTime bgw_start_time;
    int           bgw_restart_time; /* in seconds, or BGW_NEVER_RESTART */
    char          bgw_library_name[MAXPGPATH];
    char          bgw_function_name[BGW_MAXLEN];
    Datum         bgw_main_arg;
    char          bgw_extra[BGW_EXTRALEN];
    pid_t         bgw_notify_pid;
} BackgroundWorker;
```

`bgw_name` and `bgw_type` are strings to be used in log messages, process listings and similar contexts. `bgw_type` should be the same for all background workers of the same type, so that it is possible to group such workers in a process listing, for example. `bgw_name` on the other hand can contain additional information about the specific process. (Typically, the string for `bgw_name` will contain the type somehow, but that is not strictly required.)

`bgw_flags` is a bitwise-or'd bit mask indicating the capabilities that the module wants. Possible values are:

`BGWORKER_SHMEM_ACCESS`

Requests shared memory access. This flag is required.

`BGWORKER_BACKEND_DATABASE_CONNECTION`

Requests the ability to establish a database connection through which it can later run transactions and queries. A background worker using `BGWORKER_BACKEND_DATABASE_CONNECTION` to connect to a database must also attach shared memory using `BGWORKER_SHMEM_ACCESS`, or worker start-up will fail.

`bgw_start_time` is the server state during which `postgres` should start the process; it can be one of `BgWorkerStart_PostmasterStart` (start as soon as `postgres` itself has finished its own initialization; processes requesting this are not eligible for database connections), `BgWorkerStart_ConsistentState` (start as soon as a consistent state has been reached in a hot standby, allowing processes to connect to databases and run read-only queries), and `BgWorkerStart_RecoveryFinished` (start as soon as the system has entered normal read-write state). Note the last two values are equivalent in a server that's not a hot standby. Note that this setting only indicates when the processes are to be started; they do not stop when a different state is reached.

`bgw_restart_time` is the interval, in seconds, that `postgres` should wait before restarting the process in the event that it crashes. It can be any positive value, or `BGW_NEVER_RESTART`, indicating not to restart the process in case of a crash.

`bgw_library_name` is the name of a library in which the initial entry point for the background worker should be sought. The named library will be dynamically loaded by the worker process and `bgw_function_name` will be used to identify the function to be called. If calling a function in the core code, this must be set to `"postgres"`.

`bgw_function_name` is the name of the function to use as the initial entry point for the new background worker. If this function is in a dynamically loaded library, it must be marked `PGDLLEXPORT` (and not `static`).

`bgw_main_arg` is the `Datum` argument to the background worker main function. This main function should take a single argument of type `Datum` and return `void`. `bgw_main_arg` will be passed as the argument. In addition, the global variable `MyBgworkerEntry` points to a copy of the `BackgroundWorker` structure passed at registration time; the worker may find it helpful to examine this structure.

On Windows (and anywhere else where `EXEC_BACKEND` is defined) or in dynamic background workers it is not safe to pass a `Datum` by reference, only by value. If an argument is required, it is safest to pass an `int32` or other small value and use that as an index into an array allocated in shared memory. If a value like a `cstring` or `text` is passed then the pointer won't be valid from the new background worker process.

`bgw_extra` can contain extra data to be passed to the background worker. Unlike `bgw_main_arg`, this data is not passed as an argument to the worker's main function, but it can be accessed via `MyBgworkerEntry`, as discussed above.

`bgw_notify_pid` is the PID of a Postgres Pro backend process to which the postmaster should send `SIGUSR1` when the process is started or exits. It should be 0 for workers registered at postmaster startup time, or when the backend registering the worker does not wish to wait for the worker to start up. Otherwise, it should be initialized to `MyProcPid`.

Once running, the process can connect to a database by calling `BackgroundWorkerInitializeConnection(char *dbname, char *username, uint32 flags)` or `BackgroundWorkerInitializeConnectionByOid(Oid dboid, Oid useroid, uint32 flags)`. This allows the process to run transactions and queries using the SPI interface. If `dbname` is `NULL` or `dboid` is `InvalidOid`, the session is not connected to any particular database, but shared catalogs can be accessed. If `username` is `NULL` or `useroid` is `InvalidOid`, the process will run as the superuser created during `initdb`. If `BGWORKER_BYPASS_ALLOWCONN` is specified as `flags` it is possible to bypass the restriction to connect to databases not allowing user connections. If `BGWORKER_BYPASS_ROLELOGINCHECK` is specified as `flags` it is possible to bypass the login check for the role used to connect to databases. A background worker can only call one of these two functions, and only once. It is not possible to switch databases.

Signals are initially blocked when control reaches the background worker's main function, and must be unblocked by it; this is to allow the process to customize its signal handlers, if necessary. Signals can be unblocked in the new process by calling `BackgroundWorkerUnblockSignals` and blocked by calling `BackgroundWorkerBlockSignals`.

If `bgw_restart_time` for a background worker is configured as `BGW_NEVER_RESTART`, or if it exits with an exit code of 0 or is terminated by `TerminateBackgroundWorker`, it will be automatically unregis-

tered by the postmaster on exit. Otherwise, it will be restarted after the time period configured via `bgw_restart_time`, or immediately if the postmaster reinitializes the cluster due to a backend failure. Backends which need to suspend execution only temporarily should use an interruptible sleep rather than exiting; this can be achieved by calling `WaitLatch()`. Make sure the `WL_POSTMASTER_DEATH` flag is set when calling that function, and verify the return code for a prompt exit in the emergency case that `postgres` itself has terminated.

When a background worker is registered using the `RegisterDynamicBackgroundWorker` function, it is possible for the backend performing the registration to obtain information regarding the status of the worker. Backends wishing to do this should pass the address of a `BackgroundWorkerHandle *` as the second argument to `RegisterDynamicBackgroundWorker`. If the worker is successfully registered, this pointer will be initialized with an opaque handle that can subsequently be passed to `GetBackgroundWorkerPid(BackgroundWorkerHandle *, pid_t *)` or `TerminateBackgroundWorker(BackgroundWorkerHandle *)`. `GetBackgroundWorkerPid` can be used to poll the status of the worker: a return value of `BGWH_NOT_YET_STARTED` indicates that the worker has not yet been started by the postmaster; `BGWH_STOPPED` indicates that it has been started but is no longer running; and `BGWH_STARTED` indicates that it is currently running. In this last case, the PID will also be returned via the second argument. `TerminateBackgroundWorker` causes the postmaster to send `SIGTERM` to the worker if it is running, and to unregister it as soon as it is not.

In some cases, a process which registers a background worker may wish to wait for the worker to start up. This can be accomplished by initializing `bgw_notify_pid` to `MyProcPid` and then passing the `BackgroundWorkerHandle *` obtained at registration time to `WaitForBackgroundWorkerStartup(BackgroundWorkerHandle *handle, pid_t *)` function. This function will block until the postmaster has attempted to start the background worker, or until the postmaster dies. If the background worker is running, the return value will be `BGWH_STARTED`, and the PID will be written to the provided address. Otherwise, the return value will be `BGWH_STOPPED` or `BGWH_POSTMASTER_DIED`.

A process can also wait for a background worker to shut down, by using the `WaitForBackgroundWorkerShutdown(BackgroundWorkerHandle *handle)` function and passing the `BackgroundWorkerHandle *` obtained at registration. This function will block until the background worker exits, or postmaster dies. When the background worker exits, the return value is `BGWH_STOPPED`, if postmaster dies it will return `BGWH_POSTMASTER_DIED`.

Background workers can send asynchronous notification messages, either by using the `NOTIFY` command via SPI, or directly via `Async_Notify()`. Such notifications will be sent at transaction commit. Background workers should not register to receive asynchronous notifications with the `LISTEN` command, as there is no infrastructure for a worker to consume such notifications.

The maximum number of registered background workers is limited by [max_worker_processes](#).

Chapter 50. Logical Decoding

Postgres Pro provides infrastructure to stream the modifications performed via SQL to external consumers. This functionality can be used for a variety of purposes, including replication solutions and auditing.

Changes are sent out in streams identified by logical replication slots.

The format in which those changes are streamed is determined by the output plugin used. An example plugin is provided in the Postgres Pro distribution. Additional plugins can be written to extend the choice of available formats without modifying any core code. Every output plugin has access to each individual new row produced by `INSERT` and the new row version created by `UPDATE`. Availability of old row versions for `UPDATE` and `DELETE` depends on the configured replica identity (see [REPLICA IDENTITY](#)).

Changes can be consumed either using the streaming replication protocol (see [Section 56.4](#) and [Section 50.3](#)), or by calling functions via SQL (see [Section 50.4](#)). It is also possible to write additional methods of consuming the output of a replication slot without modifying core code (see [Section 50.7](#)).

50.1. Logical Decoding Examples

The following example demonstrates controlling logical decoding using the SQL interface.

Before you can use logical decoding, you must set `wal_level` to `logical` and `max_replication_slots` to at least 1. Then, you should connect to the target database (in the example below, `postgres`) as a superuser.

```
postgres=# -- Create a slot named 'regression_slot' using the output plugin
'test_decoding'
postgres=# SELECT * FROM pg_create_logical_replication_slot('regression_slot',
'test_decoding', false, true);
   slot_name   |    lsn
-----+-----
 regression_slot | 0/16B1970
(1 row)

postgres=# SELECT slot_name, plugin, slot_type, database, active, restart_lsn,
confirmed_flush_lsn FROM pg_replication_slots;
   slot_name   |   plugin   | slot_type | database | active | restart_lsn | confirmed_flush_lsn
-----+-----+-----+-----+-----+-----+-----
 regression_slot | test_decoding | logical   | postgres | f      | 0/16A4408   | 0/16A4440
(1 row)

postgres=# -- There are no changes to see yet
postgres=# SELECT * FROM pg_logical_slot_get_changes('regression_slot', NULL, NULL);
   lsn | xid | data
-----+-----+-----
(0 rows)

postgres=# CREATE TABLE data(id serial primary key, data text);
CREATE TABLE

postgres=# -- DDL isn't replicated, so all you'll see is the transaction
postgres=# SELECT * FROM pg_logical_slot_get_changes('regression_slot', NULL, NULL);
   lsn   | xid  | data
-----+-----+-----
 0/BA2DA58 | 10297 | BEGIN 10297
 0/BA5A5A0 | 10297 | COMMIT 10297
```

(2 rows)

```
postgres=# -- Once changes are read, they're consumed and not emitted
postgres=# -- in a subsequent call:
postgres=# SELECT * FROM pg_logical_slot_get_changes('regression_slot', NULL, NULL);
 lsn | xid | data
-----+-----+-----
(0 rows)
```

```
postgres=# BEGIN;
postgres=# INSERT INTO data(data) VALUES('1');
postgres=# INSERT INTO data(data) VALUES('2');
postgres=# COMMIT;
```

```
postgres=# SELECT * FROM pg_logical_slot_get_changes('regression_slot', NULL, NULL);
 lsn | xid | data
-----+-----+-----
0/BA5A688 | 10298 | BEGIN 10298
0/BA5A6F0 | 10298 | table public.data: INSERT: id[integer]:1 data[text]:'1'
0/BA5A7F8 | 10298 | table public.data: INSERT: id[integer]:2 data[text]:'2'
0/BA5A8A8 | 10298 | COMMIT 10298
(4 rows)
```

```
postgres=# INSERT INTO data(data) VALUES('3');
```

```
postgres=# -- You can also peek ahead in the change stream without consuming changes
postgres=# SELECT * FROM pg_logical_slot_peek_changes('regression_slot', NULL, NULL);
 lsn | xid | data
-----+-----+-----
0/BA5A8E0 | 10299 | BEGIN 10299
0/BA5A8E0 | 10299 | table public.data: INSERT: id[integer]:3 data[text]:'3'
0/BA5A990 | 10299 | COMMIT 10299
(3 rows)
```

```
postgres=# -- The next call to pg_logical_slot_peek_changes() returns the same changes
again
postgres=# SELECT * FROM pg_logical_slot_peek_changes('regression_slot', NULL, NULL);
 lsn | xid | data
-----+-----+-----
0/BA5A8E0 | 10299 | BEGIN 10299
0/BA5A8E0 | 10299 | table public.data: INSERT: id[integer]:3 data[text]:'3'
0/BA5A990 | 10299 | COMMIT 10299
(3 rows)
```

```
postgres=# -- options can be passed to output plugin, to influence the formatting
postgres=# SELECT * FROM pg_logical_slot_peek_changes('regression_slot', NULL, NULL,
 'include-timestamp', 'on');
 lsn | xid | data
-----+-----+-----
0/BA5A8E0 | 10299 | BEGIN 10299
0/BA5A8E0 | 10299 | table public.data: INSERT: id[integer]:3 data[text]:'3'
0/BA5A990 | 10299 | COMMIT 10299 (at 2017-05-10 12:07:21.272494-04)
(3 rows)
```

```
postgres=# -- Remember to destroy a slot you no longer need to stop it consuming
server resources:
postgres=# SELECT pg_drop_replication_slot('regression_slot');
pg_drop_replication_slot
```

```
-----
(1 row)
```

The following examples show how logical decoding is controlled over the streaming replication protocol, using the program `pg_recvlogical` included in the Postgres Pro distribution. This requires that client authentication is set up to allow replication connections (see [Section 26.2.5.1](#)) and that `max_wal_senders` is set sufficiently high to allow an additional connection. The second example shows how to stream two-phase transactions. Before you use two-phase commands, you must set `max_prepared_transactions` to at least 1.

Example 1:

```
$ pg_recvlogical -d postgres --slot=test --create-slot
$ pg_recvlogical -d postgres --slot=test --start -f -
Control+Z
$ psql -d postgres -c "INSERT INTO data(data) VALUES('4');"
$ fg
BEGIN 693
table public.data: INSERT: id[integer]:4 data[text]:'4'
COMMIT 693
Control+C
$ pg_recvlogical -d postgres --slot=test --drop-slot
```

Example 2:

```
$ pg_recvlogical -d postgres --slot=test --create-slot --two-phase
$ pg_recvlogical -d postgres --slot=test --start -f -
Control+Z
$ psql -d postgres -c "BEGIN;INSERT INTO data(data) VALUES('5');PREPARE TRANSACTION
'test';"
$ fg
BEGIN 694
table public.data: INSERT: id[integer]:5 data[text]:'5'
PREPARE TRANSACTION 'test', txid 694
Control+Z
$ psql -d postgres -c "COMMIT PREPARED 'test';"
$ fg
COMMIT PREPARED 'test', txid 694
Control+C
$ pg_recvlogical -d postgres --slot=test --drop-slot
```

The following example shows SQL interface that can be used to decode prepared transactions. Before you use two-phase commit commands, you must set `max_prepared_transactions` to at least 1. You must also have set the two-phase parameter as 'true' while creating the slot using `pg_create_logical_replication_slot`. Note that we will stream the entire transaction after the commit if it is not already decoded.

```
postgres=# BEGIN;
postgres=# INSERT INTO data(data) VALUES('5');
postgres=# PREPARE TRANSACTION 'test_prepared1';

50.2. Logical Decoding Concepts

50.2.1. Logical Decoding

Logical decoding is the process of extracting all persistent changes to a database's tables into a coherent, easy to understand format which can be interpreted without detailed knowledge of the database's internal state.

In Postgres Pro, logical decoding is implemented by decoding the contents of the [write-ahead log](#), which describe changes on a storage level, into an application-specific form such as a stream of tuples or SQL statements.

50.2.2. Replication Slots

In the context of logical replication, a slot represents a stream of changes that can be replayed to a client in the order they were made on the origin server. Each slot streams a sequence of changes from a single database.

Note

Postgres Pro also has streaming replication slots (see [Section 26.2.5](#)), but they are used somewhat differently there.

A replication slot has an identifier that is unique across all databases in a Postgres Pro cluster. Slots persist independently of the connection using them and are crash-safe.

A logical slot will emit each change just once in normal operation. The current position of each slot is persisted only at checkpoint, so in the case of a crash the slot may return to an earlier LSN, which will then cause recent changes to be sent again when the server restarts. Logical decoding clients are responsible for avoiding ill effects from handling the same message more than once. Clients may wish to record the last LSN they saw when decoding and skip over any repeated data or (when using the replication protocol) request that decoding start from that LSN rather than letting the server determine the start point. The Replication Progress Tracking feature is designed for this purpose, refer to [replication origins](#).

Multiple independent slots may exist for a single database. Each slot has its own state, allowing different consumers to receive changes from different points in the database change stream. For most applications, a separate slot will be required for each consumer.

A logical replication slot knows nothing about the state of the receiver(s). It's even possible to have multiple different receivers using the same slot at different times; they'll just get the changes following on from when the last receiver stopped consuming them. Only one receiver may consume changes from a slot at any given time.

A logical replication slot can also be created on a hot standby. To prevent `VACUUM` from removing required rows from the system catalogs, `hot_standby_feedback` should be set on the standby. In spite of that, if any required rows get removed, the slot gets invalidated. It's highly recommended to use a physical slot between the primary and the standby. Otherwise, `hot_standby_feedback` will work but only while the connection is alive (for example a node restart would break it). Then, the primary may delete system catalog rows that could be needed by the logical decoding on the standby (as it does not know about the `catalog_xmin` on the standby). Existing logical slots on standby also get invalidated if `wal_level` on the primary is reduced to less than `logical`. This is done as soon as the standby detects such a change in the WAL stream. It means that, for walsenders that are lagging (if any), some WAL records up to the `wal_level` parameter change on the primary won't be decoded.

Creation of a logical slot requires information about all the currently running transactions. On the primary, this information is available directly, but on a standby, this information has to be obtained from primary. Thus, slot creation may need to wait for some activity to happen on the primary. If the primary is idle, creating a logical slot on standby may take noticeable time. This can be sped up by calling the `pg_log_standby_snapshot` function on the primary.

Caution

Replication slots persist across crashes and know nothing about the state of their consumer(s). They will prevent removal of required resources even when there is no connection using them. This consumes storage because neither required WAL nor required rows from the system catalogs can be removed by `VACUUM` as long as they are required by a replication slot. In extreme cases this could cause the database to shut down to prevent transaction ID wraparound (see [Section 24.1.5](#)). So if a slot is no longer required it should be dropped.

50.2.3. Replication Slot Synchronization

The logical replication slots on the primary can be synchronized to the hot standby by using the `failover` parameter of `pg_create_logical_replication_slot`, or by using the `failover` option of `CREATE SUBSCRIPTION` during slot creation, and then calling `pg_sync_replication_slots` on the standby. By setting `sync_replication_slots` on the standby, the failover slots can be synchronized periodically in the `slotsync` worker. For the synchronization to work, it is mandatory to have a physical replication slot between the primary and the standby (i.e., `primary_slot_name` should be configured on the standby), and `hot_standby_feedback` must be enabled on the standby. It is also necessary to specify a valid `db-name` in the `primary_conninfo`. It's highly recommended that the said physical replication slot is named in `synchronized_standby_slots` list on the primary, to prevent the subscriber from consuming changes faster than the hot standby. Even when correctly configured, some latency is expected when sending changes to logical subscribers due to the waiting on slots named in `synchronized_standby_slots`. When `synchronized_standby_slots` is utilized, the primary server will not completely shut down until the corresponding standbys, associated with the physical replication slots specified in `synchronized_standby_slots`, have confirmed receiving the WAL up to the latest flushed position on the primary server.

The ability to resume logical replication after failover depends upon the `pg_replication_slots.synced` value for the synchronized slots on the standby at the time of failover. Only persistent slots that have attained synced state as `true` on the standby before failover can be used for logical replication after failover. Temporary synced slots cannot be used for logical decoding, therefore logical replication for

those slots cannot be resumed. For example, if the synchronized slot could not become persistent on the standby due to a disabled subscription, then the subscription cannot be resumed after failover even when it is enabled.

To resume logical replication after failover from the synced logical slots, the subscription's 'conninfo' must be altered to point to the new primary server. This is done using `ALTER SUBSCRIPTION ... CONNECTION`. It is recommended that subscriptions are first disabled before promoting the standby and are re-enabled after altering the connection string.

Caution

There is a chance that the old primary is up again during the promotion and if subscriptions are not disabled, the logical subscribers may continue to receive data from the old primary server even after promotion until the connection string is altered. This might result in data inconsistency issues, preventing the logical subscribers from being able to continue replication from the new primary server.

50.2.4. Output Plugins

Output plugins transform the data from the write-ahead log's internal representation into the format the consumer of a replication slot desires.

50.2.5. Exported Snapshots

When a new replication slot is created using the streaming replication interface (see `CREATE_REPLICATION_SLOT`), a snapshot is exported (see [Section 9.28.5](#)), which will show exactly the state of the database after which all changes will be included in the change stream. This can be used to create a new replica by using `SET TRANSACTION SNAPSHOT` to read the state of the database at the moment the slot was created. This transaction can then be used to dump the database's state at that point in time, which afterwards can be updated using the slot's contents without losing any changes.

Creation of a snapshot is not always possible. In particular, it will fail when connected to a hot standby. Applications that do not require snapshot export may suppress it with the `NOEXPORT_SNAPSHOT` option.

50.3. Streaming Replication Protocol Interface

The commands

- `CREATE_REPLICATION_SLOT slot_name LOGICAL output_plugin`
- `DROP_REPLICATION_SLOT slot_name [WAIT]`
- `START_REPLICATION SLOT slot_name LOGICAL ...`

are used to create, drop, and stream changes from a replication slot, respectively. These commands are only available over a replication connection; they cannot be used via SQL. See [Section 56.4](#) for details on these commands.

The command `pg_recvlogical` can be used to control logical decoding over a streaming replication connection. (It uses these commands internally.)

50.4. Logical Decoding SQL Interface

See [Section 9.28.6](#) for detailed documentation on the SQL-level API for interacting with logical decoding.

Synchronous replication (see [Section 26.2.8](#)) is only supported on replication slots used over the streaming replication interface. The function interface and additional, non-core interfaces do not support synchronous replication.

50.5. System Catalogs Related to Logical Decoding

The `pg_replication_slots` view and the `pg_stat_replication` view provide information about the current state of replication slots and streaming replication connections respectively. These views apply to both physical and logical replication. The `pg_stat_replication_slots` view provides statistics information about the logical replication slots.

50.6. Logical Decoding Output Plugins

50.6.1. Initialization Function

An output plugin is loaded by dynamically loading a shared library with the output plugin's name as the library base name. The normal library search path is used to locate the library. To provide the required output plugin callbacks and to indicate that the library is actually an output plugin it needs to provide a function named `_PG_output_plugin_init`. This function is passed a struct that needs to be filled with the callback function pointers for individual actions.

```
typedef struct OutputPluginCallbacks
{
    LogicalDecodeStartupCB startup_cb;
    LogicalDecodeBeginCB begin_cb;
    LogicalDecodeChangeCB change_cb;
    LogicalDecodeTruncateCB truncate_cb;
    LogicalDecodeCommitCB commit_cb;
    LogicalDecodeMessageCB message_cb;
    LogicalDecodeFilterByOriginCB filter_by_origin_cb;
    LogicalDecodeShutdownCB shutdown_cb;
    LogicalDecodeFilterPrepareCB filter_prepare_cb;
    LogicalDecodeBeginPrepareCB begin_prepare_cb;
    LogicalDecodePrepareCB prepare_cb;
    LogicalDecodeCommitPreparedCB commit_prepared_cb;
    LogicalDecodeRollbackPreparedCB rollback_prepared_cb;
    LogicalDecodeStreamStartCB stream_start_cb;
    LogicalDecodeStreamStopCB stream_stop_cb;
    LogicalDecodeStreamAbortCB stream_abort_cb;
    LogicalDecodeStreamPrepareCB stream_prepare_cb;
    LogicalDecodeStreamCommitCB stream_commit_cb;
    LogicalDecodeStreamChangeCB stream_change_cb;
    LogicalDecodeStreamMessageCB stream_message_cb;
    LogicalDecodeStreamTruncateCB stream_truncate_cb;
} OutputPluginCallbacks;
```

```
typedef void (*LogicalOutputPluginInit) (struct OutputPluginCallbacks *cb);
```

The `begin_cb`, `change_cb` and `commit_cb` callbacks are required, while `startup_cb`, `truncate_cb`, `message_cb`, `filter_by_origin_cb`, and `shutdown_cb` are optional. If `truncate_cb` is not set but a `TRUNCATE` is to be decoded, the action will be ignored.

An output plugin may also define functions to support streaming of large, in-progress transactions. The `stream_start_cb`, `stream_stop_cb`, `stream_abort_cb`, `stream_commit_cb`, and `stream_change_cb` are required, while `stream_message_cb` and `stream_truncate_cb` are optional. The `stream_prepare_cb` is also required if the output plugin also support two-phase commits.

An output plugin may also define functions to support two-phase commits, which allows actions to be decoded on the `PREPARE TRANSACTION`. The `begin_prepare_cb`, `prepare_cb`, `commit_prepared_cb` and `rollback_prepared_cb` callbacks are required, while `filter_prepare_cb` is optional. The `stream_prepare_cb` is also required if the output plugin also supports the streaming of large in-progress transactions.

50.6.2. Capabilities

To decode, format and output changes, output plugins can use most of the backend's normal infrastructure, including calling output functions. Read only access to relations is permitted as long as only relations are accessed that either have been created by `initdb` in the `pg_catalog` schema, or have been marked as user provided catalog tables using

```
ALTER TABLE user_catalog_table SET (user_catalog_table = true);
CREATE TABLE another_catalog_table(data text) WITH (user_catalog_table = true);
```

Note that access to user catalog tables or regular system catalog tables in the output plugins has to be done via the `systable_*` scan APIs only. Access via the `heap_*` scan APIs will error out. Additionally, any actions leading to transaction ID assignment are prohibited. That, among others, includes writing to tables, performing DDL changes, and calling `pg_current_xact_id()`.

50.6.3. Output Modes

Output plugin callbacks can pass data to the consumer in nearly arbitrary formats. For some use cases, like viewing the changes via SQL, returning data in a data type that can contain arbitrary data (e.g., `bytea`) is cumbersome. If the output plugin only outputs textual data in the server's encoding, it can declare that by setting `OutputPluginOptions.output_type` to `OUTPUT_PLUGIN_TEXTUAL_OUTPUT` instead of `OUTPUT_PLUGIN_BINARY_OUTPUT` in the [startup callback](#). In that case, all the data has to be in the server's encoding so that a `text` datum can contain it. This is checked in assertion-enabled builds.

50.6.4. Output Plugin Callbacks

An output plugin gets notified about changes that are happening via various callbacks it needs to provide.

Concurrent transactions are decoded in commit order, and only changes belonging to a specific transaction are decoded between the `begin` and `commit` callbacks. Transactions that were rolled back explicitly or implicitly never get decoded. Successful savepoints are folded into the transaction containing them in the order they were executed within that transaction. A transaction that is prepared for a two-phase commit using `PREPARE TRANSACTION` will also be decoded if the output plugin callbacks needed for decoding them are provided. It is possible that the current prepared transaction which is being decoded is aborted concurrently via a `ROLLBACK PREPARED` command. In that case, the logical decoding of this transaction will be aborted too. All the changes of such a transaction are skipped once the abort is detected and the `prepare_cb` callback is invoked. Thus even in case of a concurrent abort, enough information is provided to the output plugin for it to properly deal with `ROLLBACK PREPARED` once that is decoded.

Note

Only transactions that have already safely been flushed to disk will be decoded. That can lead to a `COMMIT` not immediately being decoded in a directly following `pg_logical_slot_get_changes()` when `synchronous_commit` is set to `off`.

50.6.4.1. Startup Callback

The optional `startup_cb` callback is called whenever a replication slot is created or asked to stream changes, independent of the number of changes that are ready to be put out.

```
typedef void (*LogicalDecodeStartupCB) (struct LogicalDecodingContext *ctx,
                                         OutputPluginOptions *options,
                                         bool is_init);
```

The `is_init` parameter will be true when the replication slot is being created and false otherwise. `options` points to a struct of options that output plugins can set:

```
typedef struct OutputPluginOptions
{
    OutputPluginOutputType output_type;
```

```
bool        receive_rewrites;
} OutputPluginOptions;
```

`output_type` has to either be set to `OUTPUT_PLUGIN_TEXTUAL_OUTPUT` or `OUTPUT_PLUGIN_BINARY_OUTPUT`. See also [Section 50.6.3](#). If `receive_rewrites` is true, the output plugin will also be called for changes made by heap rewrites during certain DDL operations. These are of interest to plugins that handle DDL replication, but they require special handling.

The startup callback should validate the options present in `ctx->output_plugin_options`. If the output plugin needs to have a state, it can use `ctx->output_plugin_private` to store it.

50.6.4.2. Shutdown Callback

The optional `shutdown_cb` callback is called whenever a formerly active replication slot is not used anymore and can be used to deallocate resources private to the output plugin. The slot isn't necessarily being dropped, streaming is just being stopped.

```
typedef void (*LogicalDecodeShutdownCB) (struct LogicalDecodingContext *ctx);
```

50.6.4.3. Transaction Begin Callback

The required `begin_cb` callback is called whenever a start of a committed transaction has been decoded. Aborted transactions and their contents never get decoded.

```
typedef void (*LogicalDecodeBeginCB) (struct LogicalDecodingContext *ctx,
                                     ReorderBufferTXN *txn);
```

The `txn` parameter contains meta information about the transaction, like the time stamp at which it has been committed and its `XID`.

50.6.4.4. Transaction End Callback

The required `commit_cb` callback is called whenever a transaction commit has been decoded. The `change_cb` callbacks for all modified rows will have been called before this, if there have been any modified rows.

```
typedef void (*LogicalDecodeCommitCB) (struct LogicalDecodingContext *ctx,
                                       ReorderBufferTXN *txn,
                                       XLogRecPtr commit_lsn);
```

50.6.4.5. Change Callback

The required `change_cb` callback is called for every individual row modification inside a transaction, may it be an `INSERT`, `UPDATE`, or `DELETE`. Even if the original command modified several rows at once the callback will be called individually for each row. The `change_cb` callback may access system or user catalog tables to aid in the process of outputting the row modification details. In case of decoding a prepared (but yet uncommitted) transaction or decoding of an uncommitted transaction, this change callback might also error out due to simultaneous rollback of this very same transaction. In that case, the logical decoding of this aborted transaction is stopped gracefully.

```
typedef void (*LogicalDecodeChangeCB) (struct LogicalDecodingContext *ctx,
                                       ReorderBufferTXN *txn,
                                       Relation relation,
                                       ReorderBufferChange *change);
```

The `ctx` and `txn` parameters have the same contents as for the `begin_cb` and `commit_cb` callbacks, but additionally the relation descriptor `relation` points to the relation the row belongs to and a struct `change` describing the row modification are passed in.

Note

Only changes in user defined tables that are not unlogged (see [UNLOGGED](#)) and not temporary (see [TEMPORARY](#) or [TEMP](#)) can be extracted using logical decoding.

50.6.4.6. Truncate Callback

The optional `truncate_cb` callback is called for a `TRUNCATE` command.

```
typedef void (*LogicalDecodeTruncateCB) (struct LogicalDecodingContext *ctx,
                                         ReorderBufferTXN *txn,
                                         int nrelations,
                                         Relation relations[],
                                         ReorderBufferChange *change);
```

The parameters are analogous to the `change_cb` callback. However, because `TRUNCATE` actions on tables connected by foreign keys need to be executed together, this callback receives an array of relations instead of just a single one. See the description of the [TRUNCATE](#) statement for details.

50.6.4.7. Origin Filter Callback

The optional `filter_by_origin_cb` callback is called to determine whether data that has been replayed from `origin_id` is of interest to the output plugin.

```
typedef bool (*LogicalDecodeFilterByOriginCB) (struct LogicalDecodingContext *ctx,
                                              RepOriginId origin_id);
```

The `ctx` parameter has the same contents as for the other callbacks. No information but the origin is available. To signal that changes originating on the passed in node are irrelevant, return true, causing them to be filtered away; false otherwise. The other callbacks will not be called for transactions and changes that have been filtered away.

This is useful when implementing cascading or multidirectional replication solutions. Filtering by the origin allows to prevent replicating the same changes back and forth in such setups. While transactions and changes also carry information about the origin, filtering via this callback is noticeably more efficient.

50.6.4.8. Generic Message Callback

The optional `message_cb` callback is called whenever a logical decoding message has been decoded.

```
typedef void (*LogicalDecodeMessageCB) (struct LogicalDecodingContext *ctx,
                                         ReorderBufferTXN *txn,
                                         XLogRecPtr message_lsn,
                                         bool transactional,
                                         const char *prefix,
                                         Size message_size,
                                         const char *message);
```

The `txn` parameter contains meta information about the transaction, like the time stamp at which it has been committed and its XID. Note however that it can be NULL when the message is non-transactional and the XID was not assigned yet in the transaction which logged the message. The `lsn` has WAL location of the message. The `transactional` says if the message was sent as transactional or not. Similar to the change callback, in case of decoding a prepared (but yet uncommitted) transaction or decoding of an uncommitted transaction, this message callback might also error out due to simultaneous rollback of this very same transaction. In that case, the logical decoding of this aborted transaction is stopped gracefully. The `prefix` is arbitrary null-terminated prefix which can be used for identifying interesting messages for the current plugin. And finally the `message` parameter holds the actual message of `message_size` size.

Extra care should be taken to ensure that the prefix the output plugin considers interesting is unique. Using name of the extension or the output plugin itself is often a good choice.

50.6.4.9. Prepare Filter Callback

The optional `filter_prepare_cb` callback is called to determine whether data that is part of the current two-phase commit transaction should be considered for decoding at this prepare stage or later as a regular one-phase transaction at `COMMIT PREPARED` time. To signal that decoding should be skipped,

`return true; false` otherwise. When the callback is not defined, `false` is assumed (i.e. no filtering, all transactions using two-phase commit are decoded in two phases as well).

```
typedef bool (*LogicalDecodeFilterPrepareCB) (struct LogicalDecodingContext *ctx,
                                             TransactionId xid,
                                             const char *gid);
```

The `ctx` parameter has the same contents as for the other callbacks. The parameters `xid` and `gid` provide two different ways to identify the transaction. The later `COMMIT PREPARED` or `ROLLBACK PREPARED` carries both identifiers, providing an output plugin the choice of what to use.

The callback may be invoked multiple times per transaction to decode and must provide the same static answer for a given pair of `xid` and `gid` every time it is called.

50.6.4.10. Transaction Begin Prepare Callback

The required `begin_prepare_cb` callback is called whenever the start of a prepared transaction has been decoded. The `gid` field, which is part of the `txn` parameter, can be used in this callback to check if the plugin has already received this `PREPARE` in which case it can either error out or skip the remaining changes of the transaction.

```
typedef void (*LogicalDecodeBeginPrepareCB) (struct LogicalDecodingContext *ctx,
                                             ReorderBufferTXN *txn);
```

50.6.4.11. Transaction Prepare Callback

The required `prepare_cb` callback is called whenever a transaction which is prepared for two-phase commit has been decoded. The `change_cb` callback for all modified rows will have been called before this, if there have been any modified rows. The `gid` field, which is part of the `txn` parameter, can be used in this callback.

```
typedef void (*LogicalDecodePrepareCB) (struct LogicalDecodingContext *ctx,
                                        ReorderBufferTXN *txn,
                                        XLogRecPtr prepare_lsn);
```

50.6.4.12. Transaction Commit Prepared Callback

The required `commit_prepared_cb` callback is called whenever a transaction `COMMIT PREPARED` has been decoded. The `gid` field, which is part of the `txn` parameter, can be used in this callback.

```
typedef void (*LogicalDecodeCommitPreparedCB) (struct LogicalDecodingContext *ctx,
                                                ReorderBufferTXN *txn,
                                                XLogRecPtr commit_lsn);
```

50.6.4.13. Transaction Rollback Prepared Callback

The required `rollback_prepared_cb` callback is called whenever a transaction `ROLLBACK PREPARED` has been decoded. The `gid` field, which is part of the `txn` parameter, can be used in this callback. The parameters `prepare_end_lsn` and `prepare_time` can be used to check if the plugin has received this `PREPARE TRANSACTION` in which case it can apply the rollback, otherwise, it can skip the rollback operation. The `gid` alone is not sufficient because the downstream node can have a prepared transaction with same identifier.

```
typedef void (*LogicalDecodeRollbackPreparedCB) (struct LogicalDecodingContext *ctx,
                                                  ReorderBufferTXN *txn,
                                                  XLogRecPtr prepare_end_lsn,
                                                  TimestampTz prepare_time);
```

50.6.4.14. Stream Start Callback

The required `stream_start_cb` callback is called when opening a block of streamed changes from an in-progress transaction.

```
typedef void (*LogicalDecodeStreamStartCB) (struct LogicalDecodingContext *ctx,
                                             ReorderBufferTXN *txn);
```

50.6.4.15. Stream Stop Callback

The required `stream_stop_cb` callback is called when closing a block of streamed changes from an in-progress transaction.

```
typedef void (*LogicalDecodeStreamStopCB) (struct LogicalDecodingContext *ctx,
                                           ReorderBufferTXN *txn);
```

50.6.4.16. Stream Abort Callback

The required `stream_abort_cb` callback is called to abort a previously streamed transaction.

```
typedef void (*LogicalDecodeStreamAbortCB) (struct LogicalDecodingContext *ctx,
                                           ReorderBufferTXN *txn,
                                           XLogRecPtr abort_lsn);
```

50.6.4.17. Stream Prepare Callback

The `stream_prepare_cb` callback is called to prepare a previously streamed transaction as part of a two-phase commit. This callback is required when the output plugin supports both the streaming of large in-progress transactions and two-phase commits.

```
typedef void (*LogicalDecodeStreamPrepareCB) (struct LogicalDecodingContext *ctx,
                                              ReorderBufferTXN *txn,
                                              XLogRecPtr prepare_lsn);
```

50.6.4.18. Stream Commit Callback

The required `stream_commit_cb` callback is called to commit a previously streamed transaction.

```
typedef void (*LogicalDecodeStreamCommitCB) (struct LogicalDecodingContext *ctx,
                                             ReorderBufferTXN *txn,
                                             XLogRecPtr commit_lsn);
```

50.6.4.19. Stream Change Callback

The required `stream_change_cb` callback is called when sending a change in a block of streamed changes (demarcated by `stream_start_cb` and `stream_stop_cb` calls). The actual changes are not displayed as the transaction can abort at a later point in time and we don't decode changes for aborted transactions.

```
typedef void (*LogicalDecodeStreamChangeCB) (struct LogicalDecodingContext *ctx,
                                             ReorderBufferTXN *txn,
                                             Relation relation,
                                             ReorderBufferChange *change);
```

50.6.4.20. Stream Message Callback

The optional `stream_message_cb` callback is called when sending a generic message in a block of streamed changes (demarcated by `stream_start_cb` and `stream_stop_cb` calls). The message contents for transactional messages are not displayed as the transaction can abort at a later point in time and we don't decode changes for aborted transactions.

```
typedef void (*LogicalDecodeStreamMessageCB) (struct LogicalDecodingContext *ctx,
                                              ReorderBufferTXN *txn,
                                              XLogRecPtr message_lsn,
                                              bool transactional,
                                              const char *prefix,
                                              Size message_size,
                                              const char *message);
```

50.6.4.21. Stream Truncate Callback

The optional `stream_truncate_cb` callback is called for a `TRUNCATE` command in a block of streamed changes (demarcated by `stream_start_cb` and `stream_stop_cb` calls).

```
typedef void (*LogicalDecodeStreamTruncateCB) (struct LogicalDecodingContext *ctx,
                                              ReorderBufferTXN *txn,
                                              int nrelations,
                                              Relation relations[],
                                              ReorderBufferChange *change);
```

The parameters are analogous to the `stream_change_cb` callback. However, because `TRUNCATE` actions on tables connected by foreign keys need to be executed together, this callback receives an array of relations instead of just a single one. See the description of the [TRUNCATE](#) statement for details.

50.6.5. Functions for Producing Output

To actually produce output, output plugins can write data to the `StringInfo` output buffer in `ctx->out` when inside the `begin_cb`, `commit_cb`, or `change_cb` callbacks. Before writing to the output buffer, `OutputPluginPrepareWrite(ctx, last_write)` has to be called, and after finishing writing to the buffer, `OutputPluginWrite(ctx, last_write)` has to be called to perform the write. The `last_write` indicates whether a particular write was the callback's last write.

The following example shows how to output data to the consumer of an output plugin:

```
OutputPluginPrepareWrite(ctx, true);
appendStringInfo(ctx->out, "BEGIN %u", txn->xid);
OutputPluginWrite(ctx, true);
```

50.7. Logical Decoding Output Writers

It is possible to add more output methods for logical decoding. Essentially, three functions need to be provided: one to read WAL, one to prepare writing output, and one to write the output (see [Section 50.6.5](#)).

50.8. Synchronous Replication Support for Logical Decoding

50.8.1. Overview

Logical decoding can be used to build [synchronous replication](#) solutions with the same user interface as synchronous replication for [streaming replication](#). To do this, the streaming replication interface (see [Section 50.3](#)) must be used to stream out data. Clients have to send `Standby status update (F)` (see [Section 56.4](#)) messages, just like streaming replication clients do.

Note

A synchronous replica receiving changes via logical decoding will work in the scope of a single database. Since, in contrast to that, `synchronous_standby_names` currently is server wide, this means this technique will not work properly if more than one database is actively used.

50.8.2. Caveats

In synchronous replication setup, a deadlock can happen, if the transaction has locked [user] catalog tables exclusively. See [Section 50.6.2](#) for information on user catalog tables. This is because logical decoding of transactions can lock catalog tables to access them. To avoid this users must refrain from taking an exclusive lock on [user] catalog tables. This can happen in the following ways:

- Issuing an explicit `LOCK` on `pg_class` in a transaction.
- Perform `CLUSTER` on `pg_class` in a transaction.
- `PREPARE TRANSACTION` after `LOCK` command on `pg_class` and allow logical decoding of two-phase transactions.

- `PREPARE TRANSACTION` after `CLUSTER` command on `pg_trigger` and allow logical decoding of two-phase transactions. This will lead to deadlock only when published table have a trigger.
- Executing `TRUNCATE` on [user] catalog table in a transaction.

Note that these commands can cause deadlocks not only for the system catalog tables listed above but for other catalog tables.

50.9. Streaming of Large Transactions for Logical Decoding

The basic output plugin callbacks (e.g., `begin_cb`, `change_cb`, `commit_cb` and `message_cb`) are only invoked when the transaction actually commits. The changes are still decoded from the transaction log, but are only passed to the output plugin at commit (and discarded if the transaction aborts).

This means that while the decoding happens incrementally, and may spill to disk to keep memory usage under control, all the decoded changes have to be transmitted when the transaction finally commits (or more precisely, when the commit is decoded from the transaction log). Depending on the size of the transaction and network bandwidth, the transfer time may significantly increase the apply lag.

To reduce the apply lag caused by large transactions, an output plugin may provide additional callback to support incremental streaming of in-progress transactions. There are multiple required streaming callbacks (`stream_start_cb`, `stream_stop_cb`, `stream_abort_cb`, `stream_commit_cb` and `stream_change_cb`) and two optional callbacks (`stream_message_cb` and `stream_truncate_cb`). Also, if streaming of two-phase commands is to be supported, then additional callbacks must be provided. (See [Section 50.10](#) for details).

When streaming an in-progress transaction, the changes (and messages) are streamed in blocks demarcated by `stream_start_cb` and `stream_stop_cb` callbacks. Once all the decoded changes are transmitted, the transaction can be committed using the `stream_commit_cb` callback (or possibly aborted using the `stream_abort_cb` callback). If two-phase commits are supported, the transaction can be prepared using the `stream_prepare_cb` callback, `COMMIT PREPARED` using the `commit_prepared_cb` callback or aborted using the `rollback_prepared_cb`.

One example sequence of streaming callback calls for one transaction may look like this:

```
stream_start_cb(...);    <-- start of first block of changes
  stream_change_cb(...);
  stream_change_cb(...);
  stream_message_cb(...);
  stream_change_cb(...);
  ...
  stream_change_cb(...);
stream_stop_cb(...);     <-- end of first block of changes

stream_start_cb(...);    <-- start of second block of changes
  stream_change_cb(...);
  stream_change_cb(...);
  stream_change_cb(...);
  ...
  stream_message_cb(...);
  stream_change_cb(...);
stream_stop_cb(...);     <-- end of second block of changes

[a. when using normal commit]
stream_commit_cb(...);    <-- commit of the streamed transaction

[b. when using two-phase commit]
```

```
stream_prepare_cb(...);    <-- prepare the streamed transaction
commit_prepared_cb(...);  <-- commit of the prepared transaction
```

The actual sequence of callback calls may be more complicated, of course. There may be blocks for multiple streamed transactions, some of the transactions may get aborted, etc.

Similar to spill-to-disk behavior, streaming is triggered when the total amount of changes decoded from the WAL (for all in-progress transactions) exceeds the limit defined by `logical_decoding_work_mem` setting. At that point, the largest top-level transaction (measured by the amount of memory currently used for decoded changes) is selected and streamed. However, in some cases we still have to spill to disk even if streaming is enabled because we exceed the memory threshold but still have not decoded the complete tuple e.g., only decoded toast table insert but not the main table insert.

Even when streaming large transactions, the changes are still applied in commit order, preserving the same guarantees as the non-streaming mode.

50.10. Two-phase Commit Support for Logical Decoding

With the basic output plugin callbacks (eg., `begin_cb`, `change_cb`, `commit_cb` and `message_cb`) two-phase commit commands like `PREPARE TRANSACTION`, `COMMIT PREPARED` and `ROLLBACK PREPARED` are not decoded. While the `PREPARE TRANSACTION` is ignored, `COMMIT PREPARED` is decoded as a `COMMIT` and `ROLLBACK PREPARED` is decoded as a `ROLLBACK`.

To support the streaming of two-phase commands, an output plugin needs to provide additional callbacks. There are multiple two-phase commit callbacks that are required, (`begin_prepare_cb`, `prepare_cb`, `commit_prepared_cb`, `rollback_prepared_cb` and `stream_prepare_cb`) and an optional callback (`filter_prepare_cb`).

If the output plugin callbacks for decoding two-phase commit commands are provided, then on `PREPARE TRANSACTION`, the changes of that transaction are decoded, passed to the output plugin, and the `prepare_cb` callback is invoked. This differs from the basic decoding setup where changes are only passed to the output plugin when a transaction is committed. The start of a prepared transaction is indicated by the `begin_prepare_cb` callback.

When a prepared transaction is rolled back using the `ROLLBACK PREPARED`, then the `rollback_prepared_cb` callback is invoked and when the prepared transaction is committed using `COMMIT PREPARED`, then the `commit_prepared_cb` callback is invoked.

Optionally the output plugin can define filtering rules via `filter_prepare_cb` to decode only specific transaction in two phases. This can be achieved by pattern matching on the `gid` or via lookups using the `xid`.

The users that want to decode prepared transactions need to be careful about below mentioned points:

- If the prepared transaction has locked [user] catalog tables exclusively then decoding prepare can block till the main transaction is committed.
- The logical replication solution that builds distributed two phase commit using this feature can deadlock if the prepared transaction has locked [user] catalog tables exclusively. To avoid this users must refrain from having locks on catalog tables (e.g. explicit `LOCK` command) in such transactions. See [Section 50.8.2](#) for the details.

Chapter 51. Replication Progress Tracking

Replication origins are intended to make it easier to implement logical replication solutions on top of [logical decoding](#). They provide a solution to two common problems:

- How to safely keep track of replication progress
- How to change replication behavior based on the origin of a row; for example, to prevent loops in bi-directional replication setups

Replication origins have just two properties, a name and an ID. The name, which is what should be used to refer to the origin across systems, is free-form `text`. It should be used in a way that makes conflicts between replication origins created by different replication solutions unlikely; e.g., by prefixing the replication solution's name to it. The ID is used only to avoid having to store the long version in situations where space efficiency is important. It should never be shared across systems.

Replication origins can be created using the function `pg_replication_origin_create()`; dropped using `pg_replication_origin_drop()`; and seen in the `pg_replication_origin` system catalog.

One nontrivial part of building a replication solution is to keep track of replay progress in a safe manner. When the applying process, or the whole cluster, dies, it needs to be possible to find out up to where data has successfully been replicated. Naive solutions to this, such as updating a row in a table for every replayed transaction, have problems like run-time overhead and database bloat.

Using the replication origin infrastructure a session can be marked as replaying from a remote node (using the `pg_replication_origin_session_setup()` function). Additionally the LSN and commit time stamp of every source transaction can be configured on a per transaction basis using `pg_replication_origin_xact_setup()`. If that's done replication progress will persist in a crash safe manner. Replay progress for all replication origins can be seen in the `pg_replication_origin_status` view. An individual origin's progress, e.g., when resuming replication, can be acquired using `pg_replication_origin_progress()` for any origin or `pg_replication_origin_session_progress()` for the origin configured in the current session.

In replication topologies more complex than replication from exactly one system to one other system, another problem can be that it is hard to avoid replicating replayed rows again. That can lead both to cycles in the replication and inefficiencies. Replication origins provide an optional mechanism to recognize and prevent that. When configured using the functions referenced in the previous paragraph, every change and transaction passed to output plugin callbacks (see [Section 50.6](#)) generated by the session is tagged with the replication origin of the generating session. This allows treating them differently in the output plugin, e.g., ignoring all but locally-originating rows. Additionally the `filter_by_origin_cb` callback can be used to filter the logical decoding change stream based on the source. While less flexible, filtering via that callback is considerably more efficient than doing it in the output plugin.

Chapter 52. Archive Modules

Postgres Pro provides infrastructure to create custom modules for continuous archiving (see [Section 25.1](#)). While archiving via a shell command (i.e., [archive_command](#)) is much simpler, a custom archive module will often be considerably more robust and performant.

When a custom [archive_library](#) is configured, Postgres Pro will submit completed WAL files to the module, and the server will avoid recycling or removing these WAL files until the module indicates that the files were successfully archived. It is ultimately up to the module to decide what to do with each WAL file, but many recommendations are listed at [Section 25.1.1](#).

Archiving modules must at least consist of an initialization function (see [Section 52.1](#)) and the required callbacks (see [Section 52.2](#)). However, archive modules are also permitted to do much more (e.g., declare GUCs and register background workers).

The `contrib/basic_archive` module contains a working example, which demonstrates some useful techniques.

52.1. Initialization Functions

An archive library is loaded by dynamically loading a shared library with the [archive_library](#)'s name as the library base name. The normal library search path is used to locate the library. To provide the required archive module callbacks and to indicate that the library is actually an archive module, it needs to provide a function named `_PG_archive_module_init`. The result of the function must be a pointer to a struct of type `ArchiveModuleCallbacks`, which contains everything that the core code needs to know to make use of the archive module. The return value needs to be of server lifetime, which is typically achieved by defining it as a `static const` variable in global scope.

```
typedef struct ArchiveModuleCallbacks
{
    ArchiveStartupCB startup_cb;
    ArchiveCheckConfiguredCB check_configured_cb;
    ArchiveFileCB archive_file_cb;
    ArchiveShutdownCB shutdown_cb;
} ArchiveModuleCallbacks;
typedef const ArchiveModuleCallbacks *(*ArchiveModuleInit) (void);
```

Only the `archive_file_cb` callback is required. The others are optional.

52.2. Archive Module Callbacks

The archive callbacks define the actual archiving behavior of the module. The server will call them as required to process each individual WAL file.

52.2.1. Startup Callback

The `startup_cb` callback is called shortly after the module is loaded. This callback can be used to perform any additional initialization required. If the archive module has any state, it can use `state->private_data` to store it.

```
typedef void (*ArchiveStartupCB) (ArchiveModuleState *state);
```

52.2.2. Check Callback

The `check_configured_cb` callback is called to determine whether the module is fully configured and ready to accept WAL files (e.g., its configuration parameters are set to valid values). If no `check_configured_cb` is defined, the server always assumes the module is configured.

```
typedef bool (*ArchiveCheckConfiguredCB) (ArchiveModuleState *state);
```

If `true` is returned, the server will proceed with archiving the file by calling the `archive_file_cb` callback. If `false` is returned, archiving will not proceed, and the archiver will emit the following message to the server log:

```
WARNING: archive_mode enabled, yet archiving is not configured
```

In the latter case, the server will periodically call this function, and archiving will proceed only when it returns `true`.

Note

When returning `false`, it may be useful to append some additional information to the generic warning message. To do that, provide a message to the `arch_module_check_errdetail` macro before returning `false`. Like `errdetail()`, this macro accepts a format string followed by an optional list of arguments. The resulting string will be emitted as the `DETAIL` line of the warning message.

52.2.3. Archive Callback

The `archive_file_cb` callback is called to archive a single WAL file.

```
typedef bool (*ArchiveFileCB) (ArchiveModuleState *state, const char *file, const char *path);
```

If `true` is returned, the server proceeds as if the file was successfully archived, which may include recycling or removing the original WAL file. If `false` is returned or an error is thrown, the server will keep the original WAL file and retry archiving later. `file` will contain just the file name of the WAL file to archive, while `path` contains the full path of the WAL file (including the file name).

Note

The `archive_file_cb` callback is called in a short-lived memory context that will be reset between invocations. If you need longer-lived storage, create a memory context in the module's `startup_cb` callback.

52.2.4. Shutdown Callback

The `shutdown_cb` callback is called when the archiver process exits (e.g., after an error) or the value of [archive_library](#) changes. If no `shutdown_cb` is defined, no special action is taken in these situations. If the archive module has any state, this callback should free it to avoid leaks.

```
typedef void (*ArchiveShutdownCB) (ArchiveModuleState *state);
```

Part VI. Reference

The entries in this Reference are meant to provide in reasonable length an authoritative, complete, and formal summary about their respective subjects. More information about the use of Postgres Pro, in narrative, tutorial, or example form, can be found in other parts of this book. See the cross-references listed on each reference page.

The reference entries are also available as traditional “man” pages.

SQL Commands

This part contains reference information for the SQL commands supported by Postgres Pro. By “SQL” the language in general is meant; information about the standards conformance and compatibility of each command can be found on the respective reference page.

ABORT

ABORT — abort the current transaction

Synopsis

```
ABORT [ AUTONOMOUS ] [ WORK | TRANSACTION ] [ AND [ NO ] CHAIN ]
```

Description

ABORT rolls back the current transaction and causes all the updates made by the transaction to be discarded. This command is identical in behavior to the standard SQL command [ROLLBACK](#), and is present only for historical reasons.

Parameters

AUTONOMOUS

Optional key word that can be used when aborting an autonomous transaction. For details on autonomous transactions, see [Chapter 16](#).

WORK

TRANSACTION

Optional key words. They have no effect.

AND CHAIN

If AND CHAIN is specified, a new transaction is immediately started with the same transaction characteristics (see [SET TRANSACTION](#)) as the just finished one. Otherwise, no new transaction is started.

Notes

Use [COMMIT](#) to successfully terminate a transaction.

Issuing ABORT outside of a transaction block emits a warning and otherwise has no effect.

Examples

To abort all changes:

```
ABORT;
```

Compatibility

This command is a Postgres Pro extension present for historical reasons. ROLLBACK is the equivalent standard SQL command.

[BEGIN](#), [COMMIT](#), [ROLLBACK](#)

ALTER AGGREGATE

ALTER AGGREGATE — change the definition of an aggregate function

Synopsis

```
ALTER AGGREGATE name ( aggregate_signature ) RENAME TO new_name
ALTER AGGREGATE name ( aggregate_signature )
    OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
ALTER AGGREGATE name ( aggregate_signature ) SET SCHEMA new_schema
```

where *aggregate_signature* is:

```
* |
[ argmode ] [ argname ] argtype [ , ... ] |
[ [ argmode ] [ argname ] argtype [ , ... ] ] ORDER BY [ argmode ] [ argname ] argtype
[ , ... ]
```

Description

ALTER AGGREGATE changes the definition of an aggregate function.

You must own the aggregate function to use ALTER AGGREGATE. To change the schema of an aggregate function, you must also have CREATE privilege on the new schema. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have CREATE privilege on the aggregate function's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the aggregate function. However, a superuser can alter ownership of any aggregate function anyway.)

Parameters

name

The name (optionally schema-qualified) of an existing aggregate function.

argmode

The mode of an argument: IN or VARIADIC. If omitted, the default is IN.

argname

The name of an argument. Note that ALTER AGGREGATE does not actually pay any attention to argument names, since only the argument data types are needed to determine the aggregate function's identity.

argtype

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write * in place of the list of argument specifications. To reference an ordered-set aggregate function, write ORDER BY between the direct and aggregated argument specifications.

new_name

The new name of the aggregate function.

new_owner

The new owner of the aggregate function.

new_schema

The new schema for the aggregate function.

Notes

The recommended syntax for referencing an ordered-set aggregate is to write `ORDER BY` between the direct and aggregated argument specifications, in the same style as in [CREATE AGGREGATE](#). However, it will also work to omit `ORDER BY` and just run the direct and aggregated argument specifications into a single list. In this abbreviated form, if `VARIADIC "any"` was used in both the direct and aggregated argument lists, write `VARIADIC "any"` only once.

Examples

To rename the aggregate function `myavg` for type `integer` to `my_average`:

```
ALTER AGGREGATE myavg(integer) RENAME TO my_average;
```

To change the owner of the aggregate function `myavg` for type `integer` to `joe`:

```
ALTER AGGREGATE myavg(integer) OWNER TO joe;
```

To move the ordered-set aggregate `mypercentile` with direct argument of type `float8` and aggregated argument of type `integer` into schema `myschema`:

```
ALTER AGGREGATE mypercentile(float8 ORDER BY integer) SET SCHEMA myschema;
```

This will work too:

```
ALTER AGGREGATE mypercentile(float8, integer) SET SCHEMA myschema;
```

Compatibility

There is no `ALTER AGGREGATE` statement in the SQL standard.

See Also

[CREATE AGGREGATE](#), [DROP AGGREGATE](#)

ALTER COLLATION

ALTER COLLATION — change the definition of a collation

Synopsis

```
ALTER COLLATION name REFRESH VERSION

ALTER COLLATION name RENAME TO new_name
ALTER COLLATION name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER |
    SESSION_USER }
ALTER COLLATION name SET SCHEMA new_schema
```

Description

ALTER COLLATION changes the definition of a collation.

You must own the collation to use ALTER COLLATION. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have CREATE privilege on the collation's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the collation. However, a superuser can alter ownership of any collation anyway.)

Parameters

name

The name (optionally schema-qualified) of an existing collation.

new_name

The new name of the collation.

new_owner

The new owner of the collation.

new_schema

The new schema for the collation.

REFRESH VERSION

Update the collation's version. See [Notes](#) below.

Notes

When a collation object is created, the provider-specific version of the collation is recorded in the system catalog. When the collation is used, the current version is checked against the recorded version, and a warning is issued when there is a mismatch, for example:

```
WARNING: collation "xx-x-icu" has version mismatch
DETAIL: The collation in the database was created using version 1.2.3.4, but the
operating system provides version 2.3.4.5.
HINT: Rebuild all objects affected by this collation and run ALTER COLLATION
pg_catalog."xx-x-icu" REFRESH VERSION, or build Postgres Pro with the right library
version.
```

A change in collation definitions can lead to corrupt indexes and other problems because the database system relies on stored objects having a certain sort order. Generally, this should be avoided, but it can happen in legitimate circumstances, such as when upgrading the operating system to a new major version or when using pg_upgrade to upgrade to server binaries linked with a newer version of ICU.

When this happens, all objects depending on the collation should be rebuilt, for example, using `REINDEX`. When that is done, the collation version can be refreshed using the command `ALTER COLLATION ... REFRESH VERSION`. This will update the system catalog to record the current collation version and will make the warning go away. Note that this does not actually check whether all affected objects have been rebuilt correctly.

When using collations provided by `libc`, version information is recorded on systems using the GNU C library (most Linux systems), FreeBSD and Windows. When using collations provided by ICU, the version information is provided by the ICU library and is available on all platforms.

Note

When using the GNU C library for collations, the C library's version is used as a proxy for the collation version. Many Linux distributions change collation definitions only when upgrading the C library, but this approach is imperfect as maintainers are free to back-port newer collation definitions to older C library releases.

When using Windows for collations, version information is only available for collations defined with BCP 47 language tags such as `en-US`.

For the database default collation, there is an analogous command `ALTER DATABASE ... REFRESH COLLATION VERSION`.

The following query can be used to identify all collations in the current database that need to be refreshed and the objects that depend on them:

```
SELECT pg_describe_object(refclassid, refobjid, refobjsubid) AS "Collation",
       pg_describe_object(classid, objid, objsubid) AS "Object"
FROM   pg_depend d JOIN pg_collation c
       ON refclassid = 'pg_collation'::regclass AND refobjid = c.oid
WHERE  c.collversion <> pg_collation_actual_version(c.oid)
ORDER BY 1, 2;
```

Examples

To rename the collation `ru_RU` to `russian`:

```
ALTER COLLATION "ru_RU" RENAME TO russian;
```

To change the owner of the collation `en_US` to `joe`:

```
ALTER COLLATION "en_US" OWNER TO joe;
```

Compatibility

There is no `ALTER COLLATION` statement in the SQL standard.

See Also

[CREATE COLLATION](#), [DROP COLLATION](#)

ALTER CONVERSION

ALTER CONVERSION — change the definition of a conversion

Synopsis

```
ALTER CONVERSION name RENAME TO new_name
ALTER CONVERSION name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER |
SESSION_USER }
ALTER CONVERSION name SET SCHEMA new_schema
```

Description

ALTER CONVERSION changes the definition of a conversion.

You must own the conversion to use ALTER CONVERSION. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have CREATE privilege on the conversion's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the conversion. However, a superuser can alter ownership of any conversion anyway.)

Parameters

name

The name (optionally schema-qualified) of an existing conversion.

new_name

The new name of the conversion.

new_owner

The new owner of the conversion.

new_schema

The new schema for the conversion.

Examples

To rename the conversion `iso_8859_1_to_utf8` to `latin1_to_unicode`:

```
ALTER CONVERSION iso_8859_1_to_utf8 RENAME TO latin1_to_unicode;
```

To change the owner of the conversion `iso_8859_1_to_utf8` to `joe`:

```
ALTER CONVERSION iso_8859_1_to_utf8 OWNER TO joe;
```

Compatibility

There is no ALTER CONVERSION statement in the SQL standard.

See Also

[CREATE CONVERSION](#), [DROP CONVERSION](#)

ALTER DATABASE

ALTER DATABASE — change a database

Synopsis

```
ALTER DATABASE name [ [ WITH ] option [ ... ] ]
```

where *option* can be:

```
ALLOW_CONNECTIONS allowconn  
CONNECTION LIMIT connlimit  
IS_TEMPLATE istemplate
```

```
ALTER DATABASE name RENAME TO new_name
```

```
ALTER DATABASE name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
```

```
ALTER DATABASE name SET TABLESPACE new_tablespace
```

```
ALTER DATABASE name REFRESH COLLATION VERSION
```

```
ALTER DATABASE name SET configuration_parameter { TO | = } { value | DEFAULT }
```

```
ALTER DATABASE name SET configuration_parameter FROM CURRENT
```

```
ALTER DATABASE name RESET configuration_parameter
```

```
ALTER DATABASE name RESET ALL
```

Description

ALTER DATABASE changes the attributes of a database.

The first form changes certain per-database settings. (See below for details.) Only the database owner or a superuser can change these settings.

The second form changes the name of the database. Only the database owner or a superuser can rename a database; non-superuser owners must also have the `CREATEDB` privilege. The current database cannot be renamed. (Connect to a different database if you need to do that.)

The third form changes the owner of the database. To alter the owner, you must be able to `SET ROLE` to the new owning role, and you must have the `CREATEDB` privilege. (Note that superusers have all these privileges automatically.)

The fourth form changes the default tablespace of the database. Only the database owner or a superuser can do this; you must also have create privilege for the new tablespace. This command physically moves any tables or indexes in the database's old default tablespace to the new tablespace. The new default tablespace must be empty for this database, and no one can be connected to the database. Tables and indexes in non-default tablespaces are unaffected.

The remaining forms change the session default for a run-time configuration variable for a PostgreSQL database. Whenever a new session is subsequently started in that database, the specified value becomes the session default value. The database-specific default overrides whatever setting is present in `postgresql.conf` or has been received from the `postgres` command line. Only the database owner or a superuser can change the session defaults for a database. Certain variables cannot be set this way, or can only be set by a superuser.

Parameters

name

The name of the database whose attributes are to be altered.

allowconn

If false then no one can connect to this database.

conndefault

How many concurrent connections can be made to this database. -1 means no limit.

istemplate

If true, then this database can be cloned by any user with `CREATEDB` privileges; if false, then only superusers or the owner of the database can clone it.

new_name

The new name of the database.

new_owner

The new owner of the database.

new_tablespace

The new default tablespace of the database.

This form of the command cannot be executed inside a transaction block.

`REFRESH COLLATION VERSION`

Update the database collation version. See [Notes](#) for background.

configuration_parameter

value

Set this database's session default for the specified configuration parameter to the given value. If *value* is `DEFAULT` or, equivalently, `RESET` is used, the database-specific setting is removed, so the system-wide default setting will be inherited in new sessions. Use `RESET ALL` to clear all database-specific settings. `SET FROM CURRENT` saves the session's current value of the parameter as the database-specific value.

See [SET](#) and [Chapter 19](#) for more information about allowed parameter names and values.

Notes

It is also possible to tie a session default to a specific role rather than to a database; see [ALTER ROLE](#). Role-specific settings override database-specific ones if there is a conflict.

Examples

To disable index scans by default in the database `test`:

```
ALTER DATABASE test SET enable_indexscan TO off;
```

Compatibility

The `ALTER DATABASE` statement is a Postgres Pro extension.

ALTER DEFAULT PRIVILEGES

ALTER DEFAULT PRIVILEGES — define default access privileges

Synopsis

```
ALTER DEFAULT PRIVILEGES
    [ FOR { ROLE | USER } target_role [, ...] ]
    [ IN SCHEMA schema_name [, ...] ]
    abbreviated_grant_or_revoke
```

where *abbreviated_grant_or_revoke* is one of:

```
GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER |
        MAINTAIN }
        [, ...] | ALL [ PRIVILEGES ] }
ON TABLES
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]
```

```
GRANT { { USAGE | SELECT | UPDATE }
        [, ...] | ALL [ PRIVILEGES ] }
ON SEQUENCES
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]
```

```
GRANT { EXECUTE | ALL [ PRIVILEGES ] }
ON { FUNCTIONS | ROUTINES }
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]
```

```
GRANT { USAGE | ALL [ PRIVILEGES ] }
ON TYPES
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]
```

```
GRANT { { USAGE | CREATE }
        [, ...] | ALL [ PRIVILEGES ] }
ON SCHEMAS
TO { [ GROUP ] role_name | PUBLIC } [, ...] [ WITH GRANT OPTION ]
```

```
REVOKE [ GRANT OPTION FOR ]
    { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER |
      MAINTAIN }
      [, ...] | ALL [ PRIVILEGES ] }
ON TABLES
FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
    { { USAGE | SELECT | UPDATE }
      [, ...] | ALL [ PRIVILEGES ] }
ON SEQUENCES
FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
    { EXECUTE | ALL [ PRIVILEGES ] }
ON { FUNCTIONS | ROUTINES }
FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
    { USAGE | ALL [ PRIVILEGES ] }
    ON TYPES
    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
    { { USAGE | CREATE }
    [, ...] | ALL [ PRIVILEGES ] }
    ON SCHEMAS
    FROM { [ GROUP ] role_name | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ]
```

Description

`ALTER DEFAULT PRIVILEGES` allows you to set the privileges that will be applied to objects created in the future. (It does not affect privileges assigned to already-existing objects.) Privileges can be set globally (i.e., for all objects created in the current database), or just for objects created in specified schemas.

While you can change your own default privileges and the defaults of roles that you are a member of, at object creation time, new object permissions are only affected by the default privileges of the current role, and are not inherited from any roles in which the current role is a member.

As explained in [Section 5.8](#), the default privileges for any object type normally grant all grantable permissions to the object owner, and may grant some privileges to `PUBLIC` as well. However, this behavior can be changed by altering the global default privileges with `ALTER DEFAULT PRIVILEGES`.

Currently, only the privileges for schemas, tables (including views and foreign tables), sequences, functions, and types (including domains) can be altered. For this command, functions include aggregates and procedures. The words `FUNCTIONS` and `ROUTINES` are equivalent in this command. (`ROUTINES` is preferred going forward as the standard term for functions and procedures taken together. In earlier Postgres Pro releases, only the word `FUNCTIONS` was allowed. It is not possible to set default privileges for functions and procedures separately.)

Default privileges that are specified per-schema are added to whatever the global default privileges are for the particular object type. This means you cannot revoke privileges per-schema if they are granted globally (either by default, or according to a previous `ALTER DEFAULT PRIVILEGES` command that did not specify a schema). Per-schema `REVOKE` is only useful to reverse the effects of a previous per-schema `GRANT`.

Parameters

target_role

Change default privileges for objects created by the *target_role*, or the current role if unspecified.

schema_name

The name of an existing schema. If specified, the default privileges are altered for objects later created in that schema. If `IN SCHEMA` is omitted, the global default privileges are altered. `IN SCHEMA` is not allowed when setting privileges for schemas, since schemas can't be nested.

role_name

The name of an existing role to grant or revoke privileges for. This parameter, and all the other parameters in *abbreviated_grant_or_revoke*, act as described under [GRANT](#) or [REVOKE](#), except that one is setting permissions for a whole class of objects rather than specific named objects.

Notes

Use `psql`'s `\ddp` command to obtain information about existing assignments of default privileges. The meaning of the privilege display is the same as explained for `\dp` in [Section 5.8](#).

If you wish to drop a role for which the default privileges have been altered, it is necessary to reverse the changes in its default privileges or use `DROP OWNED BY` to get rid of the default privileges entry for the role.

Examples

Grant `SELECT` privilege to everyone for all tables (and views) you subsequently create in schema `myschema`, and allow role `webuser` to `INSERT` into them too:

```
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema GRANT SELECT ON TABLES TO PUBLIC;  
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema GRANT INSERT ON TABLES TO webuser;
```

Undo the above, so that subsequently-created tables won't have any more permissions than normal:

```
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema REVOKE SELECT ON TABLES FROM PUBLIC;  
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema REVOKE INSERT ON TABLES FROM webuser;
```

Remove the public `EXECUTE` permission that is normally granted on functions, for all functions subsequently created by role `admin`:

```
ALTER DEFAULT PRIVILEGES FOR ROLE admin REVOKE EXECUTE ON FUNCTIONS FROM PUBLIC;
```

Note however that you *cannot* accomplish that effect with a command limited to a single schema. This command has no effect, unless it is undoing a matching `GRANT`:

```
ALTER DEFAULT PRIVILEGES IN SCHEMA public REVOKE EXECUTE ON FUNCTIONS FROM PUBLIC;
```

That's because per-schema default privileges can only add privileges to the global setting, not remove privileges granted by it.

Compatibility

There is no `ALTER DEFAULT PRIVILEGES` statement in the SQL standard.

See Also

[GRANT](#), [REVOKE](#)

ALTER DOMAIN

ALTER DOMAIN — change the definition of a domain

Synopsis

```
ALTER DOMAIN name
    { SET DEFAULT expression | DROP DEFAULT }
ALTER DOMAIN name
    { SET | DROP } NOT NULL
ALTER DOMAIN name
    ADD domain_constraint [ NOT VALID ]
ALTER DOMAIN name
    DROP CONSTRAINT [ IF EXISTS ] constraint_name [ RESTRICT | CASCADE ]
ALTER DOMAIN name
    RENAME CONSTRAINT constraint_name TO new_constraint_name
ALTER DOMAIN name
    VALIDATE CONSTRAINT constraint_name
ALTER DOMAIN name
    OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
ALTER DOMAIN name
    RENAME TO new_name
ALTER DOMAIN name
    SET SCHEMA new_schema
```

where *domain_constraint* is:

```
[ CONSTRAINT constraint_name ]
{ NOT NULL | CHECK (expression) }
```

Description

ALTER DOMAIN changes the definition of an existing domain. There are several sub-forms:

SET/DROP DEFAULT

These forms set or remove the default value for a domain. Note that defaults only apply to subsequent INSERT commands; they do not affect rows already in a table using the domain.

SET/DROP NOT NULL

These forms change whether a domain is marked to allow NULL values or to reject NULL values. You can only SET NOT NULL when the columns using the domain contain no null values.

ADD *domain_constraint* [NOT VALID]

This form adds a new constraint to a domain. When a new constraint is added to a domain, all columns using that domain will be checked against the newly added constraint. These checks can be suppressed by adding the new constraint using the NOT VALID option; the constraint can later be made valid using ALTER DOMAIN ... VALIDATE CONSTRAINT. Newly inserted or updated rows are always checked against all constraints, even those marked NOT VALID. NOT VALID is only accepted for CHECK constraints.

DROP CONSTRAINT [IF EXISTS]

This form drops constraints on a domain. If IF EXISTS is specified and the constraint does not exist, no error is thrown. In this case a notice is issued instead.

RENAME CONSTRAINT

This form changes the name of a constraint on a domain.

VALIDATE CONSTRAINT

This form validates a constraint previously added as `NOT VALID`, that is, it verifies that all values in table columns of the domain type satisfy the specified constraint.

OWNER

This form changes the owner of the domain to the specified user.

RENAME

This form changes the name of the domain.

SET SCHEMA

This form changes the schema of the domain. Any constraints associated with the domain are moved into the new schema as well.

You must own the domain to use `ALTER DOMAIN`. To change the schema of a domain, you must also have `CREATE` privilege on the new schema. To alter the owner, you must be able to `SET ROLE` to the new owning role, and that role must have `CREATE` privilege on the domain's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the domain. However, a superuser can alter ownership of any domain anyway.)

Parameters

name

The name (possibly schema-qualified) of an existing domain to alter.

domain_constraint

New domain constraint for the domain.

constraint_name

Name of an existing constraint to drop or rename.

NOT VALID

Do not verify existing stored data for constraint validity.

CASCADE

Automatically drop objects that depend on the constraint, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the constraint if there are any dependent objects. This is the default behavior.

new_name

The new name for the domain.

new_constraint_name

The new name for the constraint.

new_owner

The user name of the new owner of the domain.

new_schema

The new schema for the domain.

Notes

Although `ALTER DOMAIN ADD CONSTRAINT` attempts to verify that existing stored data satisfies the new constraint, this check is not bulletproof, because the command cannot “see” table rows that are newly inserted or updated and not yet committed. If there is a hazard that concurrent operations might insert bad data, the way to proceed is to add the constraint using the `NOT VALID` option, commit that command, wait until all transactions started before that commit have finished, and then issue `ALTER DOMAIN VALIDATE CONSTRAINT` to search for data violating the constraint. This method is reliable because once the constraint is committed, all new transactions are guaranteed to enforce it against new values of the domain type.

Currently, `ALTER DOMAIN ADD CONSTRAINT`, `ALTER DOMAIN VALIDATE CONSTRAINT`, and `ALTER DOMAIN SET NOT NULL` will fail if the named domain or any derived domain is used within a container-type column (a composite, array, or range column) in any table in the database. They should eventually be improved to be able to verify the new constraint for such nested values.

Examples

To add a `NOT NULL` constraint to a domain:

```
ALTER DOMAIN zipcode SET NOT NULL;
```

To remove a `NOT NULL` constraint from a domain:

```
ALTER DOMAIN zipcode DROP NOT NULL;
```

To add a check constraint to a domain:

```
ALTER DOMAIN zipcode ADD CONSTRAINT zipchk CHECK (char_length(VALUE) = 5);
```

To remove a check constraint from a domain:

```
ALTER DOMAIN zipcode DROP CONSTRAINT zipchk;
```

To rename a check constraint on a domain:

```
ALTER DOMAIN zipcode RENAME CONSTRAINT zipchk TO zip_check;
```

To move the domain into a different schema:

```
ALTER DOMAIN zipcode SET SCHEMA customers;
```

Compatibility

`ALTER DOMAIN` conforms to the SQL standard, except for the `OWNER`, `RENAME`, `SET SCHEMA`, and `VALIDATE CONSTRAINT` variants, which are Postgres Pro extensions. The `NOT VALID` clause of the `ADD CONSTRAINT` variant is also a Postgres Pro extension.

See Also

[CREATE DOMAIN](#), [DROP DOMAIN](#)

ALTER EVENT TRIGGER

ALTER EVENT TRIGGER — change the definition of an event trigger

Synopsis

```
ALTER EVENT TRIGGER name DISABLE
ALTER EVENT TRIGGER name ENABLE [ REPLICA | ALWAYS ]
ALTER EVENT TRIGGER name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER |
SESSION_USER }
ALTER EVENT TRIGGER name RENAME TO new_name
```

Description

ALTER EVENT TRIGGER changes properties of an existing event trigger.

You must be superuser to alter an event trigger.

Parameters

name

The name of an existing trigger to alter.

new_owner

The user name of the new owner of the event trigger.

new_name

The new name of the event trigger.

DISABLE/ENABLE [REPLICA | ALWAYS]

These forms configure the firing of event triggers. A disabled trigger is still known to the system, but is not executed when its triggering event occurs. See also [session_replication_role](#).

Compatibility

There is no ALTER EVENT TRIGGER statement in the SQL standard.

See Also

[CREATE EVENT TRIGGER](#), [DROP EVENT TRIGGER](#)

ALTER EXTENSION

ALTER EXTENSION — change the definition of an extension

Synopsis

```
ALTER EXTENSION name UPDATE [ TO new_version ]
ALTER EXTENSION name SET SCHEMA new_schema
ALTER EXTENSION name ADD member_object
ALTER EXTENSION name DROP member_object
```

where *member_object* is:

```
ACCESS METHOD object_name |
AGGREGATE aggregate_name ( aggregate_signature ) |
CAST ( source_type AS target_type ) |
COLLATION object_name |
CONVERSION object_name |
DOMAIN object_name |
EVENT TRIGGER object_name |
FOREIGN DATA WRAPPER object_name |
FOREIGN TABLE object_name |
FUNCTION function_name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ] |
MATERIALIZED VIEW object_name |
OPERATOR operator_name ( left_type, right_type ) |
OPERATOR CLASS object_name USING index_method |
OPERATOR FAMILY object_name USING index_method |
[ PROCEDURAL ] LANGUAGE object_name |
PROCEDURE procedure_name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ] |
ROUTINE routine_name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ] |
SCHEMA object_name |
SEQUENCE object_name |
SERVER object_name |
TABLE object_name |
TEXT SEARCH CONFIGURATION object_name |
TEXT SEARCH DICTIONARY object_name |
TEXT SEARCH PARSER object_name |
TEXT SEARCH TEMPLATE object_name |
TRANSFORM FOR type_name LANGUAGE lang_name |
TYPE object_name |
VIEW object_name
```

and *aggregate_signature* is:

```
* |
[ argmode ] [ argname ] argtype [ , ... ] |
[ [ argmode ] [ argname ] argtype [ , ... ] ] ORDER BY [ argmode ] [ argname ] argtype
[ , ... ]
```

Description

ALTER EXTENSION changes the definition of an installed extension. There are several subforms:

UPDATE

This form updates the extension to a newer version. The extension must supply a suitable update script (or series of scripts) that can modify the currently-installed version into the requested version.

SET SCHEMA

This form moves the extension's objects into another schema. The extension has to be *relocatable* for this command to succeed.

ADD *member_object*

This form adds an existing object to the extension. This is mainly useful in extension update scripts. The object will subsequently be treated as a member of the extension; notably, it can only be dropped by dropping the extension.

DROP *member_object*

This form removes a member object from the extension. This is mainly useful in extension update scripts. The object is not dropped, only disassociated from the extension.

See [Section 39.17](#) for more information about these operations.

You must own the extension to use `ALTER EXTENSION`. The `ADD/DROP` forms require ownership of the added/dropped object as well.

Parameters

name

The name of an installed extension.

new_version

The desired new version of the extension. This can be written as either an identifier or a string literal. If not specified, `ALTER EXTENSION UPDATE` attempts to update to whatever is shown as the default version in the extension's control file.

new_schema

The new schema for the extension.

*object_name**aggregate_name**function_name**operator_name**procedure_name**routine_name*

The name of an object to be added to or removed from the extension. Names of tables, aggregates, domains, foreign tables, functions, operators, operator classes, operator families, procedures, routines, sequences, text search objects, types, and views can be schema-qualified.

source_type

The name of the source data type of the cast.

target_type

The name of the target data type of the cast.

argmode

The mode of a function, procedure, or aggregate argument: `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`. Note that `ALTER EXTENSION` does not actually pay any attention to `OUT` arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the `IN`, `INOUT`, and `VARIADIC` arguments.

argname

The name of a function, procedure, or aggregate argument. Note that `ALTER EXTENSION` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype

The data type of a function, procedure, or aggregate argument.

left_type

right_type

The data type(s) of the operator's arguments (optionally schema-qualified). Write `NONE` for the missing argument of a prefix operator.

`PROCEDURAL`

This is a noise word.

type_name

The name of the data type of the transform.

lang_name

The name of the language of the transform.

Examples

To update the `hstore` extension to version 2.0:

```
ALTER EXTENSION hstore UPDATE TO '2.0';
```

To change the schema of the `hstore` extension to `utils`:

```
ALTER EXTENSION hstore SET SCHEMA utils;
```

To add an existing function to the `hstore` extension:

```
ALTER EXTENSION hstore ADD FUNCTION populate_record(anelement, hstore);
```

Compatibility

`ALTER EXTENSION` is a Postgres Pro extension.

See Also

[CREATE EXTENSION](#), [DROP EXTENSION](#)

ALTER FUNCTION

ALTER FUNCTION — change the definition of a function

Synopsis

```
ALTER FUNCTION name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
    action [ ... ] [ RESTRICT ]  
ALTER FUNCTION name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
    RENAME TO new_name  
ALTER FUNCTION name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
    OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }  
ALTER FUNCTION name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
    SET SCHEMA new_schema  
ALTER FUNCTION name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
    [ NO ] DEPENDS ON EXTENSION extension_name
```

where *action* is one of:

```
    CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT  
    IMMUTABLE | STABLE | VOLATILE  
    [ NOT ] LEAKPROOF  
    [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER  
    PARALLEL { UNSAFE | RESTRICTED | SAFE }  
    COST execution_cost  
    ROWS result_rows  
    SUPPORT support_function  
    SET configuration_parameter { TO | = } { value | DEFAULT }  
    SET configuration_parameter FROM CURRENT  
    RESET configuration_parameter  
    RESET ALL
```

Description

ALTER FUNCTION changes the definition of a function.

You must own the function to use ALTER FUNCTION. To change a function's schema, you must also have CREATE privilege on the new schema. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have CREATE privilege on the function's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the function. However, a superuser can alter ownership of any function anyway.)

Parameters

name

The name (optionally schema-qualified) of an existing function. If no argument list is specified, the name must be unique in its schema.

argmode

The mode of an argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that ALTER FUNCTION does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

argname

The name of an argument. Note that ALTER FUNCTION does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype

The data type(s) of the function's arguments (optionally schema-qualified), if any.

new_name

The new name of the function.

new_owner

The new owner of the function. Note that if the function is marked `SECURITY DEFINER`, it will subsequently execute as the new owner.

new_schema

The new schema for the function.

`DEPENDS ON EXTENSION extension_name`

`NO DEPENDS ON EXTENSION extension_name`

This form marks the function as dependent on the extension, or no longer dependent on that extension if `NO` is specified. A function that's marked as dependent on an extension is dropped when the extension is dropped, even if `CASCADE` is not specified. A function can depend upon multiple extensions, and will be dropped when any one of those extensions is dropped.

`CALLED ON NULL INPUT`

`RETURNS NULL ON NULL INPUT`

`STRICT`

`CALLED ON NULL INPUT` changes the function so that it will be invoked when some or all of its arguments are null. `RETURNS NULL ON NULL INPUT` or `STRICT` changes the function so that it is not invoked if any of its arguments are null; instead, a null result is assumed automatically. See [CREATE FUNCTION](#) for more information.

`IMMUTABLE`

`STABLE`

`VOLATILE`

Change the volatility of the function to the specified setting. See [CREATE FUNCTION](#) for details.

`[EXTERNAL] SECURITY INVOKER`

`[EXTERNAL] SECURITY DEFINER`

Change whether the function is a security definer or not. The key word `EXTERNAL` is ignored for SQL conformance. See [CREATE FUNCTION](#) for more information about this capability.

`PARALLEL`

Change whether the function is deemed safe for parallelism. See [CREATE FUNCTION](#) for details.

`LEAKPROOF`

Change whether the function is considered leakproof or not. See [CREATE FUNCTION](#) for more information about this capability.

`COST execution_cost`

Change the estimated execution cost of the function. See [CREATE FUNCTION](#) for more information.

`ROWS result_rows`

Change the estimated number of rows returned by a set-returning function. See [CREATE FUNCTION](#) for more information.

`SUPPORT support_function`

Set or change the planner support function to use for this function. See [Section 39.11](#) for details. You must be superuser to use this option.

This option cannot be used to remove the support function altogether, since it must name a new support function. Use `CREATE OR REPLACE FUNCTION` if you need to do that.

configuration_parameter
value

Add or change the assignment to be made to a configuration parameter when the function is called. If *value* is `DEFAULT` or, equivalently, `RESET` is used, the function-local setting is removed, so that the function executes with the value present in its environment. Use `RESET ALL` to clear all function-local settings. `SET FROM CURRENT` saves the value of the parameter that is current when `ALTER FUNCTION` is executed as the value to be applied when the function is entered.

See [SET](#) and [Chapter 19](#) for more information about allowed parameter names and values.

`RESTRICT`

Ignored for conformance with the SQL standard.

Examples

To rename the function `sqrt` for type `integer` to `square_root`:

```
ALTER FUNCTION sqrt(integer) RENAME TO square_root;
```

To change the owner of the function `sqrt` for type `integer` to `joe`:

```
ALTER FUNCTION sqrt(integer) OWNER TO joe;
```

To change the schema of the function `sqrt` for type `integer` to `maths`:

```
ALTER FUNCTION sqrt(integer) SET SCHEMA maths;
```

To mark the function `sqrt` for type `integer` as being dependent on the extension `mathlib`:

```
ALTER FUNCTION sqrt(integer) DEPENDS ON EXTENSION mathlib;
```

To adjust the search path that is automatically set for a function:

```
ALTER FUNCTION check_password(text) SET search_path = admin, pg_temp;
```

To disable automatic setting of `search_path` for a function:

```
ALTER FUNCTION check_password(text) RESET search_path;
```

The function will now execute with whatever search path is used by its caller.

Compatibility

This statement is partially compatible with the `ALTER FUNCTION` statement in the SQL standard. The standard allows more properties of a function to be modified, but does not provide the ability to rename a function, make a function a security definer, attach configuration parameter values to a function, or change the owner, schema, or volatility of a function. The standard also requires the `RESTRICT` key word, which is optional in Postgres Pro.

See Also

[CREATE FUNCTION](#), [DROP FUNCTION](#), [ALTER PROCEDURE](#), [ALTER ROUTINE](#)

ALTER GROUP

ALTER GROUP — change role name or membership

Synopsis

```
ALTER GROUP role_specification ADD USER user_name [, ... ]  
ALTER GROUP role_specification DROP USER user_name [, ... ]
```

where *role_specification* can be:

```
role_name  
| CURRENT_ROLE  
| CURRENT_USER  
| SESSION_USER
```

```
ALTER GROUP group_name RENAME TO new_name
```

Description

ALTER GROUP changes the attributes of a user group. This is an obsolete command, though still accepted for backwards compatibility, because groups (and users too) have been superseded by the more general concept of roles.

The first two variants add users to a group or remove them from a group. (Any role can play the part of either a “user” or a “group” for this purpose.) These variants are effectively equivalent to granting or revoking membership in the role named as the “group”; so the preferred way to do this is to use [GRANT](#) or [REVOKE](#). Note that GRANT and REVOKE have additional options which are not available with this command, such as the ability to grant and revoke ADMIN OPTION, and the ability to specify the grantor.

The third variant changes the name of the group. This is exactly equivalent to renaming the role with [ALTER ROLE](#).

Parameters

group_name

The name of the group (role) to modify.

user_name

Users (roles) that are to be added to or removed from the group. The users must already exist; ALTER GROUP does not create or drop users.

new_name

The new name of the group.

Examples

Add users to a group:

```
ALTER GROUP staff ADD USER karl, john;
```

Remove a user from a group:

```
ALTER GROUP workers DROP USER beth;
```

Compatibility

There is no ALTER GROUP statement in the SQL standard.

See Also

[GRANT](#), [REVOKE](#), [ALTER ROLE](#)

ALTER INDEX

ALTER INDEX — change the definition of an index

Synopsis

```
ALTER INDEX [ IF EXISTS ] name RENAME TO new_name
ALTER INDEX [ IF EXISTS ] name SET TABLESPACE tablespace_name
ALTER INDEX name ATTACH PARTITION index_name
ALTER INDEX name [ NO ] DEPENDS ON EXTENSION extension_name
ALTER INDEX [ IF EXISTS ] name SET ( storage_parameter [= value] [, ... ] )
ALTER INDEX [ IF EXISTS ] name RESET ( storage_parameter [, ... ] )
ALTER INDEX [ IF EXISTS ] name ALTER [ COLUMN ] column_number
    SET STATISTICS integer
ALTER INDEX ALL IN TABLESPACE name [ OWNED BY role_name [, ... ] ]
    SET TABLESPACE new_tablespace [ NOWAIT ]
```

Description

ALTER INDEX changes the definition of an existing index. There are several subforms described below. Note that the lock level required may differ for each subform. An ACCESS EXCLUSIVE lock is held unless explicitly noted. When multiple subcommands are listed, the lock held will be the strictest one required from any subcommand.

RENAME

The RENAME form changes the name of the index. If the index is associated with a table constraint (either UNIQUE, PRIMARY KEY, or EXCLUDE), the constraint is renamed as well. There is no effect on the stored data.

Renaming an index acquires a SHARE UPDATE EXCLUSIVE lock.

SET TABLESPACE

This form changes the index's tablespace to the specified tablespace and moves the data file(s) associated with the index to the new tablespace. To change the tablespace of an index, you must own the index and have CREATE privilege on the new tablespace. All indexes in the current database in a tablespace can be moved by using the ALL IN TABLESPACE form, which will lock all indexes to be moved and then move each one. This form also supports OWNED BY, which will only move indexes owned by the roles specified. If the NOWAIT option is specified then the command will fail if it is unable to acquire all of the locks required immediately. Note that system catalogs will not be moved by this command, use ALTER DATABASE or explicit ALTER INDEX invocations instead if desired. See also [CREATE TABLESPACE](#).

ATTACH PARTITION *index_name*

Causes the named index (possibly schema-qualified) to become attached to the altered index. The named index must be on a partition of the table containing the index being altered, and have an equivalent definition. An attached index cannot be dropped by itself, and will automatically be dropped if its parent index is dropped.

DEPENDS ON EXTENSION *extension_name*

NO DEPENDS ON EXTENSION *extension_name*

This form marks the index as dependent on the extension, or no longer dependent on that extension if NO is specified. An index that's marked as dependent on an extension is automatically dropped when the extension is dropped.

SET (*storage_parameter* [= *value*] [, ...])

This form changes one or more index-method-specific storage parameters for the index. See [CREATE INDEX](#) for details on the available parameters. Note that the index contents will not be modified

immediately by this command; depending on the parameter you might need to rebuild the index with [REINDEX](#) to get the desired effects.

```
RESET ( storage_parameter [, ... ] )
```

This form resets one or more index-method-specific storage parameters to their defaults. As with [SET](#), a [REINDEX](#) might be needed to update the index entirely.

```
ALTER [ COLUMN ] column_number SET STATISTICS integer
```

This form sets the per-column statistics-gathering target for subsequent [ANALYZE](#) operations, though can be used only on index columns that are defined as an expression. Since expressions lack a unique name, we refer to them using the ordinal number of the index column. The target can be set in the range 0 to 10000; alternatively, set it to -1 to revert to using the system default statistics target ([default_statistics_target](#)). For more information on the use of statistics by the Postgres Pro query planner, refer to [Section 14.2](#).

Parameters

IF EXISTS

Do not throw an error if the index does not exist. A notice is issued in this case.

column_number

The ordinal number refers to the ordinal (left-to-right) position of the index column.

name

The name (possibly schema-qualified) of an existing index to alter.

new_name

The new name for the index.

tablespace_name

The tablespace to which the index will be moved.

extension_name

The name of the extension that the index is to depend on.

storage_parameter

The name of an index-method-specific storage parameter.

value

The new value for an index-method-specific storage parameter. This might be a number or a word depending on the parameter.

Notes

These operations are also possible using [ALTER TABLE](#). `ALTER INDEX` is in fact just an alias for the forms of `ALTER TABLE` that apply to indexes.

There was formerly an `ALTER INDEX OWNER` variant, but this is now ignored (with a warning). An index cannot have an owner different from its table's owner. Changing the table's owner automatically changes the index as well.

Changing any part of a system catalog index is not permitted.

Examples

To rename an existing index:

```
ALTER INDEX distributors RENAME TO suppliers;
```

To move an index to a different tablespace:

```
ALTER INDEX distributors SET TABLESPACE fasttablespace;
```

To change an index's fill factor (assuming that the index method supports it):

```
ALTER INDEX distributors SET (fillfactor = 75);  
REINDEX INDEX distributors;
```

Set the statistics-gathering target for an expression index:

```
CREATE INDEX coord_idx ON measured (x, y, (z + t));  
ALTER INDEX coord_idx ALTER COLUMN 3 SET STATISTICS 1000;
```

Compatibility

ALTER INDEX is a Postgres Pro extension.

See Also

[CREATE INDEX](#), [REINDEX](#)

ALTER LANGUAGE

ALTER LANGUAGE — change the definition of a procedural language

Synopsis

```
ALTER [ PROCEDURAL ] LANGUAGE name RENAME TO new_name
ALTER [ PROCEDURAL ] LANGUAGE name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER |
SESSION_USER }
```

Description

ALTER LANGUAGE changes the definition of a procedural language. The only functionality is to rename the language or assign a new owner. You must be superuser or owner of the language to use ALTER LANGUAGE.

Parameters

name

Name of a language

new_name

The new name of the language

new_owner

The new owner of the language

Compatibility

There is no ALTER LANGUAGE statement in the SQL standard.

See Also

[CREATE LANGUAGE](#), [DROP LANGUAGE](#)

ALTER LARGE OBJECT

ALTER LARGE OBJECT — change the definition of a large object

Synopsis

```
ALTER LARGE OBJECT large_object_oid OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER  
| SESSION_USER }
```

Description

ALTER LARGE OBJECT changes the definition of a large object.

You must own the large object to use ALTER LARGE OBJECT. To alter the owner, you must also be able to SET ROLE to the new owning role. (However, a superuser can alter any large object anyway.) Currently, the only functionality is to assign a new owner, so both restrictions always apply.

Parameters

large_object_oid

OID of the large object to be altered

new_owner

The new owner of the large object

Compatibility

There is no ALTER LARGE OBJECT statement in the SQL standard.

See Also

[Chapter 36](#)

ALTER MATERIALIZED VIEW

ALTER MATERIALIZED VIEW — change the definition of a materialized view

Synopsis

```
ALTER MATERIALIZED VIEW [ IF EXISTS ] name
    action [, ... ]
ALTER MATERIALIZED VIEW name
    [ NO ] DEPENDS ON EXTENSION extension_name
ALTER MATERIALIZED VIEW [ IF EXISTS ] name
    RENAME [ COLUMN ] column_name TO new_column_name
ALTER MATERIALIZED VIEW [ IF EXISTS ] name
    RENAME TO new_name
ALTER MATERIALIZED VIEW [ IF EXISTS ] name
    SET SCHEMA new_schema
ALTER MATERIALIZED VIEW ALL IN TABLESPACE name [ OWNED BY role_name [, ... ] ]
    SET TABLESPACE new_tablespace [ NOWAIT ]
```

where *action* is one of:

```
ALTER [ COLUMN ] column_name SET STATISTICS integer
ALTER [ COLUMN ] column_name SET ( attribute_option = value [, ... ] )
ALTER [ COLUMN ] column_name RESET ( attribute_option [, ... ] )
ALTER [ COLUMN ] column_name SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN |
DEFAULT }
ALTER [ COLUMN ] column_name SET COMPRESSION compression_method
CLUSTER ON index_name
SET WITHOUT CLUSTER
SET ACCESS METHOD new_access_method
SET TABLESPACE new_tablespace
SET ( storage_parameter [= value] [, ... ] )
RESET ( storage_parameter [, ... ] )
OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
```

Description

ALTER MATERIALIZED VIEW changes various auxiliary properties of an existing materialized view.

You must own the materialized view to use ALTER MATERIALIZED VIEW. To change a materialized view's schema, you must also have CREATE privilege on the new schema. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have CREATE privilege on the materialized view's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the materialized view. However, a superuser can alter ownership of any view anyway.)

The statement subforms and actions available for ALTER MATERIALIZED VIEW are a subset of those available for ALTER TABLE, and have the same meaning when used for materialized views. See the descriptions for [ALTER TABLE](#) for details.

Parameters

name

The name (optionally schema-qualified) of an existing materialized view.

column_name

Name of an existing column.

extension_name

The name of the extension that the materialized view is to depend on (or no longer dependent on, if `NO` is specified). A materialized view that's marked as dependent on an extension is automatically dropped when the extension is dropped.

new_column_name

New name for an existing column.

new_owner

The user name of the new owner of the materialized view.

new_name

The new name for the materialized view.

new_schema

The new schema for the materialized view.

Examples

To rename the materialized view `foo` to `bar`:

```
ALTER MATERIALIZED VIEW foo RENAME TO bar;
```

Compatibility

`ALTER MATERIALIZED VIEW` is a Postgres Pro extension.

See Also

[CREATE MATERIALIZED VIEW](#), [DROP MATERIALIZED VIEW](#), [REFRESH MATERIALIZED VIEW](#)

ALTER OPERATOR

ALTER OPERATOR — change the definition of an operator

Synopsis

```
ALTER OPERATOR name ( { left_type | NONE } , right_type )  
    OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
```

```
ALTER OPERATOR name ( { left_type | NONE } , right_type )  
    SET SCHEMA new_schema
```

```
ALTER OPERATOR name ( { left_type | NONE } , right_type )  
    SET ( { RESTRICT = { res_proc | NONE }  
        | JOIN = { join_proc | NONE }  
        | COMMUTATOR = com_op  
        | NEGATOR = neg_op  
        | HASHES  
        | MERGES  
        } [, ... ] )
```

Description

ALTER OPERATOR changes the definition of an operator.

You must own the operator to use ALTER OPERATOR. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have CREATE privilege on the operator's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the operator. However, a superuser can alter ownership of any operator anyway.)

Parameters

name

The name (optionally schema-qualified) of an existing operator.

left_type

The data type of the operator's left operand; write NONE if the operator has no left operand.

right_type

The data type of the operator's right operand.

new_owner

The new owner of the operator.

new_schema

The new schema for the operator.

res_proc

The restriction selectivity estimator function for this operator; write NONE to remove existing selectivity estimator.

join_proc

The join selectivity estimator function for this operator; write NONE to remove existing selectivity estimator.

com_op

The commutator of this operator. Can only be changed if the operator does not have an existing commutator.

neg_op

The negator of this operator. Can only be changed if the operator does not have an existing negator.

HASHES

Indicates this operator can support a hash join. Can only be enabled and not disabled.

MERGES

Indicates this operator can support a merge join. Can only be enabled and not disabled.

Notes

Refer to [Section 39.14](#) and [Section 39.15](#) for further information.

Since commutators come in pairs that are commutators of each other, `ALTER OPERATOR SET COMMUTATOR` will also set the commutator of the *com_op* to be the target operator. Likewise, `ALTER OPERATOR SET NEGATOR` will also set the negator of the *neg_op* to be the target operator. Therefore, you must own the commutator or negator operator as well as the target operator.

Examples

Change the owner of a custom operator `a @@ b` for type `text`:

```
ALTER OPERATOR @@ (text, text) OWNER TO joe;
```

Change the restriction and join selectivity estimator functions of a custom operator `a && b` for type `int[]`:

```
ALTER OPERATOR && (int[], int[]) SET (RESTRICT = _int_contsel, JOIN =  
_int_contjoinssel);
```

Mark the `&&` operator as being its own commutator:

```
ALTER OPERATOR && (int[], int[]) SET (COMMUTATOR = &&);
```

Compatibility

There is no `ALTER OPERATOR` statement in the SQL standard.

See Also

[CREATE OPERATOR](#), [DROP OPERATOR](#)

ALTER OPERATOR CLASS

ALTER OPERATOR CLASS — change the definition of an operator class

Synopsis

```
ALTER OPERATOR CLASS name USING index_method
    RENAME TO new_name
```

```
ALTER OPERATOR CLASS name USING index_method
    OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
```

```
ALTER OPERATOR CLASS name USING index_method
    SET SCHEMA new_schema
```

Description

ALTER OPERATOR CLASS changes the definition of an operator class.

You must own the operator class to use ALTER OPERATOR CLASS. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have CREATE privilege on the operator class's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the operator class. However, a superuser can alter ownership of any operator class anyway.)

Parameters

name

The name (optionally schema-qualified) of an existing operator class.

index_method

The name of the index method this operator class is for.

new_name

The new name of the operator class.

new_owner

The new owner of the operator class.

new_schema

The new schema for the operator class.

Compatibility

There is no ALTER OPERATOR CLASS statement in the SQL standard.

See Also

[CREATE OPERATOR CLASS](#), [DROP OPERATOR CLASS](#), [ALTER OPERATOR FAMILY](#)

ALTER OPERATOR FAMILY

ALTER OPERATOR FAMILY — change the definition of an operator family

Synopsis

```
ALTER OPERATOR FAMILY name USING index_method ADD
{ OPERATOR strategy_number operator_name ( op_type, op_type )
  [ FOR SEARCH | FOR ORDER BY sort_family_name ]
| FUNCTION support_number [ ( op_type [ , op_type ] ) ]
  function_name [ ( argument_type [, ...] ) ]
} [, ... ]

ALTER OPERATOR FAMILY name USING index_method DROP
{ OPERATOR strategy_number ( op_type [ , op_type ] )
| FUNCTION support_number ( op_type [ , op_type ] )
} [, ... ]

ALTER OPERATOR FAMILY name USING index_method
  RENAME TO new_name

ALTER OPERATOR FAMILY name USING index_method
  OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }

ALTER OPERATOR FAMILY name USING index_method
  SET SCHEMA new_schema
```

Description

`ALTER OPERATOR FAMILY` changes the definition of an operator family. You can add operators and support functions to the family, remove them from the family, or change the family's name or owner.

When operators and support functions are added to a family with `ALTER OPERATOR FAMILY`, they are not part of any specific operator class within the family, but are just “loose” within the family. This indicates that these operators and functions are compatible with the family's semantics, but are not required for correct functioning of any specific index. (Operators and functions that are so required should be declared as part of an operator class, instead; see [CREATE OPERATOR CLASS](#).) Postgres Pro will allow loose members of a family to be dropped from the family at any time, but members of an operator class cannot be dropped without dropping the whole class and any indexes that depend on it. Typically, single-data-type operators and functions are part of operator classes because they are needed to support an index on that specific data type, while cross-data-type operators and functions are made loose members of the family.

You must be a superuser to use `ALTER OPERATOR FAMILY`. (This restriction is made because an erroneous operator family definition could confuse or even crash the server.)

`ALTER OPERATOR FAMILY` does not presently check whether the operator family definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user's responsibility to define a valid operator family.

Refer to [Section 39.16](#) for further information.

Parameters

name

The name (optionally schema-qualified) of an existing operator family.

index_method

The name of the index method this operator family is for.

strategy_number

The index method's strategy number for an operator associated with the operator family.

operator_name

The name (optionally schema-qualified) of an operator associated with the operator family.

op_type

In an `OPERATOR` clause, the operand data type(s) of the operator, or `NONE` to signify a prefix operator. Unlike the comparable syntax in `CREATE OPERATOR CLASS`, the operand data types must always be specified.

In an `ADD FUNCTION` clause, the operand data type(s) the function is intended to support, if different from the input data type(s) of the function. For B-tree comparison functions and hash functions it is not necessary to specify *op_type* since the function's input data type(s) are always the correct ones to use. For B-tree sort support functions, B-Tree equal image functions, and all functions in GiST, SP-GiST and GIN operator classes, it is necessary to specify the operand data type(s) the function is to be used with.

In a `DROP FUNCTION` clause, the operand data type(s) the function is intended to support must be specified.

sort_family_name

The name (optionally schema-qualified) of an existing `btree` operator family that describes the sort ordering associated with an ordering operator.

If neither `FOR SEARCH` nor `FOR ORDER BY` is specified, `FOR SEARCH` is the default.

support_number

The index method's support function number for a function associated with the operator family.

function_name

The name (optionally schema-qualified) of a function that is an index method support function for the operator family. If no argument list is specified, the name must be unique in its schema.

argument_type

The parameter data type(s) of the function.

new_name

The new name of the operator family.

new_owner

The new owner of the operator family.

new_schema

The new schema for the operator family.

The `OPERATOR` and `FUNCTION` clauses can appear in any order.

Notes

Notice that the `DROP` syntax only specifies the “slot” in the operator family, by strategy or support number and input data type(s). The name of the operator or function occupying the slot is not mentioned. Also, for `DROP FUNCTION` the type(s) to specify are the input data type(s) the function is intended to support;

for GiST, SP-GiST and GIN indexes this might have nothing to do with the actual input argument types of the function.

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator family is tantamount to granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator family.

The operators should not be defined by SQL functions. An SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

Before PostgreSQL 8.4, the `OPERATOR` clause could include a `RECHECK` option. This is no longer supported because whether an index operator is “lossy” is now determined on-the-fly at run time. This allows efficient handling of cases where an operator might or might not be lossy.

Examples

The following example command adds cross-data-type operators and support functions to an operator family that already contains B-tree operator classes for data types `int4` and `int2`.

```
ALTER OPERATOR FAMILY integer_ops USING btree ADD
```

```
-- int4 vs int2
OPERATOR 1 < (int4, int2) ,
OPERATOR 2 <= (int4, int2) ,
OPERATOR 3 = (int4, int2) ,
OPERATOR 4 >= (int4, int2) ,
OPERATOR 5 > (int4, int2) ,
FUNCTION 1 btint42cmp(int4, int2) ,

-- int2 vs int4
OPERATOR 1 < (int2, int4) ,
OPERATOR 2 <= (int2, int4) ,
OPERATOR 3 = (int2, int4) ,
OPERATOR 4 >= (int2, int4) ,
OPERATOR 5 > (int2, int4) ,
FUNCTION 1 btint24cmp(int2, int4) ;
```

To remove these entries again:

```
ALTER OPERATOR FAMILY integer_ops USING btree DROP
```

```
-- int4 vs int2
OPERATOR 1 (int4, int2) ,
OPERATOR 2 (int4, int2) ,
OPERATOR 3 (int4, int2) ,
OPERATOR 4 (int4, int2) ,
OPERATOR 5 (int4, int2) ,
FUNCTION 1 (int4, int2) ,

-- int2 vs int4
OPERATOR 1 (int2, int4) ,
OPERATOR 2 (int2, int4) ,
OPERATOR 3 (int2, int4) ,
OPERATOR 4 (int2, int4) ,
OPERATOR 5 (int2, int4) ,
FUNCTION 1 (int2, int4) ;
```

Compatibility

There is no `ALTER OPERATOR FAMILY` statement in the SQL standard.

See Also

[CREATE OPERATOR FAMILY](#), [DROP OPERATOR FAMILY](#), [CREATE OPERATOR CLASS](#), [ALTER OPERATOR CLASS](#), [DROP OPERATOR CLASS](#)

ALTER POLICY

ALTER POLICY — change the definition of a row-level security policy

Synopsis

```
ALTER POLICY name ON table_name RENAME TO new_name
```

```
ALTER POLICY name ON table_name  
[ TO { role_name | PUBLIC | CURRENT_ROLE | CURRENT_USER | SESSION_USER } [, ...] ]  
[ USING ( using_expression ) ]  
[ WITH CHECK ( check_expression ) ]
```

Description

ALTER POLICY changes the definition of an existing row-level security policy. Note that ALTER POLICY only allows the set of roles to which the policy applies and the USING and WITH CHECK expressions to be modified. To change other properties of a policy, such as the command to which it applies or whether it is permissive or restrictive, the policy must be dropped and recreated.

To use ALTER POLICY, you must own the table that the policy applies to.

In the second form of ALTER POLICY, the role list, *using_expression*, and *check_expression* are replaced independently if specified. When one of those clauses is omitted, the corresponding part of the policy is unchanged.

Parameters

name

The name of an existing policy to alter.

table_name

The name (optionally schema-qualified) of the table that the policy is on.

new_name

The new name for the policy.

role_name

The role(s) to which the policy applies. Multiple roles can be specified at one time. To apply the policy to all roles, use PUBLIC.

using_expression

The USING expression for the policy. See [CREATE POLICY](#) for details.

check_expression

The WITH CHECK expression for the policy. See [CREATE POLICY](#) for details.

Compatibility

ALTER POLICY is a Postgres Pro extension.

See Also

[CREATE POLICY](#), [DROP POLICY](#)

ALTER PROCEDURE

ALTER PROCEDURE — change the definition of a procedure

Synopsis

```
ALTER PROCEDURE name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
    action [ ... ] [ RESTRICT ]  
ALTER PROCEDURE name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
    RENAME TO new_name  
ALTER PROCEDURE name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
    OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }  
ALTER PROCEDURE name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
    SET SCHEMA new_schema  
ALTER PROCEDURE name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
    [ NO ] DEPENDS ON EXTENSION extension_name
```

where *action* is one of:

```
[ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER  
SET configuration_parameter { TO | = } { value | DEFAULT }  
SET configuration_parameter FROM CURRENT  
RESET configuration_parameter  
RESET ALL
```

Description

ALTER PROCEDURE changes the definition of a procedure.

You must own the procedure to use ALTER PROCEDURE. To change a procedure's schema, you must also have CREATE privilege on the new schema. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have CREATE privilege on the procedure's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the procedure. However, a superuser can alter ownership of any procedure anyway.)

Parameters

name

The name (optionally schema-qualified) of an existing procedure. If no argument list is specified, the name must be unique in its schema.

argmode

The mode of an argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN.

argname

The name of an argument. Note that ALTER PROCEDURE does not actually pay any attention to argument names, since only the argument data types are used to determine the procedure's identity.

argtype

The data type(s) of the procedure's arguments (optionally schema-qualified), if any. See [DROP PROCEDURE](#) for the details of how the procedure is looked up using the argument data type(s).

new_name

The new name of the procedure.

new_owner

The new owner of the procedure. Note that if the procedure is marked `SECURITY DEFINER`, it will subsequently execute as the new owner.

new_schema

The new schema for the procedure.

extension_name

This form marks the procedure as dependent on the extension, or no longer dependent on the extension if `NO` is specified. A procedure that's marked as dependent on an extension is dropped when the extension is dropped, even if `cascade` is not specified. A procedure can depend upon multiple extensions, and will be dropped when any one of those extensions is dropped.

```
[ EXTERNAL ] SECURITY INVOKER  
[ EXTERNAL ] SECURITY DEFINER
```

Change whether the procedure is a security definer or not. The key word `EXTERNAL` is ignored for SQL conformance. See [CREATE PROCEDURE](#) for more information about this capability.

configuration_parameter
value

Add or change the assignment to be made to a configuration parameter when the procedure is called. If *value* is `DEFAULT` or, equivalently, `RESET` is used, the procedure-local setting is removed, so that the procedure executes with the value present in its environment. Use `RESET ALL` to clear all procedure-local settings. `SET FROM CURRENT` saves the value of the parameter that is current when `ALTER PROCEDURE` is executed as the value to be applied when the procedure is entered.

See [SET](#) and [Chapter 19](#) for more information about allowed parameter names and values.

`RESTRICT`

Ignored for conformance with the SQL standard.

Examples

To rename the procedure `insert_data` with two arguments of type `integer` to `insert_record`:

```
ALTER PROCEDURE insert_data(integer, integer) RENAME TO insert_record;
```

To change the owner of the procedure `insert_data` with two arguments of type `integer` to `joe`:

```
ALTER PROCEDURE insert_data(integer, integer) OWNER TO joe;
```

To change the schema of the procedure `insert_data` with two arguments of type `integer` to `accounting`:

```
ALTER PROCEDURE insert_data(integer, integer) SET SCHEMA accounting;
```

To mark the procedure `insert_data(integer, integer)` as being dependent on the extension `myext`:

```
ALTER PROCEDURE insert_data(integer, integer) DEPENDS ON EXTENSION myext;
```

To adjust the search path that is automatically set for a procedure:

```
ALTER PROCEDURE check_password(text) SET search_path = admin, pg_temp;
```

To disable automatic setting of `search_path` for a procedure:

```
ALTER PROCEDURE check_password(text) RESET search_path;
```

The procedure will now execute with whatever search path is used by its caller.

Compatibility

This statement is partially compatible with the `ALTER PROCEDURE` statement in the SQL standard. The standard allows more properties of a procedure to be modified, but does not provide the ability to rename a procedure, make a procedure a security definer, attach configuration parameter values to a procedure, or change the owner, schema, or volatility of a procedure. The standard also requires the `RESTRICT` key word, which is optional in Postgres Pro.

See Also

[CREATE PROCEDURE](#), [DROP PROCEDURE](#), [ALTER FUNCTION](#), [ALTER ROUTINE](#)

ALTER PROFILE

ALTER PROFILE — change an authentication profile

Synopsis

```
ALTER PROFILE name [ LIMIT parameter value [ ... ] ]
```

where *parameter* can be:

```
    FAILED_LOGIN_ATTEMPTS
|  PASSWORD_REUSE_TIME
|  PASSWORD_REUSE_MAX
|  PASSWORD_LIFE_TIME
|  PASSWORD_GRACE_TIME
|  USER_INACTIVE_TIME
|  FAILED_AUTH_KEEP_TIME
|  PASSWORD_MIN_UNIQUE_CHARS
|  PASSWORD_MIN_LEN
|  PASSWORD_REQUIRE_COMPLEX
```

```
ALTER PROFILE name RENAME TO new_name
```

Description

The `ALTER PROFILE` command changes parameters of a Postgres Pro profile. You must be a database superuser or have the privileges of the [pg_manage_profiles](#) role to use this command.

Parameters

name

The name of the profile for which to alter parameters.

```
FAILED_LOGIN_ATTEMPTS value
PASSWORD_REUSE_TIME value
PASSWORD_REUSE_MAX value
PASSWORD_LIFE_TIME value
PASSWORD_GRACE_TIME value
USER_INACTIVE_TIME value
FAILED_AUTH_KEEP_TIME value
PASSWORD_MIN_UNIQUE_CHARS value
PASSWORD_MIN_LEN value
PASSWORD_REQUIRE_COMPLEX value
```

These clauses alter parameters originally set by [CREATE PROFILE](#). For more information, see the [CREATE PROFILE](#) reference page.

new_name

The new name of the profile.

Notes

Use [CREATE PROFILE](#) to add new profiles, and [DROP PROFILE](#) to remove a profile.

Examples

Change `PASSWORD_LIFE_TIME` and `PASSWORD_GRACE_TIME` parameters of a profile:

```
ALTER PROFILE admin_profile  
  LIMIT PASSWORD_LIFE_TIME 90  
  PASSWORD_GRACE_TIME 3;
```

See Also

[CREATE PROFILE](#), [DROP PROFILE](#), [CREATE ROLE](#)

ALTER PUBLICATION

ALTER PUBLICATION — change the definition of a publication

Synopsis

```
ALTER PUBLICATION name ADD publication_object [, ...]
ALTER PUBLICATION name SET publication_object [, ...]
ALTER PUBLICATION name DROP publication_object [, ...]
ALTER PUBLICATION name SET ( publication_parameter [= value] [, ... ] )
ALTER PUBLICATION name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER |
    SESSION_USER }
ALTER PUBLICATION name RENAME TO new_name
```

where *publication_object* is one of:

```
TABLE [ ONLY ] table_name [ * ] [ ( column_name [, ... ] ) ] [ WHERE ( expression
) ] [, ... ]
TABLES IN SCHEMA { schema_name | CURRENT_SCHEMA } [, ... ]
```

Description

The command ALTER PUBLICATION can change the attributes of a publication.

The first three variants change which tables/schemas are part of the publication. The SET clause will replace the list of tables/schemas in the publication with the specified list; the existing tables/schemas that were present in the publication will be removed. The ADD and DROP clauses will add and remove one or more tables/schemas from the publication. Note that adding tables/schemas to a publication that is already subscribed to will require an [ALTER SUBSCRIPTION ... REFRESH PUBLICATION](#) action on the subscribing side in order to become effective. Note also that DROP TABLES IN SCHEMA will not drop any schema tables that were specified using [FOR TABLE/ ADD TABLE](#), and the combination of DROP with a WHERE clause is not allowed.

The fourth variant of this command listed in the synopsis can change all of the publication properties specified in [CREATE PUBLICATION](#). Properties not mentioned in the command retain their previous settings.

The remaining variants change the owner and the name of the publication.

You must own the publication to use ALTER PUBLICATION. Adding a table to a publication additionally requires owning that table. The ADD TABLES IN SCHEMA and SET TABLES IN SCHEMA to a publication requires the invoking user to be a superuser. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have CREATE privilege on the database. Also, the new owner of a [FOR ALL TABLES](#) or [FOR TABLES IN SCHEMA](#) publication must be a superuser. However, a superuser can change the ownership of a publication regardless of these restrictions.

Adding/Setting any schema when the publication also publishes a table with a column list, and vice versa is not supported.

Parameters

name

The name of an existing publication whose definition is to be altered.

table_name

Name of an existing table. If ONLY is specified before the table name, only that table is affected. If ONLY is not specified, the table and all its descendant tables (if any) are affected. Optionally, * can be specified after the table name to explicitly indicate that descendant tables are included.

Optionally, a column list can be specified. See [CREATE PUBLICATION](#) for details. Note that a subscription having several publications in which the same table has been published with different column lists is not supported. See [Warning: Combining Column Lists from Multiple Publications](#) for details of potential problems when altering column lists.

If the optional `WHERE` clause is specified, rows for which the *expression* evaluates to false or null will not be published. Note that parentheses are required around the expression. The *expression* is evaluated with the role used for the replication connection.

schema_name

Name of an existing schema.

`SET (publication_parameter [= value] [, ...])`

This clause alters publication parameters originally set by [CREATE PUBLICATION](#). See there for more information.

new_owner

The user name of the new owner of the publication.

new_name

The new name for the publication.

Examples

Change the publication to publish only deletes and updates:

```
ALTER PUBLICATION noinsert SET (publish = 'update, delete');
```

Add some tables to the publication:

```
ALTER PUBLICATION mypublication ADD TABLE users (user_id, firstname), departments;
```

Change the set of columns published for a table:

```
ALTER PUBLICATION mypublication SET TABLE users (user_id, firstname, lastname), TABLE departments;
```

Add schemas `marketing` and `sales` to the publication `sales_publication`:

```
ALTER PUBLICATION sales_publication ADD TABLES IN SCHEMA marketing, sales;
```

Add tables `users`, `departments` and schema `production` to the publication `production_publication`:

```
ALTER PUBLICATION production_publication ADD TABLE users, departments, TABLES IN SCHEMA production;
```

Compatibility

`ALTER PUBLICATION` is a Postgres Pro extension.

[CREATE PUBLICATION](#), [DROP PUBLICATION](#), [CREATE SUBSCRIPTION](#), [ALTER SUBSCRIPTION](#)

ALTER ROLE

ALTER ROLE — change a database role

Synopsis

```
ALTER ROLE role_specification [ WITH ] option [ ... ]
```

where *option* can be:

```
SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| REPLICATION | NOREPLICATION
| BYPASSRLS | NOBYPASSRLS
| CONNECTION LIMIT connlimit
| [ ENCRYPTED ] PASSWORD 'password' | PASSWORD NULL
| VALID UNTIL 'timestamp'
| PROFILE profile_name
| ACCOUNT UNLOCK | ACCOUNT LOCK
```

```
ALTER ROLE name RENAME TO new_name
```

```
ALTER ROLE { role_specification | ALL } [ IN DATABASE database_name ]
SET configuration_parameter { TO | = } { value | DEFAULT }
ALTER ROLE { role_specification | ALL } [ IN DATABASE database_name ]
SET configuration_parameter FROM CURRENT
ALTER ROLE { role_specification | ALL } [ IN DATABASE database_name ]
RESET configuration_parameter
ALTER ROLE { role_specification | ALL } [ IN DATABASE database_name ] RESET ALL
```

where *role_specification* can be:

```
role_name
| CURRENT_ROLE
| CURRENT_USER
| SESSION_USER
```

Description

ALTER ROLE changes the attributes of a Postgres Pro role.

The first variant of this command listed in the synopsis can change many of the role attributes that can be specified in [CREATE ROLE](#). (All the possible attributes are covered, except that there are no options for adding or removing memberships; use [GRANT](#) and [REVOKE](#) for that.) Attributes not mentioned in the command retain their previous settings. Database superusers can change any of these settings for any role, except for changing the SUPERUSER property for the [bootstrap superuser](#). Non-superuser roles having CREATEROLE privilege can change most of these properties, but only for non-superuser and non-replication roles for which they have been granted ADMIN OPTION. Non-superusers cannot change the SUPERUSER property and can change the CREATEDB, REPLICATION, and BYPASSRLS properties only if they possess the corresponding property themselves. Ordinary roles can only change their own password.

The second variant changes the name of the role. Database superusers can rename any role. Roles having CREATEROLE privilege can rename non-superuser roles for which they have been granted ADMIN OPTION. The current session user cannot be renamed. (Connect as a different user if you need to do that.)

Because MD5-encrypted passwords use the role name as cryptographic salt, renaming a role clears its password if the password is MD5-encrypted.

The remaining variants change a role's session default for a configuration variable, either for all databases or, when the `IN DATABASE` clause is specified, only for sessions in the named database. If `ALL` is specified instead of a role name, this changes the setting for all roles. Using `ALL` with `IN DATABASE` is effectively the same as using the command `ALTER DATABASE ... SET ...`.

Whenever the role subsequently starts a new session, the specified value becomes the session default, overriding whatever setting is present in `postgresql.conf` or has been received from the `postgres` command line. This only happens at login time; executing `SET ROLE` or `SET SESSION AUTHORIZATION` does not cause new configuration values to be set. Settings set for all databases are overridden by database-specific settings attached to a role. Settings for specific databases or specific roles override settings for all roles.

Superusers can change anyone's session defaults. Roles having `CREATEROLE` privilege can change defaults for non-superuser roles for which they have been granted `ADMIN OPTION`. Ordinary roles can only set defaults for themselves. Certain configuration variables cannot be set this way, or can only be set if a superuser issues the command. Only superusers can change a setting for all roles in all databases.

Parameters

name

The name of the role whose attributes are to be altered.

`CURRENT_ROLE`

`CURRENT_USER`

Alter the current user instead of an explicitly identified role.

`SESSION_USER`

Alter the current session user instead of an explicitly identified role.

`SUPERUSER`

`NOSUPERUSER`

`CREATEDB`

`NOCREATEDB`

`CREATEROLE`

`NOCREATEROLE`

`INHERIT`

`NOINHERIT`

`LOGIN`

`NOLOGIN`

`REPLICATION`

`NOREPLICATION`

`BYPASSRLS`

`NOBYPASSRLS`

`CONNECTION LIMIT` *conlimit*

`[ENCRYPTED] PASSWORD` '*password*'

`PASSWORD NULL`

`VALID UNTIL` '*timestamp*'

`PROFILE` *profile_name*

These clauses alter attributes originally set by `CREATE ROLE`. For more information, see the `CREATE ROLE` reference page.

`ACCOUNT UNLOCK`

Unlock the role. A role can be locked if the allowed number of failed login attempts has been exceeded (see `CREATE PROFILE` for details).

ACCOUNT LOCK

Explicitly lock the role.

new_name

The new name of the role.

database_name

The name of the database the configuration variable should be set in.

configuration_parameter
value

Set this role's session default for the specified configuration parameter to the given value. If *value* is `DEFAULT` or, equivalently, `RESET` is used, the role-specific variable setting is removed, so the role will inherit the system-wide default setting in new sessions. Use `RESET ALL` to clear all role-specific settings. `SET FROM CURRENT` saves the session's current value of the parameter as the role-specific value. If `IN DATABASE` is specified, the configuration parameter is set or removed for the given role and database only.

Role-specific variable settings take effect only at login; `SET ROLE` and `SET SESSION AUTHORIZATION` do not process role-specific variable settings.

See [SET](#) and [Chapter 19](#) for more information about allowed parameter names and values.

Notes

Use [CREATE ROLE](#) to add new roles, and [DROP ROLE](#) to remove a role.

`ALTER ROLE` cannot change a role's memberships. Use [GRANT](#) and [REVOKE](#) to do that.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in cleartext, and it might also be logged in the client's command history or the server log. [psql](#) contains a command `\password` that can be used to change a role's password without exposing the cleartext password.

It is also possible to tie a session default to a specific database rather than to a role; see [ALTER DATABASE](#). If there is a conflict, database-role-specific settings override role-specific ones, which in turn override database-specific ones.

Examples

Change a role's password:

```
ALTER ROLE davide WITH PASSWORD 'hu8jmn3';
```

Remove a role's password:

```
ALTER ROLE davide WITH PASSWORD NULL;
```

Change a password expiration date, specifying that the password should expire at midday on 4th May 2015 using the time zone which is one hour ahead of UTC:

```
ALTER ROLE chris VALID UNTIL 'May 4 12:00:00 2015 +1';
```

Make a password valid forever:

```
ALTER ROLE fred VALID UNTIL 'infinity';
```

Give a role the ability to manage other roles and create new databases:

```
ALTER ROLE miriam CREATEROLE CREATEDB;
```

Give a role a non-default setting of the [maintenance_work_mem](#) parameter:

```
ALTER ROLE worker_bee SET maintenance_work_mem = 100000;
```

Give a role a non-default, database-specific setting of the [client_min_messages](#) parameter:

```
ALTER ROLE fred IN DATABASE devel SET client_min_messages = DEBUG;
```

Compatibility

The `ALTER ROLE` statement is a Postgres Pro extension.

See Also

[CREATE ROLE](#), [DROP ROLE](#), [ALTER DATABASE](#), [SET](#), [CREATE PROFILE](#)

ALTER ROUTINE

ALTER ROUTINE — change the definition of a routine

Synopsis

```
ALTER ROUTINE name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]
    action [ ... ] [ RESTRICT ]
ALTER ROUTINE name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]
    RENAME TO new_name
ALTER ROUTINE name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]
    OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
ALTER ROUTINE name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]
    SET SCHEMA new_schema
ALTER ROUTINE name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]
    [ NO ] DEPENDS ON EXTENSION extension_name
```

where *action* is one of:

```
IMMUTABLE | STABLE | VOLATILE
[ NOT ] LEAKPROOF
[ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER
PARALLEL { UNSAFE | RESTRICTED | SAFE }
COST execution_cost
ROWS result_rows
SET configuration_parameter { TO | = } { value | DEFAULT }
SET configuration_parameter FROM CURRENT
RESET configuration_parameter
RESET ALL
```

Description

ALTER ROUTINE changes the definition of a routine, which can be an aggregate function, a normal function, or a procedure. See under [ALTER AGGREGATE](#), [ALTER FUNCTION](#), and [ALTER PROCEDURE](#) for the description of the parameters, more examples, and further details.

Examples

To rename the routine `foo` for type `integer` to `foobar`:

```
ALTER ROUTINE foo(integer) RENAME TO foobar;
```

This command will work independent of whether `foo` is an aggregate, function, or procedure.

Compatibility

This statement is partially compatible with the ALTER ROUTINE statement in the SQL standard. See under [ALTER FUNCTION](#) and [ALTER PROCEDURE](#) for more details. Allowing routine names to refer to aggregate functions is a Postgres Pro extension.

See Also

[ALTER AGGREGATE](#), [ALTER FUNCTION](#), [ALTER PROCEDURE](#), [DROP ROUTINE](#)

Note that there is no CREATE ROUTINE command.

ALTER RULE

ALTER RULE — change the definition of a rule

Synopsis

```
ALTER RULE name ON table_name RENAME TO new_name
```

Description

ALTER RULE changes properties of an existing rule. Currently, the only available action is to change the rule's name.

To use ALTER RULE, you must own the table or view that the rule applies to.

Parameters

name

The name of an existing rule to alter.

table_name

The name (optionally schema-qualified) of the table or view that the rule applies to.

new_name

The new name for the rule.

Examples

To rename an existing rule:

```
ALTER RULE notify_all ON emp RENAME TO notify_me;
```

Compatibility

ALTER RULE is a Postgres Pro language extension, as is the entire query rewrite system.

See Also

[CREATE RULE](#), [DROP RULE](#)

ALTER SCHEMA

ALTER SCHEMA — change the definition of a schema

Synopsis

```
ALTER SCHEMA name RENAME TO new_name
ALTER SCHEMA name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
ALTER SCHEMA name SECURITY OFFICER TO new_security_officer
ALTER SCHEMA name RESET SECURITY OFFICER
```

Description

ALTER SCHEMA changes the definition of a schema.

You must own the schema to use ALTER SCHEMA. To rename a schema you must also have the CREATE privilege for the database. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have the CREATE privilege for the database. (Note that superusers have all these privileges automatically.)

The SECURITY OFFICER clause sets the security officer of the schema, while the RESET SECURITY OFFICER clause resets the security officer. When you set the security officer, the schema becomes the [vault](#) schema.

Parameters

name

The name of an existing schema.

new_name

The new name of the schema. The new name cannot begin with `pg_`, as such names are reserved for system schemas.

new_owner

The new owner of the schema.

new_security_officer

The new security officer of the schema.

Compatibility

There is no ALTER SCHEMA statement in the SQL standard.

See Also

[CREATE SCHEMA](#), [DROP SCHEMA](#)

ALTER SEQUENCE

ALTER SEQUENCE — change the definition of a sequence generator

Synopsis

For sharded objects:

```
ALTER SEQUENCE [ IF EXISTS ] name
    [ AS data_type ]
    [ INCREMENT [ BY ] increment ]
    [ MINVALUE minvalue | NO MINVALUE ] [ MAXVALUE maxvalue | NO MAXVALUE ]
    [ RESTART [ [ WITH ] restart ] ]
    [ CACHE cache ] [ [ NO ] CYCLE ]
    [ OWNED BY { table_name.column_name | NONE } ]
ALTER SEQUENCE [ IF EXISTS ] name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER |
SESSION_USER }
ALTER SEQUENCE [ IF EXISTS ] name RENAME TO new_name
ALTER SEQUENCE [ IF EXISTS ] name SET SCHEMA new_schema
```

For other objects types:

```
ALTER SEQUENCE [ IF EXISTS ] name
    [ AS data_type ]
    [ INCREMENT [ BY ] increment ]
    [ MINVALUE minvalue | NO MINVALUE ] [ MAXVALUE maxvalue | NO MAXVALUE ]
    [ START [ WITH ] start ]
    [ RESTART [ [ WITH ] restart ] ]
    [ CACHE cache ] [ [ NO ] CYCLE ]
    [ OWNED BY { table_name.column_name | NONE } ]
ALTER SEQUENCE [ IF EXISTS ] name SET { LOGGED | UNLOGGED }
ALTER SEQUENCE [ IF EXISTS ] name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER |
SESSION_USER }
ALTER SEQUENCE [ IF EXISTS ] name RENAME TO new_name
ALTER SEQUENCE [ IF EXISTS ] name SET SCHEMA new_schema
```

Description

ALTER SEQUENCE changes the parameters of an existing sequence generator. Any parameters not specifically set in the ALTER SEQUENCE command retain their prior settings.

You must own the sequence to use ALTER SEQUENCE. To change a sequence's schema, you must also have CREATE privilege on the new schema. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have CREATE privilege on the sequence's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the sequence. However, a superuser can alter ownership of any sequence anyway.)

Parameters

name

The name (optionally schema-qualified) of a sequence to be altered.

IF EXISTS

Do not throw an error if the sequence does not exist. A notice is issued in this case.

data_type

The optional clause AS *data_type* changes the data type of the sequence. Valid types are smallint, integer, and bigint.

Changing the data type automatically changes the minimum and maximum values of the sequence if and only if the previous minimum and maximum values were the minimum or maximum value of the old data type (in other words, if the sequence had been created using `NO MINVALUE` or `NO MAXVALUE`, implicitly or explicitly). Otherwise, the minimum and maximum values are preserved, unless new values are given as part of the same command. If the minimum and maximum values do not fit into the new data type, an error will be generated.

increment

The clause `INCREMENT BY increment` is optional. A positive value will make an ascending sequence, a negative one a descending sequence. If unspecified, the old increment value will be maintained.

minvalue

`NO MINVALUE`

The optional clause `MINVALUE minvalue` determines the minimum value a sequence can generate. If `NO MINVALUE` is specified, the defaults of 1 and the minimum value of the data type for ascending and descending sequences, respectively, will be used. If neither option is specified, the current minimum value will be maintained.

maxvalue

`NO MAXVALUE`

The optional clause `MAXVALUE maxvalue` determines the maximum value for the sequence. If `NO MAXVALUE` is specified, the defaults of the maximum value of the data type and -1 for ascending and descending sequences, respectively, will be used. If neither option is specified, the current maximum value will be maintained.

start

The optional clause `START WITH start` changes the recorded start value of the sequence. This has no effect on the *current* sequence value; it simply sets the value that future `ALTER SEQUENCE RESTART` commands will use.

restart

The optional clause `RESTART [WITH restart]` changes the current value of the sequence. This is similar to calling the `setval` function with `is_called = false`: the specified value will be returned by the *next* call of `nextval`. Writing `RESTART` with no *restart* value is equivalent to supplying the start value that was recorded by `CREATE SEQUENCE` or last set by `ALTER SEQUENCE START WITH`.

In contrast to a `setval` call, a `RESTART` operation on a sequence is transactional and blocks concurrent transactions from obtaining numbers from the same sequence. If that's not the desired mode of operation, `setval` should be used.

cache

The clause `CACHE cache` enables sequence numbers to be preallocated and stored in memory for faster access. The minimum value is 1 (only one value can be generated at a time, i.e., no cache). If unspecified, the old cache value will be maintained.

`CYCLE`

The optional `CYCLE` key word can be used to enable the sequence to wrap around when the *maxvalue* or *minvalue* has been reached by an ascending or descending sequence respectively. If the limit is reached, the next number generated will be the *minvalue* or *maxvalue*, respectively.

`NO CYCLE`

If the optional `NO CYCLE` key word is specified, any calls to `nextval` after the sequence has reached its maximum value will return an error. If neither `CYCLE` or `NO CYCLE` are specified, the old cycle behavior will be maintained.

SET { LOGGED | UNLOGGED }

This form changes the sequence from unlogged to logged or vice-versa (see [CREATE SEQUENCE](#)). It cannot be applied to a temporary sequence.

OWNED BY *table_name.column_name*

OWNED BY NONE

The OWNED BY option causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. If specified, this association replaces any previously specified association for the sequence. The specified table must have the same owner and be in the same schema as the sequence. Specifying OWNED BY NONE removes any existing association, making the sequence “free-standing”.

new_owner

The user name of the new owner of the sequence.

new_name

The new name for the sequence.

new_schema

The new schema for the sequence.

RESTART WITH

The minimum sequence value parameter in Postgres Pro Shardman works more like a lower boundary on the global interval of available values, so it can only be increased to make sure no duplicate numbers are generated.

The RESTART WITH clause allows restarting a sequence at any arbitrary lower bound, but in this case, there is no guarantee that previously generated numbers will not repeat.

Using both RESTART WITH and MINVALUE in a single statement is not permitted to avoid confusion.

Notes

ALTER SEQUENCE will not immediately affect `nextval` results in backends, other than the current one, that have preallocated (cached) sequence values. They will use up all cached values prior to noticing the changed sequence generation parameters. The current backend will be affected immediately.

ALTER SEQUENCE does not affect the `currval` status for the sequence. (Before PostgreSQL 8.3, it sometimes did.)

ALTER SEQUENCE blocks concurrent `nextval`, `currval`, `lastval`, and `setval` calls.

For historical reasons, ALTER TABLE can be used with sequences too; but the only variants of ALTER TABLE that are allowed with sequences are equivalent to the forms shown above.

Examples

Alter the block size parameter of a sequence called `serial`:

```
ALTER SEQUENCE serial SET (block_size = 8192);
```

Restart a sequence called `serial`, at 105:

```
ALTER SEQUENCE serial RESTART WITH 105;
```

Compatibility

ALTER SEQUENCE conforms to the SQL standard, except for the AS, START WITH, OWNED BY, OWNER TO, RENAME TO, and SET SCHEMA clauses, which are Postgres Pro extensions.

See Also

[CREATE SEQUENCE](#), [DROP SEQUENCE](#)

ALTER SERVER

ALTER SERVER — change the definition of a foreign server

Synopsis

```
ALTER SERVER name [ VERSION 'new_version' ]  
    [ OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] ) ]  
ALTER SERVER name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }  
ALTER SERVER name RENAME TO new_name
```

Description

ALTER SERVER changes the definition of a foreign server. The first form changes the server version string or the generic options of the server (at least one clause is required). The second form changes the owner of the server.

To alter the server you must be the owner of the server. Additionally to alter the owner, you must be able to SET ROLE to the new owning role, and you must have USAGE privilege on the server's foreign-data wrapper. (Note that superusers satisfy all these criteria automatically.)

Parameters

name

The name of an existing server.

new_version

New server version.

OPTIONS ([ADD | SET | DROP] *option* ['*value*'] [, ...])

Change options for the server. ADD, SET, and DROP specify the action to be performed. ADD is assumed if no operation is explicitly specified. Option names must be unique; names and values are also validated using the server's foreign-data wrapper library.

new_owner

The user name of the new owner of the foreign server.

new_name

The new name for the foreign server.

Examples

Alter server `foo`, add connection options:

```
ALTER SERVER foo OPTIONS (host 'foo', dbname 'foodb');
```

Alter server `foo`, change version, change host option:

```
ALTER SERVER foo VERSION '8.4' OPTIONS (SET host 'baz');
```

Compatibility

ALTER SERVER conforms to ISO/IEC 9075-9 (SQL/MED). The OWNER TO and RENAME forms are Postgres Pro extensions.

See Also

[CREATE SERVER](#), [DROP SERVER](#)

ALTER STATISTICS

ALTER STATISTICS — change the definition of an extended statistics object

Synopsis

```
ALTER STATISTICS name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER |  
SESSION_USER }  
ALTER STATISTICS name RENAME TO new_name  
ALTER STATISTICS name SET SCHEMA new_schema  
ALTER STATISTICS name SET STATISTICS { new_target | DEFAULT }
```

Description

ALTER STATISTICS changes the parameters of an existing extended statistics object. Any parameters not specifically set in the ALTER STATISTICS command retain their prior settings.

You must own the statistics object to use ALTER STATISTICS. To change a statistics object's schema, you must also have CREATE privilege on the new schema. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have CREATE privilege on the statistics object's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the statistics object. However, a superuser can alter ownership of any statistics object anyway.)

Parameters

name

The name (optionally schema-qualified) of the statistics object to be altered.

new_owner

The user name of the new owner of the statistics object.

new_name

The new name for the statistics object.

new_schema

The new schema for the statistics object.

new_target

The statistic-gathering target for this statistics object for subsequent [ANALYZE](#) operations. The target can be set in the range 0 to 10000. Set it to DEFAULT to revert to using the system default statistics target ([default_statistics_target](#)). (Setting to a value of -1 is an obsolete way spelling to get the same outcome.) For more information on the use of statistics by the Postgres Pro query planner, refer to [Section 14.2](#).

Compatibility

There is no ALTER STATISTICS command in the SQL standard.

See Also

[CREATE STATISTICS](#), [DROP STATISTICS](#)

ALTER SUBSCRIPTION

ALTER SUBSCRIPTION — change the definition of a subscription

Synopsis

```
ALTER SUBSCRIPTION name CONNECTION 'conninfo'
ALTER SUBSCRIPTION name SET PUBLICATION publication_name [, ...] [ WITH
( publication_option [= value] [, ... ] ) ]
ALTER SUBSCRIPTION name ADD PUBLICATION publication_name [, ...] [ WITH
( publication_option [= value] [, ... ] ) ]
ALTER SUBSCRIPTION name DROP PUBLICATION publication_name [, ...] [ WITH
( publication_option [= value] [, ... ] ) ]
ALTER SUBSCRIPTION name REFRESH PUBLICATION [ WITH ( refresh_option [= value]
[, ... ] ) ]
ALTER SUBSCRIPTION name ENABLE
ALTER SUBSCRIPTION name DISABLE
ALTER SUBSCRIPTION name SET ( subscription_parameter [= value] [, ... ] )
ALTER SUBSCRIPTION name SKIP ( skip_option = value )
ALTER SUBSCRIPTION name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER |
SESSION_USER }
ALTER SUBSCRIPTION name RENAME TO new_name
```

Description

ALTER SUBSCRIPTION can change most of the subscription properties that can be specified in [CREATE SUBSCRIPTION](#).

You must own the subscription to use ALTER SUBSCRIPTION. To rename a subscription or alter the owner, you must have CREATE permission on the database. In addition, to alter the owner, you must be able to SET ROLE to the new owning role. If the subscription has password_required=false, only superusers can modify it.

When refreshing a publication we remove the relations that are no longer part of the publication and we also remove the table synchronization slots if there are any. It is necessary to remove these slots so that the resources allocated for the subscription on the remote host are released. If due to network breakdown or some other error, Postgres Pro is unable to remove the slots, an error will be reported. To proceed in this situation, the user either needs to retry the operation or disassociate the slot from the subscription and drop the subscription as explained in [DROP SUBSCRIPTION](#).

Commands ALTER SUBSCRIPTION ... REFRESH PUBLICATION, ALTER SUBSCRIPTION ... {SET|ADD|DROP} PUBLICATION ... with refresh option as true and ALTER SUBSCRIPTION ... SET (failover = true|false) cannot be executed inside a transaction block.

Commands ALTER SUBSCRIPTION ... REFRESH PUBLICATION and ALTER SUBSCRIPTION ... {SET|ADD|DROP} PUBLICATION ... with refresh option as true also cannot be executed when the subscription has two_phase commit enabled, unless copy_data is false. See column subtwophasestate of pg_subscription to know the actual two-phase state.

Parameters

name

The name of a subscription whose properties are to be altered.

CONNECTION '*conninfo*'

This clause replaces the connection string originally set by [CREATE SUBSCRIPTION](#). See there for more information.

```
SET PUBLICATION publication_name
ADD PUBLICATION publication_name
DROP PUBLICATION publication_name
```

These forms change the list of subscribed publications. `SET` replaces the entire list of publications with a new list, `ADD` adds additional publications to the list of publications, and `DROP` removes the publications from the list of publications. We allow non-existent publications to be specified in `ADD` and `SET` variants so that users can add those later. See [CREATE SUBSCRIPTION](#) for more information. By default, this command will also act like `REFRESH PUBLICATION`.

publication_option specifies additional options for this operation. The supported options are:

`refresh` (boolean)

When false, the command will not try to refresh table information. `REFRESH PUBLICATION` should then be executed separately. The default is `true`.

Additionally, the options described under `REFRESH PUBLICATION` may be specified, to control the implicit refresh operation.

`REFRESH PUBLICATION`

Fetch missing table information from publisher. This will start replication of tables that were added to the subscribed-to publications since [CREATE SUBSCRIPTION](#) or the last invocation of `REFRESH PUBLICATION`.

refresh_option specifies additional options for the refresh operation. The supported options are:

`copy_data` (boolean)

Specifies whether to copy pre-existing data in the publications that are being subscribed to when the replication starts. The default is `true`.

Previously subscribed tables are not copied, even if a table's row filter `WHERE` clause has since been modified.

See [Notes](#) for details of how `copy_data = true` can interact with the `origin` parameter.

See the `binary` parameter of `CREATE SUBSCRIPTION` for details about copying pre-existing data in binary format.

`ENABLE`

Enables a previously disabled subscription, starting the logical replication worker at the end of the transaction.

`DISABLE`

Disables a running subscription, stopping the logical replication worker at the end of the transaction.

```
SET ( subscription_parameter [= value] [, ... ] )
```

This clause alters parameters originally set by [CREATE SUBSCRIPTION](#). See there for more information. The parameters that can be altered are `slot_name`, `synchronous_commit`, `binary`, `streaming`, `disable_on_error`, `password_required`, `run_as_owner`, `origin`, and `failover`. Only a superuser can set `password_required = false`.

When altering the `slot_name`, the `failover` and `two_phase` property values of the named slot may differ from the counterpart `failover` and `two_phase` parameters specified in the subscription. When creating the slot, ensure the slot properties `failover` and `two_phase` match their counterpart parameters of the subscription. Otherwise, the slot on the publisher may behave differently from what these subscription options say: for example, the slot on the publisher could either be synced to the standbys even when the subscription's `failover` option is disabled or could be disabled for sync even when the subscription's `failover` option is enabled.

`SKIP (skip_option = value)`

Skips applying all changes of the remote transaction. If incoming data violates any constraints, logical replication will stop until it is resolved. By using the `ALTER SUBSCRIPTION ... SKIP` command, the logical replication worker skips all data modification changes within the transaction. This option has no effect on the transactions that are already prepared by enabling [two_phase](#) on the subscriber. After the logical replication worker successfully skips the transaction or finishes a transaction, the LSN (stored in `pg_subscription.subskiplsn`) is cleared. See [Section 29.6](#) for the details of logical replication conflicts.

skip_option specifies options for this operation. The supported option is:

`lsn (pg_lsn)`

Specifies the finish LSN of the remote transaction whose changes are to be skipped by the logical replication worker. The finish LSN is the LSN at which the transaction is either committed or prepared. Skipping individual subtransactions is not supported. Setting `NONE` resets the LSN.

new_owner

The user name of the new owner of the subscription.

new_name

The new name for the subscription.

When specifying a parameter of type `boolean`, the `= value` part can be omitted, which is equivalent to specifying `TRUE`.

Examples

Change the publication subscribed by a subscription to `insert_only`:

```
ALTER SUBSCRIPTION mysub SET PUBLICATION insert_only;
```

Disable (stop) the subscription:

```
ALTER SUBSCRIPTION mysub DISABLE;
```

Compatibility

`ALTER SUBSCRIPTION` is a Postgres Pro extension.

ALTER TABLE

ALTER TABLE — change the definition of a table

Synopsis

For sharded tables:

```
ALTER TABLE [ IF EXISTS ] name [ * ]
    action [, ... ]
ALTER TABLE [ IF EXISTS ] name [ * ]
    RENAME [ COLUMN ] column_name TO new_column_name
ALTER TABLE [ IF EXISTS ] name [ * ]
    RENAME CONSTRAINT constraint_name TO new_constraint_name
ALTER TABLE [ IF EXISTS ] name
    RENAME TO new_name
ALTER TABLE [ IF EXISTS ] name
    SET SCHEMA new_schema
```

where *action* is one of:

```
    ADD [ COLUMN ] [ IF NOT EXISTS ] column_name data_type [ COLLATE collation ]
[ column_constraint [ ... ] ]
    DROP [ COLUMN ] [ IF EXISTS ] column_name [ RESTRICT | CASCADE ]
    ALTER [ COLUMN ] column_name [ SET DATA ] TYPE data_type [ COLLATE collation ]
[ USING expression ]
    ALTER [ COLUMN ] column_name SET DEFAULT expression
    ALTER [ COLUMN ] column_name DROP DEFAULT
    ALTER [ COLUMN ] column_name { SET | DROP } NOT NULL
    ALTER [ COLUMN ] column_name SET STATISTICS integer

    ADD table_constraint [ NOT VALID ]
    ADD table_constraint_using_index
    VALIDATE CONSTRAINT constraint_name
    DROP CONSTRAINT [ IF EXISTS ] constraint_name [ RESTRICT | CASCADE ]
    SET TABLESPACE new_tablespace
    RESET ( storage_parameter [, ... ] )
    OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
```

and *column_constraint* is:

```
[ CONSTRAINT constraint_name ]
{ NOT NULL |
  NULL |
  CHECK ( expression ) [ NO INHERIT ] |
  DEFAULT default_expr |
  UNIQUE index_parameters |
  PRIMARY KEY index_parameters |
  REFERENCES reftable [ ( refcolumn ) ] [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ]
  [ ON DELETE referential_action ] [ ON UPDATE referential_action ] }
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

and *sharded_table_constraint* is:

```
[ CONSTRAINT constraint_name ]
{ CHECK ( expression ) [ NO INHERIT ] |
  UNIQUE ( column_name [, ... ] ) index_parameters |
```

ALTER TABLE

```
EXCLUDE [ USING index_method ] ( exclude_element WITH operator
[, ... ] ) index_parameters [ WHERE ( predicate ) ] |
FOREIGN KEY ( column_name [, ... ] ) REFERENCES reftable [ ( refcolumn [, ... ] ) ]
[ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ] [ ON DELETE referential_action ] [ ON
UPDATE referential_action ] }
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

and *sharded_table_constraint_using_index* is:

```
[ CONSTRAINT constraint_name ]
{ UNIQUE | PRIMARY KEY } USING INDEX index_name
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

index_parameters in UNIQUE, PRIMARY KEY, and EXCLUDE constraints are:

```
[ INCLUDE ( column_name [, ... ] ) ]
[ WITH ( storage_parameter [= value] [, ... ] ) ]
[ USING INDEX TABLESPACE tablespace_name ]
```

exclude_element in an EXCLUDE constraint is:

```
{ column_name | ( expression ) } [ opclass ] [ ASC | DESC ] [ NULLS { FIRST | LAST } ]
```

referential_action in a FOREIGN KEY/REFERENCES constraint is:

```
{ NO ACTION | RESTRICT | CASCADE | SET NULL [ ( column_name [, ... ] ) ] | SET DEFAULT
[ ( column_name [, ... ] ) ] }
```

For other table types:

```
ALTER TABLE [ IF EXISTS ] [ ONLY ] name [ * ]
    action [, ... ]
ALTER TABLE [ IF EXISTS ] [ ONLY ] name [ * ]
    RENAME [ COLUMN ] column_name TO new_column_name
ALTER TABLE [ IF EXISTS ] [ ONLY ] name [ * ]
    RENAME CONSTRAINT constraint_name TO new_constraint_name
ALTER TABLE [ IF EXISTS ] name
    RENAME TO new_name
ALTER TABLE [ IF EXISTS ] name
    SET SCHEMA new_schema
ALTER TABLE ALL IN TABLESPACE name [ OWNED BY role_name [, ... ] ]
    SET TABLESPACE new_tablespace [ NOWAIT ]
ALTER TABLE [ IF EXISTS ] name
    ATTACH PARTITION partition_name { FOR VALUES partition_bound_spec | DEFAULT }
ALTER TABLE [ IF EXISTS ] name
    DETACH PARTITION partition_name [ CONCURRENTLY | FINALIZE ]
ALTER TABLE [ IF EXISTS ] name
    SPLIT PARTITION partition_name INTO
        (PARTITION partition_name1 { FOR VALUES partition_bound_spec | DEFAULT },
        PARTITION partition_name2 { FOR VALUES partition_bound_spec | DEFAULT }
    [, ...])
ALTER TABLE [ IF EXISTS ] name
    MERGE PARTITIONS (partition_name1, partition_name2 [, ...])
    INTO partition_name
```

where *action* is one of:

ALTER TABLE

```
ADD [ COLUMN ] [ IF NOT EXISTS ] column_name data_type [ COLLATE collation ]
[ column_constraint [ ... ] ]
DROP [ COLUMN ] [ IF EXISTS ] column_name [ RESTRICT | CASCADE ]
ALTER [ COLUMN ] column_name [ SET DATA ] TYPE data_type [ COLLATE collation ]
[ USING expression ]
ALTER [ COLUMN ] column_name SET DEFAULT expression
ALTER [ COLUMN ] column_name DROP DEFAULT
ALTER [ COLUMN ] column_name { SET | DROP } NOT NULL
ALTER [ COLUMN ] column_name SET EXPRESSION AS ( expression )
ALTER [ COLUMN ] column_name DROP EXPRESSION [ IF EXISTS ]
ALTER [ COLUMN ] column_name ADD GENERATED { ALWAYS | BY DEFAULT } AS IDENTITY
[ ( sequence_options ) ]
ALTER [ COLUMN ] column_name { SET GENERATED { ALWAYS | BY DEFAULT } |
SET sequence_option | RESTART [ [ WITH ] restart ] } [...]
ALTER [ COLUMN ] column_name DROP IDENTITY [ IF EXISTS ]
ALTER [ COLUMN ] column_name SET STATISTICS { integer | DEFAULT }
ALTER [ COLUMN ] column_name SET ( attribute_option = value [, ... ] )
ALTER [ COLUMN ] column_name RESET ( attribute_option [, ... ] )
ALTER [ COLUMN ] column_name SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN |
DEFAULT }
ALTER [ COLUMN ] column_name SET COMPRESSION compression_method
ADD table_constraint [ NOT VALID ]
ADD table_constraint_using_index
ALTER CONSTRAINT constraint_name [ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY
DEFERRED | INITIALLY IMMEDIATE ]
VALIDATE CONSTRAINT constraint_name
DROP CONSTRAINT [ IF EXISTS ] constraint_name [ RESTRICT | CASCADE ]
DISABLE TRIGGER [ trigger_name | ALL | USER ]
ENABLE TRIGGER [ trigger_name | ALL | USER ]
ENABLE REPLICA TRIGGER trigger_name
ENABLE ALWAYS TRIGGER trigger_name
DISABLE RULE rewrite_rule_name
ENABLE RULE rewrite_rule_name
ENABLE REPLICA RULE rewrite_rule_name
ENABLE ALWAYS RULE rewrite_rule_name
DISABLE ROW LEVEL SECURITY
ENABLE ROW LEVEL SECURITY
FORCE ROW LEVEL SECURITY
NO FORCE ROW LEVEL SECURITY
CLUSTER ON index_name
SET WITHOUT CLUSTER
SET WITHOUT OIDS
SET ACCESS METHOD { new_access_method | DEFAULT }
SET TABLESPACE new_tablespace
SET { LOGGED | UNLOGGED }
SET CONSTANT
SET ( storage_parameter [= value] [, ... ] )
RESET ( storage_parameter [, ... ] )
INHERIT parent_table
NO INHERIT parent_table
OF type_name
NOT OF
OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
REPLICA IDENTITY { DEFAULT | USING INDEX index_name | FULL | NOTHING }
```

and *partition_bound_spec* is:

```
IN ( partition_bound_expr [, ...] ) |
```

```
FROM ( { partition_bound_expr | MINVALUE | MAXVALUE } [, ...] )
TO ( { partition_bound_expr | MINVALUE | MAXVALUE } [, ...] ) |
WITH ( MODULUS numeric_literal, REMAINDER numeric_literal )
```

and *column_constraint* is:

```
[ CONSTRAINT constraint_name ]
{ NOT NULL |
  NULL |
  CHECK ( expression ) [ NO INHERIT ] |
  DEFAULT default_expr |
  GENERATED ALWAYS AS ( generation_expr ) STORED |
  GENERATED { ALWAYS | BY DEFAULT } AS IDENTITY [ ( sequence_options ) ] |
  UNIQUE [ NULLS [ NOT ] DISTINCT ] index_parameters |
  PRIMARY KEY index_parameters |
  REFERENCES reftable [ ( refcolumn ) ] [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ]
  [ ON DELETE referential_action ] [ ON UPDATE referential_action ] }
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

and *table_constraint* is:

```
[ CONSTRAINT constraint_name ]
{ CHECK ( expression ) [ NO INHERIT ] |
  UNIQUE [ NULLS [ NOT ] DISTINCT ] ( column_name [, ...] ) index_parameters |
  PRIMARY KEY ( column_name [, ...] ) index_parameters |
  EXCLUDE [ USING index_method ] ( exclude_element WITH operator
  [, ...] ) index_parameters [ WHERE ( predicate ) ] |
  FOREIGN KEY ( column_name [, ...] ) REFERENCES reftable [ ( refcolumn [, ...] ) ]
  [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ] [ ON DELETE referential_action ] [ ON
  UPDATE referential_action ] }
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

and *table_constraint_using_index* is:

```
[ CONSTRAINT constraint_name ]
{ UNIQUE | PRIMARY KEY } USING INDEX index_name
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

index_parameters in UNIQUE, PRIMARY KEY, and EXCLUDE constraints are:

```
[ INCLUDE ( column_name [, ...] ) ]
[ WITH ( storage_parameter [= value] [, ...] ) ]
[ USING INDEX TABLESPACE tablespace_name ]
```

exclude_element in an EXCLUDE constraint is:

```
{ column_name | ( expression ) } [ COLLATE collation ] [ opclass [ ( opclass_parameter
= value [, ...] ) ] ] [ ASC | DESC ] [ NULLS { FIRST | LAST } ]
```

referential_action in a FOREIGN KEY/REFERENCES constraint is:

```
{ NO ACTION | RESTRICT | CASCADE | SET NULL [ ( column_name [, ...] ) ] | SET DEFAULT
[ ( column_name [, ...] ) ] }
```

Description

ALTER TABLE changes the definition of an existing table. There are several subforms described below. Note that the lock level required may differ for each subform. An ACCESS EXCLUSIVE lock is acquired

unless explicitly noted. When multiple subcommands are given, the lock acquired will be the strictest one required by any subcommand.

ADD COLUMN [IF NOT EXISTS]

This form adds a new column to the table, using the same syntax as [CREATE TABLE](#). If `IF NOT EXISTS` is specified and a column already exists with this name, no error is thrown.

DROP COLUMN [IF EXISTS]

This form drops a column from a table. Indexes and table constraints involving the column will be automatically dropped as well. Multivariate statistics referencing the dropped column will also be removed if the removal of the column would cause the statistics to contain data for only a single column. You will need to say `CASCADE` if anything outside the table depends on the column, for example, foreign key references or views. If `IF EXISTS` is specified and the column does not exist, no error is thrown. In this case a notice is issued instead.

SET DATA TYPE

This form changes the type of a column of a table. Indexes and simple table constraints involving the column will be automatically converted to use the new column type by reparsing the originally supplied expression. The optional `COLLATE` clause specifies a collation for the new column; if omitted, the collation is the default for the new column type. The optional `USING` clause specifies how to compute the new column value from the old; if omitted, the default conversion is the same as an assignment cast from old data type to new. A `USING` clause must be provided if there is no implicit or assignment cast from old to new type.

When this form is used, the column's statistics are removed, so running [ANALYZE](#) on the table afterwards is recommended.

SET/DROP DEFAULT

These forms set or remove the default value for a column (where removal is equivalent to setting the default value to `NULL`). The new default value will only apply in subsequent `INSERT` or `UPDATE` commands; it does not cause rows already in the table to change.

SET/DROP NOT NULL

These forms change whether a column is marked to allow null values or to reject null values.

`SET NOT NULL` may only be applied to a column provided none of the records in the table contain a `NULL` value for the column. Ordinarily this is checked during the `ALTER TABLE` by scanning the entire table; however, if a valid `CHECK` constraint is found which proves no `NULL` can exist, then the table scan is skipped.

If this table is a partition, one cannot perform `DROP NOT NULL` on a column if it is marked `NOT NULL` in the parent table. To drop the `NOT NULL` constraint from all the partitions, perform `DROP NOT NULL` on the parent table. Even if there is no `NOT NULL` constraint on the parent, such a constraint can still be added to individual partitions, if desired; that is, the children can disallow nulls even if the parent allows them, but not the other way around.

SET EXPRESSION AS

This form replaces the expression of a generated column. Existing data in the column is rewritten and all the future changes will apply the new generation expression.

DROP EXPRESSION [IF EXISTS]

This form turns a stored generated column into a normal base column. Existing data in the columns is retained, but future changes will no longer apply the generation expression.

If `DROP EXPRESSION IF EXISTS` is specified and the column is not a stored generated column, no error is thrown. In this case a notice is issued instead.

```
ADD GENERATED { ALWAYS | BY DEFAULT } AS IDENTITY
SET GENERATED { ALWAYS | BY DEFAULT }
DROP IDENTITY [ IF EXISTS ]
```

These forms change whether a column is an identity column or change the generation attribute of an existing identity column. See [CREATE TABLE](#) for details. Like `SET DEFAULT`, these forms only affect the behavior of subsequent `INSERT` and `UPDATE` commands; they do not cause rows already in the table to change.

If `DROP IDENTITY IF EXISTS` is specified and the column is not an identity column, no error is thrown. In this case a notice is issued instead.

```
SET sequence_option
RESTART
```

These forms alter the sequence that underlies an existing identity column. *sequence_option* is an option supported by [ALTER SEQUENCE](#) such as `INCREMENT BY`.

```
SET STATISTICS
```

This form sets the per-column statistics-gathering target for subsequent [ANALYZE](#) operations. The target can be set in the range 0 to 10000. Set it to `DEFAULT` to revert to using the system default statistics target ([default_statistics_target](#)). (Setting to a value of -1 is an obsolete way spelling to get the same outcome.) For more information on the use of statistics by the Postgres Pro query planner, refer to [Section 14.2](#).

`SET STATISTICS` acquires a `SHARE UPDATE EXCLUSIVE` lock.

```
SET ( attribute_option = value [, ... ] )
RESET ( attribute_option [, ... ] )
```

This form sets or resets per-attribute options. Currently, the only defined per-attribute options are `n_distinct` and `n_distinct_inherited`, which override the number-of-distinct-values estimates made by subsequent [ANALYZE](#) operations. `n_distinct` affects the statistics for the table itself, while `n_distinct_inherited` affects the statistics gathered for the table plus its inheritance children. When set to a positive value, `ANALYZE` will assume that the column contains exactly the specified number of distinct nonnull values. When set to a negative value, which must be greater than or equal to -1, `ANALYZE` will assume that the number of distinct nonnull values in the column is linear in the size of the table; the exact count is to be computed by multiplying the estimated table size by the absolute value of the given number. For example, a value of -1 implies that all values in the column are distinct, while a value of -0.5 implies that each value appears twice on the average. This can be useful when the size of the table changes over time, since the multiplication by the number of rows in the table is not performed until query planning time. Specify a value of 0 to revert to estimating the number of distinct values normally. For more information on the use of statistics by the Postgres Pro query planner, refer to [Section 14.2](#).

Changing per-attribute options acquires a `SHARE UPDATE EXCLUSIVE` lock.

```
SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN | DEFAULT }
```

This form sets the storage mode for a column. This controls whether this column is held inline or in a secondary TOAST table, and whether the data should be compressed or not. `PLAIN` must be used for fixed-length values such as `integer` and is inline, uncompressed. `MAIN` is for inline, compressible data. `EXTERNAL` is for external, uncompressed data, and `EXTENDED` is for external, compressed data. Writing `DEFAULT` sets the storage mode to the default mode for the column's data type. `EXTENDED` is the default for most data types that support non-`PLAIN` storage. Use of `EXTERNAL` will make substring operations on very large `text` and `bytea` values run faster, at the penalty of increased storage space. Note that `ALTER TABLE ... SET STORAGE` doesn't itself change anything in the table; it just sets the strategy to be pursued during future table updates. See [Section 66.2](#) for more information.

```
SET COMPRESSION compression_method
```

This form sets the compression method for a column, determining how values inserted in future will be compressed (if the storage mode permits compression at all). This does not cause the table to be rewritten, so existing data may still be compressed with other compression methods. If the table is restored with `pg_restore`, then all values are rewritten with the configured compression method. However, when data is inserted from another relation (for example, by `INSERT ... SELECT`), values from the source table are not necessarily detoasted, so any previously compressed data may retain its existing compression method, rather than being recompressed with the compression method of the target column. The supported compression methods are `pglz` and `lz4`. (`lz4` is available only if `--with-lz4` was used when building Postgres Pro.) In addition, *compression_method* can be `default`, which selects the default behavior of consulting the `default_toast_compression` setting at the time of data insertion to determine the method to use.

```
ADD table_constraint [ NOT VALID ]
```

This form adds a new constraint to a table using the same constraint syntax as `CREATE TABLE`, plus the option `NOT VALID`, which is currently only allowed for foreign key and CHECK constraints.

Normally, this form will cause a scan of the table to verify that all existing rows in the table satisfy the new constraint. But if the `NOT VALID` option is used, this potentially-lengthy scan is skipped. The constraint will still be enforced against subsequent inserts or updates (that is, they'll fail unless there is a matching row in the referenced table, in the case of foreign keys, or they'll fail unless the new row matches the specified check condition). But the database will not assume that the constraint holds for all rows in the table, until it is validated by using the `VALIDATE CONSTRAINT` option. See [Notes](#) below for more information about using the `NOT VALID` option.

Although most forms of `ADD table_constraint` require an `ACCESS EXCLUSIVE` lock, `ADD FOREIGN KEY` requires only a `SHARE ROW EXCLUSIVE` lock. Note that `ADD FOREIGN KEY` also acquires a `SHARE ROW EXCLUSIVE` lock on the referenced table, in addition to the lock on the table on which the constraint is declared.

Additional restrictions apply when unique or primary key constraints are added to partitioned tables; see `CREATE TABLE`. Also, foreign key constraints on partitioned tables may not be declared `NOT VALID` at present.

```
ADD table_constraint_using_index
```

This form adds a new `PRIMARY KEY` or `UNIQUE` constraint to a table based on an existing unique index. All the columns of the index will be included in the constraint.

The index cannot have expression columns nor be a partial index. Also, it must be a b-tree index with default sort ordering. These restrictions ensure that the index is equivalent to one that would be built by a regular `ADD PRIMARY KEY` or `ADD UNIQUE` command.

If `PRIMARY KEY` is specified, and the index's columns are not already marked `NOT NULL`, then this command will attempt to do `ALTER COLUMN SET NOT NULL` against each such column. That requires a full table scan to verify the column(s) contain no nulls. In all other cases, this is a fast operation.

If a constraint name is provided then the index will be renamed to match the constraint name. Otherwise the constraint will be named the same as the index.

After this command is executed, the index is “owned” by the constraint, in the same way as if the index had been built by a regular `ADD PRIMARY KEY` or `ADD UNIQUE` command. In particular, dropping the constraint will make the index disappear too.

This form is not currently supported on partitioned tables.

Note

Adding a constraint using an existing index can be helpful in situations where a new constraint needs to be added without blocking table updates for a long time. To do that, create the index

using `CREATE UNIQUE INDEX CONCURRENTLY`, and then convert it to a constraint using this syntax. See the example below.

ALTER CONSTRAINT

This form alters the attributes of a constraint that was previously created. Currently only foreign key constraints may be altered.

VALIDATE CONSTRAINT

This form validates a foreign key or check constraint that was previously created as `NOT VALID`, by scanning the table to ensure there are no rows for which the constraint is not satisfied. Nothing happens if the constraint is already marked valid. (See [Notes](#) below for an explanation of the usefulness of this command.)

This command acquires a `SHARE UPDATE EXCLUSIVE` lock.

DROP CONSTRAINT [IF EXISTS]

This form drops the specified constraint on a table, along with any index underlying the constraint. If `IF EXISTS` is specified and the constraint does not exist, no error is thrown. In this case a notice is issued instead.

DISABLE/ENABLE [REPLICA | ALWAYS] TRIGGER

These forms configure the firing of trigger(s) belonging to the table. A disabled trigger is still known to the system, but is not executed when its triggering event occurs. (For a deferred trigger, the enable status is checked when the event occurs, not when the trigger function is actually executed.) One can disable or enable a single trigger specified by name, or all triggers on the table, or only user triggers (this option excludes internally generated constraint triggers, such as those that are used to implement foreign key constraints or deferrable uniqueness and exclusion constraints). Disabling or enabling internally generated constraint triggers requires superuser privileges; it should be done with caution since of course the integrity of the constraint cannot be guaranteed if the triggers are not executed.

The trigger firing mechanism is also affected by the configuration variable [session_replication_role](#). Simply enabled triggers (the default) will fire when the replication role is “origin” (the default) or “local”. Triggers configured as `ENABLE REPLICA` will only fire if the session is in “replica” mode, and triggers configured as `ENABLE ALWAYS` will fire regardless of the current replication role.

The effect of this mechanism is that in the default configuration, triggers do not fire on replicas. This is useful because if a trigger is used on the origin to propagate data between tables, then the replication system will also replicate the propagated data; so the trigger should not fire a second time on the replica, because that would lead to duplication. However, if a trigger is used for another purpose such as creating external alerts, then it might be appropriate to set it to `ENABLE ALWAYS` so that it is also fired on replicas.

When this command is applied to a partitioned table, the states of corresponding clone triggers in the partitions are updated too, unless `ONLY` is specified.

This command acquires a `SHARE ROW EXCLUSIVE` lock.

DISABLE/ENABLE [REPLICA | ALWAYS] RULE

These forms configure the firing of rewrite rules belonging to the table. A disabled rule is still known to the system, but is not applied during query rewriting. The semantics are as for disabled/enabled triggers. This configuration is ignored for `ON SELECT` rules, which are always applied in order to keep views working even if the current session is in a non-default replication role.

The rule firing mechanism is also affected by the configuration variable [session_replication_role](#), analogous to triggers as described above.

DISABLE/ENABLE ROW LEVEL SECURITY

These forms control the application of row security policies belonging to the table. If enabled and no policies exist for the table, then a default-deny policy is applied. Note that policies can exist for a table even if row-level security is disabled. In this case, the policies will *not* be applied and the policies will be ignored. See also [CREATE POLICY](#).

NO FORCE/FORCE ROW LEVEL SECURITY

These forms control the application of row security policies belonging to the table when the user is the table owner. If enabled, row-level security policies will be applied when the user is the table owner. If disabled (the default) then row-level security will not be applied when the user is the table owner. See also [CREATE POLICY](#).

CLUSTER ON

This form selects the default index for future [CLUSTER](#) operations. It does not actually re-cluster the table.

Changing cluster options acquires a `SHARE UPDATE EXCLUSIVE` lock.

SET WITHOUT CLUSTER

This form removes the most recently used [CLUSTER](#) index specification from the table. This affects future cluster operations that don't specify an index.

Changing cluster options acquires a `SHARE UPDATE EXCLUSIVE` lock.

SET WITHOUT OIDS

Backward-compatible syntax for removing the `oid` system column. As `oid` system columns cannot be added anymore, this never has an effect.

SET ACCESS METHOD

This form changes the access method of the table by rewriting it using the indicated access method; specifying `DEFAULT` selects the access method set as the [default_table_access_method](#) configuration parameter. See [Chapter 62](#) for more information.

When applied to a partitioned table, there is no data to rewrite, but partitions created afterwards will default to the given access method unless overridden by a `USING` clause. Specifying `DEFAULT` removes a previous value, causing future partitions to default to `default_table_access_method`.

SET TABLESPACE

This form changes the table's tablespace to the specified tablespace and moves the data file(s) associated with the table to the new tablespace. Indexes on the table, if any, are not moved; but they can be moved separately with additional `SET TABLESPACE` commands. When applied to a partitioned table, nothing is moved, but any partitions created afterwards with `CREATE TABLE PARTITION OF` will use that tablespace, unless overridden by a `TABLESPACE` clause.

All tables in the current database in a tablespace can be moved by using the `ALL IN TABLESPACE` form, which will lock all tables to be moved first and then move each one. This form also supports `OWNED BY`, which will only move tables owned by the roles specified. If the `NOWAIT` option is specified then the command will fail if it is unable to acquire all of the locks required immediately. Note that system catalogs are not moved by this command; use `ALTER DATABASE` or explicit `ALTER TABLE` invocations instead if desired. The `information_schema` relations are not considered part of the system catalogs and will be moved. See also [CREATE TABLESPACE](#).

SET { LOGGED | UNLOGGED }

This form changes the table from unlogged to logged or vice-versa (see [UNLOGGED](#)). It cannot be applied to a temporary table.

This also changes the persistence of any sequences linked to the table (for identity or serial columns). However, it is also possible to change the persistence of such sequences separately.

SET CONSTANT

This form changes the table into read-only mode. No data can be modified or added to constant tables, and they are not processed by [autovacuum](#). Constant tables cannot be changed back to read-write mode.

SET (*storage_parameter* [= *value*] [, ...])

This form changes one or more storage parameters for the table. See [Storage Parameters](#) in the [CREATE TABLE](#) documentation for details on the available parameters. Note that the table contents will not be modified immediately by this command; depending on the parameter you might need to rewrite the table to get the desired effects. That can be done with [VACUUM FULL](#), [CLUSTER](#) or one of the forms of [ALTER TABLE](#) that forces a table rewrite. For planner related parameters, changes will take effect from the next time the table is locked so currently executing queries will not be affected.

SHARE UPDATE EXCLUSIVE lock will be taken for fillfactor, toast and autovacuum storage parameters, as well as the planner parameter `parallel_workers`.

RESET (*storage_parameter* [, ...])

This form resets one or more storage parameters to their defaults. As with `SET`, a table rewrite might be needed to update the table entirely.

INHERIT *parent_table*

This form adds the target table as a new child of the specified parent table. Subsequently, queries against the parent will include records of the target table. To be added as a child, the target table must already contain all the same columns as the parent (it could have additional columns, too). The columns must have matching data types, and if they have `NOT NULL` constraints in the parent then they must also have `NOT NULL` constraints in the child.

There must also be matching child-table constraints for all `CHECK` constraints of the parent, except those marked non-inheritable (that is, created with `ALTER TABLE ... ADD CONSTRAINT ... NO INHERIT`) in the parent, which are ignored; all child-table constraints matched must not be marked non-inheritable. Currently `UNIQUE`, `PRIMARY KEY`, and `FOREIGN KEY` constraints are not considered, but this might change in the future.

NO INHERIT *parent_table*

This form removes the target table from the list of children of the specified parent table. Queries against the parent table will no longer include records drawn from the target table.

OF *type_name*

This form links the table to a composite type as though `CREATE TABLE OF` had formed it. The table's list of column names and types must precisely match that of the composite type. The table must not inherit from any other table. These restrictions ensure that `CREATE TABLE OF` would permit an equivalent table definition.

NOT OF

This form dissociates a typed table from its type.

OWNER TO

This form changes the owner of the table, sequence, view, materialized view, or foreign table to the specified user.

REPLICA IDENTITY

This form changes the information which is written to the write-ahead log to identify rows which are updated or deleted. In most cases, the old value of each column is only logged if it differs from the

new value; however, if the old value is stored externally, it is always logged regardless of whether it changed. This option has no effect except when logical replication is in use.

DEFAULT

Records the old values of the columns of the primary key, if any. This is the default for non-system tables.

USING INDEX *index_name*

Records the old values of the columns covered by the named index, that must be unique, not partial, not deferrable, and include only columns marked `NOT NULL`. If this index is dropped, the behavior is the same as `NOTHING`.

FULL

Records the old values of all columns in the row.

NOTHING

Records no information about the old row. This is the default for system tables.

RENAME

The `RENAME` forms change the name of a table (or an index, sequence, view, materialized view, or foreign table), the name of an individual column in a table, or the name of a constraint of the table. When renaming a constraint that has an underlying index, the index is renamed as well. There is no effect on the stored data.

SET SCHEMA

This form moves the table into another schema. Associated indexes, constraints, and sequences owned by table columns are moved as well.

ATTACH PARTITION *partition_name* { FOR VALUES *partition_bound_spec* | DEFAULT }

This form attaches an existing table (which might itself be partitioned) as a partition of the target table. The table can be attached as a partition for specific values using `FOR VALUES` or as a default partition by using `DEFAULT`. For each index in the target table, a corresponding one will be created in the attached table; or, if an equivalent index already exists, it will be attached to the target table's index, as if `ALTER INDEX ATTACH PARTITION` had been executed. Note that if the existing table is a foreign table, it is currently not allowed to attach the table as a partition of the target table if there are `UNIQUE` indexes on the target table. For each user-defined row-level trigger that exists in the target table, a corresponding one is created in the attached table.

A partition using `FOR VALUES` uses same syntax for *partition_bound_spec* as `CREATE TABLE`. The partition bound specification must correspond to the partitioning strategy and partition key of the target table. The table to be attached must have all the same columns as the target table and no more; moreover, the column types must also match. Also, it must have all the `NOT NULL` and `CHECK` constraints of the target table, not marked `NO INHERIT`. Currently `FOREIGN KEY` constraints are not considered. `UNIQUE` and `PRIMARY KEY` constraints from the parent table will be created in the partition, if they don't already exist.

If the new partition is a regular table, a full table scan is performed to check that existing rows in the table do not violate the partition constraint. It is possible to avoid this scan by adding a valid `CHECK` constraint to the table that allows only rows satisfying the desired partition constraint before running this command. The `CHECK` constraint will be used to determine that the table need not be scanned to validate the partition constraint. This does not work, however, if any of the partition keys is an expression and the partition does not accept `NULL` values. If attaching a list partition that will not accept `NULL` values, also add a `NOT NULL` constraint to the partition key column, unless it's an expression.

If the new partition is a foreign table, nothing is done to verify that all the rows in the foreign table obey the partition constraint.

When a table has a default partition, defining a new partition changes the partition constraint for the default partition. The default partition can't contain any rows that would need to be moved to the new partition, and will be scanned to verify that none are present. This scan, like the scan of the new partition, can be avoided if an appropriate `CHECK` constraint is present. Also like the scan of the new partition, it is always skipped when the default partition is a foreign table.

Attaching a partition acquires a `SHARE UPDATE EXCLUSIVE` lock on the parent table, in addition to the `ACCESS EXCLUSIVE` locks on the table being attached and on the default partition (if any).

Further locks must also be held on all sub-partitions if the table being attached is itself a partitioned table. Likewise if the default partition is itself a partitioned table. The locking of the sub-partitions can be avoided by adding a `CHECK` constraint as described in [Section 5.12.2.2](#).

```
DETACH PARTITION partition_name [ CONCURRENTLY | FINALIZE ]
```

This form detaches the specified partition of the target table. The detached partition continues to exist as a standalone table, but no longer has any ties to the table from which it was detached. Any indexes that were attached to the target table's indexes are detached. Any triggers that were created as clones of those in the target table are removed. `SHARE` lock is obtained on any tables that reference this partitioned table in foreign key constraints.

If `CONCURRENTLY` is specified, it runs using a reduced lock level to avoid blocking other sessions that might be accessing the partitioned table. In this mode, two transactions are used internally. During the first transaction, a `SHARE UPDATE EXCLUSIVE` lock is taken on both parent table and partition, and the partition is marked as undergoing detach; at that point, the transaction is committed and all other transactions using the partitioned table are waited for. Once all those transactions have completed, the second transaction acquires `SHARE UPDATE EXCLUSIVE` on the partitioned table and `ACCESS EXCLUSIVE` on the partition, and the detach process completes. A `CHECK` constraint that duplicates the partition constraint is added to the partition. `CONCURRENTLY` cannot be run in a transaction block and is not allowed if the partitioned table contains a default partition.

If `FINALIZE` is specified, a previous `DETACH CONCURRENTLY` invocation that was canceled or interrupted is completed. At most one partition in a partitioned table can be pending detach at a time.

```
SPLIT PARTITION partition_name INTO (PARTITION partition_name1 { FOR VALUES partition_bound_spec | DEFAULT }, PARTITION partition_name2 { FOR VALUES partition_bound_spec | DEFAULT } [, ...])
```

This form splits a single partition of the target table. Hash-partitioning is not supported. Bounds of new partitions should not overlap with new and existing partitions (except *partition_name*). If the split partition is a `DEFAULT` partition, one of the new partitions must be `DEFAULT`. In case one of the new partitions or one of existing partitions is `DEFAULT`, new partitions *partition_name1*, *partition_name2*, ... can have spaces between partitions bounds. If the partitioned table does not have a `DEFAULT` partition, the `DEFAULT` partition can be defined as one of the new partitions.

In case new partitions do not contain a `DEFAULT` partition and the partitioned table does not have a `DEFAULT` partition, the following must be true: sum bounds of new partitions *partition_name1*, *partition_name2*, ... should be equal to bound of split partition *partition_name*. One of the new partitions *partition_name1*, *partition_name2*, ... can have the same name as split partition *partition_name* (this is suitable in case of splitting a `DEFAULT` partition: we split it, but after splitting we have a partition with the same name). Only simple, non-partitioned partition can be split.

The new partitions will be created the same as tables created with the SQL command `CREATE TABLE partition_nameN (LIKE name INCLUDING ALL EXCLUDING INDEXES EXCLUDING IDENTITY EXCLUDING STATISTICS)`. The indexes and identity are created later, after moving the data into the new partitions. Extended statistics aren't copied from the parent table, for consistency with `CREATE TABLE PARTITION OF`. New partitions will have the same table access method as the parent. If the parent table is persistent then new partitions are created persistent. If the parent table is temporary then new partitions are also created temporary. New partitions will also be created in the same tablespace as the parent.

Note

This command acquires an `ACCESS EXCLUSIVE` lock. This is a significant limitation, which limits the usage of this command with large partitioned tables under a high load.

```
MERGE PARTITIONS (partition_name1, partition_name2 [, ...]) INTO partition_name
```

This form merges several partitions into the one partition of the target table. Hash-partitioning is not supported. If `DEFAULT` partition is not in the list of partitions *partition_name1*, *partition_name2* [, ...]:

- For range-partitioned tables it is necessary that the ranges of the partitions *partition_name1*, *partition_name2* [, ...] can be merged into one range without spaces and overlaps (otherwise an error will be generated). The combined range will be the range for the partition *partition_name*.

- For list-partitioned tables the value lists of all partitions *partition_name1*, *partition_name2* [, ...] are combined and form the list of values of partition *partition_name*.

If `DEFAULT` partition is in the list of partitions *partition_name1*, *partition_name2* [, ...]:

- The partition *partition_name* will be the `DEFAULT` partition.
- For range- and list-partitioned tables the ranges and lists of values of the merged partitions can be any.

The new partition *partition_name* can have the same name as one of the merged partitions. Only simple, non-partitioned partitions can be merged.

The new partition will be created the same as a table created with the SQL command `CREATE TABLE partition_name (LIKE name INCLUDING ALL EXCLUDING INDEXES EXCLUDING IDENTITY EXCLUDING STATISTICS)`. The indexes and identity are created later, after moving the data into the new partition. Extended statistics aren't copied from the parent table, for consistency with `CREATE TABLE PARTITION OF`. The new partition will have the same table access method as the parent. If the parent table is persistent then the new partition is created persistent. If the parent table is temporary then the new partition is also created temporary. The new partition will also be created in the same tablespace as the parent.

Note

This command acquires an `ACCESS EXCLUSIVE` lock. This is a significant limitation, which limits the usage of this command with large partitioned tables under a high load.

All the forms of `ALTER TABLE` that act on a single table, except `RENAME`, `SET SCHEMA`, `ATTACH PARTITION`, `DETACH PARTITION`, `SPLIT PARTITION`, and `MERGE PARTITIONS`, can be combined into a list of multiple alterations to be applied together. For example, it is possible to add several columns and/or alter the type of several columns in a single command. This is particularly useful with large tables, since only one pass over the table need be made.

You must own the table to use `ALTER TABLE`. To change the schema or tablespace of a table, you must also have `CREATE` privilege on the new schema or tablespace. To add the table as a new child of a parent table, you must own the parent table as well. Also, to attach a table as a new partition of the table, you must own the table being attached. To alter the owner, you must be able to `SET ROLE` to the new owning role, and that role must have `CREATE` privilege on the table's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the table. However, a superuser can alter ownership of any table anyway.) To add a column or alter a column type or use the `OF` clause, you must also have `USAGE` privilege on the data type.

Parameters

IF EXISTS

Do not throw an error if the table does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing table to alter. If `ONLY` is specified before the table name, only that table is altered. If `ONLY` is not specified, the table and all its descendant tables (if any) are altered. Optionally, `*` can be specified after the table name to explicitly indicate that descendant tables are included.

column_name

Name of a new or existing column.

new_column_name

New name for an existing column.

new_name

New name for the table.

data_type

Data type of the new column, or new data type for an existing column.

table_constraint

New table constraint for the table.

constraint_name

Name of a new or existing constraint.

CASCADE

Automatically drop objects that depend on the dropped column or constraint (for example, views referencing the column), and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.

trigger_name

Name of a single trigger to disable or enable.

ALL

Disable or enable all triggers belonging to the table. (This requires superuser privilege if any of the triggers are internally generated constraint triggers, such as those that are used to implement foreign key constraints or deferrable uniqueness and exclusion constraints.)

USER

Disable or enable all triggers belonging to the table except for internally generated constraint triggers, such as those that are used to implement foreign key constraints or deferrable uniqueness and exclusion constraints.

index_name

The name of an existing index.

storage_parameter

The name of a table storage parameter.

value

The new value for a table storage parameter. This might be a number or a word depending on the parameter.

parent_table

A parent table to associate or de-associate with this table.

new_owner

The user name of the new owner of the table.

new_access_method

The name of the access method to which the table will be converted.

new_tablespace

The name of the tablespace to which the table will be moved.

new_schema

The name of the schema to which the table will be moved.

partition_name

The name of the table to attach as a new partition or to detach from this table, or the name of split partition, or the name of the new merged partition.

partition_bound_spec

The partition bound specification for a new partition. Refer to [CREATE TABLE](#) for more details on the syntax of the same.

Storage Parameters

Postgres Pro Shardman extends *storage parameters* of tables with its own *storage metaparameters*. They are not stored in the corresponding catalog entry, but are used to tell the Postgres Pro Shardman extension to perform some additional actions.

global

This parameter can be specified only for global tables. If set to 0, the global table will be converted to a regular one on the replication group where the command is executed. The global table will not exist on other nodes after completion of this statement. However, setting storage options is allowed for global tables.

Notes

The key word `COLUMN` is noise and can be omitted.

When a column is added with `ADD COLUMN` and a non-volatile `DEFAULT` is specified, the default is evaluated at the time of the statement and the result stored in the table's metadata. That value will be used for the column for all existing rows. If no `DEFAULT` is specified, `NULL` is used. In neither case is a rewrite of the table required.

Adding a column with a volatile `DEFAULT` or changing the type of an existing column will require the entire table and its indexes to be rewritten. As an exception, when changing the type of an existing column, if the `USING` clause does not change the column contents and the old type is either binary coercible to the new type or an unconstrained domain over the new type, a table rewrite is not needed. However, indexes

must always be rebuilt unless the system can verify that the new index would be logically equivalent to the existing one. For example, if the collation for a column has been changed, an index rebuild is always required because the new sort order might be different. However, in the absence of a collation change, a column can be changed from `text` to `varchar` (or vice versa) without rebuilding the indexes because these data types sort identically. Table and/or index rebuilds may take a significant amount of time for a large table; and will temporarily require as much as double the disk space.

Adding a `CHECK` or `NOT NULL` constraint requires scanning the table to verify that existing rows meet the constraint, but does not require a table rewrite.

Similarly, when attaching a new partition it may be scanned to verify that existing rows meet the partition constraint.

The main reason for providing the option to specify multiple changes in a single `ALTER TABLE` is that multiple table scans or rewrites can thereby be combined into a single pass over the table.

Scanning a large table to verify a new foreign key or check constraint can take a long time, and other updates to the table are locked out until the `ALTER TABLE ADD CONSTRAINT` command is committed. The main purpose of the `NOT VALID` constraint option is to reduce the impact of adding a constraint on concurrent updates. With `NOT VALID`, the `ADD CONSTRAINT` command does not scan the table and can be committed immediately. After that, a `VALIDATE CONSTRAINT` command can be issued to verify that existing rows satisfy the constraint. The validation step does not need to lock out concurrent updates, since it knows that other transactions will be enforcing the constraint for rows that they insert or update; only pre-existing rows need to be checked. Hence, validation acquires only a `SHARE UPDATE EXCLUSIVE` lock on the table being altered. (If the constraint is a foreign key then a `ROW SHARE` lock is also required on the table referenced by the constraint.) In addition to improving concurrency, it can be useful to use `NOT VALID` and `VALIDATE CONSTRAINT` in cases where the table is known to contain pre-existing violations. Once the constraint is in place, no new violations can be inserted, and the existing problems can be corrected at leisure until `VALIDATE CONSTRAINT` finally succeeds.

The `DROP COLUMN` form does not physically remove the column, but simply makes it invisible to SQL operations. Subsequent insert and update operations in the table will store a null value for the column. Thus, dropping a column is quick but it will not immediately reduce the on-disk size of your table, as the space occupied by the dropped column is not reclaimed. The space will be reclaimed over time as existing rows are updated.

To force immediate reclamation of space occupied by a dropped column, you can execute one of the forms of `ALTER TABLE` that performs a rewrite of the whole table. This results in reconstructing each row with the dropped column replaced by a null value.

The rewriting forms of `ALTER TABLE` are not MVCC-safe. After a table rewrite, the table will appear empty to concurrent transactions, if they are using a snapshot taken before the rewrite occurred. See [Section 13.6](#) for more details.

The `USING` option of `SET DATA TYPE` can actually specify any expression involving the old values of the row; that is, it can refer to other columns as well as the one being converted. This allows very general conversions to be done with the `SET DATA TYPE` syntax. Because of this flexibility, the `USING` expression is not applied to the column's default value (if any); the result might not be a constant expression as required for a default. This means that when there is no implicit or assignment cast from old to new type, `SET DATA TYPE` might fail to convert the default even though a `USING` clause is supplied. In such cases, drop the default with `DROP DEFAULT`, perform the `ALTER TYPE`, and then use `SET DEFAULT` to add a suitable new default. Similar considerations apply to indexes and constraints involving the column.

If a table has any descendant tables, it is not permitted to add, rename, or change the type of a column in the parent table without doing the same to the descendants. This ensures that the descendants always have columns matching the parent. Similarly, a `CHECK` constraint cannot be renamed in the parent without also renaming it in all descendants, so that `CHECK` constraints also match between the parent and its descendants. (That restriction does not apply to index-based constraints, however.) Also, because selecting from the parent also selects from its descendants, a constraint on the parent cannot be marked

valid unless it is also marked valid for those descendants. In all of these cases, `ALTER TABLE ONLY` will be rejected.

A recursive `DROP COLUMN` operation will remove a descendant table's column only if the descendant does not inherit that column from any other parents and never had an independent definition of the column. A nonrecursive `DROP COLUMN` (i.e., `ALTER TABLE ONLY ... DROP COLUMN`) never removes any descendant columns, but instead marks them as independently defined rather than inherited. A nonrecursive `DROP COLUMN` command will fail for a partitioned table, because all partitions of a table must have the same columns as the partitioning root.

The actions for identity columns (`ADD GENERATED`, `SET` etc., `DROP IDENTITY`), as well as the actions `CLUSTER`, `OWNER`, and `TABLESPACE` never recurse to descendant tables; that is, they always act as though `ONLY` were specified. Actions affecting trigger states recurse to partitions of partitioned tables (unless `ONLY` is specified), but never to traditional-inheritance descendants. Adding a constraint recurses only for `CHECK` constraints that are not marked `NO INHERIT`.

Changing any part of a system catalog table is not permitted.

Refer to [CREATE TABLE](#) for a further description of valid parameters. [Chapter 5](#) has further information on inheritance.

Examples

To add a column of type `varchar` to a table:

```
ALTER TABLE distributors ADD COLUMN address varchar(30);
```

That will cause all existing rows in the table to be filled with null values for the new column.

To add a column with a non-null default:

```
ALTER TABLE measurements
  ADD COLUMN mtime timestamp with time zone DEFAULT now();
```

Existing rows will be filled with the current time as the value of the new column, and then new rows will receive the time of their insertion.

To add a column and fill it with a value different from the default to be used later:

```
ALTER TABLE transactions
  ADD COLUMN status varchar(30) DEFAULT 'old',
  ALTER COLUMN status SET default 'current';
```

Existing rows will be filled with `old`, but then the default for subsequent commands will be `current`. The effects are the same as if the two sub-commands had been issued in separate `ALTER TABLE` commands.

To drop a column from a table:

```
ALTER TABLE distributors DROP COLUMN address RESTRICT;
```

To change the types of two existing columns in one operation:

```
ALTER TABLE distributors
  ALTER COLUMN address TYPE varchar(80),
  ALTER COLUMN name TYPE varchar(100);
```

To change an integer column containing Unix timestamps to `timestamp with time zone` via a `USING` clause:

```
ALTER TABLE foo
  ALTER COLUMN foo_timestamp SET DATA TYPE timestamp with time zone
  USING
    timestamp with time zone 'epoch' + foo_timestamp * interval '1 second';
```

The same, when the column has a default expression that won't automatically cast to the new data type:

```
ALTER TABLE foo
  ALTER COLUMN foo_timestamp DROP DEFAULT,
  ALTER COLUMN foo_timestamp TYPE timestamp with time zone
  USING
    timestamp with time zone 'epoch' + foo_timestamp * interval '1 second',
  ALTER COLUMN foo_timestamp SET DEFAULT now();
```

To rename an existing column:

```
ALTER TABLE distributors RENAME COLUMN address TO city;
```

To rename an existing table:

```
ALTER TABLE distributors RENAME TO suppliers;
```

To rename an existing constraint:

```
ALTER TABLE distributors RENAME CONSTRAINT zipchk TO zip_check;
```

To add a not-null constraint to a column:

```
ALTER TABLE distributors ALTER COLUMN street SET NOT NULL;
```

To remove a not-null constraint from a column:

```
ALTER TABLE distributors ALTER COLUMN street DROP NOT NULL;
```

To add a check constraint to a table and all its children:

```
ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK (char_length(zipcode) = 5);
```

To add a check constraint only to a table and not to its children:

```
ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK (char_length(zipcode) = 5) NO
  INHERIT;
```

(The check constraint will not be inherited by future children, either.)

To remove a check constraint from a table and all its children:

```
ALTER TABLE distributors DROP CONSTRAINT zipchk;
```

To remove a check constraint from one table only:

```
ALTER TABLE ONLY distributors DROP CONSTRAINT zipchk;
```

(The check constraint remains in place for any child tables.)

To add a foreign key constraint to a table:

```
ALTER TABLE distributors ADD CONSTRAINT distfk FOREIGN KEY (address) REFERENCES
  addresses (address);
```

To add a foreign key constraint to a table with the least impact on other work:

```
ALTER TABLE distributors ADD CONSTRAINT distfk FOREIGN KEY (address) REFERENCES
  addresses (address) NOT VALID;
ALTER TABLE distributors VALIDATE CONSTRAINT distfk;
```

To add a (multicolumn) unique constraint to a table:

```
ALTER TABLE distributors ADD CONSTRAINT dist_id_zipcode_key UNIQUE (dist_id, zipcode);
```

To add an automatically named primary key constraint to a table, noting that a table can only ever have one primary key:

```
ALTER TABLE distributors ADD PRIMARY KEY (dist_id);
```

To move a table to a different tablespace:

```
ALTER TABLE distributors SET TABLESPACE fasttablespace;
```

To move a table to a different schema:

```
ALTER TABLE myschema.distributors SET SCHEMA yourschema;
```

To recreate a primary key constraint, without blocking updates while the index is rebuilt:

```
CREATE UNIQUE INDEX CONCURRENTLY dist_id_temp_idx ON distributors (dist_id);
ALTER TABLE distributors DROP CONSTRAINT distributors_pkey,
    ADD CONSTRAINT distributors_pkey PRIMARY KEY USING INDEX dist_id_temp_idx;
```

To attach a partition to a range-partitioned table:

```
ALTER TABLE measurement
    ATTACH PARTITION measurement_y2016m07 FOR VALUES FROM ('2016-07-01') TO
    ('2016-08-01');
```

To attach a partition to a list-partitioned table:

```
ALTER TABLE cities
    ATTACH PARTITION cities_ab FOR VALUES IN ('a', 'b');
```

To attach a partition to a hash-partitioned table:

```
ALTER TABLE orders
    ATTACH PARTITION orders_p4 FOR VALUES WITH (MODULUS 4, REMAINDER 3);
```

To attach a default partition to a partitioned table:

```
ALTER TABLE cities
    ATTACH PARTITION cities_partdef DEFAULT;
```

To detach a partition from a partitioned table:

```
ALTER TABLE measurement
    DETACH PARTITION measurement_y2015m12;
```

To split a single partition of the range-partitioned table:

```
ALTER TABLE sales_range SPLIT PARTITION sales_feb_mar_apr2023 INTO
    (PARTITION sales_feb2023 FOR VALUES FROM ('2023-02-01') TO ('2023-03-01'),
    PARTITION sales_mar2023 FOR VALUES FROM ('2023-03-01') TO ('2023-04-01'),
    PARTITION sales_apr2023 FOR VALUES FROM ('2023-04-01') TO ('2023-05-01'));
```

To split a single partition of the list-partitioned table:

```
ALTER TABLE sales_list SPLIT PARTITION sales_all INTO
    (PARTITION sales_west FOR VALUES IN ('Lisbon', 'New York', 'Madrid'),
    PARTITION sales_east FOR VALUES IN ('Beijing', 'Delhi', 'Vladivostok'),
    PARTITION sales_central FOR VALUES IN ('Warsaw', 'Berlin', 'Kyiv'));
```

To merge several partitions into one partition of the target table:

```
ALTER TABLE sales_list MERGE PARTITIONS (sales_west, sales_east, sales_central)
    INTO sales_all;
```

To alter a global table, create a global table pgbench_tellers and then convert it to local.

```
CREATE TABLE pgbench_tellers (
    tid        integer PRIMARY KEY,
    bid        integer,
    tbalance   integer,
    filler     character(84)
)
```

```
WITH (global);  
ALTER TABLE pgbench_tellers SET (global=0);
```

Compatibility

The forms `ADD (without USING INDEX)`, `DROP [COLUMN]`, `DROP IDENTITY`, `RESTART`, `SET DEFAULT`, `SET DATA TYPE (without USING)`, `SET GENERATED`, and `SET sequence_option` conform with the SQL standard. The other forms are Postgres Pro extensions of the SQL standard. Also, the ability to specify more than one manipulation in a single `ALTER TABLE` command is an extension.

`ALTER TABLE DROP COLUMN` can be used to drop the only column of a table, leaving a zero-column table. This is an extension of SQL, which disallows zero-column tables.

ALTER TABLE Limitations for Postgres Pro Shardman

- `ALTER TABLE` is prohibited for partitions of sharded tables.
- `ALTER TABLE OWNER` is allowed. For sharded table it also changes the owner of table partitions. Only the global user can be an owner of sharded or global table.
- `ALTER TABLE COLUMN TYPE` is allowed with limitations. You cannot alter type of sharded table column participating in sharding or partitioning key. You cannot alter type of sharded table column with `USING` clause (but for global tables it is allowed). Also, it is a user's duty for now to create and keep new type exactly equal on every cluster node.
- Adding or dropping table-wide unique constraints and checks is allowed. For global tables dropping primary key constraint or dropping columns, participating in primary key, is forbidden.
- Adding foreign keys between sharded tables is possible only when they are colocated and a foreign key references tuples that are stored in the same replication group. A foreign key between sharded tables must begin with the columns used for table partitioning in both tables. A foreign key on a global table can reference only another global table. A foreign key on a sharded table can reference a colocated sharded table or a global table.
- `SET/DROP NOT NULL` is allowed.
- If the parent table is global, the `ON DELETE` can only perform `NO ACTION`, `RESTRICT`, `CASCADE`, and `ON UPDATE` can only perform `NO ACTION`, `RESTRICT`.
- Setting storage options is allowed for global tables.
- Global and sharded tables cannot inherit other tables.
- `ALTER COLUMN SET STATISTICS` is allowed for global and sharded tables.

See Also

[CREATE TABLE](#)

ALTER TABLESPACE

ALTER TABLESPACE — change the definition of a tablespace

Synopsis

```
ALTER TABLESPACE name RENAME TO new_name
ALTER TABLESPACE name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER |
SESSION_USER }
ALTER TABLESPACE name SET ( tablespace_option = value [, ... ] )
ALTER TABLESPACE name RESET ( tablespace_option [, ... ] )
```

Description

ALTER TABLESPACE can be used to change the definition of a tablespace.

You must own the tablespace to change the definition of a tablespace. To alter the owner, you must also be able to SET ROLE to the new owning role. (Note that superusers have these privileges automatically.)

Parameters

name

The name of an existing tablespace.

new_name

The new name of the tablespace. The new name cannot begin with `pg_`, as such names are reserved for system tablespaces.

new_owner

The new owner of the tablespace.

tablespace_option

A tablespace parameter to be set or reset. Currently, the only available parameters are `seq_page_cost`, `random_page_cost`, `effective_io_concurrency` and `maintenance_io_concurrency`. Setting these values for a particular tablespace will override the planner's usual estimate of the cost of reading pages from tables in that tablespace, and the executor's prefetching behavior, as established by the configuration parameters of the same name (see [seq_page_cost](#), [random_page_cost](#), [effective_io_concurrency](#), [maintenance_io_concurrency](#)). This may be useful if one tablespace is located on a disk which is faster or slower than the remainder of the I/O subsystem.

Examples

Rename tablespace `index_space` to `fast_raid`:

```
ALTER TABLESPACE index_space RENAME TO fast_raid;
```

Change the owner of tablespace `index_space`:

```
ALTER TABLESPACE index_space OWNER TO mary;
```

Compatibility

There is no ALTER TABLESPACE statement in the SQL standard.

[CREATE TABLESPACE](#), [DROP TABLESPACE](#)

ALTER TEXT SEARCH CONFIGURATION

ALTER TEXT SEARCH CONFIGURATION — change the definition of a text search configuration

Synopsis

```
ALTER TEXT SEARCH CONFIGURATION name
    ADD MAPPING FOR token_type [, ... ] WITH dictionary_name [, ... ]
ALTER TEXT SEARCH CONFIGURATION name
    ALTER MAPPING FOR token_type [, ... ] WITH dictionary_name [, ... ]
ALTER TEXT SEARCH CONFIGURATION name
    ALTER MAPPING REPLACE old_dictionary WITH new_dictionary
ALTER TEXT SEARCH CONFIGURATION name
    ALTER MAPPING FOR token_type [, ... ] REPLACE old_dictionary WITH new_dictionary
ALTER TEXT SEARCH CONFIGURATION name
    DROP MAPPING [ IF EXISTS ] FOR token_type [, ... ]
ALTER TEXT SEARCH CONFIGURATION name RENAME TO new_name
ALTER TEXT SEARCH CONFIGURATION name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER
    | SESSION_USER }
ALTER TEXT SEARCH CONFIGURATION name SET SCHEMA new_schema
```

Description

ALTER TEXT SEARCH CONFIGURATION changes the definition of a text search configuration. You can modify its mappings from token types to dictionaries, or change the configuration's name or owner.

You must be the owner of the configuration to use ALTER TEXT SEARCH CONFIGURATION.

Parameters

name

The name (optionally schema-qualified) of an existing text search configuration.

token_type

The name of a token type that is emitted by the configuration's parser.

dictionary_name

The name of a text search dictionary to be consulted for the specified token type(s). If multiple dictionaries are listed, they are consulted in the specified order.

old_dictionary

The name of a text search dictionary to be replaced in the mapping.

new_dictionary

The name of a text search dictionary to be substituted for *old_dictionary*.

new_name

The new name of the text search configuration.

new_owner

The new owner of the text search configuration.

new_schema

The new schema for the text search configuration.

The `ADD MAPPING FOR` form installs a list of dictionaries to be consulted for the specified token type(s); it is an error if there is already a mapping for any of the token types. The `ALTER MAPPING FOR` form does the same, but first removing any existing mapping for those token types. The `ALTER MAPPING REPLACE` forms substitute *new_dictionary* for *old_dictionary* anywhere the latter appears. This is done for only the specified token types when `FOR` appears, or for all mappings of the configuration when it doesn't. The `DROP MAPPING` form removes all dictionaries for the specified token type(s), causing tokens of those types to be ignored by the text search configuration. It is an error if there is no mapping for the token types, unless `IF EXISTS` appears.

Examples

The following example replaces the `english` dictionary with the `swedish` dictionary anywhere that `english` is used within `my_config`.

```
ALTER TEXT SEARCH CONFIGURATION my_config
    ALTER MAPPING REPLACE english WITH swedish;
```

Compatibility

There is no `ALTER TEXT SEARCH CONFIGURATION` statement in the SQL standard.

[CREATE TEXT SEARCH CONFIGURATION](#), [DROP TEXT SEARCH CONFIGURATION](#)

ALTER TEXT SEARCH DICTIONARY

ALTER TEXT SEARCH DICTIONARY — change the definition of a text search dictionary

Synopsis

```
ALTER TEXT SEARCH DICTIONARY name (  
    option [ = value ] [, ... ]  
)  
ALTER TEXT SEARCH DICTIONARY name RENAME TO new_name  
ALTER TEXT SEARCH DICTIONARY name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER |  
    SESSION_USER }  
ALTER TEXT SEARCH DICTIONARY name SET SCHEMA new_schema
```

Description

ALTER TEXT SEARCH DICTIONARY changes the definition of a text search dictionary. You can change the dictionary's template-specific options, or change the dictionary's name or owner.

You must be the owner of the dictionary to use ALTER TEXT SEARCH DICTIONARY.

Parameters

name

The name (optionally schema-qualified) of an existing text search dictionary.

option

The name of a template-specific option to be set for this dictionary.

value

The new value to use for a template-specific option. If the equal sign and value are omitted, then any previous setting for the option is removed from the dictionary, allowing the default to be used.

new_name

The new name of the text search dictionary.

new_owner

The new owner of the text search dictionary.

new_schema

The new schema for the text search dictionary.

Template-specific options can appear in any order.

Examples

The following example command changes the stopword list for a Snowball-based dictionary. Other parameters remain unchanged.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( StopWords = newrussian );
```

The following example command changes the language option to `dutch`, and removes the stopword option entirely.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( language = dutch, StopWords );
```

The following example command “updates” the dictionary's definition without actually changing anything.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( dummy );
```

(The reason this works is that the option removal code doesn't complain if there is no such option.) This trick is useful when changing configuration files for the dictionary: the `ALTER` will force existing database sessions to re-read the configuration files, which otherwise they would never do if they had read them earlier.

Compatibility

There is no `ALTER TEXT SEARCH DICTIONARY` statement in the SQL standard.

See Also

[CREATE TEXT SEARCH DICTIONARY](#), [DROP TEXT SEARCH DICTIONARY](#)

ALTER TEXT SEARCH PARSER

ALTER TEXT SEARCH PARSER — change the definition of a text search parser

Synopsis

```
ALTER TEXT SEARCH PARSER name RENAME TO new_name
ALTER TEXT SEARCH PARSER name SET SCHEMA new_schema
```

Description

ALTER TEXT SEARCH PARSER changes the definition of a text search parser. Currently, the only supported functionality is to change the parser's name.

You must be a superuser to use ALTER TEXT SEARCH PARSER.

Parameters

name

The name (optionally schema-qualified) of an existing text search parser.

new_name

The new name of the text search parser.

new_schema

The new schema for the text search parser.

Compatibility

There is no ALTER TEXT SEARCH PARSER statement in the SQL standard.

See Also

[CREATE TEXT SEARCH PARSER](#), [DROP TEXT SEARCH PARSER](#)

ALTER TEXT SEARCH TEMPLATE

ALTER TEXT SEARCH TEMPLATE — change the definition of a text search template

Synopsis

```
ALTER TEXT SEARCH TEMPLATE name RENAME TO new_name
ALTER TEXT SEARCH TEMPLATE name SET SCHEMA new_schema
```

Description

ALTER TEXT SEARCH TEMPLATE changes the definition of a text search template. Currently, the only supported functionality is to change the template's name.

You must be a superuser to use ALTER TEXT SEARCH TEMPLATE.

Parameters

name

The name (optionally schema-qualified) of an existing text search template.

new_name

The new name of the text search template.

new_schema

The new schema for the text search template.

Compatibility

There is no ALTER TEXT SEARCH TEMPLATE statement in the SQL standard.

See Also

[CREATE TEXT SEARCH TEMPLATE](#), [DROP TEXT SEARCH TEMPLATE](#)

ALTER TRIGGER

ALTER TRIGGER — change the definition of a trigger

Synopsis

```
ALTER TRIGGER name ON table_name RENAME TO new_name
ALTER TRIGGER name ON table_name [ NO ] DEPENDS ON EXTENSION extension_name
```

Description

ALTER TRIGGER changes properties of an existing trigger.

The RENAME clause changes the name of the given trigger without otherwise changing the trigger definition. If the table that the trigger is on is a partitioned table, then corresponding clone triggers in the partitions are renamed too.

The DEPENDS ON EXTENSION clause marks the trigger as dependent on an extension, such that if the extension is dropped, the trigger will automatically be dropped as well.

You must own the table on which the trigger acts to be allowed to change its properties.

Parameters

name

The name of an existing trigger to alter.

table_name

The name of the table on which this trigger acts.

new_name

The new name for the trigger.

extension_name

The name of the extension that the trigger is to depend on (or no longer dependent on, if NO is specified). A trigger that's marked as dependent on an extension is automatically dropped when the extension is dropped.

Notes

The ability to temporarily enable or disable a trigger is provided by [ALTER TABLE](#), not by ALTER TRIGGER, because ALTER TRIGGER has no convenient way to express the option of enabling or disabling all of a table's triggers at once.

Examples

To rename an existing trigger:

```
ALTER TRIGGER emp_stamp ON emp RENAME TO emp_track_chgs;
```

To mark a trigger as being dependent on an extension:

```
ALTER TRIGGER emp_stamp ON emp DEPENDS ON EXTENSION emplib;
```

Compatibility

ALTER TRIGGER is a Postgres Pro extension of the SQL standard.

See Also

[ALTER TABLE](#)

ALTER TYPE

ALTER TYPE — change the definition of a type

Synopsis

```
ALTER TYPE name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
ALTER TYPE name RENAME TO new_name
ALTER TYPE name SET SCHEMA new_schema
ALTER TYPE name RENAME ATTRIBUTE attribute_name TO new_attribute_name [ CASCADE |
    RESTRICT ]
ALTER TYPE name action [, ... ]
ALTER TYPE name ADD VALUE [ IF NOT EXISTS ] new_enum_value [ { BEFORE |
    AFTER } neighbor_enum_value ]
ALTER TYPE name RENAME VALUE existing_enum_value TO new_enum_value
ALTER TYPE name SET ( property = value [, ... ] )
```

where *action* is one of:

```
    ADD ATTRIBUTE attribute_name data_type [ COLLATE collation ] [ CASCADE | RESTRICT ]
    DROP ATTRIBUTE [ IF EXISTS ] attribute_name [ CASCADE | RESTRICT ]
    ALTER ATTRIBUTE attribute_name [ SET DATA ] TYPE data_type [ COLLATE collation ]
[ CASCADE | RESTRICT ]
```

Description

ALTER TYPE changes the definition of an existing type. There are several subforms:

OWNER

This form changes the owner of the type.

RENAME

This form changes the name of the type.

SET SCHEMA

This form moves the type into another schema.

RENAME ATTRIBUTE

This form is only usable with composite types. It changes the name of an individual attribute of the type.

ADD ATTRIBUTE

This form adds a new attribute to a composite type, using the same syntax as [CREATE TYPE](#).

DROP ATTRIBUTE [IF EXISTS]

This form drops an attribute from a composite type. If IF EXISTS is specified and the attribute does not exist, no error is thrown. In this case a notice is issued instead.

ALTER ATTRIBUTE ... SET DATA TYPE

This form changes the type of an attribute of a composite type.

ADD VALUE [IF NOT EXISTS] [BEFORE | AFTER]

This form adds a new value to an enum type. The new value's place in the enum's ordering can be specified as being BEFORE or AFTER one of the existing values. Otherwise, the new item is added at the end of the list of values.

If `IF NOT EXISTS` is specified, it is not an error if the type already contains the new value: a notice is issued but no other action is taken. Otherwise, an error will occur if the new value is already present.

RENAME VALUE

This form renames a value of an enum type. The value's place in the enum's ordering is not affected. An error will occur if the specified value is not present or the new name is already present.

`SET (property = value [, ...])`

This form is only applicable to base types. It allows adjustment of a subset of the base-type properties that can be set in `CREATE TYPE`. Specifically, these properties can be changed:

- `RECEIVE` can be set to the name of a binary input function, or `NONE` to remove the type's binary input function. Using this option requires superuser privilege.
- `SEND` can be set to the name of a binary output function, or `NONE` to remove the type's binary output function. Using this option requires superuser privilege.
- `TYPMOD_IN` can be set to the name of a type modifier input function, or `NONE` to remove the type's type modifier input function. Using this option requires superuser privilege.
- `TYPMOD_OUT` can be set to the name of a type modifier output function, or `NONE` to remove the type's type modifier output function. Using this option requires superuser privilege.
- `ANALYZE` can be set to the name of a type-specific statistics collection function, or `NONE` to remove the type's statistics collection function. Using this option requires superuser privilege.
- `SUBSCRIPT` can be set to the name of a type-specific subscripting handler function, or `NONE` to remove the type's subscripting handler function. Using this option requires superuser privilege.
- `STORAGE` can be set to `plain`, `extended`, `external`, or `main` (see [Section 66.2](#) for more information about what these mean). However, changing from `plain` to another setting requires superuser privilege (because it requires that the type's C functions all be TOAST-ready), and changing to `plain` from another setting is not allowed at all (since the type may already have TOAST-ed values present in the database). Note that changing this option doesn't by itself change any stored data, it just sets the default TOAST strategy to be used for table columns created in the future. See [ALTER TABLE](#) to change the TOAST strategy for existing table columns.

See [CREATE TYPE](#) for more details about these type properties. Note that where appropriate, a change in these properties for a base type will be propagated automatically to domains based on that type.

The `ADD ATTRIBUTE`, `DROP ATTRIBUTE`, and `ALTER ATTRIBUTE` actions can be combined into a list of multiple alterations to apply in parallel. For example, it is possible to add several attributes and/or alter the type of several attributes in a single command.

You must own the type to use `ALTER TYPE`. To change the schema of a type, you must also have `CREATE` privilege on the new schema. To alter the owner, you must be able to `SET ROLE` to the new owning role, and that role must have `CREATE` privilege on the type's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the type. However, a superuser can alter ownership of any type anyway.) To add an attribute or alter an attribute type, you must also have `USAGE` privilege on the attribute's data type.

Parameters

name

The name (possibly schema-qualified) of an existing type to alter.

new_name

The new name for the type.

new_owner

The user name of the new owner of the type.

new_schema

The new schema for the type.

attribute_name

The name of the attribute to add, alter, or drop.

new_attribute_name

The new name of the attribute to be renamed.

data_type

The data type of the attribute to add, or the new type of the attribute to alter.

new_enum_value

The new value to be added to an enum type's list of values, or the new name to be given to an existing value. Like all enum literals, it needs to be quoted.

neighbor_enum_value

The existing enum value that the new value should be added immediately before or after in the enum type's sort ordering. Like all enum literals, it needs to be quoted.

existing_enum_value

The existing enum value that should be renamed. Like all enum literals, it needs to be quoted.

property

The name of a base-type property to be modified; see above for possible values.

CASCADE

Automatically propagate the operation to typed tables of the type being altered, and their descendants.

RESTRICT

Refuse the operation if the type being altered is the type of a typed table. This is the default.

Notes

If `ALTER TYPE ... ADD VALUE` (the form that adds a new value to an enum type) is executed inside a transaction block, the new value cannot be used until after the transaction has been committed.

Comparisons involving an added enum value will sometimes be slower than comparisons involving only original members of the enum type. This will usually only occur if `BEFORE` or `AFTER` is used to set the new value's sort position somewhere other than at the end of the list. However, sometimes it will happen even though the new value is added at the end (this occurs if the OID counter “wrapped around” since the original creation of the enum type). The slowdown is usually insignificant; but if it matters, optimal performance can be regained by dropping and recreating the enum type, or by dumping and restoring the database.

Examples

To rename a data type:

```
ALTER TYPE electronic_mail RENAME TO email;
```

To change the owner of the type `email` to `joe`:

```
ALTER TYPE email OWNER TO joe;
```

To change the schema of the type email to customers:

```
ALTER TYPE email SET SCHEMA customers;
```

To add a new attribute to a composite type:

```
ALTER TYPE compfoo ADD ATTRIBUTE f3 int;
```

To add a new value to an enum type in a particular sort position:

```
ALTER TYPE colors ADD VALUE 'orange' AFTER 'red';
```

To rename an enum value:

```
ALTER TYPE colors RENAME VALUE 'purple' TO 'mauve';
```

To create binary I/O functions for an existing base type:

```
CREATE FUNCTION mytypesend(mytype) RETURNS bytea ...;
CREATE FUNCTION mytyperecv(internal, oid, integer) RETURNS mytype ...;
ALTER TYPE mytype SET (
    SEND = mytypesend,
    RECEIVE = mytyperecv
);
```

Compatibility

The variants to add and drop attributes are part of the SQL standard; the other variants are Postgres Pro extensions.

See Also

[CREATE TYPE](#), [DROP TYPE](#)

ALTER USER

ALTER USER — change a database role

Synopsis

```
ALTER USER role_specification [ WITH ] option [ ... ]
```

where *option* can be:

```
SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| REPLICATION | NOREPLICATION
| BYPASSRLS | NOBYPASSRLS
| CONNECTION LIMIT connlimit
| [ ENCRYPTED ] PASSWORD 'password' | PASSWORD NULL
| VALID UNTIL 'timestamp'
| PROFILE profile_name
| ACCOUNT UNLOCK | ACCOUNT LOCK
```

```
ALTER USER name RENAME TO new_name
```

```
ALTER USER { role_specification | ALL } [ IN DATABASE database_name ]
SET configuration_parameter { TO | = } { value | DEFAULT }
ALTER USER { role_specification | ALL } [ IN DATABASE database_name ]
SET configuration_parameter FROM CURRENT
ALTER USER { role_specification | ALL } [ IN DATABASE database_name ]
RESET configuration_parameter
ALTER USER { role_specification | ALL } [ IN DATABASE database_name ] RESET ALL
```

where *role_specification* can be:

```
role_name
| CURRENT_ROLE
| CURRENT_USER
| SESSION_USER
```

Description

ALTER USER is now an alias for [ALTER ROLE](#).

Compatibility

The ALTER USER statement is a Postgres Pro extension. The SQL standard leaves the definition of users to the implementation.

See Also

[ALTER ROLE](#)

ALTER VIEW

ALTER VIEW — change the definition of a view

Synopsis

```
ALTER VIEW [ IF EXISTS ] name ALTER [ COLUMN ] column_name SET DEFAULT expression
ALTER VIEW [ IF EXISTS ] name ALTER [ COLUMN ] column_name DROP DEFAULT
ALTER VIEW [ IF EXISTS ] name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER |
SESSION_USER }
ALTER VIEW [ IF EXISTS ] name RENAME [ COLUMN ] column_name TO new_column_name
ALTER VIEW [ IF EXISTS ] name RENAME TO new_name
ALTER VIEW [ IF EXISTS ] name SET SCHEMA new_schema
ALTER VIEW [ IF EXISTS ] name SET ( view_option_name [= view_option_value] [, ... ] )
ALTER VIEW [ IF EXISTS ] name RESET ( view_option_name [, ... ] )
```

Description

ALTER VIEW changes various auxiliary properties of a view. (If you want to modify the view's defining query, use CREATE OR REPLACE VIEW.)

You must own the view to use ALTER VIEW. To change a view's schema, you must also have CREATE privilege on the new schema. To alter the owner, you must be able to SET ROLE to the new owning role, and that role must have CREATE privilege on the view's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the view. However, a superuser can alter ownership of any view anyway.)

Parameters

name

The name (optionally schema-qualified) of an existing view.

column_name

Name of an existing column.

new_column_name

New name for an existing column.

IF EXISTS

Do not throw an error if the view does not exist. A notice is issued in this case.

SET/DROP DEFAULT

These forms set or remove the default value for a column. A view column's default value is substituted into any INSERT or UPDATE command whose target is the view, before applying any rules or triggers for the view. The view's default will therefore take precedence over any default values from underlying relations.

new_owner

The user name of the new owner of the view.

new_name

The new name for the view.

new_schema

The new schema for the view.

```
SET ( view_option_name [= view_option_value] [, ... ] )
RESET ( view_option_name [, ... ] )
```

Sets or resets a view option. Currently supported options are:

`check_option` (enum)

Changes the check option of the view. The value must be `local` or `cascaded`.

`security_barrier` (boolean)

Changes the security-barrier property of the view. The value must be a Boolean value, such as `true` or `false`.

`security_invoker` (boolean)

Changes the security-invoker property of the view. The value must be a Boolean value, such as `true` or `false`.

Notes

For historical reasons, `ALTER TABLE` can be used with views too; but the only variants of `ALTER TABLE` that are allowed with views are equivalent to the ones shown above.

Examples

To rename the view `foo` to `bar`:

```
ALTER VIEW foo RENAME TO bar;
```

To attach a default column value to an updatable view:

```
CREATE TABLE base_table (id int, ts timestamptz);
CREATE VIEW a_view AS SELECT * FROM base_table;
ALTER VIEW a_view ALTER COLUMN ts SET DEFAULT now();
INSERT INTO base_table(id) VALUES(1); -- ts will receive a NULL
INSERT INTO a_view(id) VALUES(2); -- ts will receive the current time
```

Compatibility

`ALTER VIEW` is a Postgres Pro extension of the SQL standard.

See Also

[CREATE VIEW](#), [DROP VIEW](#)

ANALYZE

ANALYZE — collect statistics about a database

Synopsis

```
ANALYZE [ ( option [, ...] ) ] [ table_and_columns [, ...] ]
```

where *option* can be one of:

```
VERBOSE [ boolean ]
SKIP_LOCKED [ boolean ]
BUFFER_USAGE_LIMIT size
```

and *table_and_columns* is:

```
table_name [ ( column_name [, ...] ) ]
```

Description

ANALYZE collects statistics about the contents of tables in the database, and stores the results in the `pg_statistic` system catalog. Subsequently, the query planner uses these statistics to help determine the most efficient execution plans for queries.

Without a *table_and_columns* list, ANALYZE processes every table and materialized view in the current database that the current user has permission to analyze. With a list, ANALYZE processes only those table(s). It is further possible to give a list of column names for a table, in which case only the statistics for those columns are collected.

For information about using ANALYZE in distributed systems, see [Analyzing and Vacuuming in Distributed System](#).

Parameters

VERBOSE

Enables display of progress messages.

SKIP_LOCKED

Specifies that ANALYZE should not wait for any conflicting locks to be released when beginning work on a relation: if a relation cannot be locked immediately without waiting, the relation is skipped. Note that even with this option, ANALYZE may still block when opening the relation's indexes or when acquiring sample rows from partitions, table inheritance children, and some types of foreign tables. Also, while ANALYZE ordinarily processes all partitions of specified partitioned tables, this option will cause ANALYZE to skip all partitions if there is a conflicting lock on the partitioned table.

BUFFER_USAGE_LIMIT

Specifies the [Buffer Access Strategy](#) ring buffer size for ANALYZE. This size is used to calculate the number of shared buffers which will be reused as part of this strategy. 0 disables use of a Buffer Access Strategy. When this option is not specified, ANALYZE uses the value from [vacuum_buffer_usage_limit](#). Higher settings can allow ANALYZE to run more quickly, but having too large a setting may cause too many other useful pages to be evicted from shared buffers. The minimum value is 128 kB and the maximum value is 16 GB.

boolean

Specifies whether the selected option should be turned on or off. You can write TRUE, ON, or 1 to enable the option, and FALSE, OFF, or 0 to disable it. The *boolean* value can also be omitted, in which case TRUE is assumed.

size

Specifies an amount of memory in kilobytes. Sizes may also be specified as a string containing the numerical size followed by any one of the following memory units: B (bytes), kB (kilobytes), MB (megabytes), GB (gigabytes), or TB (terabytes).

table_name

The name (possibly schema-qualified) of a specific table to analyze. If omitted, all regular tables, partitioned tables, and materialized views in the current database are analyzed (but not foreign tables). If the specified table is a partitioned table, both the inheritance statistics of the partitioned table as a whole and statistics of the individual partitions are updated.

column_name

The name of a specific column to analyze. Defaults to all columns.

Outputs

When `VERBOSE` is specified, `ANALYZE` emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

Notes

To analyze a table, one must ordinarily have the `MAINTAIN` privilege on the table. However, database owners are allowed to analyze all tables in their databases, except shared catalogs. `ANALYZE` will skip over any tables that the calling user does not have permission to analyze.

Foreign tables are analyzed only when explicitly selected. Not all foreign data wrappers support `ANALYZE`. If the table's wrapper does not support `ANALYZE`, the command prints a warning and does nothing.

In the default Postgres Pro configuration, the autovacuum daemon (see [Section 24.1.6](#)) takes care of automatic analyzing of tables when they are first loaded with data, and as they change throughout regular operation. When autovacuum is disabled, it is a good idea to run `ANALYZE` periodically, or just after making major changes in the contents of a table. Accurate statistics will help the planner to choose the most appropriate query plan, and thereby improve the speed of query processing. A common strategy for read-mostly databases is to run `VACUUM` and `ANALYZE` once a day during a low-usage time of day. (This will not be sufficient if there is heavy update activity.)

While `ANALYZE` is running, the [search_path](#) is temporarily changed to `pg_catalog`, `pg_temp`.

`ANALYZE` requires only a read lock on the target table, so it can run in parallel with other non-DDL activity on the table.

The statistics collected by `ANALYZE` usually include a list of some of the most common values in each column and a histogram showing the approximate data distribution in each column. One or both of these can be omitted if `ANALYZE` deems them uninteresting (for example, in a unique-key column, there are no common values) or if the column data type does not support the appropriate operators. There is more information about the statistics in [Chapter 24](#).

For large tables, `ANALYZE` takes a random sample of the table contents, rather than examining every row. This allows even very large tables to be analyzed in a small amount of time. Note, however, that the statistics are only approximate, and will change slightly each time `ANALYZE` is run, even if the actual table contents did not change. This might result in small changes in the planner's estimated costs shown by `EXPLAIN`. In rare situations, this non-determinism will cause the planner's choices of query plans to change after `ANALYZE` is run. To avoid this, raise the amount of statistics collected by `ANALYZE`, as described below.

The extent of analysis can be controlled by adjusting the [default_statistics_target](#) configuration variable, or on a column-by-column basis by setting the per-column statistics target with `ALTER TABLE ... ALTER COLUMN ... SET STATISTICS`. The target value sets the maximum number of entries in the most-

common-value list and the maximum number of bins in the histogram. The default target value is 100, but this can be adjusted up or down to trade off accuracy of planner estimates against the time taken for `ANALYZE` and the amount of space occupied in `pg_statistic`. In particular, setting the statistics target to zero disables collection of statistics for that column. It might be useful to do that for columns that are never used as part of the `WHERE`, `GROUP BY`, or `ORDER BY` clauses of queries, since the planner will have no use for statistics on such columns.

The largest statistics target among the columns being analyzed determines the number of table rows sampled to prepare the statistics. Increasing the target causes a proportional increase in the time and space needed to do `ANALYZE`.

One of the values estimated by `ANALYZE` is the number of distinct values that appear in each column. Because only a subset of the rows are examined, this estimate can sometimes be quite inaccurate, even with the largest possible statistics target. If this inaccuracy leads to bad query plans, a more accurate value can be determined manually and then installed with `ALTER TABLE ... ALTER COLUMN ... SET (n_distinct = ...)`.

If the table being analyzed has inheritance children, `ANALYZE` gathers two sets of statistics: one on the rows of the parent table only, and a second including rows of both the parent table and all of its children. This second set of statistics is needed when planning queries that process the inheritance tree as a whole. The child tables themselves are not individually analyzed in this case. The autovacuum daemon, however, will only consider inserts or updates on the parent table itself when deciding whether to trigger an automatic analyze for that table. If that table is rarely inserted into or updated, the inheritance statistics will not be up to date unless you run `ANALYZE` manually.

For partitioned tables, `ANALYZE` gathers statistics by sampling rows from all partitions; in addition, it will recurse into each partition and update its statistics. Each leaf partition is analyzed only once, even with multi-level partitioning. No statistics are collected for only the parent table (without data from its partitions), because with partitioning it's guaranteed to be empty.

The autovacuum daemon does not process partitioned tables, nor does it process inheritance parents if only the children are ever modified. It is usually necessary to periodically run a manual `ANALYZE` to keep the statistics of the table hierarchy up to date.

If any child tables or partitions are foreign tables whose foreign data wrappers do not support `ANALYZE`, those tables are ignored while gathering inheritance statistics.

If the table being analyzed is completely empty, `ANALYZE` will not record new statistics for that table. Any existing statistics will be retained.

Each backend running `ANALYZE` will report its progress in the `pg_stat_progress_analyze` view. See [Section 27.4.1](#) for details.

Compatibility

There is no `ANALYZE` statement in the SQL standard.

The following syntax was used before Postgres Pro version 11 and is still supported:

```
ANALYZE [ VERBOSE ] [ table_and_columns [, ...] ]
```

See Also

[VACUUM](#), [vacuumdb](#), [Section 19.4.4](#), [Section 24.1.6](#), [Section 27.4.1](#)

BEGIN

BEGIN — start a transaction block

Synopsis

```
BEGIN [ AUTONOMOUS ] [ WORK | TRANSACTION ] [ transaction_mode [, ...] ]
```

where *transaction_mode* is one of:

```
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ  
UNCOMMITTED }  
READ WRITE | READ ONLY  
[ NOT ] DEFERRABLE
```

Description

BEGIN initiates a transaction block, that is, all statements after a BEGIN command will be executed in a single transaction until an explicit COMMIT or ROLLBACK is given. By default (without BEGIN), Postgres Pro executes transactions in “autocommit” mode, that is, each statement is executed in its own transaction and a commit is implicitly performed at the end of the statement (if execution was successful, otherwise a rollback is done).

Statements are executed more quickly in a transaction block, because transaction start/commit requires significant CPU and disk activity. Execution of multiple statements inside a transaction is also useful to ensure consistency when making several related changes: other sessions will be unable to see the intermediate states wherein not all the related updates have been done.

If the isolation level, read/write mode, or deferrable mode is specified, the new transaction has those characteristics, as if SET TRANSACTION was executed.

If you specify an optional AUTONOMOUS keyword, an autonomous transaction is started. Autonomous transactions can be started only within another transaction. For details, see [Chapter 16](#).

Parameters

AUTONOMOUS

Starts an autonomous transaction within another transaction.

WORK

TRANSACTION

Optional key words. They have no effect.

Refer to [SET TRANSACTION](#) for information on the meaning of the other parameters to this statement.

Notes

[START TRANSACTION](#) has the same functionality as BEGIN.

Use COMMIT or ROLLBACK to terminate a transaction block.

Issuing BEGIN when already inside a transaction block will provoke a warning message. The state of the transaction is not affected. To nest transactions within a transaction block, use savepoints (see [SAVEPOINT](#)).

For reasons of backwards compatibility, the commas between successive *transaction_modes* can be omitted.

Examples

To begin a transaction block:

```
BEGIN;
```

Compatibility

BEGIN is a Postgres Pro language extension. It is equivalent to the SQL-standard command [START TRANSACTION](#), whose reference page contains additional compatibility information.

The DEFERRABLE *transaction_mode* is a Postgres Pro language extension.

Incidentally, the BEGIN key word is used for a different purpose in embedded SQL. You are advised to be careful about the transaction semantics when porting database applications.

See Also

[COMMIT](#), [ROLLBACK](#), [START TRANSACTION](#), [SAVEPOINT](#)

CALL

CALL — invoke a procedure

Synopsis

```
CALL name ( [ argument ] [, ...] )
```

Description

CALL executes a procedure.

If the procedure has any output parameters, then a result row will be returned, containing the values of those parameters.

Parameters

name

The name (optionally schema-qualified) of the procedure.

argument

An argument expression for the procedure call.

Arguments can include parameter names, using the syntax *name* => *value*. This works the same as in ordinary function calls; see [Section 4.3](#) for details.

Arguments must be supplied for all procedure parameters that lack defaults, including OUT parameters. However, arguments matching OUT parameters are not evaluated, so it's customary to just write NULL for them. (Writing something else for an OUT parameter might cause compatibility problems with future Postgres Pro versions.)

Notes

The user must have EXECUTE privilege on the procedure in order to be allowed to invoke it.

To call a function (not a procedure), use SELECT instead.

If CALL is executed in a transaction block, then the called procedure cannot execute transaction control statements. Transaction control statements are only allowed if CALL is executed in its own transaction.

PL/pgSQL handles output parameters in CALL commands differently; see [Section 44.6.3](#).

Examples

```
CALL do_db_maintenance();
```

Compatibility

CALL conforms to the SQL standard, except for the handling of output parameters. The standard says that users should write variables to receive the values of output parameters.

[CREATE PROCEDURE](#)

CHECKPOINT

CHECKPOINT — force a write-ahead log checkpoint

Synopsis

CHECKPOINT

Description

A checkpoint is a point in the write-ahead log sequence at which all data files have been updated to reflect the information in the log. All data files will be flushed to disk. Refer to [Section 28.5](#) for more details about what happens during a checkpoint.

The `CHECKPOINT` command forces an immediate checkpoint when the command is issued, without waiting for a regular checkpoint scheduled by the system (controlled by the settings in [Section 19.5.2](#)). `CHECKPOINT` is not intended for use during normal operation.

If executed during recovery, the `CHECKPOINT` command will force a restartpoint (see [Section 28.5](#)) rather than writing a new checkpoint.

Only superusers or users with the privileges of the `pg_checkpoint` role can call `CHECKPOINT`.

Compatibility

The `CHECKPOINT` command is a Postgres Pro language extension.

CLOSE

CLOSE — close a cursor

Synopsis

```
CLOSE { name | ALL }
```

Description

CLOSE frees the resources associated with an open cursor. After the cursor is closed, no subsequent operations are allowed on it. A cursor should be closed when it is no longer needed.

Every non-holdable open cursor is implicitly closed when a transaction is terminated by COMMIT or ROLLBACK. A holdable cursor is implicitly closed if the transaction that created it aborts via ROLLBACK. If the creating transaction successfully commits, the holdable cursor remains open until an explicit CLOSE is executed, or the client disconnects.

Parameters

name

The name of an open cursor to close.

ALL

Close all open cursors.

Notes

Postgres Pro does not have an explicit OPEN cursor statement; a cursor is considered open when it is declared. Use the DECLARE statement to declare a cursor.

You can see all available cursors by querying the [pg_cursors](#) system view.

If a cursor is closed after a savepoint which is later rolled back, the CLOSE is not rolled back; that is, the cursor remains closed.

Examples

Close the cursor `liahona`:

```
CLOSE liahona;
```

Compatibility

CLOSE is fully conforming with the SQL standard. CLOSE ALL is a Postgres Pro extension.

CLUSTER

CLUSTER — cluster a table according to an index

Synopsis

```
CLUSTER [ ( option [, ...] ) ] [ table_name [ USING index_name ] ]
```

where *option* can be one of:

```
VERBOSE [ boolean ]
```

Description

CLUSTER instructs Postgres Pro to cluster the table specified by *table_name* based on the index specified by *index_name*. The index must already have been defined on *table_name*.

When a table is clustered, it is physically reordered based on the index information. Clustering is a one-time operation: when the table is subsequently updated, the changes are not clustered. That is, no attempt is made to store new or updated rows according to their index order. (If one wishes, one can periodically recluster by issuing the command again. Also, setting the table's `fillfactor` storage parameter to less than 100% can aid in preserving cluster ordering during updates, since updated rows are kept on the same page if enough space is available there.)

When a table is clustered, Postgres Pro remembers which index it was clustered by. The form `CLUSTER table_name` reclusters the table using the same index as before. You can also use the `CLUSTER` or `SET WITHOUT CLUSTER` forms of `ALTER TABLE` to set the index to be used for future cluster operations, or to clear any previous setting.

CLUSTER without a *table_name* reclusters all the previously-clustered tables in the current database that the calling user has privileges for. This form of CLUSTER cannot be executed inside a transaction block.

When a table is being clustered, an `ACCESS EXCLUSIVE` lock is acquired on it. This prevents any other database operations (both reads and writes) from operating on the table until the `CLUSTER` is finished.

Parameters

table_name

The name (possibly schema-qualified) of a table.

index_name

The name of an index.

VERBOSE

Prints a progress report as each table is clustered.

boolean

Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to disable it. The *boolean* value can also be omitted, in which case `TRUE` is assumed.

Notes

To cluster a table, one must have the `MAINTAIN` privilege on the table.

In cases where you are accessing single rows randomly within a table, the actual order of the data in the table is unimportant. However, if you tend to access some data more than others, and there is an index

that groups them together, you will benefit from using `CLUSTER`. If you are requesting a range of indexed values from a table, or a single indexed value that has multiple rows that match, `CLUSTER` will help because once the index identifies the table page for the first row that matches, all other rows that match are probably already on the same table page, and so you save disk accesses and speed up the query.

`CLUSTER` can re-sort the table using either an index scan on the specified index, or (if the index is a b-tree) a sequential scan followed by sorting. It will attempt to choose the method that will be faster, based on planner cost parameters and available statistical information.

While `CLUSTER` is running, the [search_path](#) is temporarily changed to `pg_catalog`, `pg_temp`.

When an index scan is used, a temporary copy of the table is created that contains the table data in the index order. Temporary copies of each index on the table are created as well. Therefore, you need free space on disk at least equal to the sum of the table size and the index sizes.

When a sequential scan and sort is used, a temporary sort file is also created, so that the peak temporary space requirement is as much as double the table size, plus the index sizes. This method is often faster than the index scan method, but if the disk space requirement is intolerable, you can disable this choice by temporarily setting [enable_sort](#) to `off`.

It is advisable to set [maintenance_work_mem](#) to a reasonably large value (but not more than the amount of RAM you can dedicate to the `CLUSTER` operation) before clustering.

Because the planner records statistics about the ordering of tables, it is advisable to run [ANALYZE](#) on the newly clustered table. Otherwise, the planner might make poor choices of query plans.

Because `CLUSTER` remembers which indexes are clustered, one can cluster the tables one wants clustered manually the first time, then set up a periodic maintenance script that executes `CLUSTER` without any parameters, so that the desired tables are periodically reclustered.

Each backend running `CLUSTER` will report its progress in the `pg_stat_progress_cluster` view. See [Section 27.4.2](#) for details.

Clustering a partitioned table clusters each of its partitions using the partition of the specified partitioned index. When clustering a partitioned table, the index may not be omitted. `CLUSTER` on a partitioned table cannot be executed inside a transaction block.

Examples

Cluster the table `employees` on the basis of its index `employees_ind`:

```
CLUSTER employees USING employees_ind;
```

Cluster the `employees` table using the same index that was used before:

```
CLUSTER employees;
```

Cluster all tables in the database that have previously been clustered:

```
CLUSTER;
```

Compatibility

There is no `CLUSTER` statement in the SQL standard.

The following syntax was used before PostgreSQL 17 and is still supported:

```
CLUSTER [ VERBOSE ] [ table_name [ USING index_name ] ]
```

The following syntax was used before PostgreSQL 8.3 and is still supported:

```
CLUSTER index_name ON table_name
```

[ [ argmode ] [ argname ] argtype [ , ... ] ] ORDER BY [ argmode ] [ argname ] argtype  
[ , ... ]
```

Description

COMMENT stores a comment about a database object.

Only one comment string is stored for each object, so to modify a comment, issue a new COMMENT command for the same object. To remove a comment, write NULL in place of the text string. Comments are automatically dropped when their object is dropped.

A SHARE UPDATE EXCLUSIVE lock is acquired on the object to be commented.

For most kinds of object, only the object's owner can set the comment. Roles don't have owners, so the rule for COMMENT ON ROLE is that you must be superuser to comment on a superuser role, or have the CREATEROLE privilege and have been granted ADMIN OPTION on the target role. Likewise, access methods don't have owners either; you must be superuser to comment on an access method. Of course, a superuser can comment on anything.

Comments can be viewed using psql's \d family of commands. Other user interfaces to retrieve comments can be built atop the same built-in functions that psql uses, namely obj_description, col_description, and shobj_description (see [Table 9.80](#)).

Parameters

object_name
relation_name.column_name
aggregate_name
constraint_name
function_name
operator_name
policy_name
procedure_name
routine_name
rule_name
trigger_name

The name of the object to be commented. Names of objects that reside in schemas (tables, functions, etc.) can be schema-qualified. When commenting on a column, *relation_name* must refer to a table, view, composite type, or foreign table.

table_name
domain_name

When creating a comment on a constraint, a trigger, a rule or a policy these parameters specify the name of the table or domain on which that object is defined.

source_type

The name of the source data type of the cast.

target_type

The name of the target data type of the cast.

argmode

The mode of a function, procedure, or aggregate argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that COMMENT does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

argname

The name of a function, procedure, or aggregate argument. Note that `COMMENT` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype

The data type of a function, procedure, or aggregate argument.

large_object_oid

The OID of the large object.

left_type

right_type

The data type(s) of the operator's arguments (optionally schema-qualified). Write `NONE` for the missing argument of a prefix operator.

`PROCEDURAL`

This is a noise word.

type_name

The name of the data type of the transform.

lang_name

The name of the language of the transform.

string_literal

The new comment contents, written as a string literal.

`NULL`

Write `NULL` to drop the comment.

Notes

There is presently no security mechanism for viewing comments: any user connected to a database can see all the comments for objects in that database. For shared objects such as databases, roles, and tablespaces, comments are stored globally so any user connected to any database in the cluster can see all the comments for shared objects. Therefore, don't put security-critical information in comments.

Examples

Attach a comment to the table `mytable`:

```
COMMENT ON TABLE mytable IS 'This is my table.';
```

Remove it again:

```
COMMENT ON TABLE mytable IS NULL;
```

Some more examples:

```
COMMENT ON ACCESS METHOD gin IS 'GIN index access method';
COMMENT ON AGGREGATE my_aggregate (double precision) IS 'Computes sample variance';
COMMENT ON CAST (text AS int4) IS 'Allow casts from text to int4';
COMMENT ON COLLATION "fr_CA" IS 'Canadian French';
COMMENT ON COLUMN my_table.my_column IS 'Employee ID number';
COMMENT ON CONVERSION my_conv IS 'Conversion to UTF8';
COMMENT ON CONSTRAINT bar_col_cons ON bar IS 'Constrains column col';
```

```
COMMENT ON CONSTRAINT dom_col_constr ON DOMAIN dom IS 'Constrains col of domain';
COMMENT ON DATABASE my_database IS 'Development Database';
COMMENT ON DOMAIN my_domain IS 'Email Address Domain';
COMMENT ON EVENT TRIGGER abort_ddl IS 'Aborts all DDL commands';
COMMENT ON EXTENSION hstore IS 'implements the hstore data type';
COMMENT ON FOREIGN DATA WRAPPER mywrapper IS 'my foreign data wrapper';
COMMENT ON FOREIGN TABLE my_foreign_table IS 'Employee Information in other database';
COMMENT ON FUNCTION my_function (timestamp) IS 'Returns Roman Numeral';
COMMENT ON INDEX my_index IS 'Enforces uniqueness on employee ID';
COMMENT ON LANGUAGE plpython IS 'Python support for stored procedures';
COMMENT ON LARGE OBJECT 346344 IS 'Planning document';
COMMENT ON MATERIALIZED VIEW my_matview IS 'Summary of order history';
COMMENT ON OPERATOR ^ (text, text) IS 'Performs intersection of two texts';
COMMENT ON OPERATOR - (NONE, integer) IS 'Unary minus';
COMMENT ON OPERATOR CLASS int4ops USING btree IS '4 byte integer operators for btrees';
COMMENT ON OPERATOR FAMILY integer_ops USING btree IS 'all integer operators for
  btrees';
COMMENT ON POLICY my_policy ON mytable IS 'Filter rows by users';
COMMENT ON PROCEDURE my_proc (integer, integer) IS 'Runs a report';
COMMENT ON PUBLICATION alltables IS 'Publishes all operations on all tables';
COMMENT ON ROLE my_role IS 'Administration group for finance tables';
COMMENT ON ROUTINE my_routine (integer, integer) IS 'Runs a routine (which is a
  function or procedure)';
COMMENT ON RULE my_rule ON my_table IS 'Logs updates of employee records';
COMMENT ON SCHEMA my_schema IS 'Departmental data';
COMMENT ON SEQUENCE my_sequence IS 'Used to generate primary keys';
COMMENT ON SERVER myserver IS 'my foreign server';
COMMENT ON STATISTICS my_statistics IS 'Improves planner row estimations';
COMMENT ON SUBSCRIPTION alltables IS 'Subscription for all operations on all tables';
COMMENT ON TABLE my_schema.my_table IS 'Employee Information';
COMMENT ON TABLESPACE my_tablespace IS 'Tablespace for indexes';
COMMENT ON TEXT SEARCH CONFIGURATION my_config IS 'Special word filtering';
COMMENT ON TEXT SEARCH DICTIONARY swedish IS 'Snowball stemmer for Swedish language';
COMMENT ON TEXT SEARCH PARSER my_parser IS 'Splits text into words';
COMMENT ON TEXT SEARCH TEMPLATE snowball IS 'Snowball stemmer';
COMMENT ON TRANSFORM FOR hstore LANGUAGE plpython3u IS 'Transform between hstore and
  Python dict';
COMMENT ON TRIGGER my_trigger ON my_table IS 'Used for RI';
COMMENT ON TYPE complex IS 'Complex number data type';
COMMENT ON VIEW my_view IS 'View of departmental costs';
```

Compatibility

There is no `COMMENT` command in the SQL standard.

COMMIT

COMMIT — commit the current transaction

Synopsis

```
COMMIT [ AUTONOMOUS ] [ WORK | TRANSACTION ] [ AND [ NO ] CHAIN ]
```

Description

COMMIT commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs.

Parameters

AUTONOMOUS

Optional key word that can be used when committing an autonomous transaction. For details on autonomous transactions, see [Chapter 16](#).

WORK

TRANSACTION

Optional key words. They have no effect.

AND CHAIN

If AND CHAIN is specified, a new transaction is immediately started with the same transaction characteristics (see [SET TRANSACTION](#)) as the just finished one. Otherwise, no new transaction is started.

Notes

Use [ROLLBACK](#) to abort a transaction.

Issuing COMMIT when not inside a transaction does no harm, but it will provoke a warning message. COMMIT AND CHAIN when not inside a transaction is an error.

Examples

To commit the current transaction and make all changes permanent:

```
COMMIT;
```

Compatibility

The command COMMIT conforms to the SQL standard. The form COMMIT TRANSACTION is a Postgres Pro extension.

See Also

[BEGIN](#), [ROLLBACK](#)

COMMIT PREPARED

COMMIT PREPARED — commit a transaction that was earlier prepared for two-phase commit

Synopsis

```
COMMIT PREPARED transaction_id
```

Description

COMMIT PREPARED commits a transaction that is in prepared state.

Parameters

transaction_id

The transaction identifier of the transaction that is to be committed.

Notes

To commit a prepared transaction, you must be either the same user that executed the transaction originally, or a superuser. But you do not have to be in the same session that executed the transaction.

This command cannot be executed inside a transaction block. The prepared transaction is committed immediately.

All currently available prepared transactions are listed in the [pg_prepared_xacts](#) system view.

Examples

Commit the transaction identified by the transaction identifier `foobar`:

```
COMMIT PREPARED 'foobar';
```

Compatibility

COMMIT PREPARED is a Postgres Pro extension. It is intended for use by external transaction management systems, some of which are covered by standards (such as X/Open XA), but the SQL side of those systems is not standardized.

See Also

[PREPARE TRANSACTION](#), [ROLLBACK PREPARED](#)

COPY

COPY — copy data between a file and a table

Synopsis

```
COPY table_name [ ( column_name [, ...] ) ]  
  FROM { 'filename' | PROGRAM 'command' | STDIN }  
  [ [ WITH ] ( option [, ...] ) ]  
  [ WHERE condition ]  
  
COPY { table_name [ ( column_name [, ...] ) ] | ( query ) }  
  TO { 'filename' | PROGRAM 'command' | STDOUT }  
  [ [ WITH ] ( option [, ...] ) ]
```

where *option* can be one of:

```
FORMAT format_name  
FREEZE [ boolean ]  
DELIMITER 'delimiter_character'  
NULL 'null_string'  
DEFAULT 'default_string'  
HEADER [ boolean | MATCH ]  
QUOTE 'quote_character'  
ESCAPE 'escape_character'  
FORCE_QUOTE { ( column_name [, ...] ) | * }  
FORCE_NOT_NULL { ( column_name [, ...] ) | * }  
FORCE_NULL { ( column_name [, ...] ) | * }  
ON_ERROR error_action  
ENCODING 'encoding_name'  
LOG_VERBOSITY verbosity
```

Description

COPY moves data between Postgres Pro tables and standard file-system files. COPY TO copies the contents of a table *to* a file, while COPY FROM copies data *from* a file to a table (appending the data to whatever is in the table already). COPY TO can also copy the results of a SELECT query.

If a column list is specified, COPY TO copies only the data in the specified columns to the file. For COPY FROM, each field in the file is inserted, in order, into the specified column. Table columns not specified in the COPY FROM column list will receive their default values.

COPY with a file name instructs the Postgres Pro server to directly read from or write to a file. The file must be accessible by the Postgres Pro user (the user ID the server runs as) and the name must be specified from the viewpoint of the server. When PROGRAM is specified, the server executes the given command and reads from the standard output of the program, or writes to the standard input of the program. The command must be specified from the viewpoint of the server, and be executable by the Postgres Pro user. When STDIN or STDOUT is specified, data is transmitted via the connection between the client and the server.

Each backend running COPY will report its progress in the `pg_stat_progress_copy` view. See [Section 27.4.3](#) for details.

By default, COPY will fail if it encounters an error during processing. For use cases where a best-effort attempt at loading the entire file is desired, the `ON_ERROR` clause can be used to specify some other behavior.

Parameters

table_name

The name (optionally schema-qualified) of an existing table.

column_name

An optional list of columns to be copied. If no column list is specified, all columns of the table except generated columns will be copied.

query

A `SELECT`, `VALUES`, `INSERT`, `UPDATE`, `DELETE`, or `MERGE` command whose results are to be copied. Note that parentheses are required around the query.

For `INSERT`, `UPDATE`, `DELETE`, and `MERGE` queries a `RETURNING` clause must be provided, and the target relation must not have a conditional rule, nor an `ALSO` rule, nor an `INSTEAD` rule that expands to multiple statements.

filename

The path name of the input or output file. An input file name can be an absolute or relative path, but an output file name must be an absolute path. Windows users might need to use an `E''` string and double any backslashes used in the path name.

PROGRAM

A command to execute. In `COPY FROM`, the input is read from standard output of the command, and in `COPY TO`, the output is written to the standard input of the command.

Note that the command is invoked by the shell, so if you need to pass any arguments that come from an untrusted source, you must be careful to strip or escape any special characters that might have a special meaning for the shell. For security reasons, it is best to use a fixed command string, or at least avoid including any user input in it.

STDIN

Specifies that input comes from the client application.

STDOUT

Specifies that output goes to the client application.

boolean

Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to disable it. The *boolean* value can also be omitted, in which case `TRUE` is assumed.

FORMAT

Selects the data format to be read or written: `text`, `csv` (Comma Separated Values), or `binary`. The default is `text`.

FREEZE

Requests copying the data with rows already frozen, just as they would be after running the `VACUUM FREEZE` command. This is intended as a performance option for initial data loading. Rows will be frozen only if the table being loaded has been created or truncated in the current subtransaction, there are no cursors open and there are no older snapshots held by this transaction. It is currently not possible to perform a `COPY FREEZE` on a partitioned table. This option is only allowed in `COPY FROM`.

Note that all other sessions will immediately be able to see the data once it has been successfully loaded. This violates the normal rules of MVCC visibility and users should be aware of the potential problems this might cause.

DELIMITER

Specifies the character that separates columns within each row (line) of the file. The default is a tab character in text format, a comma in CSV format. This must be a single one-byte character. This option is not allowed when using `binary` format.

NULL

Specifies the string that represents a null value. The default is `\N` (backslash-N) in text format, and an unquoted empty string in CSV format. You might prefer an empty string even in text format for cases where you don't want to distinguish nulls from empty strings. This option is not allowed when using `binary` format.

Note

When using `COPY FROM`, any data item that matches this string will be stored as a null value, so you should make sure that you use the same string as you used with `COPY TO`.

DEFAULT

Specifies the string that represents a default value. Each time the string is found in the input file, the default value of the corresponding column will be used. This option is allowed only in `COPY FROM`, and only when not using `binary` format.

HEADER

Specifies that the file contains a header line with the names of each column in the file. On output, the first line contains the column names from the table. On input, the first line is discarded when this option is set to `true` (or equivalent Boolean value). If this option is set to `MATCH`, the number and names of the columns in the header line must match the actual column names of the table, in order; otherwise an error is raised. This option is not allowed when using `binary` format. The `MATCH` option is only valid for `COPY FROM` commands.

QUOTE

Specifies the quoting character to be used when a data value is quoted. The default is double-quote. This must be a single one-byte character. This option is allowed only when using CSV format.

ESCAPE

Specifies the character that should appear before a data character that matches the `QUOTE` value. The default is the same as the `QUOTE` value (so that the quoting character is doubled if it appears in the data). This must be a single one-byte character. This option is allowed only when using CSV format.

FORCE_QUOTE

Forces quoting to be used for all non-NULL values in each specified column. NULL output is never quoted. If `*` is specified, non-NULL values will be quoted in all columns. This option is allowed only in `COPY TO`, and only when using CSV format.

FORCE_NOT_NULL

Do not match the specified columns' values against the null string. In the default case where the null string is empty, this means that empty values will be read as zero-length strings rather than nulls, even when they are not quoted. If `*` is specified, the option will be applied to all columns. This option is allowed only in `COPY FROM`, and only when using CSV format.

FORCE_NULL

Match the specified columns' values against the null string, even if it has been quoted, and if a match is found set the value to NULL. In the default case where the null string is empty, this converts a

quoted empty string into NULL. If `*` is specified, the option will be applied to all columns. This option is allowed only in `COPY FROM`, and only when using `CSV` format.

ON_ERROR

Specifies how to behave when encountering an error converting a column's input value into its data type. An *error_action* value of `stop` means fail the command, while `ignore` means discard the input row and continue with the next one. The default is `stop`.

The `ignore` option is applicable only for `COPY FROM` when the `FORMAT` is `text` or `csv`.

A `NOTICE` message containing the ignored row count is emitted at the end of the `COPY FROM` if at least one row was discarded. When `LOG_VERBOSITY` option is set to `verbose`, a `NOTICE` message containing the line of the input file and the column name whose input conversion has failed is emitted for each discarded row.

ENCODING

Specifies that the file is encoded in the *encoding_name*. If this option is omitted, the current client encoding is used. See the Notes below for more details.

LOG_VERBOSITY

Specify the amount of messages emitted by a `COPY` command: `default` or `verbose`. If `verbose` is specified, additional messages are emitted during processing.

This is currently used in `COPY FROM` command when `ON_ERROR` option is set to `ignore`.

WHERE

The optional `WHERE` clause has the general form

`WHERE condition`

where *condition* is any expression that evaluates to a result of type `boolean`. Any row that does not satisfy this condition will not be inserted to the table. A row satisfies the condition if it returns true when the actual row values are substituted for any variable references.

Currently, subqueries are not allowed in `WHERE` expressions, and the evaluation does not see any changes made by the `COPY` itself (this matters when the expression contains calls to `VOLATILE` functions).

Outputs

On successful completion, a `COPY` command returns a command tag of the form

`COPY count`

The *count* is the number of rows copied.

Note

psql will print this command tag only if the command was not `COPY ... TO STDOUT`, or the equivalent psql meta-command `\copy ... to stdout`. This is to prevent confusing the command tag with the data that was just printed.

Notes

`COPY TO` can be used only with plain tables, not views, and does not copy rows from child tables or child partitions. For example, `COPY table TO` copies the same rows as `SELECT * FROM ONLY table`. The syntax `COPY (SELECT * FROM table) TO ...` can be used to dump all of the rows in an inheritance hierarchy, partitioned table, or view.

`COPY FROM` can be used with plain, foreign, or partitioned tables or with views that have `INSTEAD OF INSERT` triggers.

You must have `select` privilege on the table whose values are read by `COPY TO`, and `insert` privilege on the table into which values are inserted by `COPY FROM`. It is sufficient to have column privileges on the column(s) listed in the command.

If row-level security is enabled for the table, the relevant `SELECT` policies will apply to `COPY table TO` statements. Currently, `COPY FROM` is not supported for tables with row-level security. Use equivalent `INSERT` statements instead.

Files named in a `COPY` command are read or written directly by the server, not by the client application. Therefore, they must reside on or be accessible to the database server machine, not the client. They must be accessible to and readable or writable by the Postgres Pro user (the user ID the server runs as), not the client. Similarly, the command specified with `PROGRAM` is executed directly by the server, not by the client application, must be executable by the Postgres Pro user. `COPY` naming a file or command is only allowed to database superusers or users who are granted one of the roles `pg_read_server_files`, `pg_write_server_files`, or `pg_execute_server_program`, since it allows reading or writing any file or running a program that the server has privileges to access.

Do not confuse `COPY` with the `psql` instruction `\copy`. `\copy` invokes `COPY FROM STDIN` or `COPY TO STDOUT`, and then fetches/stores the data in a file accessible to the `psql` client. Thus, file accessibility and access rights depend on the client rather than the server when `\copy` is used.

It is recommended that the file name used in `COPY` always be specified as an absolute path. This is enforced by the server in the case of `COPY TO`, but for `COPY FROM` you do have the option of reading from a file specified by a relative path. The path will be interpreted relative to the working directory of the server process (normally the cluster's data directory), not the client's working directory.

Executing a command with `PROGRAM` might be restricted by the operating system's access control mechanisms, such as SELinux.

`COPY FROM` will invoke any triggers and check constraints on the destination table. However, it will not invoke rules.

For identity columns, the `COPY FROM` command will always write the column values provided in the input data, like the `INSERT` option `OVERRIDING SYSTEM VALUE`.

`COPY` input and output is affected by `DateStyle`. To ensure portability to other Postgres Pro installations that might use non-default `DateStyle` settings, `DateStyle` should be set to `ISO` before using `COPY TO`. It is also a good idea to avoid dumping data with `IntervalStyle` set to `sql_standard`, because negative interval values might be misinterpreted by a server that has a different setting for `IntervalStyle`.

Input data is interpreted according to `ENCODING` option or the current client encoding, and output data is encoded in `ENCODING` or the current client encoding, even if the data does not pass through the client but is read from or written to a file directly by the server.

The `COPY FROM` command physically inserts input rows into the table as it progresses. If the command fails, these rows are left in a deleted state; these rows will not be visible, but still occupy disk space. This might amount to considerable wasted disk space if the failure happened well into a large copy operation. `VACUUM` should be used to recover the wasted space.

`FORCE_NULL` and `FORCE_NOT_NULL` can be used simultaneously on the same column. This results in converting quoted null strings to null values and unquoted null strings to empty strings.

Postgres Pro does not allow NUL bytes in data. If you are going to import such data using the `COPY FROM` command, you can specify an ASCII character in the [nul_byte_replacement_on_import](#) configuration parameter to replace NUL bytes on the fly.

File Formats

Text Format

When the `text` format is used, the data read or written is a text file with one line per table row. Columns in a row are separated by the delimiter character. The column values themselves are strings generated by the output function, or acceptable to the input function, of each attribute's data type. The specified null string is used in place of columns that are null. `COPY FROM` will raise an error if any line of the input file contains more or fewer columns than are expected.

End of data can be represented by a single line containing just backslash-period (`\.`). An end-of-data marker is not necessary when reading from a file, since the end of file serves perfectly well; it is needed only when copying data to or from client applications using pre-3.0 client protocol.

Backslash characters (`\`) can be used in the `COPY` data to quote data characters that might otherwise be taken as row or column delimiters. In particular, the following characters *must* be preceded by a backslash if they appear as part of a column value: backslash itself, newline, carriage return, and the current delimiter character.

The specified null string is sent by `COPY TO` without adding any backslashes; conversely, `COPY FROM` matches the input against the null string before removing backslashes. Therefore, a null string such as `\N` cannot be confused with the actual data value `\N` (which would be represented as `\\N`).

The following special backslash sequences are recognized by `COPY FROM`:

Sequence	Represents
<code>\b</code>	Backspace (ASCII 8)
<code>\f</code>	Form feed (ASCII 12)
<code>\n</code>	Newline (ASCII 10)
<code>\r</code>	Carriage return (ASCII 13)
<code>\t</code>	Tab (ASCII 9)
<code>\v</code>	Vertical tab (ASCII 11)
<code>\digits</code>	Backslash followed by one to three octal digits specifies the byte with that numeric code
<code>\xdigits</code>	Backslash <code>x</code> followed by one or two hex digits specifies the byte with that numeric code

Presently, `COPY TO` will never emit an octal or hex-digits backslash sequence, but it does use the other sequences listed above for those control characters.

Any other backslashed character that is not mentioned in the above table will be taken to represent itself. However, beware of adding backslashes unnecessarily, since that might accidentally produce a string matching the end-of-data marker (`\.`) or the null string (`\N` by default). These strings will be recognized before any other backslash processing is done.

It is strongly recommended that applications generating `COPY` data convert data newlines and carriage returns to the `\n` and `\r` sequences respectively. At present it is possible to represent a data carriage return by a backslash and carriage return, and to represent a data newline by a backslash and newline. However, these representations might not be accepted in future releases. They are also highly vulnerable to corruption if the `COPY` file is transferred across different machines (for example, from Unix to Windows or vice versa).

All backslash sequences are interpreted after encoding conversion. The bytes specified with the octal and hex-digit backslash sequences must form valid characters in the database encoding.

`COPY TO` will terminate each row with a Unix-style newline (`"\n"`). Servers running on Microsoft Windows instead output carriage return/newline (`"\r\n"`), but only for `COPY` to a server file; for consistency across

platforms, `COPY TO STDOUT` always sends “\n” regardless of server platform. `COPY FROM` can handle lines ending with newlines, carriage returns, or carriage return/newlines. To reduce the risk of error due to un-backslashed newlines or carriage returns that were meant as data, `COPY FROM` will complain if the line endings in the input are not all alike.

CSV Format

This format option is used for importing and exporting the Comma Separated Value (CSV) file format used by many other programs, such as spreadsheets. Instead of the escaping rules used by Postgres Pro's standard text format, it produces and recognizes the common CSV escaping mechanism.

The values in each record are separated by the `DELIMITER` character. If the value contains the delimiter character, the `QUOTE` character, the `NULL` string, a carriage return, or line feed character, then the whole value is prefixed and suffixed by the `QUOTE` character, and any occurrence within the value of a `QUOTE` character or the `ESCAPE` character is preceded by the escape character. You can also use `FORCE_QUOTE` to force quotes when outputting non-`NULL` values in specific columns.

The CSV format has no standard way to distinguish a `NULL` value from an empty string. Postgres Pro's `COPY` handles this by quoting. A `NULL` is output as the `NULL` parameter string and is not quoted, while a non-`NULL` value matching the `NULL` parameter string is quoted. For example, with the default settings, a `NULL` is written as an unquoted empty string, while an empty string data value is written with double quotes (“”). Reading values follows similar rules. You can use `FORCE_NOT_NULL` to prevent `NULL` input comparisons for specific columns. You can also use `FORCE_NULL` to convert quoted null string data values to `NULL`.

Because backslash is not a special character in the CSV format, `\.`, the end-of-data marker, could also appear as a data value. To avoid any misinterpretation, a `\.` data value appearing as a lone entry on a line is automatically quoted on output, and on input, if quoted, is not interpreted as the end-of-data marker. If you are loading a file created by another application that has a single unquoted column and might have a value of `\.`, you might need to quote that value in the input file.

Note

In CSV format, all characters are significant. A quoted value surrounded by white space, or any characters other than `DELIMITER`, will include those characters. This can cause errors if you import data from a system that pads CSV lines with white space out to some fixed width. If such a situation arises you might need to preprocess the CSV file to remove the trailing white space, before importing the data into Postgres Pro.

Note

CSV format will both recognize and produce CSV files with quoted values containing embedded carriage returns and line feeds. Thus the files are not strictly one line per table row like text-format files.

Note

Many programs produce strange and occasionally perverse CSV files, so the file format is more a convention than a standard. Thus you might encounter some files that cannot be imported using this mechanism, and `COPY` might produce files that other programs cannot process.

Binary Format

The `binary` format option causes all data to be stored/read as binary format rather than as text. It is somewhat faster than the text and CSV formats, but a binary-format file is less portable across machine

architectures and Postgres Pro versions. Also, the binary format is very data type specific; for example it will not work to output binary data from a `smallint` column and read it into an `integer` column, even though that would work fine in text format.

The `binary` file format consists of a file header, zero or more tuples containing the row data, and a file trailer. Headers and data are in network byte order.

Note

PostgreSQL releases before 7.4 used a different binary file format.

File Header

The file header consists of 15 bytes of fixed fields, followed by a variable-length header extension area. The fixed fields are:

Signature

11-byte sequence `PGCOPY\n\377\r\n\0` — note that the zero byte is a required part of the signature. (The signature is designed to allow easy identification of files that have been munged by a non-8-bit-clean transfer. This signature will be changed by end-of-line-translation filters, dropped zero bytes, dropped high bits, or parity changes.)

Flags field

32-bit integer bit mask to denote important aspects of the file format. Bits are numbered from 0 (LSB) to 31 (MSB). Note that this field is stored in network byte order (most significant byte first), as are all the integer fields used in the file format. Bits 16–31 are reserved to denote critical file format issues; a reader should abort if it finds an unexpected bit set in this range. Bits 0–15 are reserved to signal backwards-compatible format issues; a reader should simply ignore any unexpected bits set in this range. Currently only one flag bit is defined, and the rest must be zero:

Bit 16

If 1, OIDs are included in the data; if 0, not. Oid system columns are not supported in Postgres Pro anymore, but the format still contains the indicator.

Header extension area length

32-bit integer, length in bytes of remainder of header, not including self. Currently, this is zero, and the first tuple follows immediately. Future changes to the format might allow additional data to be present in the header. A reader should silently skip over any header extension data it does not know what to do with.

The header extension area is envisioned to contain a sequence of self-identifying chunks. The flags field is not intended to tell readers what is in the extension area. Specific design of header extension contents is left for a later release.

This design allows for both backwards-compatible header additions (add header extension chunks, or set low-order flag bits) and non-backwards-compatible changes (set high-order flag bits to signal such changes, and add supporting data to the extension area if needed).

Tuples

Each tuple begins with a 16-bit integer count of the number of fields in the tuple. (Presently, all tuples in a table will have the same count, but that might not always be true.) Then, repeated for each field in the tuple, there is a 32-bit length word followed by that many bytes of field data. (The length word does not include itself, and can be zero.) As a special case, -1 indicates a NULL field value. No value bytes follow in the NULL case.

There is no alignment padding or any other extra data between fields.

Presently, all data values in a binary-format file are assumed to be in binary format (format code one). It is anticipated that a future extension might add a header field that allows per-column format codes to be specified.

If OIDs are included in the file, the OID field immediately follows the field-count word. It is a normal field except that it's not included in the field-count. Note that oid system columns are not supported in current versions of Postgres Pro.

File Trailer

The file trailer consists of a 16-bit integer word containing -1. This is easily distinguished from a tuple's field-count word.

A reader should report an error if a field-count word is neither -1 nor the expected number of columns. This provides an extra check against somehow getting out of sync with the data.

Examples

The following example copies a table to the client using the vertical bar (|) as the field delimiter:

```
COPY country TO STDOUT (DELIMITER '|');
```

To copy data from a file into the `country` table:

```
COPY country FROM '/usr1/proj/bray/sql/country_data';
```

To copy into a file just the countries whose names start with 'A':

```
COPY (SELECT * FROM country WHERE country_name LIKE 'A%') TO '/usr1/proj/bray/sql/a_list_countries.copy';
```

To copy into a compressed file, you can pipe the output through an external compression program:

```
COPY country TO PROGRAM 'gzip > /usr1/proj/bray/sql/country_data.gz';
```

Here is a sample of data suitable for copying into a table from STDIN:

```
AF      AFGHANISTAN
AL      ALBANIA
DZ      ALGERIA
ZM      ZAMBIA
ZW      ZIMBABWE
```

Note that the white space on each line is actually a tab character.

The following is the same data, output in binary format. The data is shown after filtering through the Unix utility `od -c`. The table has three columns; the first has type `char(2)`, the second has type `text`, and the third has type `integer`. All the rows have a null value in the third column.

```
00000000  P   G   C   O   P   Y  \n 377  \r  \n  \0  \0  \0  \0  \0  \0
00000020  \0  \0  \0  \0  \0 003  \0  \0  \0 002  A   F  \0  \0  \0 013  A
00000040  F   G   H   A   N   I   S   T   A   N 377 377 377 377  \0 003
00000060  \0  \0  \0 002  A   L  \0  \0 007  A   L   B   A   N   I
00000100  A 377 377 377 377  \0 003  \0  \0  \0 002  D   Z  \0  \0  \0
00000120 007  A   L   G   E   R   I   A 377 377 377 377  \0 003  \0  \0
00000140  \0 002  Z   M  \0  \0  \0 006  Z   A   M   B   I   A 377 377
00000160 377 377  \0 003  \0  \0  \0 002  Z   W  \0  \0  \0  \b  Z   I
00000200  M   B   A   B   W   E 377 377 377 377 377 377
```

Compatibility

There is no `COPY` statement in the SQL standard.

The following syntax was used before PostgreSQL version 9.0 and is still supported:

```
COPY table_name [ ( column_name [, ...] ) ]
FROM { 'filename' | STDIN }
[ [ WITH ]
    [ BINARY ]
    [ DELIMITER [ AS ] 'delimiter_character' ]
    [ NULL [ AS ] 'null_string' ]
    [ CSV [ HEADER ]
        [ QUOTE [ AS ] 'quote_character' ]
        [ ESCAPE [ AS ] 'escape_character' ]
        [ FORCE NOT NULL column_name [, ...] ] ] ] ]

COPY { table_name [ ( column_name [, ...] ) ] | ( query ) }
TO { 'filename' | STDOUT }
[ [ WITH ]
    [ BINARY ]
    [ DELIMITER [ AS ] 'delimiter_character' ]
    [ NULL [ AS ] 'null_string' ]
    [ CSV [ HEADER ]
        [ QUOTE [ AS ] 'quote_character' ]
        [ ESCAPE [ AS ] 'escape_character' ]
        [ FORCE QUOTE { column_name [, ...] | * } ] ] ] ]
```

Note that in this syntax, **BINARY** and **CSV** are treated as independent keywords, not as arguments of a **FORMAT** option.

The following syntax was used before PostgreSQL version 7.3 and is still supported:

```
COPY [ BINARY ] table_name
FROM { 'filename' | STDIN }
[ [USING] DELIMITERS 'delimiter_character' ]
[ WITH NULL AS 'null_string' ]

COPY [ BINARY ] table_name
TO { 'filename' | STDOUT }
[ [USING] DELIMITERS 'delimiter_character' ]
[ WITH NULL AS 'null_string' ]
```

CREATE ACCESS METHOD

CREATE ACCESS METHOD — define a new access method

Synopsis

```
CREATE ACCESS METHOD name
    TYPE access_method_type
    HANDLER handler_function
```

Description

CREATE ACCESS METHOD creates a new access method.

The access method name must be unique within the database.

Only superusers can define new access methods.

Parameters

name

The name of the access method to be created.

access_method_type

This clause specifies the type of access method to define. Only TABLE and INDEX are supported at present.

handler_function

handler_function is the name (possibly schema-qualified) of a previously registered function that represents the access method. The handler function must be declared to take a single argument of type `internal`, and its return type depends on the type of access method; for TABLE access methods, it must be `table_am_handler` and for INDEX access methods, it must be `index_am_handler`. The C-level API that the handler function must implement varies depending on the type of access method. The table access method API is described in [Chapter 62](#) and the index access method API is described in [Chapter 63](#).

Examples

Create an index access method `heptree` with handler function `heptree_handler`:

```
CREATE ACCESS METHOD heptree TYPE INDEX HANDLER heptree_handler;
```

Compatibility

CREATE ACCESS METHOD is a Postgres Pro extension.

CREATE AGGREGATE

CREATE AGGREGATE — define a new aggregate function

Synopsis

```
CREATE [ OR REPLACE ] AGGREGATE name ( [ argmode ] [ argname ] arg_data_type
[ , ... ] ) (
    SFUNC = sfunc,
    STYPE = state_data_type
    [ , SSPACE = state_data_size ]
    [ , FINALFUNC = ffunc ]
    [ , FINALFUNC_EXTRA ]
    [ , FINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE } ]
    [ , COMBINEFUNC = combinefunc ]
    [ , SERIALFUNC = serialfunc ]
    [ , DESERIALFUNC = deserialfunc ]
    [ , INITCOND = initial_condition ]
    [ , MSFUNC = msfunc ]
    [ , MINVFUNC = minvfunc ]
    [ , MSTYPE = mstate_data_type ]
    [ , MSSPACE = mstate_data_size ]
    [ , MFINALFUNC = mffunc ]
    [ , MFINALFUNC_EXTRA ]
    [ , MFINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE } ]
    [ , MINITCOND = minitial_condition ]
    [ , SORTOP = sort_operator ]
    [ , PARALLEL = { SAFE | RESTRICTED | UNSAFE } ]
)
```

```
CREATE [ OR REPLACE ] AGGREGATE name ( [ [ argmode ] [ argname ] arg_data_type
[ , ... ] ]
                                ORDER BY [ argmode ] [ argname ] arg_data_type [ , ... ] ) (
    SFUNC = sfunc,
    STYPE = state_data_type
    [ , SSPACE = state_data_size ]
    [ , FINALFUNC = ffunc ]
    [ , FINALFUNC_EXTRA ]
    [ , FINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE } ]
    [ , INITCOND = initial_condition ]
    [ , PARALLEL = { SAFE | RESTRICTED | UNSAFE } ]
    [ , HYPOTHETICAL ]
)
```

or the old syntax

```
CREATE [ OR REPLACE ] AGGREGATE name (
    BASETYPE = base_type,
    SFUNC = sfunc,
    STYPE = state_data_type
    [ , SSPACE = state_data_size ]
    [ , FINALFUNC = ffunc ]
    [ , FINALFUNC_EXTRA ]
    [ , FINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE } ]
    [ , COMBINEFUNC = combinefunc ]
    [ , SERIALFUNC = serialfunc ]
)
```

```
[ , DESERIALFUNC = deserialfunc ]
[ , INITCOND = initial_condition ]
[ , MSFUNC = msfunc ]
[ , MINVFUNC = minvfunc ]

[ , MSSPACE = mstate_data_size ]
[ , MFINALFUNC = mffunc ]
[ , MFINALFUNC_EXTRA ]
[ , MFINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE } ]
[ , MINITCOND = minitial_condition ]
[ , SORTOP = sort_operator ]
)
```

Description

`CREATE AGGREGATE` defines a new aggregate function. `CREATE OR REPLACE AGGREGATE` will either define a new aggregate function or replace an existing definition. Some basic and commonly-used aggregate functions are included with the distribution; they are documented in [Section 9.21](#). If one defines new types or needs an aggregate function not already provided, then `CREATE AGGREGATE` can be used to provide the desired features.

When replacing an existing definition, the argument types, result type, and number of direct arguments may not be changed. Also, the new definition must be of the same kind (ordinary aggregate, ordered-set aggregate, or hypothetical-set aggregate) as the old one.

If a schema name is given (for example, `CREATE AGGREGATE myschema.myagg ...`) then the aggregate function is created in the specified schema. Otherwise it is created in the current schema.

An aggregate function is identified by its name and input data type(s). Two aggregates in the same schema can have the same name if they operate on different input types. The name and input data type(s) of an aggregate must also be distinct from the name and input data type(s) of every ordinary function in the same schema. This behavior is identical to overloading of ordinary function names (see [CREATE FUNCTION](#)).

A simple aggregate function is made from one or two ordinary functions: a state transition function *sfunc*, and an optional final calculation function *ffunc*. These are used as follows:

```
sfunc( internal-state, next-data-values ) ---> next-internal-state
ffunc( internal-state ) ---> aggregate-value
```

Postgres Pro creates a temporary variable of data type *stype* to hold the current internal state of the aggregate. At each input row, the aggregate argument value(s) are calculated and the state transition function is invoked with the current state value and the new argument value(s) to calculate a new internal state value. After all the rows have been processed, the final function is invoked once to calculate the aggregate's return value. If there is no final function then the ending state value is returned as-is.

An aggregate function can provide an initial condition, that is, an initial value for the internal state value. This is specified and stored in the database as a value of type `text`, but it must be a valid external representation of a constant of the state value data type. If it is not supplied then the state value starts out null.

If the state transition function is declared “strict”, then it cannot be called with null inputs. With such a transition function, aggregate execution behaves as follows. Rows with any null input values are ignored (the function is not called and the previous state value is retained). If the initial state value is null, then at the first row with all-nonnull input values, the first argument value replaces the state value, and the transition function is invoked at each subsequent row with all-nonnull input values. This is handy for implementing aggregates like `max`. Note that this behavior is only available when *state_data_type* is the same as the first *arg_data_type*. When these types are different, you must supply a nonnull initial condition or use a nonstrict transition function.

If the state transition function is not strict, then it will be called unconditionally at each input row, and must deal with null inputs and null state values for itself. This allows the aggregate author to have full control over the aggregate's handling of null values.

If the final function is declared “strict”, then it will not be called when the ending state value is null; instead a null result will be returned automatically. (Of course this is just the normal behavior of strict functions.) In any case the final function has the option of returning a null value. For example, the final function for `avg` returns null when it sees there were zero input rows.

Sometimes it is useful to declare the final function as taking not just the state value, but extra parameters corresponding to the aggregate's input values. The main reason for doing this is if the final function is polymorphic and the state value's data type would be inadequate to pin down the result type. These extra parameters are always passed as NULL (and so the final function must not be strict when the `FINALFUNC_EXTRA` option is used), but nonetheless they are valid parameters. The final function could for example make use of `get_fn_expr_argtype` to identify the actual argument type in the current call.

An aggregate can optionally support *moving-aggregate mode*, as described in [Section 39.12.1](#). This requires specifying the `MSFUNC`, `MINVFUNC`, and `MSTYPE` parameters, and optionally the `MSSPACE`, `MFINALFUNC`, `MFINALFUNC_EXTRA`, `MFINALFUNC_MODIFY`, and `MINITCOND` parameters. Except for `MINVFUNC`, these parameters work like the corresponding simple-aggregate parameters without `M`; they define a separate implementation of the aggregate that includes an inverse transition function.

The syntax with `ORDER BY` in the parameter list creates a special type of aggregate called an *ordered-set aggregate*; or if `HYPOTHETICAL` is specified, then a *hypothetical-set aggregate* is created. These aggregates operate over groups of sorted values in order-dependent ways, so that specification of an input sort order is an essential part of a call. Also, they can have *direct* arguments, which are arguments that are evaluated only once per aggregation rather than once per input row. Hypothetical-set aggregates are a subclass of ordered-set aggregates in which some of the direct arguments are required to match, in number and data types, the aggregated argument columns. This allows the values of those direct arguments to be added to the collection of aggregate-input rows as an additional “hypothetical” row.

An aggregate can optionally support *partial aggregation*, as described in [Section 39.12.4](#). This requires specifying the `COMBINEFUNC` parameter. If the `state_data_type` is `internal`, it's usually also appropriate to provide the `SERIALFUNC` and `DESERIALFUNC` parameters so that parallel aggregation is possible. Note that the aggregate must also be marked `PARALLEL SAFE` to enable parallel aggregation.

Aggregates that behave like `MIN` or `MAX` can sometimes be optimized by looking into an index instead of scanning every input row. If this aggregate can be so optimized, indicate it by specifying a *sort operator*. The basic requirement is that the aggregate must yield the first element in the sort ordering induced by the operator; in other words:

```
SELECT agg(col) FROM tab;
```

must be equivalent to:

```
SELECT col FROM tab ORDER BY col USING sortop LIMIT 1;
```

Further assumptions are that the aggregate ignores null inputs, and that it delivers a null result if and only if there were no non-null inputs. Ordinarily, a data type's `<` operator is the proper sort operator for `MIN`, and `>` is the proper sort operator for `MAX`. Note that the optimization will never actually take effect unless the specified operator is the “less than” or “greater than” strategy member of a B-tree index operator class.

To be able to create an aggregate function, you must have `USAGE` privilege on the argument types, the state type(s), and the return type, as well as `EXECUTE` privilege on the supporting functions.

Parameters

name

The name (optionally schema-qualified) of the aggregate function to create.

argmode

The mode of an argument: `IN` or `VARIADIC`. (Aggregate functions do not support `OUT` arguments.) If omitted, the default is `IN`. Only the last argument can be marked `VARIADIC`.

argname

The name of an argument. This is currently only useful for documentation purposes. If omitted, the argument has no name.

arg_data_type

An input data type on which this aggregate function operates. To create a zero-argument aggregate function, write `*` in place of the list of argument specifications. (An example of such an aggregate is `count(*)`.)

base_type

In the old syntax for `CREATE AGGREGATE`, the input data type is specified by a `basetype` parameter rather than being written next to the aggregate name. Note that this syntax allows only one input parameter. To define a zero-argument aggregate function with this syntax, specify the `basetype` as `"ANY"` (not `*`). Ordered-set aggregates cannot be defined with the old syntax.

sfunc

The name of the state transition function to be called for each input row. For a normal N -argument aggregate function, the *sfunc* must take $N+1$ arguments, the first being of type *state_data_type* and the rest matching the declared input data type(s) of the aggregate. The function must return a value of type *state_data_type*. This function takes the current state value and the current input data value(s), and returns the next state value.

For ordered-set (including hypothetical-set) aggregates, the state transition function receives only the current state value and the aggregated arguments, not the direct arguments. Otherwise it is the same.

state_data_type

The data type for the aggregate's state value.

state_data_size

The approximate average size (in bytes) of the aggregate's state value. If this parameter is omitted or is zero, a default estimate is used based on the *state_data_type*. The planner uses this value to estimate the memory required for a grouped aggregate query.

ffunc

The name of the final function called to compute the aggregate's result after all input rows have been traversed. For a normal aggregate, this function must take a single argument of type *state_data_type*. The return data type of the aggregate is defined as the return type of this function. If *ffunc* is not specified, then the ending state value is used as the aggregate's result, and the return type is *state_data_type*.

For ordered-set (including hypothetical-set) aggregates, the final function receives not only the final state value, but also the values of all the direct arguments.

If `FINALFUNC_EXTRA` is specified, then in addition to the final state value and any direct arguments, the final function receives extra `NULL` values corresponding to the aggregate's regular (aggregated) arguments. This is mainly useful to allow correct resolution of the aggregate result type when a polymorphic aggregate is being defined.

`FINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE }`

This option specifies whether the final function is a pure function that does not modify its arguments. `READ_ONLY` indicates it does not; the other two values indicate that it may change the transition state

value. See [Notes](#) below for more detail. The default is `READ_ONLY`, except for ordered-set aggregates, for which the default is `READ_WRITE`.

combinefunc

The *combinefunc* function may optionally be specified to allow the aggregate function to support partial aggregation. If provided, the *combinefunc* must combine two *state_data_type* values, each containing the result of aggregation over some subset of the input values, to produce a new *state_data_type* that represents the result of aggregating over both sets of inputs. This function can be thought of as an *sfunc*, where instead of acting upon an individual input row and adding it to the running aggregate state, it adds another aggregate state to the running state.

The *combinefunc* must be declared as taking two arguments of the *state_data_type* and returning a value of the *state_data_type*. Optionally this function may be “strict”. In this case the function will not be called when either of the input states are null; the other state will be taken as the correct result.

For aggregate functions whose *state_data_type* is *internal*, the *combinefunc* must not be strict. In this case the *combinefunc* must ensure that null states are handled correctly and that the state being returned is properly stored in the aggregate memory context.

serialfunc

An aggregate function whose *state_data_type* is *internal* can participate in parallel aggregation only if it has a *serialfunc* function, which must serialize the aggregate state into a *bytea* value for transmission to another process. This function must take a single argument of type *internal* and return type *bytea*. A corresponding *deserialfunc* is also required.

deserialfunc

Deserialize a previously serialized aggregate state back into *state_data_type*. This function must take two arguments of types *bytea* and *internal*, and produce a result of type *internal*. (Note: the second, *internal* argument is unused, but is required for type safety reasons.)

initial_condition

The initial setting for the state value. This must be a string constant in the form accepted for the data type *state_data_type*. If not specified, the state value starts out null.

msfunc

The name of the forward state transition function to be called for each input row in moving-aggregate mode. This is exactly like the regular transition function, except that its first argument and result are of type *mstate_data_type*, which might be different from *state_data_type*.

minvfunc

The name of the inverse state transition function to be used in moving-aggregate mode. This function has the same argument and result types as *msfunc*, but it is used to remove a value from the current aggregate state, rather than add a value to it. The inverse transition function must have the same strictness attribute as the forward state transition function.

mstate_data_type

The data type for the aggregate's state value, when using moving-aggregate mode.

mstate_data_size

The approximate average size (in bytes) of the aggregate's state value, when using moving-aggregate mode. This works the same as *state_data_size*.

mffunc

The name of the final function called to compute the aggregate's result after all input rows have been traversed, when using moving-aggregate mode. This works the same as *ffunc*, except that

its first argument's type is `mstate_data_type` and extra dummy arguments are specified by writing `MFINALFUNC_EXTRA`. The aggregate result type determined by `mffunc` or `mstate_data_type` must match that determined by the aggregate's regular implementation.

`MFINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE }`

This option is like `FINALFUNC_MODIFY`, but it describes the behavior of the moving-aggregate final function.

minitial_condition

The initial setting for the state value, when using moving-aggregate mode. This works the same as *initial_condition*.

sort_operator

The associated sort operator for a `MIN`- or `MAX`-like aggregate. This is just an operator name (possibly schema-qualified). The operator is assumed to have the same input data types as the aggregate (which must be a single-argument normal aggregate).

`PARALLEL = { SAFE | RESTRICTED | UNSAFE }`

The meanings of `PARALLEL SAFE`, `PARALLEL RESTRICTED`, and `PARALLEL UNSAFE` are the same as in [CREATE FUNCTION](#). An aggregate will not be considered for parallelization if it is marked `PARALLEL UNSAFE` (which is the default!) or `PARALLEL RESTRICTED`. Note that the parallel-safety markings of the aggregate's support functions are not consulted by the planner, only the marking of the aggregate itself.

`HYPOTHETICAL`

For ordered-set aggregates only, this flag specifies that the aggregate arguments are to be processed according to the requirements for hypothetical-set aggregates: that is, the last few direct arguments must match the data types of the aggregated (`WITHIN GROUP`) arguments. The `HYPOTHETICAL` flag has no effect on run-time behavior, only on parse-time resolution of the data types and collations of the aggregate's arguments.

The parameters of `CREATE AGGREGATE` can be written in any order, not just the order illustrated above.

Notes

In parameters that specify support function names, you can write a schema name if needed, for example `SFUNC = public.sum`. Do not write argument types there, however — the argument types of the support functions are determined from other parameters.

Ordinarily, Postgres Pro functions are expected to be true functions that do not modify their input values. However, an aggregate transition function, *when used in the context of an aggregate*, is allowed to cheat and modify its transition-state argument in place. This can provide substantial performance benefits compared to making a fresh copy of the transition state each time.

Likewise, while an aggregate final function is normally expected not to modify its input values, sometimes it is impractical to avoid modifying the transition-state argument. Such behavior must be declared using the `FINALFUNC_MODIFY` parameter. The `READ_WRITE` value indicates that the final function modifies the transition state in unspecified ways. This value prevents use of the aggregate as a window function, and it also prevents merging of transition states for aggregate calls that share the same input values and transition functions. The `SHAREABLE` value indicates that the transition function cannot be applied after the final function, but multiple final-function calls can be performed on the ending transition state value. This value prevents use of the aggregate as a window function, but it allows merging of transition states. (That is, the optimization of interest here is not applying the same final function repeatedly, but applying different final functions to the same ending transition state value. This is allowed as long as none of the final functions are marked `READ_WRITE`.)

If an aggregate supports moving-aggregate mode, it will improve calculation efficiency when the aggregate is used as a window function for a window with moving frame start (that is, a frame start mode other

than `UNBOUNDED PRECEDING`). Conceptually, the forward transition function adds input values to the aggregate's state when they enter the window frame from the bottom, and the inverse transition function removes them again when they leave the frame at the top. So, when values are removed, they are always removed in the same order they were added. Whenever the inverse transition function is invoked, it will thus receive the earliest added but not yet removed argument value(s). The inverse transition function can assume that at least one row will remain in the current state after it removes the oldest row. (When this would not be the case, the window function mechanism simply starts a fresh aggregation, rather than using the inverse transition function.)

The forward transition function for moving-aggregate mode is not allowed to return `NULL` as the new state value. If the inverse transition function returns `NULL`, this is taken as an indication that the inverse function cannot reverse the state calculation for this particular input, and so the aggregate calculation will be redone from scratch for the current frame starting position. This convention allows moving-aggregate mode to be used in situations where there are some infrequent cases that are impractical to reverse out of the running state value.

If no moving-aggregate implementation is supplied, the aggregate can still be used with moving frames, but Postgres Pro will recompute the whole aggregation whenever the start of the frame moves. Note that whether or not the aggregate supports moving-aggregate mode, Postgres Pro can handle a moving frame end without recalculation; this is done by continuing to add new values to the aggregate's state. This is why use of an aggregate as a window function requires that the final function be read-only: it must not damage the aggregate's state value, so that the aggregation can be continued even after an aggregate result value has been obtained for one set of frame boundaries.

The syntax for ordered-set aggregates allows `VARIADIC` to be specified for both the last direct parameter and the last aggregated (`WITHIN GROUP`) parameter. However, the current implementation restricts use of `VARIADIC` in two ways. First, ordered-set aggregates can only use `VARIADIC "any"`, not other variadic array types. Second, if the last direct parameter is `VARIADIC "any"`, then there can be only one aggregated parameter and it must also be `VARIADIC "any"`. (In the representation used in the system catalogs, these two parameters are merged into a single `VARIADIC "any"` item, since `pg_proc` cannot represent functions with more than one `VARIADIC` parameter.) If the aggregate is a hypothetical-set aggregate, the direct arguments that match the `VARIADIC "any"` parameter are the hypothetical ones; any preceding parameters represent additional direct arguments that are not constrained to match the aggregated arguments.

Currently, ordered-set aggregates do not need to support moving-aggregate mode, since they cannot be used as window functions.

Partial (including parallel) aggregation is currently not supported for ordered-set aggregates. Also, it will never be used for aggregate calls that include `DISTINCT` or `ORDER BY` clauses, since those semantics cannot be supported during partial aggregation.

Examples

See [Section 39.12](#).

Compatibility

`CREATE AGGREGATE` is a Postgres Pro language extension. The SQL standard does not provide for user-defined aggregate functions.

[ALTER AGGREGATE](#), [DROP AGGREGATE](#)

CREATE CAST

CREATE CAST — define a new cast

Synopsis

```
CREATE CAST (source_type AS target_type)
  WITH FUNCTION function_name [ (argument_type [, ...]) ]
  [ AS ASSIGNMENT | AS IMPLICIT ]
```

```
CREATE CAST (source_type AS target_type)
  WITHOUT FUNCTION
  [ AS ASSIGNMENT | AS IMPLICIT ]
```

```
CREATE CAST (source_type AS target_type)
  WITH INOUT
  [ AS ASSIGNMENT | AS IMPLICIT ]
```

Description

CREATE CAST defines a new cast. A cast specifies how to perform a conversion between two data types. For example,

```
SELECT CAST(42 AS float8);
```

converts the integer constant 42 to type `float8` by invoking a previously specified function, in this case `float8(int4)`. (If no suitable cast has been defined, the conversion fails.)

Two types can be *binary coercible*, which means that the conversion can be performed “for free” without invoking any function. This requires that corresponding values use the same internal representation. For instance, the types `text` and `varchar` are binary coercible both ways. Binary coercibility is not necessarily a symmetric relationship. For example, the cast from `xml` to `text` can be performed for free in the present implementation, but the reverse direction requires a function that performs at least a syntax check. (Two types that are binary coercible both ways are also referred to as binary compatible.)

You can define a cast as an *I/O conversion cast* by using the `WITH INOUT` syntax. An I/O conversion cast is performed by invoking the output function of the source data type, and passing the resulting string to the input function of the target data type. In many common cases, this feature avoids the need to write a separate cast function for conversion. An I/O conversion cast acts the same as a regular function-based cast; only the implementation is different.

By default, a cast can be invoked only by an explicit cast request, that is an explicit `CAST(x AS typename)` or `x::typename` construct.

If the cast is marked `AS ASSIGNMENT` then it can be invoked implicitly when assigning a value to a column of the target data type. For example, supposing that `foo.f1` is a column of type `text`, then:

```
INSERT INTO foo (f1) VALUES (42);
```

will be allowed if the cast from type `integer` to type `text` is marked `AS ASSIGNMENT`, otherwise not. (We generally use the term *assignment cast* to describe this kind of cast.)

If the cast is marked `AS IMPLICIT` then it can be invoked implicitly in any context, whether assignment or internally in an expression. (We generally use the term *implicit cast* to describe this kind of cast.) For example, consider this query:

```
SELECT 2 + 4.0;
```

The parser initially marks the constants as being of type `integer` and `numeric` respectively. There is no `integer + numeric` operator in the system catalogs, but there is a `numeric + numeric` operator. The

query will therefore succeed if a cast from `integer` to `numeric` is available and is marked `AS IMPLICIT` — which in fact it is. The parser will apply the implicit cast and resolve the query as if it had been written

```
SELECT CAST ( 2 AS numeric ) + 4.0;
```

Now, the catalogs also provide a cast from `numeric` to `integer`. If that cast were marked `AS IMPLICIT` — which it is not — then the parser would be faced with choosing between the above interpretation and the alternative of casting the `numeric` constant to `integer` and applying the `integer + integer` operator. Lacking any knowledge of which choice to prefer, it would give up and declare the query ambiguous. The fact that only one of the two casts is implicit is the way in which we teach the parser to prefer resolution of a mixed `numeric-and-integer` expression as `numeric`; there is no built-in knowledge about that.

It is wise to be conservative about marking casts as implicit. An overabundance of implicit casting paths can cause Postgres Pro to choose surprising interpretations of commands, or to be unable to resolve commands at all because there are multiple possible interpretations. A good rule of thumb is to make a cast implicitly invocable only for information-preserving transformations between types in the same general type category. For example, the cast from `int2` to `int4` can reasonably be implicit, but the cast from `float8` to `int4` should probably be assignment-only. Cross-type-category casts, such as `text` to `int4`, are best made explicit-only.

Note

Sometimes it is necessary for usability or standards-compliance reasons to provide multiple implicit casts among a set of types, resulting in ambiguity that cannot be avoided as above. The parser has a fallback heuristic based on *type categories* and *preferred types* that can help to provide desired behavior in such cases. See [CREATE TYPE](#) for more information.

To be able to create a cast, you must own the source or the target data type and have `USAGE` privilege on the other type. To create a binary-coercible cast, you must be superuser. (This restriction is made because an erroneous binary-coercible cast conversion can easily crash the server.)

Parameters

source_type

The name of the source data type of the cast.

target_type

The name of the target data type of the cast.

function_name[(*argument_type* [, ...])]

The function used to perform the cast. The function name can be schema-qualified. If it is not, the function will be looked up in the schema search path. The function's result data type must match the target type of the cast. Its arguments are discussed below. If no argument list is specified, the function name must be unique in its schema.

`WITHOUT FUNCTION`

Indicates that the source type is binary-coercible to the target type, so no function is required to perform the cast.

`WITH INOUT`

Indicates that the cast is an I/O conversion cast, performed by invoking the output function of the source data type, and passing the resulting string to the input function of the target data type.

`AS ASSIGNMENT`

Indicates that the cast can be invoked implicitly in assignment contexts.

AS IMPLICIT

Indicates that the cast can be invoked implicitly in any context.

Cast implementation functions can have one to three arguments. The first argument type must be identical to or binary-coercible from the cast's source type. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or `-1` if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise. (Bizarrely, the SQL standard demands different behaviors for explicit and implicit casts in some cases. This argument is supplied for functions that must implement such casts. It is not recommended that you design your own data types so that this matters.)

The return type of a cast function must be identical to or binary-coercible to the cast's target type.

Ordinarily a cast must have different source and target data types. However, it is allowed to declare a cast with identical source and target types if it has a cast implementation function with more than one argument. This is used to represent type-specific length coercion functions in the system catalogs. The named function is used to coerce a value of the type to the type modifier value given by its second argument.

When a cast has different source and target types and a function that takes more than one argument, it supports converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two cast steps, one to convert between data types and a second to apply the modifier.

A cast to or from a domain type currently has no effect. Casting to or from a domain uses the casts associated with its underlying type.

Notes

Use `DROP CAST` to remove user-defined casts.

Remember that if you want to be able to convert types both ways you need to declare casts both ways explicitly.

It is normally not necessary to create casts between user-defined types and the standard string types (`text`, `varchar`, and `char(n)`, as well as user-defined types that are defined to be in the string category). Postgres Pro provides automatic I/O conversion casts for that. The automatic casts to string types are treated as assignment casts, while the automatic casts from string types are explicit-only. You can override this behavior by declaring your own cast to replace an automatic cast, but usually the only reason to do so is if you want the conversion to be more easily invocable than the standard assignment-only or explicit-only setting. Another possible reason is that you want the conversion to behave differently from the type's I/O function; but that is sufficiently surprising that you should think twice about whether it's a good idea. (A small number of the built-in types do indeed have different behaviors for conversions, mostly because of requirements of the SQL standard.)

While not required, it is recommended that you continue to follow this old convention of naming cast implementation functions after the target data type. Many users are used to being able to cast data types using a function-style notation, that is `typename(x)`. This notation is in fact nothing more nor less than a call of the cast implementation function; it is not specially treated as a cast. If your conversion functions are not named to support this convention then you will have surprised users. Since Postgres Pro allows overloading of the same function name with different argument types, there is no difficulty in having multiple conversion functions from different types that all use the target type's name.

Note

Actually the preceding paragraph is an oversimplification: there are two cases in which a function-call construct will be treated as a cast request without having matched it to an actual function. If a function call `name(x)` does not exactly match any existing function, but `name` is the name of a

data type and `pg_cast` provides a binary-coercible cast to this type from the type of `x`, then the call will be construed as a binary-coercible cast. This exception is made so that binary-coercible casts can be invoked using functional syntax, even though they lack any function. Likewise, if there is no `pg_cast` entry but the cast would be to or from a string type, the call will be construed as an I/O conversion cast. This exception allows I/O conversion casts to be invoked using functional syntax.

Note

There is also an exception to the exception: I/O conversion casts from composite types to string types cannot be invoked using functional syntax, but must be written in explicit cast syntax (either `CAST` or `::` notation). This exception was added because after the introduction of automatically-provided I/O conversion casts, it was found too easy to accidentally invoke such a cast when a function or column reference was intended.

Examples

To create an assignment cast from type `bigint` to type `int4` using the function `int4(bigint)`:

```
CREATE CAST (bigint AS int4) WITH FUNCTION int4(bigint) AS ASSIGNMENT;
```

(This cast is already predefined in the system.)

Compatibility

The `CREATE CAST` command conforms to the SQL standard, except that SQL does not make provisions for binary-coercible types or extra arguments to implementation functions. `AS IMPLICIT` is a PostgreSQL extension, too.

[CREATE FUNCTION](#), [CREATE TYPE](#), [DROP CAST](#)

CREATE COLLATION

CREATE COLLATION — define a new collation

Synopsis

```
CREATE COLLATION [ IF NOT EXISTS ] name (  
    [ LOCALE = locale, ]  
    [ LC_COLLATE = lc_collate, ]  
    [ LC_CTYPE = lc_ctype, ]  
    [ PROVIDER = provider, ]  
    [ DETERMINISTIC = boolean, ]  
    [ RULES = rules, ]  
    [ VERSION = version ]  
)  
CREATE COLLATION [ IF NOT EXISTS ] name FROM existing_collation
```

Description

CREATE COLLATION defines a new collation using the specified operating system locale settings, or by copying an existing collation.

To be able to create a collation, you must have CREATE privilege on the destination schema.

Parameters

IF NOT EXISTS

Do not throw an error if a collation with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing collation is anything like the one that would have been created.

name

The name of the collation. The collation name can be schema-qualified. If it is not, the collation is defined in the current schema. The collation name must be unique within that schema. (The system catalogs can contain collations with the same name for other encodings, but these are ignored if the database encoding does not match.)

locale

The locale name for this collation. See [Section 23.2.2.3.1](#) and [Section 23.2.2.3.2](#) for details.

If *provider* is `libc`, this is a shortcut for setting `LC_COLLATE` and `LC_CTYPE` at once. If you specify *locale*, you cannot specify either of those parameters.

If *provider* is `builtin`, then *locale* must be specified and set to either `C` or `C.UTF-8`.

lc_collate

If *provider* is `libc`, use the specified operating system locale for the `LC_COLLATE` locale category.

lc_ctype

If *provider* is `libc`, use the specified operating system locale for the `LC_CTYPE` locale category.

provider

Specifies the provider to use for locale services associated with this collation. Possible values are `builtin`, `icu` (if the server was built with ICU support) or `libc`. `libc` is the default. See [Section 23.1.4](#) for details.

DETERMINISTIC

Specifies whether the collation should use deterministic comparisons. The default is true. A deterministic comparison considers strings that are not byte-wise equal to be unequal even if they are considered logically equal by the comparison. Postgres Pro breaks ties using a byte-wise comparison. Comparison that is not deterministic can make the collation be, say, case- or accent-insensitive. For that, you need to choose an appropriate `LOCALE` setting *and* set the collation to not deterministic here.

Nondeterministic collations are only supported with the ICU provider.

rules

Specifies additional collation rules to customize the behavior of the collation. This is supported for ICU only. See [Section 23.2.3.4](#) for details.

version

Specifies the version string to store with the collation. Normally, this should be omitted, which will cause the version to be computed from the actual version of the collation as provided by the operating system. This option is intended to be used by `pg_upgrade` for copying the version from an existing installation.

See also [ALTER COLLATION](#) for how to handle collation version mismatches.

existing_collation

The name of an existing collation to copy. The new collation will have the same properties as the existing one, but it will be an independent object.

Notes

`CREATE COLLATION` takes a `SHARE ROW EXCLUSIVE` lock, which is self-conflicting, on the `pg_collation` system catalog, so only one `CREATE COLLATION` command can run at a time.

Use `DROP COLLATION` to remove user-defined collations.

See [Section 23.2.2.3](#) for more information on how to create collations.

When using the `libc` collation provider, the locale must be applicable to the current database encoding. See [CREATE DATABASE](#) for the precise rules.

Examples

To create a collation from the operating system locale `ru_RU.utf8` (assuming the current database encoding is UTF8):

```
CREATE COLLATION russian (locale = 'ru_RU.utf8');
```

To create a collation using the ICU provider where Latin characters precede Cyrillic ones:

```
CREATE COLLATION latn_cyrl (provider = icu, locale = 'ru-RU-u-kr-latn-cyrl');
```

To create a collation using the ICU provider, based on the root ICU locale, with custom rules:

```
CREATE COLLATION custom (provider = icu, locale = 'und', rules = '&V << w <<< W');
```

See [Section 23.2.3.4](#) for further details and examples on the rules syntax.

To create a collation from an existing collation:

```
CREATE COLLATION german FROM "de_DE";
```

This can be convenient to be able to use operating-system-independent collation names in applications.

Compatibility

There is a `CREATE COLLATION` statement in the SQL standard, but it is limited to copying an existing collation. The syntax to create a new collation is a Postgres Pro extension.

See Also

[ALTER COLLATION](#), [DROP COLLATION](#)

CREATE CONVERSION

CREATE CONVERSION — define a new encoding conversion

Synopsis

```
CREATE [ DEFAULT ] CONVERSION name
    FOR source_encoding TO dest_encoding FROM function_name
```

Description

CREATE CONVERSION defines a new conversion between two character set encodings.

Conversions that are marked `DEFAULT` can be used for automatic encoding conversion between client and server. To support that usage, two conversions, from encoding A to B *and* from encoding B to A, must be defined.

To be able to create a conversion, you must have `EXECUTE` privilege on the function and `CREATE` privilege on the destination schema.

Parameters

DEFAULT

The `DEFAULT` clause indicates that this conversion is the default for this particular source to destination encoding. There should be only one default encoding in a schema for the encoding pair.

name

The name of the conversion. The conversion name can be schema-qualified. If it is not, the conversion is defined in the current schema. The conversion name must be unique within a schema.

source_encoding

The source encoding name.

dest_encoding

The destination encoding name.

function_name

The function used to perform the conversion. The function name can be schema-qualified. If it is not, the function will be looked up in the path.

The function must have the following signature:

```
conv_proc (
    integer,  -- source encoding ID
    integer,  -- destination encoding ID
    cstring,  -- source string (null terminated C string)
    internal, -- destination (fill with a null terminated C string)
    integer,  -- source string length
    boolean   -- if true, don't throw an error if conversion fails
) RETURNS integer;
```

The return value is the number of source bytes that were successfully converted. If the last argument is false, the function must throw an error on invalid input, and the return value is always equal to the source string length.

Notes

Neither the source nor the destination encoding can be `SQL_ASCII`, as the server's behavior for cases involving the `SQL_ASCII` “encoding” is hard-wired.

Use `DROP CONVERSION` to remove user-defined conversions.

The privileges required to create a conversion might be changed in a future release.

Examples

To create a conversion from encoding `UTF8` to `LATIN1` using `myfunc`:

```
CREATE CONVERSION myconv FOR 'UTF8' TO 'LATIN1' FROM myfunc;
```

Compatibility

`CREATE CONVERSION` is a Postgres Pro extension. There is no `CREATE CONVERSION` statement in the SQL standard, but a `CREATE TRANSLATION` statement that is very similar in purpose and syntax.

See Also

[ALTER CONVERSION](#), [CREATE FUNCTION](#), [DROP CONVERSION](#)

CREATE DATABASE

CREATE DATABASE — create a new database

Synopsis

```
CREATE DATABASE name
    [ WITH ] [ OWNER [=] user_name ]
    [ TEMPLATE [=] template ]
    [ ENCODING [=] encoding ]
    [ STRATEGY [=] strategy ]
    [ LOCALE [=] locale ]
    [ LC_COLLATE [=] lc_collate ]
    [ LC_CTYPE [=] lc_ctype ]
    [ BUILTIN_LOCALE [=] builtin_locale ]
    [ ICU_LOCALE [=] icu_locale ]
    [ ICU_RULES [=] icu_rules ]
    [ LOCALE_PROVIDER [=] locale_provider ]
    [ COLLATION_VERSION = collation_version ]
    [ TABLESPACE [=] tablespace_name ]
    [ ALLOW_CONNECTIONS [=] allowconn ]
    [ CONNECTION LIMIT [=] conlimit ]
    [ IS_TEMPLATE [=] istemplate ]
    [ OID [=] oid ]
```

Description

CREATE DATABASE creates a new Postgres Pro database.

To create a database, you must be a superuser or have the special `CREATEDB` privilege. See [CREATE ROLE](#).

By default, the new database will be created by cloning the standard system database `template1`. A different template can be specified by writing `TEMPLATE name`. In particular, by writing `TEMPLATE template0`, you can create a pristine database (one where no user-defined objects exist and where the system objects have not been altered) containing only the standard objects predefined by your version of Postgres Pro. This is useful if you wish to avoid copying any installation-local objects that might have been added to `template1`.

Parameters

name

The name of a database to create.

user_name

The role name of the user who will own the new database, or `DEFAULT` to use the default (namely, the user executing the command). To create a database owned by another role, you must be able to `SET ROLE` to that role.

template

The name of the template from which to create the new database, or `DEFAULT` to use the default template (`template1`).

encoding

Character set encoding to use in the new database. Specify a string constant (e.g., `'SQL_ASCII'`), or an integer encoding number, or `DEFAULT` to use the default encoding (namely, the encoding of

the template database). The character sets supported by the Postgres Pro server are described in [Section 23.3.1](#). See below for additional restrictions.

strategy

Strategy to be used in creating the new database. If the `WAL_LOG` strategy is used, the database will be copied block by block and each block will be separately written to the write-ahead log. This is the most efficient strategy in cases where the template database is small, and therefore it is the default. The older `FILE_COPY` strategy is also available. This strategy writes a small record to the write-ahead log for each tablespace used by the target database. Each such record represents copying an entire directory to a new location at the filesystem level. While this does reduce the write-ahead log volume substantially, especially if the template database is large, it also forces the system to perform a checkpoint both before and after the creation of the new database. In some situations, this may have a noticeable negative impact on overall system performance.

locale

Sets the default collation order and character classification in the new database. Collation affects the sort order applied to strings, e.g., in queries with `ORDER BY`, as well as the order used in indexes on text columns. Character classification affects the categorization of characters, e.g., lower, upper, and digit. Also sets the associated aspects of the operating system environment, `LC_COLLATE` and `LC_CTYPE`. The default is the same setting as the template database. See [Section 23.2.2.3.1](#) and [Section 23.2.2.3.2](#) for details.

Can be overridden by setting `lc_collate`, `lc_ctype`, `builtin_locale`, or `icu_locale` individually.

If `locale_provider` is `builtin`, then `locale` or `builtin_locale` must be specified and set to either `C` or `C.UTF-8`.

Tip

The other locale settings `lc_messages`, `lc_monetary`, `lc_numeric`, and `lc_time` are not fixed per database and are not set by this command. If you want to make them the default for a specific database, you can use `ALTER DATABASE ... SET`.

lc_collate

Sets `LC_COLLATE` in the database server's operating system environment. The default is the setting of `locale` if specified, otherwise the same setting as the template database. See below for additional restrictions.

If `locale_provider` is `libc`, also sets the default collation order to use in the new database, overriding the setting `locale`.

lc_ctype

Sets `LC_CTYPE` in the database server's operating system environment. The default is the setting of `locale` if specified, otherwise the same setting as the template database. See below for additional restrictions.

If `locale_provider` is `libc`, also sets the default character classification to use in the new database, overriding the setting `locale`.

builtin_locale

Specifies the builtin provider locale for the database default collation order and character classification, overriding the setting `locale`. The `locale provider` must be `builtin`. The default is the setting of `locale` if specified; otherwise the same setting as the template database.

The locales available for the `builtin` provider are `C` and `C.UTF-8`.

icu_locale

Specifies the ICU locale (see [Section 23.2.2.3.2](#)) for the database default collation order and character classification, overriding the setting *locale*. The *locale provider* must be ICU. The default is the setting of *locale* if specified; otherwise the same setting as the template database.

icu_rules

Specifies additional collation rules to customize the behavior of the default collation of this database. This is supported for ICU only. See [Section 23.2.3.4](#) for details.

locale_provider

Specifies the provider to use for the default collation in this database. Possible values are *builtin*, *icu* (if the server was built with ICU support) or *libc*. By default, the provider is the same as that of the *template*. See [Section 23.1.4](#) for details.

collation_version

Specifies the collation version string to store with the database. Normally, this should be omitted, which will cause the version to be computed from the actual version of the database collation as provided by the operating system. This option is intended to be used by *pg_upgrade* for copying the version from an existing installation.

See also [ALTER DATABASE](#) for how to handle database collation version mismatches.

tablespace_name

The name of the tablespace that will be associated with the new database, or *DEFAULT* to use the template database's tablespace. This tablespace will be the default tablespace used for objects created in this database. See [CREATE TABLESPACE](#) for more information.

allowconn

If false then no one can connect to this database. The default is true, allowing connections (except as restricted by other mechanisms, such as *GRANT/REVOKE CONNECT*).

connlimit

How many concurrent connections can be made to this database. -1 (the default) means no limit.

istemplate

If true, then this database can be cloned by any user with *CREATEDB* privileges; if false (the default), then only superusers or the owner of the database can clone it.

oid

The object identifier to be used for the new database. If this parameter is not specified, Postgres Pro will choose a suitable OID automatically. This parameter is primarily intended for internal use by *pg_upgrade*, and only *pg_upgrade* can specify a value less than 16384.

Optional parameters can be written in any order, not only the order illustrated above.

Notes

CREATE DATABASE cannot be executed inside a transaction block.

Errors along the line of “could not initialize database directory” are most likely related to insufficient permissions on the data directory, a full disk, or other file system problems.

Use [DROP DATABASE](#) to remove a database.

The program `createdb` is a wrapper program around this command, provided for convenience.

Database-level configuration parameters (set via `ALTER DATABASE`) and database-level permissions (set via `GRANT`) are not copied from the template database.

Although it is possible to copy a database other than `template1` by specifying its name as the template, this is not (yet) intended as a general-purpose “COPY DATABASE” facility. The principal limitation is that no other sessions can be connected to the template database while it is being copied. `CREATE DATABASE` will fail if any other connection exists when it starts; otherwise, new connections to the template database are locked out until `CREATE DATABASE` completes. See [Section 22.4](#) for more information.

The character set encoding specified for the new database must be compatible with the chosen locale settings (`LC_COLLATE` and `LC_CTYPE`). If the locale is `C` (or equivalently `POSIX`), then all encodings are allowed, but for other locale settings there is only one encoding that will work properly. (On Windows, however, UTF-8 encoding can be used with any locale.) `CREATE DATABASE` will allow superusers to specify `SQL_ASCII` encoding regardless of the locale settings, but this choice is deprecated and may result in misbehavior of character-string functions if data that is not encoding-compatible with the locale is stored in the database.

The encoding and locale settings must match those of the template database, except when `template0` is used as template. This is because other databases might contain data that does not match the specified encoding, or might contain indexes whose sort ordering is affected by `LC_COLLATE` and `LC_CTYPE`. Copying such data would result in a database that is corrupt according to the new settings. `template0`, however, is known to not contain any data or indexes that would be affected.

There is currently no option to use a database locale with nondeterministic comparisons (see [CREATE COLLATION](#) for an explanation). If this is needed, then per-column collations would need to be used.

The `CONNECTION LIMIT` option is only enforced approximately; if two new sessions start at about the same time when just one connection “slot” remains for the database, it is possible that both will fail. Also, the limit is not enforced against superusers or background worker processes.

Examples

To create a new database:

```
CREATE DATABASE lusiadas;
```

To create a database `sales` owned by user `salesapp` with a default tablespace of `salesspace`:

```
CREATE DATABASE sales OWNER salesapp TABLESPACE salesspace;
```

To create a database `music` with a different locale:

```
CREATE DATABASE music
    LOCALE 'sv_SE.utf8'
    TEMPLATE template0;
```

In this example, the `TEMPLATE template0` clause is required if the specified locale is different from the one in `template1`. (If it is not, then specifying the locale explicitly is redundant.)

To create a database `music2` with a different locale and a different character set encoding:

```
CREATE DATABASE music2
    LOCALE 'sv_SE.iso885915'
    ENCODING LATIN9
    TEMPLATE template0;
```

The specified locale and encoding settings must match, or an error will be reported.

Note that locale names are specific to the operating system, so that the above commands might not work in the same way everywhere.

Compatibility

There is no `CREATE DATABASE` statement in the SQL standard. Databases are equivalent to catalogs, whose creation is implementation-defined.

CREATE DOMAIN

CREATE DOMAIN — define a new domain

Synopsis

```
CREATE DOMAIN name [ AS ] data_type
    [ COLLATE collation ]
    [ DEFAULT expression ]
    [ domain_constraint [ ... ] ]
```

where *domain_constraint* is:

```
[ CONSTRAINT constraint_name ]
{ NOT NULL | NULL | CHECK (expression) }
```

Description

CREATE DOMAIN creates a new domain. A domain is essentially a data type with optional constraints (restrictions on the allowed set of values). The user who defines a domain becomes its owner.

If a schema name is given (for example, CREATE DOMAIN myschema.mydomain ...) then the domain is created in the specified schema. Otherwise it is created in the current schema. The domain name must be unique among the types and domains existing in its schema.

Domains are useful for abstracting common constraints on fields into a single location for maintenance. For example, several tables might contain email address columns, all requiring the same CHECK constraint to verify the address syntax. Define a domain rather than setting up each table's constraint individually.

To be able to create a domain, you must have USAGE privilege on the underlying type.

Parameters

name

The name (optionally schema-qualified) of a domain to be created.

data_type

The underlying data type of the domain. This can include array specifiers.

collation

An optional collation for the domain. If no collation is specified, the domain has the same collation behavior as its underlying data type. The underlying type must be collatable if COLLATE is specified.

DEFAULT *expression*

The DEFAULT clause specifies a default value for columns of the domain data type. The value is any variable-free expression (but subqueries are not allowed). The data type of the default expression must match the data type of the domain. If no default value is specified, then the default value is the null value.

The default expression will be used in any insert operation that does not specify a value for the column. If a default value is defined for a particular column, it overrides any default associated with the domain. In turn, the domain default overrides any default value associated with the underlying data type.

CONSTRAINT *constraint_name*

An optional name for a constraint. If not specified, the system generates a name.

`NOT NULL`

Values of this domain are prevented from being null (but see notes below).

`NULL`

Values of this domain are allowed to be null. This is the default.

This clause is only intended for compatibility with nonstandard SQL databases. Its use is discouraged in new applications.

`CHECK (expression)`

`CHECK` clauses specify integrity constraints or tests which values of the domain must satisfy. Each constraint must be an expression producing a Boolean result. It should use the key word `VALUE` to refer to the value being tested. Expressions evaluating to `TRUE` or `UNKNOWN` succeed. If the expression produces a `FALSE` result, an error is reported and the value is not allowed to be converted to the domain type.

Currently, `CHECK` expressions cannot contain subqueries nor refer to variables other than `VALUE`.

When a domain has multiple `CHECK` constraints, they will be tested in alphabetical order by name. (PostgreSQL versions before 9.5 did not honor any particular firing order for `CHECK` constraints.)

Notes

Domain constraints, particularly `NOT NULL`, are checked when converting a value to the domain type. It is possible for a column that is nominally of the domain type to read as null despite there being such a constraint. For example, this can happen in an outer-join query, if the domain column is on the nullable side of the outer join. A more subtle example is

```
INSERT INTO tab (domcol) VALUES ((SELECT domcol FROM tab WHERE false));
```

The empty scalar sub-`SELECT` will produce a null value that is considered to be of the domain type, so no further constraint checking is applied to it, and the insertion will succeed.

It is very difficult to avoid such problems, because of SQL's general assumption that a null value is a valid value of every data type. Best practice therefore is to design a domain's constraints so that a null value is allowed, and then to apply column `NOT NULL` constraints to columns of the domain type as needed, rather than directly to the domain type.

Postgres Pro assumes that `CHECK` constraints' conditions are immutable, that is, they will always give the same result for the same input value. This assumption is what justifies examining `CHECK` constraints only when a value is first converted to be of a domain type, and not at other times. (This is essentially the same as the treatment of table `CHECK` constraints, as described in [Section 5.5.1](#).)

An example of a common way to break this assumption is to reference a user-defined function in a `CHECK` expression, and then change the behavior of that function. Postgres Pro does not disallow that, but it will not notice if there are stored values of the domain type that now violate the `CHECK` constraint. That would cause a subsequent database dump and restore to fail. The recommended way to handle such a change is to drop the constraint (using `ALTER DOMAIN`), adjust the function definition, and re-add the constraint, thereby rechecking it against stored data.

It's also good practice to ensure that domain `CHECK` expressions will not throw errors.

Examples

This example creates the `us_postal_code` data type and then uses the type in a table definition. A regular expression test is used to verify that the value looks like a valid US postal code:

```
CREATE DOMAIN us_postal_code AS TEXT
CHECK (
    VALUE ~ '^\d{5}$'
```

```
OR VALUE ~ '^\\d{5}-\\d{4}$'
);
```

```
CREATE TABLE us_snail_addy (
  address_id SERIAL PRIMARY KEY,
  street1 TEXT NOT NULL,
  street2 TEXT,
  street3 TEXT,
  city TEXT NOT NULL,
  postal us_postal_code NOT NULL
);
```

Compatibility

The command `CREATE DOMAIN` conforms to the SQL standard.

The syntax `NOT NULL` in this command is a Postgres Pro extension. (A standard-conforming way to write the same for non-composite data types would be `CHECK (VALUE IS NOT NULL)`. However, per [the section called “Notes”](#), such constraints are best avoided in practice anyway.) The `NULL` “constraint” is a Postgres Pro extension (see also [Compatibility](#)).

[ALTER DOMAIN](#), [DROP DOMAIN](#)

CREATE EVENT TRIGGER

CREATE EVENT TRIGGER — define a new event trigger

Synopsis

```
CREATE EVENT TRIGGER name
  ON event
  [ WHEN filter_variable IN (filter_value [, ... ]) [ AND ... ] ]
  EXECUTE { FUNCTION | PROCEDURE } function_name()
```

Description

CREATE EVENT TRIGGER creates a new event trigger. Whenever the designated event occurs and the WHEN condition associated with the trigger, if any, is satisfied, the trigger function will be executed. For a general introduction to event triggers, see [Chapter 41](#). The user who creates an event trigger becomes its owner.

Parameters

name

The name to give the new trigger. This name must be unique within the database.

event

The name of the event that triggers a call to the given function. See [Section 41.1](#) for more information on event names.

filter_variable

The name of a variable used to filter events. This makes it possible to restrict the firing of the trigger to a subset of the cases in which it is supported. Currently the only supported *filter_variable* is TAG.

filter_value

A list of values for the associated *filter_variable* for which the trigger should fire. For TAG, this means a list of command tags (e.g., 'DROP FUNCTION').

function_name

A user-supplied function that is declared as taking no argument and returning type event_trigger.

In the syntax of CREATE EVENT TRIGGER, the keywords FUNCTION and PROCEDURE are equivalent, but the referenced function must in any case be a function, not a procedure. The use of the keyword PROCEDURE here is historical and deprecated.

Notes

Only superusers can create event triggers.

Event triggers are disabled in single-user mode (see [postgres](#)) as well as when [event_triggers](#) is set to false. If an erroneous event trigger disables the database so much that you can't even drop the trigger, restart with [event_triggers](#) set to false to temporarily disable event triggers, or in single-user mode, and you'll be able to do that.

Examples

Forbid the execution of any [DDL](#) command:

```
CREATE OR REPLACE FUNCTION abort_any_command()
  RETURNS event_trigger
  LANGUAGE plpgsql
  AS $$
BEGIN
  RAISE EXCEPTION 'command % is disabled', tg_tag;
END;
$$;

CREATE EVENT TRIGGER abort_ddl ON ddl_command_start
  EXECUTE FUNCTION abort_any_command();
```

Compatibility

There is no `CREATE EVENT TRIGGER` statement in the SQL standard.

[ALTER EVENT TRIGGER](#), [DROP EVENT TRIGGER](#), [CREATE FUNCTION](#)

CREATE EXTENSION

CREATE EXTENSION — install an extension

Synopsis

```
CREATE EXTENSION [ IF NOT EXISTS ] extension_name
    [ WITH ] [ SCHEMA schema_name ]
    [ VERSION version ]
    [ CASCADE ]
```

Description

`CREATE EXTENSION` loads a new extension into the current database. There must not be an extension of the same name already loaded.

Loading an extension essentially amounts to running the extension's script file. The script will typically create new SQL objects such as functions, data types, operators and index support methods. `CREATE EXTENSION` additionally records the identities of all the created objects, so that they can be dropped again if `DROP EXTENSION` is issued.

The user who runs `CREATE EXTENSION` becomes the owner of the extension for purposes of later privilege checks, and normally also becomes the owner of any objects created by the extension's script.

Loading an extension ordinarily requires the same privileges that would be required to create its component objects. For many extensions this means superuser privileges are needed. However, if the extension is marked *trusted* in its control file, then it can be installed by any user who has `CREATE` privilege on the current database. In this case the extension object itself will be owned by the calling user, but the contained objects will be owned by the bootstrap superuser (unless the extension's script explicitly assigns them to the calling user). This configuration gives the calling user the right to drop the extension, but not to modify individual objects within it.

Parameters

`IF NOT EXISTS`

Do not throw an error if an extension with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing extension is anything like the one that would have been created from the currently-available script file.

extension_name

The name of the extension to be installed. Postgres Pro will create the extension using details from the file `SHAREDIR/extension/extension_name.control`.

schema_name

The name of the schema in which to install the extension's objects, given that the extension allows its contents to be relocated. The named schema must already exist. If not specified, and the extension's control file does not specify a schema either, the current default object creation schema is used.

If the extension specifies a `schema` parameter in its control file, then that schema cannot be overridden with a `SCHEMA` clause. Normally, an error will be raised if a `SCHEMA` clause is given and it conflicts with the extension's `schema` parameter. However, if the `CASCADE` clause is also given, then *schema_name* is ignored when it conflicts. The given *schema_name* will be used for installation of any needed extensions that do not specify `schema` in their control files.

Remember that the extension itself is not considered to be within any schema: extensions have unqualified names that must be unique database-wide. But objects belonging to the extension can be within schemas.

version

The version of the extension to install. This can be written as either an identifier or a string literal. The default version is whatever is specified in the extension's control file.

CASCADE

Automatically install any extensions that this extension depends on that are not already installed. Their dependencies are likewise automatically installed, recursively. The `SCHEMA` clause, if given, applies to all extensions that get installed this way. Other options of the statement are not applied to automatically-installed extensions; in particular, their default versions are always selected.

Notes

Before you can use `CREATE EXTENSION` to load an extension into a database, the extension's supporting files must be installed. Information about installing the extensions supplied with Postgres Pro can be found in [Additional Supplied Modules](#).

The extensions currently available for loading can be identified from the `pg_available_extensions` or `pg_available_extension_versions` system views.

Caution

Installing an extension as superuser requires trusting that the extension's author wrote the extension installation script in a secure fashion. It is not terribly difficult for a malicious user to create trojan-horse objects that will compromise later execution of a carelessly-written extension script, allowing that user to acquire superuser privileges. However, trojan-horse objects are only hazardous if they are in the `search_path` during script execution, meaning that they are in the extension's installation target schema or in the schema of some extension it depends on. Therefore, a good rule of thumb when dealing with extensions whose scripts have not been carefully vetted is to install them only into schemas for which `CREATE` privilege has not been and will not be granted to any untrusted users. Likewise for any extensions they depend on.

The extensions supplied with Postgres Pro are believed to be secure against installation-time attacks of this sort, except for a few that depend on other extensions. As stated in the documentation for those extensions, they should be installed into secure schemas, or installed into the same schemas as the extensions they depend on, or both.

For information about writing new extensions, see [Section 39.17](#).

Compatibility

`CREATE EXTENSION` is a Postgres Pro extension.

[ALTER EXTENSION](#), [DROP EXTENSION](#)

CREATE FUNCTION

CREATE FUNCTION — define a new function

Synopsis

```
CREATE [ OR REPLACE ] FUNCTION
    name ( [ [ argmode ] [ argname ] argtype [ { DEFAULT | = } default_expr ]
    [, ...] ] )
    [ RETURNS rettype
      | RETURNS TABLE ( column_name column_type [, ...] ) ]
    { LANGUAGE lang_name
      | TRANSFORM { FOR TYPE type_name } [, ... ]
      | WINDOW
      | { IMMUTABLE | STABLE | VOLATILE }
      | [ NOT ] LEAKPROOF
      | { CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
      | { [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER }
      | PARALLEL { UNSAFE | RESTRICTED | SAFE }
      | COST execution_cost
      | ROWS result_rows
      | SUPPORT support_function
      | SET configuration_parameter { TO value | = value | FROM CURRENT }
      | AS 'definition'
      | AS 'obj_file', 'link_symbol'
      | sql_body
    } ...
```

Description

`CREATE FUNCTION` defines a new function. `CREATE OR REPLACE FUNCTION` will either create a new function, or replace an existing definition. To be able to define a function, the user must have the `USAGE` privilege on the language.

If a schema name is included, then the function is created in the specified schema. Otherwise it is created in the current schema. The name of the new function must not match any existing function or procedure with the same input argument types in the same schema. However, functions and procedures of different argument types can share a name (this is called *overloading*).

To replace the current definition of an existing function, use `CREATE OR REPLACE FUNCTION`. It is not possible to change the name or argument types of a function this way (if you tried, you would actually be creating a new, distinct function). Also, `CREATE OR REPLACE FUNCTION` will not let you change the return type of an existing function. To do that, you must drop and recreate the function. (When using `OUT` parameters, that means you cannot change the types of any `OUT` parameters except by dropping the function.)

When `CREATE OR REPLACE FUNCTION` is used to replace an existing function, the ownership and permissions of the function do not change. All other function properties are assigned the values specified or implied in the command. You must own the function to replace it (this includes being a member of the owning role).

If you drop and then recreate a function, the new function is not the same entity as the old; you will have to drop existing rules, views, triggers, etc. that refer to the old function. Use `CREATE OR REPLACE FUNCTION` to change a function definition without breaking objects that refer to the function. Also, `ALTER FUNCTION` can be used to change most of the auxiliary properties of an existing function.

The user that creates the function becomes the owner of the function.

To be able to create a function, you must have `USAGE` privilege on the argument types and the return type.

Refer to [Section 39.3](#) for further information on writing functions.

Parameters

name

The name (optionally schema-qualified) of the function to create.

argmode

The mode of an argument: `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`. Only `OUT` arguments can follow a `VARIADIC` one. Also, `OUT` and `INOUT` arguments cannot be used together with the `RETURNS TABLE` notation.

argname

The name of an argument. Some languages (including SQL and PL/pgSQL) let you use the name in the function body. For other languages the name of an input argument is just extra documentation, so far as the function itself is concerned; but you can use input argument names when calling a function to improve readability (see [Section 4.3](#)). In any case, the name of an output argument is significant, because it defines the column name in the result row type. (If you omit the name for an output argument, the system will choose a default column name.)

argtype

The data type(s) of the function's arguments (optionally schema-qualified), if any. The argument types can be base, composite, or domain types, or can reference the type of a table column.

Depending on the implementation language it might also be allowed to specify “pseudo-types” such as `cstring`. Pseudo-types indicate that the actual argument type is either incompletely specified, or outside the set of ordinary SQL data types.

The type of a column is referenced by writing `table_name.column_name%TYPE`. Using this feature can sometimes help make a function independent of changes to the definition of a table.

default_expr

An expression to be used as default value if the parameter is not specified. The expression has to be coercible to the argument type of the parameter. Only input (including `INOUT`) parameters can have a default value. All input parameters following a parameter with a default value must have default values as well.

rettype

The return data type (optionally schema-qualified). The return type can be a base, composite, or domain type, or can reference the type of a table column. Depending on the implementation language it might also be allowed to specify “pseudo-types” such as `cstring`. If the function is not supposed to return a value, specify `void` as the return type.

When there are `OUT` or `INOUT` parameters, the `RETURNS` clause can be omitted. If present, it must agree with the result type implied by the output parameters: `RECORD` if there are multiple output parameters, or the same type as the single output parameter.

The `SETOF` modifier indicates that the function will return a set of items, rather than a single item.

The type of a column is referenced by writing `table_name.column_name%TYPE`.

column_name

The name of an output column in the `RETURNS TABLE` syntax. This is effectively another way of declaring a named `OUT` parameter, except that `RETURNS TABLE` also implies `RETURNS SETOF`.

column_type

The data type of an output column in the `RETURNS TABLE` syntax.

lang_name

The name of the language that the function is implemented in. It can be `sql`, `c`, `internal`, or the name of a user-defined procedural language, e.g., `plpgsql`. The default is `sql` if *sql_body* is specified. Enclosing the name in single quotes is deprecated and requires matching case.

`TRANSFORM { FOR TYPE type_name } [, ...] }`

Lists which transforms a call to the function should apply. Transforms convert between SQL types and language-specific data types; see [CREATE TRANSFORM](#). Procedural language implementations usually have hardcoded knowledge of the built-in types, so those don't need to be listed here. If a procedural language implementation does not know how to handle a type and no transform is supplied, it will fall back to a default behavior for converting data types, but this depends on the implementation.

`WINDOW`

`WINDOW` indicates that the function is a *window function* rather than a plain function. This is currently only useful for functions written in C. The `WINDOW` attribute cannot be changed when replacing an existing function definition.

`IMMUTABLE`

`STABLE`

`VOLATILE`

These attributes inform the query optimizer about the behavior of the function. At most one choice can be specified. If none of these appear, `VOLATILE` is the default assumption.

`IMMUTABLE` indicates that the function cannot modify the database and always returns the same result when given the same argument values; that is, it does not do database lookups or otherwise use information not directly present in its argument list. If this option is given, any call of the function with all-constant arguments can be immediately replaced with the function value.

`STABLE` indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same argument values, but that its result could change across SQL statements. This is the appropriate selection for functions whose results depend on database lookups, parameter variables (such as the current time zone), etc. (It is inappropriate for `AFTER` triggers that wish to query rows modified by the current command.) Also note that the `current_timestamp` family of functions qualify as stable, since their values do not change within a transaction.

`VOLATILE` indicates that the function value can change even within a single table scan, so no optimizations can be made. Relatively few database functions are volatile in this sense; some examples are `random()`, `currval()`, `timeofday()`. But note that any function that has side-effects must be classified volatile, even if its result is quite predictable, to prevent calls from being optimized away; an example is `setval()`.

For additional details see [Section 39.7](#).

`LEAKPROOF`

`LEAKPROOF` indicates that the function has no side effects. It reveals no information about its arguments other than by its return value. For example, a function which throws an error message for some argument values but not others, or which includes the argument values in any error message, is not leakproof. This affects how the system executes queries against views created with the `security_barrier` option or tables with row level security enabled. The system will enforce conditions from security policies and security barrier views before any user-supplied conditions from the query itself that contain non-leakproof functions, in order to prevent the inadvertent exposure of data.

Functions and operators marked as leakproof are assumed to be trustworthy, and may be executed before conditions from security policies and security barrier views. In addition, functions which do not take arguments or which are not passed any arguments from the security barrier view or table do not have to be marked as leakproof to be executed before security conditions. See [CREATE VIEW](#) and [Section 42.5](#). This option can only be set by the superuser.

`CALLED ON NULL INPUT`

`RETURNS NULL ON NULL INPUT`

`STRICT`

`CALLED ON NULL INPUT` (the default) indicates that the function will be called normally when some of its arguments are null. It is then the function author's responsibility to check for null values if necessary and respond appropriately.

`RETURNS NULL ON NULL INPUT` or `STRICT` indicates that the function always returns null whenever any of its arguments are null. If this parameter is specified, the function is not executed when there are null arguments; instead a null result is assumed automatically.

`[EXTERNAL] SECURITY INVOKER`

`[EXTERNAL] SECURITY DEFINER`

`SECURITY INVOKER` indicates that the function is to be executed with the privileges of the user that calls it. That is the default. `SECURITY DEFINER` specifies that the function is to be executed with the privileges of the user that owns it. For information on how to write `SECURITY DEFINER` functions safely, [see below](#).

The key word `EXTERNAL` is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all functions not only external ones.

`PARALLEL`

`PARALLEL UNSAFE` indicates that the function can't be executed in parallel mode; the presence of such a function in an SQL statement forces a serial execution plan. This is the default. `PARALLEL RESTRICTED` indicates that the function can be executed in parallel mode, but only in the parallel group leader process. `PARALLEL SAFE` indicates that the function is safe to run in parallel mode without restriction, including in parallel worker processes.

Functions should be labeled parallel unsafe if they modify any database state, change the transaction state (other than by using a subtransaction for error recovery), access sequences (e.g., by calling `currval`) or make persistent changes to settings. They should be labeled parallel restricted if they access temporary tables, client connection state, cursors, prepared statements, or miscellaneous backend-local state which the system cannot synchronize in parallel mode (e.g., `setseed` cannot be executed other than by the group leader because a change made by another process would not be reflected in the leader). In general, if a function is labeled as being safe when it is restricted or unsafe, or if it is labeled as being restricted when it is in fact unsafe, it may throw errors or produce wrong answers when used in a parallel query. C-language functions could in theory exhibit totally undefined behavior if mislabeled, since there is no way for the system to protect itself against arbitrary C code, but in most likely cases the result will be no worse than for any other function. If in doubt, functions should be labeled as `UNSAFE`, which is the default.

`COST execution_cost`

A positive number giving the estimated execution cost for the function, in units of [cpu_operator_cost](#). If the function returns a set, this is the cost per returned row. If the cost is not specified, 1 unit is assumed for C-language and internal functions, and 100 units for functions in all other languages. Larger values cause the planner to try to avoid evaluating the function more often than necessary.

`ROWS result_rows`

A positive number giving the estimated number of rows that the planner should expect the function to return. This is only allowed when the function is declared to return a set. The default assumption is 1000 rows.

SUPPORT *support_function*

The name (optionally schema-qualified) of a *planner support function* to use for this function. See [Section 39.11](#) for details. You must be superuser to use this option.

configuration_parameter
value

The SET clause causes the specified configuration parameter to be set to the specified value when the function is entered, and then restored to its prior value when the function exits. SET FROM CURRENT saves the value of the parameter that is current when CREATE FUNCTION is executed as the value to be applied when the function is entered.

If a SET clause is attached to a function, then the effects of a SET LOCAL command executed inside the function for the same variable are restricted to the function: the configuration parameter's prior value is still restored at function exit. However, an ordinary SET command (without LOCAL) overrides the SET clause, much as it would do for a previous SET LOCAL command: the effects of such a command will persist after function exit, unless the current transaction is rolled back.

See [SET](#) and [Chapter 19](#) for more information about allowed parameter names and values.

definition

A string constant defining the function; the meaning depends on the language. It can be an internal function name, the path to an object file, an SQL command, or text in a procedural language.

It is often helpful to use dollar quoting (see [Section 4.1.2.4](#)) to write the function definition string, rather than the normal single quote syntax. Without dollar quoting, any single quotes or backslashes in the function definition must be escaped by doubling them.

obj_file, link_symbol

This form of the AS clause is used for dynamically loadable C language functions when the function name in the C language source code is not the same as the name of the SQL function. The string *obj_file* is the name of the shared library file containing the compiled C function, and is interpreted as for the [LOAD](#) command. The string *link_symbol* is the function's link symbol, that is, the name of the function in the C language source code. If the link symbol is omitted, it is assumed to be the same as the name of the SQL function being defined. The C names of all functions must be different, so you must give overloaded C functions different C names (for example, use the argument types as part of the C names).

When repeated CREATE FUNCTION calls refer to the same object file, the file is only loaded once per session. To unload and reload the file (perhaps during development), start a new session.

sql_body

The body of a LANGUAGE SQL function. This can either be a single statement

RETURN *expression*

or a block

```
BEGIN ATOMIC
    statement;
    statement;
    ...
    statement;
END
```

This is similar to writing the text of the function body as a string constant (see *definition* above), but there are some differences: This form only works for LANGUAGE SQL, the string constant form works for all languages. This form is parsed at function definition time, the string constant form is parsed at execution time; therefore this form cannot support polymorphic argument types and other

constructs that are not resolvable at function definition time. This form tracks dependencies between the function and objects used in the function body, so `DROP ... CASCADE` will work correctly, whereas the form using string literals may leave dangling functions. Finally, this form is more compatible with the SQL standard and other SQL implementations.

Overloading

Postgres Pro allows function *overloading*; that is, the same name can be used for several different functions so long as they have distinct input argument types. Whether or not you use it, this capability entails security precautions when calling functions in databases where some users mistrust other users; see [Section 10.3](#).

Two functions are considered the same if they have the same names and *input* argument types, ignoring any `OUT` parameters. Thus for example these declarations conflict:

```
CREATE FUNCTION foo(int) ...
CREATE FUNCTION foo(int, out text) ...
```

Functions that have different argument type lists will not be considered to conflict at creation time, but if defaults are provided they might conflict in use. For example, consider

```
CREATE FUNCTION foo(int) ...
CREATE FUNCTION foo(int, int default 42) ...
```

A call `foo(10)` will fail due to the ambiguity about which function should be called.

Notes

The full SQL type syntax is allowed for declaring a function's arguments and return value. However, parenthesized type modifiers (e.g., the precision field for type `numeric`) are discarded by `CREATE FUNCTION`. Thus for example `CREATE FUNCTION foo (varchar(10)) ...` is exactly the same as `CREATE FUNCTION foo (varchar)`

When replacing an existing function with `CREATE OR REPLACE FUNCTION`, there are restrictions on changing parameter names. You cannot change the name already assigned to any input parameter (although you can add names to parameters that had none before). If there is more than one output parameter, you cannot change the names of the output parameters, because that would change the column names of the anonymous composite type that describes the function's result. These restrictions are made to ensure that existing calls of the function do not stop working when it is replaced.

If a function is declared `STRICT` with a `VARIADIC` argument, the strictness check tests that the variadic array *as a whole* is non-null. The function will still be called if the array has null elements.

Examples

Add two integers using an SQL function:

```
CREATE FUNCTION add(integer, integer) RETURNS integer
  AS 'select $1 + $2;'
  LANGUAGE SQL
  IMMUTABLE
  RETURNS NULL ON NULL INPUT;
```

The same function written in a more SQL-conforming style, using argument names and an unquoted body:

```
CREATE FUNCTION add(a integer, b integer) RETURNS integer
  LANGUAGE SQL
  IMMUTABLE
  RETURNS NULL ON NULL INPUT
  RETURN a + b;
```

Increment an integer, making use of an argument name, in PL/pgSQL:

```
CREATE OR REPLACE FUNCTION increment(i integer) RETURNS integer AS $$
    BEGIN
        RETURN i + 1;
    END;
$$ LANGUAGE plpgsql;
```

Return a record containing multiple output parameters:

```
CREATE FUNCTION dup(in int, out f1 int, out f2 text)
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(42);
```

You can do the same thing more verbosely with an explicitly named composite type:

```
CREATE TYPE dup_result AS (f1 int, f2 text);

CREATE FUNCTION dup(int) RETURNS dup_result
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(42);
```

Another way to return multiple columns is to use a TABLE function:

```
CREATE FUNCTION dup(int) RETURNS TABLE(f1 int, f2 text)
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(42);
```

However, a TABLE function is different from the preceding examples, because it actually returns a *set* of records, not just one record.

Writing SECURITY DEFINER Functions Safely

Because a SECURITY DEFINER function is executed with the privileges of the user that owns it, care is needed to ensure that the function cannot be misused. For security, [search_path](#) should be set to exclude any schemas writable by untrusted users. This prevents malicious users from creating objects (e.g., tables, functions, and operators) that mask objects intended to be used by the function. Particularly important in this regard is the temporary-table schema, which is searched first by default, and is normally writable by anyone. A secure arrangement can be obtained by forcing the temporary schema to be searched last. To do this, write `pg_temp` as the last entry in `search_path`. This function illustrates safe usage:

```
CREATE FUNCTION check_password(uname TEXT, pass TEXT)
    RETURNS BOOLEAN AS $$
    DECLARE passed BOOLEAN;
    BEGIN
        SELECT (pwd = $2) INTO passed
        FROM   pwds
        WHERE  username = $1;

        RETURN passed;
    END;
$$ LANGUAGE plpgsql
    SECURITY DEFINER
    -- Set a secure search_path: trusted schema(s), then 'pg_temp'.
    SET search_path = admin, pg_temp;
```

This function's intention is to access a table `admin.pwds`. But without the SET clause, or with a SET clause mentioning only `admin`, the function could be subverted by creating a temporary table named `pwds`.

If the security definer function intends to create roles, and if it is running as a non-superuser, `create_role_self_grant` should also be set to a known value using the `SET` clause.

Another point to keep in mind is that by default, execute privilege is granted to `PUBLIC` for newly created functions (see [Section 5.8](#) for more information). Frequently you will wish to restrict use of a security definer function to only some users. To do that, you must revoke the default `PUBLIC` privileges and then grant execute privilege selectively. To avoid having a window where the new function is accessible to all, create it and set the privileges within a single transaction. For example:

```
BEGIN;
CREATE FUNCTION check_password(uname TEXT, pass TEXT) ... SECURITY DEFINER;
REVOKE ALL ON FUNCTION check_password(uname TEXT, pass TEXT) FROM PUBLIC;
GRANT EXECUTE ON FUNCTION check_password(uname TEXT, pass TEXT) TO admins;
COMMIT;
```

Compatibility

A `CREATE FUNCTION` command is defined in the SQL standard. The Postgres Pro implementation can be used in a compatible way but has many extensions. Conversely, the SQL standard specifies a number of optional features that are not implemented in Postgres Pro.

The following are important compatibility issues:

- `OR REPLACE` is a Postgres Pro extension.
- For compatibility with some other database systems, *argmode* can be written either before or after *argname*. But only the first way is standard-compliant.
- For parameter defaults, the SQL standard specifies only the syntax with the `DEFAULT` key word. The syntax with `=` is used in T-SQL and Firebird.
- The `SETOF` modifier is a Postgres Pro extension.
- Only `SQL` is standardized as a language.
- All other attributes except `CALLED ON NULL INPUT` and `RETURNS NULL ON NULL INPUT` are not standardized.
- For the body of `LANGUAGE SQL` functions, the SQL standard only specifies the *sql_body* form.

Simple `LANGUAGE SQL` functions can be written in a way that is both standard-conforming and portable to other implementations. More complex functions using advanced features, optimization attributes, or other languages will necessarily be specific to Postgres Pro in a significant way.

CREATE GROUP

CREATE GROUP — define a new database role

Synopsis

```
CREATE GROUP name [ [ WITH ] option [ ... ] ]
```

where *option* can be:

```
SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| REPLICATION | NOREPLICATION
| BYPASSRLS | NOBYPASSRLS
| CONNECTION LIMIT connlimit
| [ ENCRYPTED ] PASSWORD 'password' | PASSWORD NULL
| VALID UNTIL 'timestamp'
| IN ROLE role_name [, ...]
| IN GROUP role_name [, ...]
| ROLE role_name [, ...]
| ADMIN role_name [, ...]
| USER role_name [, ...]
| SYSID uid
```

Description

CREATE GROUP is now an alias for [CREATE ROLE](#).

Compatibility

There is no CREATE GROUP statement in the SQL standard.

[CREATE ROLE](#)

CREATE INDEX

CREATE INDEX — define a new index

Synopsis

```
CREATE [ UNIQUE ] INDEX [ CONCURRENTLY ] [ [ IF NOT EXISTS ] name ] ON
[ ONLY ] table_name [ USING method ]
    ( { column_name | ( expression ) } [ COLLATE collation ] [ opclass
[ ( opclass_parameter = value [, ... ] ) ] ] [ ASC | DESC ] [ NULLS { FIRST | LAST } ]
[, ...] )
    [ INCLUDE ( column_name [, ...] ) ]
    [ NULLS [ NOT ] DISTINCT ]
    [ WITH ( storage_parameter [= value] [, ... ] ) ]
    [ TABLESPACE tablespace_name ]
    [ WHERE predicate ]
```

Description

`CREATE INDEX` constructs an index on the specified column(s) of the specified relation, which can be a table or a materialized view. Indexes are primarily used to enhance database performance (though inappropriate use can result in slower performance).

The key field(s) for the index are specified as column names, or alternatively as expressions written in parentheses. Multiple fields can be specified if the index method supports multicolumn indexes.

An index field can be an expression computed from the values of one or more columns of the table row. This feature can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on `upper(col)` would allow the clause `WHERE upper(col) = 'JIM'` to use an index.

Postgres Pro provides the index methods B-tree, hash, GiST, SP-GiST, GIN, RUM, and BRIN. Users can also define their own index methods, but that is fairly complicated.

When the `WHERE` clause is present, a *partial index* is created. A partial index is an index that contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small fraction of the total table and yet that is an often used section, you can improve performance by creating an index on just that portion. Another possible application is to use `WHERE` with `UNIQUE` to enforce uniqueness over a subset of a table. See [Section 11.8](#) for more discussion.

The expression used in the `WHERE` clause can refer only to columns of the underlying table, but it can use all columns, not just the ones being indexed. Presently, subqueries and aggregate expressions are also forbidden in `WHERE`. The same restrictions apply to index fields that are expressions.

All functions and operators used in an index definition must be “immutable”, that is, their results must depend only on their arguments and never on any outside influence (such as the contents of another table or the current time). This restriction ensures that the behavior of the index is well-defined. To use a user-defined function in an index expression or `WHERE` clause, remember to mark the function immutable when you create it.

Parameters

`UNIQUE`

Causes the system to check for duplicate values in the table when the index is created (if data already exist) and each time data is added. Attempts to insert or update data which would result in duplicate entries will generate an error.

Additional restrictions apply when unique indexes are applied to partitioned tables; see [CREATE TABLE](#).

CONCURRENTLY

When this option is used, Postgres Pro will build the index without taking any locks that prevent concurrent inserts, updates, or deletes on the table; whereas a standard index build locks out writes (but not reads) on the table until it's done. There are several caveats to be aware of when using this option — see [Building Indexes Concurrently](#) below.

For temporary tables, `CREATE INDEX` is always non-concurrent, as no other session can access them, and non-concurrent index creation is cheaper.

IF NOT EXISTS

Do not throw an error if a relation with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing index is anything like the one that would have been created. Index name is required when `IF NOT EXISTS` is specified.

INCLUDE

The optional `INCLUDE` clause specifies a list of columns which will be included in the index as *non-key* columns. A non-key column cannot be used in an index scan search qualification, and it is disregarded for purposes of any uniqueness or exclusion constraint enforced by the index. However, an index-only scan can return the contents of non-key columns without having to visit the index's table, since they are available directly from the index entry. Thus, addition of non-key columns allows index-only scans to be used for queries that otherwise could not use them.

It's wise to be conservative about adding non-key columns to an index, especially wide columns. If an index tuple exceeds the maximum size allowed for the index type, data insertion will fail. In any case, non-key columns duplicate data from the index's table and bloat the size of the index, thus potentially slowing searches. Furthermore, B-tree deduplication is never used with indexes that have a non-key column.

Columns listed in the `INCLUDE` clause don't need appropriate operator classes; the clause can include columns whose data types don't have operator classes defined for a given access method.

Expressions are not supported as included columns since they cannot be used in index-only scans.

Currently, the B-tree, GiST and SP-GiST index access methods support this feature. In these indexes, the values of columns listed in the `INCLUDE` clause are included in leaf tuples which correspond to heap tuples, but are not included in upper-level index entries used for tree navigation.

name

The name of the index to be created. No schema name can be included here; the index is always created in the same schema as its parent table. The name of the index must be distinct from the name of any other relation (table, sequence, index, view, materialized view, or foreign table) in that schema. If the name is omitted, Postgres Pro chooses a suitable name based on the parent table's name and the indexed column name(s).

ONLY

Indicates not to recurse creating indexes on partitions, if the table is partitioned. The default is to recurse.

table_name

The name (possibly schema-qualified) of the table to be indexed.

method

The name of the index method to be used. Choices are `btree`, `hash`, `gist`, `spgist`, `gin`, `brin`, or user-installed access methods . The default method is `btree`.

column_name

The name of a column of the table.

expression

An expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax. However, the parentheses can be omitted if the expression has the form of a function call.

collation

The name of the collation to use for the index. By default, the index uses the collation declared for the column to be indexed or the result collation of the expression to be indexed. Indexes with non-default collations can be useful for queries that involve expressions using non-default collations.

opclass

The name of an operator class. See below for details.

opclass_parameter

The name of an operator class parameter. See below for details.

ASC

Specifies ascending sort order (which is the default).

DESC

Specifies descending sort order.

NULLS FIRST

Specifies that nulls sort before non-nulls. This is the default when DESC is specified.

NULLS LAST

Specifies that nulls sort after non-nulls. This is the default when DESC is not specified.

NULLS DISTINCT

NULLS NOT DISTINCT

Specifies whether for a unique index, null values should be considered distinct (not equal). The default is that they are distinct, so that a unique index could contain multiple null values in a column.

storage_parameter

The name of an index-method-specific storage parameter. See [Index Storage Parameters](#) below for details.

tablespace_name

The tablespace in which to create the index. If not specified, [default_tablespace](#) is consulted, or [temp_tablespaces](#) for indexes on temporary tables.

predicate

The constraint expression for a partial index.

Index Storage Parameters

The optional WITH clause specifies *storage parameters* for the index. Each index method has its own set of allowed storage parameters. The B-tree, hash, GiST and SP-GiST index methods all accept this parameter:

`fillfactor (integer)`

The fillfactor for an index is a percentage that determines how full the index method will try to pack index pages. For B-trees, leaf pages are filled to this percentage during initial index builds, and also when extending the index at the right (adding new largest key values). If pages subsequently become completely full, they will be split, leading to fragmentation of the on-disk index structure. B-trees use a default fillfactor of 90, but any integer value from 10 to 100 can be selected.

B-tree indexes on tables where many inserts and/or updates are anticipated can benefit from lower fillfactor settings at `CREATE INDEX` time (following bulk loading into the table). Values in the range of 50 - 90 can usefully “smooth out” the *rate* of page splits during the early life of the B-tree index (lowering fillfactor like this may even lower the absolute number of page splits, though this effect is highly workload dependent). The B-tree bottom-up index deletion technique described in [Section 65.1.4.2](#) is dependent on having some “extra” space on pages to store “extra” tuple versions, and so can be affected by fillfactor (though the effect is usually not significant).

In other specific cases it might be useful to increase fillfactor to 100 at `CREATE INDEX` time as a way of maximizing space utilization. You should only consider this when you are completely sure that the table is static (i.e. that it will never be affected by either inserts or updates). A fillfactor setting of 100 otherwise risks *harming* performance: even a few updates or inserts will cause a sudden flood of page splits.

The other index methods use fillfactor in different but roughly analogous ways; the default fillfactor varies between methods.

B-tree indexes additionally accept this parameter:

`deduplicate_items (boolean)`

Controls usage of the B-tree deduplication technique described in [Section 65.1.4.3](#). Set to `ON` or `OFF` to enable or disable the optimization. (Alternative spellings of `ON` and `OFF` are allowed as described in [Section 19.1](#).) The default is `ON`.

Note

Turning `deduplicate_items` off via `ALTER INDEX` prevents future insertions from triggering deduplication, but does not in itself make existing posting list tuples use the standard tuple representation.

GiST indexes additionally accept this parameter:

`buffering (enum)`

Determines whether the buffered build technique described in [Section 65.2.4.1](#) is used to build the index. With `OFF` buffering is disabled, with `ON` it is enabled, and with `AUTO` it is initially disabled, but is turned on on-the-fly once the index size reaches `effective_cache_size`. The default is `AUTO`. Note that if sorted build is possible, it will be used instead of buffered build unless `buffering=ON` is specified.

GIN indexes accept different parameters:

`fastupdate (boolean)`

This setting controls usage of the fast update technique described in [Section 65.4.4.1](#). It is a Boolean parameter: `ON` enables fast update, `OFF` disables it. The default is `ON`.

Note

Turning `fastupdate` off via `ALTER INDEX` prevents future insertions from going into the list of pending index entries, but does not in itself flush previous entries. You might want to `VACUUM`

the table or call `gin_clean_pending_list` function afterward to ensure the pending list is emptied.

`gin_pending_list_limit (integer)`

Custom [gin_pending_list_limit](#) parameter. This value is specified in kilobytes.

RUM indexes accept different parameters:

`attach (text)`

This setting specifies the name of the column to attach as additional information.

`to (text)`

This setting specifies the name of the column to add ordering by.

`order_by_attach (boolean)`

This setting controls whether to use the `(attach, itempointer)` order instead of just `itempointer`.

BRIN indexes accept different parameters:

`pages_per_range (integer)`

Defines the number of table blocks that make up one block range for each entry of a BRIN index (see [Section 65.5.1](#) for more details). The default is `128`.

`autosummarize (boolean)`

Defines whether a summarization run is queued for the previous page range whenever an insertion is detected on the next one. See [Section 65.5.1.1](#) for more details. The default is `off`.

Building Indexes Concurrently

Creating an index can interfere with regular operation of a database. Normally Postgres Pro locks the table to be indexed against writes and performs the entire index build with a single scan of the table. Other transactions can still read the table, but if they try to insert, update, or delete rows in the table they will block until the index build is finished. This could have a severe effect if the system is a live production database. Very large tables can take many hours to be indexed, and even for smaller tables, an index build can lock out writers for periods that are unacceptably long for a production system.

Postgres Pro supports building indexes without locking out writes. This method is invoked by specifying the `CONCURRENTLY` option of `CREATE INDEX`. When this option is used, Postgres Pro must perform two scans of the table, and in addition it must wait for all existing transactions that could potentially modify or use the index to terminate. Thus this method requires more total work than a standard index build and takes significantly longer to complete. However, since it allows normal operations to continue while the index is built, this method is useful for adding new indexes in a production environment. Of course, the extra CPU and I/O load imposed by the index creation might slow other operations.

In a concurrent index build, the index is actually entered as an “invalid” index into the system catalogs in one transaction, then two table scans occur in two more transactions. Before each table scan, the index build must wait for existing transactions that have modified the table to terminate. After the second scan, the index build must wait for any transactions that have a snapshot (see [Chapter 13](#)) predating the second scan to terminate, including transactions used by any phase of concurrent index builds on other tables, if the indexes involved are partial or have columns that are not simple column references. Then finally the index can be marked “valid” and ready for use, and the `CREATE INDEX` command terminates. Even then, however, the index may not be immediately usable for queries: in the worst case, it cannot be used as long as transactions exist that predate the start of the index build.

If a problem arises while scanning the table, such as a deadlock or a uniqueness violation in a unique index, the `CREATE INDEX` command will fail but leave behind an “invalid” index. If this happens while build an index concurrently on a partitioned table, the command can also leave behind “valid” or “invalid”

indexes on table partitions. The invalid index will be ignored for querying purposes because it might be incomplete; however it will still consume update overhead. The `psql \d` command will report such an index as `INVALID`:

```
postgres=# \d tab
          Table "public.tab"
  Column | Type   | Collation | Nullable | Default
-----+-----+-----+-----+-----
 col    | integer |           |          |
Indexes:
    "idx" btree (col) INVALID
```

The recommended recovery method in such cases is to drop the index and try again to perform `CREATE INDEX CONCURRENTLY`. (Another possibility is to rebuild the index with `REINDEX INDEX CONCURRENTLY`).

Another caveat when building a unique index concurrently is that the uniqueness constraint is already being enforced against other transactions when the second table scan begins. This means that constraint violations could be reported in other queries prior to the index becoming available for use, or even in cases where the index build eventually fails. Also, if a failure does occur in the second scan, the “invalid” index continues to enforce its uniqueness constraint afterwards.

Concurrent builds of expression indexes and partial indexes are supported. Errors occurring in the evaluation of these expressions could cause behavior similar to that described above for unique constraint violations.

Regular index builds permit other regular index builds on the same table to occur simultaneously, but only one concurrent index build can occur on a table at a time. In either case, schema modification of the table is not allowed while the index is being built. Another difference is that a regular `CREATE INDEX` command can be performed within a transaction block, but `CREATE INDEX CONCURRENTLY` cannot.

Notes

See [Chapter 11](#) for information about when indexes can be used, when they are not used, and in which particular situations they can be useful.

Currently, only the B-tree, GiST, GIN, and BRIN index methods support multiple-key-column indexes. Whether there can be multiple key columns is independent of whether `INCLUDE` columns can be added to the index. Indexes can have up to 32 columns, including `INCLUDE` columns. (This limit can be altered when building Postgres Pro.) Only B-tree currently supports unique indexes.

An *operator class* with optional parameters can be specified for each column of an index. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on four-byte integers would use the `int4_ops` class; this operator class includes comparison functions for four-byte integers. In practice the default operator class for the column's data type is usually sufficient. The main point of having operator classes is that for some data types, there could be more than one meaningful ordering. For example, we might want to sort a complex-number data type either by absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when creating an index. More information about operator classes is in [Section 11.10](#) and in [Section 39.16](#).

When `CREATE INDEX` is invoked on a partitioned table, the default behavior is to recurse to all partitions to ensure they all have matching indexes. Each partition is first checked to determine whether an equivalent index already exists, and if so, that index will become attached as a partition index to the index being created, which will become its parent index. If no matching index exists, a new index will be created and automatically attached; the name of the new index in each partition will be determined as if no index name had been specified in the command. If the `ONLY` option is specified, no recursion is done, and the index is marked invalid. (`ALTER INDEX ... ATTACH PARTITION` marks the index valid, once all partitions acquire matching indexes.) Note, however, that any partition that is created in the future using `CREATE TABLE ... PARTITION OF` will automatically have a matching index, regardless of whether `ONLY` is specified.

For index methods that support ordered scans (currently, only B-tree), the optional clauses `ASC`, `DESC`, `NULLS FIRST`, and/or `NULLS LAST` can be specified to modify the sort ordering of the index. Since an ordered index can be scanned either forward or backward, it is not normally useful to create a single-column `DESC` index — that sort ordering is already available with a regular index. The value of these options is that multicolumn indexes can be created that match the sort ordering requested by a mixed-ordering query, such as `SELECT ... ORDER BY x ASC, y DESC`. The `NULLS` options are useful if you need to support “nulls sort low” behavior, rather than the default “nulls sort high”, in queries that depend on indexes to avoid sorting steps.

The system regularly collects statistics on all of a table's columns. Newly-created non-expression indexes can immediately use these statistics to determine an index's usefulness. For new expression indexes, it is necessary to run `ANALYZE` or wait for the `autovacuum daemon` to analyze the table to generate statistics for these indexes.

While `CREATE INDEX` is running, the `search_path` is temporarily changed to `pg_catalog, pg_temp`.

For most index methods, the speed of creating an index is dependent on the setting of `maintenance_work_mem`. Larger values will reduce the time needed for index creation, so long as you don't make it larger than the amount of memory really available, which would drive the machine into swapping.

Postgres Pro can build indexes while leveraging multiple CPUs in order to process the table rows faster. This feature is known as *parallel index build*. For index methods that support building indexes in parallel (currently, B-tree and BRIN), `maintenance_work_mem` specifies the maximum amount of memory that can be used by each index build operation as a whole, regardless of how many worker processes were started. Generally, a cost model automatically determines how many worker processes should be requested, if any.

Parallel index builds may benefit from increasing `maintenance_work_mem` where an equivalent serial index build will see little or no benefit. Note that `maintenance_work_mem` may influence the number of worker processes requested, since parallel workers must have at least a 32MB share of the total `maintenance_work_mem` budget. There must also be a remaining 32MB share for the leader process. Increasing `max_parallel_maintenance_workers` may allow more workers to be used, which will reduce the time needed for index creation, so long as the index build is not already I/O bound. Of course, there should also be sufficient CPU capacity that would otherwise lie idle.

Setting a value for `parallel_workers` via `ALTER TABLE` directly controls how many parallel worker processes will be requested by a `CREATE INDEX` against the table. This bypasses the cost model completely, and prevents `maintenance_work_mem` from affecting how many parallel workers are requested. Setting `parallel_workers` to 0 via `ALTER TABLE` will disable parallel index builds on the table in all cases.

Tip

You might want to reset `parallel_workers` after setting it as part of tuning an index build. This avoids inadvertent changes to query plans, since `parallel_workers` affects *all* parallel table scans.

While `CREATE INDEX` with the `CONCURRENTLY` option supports parallel builds without special restrictions, only the first table scan is actually performed in parallel.

Use `DROP INDEX` to remove an index.

Like any long-running transaction, `CREATE INDEX` on a table can affect which tuples can be removed by concurrent `VACUUM` on any other table.

Prior releases of Postgres Pro also had an R-tree index method. This method has been removed because it had no significant advantages over the GiST method. If `USING rtree` is specified, `CREATE INDEX` will interpret it as `USING gist`, to simplify conversion of old databases to GiST.

Each backend running `CREATE INDEX` will report its progress in the `pg_stat_progress_create_index` view. See [Section 27.4.4](#) for details.

Examples

To create a unique B-tree index on the column `title` in the table `films`:

```
CREATE UNIQUE INDEX title_idx ON films (title);
```

To create a unique B-tree index on the column `title` with included columns `director` and `rating` in the table `films`:

```
CREATE UNIQUE INDEX title_idx ON films (title) INCLUDE (director, rating);
```

To create a B-Tree index with deduplication disabled:

```
CREATE INDEX title_idx ON films (title) WITH (deduplicate_items = off);
```

To create an index on the expression `lower(title)`, allowing efficient case-insensitive searches:

```
CREATE INDEX ON films ((lower(title)));
```

(In this example we have chosen to omit the index name, so the system will choose a name, typically `films_lower_idx`.)

To create an index with non-default collation:

```
CREATE INDEX title_idx_german ON films (title COLLATE "de_DE");
```

To create an index with non-default sort ordering of nulls:

```
CREATE INDEX title_idx_nulls_low ON films (title NULLS FIRST);
```

To create an index with non-default fill factor:

```
CREATE UNIQUE INDEX title_idx ON films (title) WITH (fillfactor = 70);
```

To create a GIN index with fast updates disabled:

```
CREATE INDEX gin_idx ON documents_table USING GIN (locations) WITH (fastupdate = off);
```

To create an index on the column `code` in the table `films` and have the index reside in the tablespace `indexspace`:

```
CREATE INDEX code_idx ON films (code) TABLESPACE indexspace;
```

To create a GiST index on a point attribute so that we can efficiently use box operators on the result of the conversion function:

```
CREATE INDEX pointloc
  ON points USING gist (box(location,location));
SELECT * FROM points
  WHERE box(location,location) && '(0,0),(1,1)::box;
```

To create an index without locking out writes to the table:

```
CREATE INDEX CONCURRENTLY sales_quantity_index ON sales_table (quantity);
```

Compatibility

`CREATE INDEX` is a Postgres Pro language extension. There are no provisions for indexes in the SQL standard.

[ALTER INDEX](#), [DROP INDEX](#), [REINDEX](#), [Section 27.4.4](#)

CREATE LANGUAGE

CREATE LANGUAGE — define a new procedural language

Synopsis

```
CREATE [ OR REPLACE ] [ TRUSTED ] [ PROCEDURAL ] LANGUAGE name
    HANDLER call_handler [ INLINE inline_handler ] [ VALIDATOR valfunction ]
CREATE [ OR REPLACE ] [ TRUSTED ] [ PROCEDURAL ] LANGUAGE name
```

Description

CREATE LANGUAGE registers a new procedural language with a Postgres Pro database. Subsequently, functions and procedures can be defined in this new language.

CREATE LANGUAGE effectively associates the language name with handler function(s) that are responsible for executing functions written in the language. Refer to [Chapter 57](#) for more information about language handlers.

CREATE OR REPLACE LANGUAGE will either create a new language, or replace an existing definition. If the language already exists, its parameters are updated according to the command, but the language's ownership and permissions settings do not change, and any existing functions written in the language are assumed to still be valid.

One must have the Postgres Pro superuser privilege to register a new language or change an existing language's parameters. However, once the language is created it is valid to assign ownership of it to a non-superuser, who may then drop it, change its permissions, rename it, or assign it to a new owner. (Do not, however, assign ownership of the underlying C functions to a non-superuser; that would create a privilege escalation path for that user.)

The form of CREATE LANGUAGE that does not supply any handler function is obsolete. For backwards compatibility with old dump files, it is interpreted as CREATE EXTENSION. That will work if the language has been packaged into an extension of the same name, which is the conventional way to set up procedural languages.

Parameters

TRUSTED

TRUSTED specifies that the language does not grant access to data that the user would not otherwise have. If this key word is omitted when registering the language, only users with the Postgres Pro superuser privilege can use this language to create new functions.

PROCEDURAL

This is a noise word.

name

The name of the new procedural language. The name must be unique among the languages in the database.

HANDLER *call_handler*

call_handler is the name of a previously registered function that will be called to execute the procedural language's functions. The call handler for a procedural language must be written in a compiled language such as C with version 1 call convention and registered with Postgres Pro as a function taking no arguments and returning the `language_handler` type, a placeholder type that is simply used to identify the function as a call handler.

`INLINE inline_handler`

inline_handler is the name of a previously registered function that will be called to execute an anonymous code block (`DO` command) in this language. If no *inline_handler* function is specified, the language does not support anonymous code blocks. The handler function must take one argument of type `internal`, which will be the `DO` command's internal representation, and it will typically return `void`. The return value of the handler is ignored.

`VALIDATOR valfunction`

valfunction is the name of a previously registered function that will be called when a new function in the language is created, to validate the new function. If no validator function is specified, then a new function will not be checked when it is created. The validator function must take one argument of type `oid`, which will be the OID of the to-be-created function, and will typically return `void`.

A validator function would typically inspect the function body for syntactical correctness, but it can also look at other properties of the function, for example if the language cannot handle certain argument types. To signal an error, the validator function should use the `ereport()` function. The return value of the function is ignored.

Notes

Use `DROP LANGUAGE` to drop procedural languages.

The system catalog `pg_language` (see [Section 54.29](#)) records information about the currently installed languages. Also, the `psql` command `\dL` lists the installed languages.

To create functions in a procedural language, a user must have the `USAGE` privilege for the language. By default, `USAGE` is granted to `PUBLIC` (i.e., everyone) for trusted languages. This can be revoked if desired.

Procedural languages are local to individual databases. However, a language can be installed into the `template1` database, which will cause it to be available automatically in all subsequently-created databases.

Examples

A minimal sequence for creating a new procedural language is:

```
CREATE FUNCTION plsample_call_handler() RETURNS language_handler
AS '$libdir/plsample'
LANGUAGE C;
CREATE LANGUAGE plsample
HANDLER plsample_call_handler;
```

Typically that would be written in an extension's creation script, and users would do this to install the extension:

```
CREATE EXTENSION plsample;
```

Compatibility

`CREATE LANGUAGE` is a Postgres Pro extension.

CREATE MATERIALIZED VIEW

CREATE MATERIALIZED VIEW — define a new materialized view

Synopsis

```
CREATE MATERIALIZED VIEW [ IF NOT EXISTS ] table_name
    [ ( column_name [, ...] ) ]
    [ USING method ]
    [ WITH ( storage_parameter [= value] [, ... ] ) ]
    [ TABLESPACE tablespace_name ]
    AS query
    [ WITH [ NO ] DATA ]
```

Description

CREATE MATERIALIZED VIEW defines a materialized view of a query. The query is executed and used to populate the view at the time the command is issued (unless WITH NO DATA is used) and may be refreshed later using REFRESH MATERIALIZED VIEW.

CREATE MATERIALIZED VIEW is similar to CREATE TABLE AS, except that it also remembers the query used to initialize the view, so that it can be refreshed later upon demand. A materialized view has many of the same properties as a table, but there is no support for temporary materialized views.

CREATE MATERIALIZED VIEW requires CREATE privilege on the schema used for the materialized view.

Parameters

IF NOT EXISTS

Do not throw an error if a materialized view with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing materialized view is anything like the one that would have been created.

table_name

The name (optionally schema-qualified) of the materialized view to be created. The name must be distinct from the name of any other relation (table, sequence, index, view, materialized view, or foreign table) in the same schema.

column_name

The name of a column in the new materialized view. If column names are not provided, they are taken from the output column names of the query.

USING *method*

This optional clause specifies the table access method to use to store the contents for the new materialized view; the method needs be an access method of type TABLE. See [Chapter 62](#) for more information. If this option is not specified, the default table access method is chosen for the new materialized view. See [default_table_access_method](#) for more information.

WITH (*storage_parameter* [= *value*] [, ...])

This clause specifies optional storage parameters for the new materialized view; see [Storage Parameters](#) in the [CREATE TABLE](#) documentation for more information. All parameters supported for CREATE TABLE are also supported for CREATE MATERIALIZED VIEW. See [CREATE TABLE](#) for more information.

TABLESPACE *tablespace_name*

The *tablespace_name* is the name of the tablespace in which the new materialized view is to be created. If not specified, [default_tablespace](#) is consulted.

query

A [SELECT](#), [TABLE](#), or [VALUES](#) command. This query will run within a security-restricted operation; in particular, calls to functions that themselves create temporary tables will fail. Also, while the query is running, the [search_path](#) is temporarily changed to `pg_catalog`, `pg_temp`.

WITH [NO] DATA

This clause specifies whether or not the materialized view should be populated at creation time. If not, the materialized view will be flagged as unscannable and cannot be queried until `REFRESH MATERIALIZED VIEW` is used.

Compatibility

`CREATE MATERIALIZED VIEW` is a Postgres Pro extension.

See Also

CREATE OPERATOR

CREATE OPERATOR — define a new operator

Synopsis

```
CREATE OPERATOR name (  
    {FUNCTION|PROCEDURE} = function_name  
    [, LEFTARG = left_type ] [, RIGHTARG = right_type ]  
    [, COMMUTATOR = com_op ] [, NEGATOR = neg_op ]  
    [, RESTRICT = res_proc ] [, JOIN = join_proc ]  
    [, HASHES ] [, MERGES ]  
)
```

Description

CREATE OPERATOR defines a new operator, *name*. The user who defines an operator becomes its owner. If a schema name is given then the operator is created in the specified schema. Otherwise it is created in the current schema.

The operator name is a sequence of up to NAMEDATALEN-1 (63 by default) characters from the following list:

+ - * / < > = ~ ! @ # % ^ & | ` ?

There are a few restrictions on your choice of name:

- -- and /* cannot appear anywhere in an operator name, since they will be taken as the start of a comment.
- A multicharacter operator name cannot end in + or -, unless the name also contains at least one of these characters:

~ ! @ # % ^ & | ` ?

For example, @- is an allowed operator name, but *- is not. This restriction allows Postgres Pro to parse SQL-compliant commands without requiring spaces between tokens.

- The symbol => is reserved by the SQL grammar, so it cannot be used as an operator name.

The operator != is mapped to <> on input, so these two names are always equivalent.

For binary operators, both LEFTARG and RIGHTARG must be defined. For prefix operators only RIGHTARG should be defined. The *function_name* function must have been previously defined using CREATE FUNCTION and must be defined to accept the correct number of arguments (either one or two) of the indicated types.

In the syntax of CREATE OPERATOR, the keywords FUNCTION and PROCEDURE are equivalent, but the referenced function must in any case be a function, not a procedure. The use of the keyword PROCEDURE here is historical and deprecated.

The other clauses specify optional operator optimization attributes. Their meaning is detailed in [Section 39.15](#).

To be able to create an operator, you must have USAGE privilege on the argument types and the return type, as well as EXECUTE privilege on the underlying function. If a commutator or negator operator is specified, you must own those operators.

Parameters

name

The name of the operator to be defined. See above for allowable characters. The name can be schema-qualified, for example CREATE OPERATOR myschema.+ (...). If not, then the operator is created in

the current schema. Two operators in the same schema can have the same name if they operate on different data types. This is called *overloading*.

function_name

The function used to implement this operator.

left_type

The data type of the operator's left operand, if any. This option would be omitted for a prefix operator.

right_type

The data type of the operator's right operand.

com_op

The commutator of this operator.

neg_op

The negator of this operator.

res_proc

The restriction selectivity estimator function for this operator.

join_proc

The join selectivity estimator function for this operator.

HASHES

Indicates this operator can support a hash join.

MERGES

Indicates this operator can support a merge join.

To give a schema-qualified operator name in *com_op* or the other optional arguments, use the `OPERATOR()` syntax, for example:

```
COMMUTATOR = OPERATOR(myschema.===) ,
```

Notes

Refer to [Section 39.14](#) and [Section 39.15](#) for further information.

When you are defining a self-commutative operator, you just do it. When you are defining a pair of commutative operators, things are a little trickier: how can the first one to be defined refer to the other one, which you haven't defined yet? There are three solutions to this problem:

- One way is to omit the `COMMUTATOR` clause in the first operator that you define, and then provide one in the second operator's definition. Since Postgres Pro knows that commutative operators come in pairs, when it sees the second definition it will automatically go back and fill in the missing `COMMUTATOR` clause in the first definition.
- Another, more straightforward way is just to include `COMMUTATOR` clauses in both definitions. When Postgres Pro processes the first definition and realizes that `COMMUTATOR` refers to a nonexistent operator, the system will make a dummy entry for that operator in the system catalog. This dummy entry will have valid data only for the operator name, left and right operand types, and owner, since that's all that Postgres Pro can deduce at this point. The first operator's catalog entry will link to this dummy entry. Later, when you define the second operator, the system updates the dummy entry with the additional information from the second definition. If you try to use the dummy operator before it's been filled in, you'll just get an error message.

- Alternatively, both operators can be defined without `COMMUTATOR` clauses and then `ALTER OPERATOR` can be used to set their commutator links. It's sufficient to `ALTER` either one of the pair.

In all three cases, you must own both operators in order to mark them as commutators.

Pairs of negator operators can be defined using the same methods as for commutator pairs.

It is not possible to specify an operator's lexical precedence in `CREATE OPERATOR`, because the parser's precedence behavior is hard-wired. See [Section 4.1.6](#) for precedence details.

The obsolete options `SORT1`, `SORT2`, `LTCMP`, and `GTCMP` were formerly used to specify the names of sort operators associated with a merge-joinable operator. This is no longer necessary, since information about associated operators is found by looking at B-tree operator families instead. If one of these options is given, it is ignored except for implicitly setting `MERGES` true.

Use `DROP OPERATOR` to delete user-defined operators from a database. Use `ALTER OPERATOR` to modify operators in a database.

Examples

The following command defines a new operator, area-equality, for the data type `box`:

```
CREATE OPERATOR === (  
    LEFTARG = box,  
    RIGHTARG = box,  
    FUNCTION = area_equal_function,  
    COMMUTATOR = ==,  
    NEGATOR = !=,  
    RESTRICT = area_restriction_function,  
    JOIN = area_join_function,  
    HASHES, MERGES  
);
```

Compatibility

`CREATE OPERATOR` is a Postgres Pro extension. There are no provisions for user-defined operators in the SQL standard.

See Also

[ALTER OPERATOR](#), [CREATE OPERATOR CLASS](#), [DROP OPERATOR](#)

CREATE OPERATOR CLASS

CREATE OPERATOR CLASS — define a new operator class

Synopsis

```
CREATE OPERATOR CLASS name [ DEFAULT ] FOR TYPE data_type
  USING index_method [ FAMILY family_name ] AS
  { OPERATOR strategy_number operator_name [ ( op_type, op_type ) ] [ FOR SEARCH | FOR
ORDER BY sort_family_name ]
    | FUNCTION support_number [ ( op_type [ , op_type ] ) ] function_name
    ( argument_type [, ...] )
    | STORAGE storage_type
  } [, ... ]
```

Description

CREATE OPERATOR CLASS creates a new operator class. An operator class defines how a particular data type can be used with an index. The operator class specifies that certain operators will fill particular roles or “strategies” for this data type and this index method. The operator class also specifies the support functions to be used by the index method when the operator class is selected for an index column. All the operators and functions used by an operator class must be defined before the operator class can be created.

If a schema name is given then the operator class is created in the specified schema. Otherwise it is created in the current schema. Two operator classes in the same schema can have the same name only if they are for different index methods.

The user who defines an operator class becomes its owner. Presently, the creating user must be a superuser. (This restriction is made because an erroneous operator class definition could confuse or even crash the server.)

CREATE OPERATOR CLASS does not presently check whether the operator class definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user's responsibility to define a valid operator class.

Related operator classes can be grouped into *operator families*. To add a new operator class to an existing family, specify the FAMILY option in CREATE OPERATOR CLASS. Without this option, the new class is placed into a family named the same as the new class (creating that family if it doesn't already exist).

Refer to [Section 39.16](#) for further information.

Parameters

name

The name of the operator class to be created. The name can be schema-qualified.

DEFAULT

If present, the operator class will become the default operator class for its data type. At most one operator class can be the default for a specific data type and index method.

data_type

The column data type that this operator class is for.

index_method

The name of the index method this operator class is for.

family_name

The name of the existing operator family to add this operator class to. If not specified, a family named the same as the operator class is used (creating it, if it doesn't already exist).

strategy_number

The index method's strategy number for an operator associated with the operator class.

operator_name

The name (optionally schema-qualified) of an operator associated with the operator class.

op_type

In an `OPERATOR` clause, the operand data type(s) of the operator, or `NONE` to signify a prefix operator. The operand data types can be omitted in the normal case where they are the same as the operator class's data type.

In a `FUNCTION` clause, the operand data type(s) the function is intended to support, if different from the input data type(s) of the function (for B-tree comparison functions and hash functions) or the class's data type (for B-tree sort support functions, B-tree equal image functions, and all functions in GiST, SP-GiST, GIN and BRIN operator classes). These defaults are correct, and so *op_type* need not be specified in `FUNCTION` clauses, except for the case of a B-tree sort support function that is meant to support cross-data-type comparisons.

sort_family_name

The name (optionally schema-qualified) of an existing `btree` operator family that describes the sort ordering associated with an ordering operator.

If neither `FOR SEARCH` nor `FOR ORDER BY` is specified, `FOR SEARCH` is the default.

support_number

The index method's support function number for a function associated with the operator class.

function_name

The name (optionally schema-qualified) of a function that is an index method support function for the operator class.

argument_type

The parameter data type(s) of the function.

storage_type

The data type actually stored in the index. Normally this is the same as the column data type, but some index methods (currently GiST, GIN, SP-GiST and BRIN) allow it to be different. The `STORAGE` clause must be omitted unless the index method allows a different type to be used. If the column *data_type* is specified as `anyarray`, the *storage_type* can be declared as `anyelement` to indicate that the index entries are members of the element type belonging to the actual array type that each particular index is created for.

The `OPERATOR`, `FUNCTION`, and `STORAGE` clauses can appear in any order.

Notes

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator class is tantamount to granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator class.

The operators should not be defined by SQL functions. An SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

Before PostgreSQL 8.4, the `OPERATOR` clause could include a `RECHECK` option. This is no longer supported because whether an index operator is “lossy” is now determined on-the-fly at run time. This allows efficient handling of cases where an operator might or might not be lossy.

Examples

The following example command defines a GiST index operator class for the data type `_int4` (array of `int4`).

```
CREATE OPERATOR CLASS gist__int_ops
  DEFAULT FOR TYPE _int4 USING gist AS
    OPERATOR          3      &&,
    OPERATOR          6      = (anyarray, anyarray),
    OPERATOR          7      @>,
    OPERATOR          8      <@,
    OPERATOR          20     @@ (_int4, query_int),
    FUNCTION           1      g_int_consistent (internal, _int4, smallint, oid,
internal),
    FUNCTION           2      g_int_union (internal, internal),
    FUNCTION           3      g_int_compress (internal),
    FUNCTION           4      g_int_decompress (internal),
    FUNCTION           5      g_int_penalty (internal, internal, internal),
    FUNCTION           6      g_int_picksplit (internal, internal),
    FUNCTION           7      g_int_same (_int4, _int4, internal);
```

Compatibility

`CREATE OPERATOR CLASS` is a Postgres Pro extension. There is no `CREATE OPERATOR CLASS` statement in the SQL standard.

See Also

[ALTER OPERATOR CLASS](#), [DROP OPERATOR CLASS](#), [CREATE OPERATOR FAMILY](#), [ALTER OPERATOR FAMILY](#)

CREATE OPERATOR FAMILY

CREATE OPERATOR FAMILY — define a new operator family

Synopsis

```
CREATE OPERATOR FAMILY name USING index_method
```

Description

CREATE OPERATOR FAMILY creates a new operator family. An operator family defines a collection of related operator classes, and perhaps some additional operators and support functions that are compatible with these operator classes but not essential for the functioning of any individual index. (Operators and functions that are essential to indexes should be grouped within the relevant operator class, rather than being “loose” in the operator family. Typically, single-data-type operators are bound to operator classes, while cross-data-type operators can be loose in an operator family containing operator classes for both data types.)

The new operator family is initially empty. It should be populated by issuing subsequent CREATE OPERATOR CLASS commands to add contained operator classes, and optionally ALTER OPERATOR FAMILY commands to add “loose” operators and their corresponding support functions.

If a schema name is given then the operator family is created in the specified schema. Otherwise it is created in the current schema. Two operator families in the same schema can have the same name only if they are for different index methods.

The user who defines an operator family becomes its owner. Presently, the creating user must be a superuser. (This restriction is made because an erroneous operator family definition could confuse or even crash the server.)

Refer to [Section 39.16](#) for further information.

Parameters

name

The name of the operator family to be created. The name can be schema-qualified.

index_method

The name of the index method this operator family is for.

Compatibility

CREATE OPERATOR FAMILY is a Postgres Pro extension. There is no CREATE OPERATOR FAMILY statement in the SQL standard.

See Also

[ALTER OPERATOR FAMILY](#), [DROP OPERATOR FAMILY](#), [CREATE OPERATOR CLASS](#), [ALTER OPERATOR CLASS](#), [DROP OPERATOR CLASS](#)

CREATE PACKAGE

CREATE PACKAGE — define a new package

Synopsis

```
CREATE [ OR REPLACE ] PACKAGE package_name package_element [ ... ]
```

Description

CREATE PACKAGE enters a new package into the current database.

A package is essentially a schema that helps to organize the named objects with a related purpose so it can be also created using [CREATE SCHEMA](#) and is subject to the same actions as a schema. A package should contain only functions, procedures and composite types.

CREATE OR REPLACE PACKAGE will either create a new package, or replace an existing definition. You can replace the existing package if it contains only functions and types, other objects must be previously dropped. If you replace the package without changing the function signature, its body is replaced, while dependent objects still remain. If the function signature changes, you would actually be creating a new, distinct function. The latter would only work when there are no dependent objects, otherwise the CREATE OR REPLACE PACKAGE is forced to fail. The same restriction applies to replacing types. When replacing packages, make sure that no other sessions use them (which can be done by stopping the application before replacing the packages).

Parameters

package_name

The name of a package to be created. The package name must be distinct from the name of any existing package or schema in the current database. The name cannot begin with `pg_`, as such names are reserved for system schemas.

package_element

An SQL statement defining an object to be created within the package. Currently, only CREATE FUNCTION, CREATE TYPE, and CREATE PROCEDURE are accepted as clauses within CREATE PACKAGE. The subcommands are treated essentially the same as separate commands issued after creating the package. By default, all the variables declared in the package initialization function, package functions and package procedures are public, so they can be called using dot notation from outside the package by other functions, procedures and anonymous blocks that import the package. The `#private` modifier defines functions and procedures as private, and the `#export` modifier defines which package variables are public. For more information on package functions and modifiers, see [Section 44.11](#).

Notes

To create a package, the invoking user must be a superuser or have the CREATE privilege for the current database.

Examples

Create a package named `counter` and create functions within it:

```
CREATE PACKAGE counter
CREATE FUNCTION __init__() RETURNS void AS $$ -- package initialization
#export on
DECLARE
    n int := 1; -- public package variable n
    k int := 3; -- public package variable k
```

```
BEGIN
    FOR i IN 1..10 LOOP
        n := n + n;
    END LOOP;
END;
$$

CREATE FUNCTION inc() RETURNS int AS $$ -- public package function inc()
BEGIN
    n := n + 1;
    RETURN n;
END;
$$
;
```

Notice that the individual subcommands do not end with semicolons, just as in [CREATE SCHEMA](#), and no language is specified when creating functions.

The `#export` on modifier inside the package initialization function renders all the declared variables public, meaning they are available outside the package. The same result is achieved if the package does not contain the `#export` modifier (default). The `inc()` function is public by default and is available outside the package, as any other package function or procedure.

The example below shows how the above-described package can be used.

```
DO $$
#import counter
BEGIN
    RAISE NOTICE '%', counter.n;
    RAISE NOTICE '%', counter.inc();
END;
$$;
```

```
NOTICE: 1024
NOTICE: 1025
```

A variation of the previous example:

```
CREATE PACKAGE foo
CREATE TYPE footype AS (a int, b int)

CREATE FUNCTION __init__() RETURNS void AS $$
#export y
DECLARE
    x int := 1; -- private package variable x
    y int := 5; -- public package variable y
BEGIN
    RAISE NOTICE 'foo initialized';
END;
$$

CREATE FUNCTION get_x() RETURNS int AS $$ -- public package function get_x()
BEGIN
    RETURN x;
END;
$$

CREATE PROCEDURE set_x(val int) AS $$ -- public package procedure set_x()
BEGIN
    x := val;
```

```

    CALL foo.check_x();
END;
$$

CREATE PROCEDURE check_x() AS $$ -- private package procedure check_x()
#private
BEGIN
    IF x <= 0 THEN
        RAISE INFO 'now x is not natural number';
    ELSE
        RAISE INFO 'now x is natural number';
    END IF;
END;
$$
;

```

In this example, the `y` variable, the `get_x()` function and the `set_x(int)` procedure of the `foo` package are public.

A variation of the previous example:

```

DO $$
#import foo
BEGIN
    RAISE INFO 'y = %', foo.y;
    RAISE INFO 'x = %', foo.get_x();
    CALL foo.set_x(25);
    RAISE INFO 'x = %', foo.get_x();
END;
$$;

INFO:  y = 5
INFO:  x = 1
INFO:  x set to natural value
INFO:  x = 25

```

The following is an equivalent way of achieving the same result using the `CREATE SCHEMA` command:

```

CREATE SCHEMA foo;
CREATE TYPE foo.footype AS (a int, b int);

CREATE FUNCTION foo.__init__() RETURNS void AS $$
#export y
DECLARE
    x int := 1; -- private package variable x
    y int := 5; -- public package variable y
BEGIN
    RAISE NOTICE 'foo initialized';
END;
$$ LANGUAGE plpgsql;

CREATE FUNCTION foo.get_x() RETURNS int AS $$ -- public package function get_x()
#package
BEGIN
    RETURN x;
END;
$$ LANGUAGE plpgsql;

CREATE PROCEDURE foo.set_x(val int) AS $$ -- public package procedure set_x()
#package

```

```
BEGIN
  x := val;
  CALL foo.check_x();
END;
$$ LANGUAGE plpgsql;

CREATE PROCEDURE foo.check_x() AS $$ -- private package procedure check_x()
#package
#private
BEGIN
  IF x <= 0 THEN
    RAISE INFO 'x set to not natural value';
  ELSE
    RAISE INFO 'x set to natural value';
  END IF;
END;
$$ LANGUAGE plpgsql;
```

Note that in this case you must use [#package modifiers](#).

[DROP PACKAGE](#)

CREATE POLICY

CREATE POLICY — define a new row-level security policy for a table

Synopsis

```
CREATE POLICY name ON table_name
[ AS { PERMISSIVE | RESTRICTIVE } ]
[ FOR { ALL | SELECT | INSERT | UPDATE | DELETE } ]
[ TO { role_name | PUBLIC | CURRENT_ROLE | CURRENT_USER | SESSION_USER } [, ...] ]
[ USING ( using_expression ) ]
[ WITH CHECK ( check_expression ) ]
```

Description

The `CREATE POLICY` command defines a new row-level security policy for a table. Note that row-level security must be enabled on the table (using `ALTER TABLE ... ENABLE ROW LEVEL SECURITY`) in order for created policies to be applied.

A policy grants the permission to select, insert, update, or delete rows that match the relevant policy expression. Existing table rows are checked against the expression specified in `USING`, while new rows that would be created via `INSERT` or `UPDATE` are checked against the expression specified in `WITH CHECK`. When a `USING` expression returns true for a given row then that row is visible to the user, while if false or null is returned then the row is not visible. When a `WITH CHECK` expression returns true for a row then that row is inserted or updated, while if false or null is returned then an error occurs.

For `INSERT`, `UPDATE`, and `MERGE` statements, `WITH CHECK` expressions are enforced after `BEFORE` triggers are fired, and before any actual data modifications are made. Thus a `BEFORE ROW` trigger may modify the data to be inserted, affecting the result of the security policy check. `WITH CHECK` expressions are enforced before any other constraints.

Policy names are per-table. Therefore, one policy name can be used for many different tables and have a definition for each table which is appropriate to that table.

Policies can be applied for specific commands or for specific roles. The default for newly created policies is that they apply for all commands and roles, unless otherwise specified. Multiple policies may apply to a single command; see below for more details. [Table 311](#) summarizes how the different types of policy apply to specific commands.

For policies that can have both `USING` and `WITH CHECK` expressions (`ALL` and `UPDATE`), if no `WITH CHECK` expression is defined, then the `USING` expression will be used both to determine which rows are visible (normal `USING` case) and which new rows will be allowed to be added (`WITH CHECK` case).

If row-level security is enabled for a table, but no applicable policies exist, a “default deny” policy is assumed, so that no rows will be visible or updatable.

Parameters

name

The name of the policy to be created. This must be distinct from the name of any other policy for the table.

table_name

The name (optionally schema-qualified) of the table the policy applies to.

`PERMISSIVE`

Specify that the policy is to be created as a permissive policy. All permissive policies which are applicable to a given query will be combined together using the Boolean “OR” operator. By creating

permissive policies, administrators can add to the set of records which can be accessed. Policies are permissive by default.

RESTRICTIVE

Specify that the policy is to be created as a restrictive policy. All restrictive policies which are applicable to a given query will be combined together using the Boolean “AND” operator. By creating restrictive policies, administrators can reduce the set of records which can be accessed as all restrictive policies must be passed for each record.

Note that there needs to be at least one permissive policy to grant access to records before restrictive policies can be usefully used to reduce that access. If only restrictive policies exist, then no records will be accessible. When a mix of permissive and restrictive policies are present, a record is only accessible if at least one of the permissive policies passes, in addition to all the restrictive policies.

command

The command to which the policy applies. Valid options are `ALL`, `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. `ALL` is the default. See below for specifics regarding how these are applied.

role_name

The role(s) to which the policy is to be applied. The default is `PUBLIC`, which will apply the policy to all roles.

using_expression

Any SQL conditional expression (returning `boolean`). The conditional expression cannot contain any aggregate or window functions. This expression will be added to queries that refer to the table if row-level security is enabled. Rows for which the expression returns true will be visible. Any rows for which the expression returns false or null will not be visible to the user (in a `SELECT`), and will not be available for modification (in an `UPDATE` or `DELETE`). Such rows are silently suppressed; no error is reported.

check_expression

Any SQL conditional expression (returning `boolean`). The conditional expression cannot contain any aggregate or window functions. This expression will be used in `INSERT` and `UPDATE` queries against the table if row-level security is enabled. Only rows for which the expression evaluates to true will be allowed. An error will be thrown if the expression evaluates to false or null for any of the records inserted or any of the records that result from the update. Note that the *check_expression* is evaluated against the proposed new contents of the row, not the original contents.

Per-Command Policies

`ALL`

Using `ALL` for a policy means that it will apply to all commands, regardless of the type of command. If an `ALL` policy exists and more specific policies exist, then both the `ALL` policy and the more specific policy (or policies) will be applied. Additionally, `ALL` policies will be applied to both the selection side of a query and the modification side, using the `USING` expression for both cases if only a `USING` expression has been defined.

As an example, if an `UPDATE` is issued, then the `ALL` policy will be applicable both to what the `UPDATE` will be able to select as rows to be updated (applying the `USING` expression), and to the resulting updated rows, to check if they are permitted to be added to the table (applying the `WITH CHECK` expression, if defined, and the `USING` expression otherwise). If an `INSERT` or `UPDATE` command attempts to add rows to the table that do not pass the `ALL` policy's `WITH CHECK` expression, the entire command will be aborted.

`SELECT`

Using `SELECT` for a policy means that it will apply to `SELECT` queries and whenever `SELECT` permissions are required on the relation the policy is defined for. The result is that only those records from the

relation that pass the `SELECT` policy will be returned during a `SELECT` query, and that queries that require `SELECT` permissions, such as `UPDATE`, will also only see those records that are allowed by the `SELECT` policy. A `SELECT` policy cannot have a `WITH CHECK` expression, as it only applies in cases where records are being retrieved from the relation.

INSERT

Using `INSERT` for a policy means that it will apply to `INSERT` commands and `MERGE` commands that contain `INSERT` actions. Rows being inserted that do not pass this policy will result in a policy violation error, and the entire `INSERT` command will be aborted. An `INSERT` policy cannot have a `USING` expression, as it only applies in cases where records are being added to the relation.

Note that `INSERT` with `ON CONFLICT DO UPDATE` checks `INSERT` policies' `WITH CHECK` expressions only for rows appended to the relation by the `INSERT` path.

UPDATE

Using `UPDATE` for a policy means that it will apply to `UPDATE`, `SELECT FOR UPDATE` and `SELECT FOR SHARE` commands, as well as auxiliary `ON CONFLICT DO UPDATE` clauses of `INSERT` commands. `MERGE` commands containing `UPDATE` actions are affected as well. Since `UPDATE` involves pulling an existing record and replacing it with a new modified record, `UPDATE` policies accept both a `USING` expression and a `WITH CHECK` expression. The `USING` expression determines which records the `UPDATE` command will see to operate against, while the `WITH CHECK` expression defines which modified rows are allowed to be stored back into the relation.

Any rows whose updated values do not pass the `WITH CHECK` expression will cause an error, and the entire command will be aborted. If only a `USING` clause is specified, then that clause will be used for both `USING` and `WITH CHECK` cases.

Typically an `UPDATE` command also needs to read data from columns in the relation being updated (e.g., in a `WHERE` clause or a `RETURNING` clause, or in an expression on the right hand side of the `SET` clause). In this case, `SELECT` rights are also required on the relation being updated, and the appropriate `SELECT` or `ALL` policies will be applied in addition to the `UPDATE` policies. Thus the user must have access to the row(s) being updated through a `SELECT` or `ALL` policy in addition to being granted permission to update the row(s) via an `UPDATE` or `ALL` policy.

When an `INSERT` command has an auxiliary `ON CONFLICT DO UPDATE` clause, if the `UPDATE` path is taken, the row to be updated is first checked against the `USING` expressions of any `UPDATE` policies, and then the new updated row is checked against the `WITH CHECK` expressions. Note, however, that unlike a standalone `UPDATE` command, if the existing row does not pass the `USING` expressions, an error will be thrown (the `UPDATE` path will *never* be silently avoided).

DELETE

Using `DELETE` for a policy means that it will apply to `DELETE` commands. Only rows that pass this policy will be seen by a `DELETE` command. There can be rows that are visible through a `SELECT` that are not available for deletion, if they do not pass the `USING` expression for the `DELETE` policy.

In most cases a `DELETE` command also needs to read data from columns in the relation that it is deleting from (e.g., in a `WHERE` clause or a `RETURNING` clause). In this case, `SELECT` rights are also required on the relation, and the appropriate `SELECT` or `ALL` policies will be applied in addition to the `DELETE` policies. Thus the user must have access to the row(s) being deleted through a `SELECT` or `ALL` policy in addition to being granted permission to delete the row(s) via a `DELETE` or `ALL` policy.

A `DELETE` policy cannot have a `WITH CHECK` expression, as it only applies in cases where records are being deleted from the relation, so that there is no new row to check.

Table 311. Policies Applied by Command Type

Command	SELECT/ALL policy	INSERT/ALL policy	UPDATE/ALL policy		DELETE/ALL policy
	USING expression	WITH CHECK expression	USING expression	WITH CHECK expression	USING expression
SELECT	Existing row	—	—	—	—
SELECT FOR UPDATE/SHARE	Existing row	—	Existing row	—	—
INSERT / MERGE ... THEN INSERT	—	New row	—	—	—
INSERT ... RETURNING	New row ^a	New row	—	—	—
UPDATE / MERGE ... THEN UPDATE	Existing & new rows ^a	—	Existing row	New row	—
DELETE	Existing row ^a	—	—	—	Existing row
ON CONFLICT DO UPDATE	Existing & new rows	—	Existing row	New row	—

^a If read access is required to the existing or new row (for example, a WHERE or RETURNING clause that refers to columns from the relation).

Application of Multiple Policies

When multiple policies of different command types apply to the same command (for example, `SELECT` and `UPDATE` policies applied to an `UPDATE` command), then the user must have both types of permissions (for example, permission to select rows from the relation as well as permission to update them). Thus the expressions for one type of policy are combined with the expressions for the other type of policy using the `AND` operator.

When multiple policies of the same command type apply to the same command, then there must be at least one `PERMISSIVE` policy granting access to the relation, and all of the `RESTRICTIVE` policies must pass. Thus all the `PERMISSIVE` policy expressions are combined using `OR`, all the `RESTRICTIVE` policy expressions are combined using `AND`, and the results are combined using `AND`. If there are no `PERMISSIVE` policies, then access is denied.

Note that, for the purposes of combining multiple policies, `ALL` policies are treated as having the same type as whichever other type of policy is being applied.

For example, in an `UPDATE` command requiring both `SELECT` and `UPDATE` permissions, if there are multiple applicable policies of each type, they will be combined as follows:

```
expression from RESTRICTIVE SELECT/ALL policy 1
AND
expression from RESTRICTIVE SELECT/ALL policy 2
AND
...
AND
(
  expression from PERMISSIVE SELECT/ALL policy 1
  OR
  expression from PERMISSIVE SELECT/ALL policy 2
  OR
  ...
)
AND
```

```
expression from RESTRICTIVE UPDATE/ALL policy 1
AND
expression from RESTRICTIVE UPDATE/ALL policy 2
AND
...
AND
(
    expression from PERMISSIVE UPDATE/ALL policy 1
    OR
    expression from PERMISSIVE UPDATE/ALL policy 2
    OR
    ...
)
```

Notes

You must be the owner of a table to create or change policies for it.

While policies will be applied for explicit queries against tables in the database, they are not applied when the system is performing internal referential integrity checks or validating constraints. This means there are indirect ways to determine that a given value exists. An example of this is attempting to insert a duplicate value into a column that is a primary key or has a unique constraint. If the insert fails then the user can infer that the value already exists. (This example assumes that the user is permitted by policy to insert records which they are not allowed to see.) Another example is where a user is allowed to insert into a table which references another, otherwise hidden table. Existence can be determined by the user inserting values into the referencing table, where success would indicate that the value exists in the referenced table. These issues can be addressed by carefully crafting policies to prevent users from being able to insert, delete, or update records at all which might possibly indicate a value they are not otherwise able to see, or by using generated values (e.g., surrogate keys) instead of keys with external meanings.

Generally, the system will enforce filter conditions imposed using security policies prior to qualifications that appear in user queries, in order to prevent inadvertent exposure of the protected data to user-defined functions which might not be trustworthy. However, functions and operators marked by the system (or the system administrator) as `LEAKPROOF` may be evaluated before policy expressions, as they are assumed to be trustworthy.

Since policy expressions are added to the user's query directly, they will be run with the rights of the user running the overall query. Therefore, users who are using a given policy must be able to access any tables or functions referenced in the expression or they will simply receive a permission denied error when attempting to query the table that has row-level security enabled. This does not change how views work, however. As with normal queries and views, permission checks and policies for the tables which are referenced by a view will use the view owner's rights and any policies which apply to the view owner, except if the view is defined using the `security_invoker` option (see [CREATE VIEW](#)).

No separate policy exists for `MERGE`. Instead, the policies defined for `SELECT`, `INSERT`, `UPDATE`, and `DELETE` are applied while executing `MERGE`, depending on the actions that are performed.

Additional discussion and practical examples can be found in [Section 5.9](#).

Compatibility

`CREATE POLICY` is a Postgres Pro extension.

[ALTER POLICY](#), [DROP POLICY](#), [ALTER TABLE](#)

CREATE PROCEDURE

CREATE PROCEDURE — define a new procedure

Synopsis

```
CREATE [ OR REPLACE ] PROCEDURE
    name ( [ [ argmode ] [ argname ] argtype [ { DEFAULT | = } default_expr ]
    [, ...] ] )
    { LANGUAGE lang_name
    | TRANSFORM { FOR TYPE type_name } [, ... ]
    | [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER
    | SET configuration_parameter { TO value | = value | FROM CURRENT }
    | AS 'definition'
    | AS 'obj_file', 'link_symbol'
    | sql_body
    } ...
```

Description

CREATE PROCEDURE defines a new procedure. CREATE OR REPLACE PROCEDURE will either create a new procedure, or replace an existing definition. To be able to define a procedure, the user must have the USAGE privilege on the language.

If a schema name is included, then the procedure is created in the specified schema. Otherwise it is created in the current schema. The name of the new procedure must not match any existing procedure or function with the same input argument types in the same schema. However, procedures and functions of different argument types can share a name (this is called *overloading*).

To replace the current definition of an existing procedure, use CREATE OR REPLACE PROCEDURE. It is not possible to change the name or argument types of a procedure this way (if you tried, you would actually be creating a new, distinct procedure).

When CREATE OR REPLACE PROCEDURE is used to replace an existing procedure, the ownership and permissions of the procedure do not change. All other procedure properties are assigned the values specified or implied in the command. You must own the procedure to replace it (this includes being a member of the owning role).

The user that creates the procedure becomes the owner of the procedure.

To be able to create a procedure, you must have USAGE privilege on the argument types.

Refer to [Section 39.4](#) for further information on writing procedures.

Parameters

name

The name (optionally schema-qualified) of the procedure to create.

argmode

The mode of an argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN.

argname

The name of an argument.

argtype

The data type(s) of the procedure's arguments (optionally schema-qualified), if any. The argument types can be base, composite, or domain types, or can reference the type of a table column.

Depending on the implementation language it might also be allowed to specify “pseudo-types” such as `cstring`. Pseudo-types indicate that the actual argument type is either incompletely specified, or outside the set of ordinary SQL data types.

The type of a column is referenced by writing `table_name.column_name%TYPE`. Using this feature can sometimes help make a procedure independent of changes to the definition of a table.

default_expr

An expression to be used as default value if the parameter is not specified. The expression has to be coercible to the argument type of the parameter. All input parameters following a parameter with a default value must have default values as well.

lang_name

The name of the language that the procedure is implemented in. It can be `sql`, `c`, `internal`, or the name of a user-defined procedural language, e.g., `plpgsql`. The default is `sql` if `sql_body` is specified. Enclosing the name in single quotes is deprecated and requires matching case.

`TRANSFORM { FOR TYPE type_name } [, ...] }`

Lists which transforms a call to the procedure should apply. Transforms convert between SQL types and language-specific data types; see [CREATE TRANSFORM](#). Procedural language implementations usually have hardcoded knowledge of the built-in types, so those don't need to be listed here. If a procedural language implementation does not know how to handle a type and no transform is supplied, it will fall back to a default behavior for converting data types, but this depends on the implementation.

`[EXTERNAL] SECURITY INVOKER`

`[EXTERNAL] SECURITY DEFINER`

`SECURITY INVOKER` indicates that the procedure is to be executed with the privileges of the user that calls it. That is the default. `SECURITY DEFINER` specifies that the procedure is to be executed with the privileges of the user that owns it.

The key word `EXTERNAL` is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all procedures not only external ones.

A `SECURITY DEFINER` procedure cannot execute transaction control statements (for example, `COMMIT` and `ROLLBACK`, depending on the language).

configuration_parameter value

The `SET` clause causes the specified configuration parameter to be set to the specified value when the procedure is entered, and then restored to its prior value when the procedure exits. `SET FROM CURRENT` saves the value of the parameter that is current when `CREATE PROCEDURE` is executed as the value to be applied when the procedure is entered.

If a `SET` clause is attached to a procedure, then the effects of a `SET LOCAL` command executed inside the procedure for the same variable are restricted to the procedure: the configuration parameter's prior value is still restored at procedure exit. However, an ordinary `SET` command (without `LOCAL`) overrides the `SET` clause, much as it would do for a previous `SET LOCAL` command: the effects of such a command will persist after procedure exit, unless the current transaction is rolled back.

If a `SET` clause is attached to a procedure, then that procedure cannot execute transaction control statements (for example, `COMMIT` and `ROLLBACK`, depending on the language).

See [SET](#) and [Chapter 19](#) for more information about allowed parameter names and values.

definition

A string constant defining the procedure; the meaning depends on the language. It can be an internal procedure name, the path to an object file, an SQL command, or text in a procedural language.

It is often helpful to use dollar quoting (see [Section 4.1.2.4](#)) to write the procedure definition string, rather than the normal single quote syntax. Without dollar quoting, any single quotes or backslashes in the procedure definition must be escaped by doubling them.

obj_file, link_symbol

This form of the `AS` clause is used for dynamically loadable C language procedures when the procedure name in the C language source code is not the same as the name of the SQL procedure. The string *obj_file* is the name of the shared library file containing the compiled C procedure, and is interpreted as for the `LOAD` command. The string *link_symbol* is the procedure's link symbol, that is, the name of the procedure in the C language source code. If the link symbol is omitted, it is assumed to be the same as the name of the SQL procedure being defined.

When repeated `CREATE PROCEDURE` calls refer to the same object file, the file is only loaded once per session. To unload and reload the file (perhaps during development), start a new session.

sql_body

The body of a `LANGUAGE SQL` procedure. This should be a block

```
BEGIN ATOMIC
  statement;
  statement;
  ...
  statement;
END
```

This is similar to writing the text of the procedure body as a string constant (see *definition* above), but there are some differences: This form only works for `LANGUAGE SQL`, the string constant form works for all languages. This form is parsed at procedure definition time, the string constant form is parsed at execution time; therefore this form cannot support polymorphic argument types and other constructs that are not resolvable at procedure definition time. This form tracks dependencies between the procedure and objects used in the procedure body, so `DROP ... CASCADE` will work correctly, whereas the form using string literals may leave dangling procedures. Finally, this form is more compatible with the SQL standard and other SQL implementations.

Notes

See [CREATE FUNCTION](#) for more details on function creation that also apply to procedures.

Use [CALL](#) to execute a procedure.

Examples

```
CREATE PROCEDURE insert_data(a integer, b integer)
LANGUAGE SQL
AS $$
INSERT INTO tbl VALUES (a);
INSERT INTO tbl VALUES (b);
$$;
```

or

```
CREATE PROCEDURE insert_data(a integer, b integer)
LANGUAGE SQL
BEGIN ATOMIC
  INSERT INTO tbl VALUES (a);
  INSERT INTO tbl VALUES (b);
END;
```

and call like this:

```
CALL insert_data(1, 2);
```

Compatibility

A `CREATE PROCEDURE` command is defined in the SQL standard. The Postgres Pro implementation can be used in a compatible way but has many extensions. For details see also [CREATE FUNCTION](#).

[ALTER PROCEDURE](#), [DROP PROCEDURE](#), [CALL](#), [CREATE FUNCTION](#)

CREATE PROFILE

CREATE PROFILE — define a new profile

Synopsis

```
CREATE PROFILE [ IF NOT EXISTS ] name [ LIMIT parameter value [ ... ] ]
```

where *parameter* can be:

```
    FAILED_LOGIN_ATTEMPTS
| PASSWORD_REUSE_TIME
| PASSWORD_REUSE_MAX
| PASSWORD_LIFE_TIME
| PASSWORD_GRACE_TIME
| USER_INACTIVE_TIME
| FAILED_AUTH_KEEP_TIME
| PASSWORD_MIN_UNIQUE_CHARS
| PASSWORD_MIN_LEN
| PASSWORD_REQUIRE_COMPLEX
```

```
CREATE PROFILE [ IF NOT EXISTS ] name FROM existing_profile
```

Description

The `CREATE PROFILE` command adds a new profile for the Postgres Pro database cluster. You must be a database superuser or have the privileges of the `pg_manage_profiles` role to use this command.

A *profile* defines a set of parameters that restrict database usage. In particular, Postgres Pro profiles enforce password management policy for the roles assigned to them. Profiles are defined at the database cluster level, so they apply to all databases in the cluster.

By default, all parameter values of a new profile are set to `DEFAULT`, which inherits the actual values from the built-in `default` profile. Initially, the `default` profile provides no usage restrictions, but it can be changed by the `ALTER PROFILE` command. The `UNLIMITED` value indicates that no restrictions apply to a particular parameter.

Once a profile is assigned to a role, all restrictions of this profile apply to this role. All newly created roles have the `default` profile, unless you explicitly assign a different profile to this role.

Parameters

name

The name of the new profile.

`FAILED_LOGIN_ATTEMPTS` *value*

Specifies the number of failed login attempts before the role is locked. A superuser can unlock the locked role by running the `ALTER ROLE` command with the `ACCOUNT UNLOCK` clause.

Note that there can be several actual login attempts made behind each user-perceived login attempt. For example, when the user tries to log in with SSL enabled, libpq-based clients by default also make a non-SSL connection attempt if an SSL connection fails.

Possible values are integers greater than 0, `DEFAULT`, or `UNLIMITED`.

PASSWORD_REUSE_TIME *value*

Specifies for how long an old password cannot be reused. Measured in days. Possible values are real numbers greater than or equal to 0, interval values, **DEFAULT**, or **UNLIMITED**.

Set this parameter together with **PASSWORD_REUSE_MAX** as its effect depends on the combination. If both these parameters are set to **UNLIMITED**, there are no restrictions on password reuse. If only one of them is set to **UNLIMITED**, password reuse is always forbidden.

PASSWORD_REUSE_MAX *value*

Specifies the number of password changes required before the current password can be reused. Possible values are integers greater than or equal to 0, **DEFAULT**, or **UNLIMITED**.

Set this parameter together with **PASSWORD_REUSE_TIME** as its effect depends on the combination. If both these parameters are set to **UNLIMITED**, there are no restrictions on password reuse. If only one of them is set to **UNLIMITED**, password reuse is always forbidden.

PASSWORD_LIFE_TIME *value*

Specifies for how long the password can be used for authentication on the primary server. Measured in days. Possible values are real numbers, interval values, **DEFAULT**, or **UNLIMITED**. The resulting value in seconds must be greater than 0. Once the password expires, all further connections of the corresponding role are rejected. The role can be unlocked with the [ALTER ROLE](#) command.

However, if the [LDAP authentication](#) is configured, this role still can connect to standby servers, unless it is locked in LDAP too.

If **PASSWORD_GRACE_TIME** parameter is also set, the specified grace period is added to the password lifetime. During the grace period, the role is prompted to change the password while still allowed to log in.

PASSWORD_GRACE_TIME *value*

Specifies for how long a warning is raised that the password is going to expire while login is still allowed, measured in days. You can set the password life time in the **VALID UNTIL** attribute of the role or in the **PASSWORD_LIFE_TIME** parameter of the profile.

Possible values are real numbers greater than or equal to 0, interval values, **DEFAULT**, or **UNLIMITED**. If the **PASSWORD_GRACE_TIME** parameter is set to **UNLIMITED**, the password life time effectively becomes unlimited.

USER_INACTIVE_TIME *value*

Specifies for how long the user can be inactive since the last login before the role is locked. Measured in days. A superuser can unlock the locked role by running the [ALTER ROLE](#) command with the **ACCOUNT UNLOCK** clause. Possible values are real numbers, interval values, **DEFAULT**, or **UNLIMITED**. The resulting value in seconds must be greater than 0.

FAILED_AUTH_KEEP_TIME *value*

Specifies for how long the information on the user's first authentication failure is kept. Measured in days. Possible values are real numbers, interval values, **DEFAULT**, or **UNLIMITED**. The resulting value in seconds must be greater than 0. When the user attempts to log in after this time interval expires, the failed login attempts counter (see **FAILED_LOGIN_ATTEMPTS** parameter) is reset and the user is unlocked if they were locked previously due to authentication failures.

PASSWORD_MIN_UNIQUE_CHARS *value*

Specifies minimum number of unique characters for a password. Possible values are integers greater than 0, **DEFAULT**, or **UNLIMITED**.

`PASSWORD_MIN_LEN` *value*

Specifies minimum number of characters for a password. Possible values are positive integers, `DEFAULT`, or `UNLIMITED`.

`PASSWORD_REQUIRE_COMPLEX` [*value*]

Specifies whether password complexity is checked. If this check is enabled, a password must meet the following requirements:

- Password contains at least one character from three of the following groups: lowercase letters, uppercase letters, digits, and special characters
- Password doesn't contain the user name

Possible values are booleans or `DEFAULT`. If the parameter is used without a value, it is set as `true`.

`IF NOT EXISTS`

Do not throw an error if a profile with the same name already exists.

existing_profile

The name of an existing profile to copy. The new profile will have the same properties as the existing one, but it will be an independent object.

Important

All letters of languages without case distinction (Hindi, Chinese, etc.) in the UTF-8 encoding are considered lowercase.

Notes

Use [ALTER PROFILE](#) to change the parameter values of a profile, and [DROP PROFILE](#) to remove a profile. All the parameters specified by `CREATE PROFILE` can be modified later by running the `ALTER PROFILE` command.

Warning

`PASSWORD_REUSE_TIME` and `PASSWORD_REUSE_MAX` parameters might not work if the password is passed in an encrypted form during the password change. The `\password` command of `psql` encrypts the password (see [the section called “Meta-Commands”](#) for details). If the password is MD5 encrypted, it can be checked for equivalence, and `PASSWORD_REUSE_TIME` or `PASSWORD_REUSE_MAX` parameters can be applied. But there is no way to check for equivalence for SCRAM-SHA-256 encrypted passwords.

Warning

`PASSWORD_MIN_UNIQUE_CHARS`, `PASSWORD_MIN_LEN`, and `PASSWORD_REQUIRE_COMPLEX` parameters don't work if the password is passed in an encrypted form during the password change.

Examples

Create a profile `admin_profile`:

```
CREATE PROFILE admin_profile
    LIMIT PASSWORD_REUSE_MAX 10
    PASSWORD_REUSE_TIME 30;
```

Create a role having `admin_profile`:

```
CREATE ROLE admin WITH PROFILE admin_profile;
```

Create a profile from an existing profile:

```
CREATE PROFILE administrator FROM admin_profile;
```

This can be convenient to be able to use an existing profile as a template for a new one.

[ALTER PROFILE](#), [DROP PROFILE](#), [CREATE ROLE](#)

CREATE PUBLICATION

CREATE PUBLICATION — define a new publication

Synopsis

```
CREATE PUBLICATION name
  [ FOR ALL TABLES
    | FOR publication_object [, ... ] ]
  [ WITH ( publication_parameter [= value] [, ... ] ) ]
```

where *publication_object* is one of:

```
TABLE [ ONLY ] table_name [ * ] [ ( column_name [, ... ] ) ] [ WHERE ( expression
) ] [, ... ]
TABLES IN SCHEMA { schema_name | CURRENT_SCHEMA } [, ... ]
```

Description

CREATE PUBLICATION adds a new publication into the current database. The publication name must be distinct from the name of any existing publication in the current database.

A publication is essentially a group of tables whose data changes are intended to be replicated through logical replication. See [Section 29.1](#) for details about how publications fit into the logical replication setup.

Parameters

name

The name of the new publication.

FOR TABLE

Specifies a list of tables to add to the publication. If ONLY is specified before the table name, only that table is added to the publication. If ONLY is not specified, the table and all its descendant tables (if any) are added. Optionally, * can be specified after the table name to explicitly indicate that descendant tables are included. This does not apply to a partitioned table, however. The partitions of a partitioned table are always implicitly considered part of the publication, so they are never explicitly added to the publication.

If the optional WHERE clause is specified, it defines a *row filter* expression. Rows for which the *expression* evaluates to false or null will not be published. Note that parentheses are required around the expression. It has no effect on TRUNCATE commands.

When a column list is specified, only the named columns are replicated. If no column list is specified, all columns of the table are replicated through this publication, including any columns added later. It has no effect on TRUNCATE commands. See [Section 29.5](#) for details about column lists.

Only persistent base tables and partitioned tables can be part of a publication. Temporary tables, unlogged tables, foreign tables, materialized views, and regular views cannot be part of a publication.

Specifying a column list when the publication also publishes FOR TABLES IN SCHEMA is not supported.

When a partitioned table is added to a publication, all of its existing and future partitions are implicitly considered to be part of the publication. So, even operations that are performed directly on a partition are also published via publications that its ancestors are part of.

FOR ALL TABLES

Marks the publication as one that replicates changes for all tables in the database, including tables created in the future.

FOR TABLES IN SCHEMA

Marks the publication as one that replicates changes for all tables in the specified list of schemas, including tables created in the future.

Specifying a schema when the publication also publishes a table with a column list is not supported.

Only persistent base tables and partitioned tables present in the schema will be included as part of the publication. Temporary tables, unlogged tables, foreign tables, materialized views, and regular views from the schema will not be part of the publication.

When a partitioned table is published via schema level publication, all of its existing and future partitions are implicitly considered to be part of the publication, regardless of whether they are from the publication schema or not. So, even operations that are performed directly on a partition are also published via publications that its ancestors are part of.

WITH (*publication_parameter* [= *value*] [, ...])

This clause specifies optional parameters for a publication. The following parameters are supported:

publish (*string*)

This parameter determines which DML operations will be published by the new publication to the subscribers. The value is comma-separated list of operations. The allowed operations are `insert`, `update`, `delete`, and `truncate`. The default is to publish all actions, and so the default value for this option is `'insert, update, delete, truncate'`.

This parameter only affects DML operations. In particular, the initial data synchronization (see [Section 29.8.1](#)) for logical replication does not take this parameter into account when copying existing table data.

publish_via_partition_root (*boolean*)

This parameter determines whether changes in a partitioned table (or on its partitions) contained in the publication will be published using the identity and schema of the partitioned table rather than that of the individual partitions that are actually changed; the latter is the default. Enabling this allows the changes to be replicated into a non-partitioned table or a partitioned table consisting of a different set of partitions.

There can be a case where a subscription combines multiple publications. If a partitioned table is published by any subscribed publications which set `publish_via_partition_root = true`, changes on this partitioned table (or on its partitions) will be published using the identity and schema of this partitioned table rather than that of the individual partitions.

This parameter also affects how row filters and column lists are chosen for partitions; see below for details.

If this is enabled, `TRUNCATE` operations performed directly on partitions are not replicated.

When specifying a parameter of type `boolean`, the `= value` part can be omitted, which is equivalent to specifying `TRUE`.

Notes

If `FOR TABLE`, `FOR ALL TABLES` or `FOR TABLES IN SCHEMA` are not specified, then the publication starts out with an empty set of tables. That is useful if tables or schemas are to be added later.

The creation of a publication does not start replication. It only defines a grouping and filtering logic for future subscribers.

To create a publication, the invoking user must have the `CREATE` privilege for the current database. (Of course, superusers bypass this check.)

To add a table to a publication, the invoking user must have ownership rights on the table. The `FOR ALL TABLES` and `FOR TABLES IN SCHEMA` clauses require the invoking user to be a superuser.

The tables added to a publication that publishes `UPDATE` and/or `DELETE` operations must have `REPLICA IDENTITY` defined. Otherwise those operations will be disallowed on those tables.

Any column list must include the `REPLICA IDENTITY` columns in order for `UPDATE` or `DELETE` operations to be published. There are no column list restrictions if the publication publishes only `INSERT` operations.

A row filter expression (i.e., the `WHERE` clause) must contain only columns that are covered by the `REPLICA IDENTITY`, in order for `UPDATE` and `DELETE` operations to be published. For publication of `INSERT` operations, any column may be used in the `WHERE` expression. The row filter allows simple expressions that don't have user-defined functions, user-defined operators, user-defined types, user-defined collations, non-immutable built-in functions, or references to system columns.

The row filter on a table becomes redundant if `FOR TABLES IN SCHEMA` is specified and the table belongs to the referred schema.

For published partitioned tables, the row filter for each partition is taken from the published partitioned table if the publication parameter `publish_via_partition_root` is true, or from the partition itself if it is false (the default). See [Section 29.4](#) for details about row filters. Similarly, for published partitioned tables, the column list for each partition is taken from the published partitioned table if the publication parameter `publish_via_partition_root` is true, or from the partition itself if it is false.

For an `INSERT ... ON CONFLICT` command, the publication will publish the operation that results from the command. Depending on the outcome, it may be published as either `INSERT` or `UPDATE`, or it may not be published at all.

For a `MERGE` command, the publication will publish an `INSERT`, `UPDATE`, or `DELETE` for each row inserted, updated, or deleted.

ATTACHing a table into a partition tree whose root is published using a publication with `publish_via_partition_root` set to true does not result in the table's existing contents being replicated.

`COPY ... FROM` commands are published as `INSERT` operations.

DDL operations are not published.

The `WHERE` clause expression is executed with the role used for the replication connection.

Examples

Create a publication that publishes all changes in two tables:

```
CREATE PUBLICATION mypublication FOR TABLE users, departments;
```

Create a publication that publishes all changes from active departments:

```
CREATE PUBLICATION active_departments FOR TABLE departments WHERE (active IS TRUE);
```

Create a publication that publishes all changes in all tables:

```
CREATE PUBLICATION alltables FOR ALL TABLES;
```

Create a publication that only publishes `INSERT` operations in one table:

```
CREATE PUBLICATION insert_only FOR TABLE mydata
WITH (publish = 'insert');
```

Create a publication that publishes all changes for tables `users`, `departments` and all changes for all the tables present in the schema `production`:

```
CREATE PUBLICATION production_publication FOR TABLE users, departments, TABLES IN
  SCHEMA production;
```

Create a publication that publishes all changes for all the tables present in the schemas `marketing` and `sales`:

```
CREATE PUBLICATION sales_publication FOR TABLES IN SCHEMA marketing, sales;
```

Create a publication that publishes all changes for table `users`, but replicates only columns `user_id` and `firstname`:

```
CREATE PUBLICATION users_filtered FOR TABLE users (user_id, firstname);
```

Compatibility

`CREATE PUBLICATION` is a Postgres Pro extension.

[ALTER PUBLICATION](#), [DROP PUBLICATION](#), [CREATE SUBSCRIPTION](#), [ALTER SUBSCRIPTION](#)

CREATE ROLE

CREATE ROLE — define a new database role

Synopsis

```
CREATE ROLE name [ [ WITH ] option [ ... ] ]
```

where *option* can be:

```
SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| REPLICATION | NOREPLICATION
| BYPASSRLS | NOBYPASSRLS
| CONNECTION LIMIT connlimit
| [ ENCRYPTED ] PASSWORD 'password' | PASSWORD NULL
| VALID UNTIL 'timestamp'
| IN ROLE role_name [, ...]
| ROLE role_name [, ...]
| ADMIN role_name [, ...]
| SYSID uid
| PROFILE profile_name
```

Description

CREATE ROLE adds a new role to a Postgres Pro database cluster. A role is an entity that can own database objects and have database privileges; a role can be considered a “user”, a “group”, or both depending on how it is used. Refer to [Chapter 21](#) and [Chapter 20](#) for information about managing users and authentication. You must have CREATEROLE privilege or be a database superuser to use this command.

Note that roles are defined at the database cluster level, and so are valid in all databases in the cluster.

During role creation it is possible to immediately assign the newly created role to be a member of an existing role, and also assign existing roles to be members of the newly created role. The rules for which initial role membership options are enabled are described below in the IN ROLE, ROLE, and ADMIN clauses. The GRANT command has fine-grained option control during membership creation, and the ability to modify these options after the new role is created.

Parameters

name

The name of the new role.

SUPERUSER

NOSUPERUSER

These clauses determine whether the new role is a “superuser”, who can override all access restrictions within the database. Superuser status is dangerous and should be used only when really needed. You must yourself be a superuser to create a new superuser. If not specified, NOSUPERUSER is the default.

CREATEDB

NOCREATEDB

These clauses define a role's ability to create databases. If CREATEDB is specified, the role being defined will be allowed to create new databases. Specifying NOCREATEDB will deny a role the ability

to create databases. If not specified, `NOCREATEDB` is the default. Only superuser roles or roles with `CREATEDB` can specify `CREATEDB`.

`CREATEROLE`
`NOCREATEROLE`

These clauses determine whether a role will be permitted to create, alter, drop, comment on, and change the security label for other roles. See [role creation](#) for more details about what capabilities are conferred by this privilege. If not specified, `NOCREATEROLE` is the default.

`INHERIT`
`NOINHERIT`

This affects the membership inheritance status when this role is added as a member of another role, both in this and future commands. Specifically, it controls the inheritance status of memberships added with this command using the `IN ROLE` clause, and in later commands using the `ROLE` clause. It is also used as the default inheritance status when adding this role as a member using the `GRANT` command. If not specified, `INHERIT` is the default.

In Postgres Pro versions before 16, inheritance was a role-level attribute that controlled all runtime membership checks for that role.

`LOGIN`
`NOLOGIN`

These clauses determine whether a role is allowed to log in; that is, whether the role can be given as the initial session authorization name during client connection. A role having the `LOGIN` attribute can be thought of as a user. Roles without this attribute are useful for managing database privileges, but are not users in the usual sense of the word. If not specified, `NOLOGIN` is the default, except when `CREATE ROLE` is invoked through its alternative spelling `CREATE USER`.

`REPLICATION`
`NOREPLICATION`

These clauses determine whether a role is a replication role. A role must have this attribute (or be a superuser) in order to be able to connect to the server in replication mode (physical or logical replication) and in order to be able to create or drop replication slots. A role having the `REPLICATION` attribute is a very highly privileged role, and should only be used on roles actually used for replication. If not specified, `NOREPLICATION` is the default. Only superuser roles or roles with `REPLICATION` can specify `REPLICATION`.

`BYPASSRLS`
`NOBYPASSRLS`

These clauses determine whether a role bypasses every row-level security (RLS) policy. `NOBYPASSRLS` is the default. Only superuser roles or roles with `BYPASSRLS` can specify `BYPASSRLS`.

Note that `pg_dump` will set `row_security` to `OFF` by default, to ensure all contents of a table are dumped out. If the user running `pg_dump` does not have appropriate permissions, an error will be returned. However, superusers and the owner of the table being dumped always bypass RLS.

`CONNECTION LIMIT` *conlimit*

If role can log in, this specifies how many concurrent connections the role can make. `-1` (the default) means no limit. Note that only normal connections are counted towards this limit. Neither prepared transactions nor background worker connections are counted towards this limit.

`[ENCRYPTED] PASSWORD 'password'`
`PASSWORD NULL`

Sets the role's password. (A password is only of use for roles having the `LOGIN` attribute, but you can nonetheless define one for roles without it.) If you do not plan to use password authentication

you can omit this option. If no password is specified, the password will be set to null and password authentication will always fail for that user. A null password can optionally be written explicitly as `PASSWORD NULL`.

Note

Specifying an empty string will also set the password to null, but that was not the case before Postgres Pro version 10. In earlier versions, an empty string could be used, or not, depending on the authentication method and the exact version, and libpq would refuse to use it in any case. To avoid the ambiguity, specifying an empty string should be avoided.

The password is always stored encrypted in the system catalogs. The `ENCRYPTED` keyword has no effect, but is accepted for backwards compatibility. The method of encryption is determined by the configuration parameter `password_encryption`. If the presented password string is already in MD5-encrypted or SCRAM-encrypted format, then it is stored as-is regardless of `password_encryption` (since the system cannot decrypt the specified encrypted password string, to encrypt it in a different format). This allows reloading of encrypted passwords during dump/restore.

`VALID UNTIL 'timestamp'`

The `VALID UNTIL` clause sets a date and time after which the role's password is no longer valid. If this clause is omitted the password will be valid for all time.

`IN ROLE role_name`

The `IN ROLE` clause causes the new role to be automatically added as a member of the specified existing roles. The new membership will have the `SET` option enabled and the `ADMIN` option disabled. The `INHERIT` option will be enabled unless the `NOINHERIT` option is specified.

`ROLE role_name`

The `ROLE` clause causes one or more specified existing roles to be automatically added as members, with the `SET` option enabled. This in effect makes the new role a “group”. Roles named in this clause with the role-level `INHERIT` attribute will have the `INHERIT` option enabled in the new membership. New memberships will have the `ADMIN` option disabled.

`ADMIN role_name`

The `ADMIN` clause has the same effect as `ROLE`, but the named roles are added as members of the new role with `ADMIN` enabled, giving them the right to grant membership in the new role to others.

`SYSID uid`

The `SYSID` clause is ignored, but is accepted for backwards compatibility.

`PROFILE profile_name`

Sets the role's profile. If this clause is omitted, the `default` profile is assigned to a role (see [CREATE PROFILE](#) for details).

Notes

Use [ALTER ROLE](#) to change the attributes of a role, and [DROP ROLE](#) to remove a role. All the attributes specified by `CREATE ROLE` can be modified by later `ALTER ROLE` commands.

The preferred way to add and remove members of roles that are being used as groups is to use [GRANT](#) and [REVOKE](#).

The `VALID UNTIL` clause defines an expiration time for a password only, not for the role per se. In particular, the expiration time is not enforced when logging in using a non-password-based authentication method.

The role attributes defined here are non-inheritable, i.e., being a member of a role with, e.g., `CREATEDB` will not allow the member to create new databases even if the membership grant has the `INHERIT` option. Of course, if the membership grant has the `SET` option the member role would be able to `SET ROLE` to the `createdb` role and then create a new database.

The membership grants created by the `IN ROLE`, `ROLE`, and `ADMIN` clauses have the role executing this command as the grantor.

The `INHERIT` attribute is the default for reasons of backwards compatibility: in prior releases of Postgres Pro, users always had access to all privileges of groups they were members of. However, `NOINHERIT` provides a closer match to the semantics specified in the SQL standard.

Postgres Pro includes a program `createuser` that has the same functionality as `CREATE ROLE` (in fact, it calls this command) but can be run from the command shell.

The `CONNECTION LIMIT` option is only enforced approximately; if two new sessions start at about the same time when just one connection “slot” remains for the role, it is possible that both will fail. Also, the limit is never enforced for superusers.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in cleartext, and it might also be logged in the client's command history or the server log. The command `createuser`, however, transmits the password encrypted. Also, `psql` contains a command `\password` that can be used to safely change the password later.

Examples

Create a role that can log in, but don't give it a password:

```
CREATE ROLE jonathan LOGIN;
```

Create a role with a password:

```
CREATE USER davide WITH PASSWORD 'jw8s0F4';
```

(`CREATE USER` is the same as `CREATE ROLE` except that it implies `LOGIN`.)

Create a role with a profile:

```
CREATE ROLE davide WITH PROFILE admin_profile;
```

Create a role with a password that is valid until the end of 2004. After one second has ticked in 2005, the password is no longer valid.

```
CREATE ROLE miriam WITH LOGIN PASSWORD 'jw8s0F4' VALID UNTIL '2005-01-01';
```

Create a role that can create databases and manage roles:

```
CREATE ROLE admin WITH CREATEDB CREATEROLE;
```

Compatibility

The `CREATE ROLE` statement is in the SQL standard, but the standard only requires the syntax

```
CREATE ROLE name [ WITH ADMIN role_name ]
```

Multiple initial administrators, and all the other options of `CREATE ROLE`, are Postgres Pro extensions.

The SQL standard defines the concepts of users and roles, but it regards them as distinct concepts and leaves all commands defining users to be specified by each database implementation. In Postgres Pro we have chosen to unify users and roles into a single kind of entity. Roles therefore have many more optional attributes than they do in the standard.

The behavior specified by the SQL standard is most closely approximated creating SQL-standard users as Postgres Pro roles with the `NOINHERIT` option, and SQL-standard roles as Postgres Pro roles with the `INHERIT` option.

The `USER` clause has the same behavior as `ROLE` but has been deprecated:

```
USER role_name [, ...]
```

The `IN GROUP` clause has the same behavior as `IN ROLE` but has been deprecated:

```
IN GROUP role_name [, ...]
```

[SET ROLE](#), [ALTER ROLE](#), [DROP ROLE](#), [GRANT](#), [REVOKE](#), [createuser](#), [createrole_self_grant](#), [CREATE PROFILE](#)

CREATE RULE

CREATE RULE — define a new rewrite rule

Synopsis

```
CREATE [ OR REPLACE ] RULE name AS ON event
  TO table_name [ WHERE condition ]
  DO [ ALSO | INSTEAD ] { NOTHING | command | ( command ; command ... ) }
```

where *event* can be one of:

```
SELECT | INSERT | UPDATE | DELETE
```

Description

CREATE RULE defines a new rule applying to a specified table or view. CREATE OR REPLACE RULE will either create a new rule, or replace an existing rule of the same name for the same table.

The Postgres Pro rule system allows one to define an alternative action to be performed on insertions, updates, or deletions in database tables. Roughly speaking, a rule causes additional commands to be executed when a given command on a given table is executed. Alternatively, an INSTEAD rule can replace a given command by another, or cause a command not to be executed at all. Rules are used to implement SQL views as well. It is important to realize that a rule is really a command transformation mechanism, or command macro. The transformation happens before the execution of the command starts. If you actually want an operation that fires independently for each physical row, you probably want to use a trigger, not a rule. More information about the rules system is in [Chapter 42](#).

Presently, ON SELECT rules can only be attached to views. Such a rule must be named "_RETURN", must be an unconditional INSTEAD rule, and must have an action that consists of a single SELECT command. This command defines the visible contents of the view. (The view itself is basically a dummy table with no storage.) It's best to regard such a rule as an implementation detail. While a view can be redefined via CREATE OR REPLACE RULE "_RETURN" AS ..., it's better style to use CREATE OR REPLACE VIEW.

You can create the illusion of an updatable view by defining ON INSERT, ON UPDATE, and ON DELETE rules (or any subset of those that's sufficient for your purposes) to replace update actions on the view with appropriate updates on other tables. If you want to support INSERT RETURNING and so on, then be sure to put a suitable RETURNING clause into each of these rules.

There is a catch if you try to use conditional rules for complex view updates: there *must* be an unconditional INSTEAD rule for each action you wish to allow on the view. If the rule is conditional, or is not INSTEAD, then the system will still reject attempts to perform the update action, because it thinks it might end up trying to perform the action on the dummy table of the view in some cases. If you want to handle all the useful cases in conditional rules, add an unconditional DO INSTEAD NOTHING rule to ensure that the system understands it will never be called on to update the dummy table. Then make the conditional rules non-INSTEAD; in the cases where they are applied, they add to the default INSTEAD NOTHING action. (This method does not currently work to support RETURNING queries, however.)

Note

A view that is simple enough to be automatically updatable (see [CREATE VIEW](#)) does not require a user-created rule in order to be updatable. While you can create an explicit rule anyway, the automatic update transformation will generally outperform an explicit rule.

Another alternative worth considering is to use INSTEAD OF triggers (see [CREATE TRIGGER](#)) in place of rules.

Parameters

name

The name of a rule to create. This must be distinct from the name of any other rule for the same table. Multiple rules on the same table and same event type are applied in alphabetical name order.

event

The event is one of `SELECT`, `INSERT`, `UPDATE`, or `DELETE`. Note that an `INSERT` containing an `ON CONFLICT` clause cannot be used on tables that have either `INSERT` or `UPDATE` rules. Consider using an updatable view instead.

table_name

The name (optionally schema-qualified) of the table or view the rule applies to.

condition

Any SQL conditional expression (returning `boolean`). The condition expression cannot refer to any tables except `NEW` and `OLD`, and cannot contain aggregate functions.

`INSTEAD`

`INSTEAD` indicates that the commands should be executed *instead of* the original command.

`ALSO`

`ALSO` indicates that the commands should be executed *in addition to* the original command.

If neither `ALSO` nor `INSTEAD` is specified, `ALSO` is the default.

command

The command or commands that make up the rule action. Valid commands are `SELECT`, `INSERT`, `UPDATE`, `DELETE`, or `NOTIFY`.

Within *condition* and *command*, the special table names `NEW` and `OLD` can be used to refer to values in the referenced table. `NEW` is valid in `ON INSERT` and `ON UPDATE` rules to refer to the new row being inserted or updated. `OLD` is valid in `ON UPDATE` and `ON DELETE` rules to refer to the existing row being updated or deleted.

Notes

You must be the owner of a table to create or change rules for it.

In a rule for `INSERT`, `UPDATE`, or `DELETE` on a view, you can add a `RETURNING` clause that emits the view's columns. This clause will be used to compute the outputs if the rule is triggered by an `INSERT RETURNING`, `UPDATE RETURNING`, or `DELETE RETURNING` command respectively. When the rule is triggered by a command without `RETURNING`, the rule's `RETURNING` clause will be ignored. The current implementation allows only unconditional `INSTEAD` rules to contain `RETURNING`; furthermore there can be at most one `RETURNING` clause among all the rules for the same event. (This ensures that there is only one candidate `RETURNING` clause to be used to compute the results.) `RETURNING` queries on the view will be rejected if there is no `RETURNING` clause in any available rule.

It is very important to take care to avoid circular rules. For example, though each of the following two rule definitions are accepted by Postgres Pro, the `SELECT` command would cause Postgres Pro to report an error because of recursive expansion of a rule:

```
CREATE RULE "_RETURN" AS
  ON SELECT TO t1
  DO INSTEAD
    SELECT * FROM t2;
```

```
CREATE RULE "_RETURN" AS
  ON SELECT TO t2
  DO INSTEAD
    SELECT * FROM t1;
```

```
SELECT * FROM t1;
```

Presently, if a rule action contains a `NOTIFY` command, the `NOTIFY` command will be executed unconditionally, that is, the `NOTIFY` will be issued even if there are not any rows that the rule should apply to. For example, in:

```
CREATE RULE notify_me AS ON UPDATE TO mytable DO ALSO NOTIFY mytable;
```

```
UPDATE mytable SET name = 'foo' WHERE id = 42;
```

one `NOTIFY` event will be sent during the `UPDATE`, whether or not there are any rows that match the condition `id = 42`. This is an implementation restriction that might be fixed in future releases.

Compatibility

`CREATE RULE` is a Postgres Pro language extension, as is the entire query rewrite system.

See Also

[ALTER RULE](#), [DROP RULE](#)

CREATE SCHEMA

CREATE SCHEMA — define a new schema

Synopsis

```
CREATE SCHEMA schema_name [ AUTHORIZATION role_specification ] [ schema_element
[ ... ] ]
CREATE SCHEMA AUTHORIZATION role_specification [ schema_element [ ... ] ]
CREATE SCHEMA IF NOT EXISTS schema_name [ AUTHORIZATION role_specification ]
CREATE SCHEMA IF NOT EXISTS AUTHORIZATION role_specification
```

where *role_specification* can be:

```
user_name
| CURRENT_ROLE
| CURRENT_USER
| SESSION_USER
```

Description

CREATE SCHEMA enters a new schema into the current database. The schema name must be distinct from the name of any existing schema in the current database.

A schema is essentially a namespace: it contains named objects (tables, data types, functions, and operators) whose names can duplicate those of other objects existing in other schemas. Named objects are accessed either by “qualifying” their names with the schema name as a prefix, or by setting a search path that includes the desired schema(s). A CREATE command specifying an unqualified object name creates the object in the current schema (the one at the front of the search path, which can be determined with the function `current_schema()`).

Optionally, CREATE SCHEMA can include subcommands to create objects within the new schema. The subcommands are treated essentially the same as separate commands issued after creating the schema, except that if the AUTHORIZATION clause is used, all the created objects will be owned by that user.

Parameters

schema_name

The name of a schema to be created. If this is omitted, the *user_name* is used as the schema name. The name cannot begin with `pg_`, as such names are reserved for system schemas.

user_name

The role name of the user who will own the new schema. If omitted, defaults to the user executing the command. To create a schema owned by another role, you must be able to SET ROLE to that role.

schema_element

An SQL statement defining an object to be created within the schema. Currently, only CREATE TABLE, CREATE VIEW, CREATE INDEX, CREATE SEQUENCE, CREATE TRIGGER and GRANT are accepted as clauses within CREATE SCHEMA. Other kinds of objects may be created in separate commands after the schema is created.

IF NOT EXISTS

Do nothing (except issuing a notice) if a schema with the same name already exists. *schema_element* subcommands cannot be included when this option is used.

Notes

To create a schema, the invoking user must have the `CREATE` privilege for the current database. (Of course, superusers bypass this check.)

Examples

Create a schema:

```
CREATE SCHEMA myschema;
```

Create a schema for user `joe`; the schema will also be named `joe`:

```
CREATE SCHEMA AUTHORIZATION joe;
```

Create a schema named `test` that will be owned by user `joe`, unless there already is a schema named `test`. (It does not matter whether `joe` owns the pre-existing schema.)

```
CREATE SCHEMA IF NOT EXISTS test AUTHORIZATION joe;
```

Create a schema and create a table and view within it:

```
CREATE SCHEMA hollywood
    CREATE TABLE films (title text, release date, awards text[])
    CREATE VIEW winners AS
        SELECT title, release FROM films WHERE awards IS NOT NULL;
```

Notice that the individual subcommands do not end with semicolons.

The following is an equivalent way of accomplishing the same result:

```
CREATE SCHEMA hollywood;
CREATE TABLE hollywood.films (title text, release date, awards text[]);
CREATE VIEW hollywood.winners AS
    SELECT title, release FROM hollywood.films WHERE awards IS NOT NULL;
```

Compatibility

The SQL standard allows a `DEFAULT CHARACTER SET` clause in `CREATE SCHEMA`, as well as more subcommand types than are presently accepted by Postgres Pro.

The SQL standard specifies that the subcommands in `CREATE SCHEMA` can appear in any order. The present Postgres Pro implementation does not handle all cases of forward references in subcommands; it might sometimes be necessary to reorder the subcommands in order to avoid forward references.

According to the SQL standard, the owner of a schema always owns all objects within it. Postgres Pro allows schemas to contain objects owned by users other than the schema owner. This can happen only if the schema owner grants the `CREATE` privilege on their schema to someone else, or a superuser chooses to create objects in it.

The `IF NOT EXISTS` option is a Postgres Pro extension.

See Also

[ALTER SCHEMA](#), [DROP SCHEMA](#)

CREATE SEQUENCE

CREATE SEQUENCE — define a new sequence generator

Synopsis

For sharded objects:

```
CREATE SEQUENCE [ IF NOT EXISTS ] name
  [ AS data_type ]
  [ INCREMENT [ BY ] increment ]
  [ MINVALUE minvalue | NO MINVALUE ] [ MAXVALUE maxvalue | NO MAXVALUE ]

  [ CACHE cache ] [ [ NO CYCLE ]
  [ OWNED BY { table_name.column_name | NONE } ]
WITH ( [ global = true ],
      [ block_size = block_size ]
      )
```

For other object types:

```
CREATE [ { TEMPORARY | TEMP } | UNLOGGED ] SEQUENCE [ IF NOT EXISTS ] name
  [ AS data_type ]
  [ INCREMENT [ BY ] increment ]
  [ MINVALUE minvalue | NO MINVALUE ] [ MAXVALUE maxvalue | NO MAXVALUE ]
  [ START [ WITH ] start ] [ CACHE cache ] [ [ NO ] CYCLE ]
  [ OWNED BY { table_name.column_name | NONE } ]
```

Description

CREATE SEQUENCE creates a new sequence number generator. This involves creating and initializing a new special single-row table with the name *name*. The generator will be owned by the user issuing the command.

Postgres Pro Shardman extensions to the CREATE SEQUENCE command enable creation of global sequence number generators. This command creates an ordinary PostgreSQL sequence on all nodes in a cluster and records sequence parameters in the global sequence state dictionary.

After a global sequence is created, usual nextval function can be used to generate next sequence values that are guaranteed be unique across the entire cluster. Other standard sequence manipulation functions (e.g. setval) must not be used on global sequences as this may lead to unexpected results.

Although you cannot update a sequence directly, you can use a query like:

```
SELECT * FROM name;
```

to examine the parameters and current state of a sequence. In particular, the last_value field of the sequence shows the last value allocated by any session. (Of course, this value might be obsolete by the time it's printed, if other sessions are actively doing nextval calls.)

Parameters

TEMPORARY or TEMP

If specified, the sequence object is created only for this session, and is automatically dropped on session exit. Existing permanent sequences with the same name are not visible (in this session) while the temporary sequence exists, unless they are referenced with schema-qualified names.

UNLOGGED

If specified, the sequence is created as an unlogged sequence. Changes to unlogged sequences are not written to the write-ahead log. They are not crash-safe: an unlogged sequence is automatically

reset to its initial state after a crash or unclean shutdown. Unlogged sequences are also not replicated to standby servers.

Unlike unlogged tables, unlogged sequences do not offer a significant performance advantage. This option is mainly intended for sequences associated with unlogged tables via identity columns or serial columns. In those cases, it usually wouldn't make sense to have the sequence WAL-logged and replicated but not its associated table.

IF NOT EXISTS

Do not throw an error if a relation with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing relation is anything like the sequence that would have been created — it might not even be a sequence.

name

The name (optionally schema-qualified) of the sequence to be created.

data_type

The optional clause `AS data_type` specifies the data type of the sequence. Valid types are `smallint`, `integer`, and `bigint`. `bigint` is the default. The data type determines the default minimum and maximum values of the sequence.

increment

The optional clause `INCREMENT BY increment` specifies which value is added to the current sequence value to create a new value. A positive value will make an ascending sequence, a negative one a descending sequence. The default value is 1.

minvalue

NO MINVALUE

The optional clause `MINVALUE minvalue` determines the minimum value a sequence can generate. If this clause is not supplied or `NO MINVALUE` is specified, then defaults will be used. The default for an ascending sequence is 1. The default for a descending sequence is the minimum value of the data type.

maxvalue

NO MAXVALUE

The optional clause `MAXVALUE maxvalue` determines the maximum value for the sequence. If this clause is not supplied or `NO MAXVALUE` is specified, then default values will be used. The default for an ascending sequence is the maximum value of the data type. The default for a descending sequence is -1.

start

The optional clause `START WITH start` allows the sequence to begin anywhere. The default starting value is *minvalue* for ascending sequences and *maxvalue* for descending ones.

cache

The optional clause `CACHE cache` specifies how many sequence numbers are to be preallocated and stored in memory for faster access. The minimum value is 1 (only one value can be generated at a time, i.e., no cache), and this is also the default.

CYCLE

NO CYCLE

The `CYCLE` option allows the sequence to wrap around when the *maxvalue* or *minvalue* has been reached by an ascending or descending sequence respectively. If the limit is reached, the next number generated will be the *minvalue* or *maxvalue*, respectively.

If `NO CYCLE` is specified, any calls to `nextval` after the sequence has reached its maximum value will return an error. If neither `CYCLE` or `NO CYCLE` are specified, `NO CYCLE` is the default.

`OWNED BY table_name.column_name`
`OWNED BY NONE`

The `OWNED BY` option causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. The specified table must have the same owner and be in the same schema as the sequence. `OWNED BY NONE`, the default, specifies that there is no such association.

`global`

If specified, the sequence object is created as a Postgres Pro Shardman-managed global sequence.

`block_size`

The number of elements allocated for a local sequence. The default value is 65536.

Notes

Use `DROP SEQUENCE` to remove a sequence.

Sequences are based on `bigint` arithmetic, so the range cannot exceed the range of an eight-byte integer (-9223372036854775808 to 9223372036854775807).

Because `nextval` and `setval` calls are never rolled back, sequence objects cannot be used if “gapless” assignment of sequence numbers is needed. It is possible to build gapless assignment by using exclusive locking of a table containing a counter; but this solution is much more expensive than sequence objects, especially if many transactions need sequence numbers concurrently.

Unexpected results might be obtained if a `cache` setting greater than one is used for a sequence object that will be used concurrently by multiple sessions. Each session will allocate and cache successive sequence values during one access to the sequence object and increase the sequence object's `last_value` accordingly. Then, the next `cache-1` uses of `nextval` within that session simply return the preallocated values without touching the sequence object. So, any numbers allocated but not used within a session will be lost when that session ends, resulting in “holes” in the sequence.

Furthermore, although multiple sessions are guaranteed to allocate distinct sequence values, the values might be generated out of sequence when all the sessions are considered. For example, with a `cache` setting of 10, session A might reserve values 1..10 and return `nextval=1`, then session B might reserve values 11..20 and return `nextval=11` before session A has generated `nextval=2`. Thus, with a `cache` setting of one it is safe to assume that `nextval` values are generated sequentially; with a `cache` setting greater than one you should only assume that the `nextval` values are all distinct, not that they are generated purely sequentially. Also, `last_value` will reflect the latest value reserved by any session, whether or not it has yet been returned by `nextval`.

Another consideration is that a `setval` executed on such a sequence will not be noticed by other sessions until they have used up any preallocated values they have cached.

Examples

Create a global sequence called `serial`.

```
CREATE SEQUENCE serial MINVALUE 100 WITH (global);
```

Select the next number from this sequence:

```
SELECT nextval('serial');
 nextval
-----
      100
```

(1 row)

Create an ascending sequence called `serial`, starting at 101:

```
CREATE SEQUENCE serial START 101;
```

Select the next number from this sequence:

```
SELECT nextval('serial');
```

```
nextval
-----
      101
```

Select the next number from this sequence:

```
SELECT nextval('serial');
```

```
nextval
-----
      102
```

Use this sequence in an `INSERT` command:

```
INSERT INTO distributors VALUES (nextval('serial'), 'nothing');
```

Update the sequence value after a `COPY FROM`:

```
BEGIN;
COPY distributors FROM 'input_file';
SELECT setval('serial', max(id)) FROM distributors;
END;
```

Compatibility

`CREATE SEQUENCE` conforms to the SQL standard, with the following exceptions:

- Obtaining the next value is done using the `nextval()` function instead of the standard's `NEXT VALUE FOR expression`.
- The `OWNED BY` clause is a Postgres Pro extension.

CREATE SERVER

CREATE SERVER — define a new foreign server

Synopsis

```
CREATE SERVER [ IF NOT EXISTS ] server_name [ TYPE 'server_type' ] [ VERSION 'server_version' ]  
    FOREIGN DATA WRAPPER fdw_name  
    [ OPTIONS ( option 'value' [, ... ] ) ]
```

Description

CREATE SERVER defines a new foreign server. The user who defines the server becomes its owner.

A foreign server typically encapsulates connection information that a foreign-data wrapper uses to access an external data resource. Additional user-specific connection information may be specified by means of user mappings.

The server name must be unique within the database.

Creating a server requires USAGE privilege on the foreign-data wrapper being used.

Parameters

IF NOT EXISTS

Do not throw an error if a server with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing server is anything like the one that would have been created.

server_name

The name of the foreign server to be created.

server_type

Optional server type, potentially useful to foreign-data wrappers.

server_version

Optional server version, potentially useful to foreign-data wrappers.

fdw_name

The name of the foreign-data wrapper that manages the server.

OPTIONS (*option* '*value*' [, ...])

This clause specifies the options for the server. The options typically define the connection details of the server, but the actual names and values are dependent on the server's foreign-data wrapper.

Notes

When using the [dblink](#) module, a foreign server's name can be used as an argument of the [dblink_connect](#) function to indicate the connection parameters. It is necessary to have the USAGE privilege on the foreign server to be able to use it in this way.

If the foreign server supports sort pushdown, it is necessary for it to have the same sort ordering as the local server.

Examples

Create a server `myserver` that uses the foreign-data wrapper `postgres_fdw`:

```
CREATE SERVER myserver FOREIGN DATA WRAPPER postgres_fdw OPTIONS (host 'foo', dbname 'foodb', port '5432');
```

See [postgres_fdw](#) for more details.

Compatibility

`CREATE SERVER` conforms to ISO/IEC 9075-9 (SQL/MED).

[ALTER SERVER](#), [DROP SERVER](#)

CREATE STATISTICS

CREATE STATISTICS — define extended statistics

Synopsis

```
CREATE STATISTICS [ [ IF NOT EXISTS ] statistics_name ]
    ON ( expression )
    FROM table_name

CREATE STATISTICS [ [ IF NOT EXISTS ] statistics_name ]
    [ ( statistics_kind [, ...] ) ]
    ON { column_name | ( expression ) }, { column_name | ( expression ) } [, ...]
    FROM table_name
```

Description

CREATE STATISTICS will create a new extended statistics object tracking data about the specified table, foreign table or materialized view. The statistics object will be created in the current database and will be owned by the user issuing the command.

The CREATE STATISTICS command has two basic forms. The first form allows univariate statistics for a single expression to be collected, providing benefits similar to an expression index without the overhead of index maintenance. This form does not allow the statistics kind to be specified, since the various statistics kinds refer only to multivariate statistics. The second form of the command allows multivariate statistics on multiple columns and/or expressions to be collected, optionally specifying which statistics kinds to include. This form will also automatically cause univariate statistics to be collected on any expressions included in the list.

If a schema name is given (for example, CREATE STATISTICS myschema.mystat ...) then the statistics object is created in the specified schema. Otherwise it is created in the current schema. If given, the name of the statistics object must be distinct from the name of any other statistics object in the same schema.

Parameters

IF NOT EXISTS

Do not throw an error if a statistics object with the same name already exists. A notice is issued in this case. Note that only the name of the statistics object is considered here, not the details of its definition. Statistics name is required when IF NOT EXISTS is specified.

statistics_name

The name (optionally schema-qualified) of the statistics object to be created. If the name is omitted, Postgres Pro chooses a suitable name based on the parent table's name and the defined column name(s) and/or expression(s).

statistics_kind

A multivariate statistics kind to be computed in this statistics object. Currently supported kinds are `ndistinct`, which enables n-distinct statistics, `dependencies`, which enables functional dependency statistics, and `mcv` which enables most-common values lists. If this clause is omitted, all supported statistics kinds are included in the statistics object. Univariate expression statistics are built automatically if the statistics definition includes any complex expressions rather than just simple column references. For more information, see [Section 14.2.2](#) and [Section 68.2](#).

column_name

The name of a table column to be covered by the computed statistics. This is only allowed when building multivariate statistics. At least two column names or expressions must be specified, and their order is not significant.

expression

An expression to be covered by the computed statistics. This may be used to build univariate statistics on a single expression, or as part of a list of multiple column names and/or expressions to build multivariate statistics. In the latter case, separate univariate statistics are built automatically for each expression in the list.

table_name

The name (optionally schema-qualified) of the table containing the column(s) the statistics are computed on; see [ANALYZE](#) for an explanation of the handling of inheritance and partitions.

Notes

You must be the owner of a table to create a statistics object reading it. Once created, however, the ownership of the statistics object is independent of the underlying table(s).

Expression statistics are per-expression and are similar to creating an index on the expression, except that they avoid the overhead of index maintenance. Expression statistics are built automatically for each expression in the statistics object definition.

Extended statistics are not currently used by the planner for selectivity estimations made for table joins. This limitation will likely be removed in a future version of Postgres Pro.

Examples

Create table `t1` with two functionally dependent columns, i.e., knowledge of a value in the first column is sufficient for determining the value in the other column. Then functional dependency statistics are built on those columns:

```
CREATE TABLE t1 (  
    a    int,  
    b    int  
);  
  
INSERT INTO t1 SELECT i/100, i/500  
    FROM generate_series(1,1000000) s(i);  
  
ANALYZE t1;  
  
-- the number of matching rows will be drastically underestimated:  
EXPLAIN ANALYZE SELECT * FROM t1 WHERE (a = 1) AND (b = 0);  
  
CREATE STATISTICS s1 (dependencies) ON a, b FROM t1;  
  
ANALYZE t1;  
  
-- now the row count estimate is more accurate:  
EXPLAIN ANALYZE SELECT * FROM t1 WHERE (a = 1) AND (b = 0);
```

Without functional-dependency statistics, the planner would assume that the two `WHERE` conditions are independent, and would multiply their selectivities together to arrive at a much-too-small row count estimate. With such statistics, the planner recognizes that the `WHERE` conditions are redundant and does not underestimate the row count.

Create table `t2` with two perfectly correlated columns (containing identical data), and an MCV list on those columns:

```
CREATE TABLE t2 (  
    a    int,  
    b    int  
);
```

```
INSERT INTO t2 SELECT mod(i,100), mod(i,100)
      FROM generate_series(1,1000000) s(i);
```

```
CREATE STATISTICS s2 (mcv) ON a, b FROM t2;
```

```
ANALYZE t2;
```

```
-- valid combination (found in MCV)
EXPLAIN ANALYZE SELECT * FROM t2 WHERE (a = 1) AND (b = 1);
```

```
-- invalid combination (not found in MCV)
EXPLAIN ANALYZE SELECT * FROM t2 WHERE (a = 1) AND (b = 2);
```

The MCV list gives the planner more detailed information about the specific values that commonly appear in the table, as well as an upper bound on the selectivities of combinations of values that do not appear in the table, allowing it to generate better estimates in both cases.

Create table `t3` with a single timestamp column, and run queries using expressions on that column. Without extended statistics, the planner has no information about the data distribution for the expressions, and uses default estimates. The planner also does not realize that the value of the date truncated to the month is fully determined by the value of the date truncated to the day. Then expression and `ndistinct` statistics are built on those two expressions:

```
CREATE TABLE t3 (
    a    timestamp
);
```

```
INSERT INTO t3 SELECT i FROM generate_series('2020-01-01'::timestamp,
      '2020-12-31'::timestamp,
      '1 minute'::interval) s(i);
```

```
ANALYZE t3;
```

```
-- the number of matching rows will be drastically underestimated:
EXPLAIN ANALYZE SELECT * FROM t3
    WHERE date_trunc('month', a) = '2020-01-01'::timestamp;
```

```
EXPLAIN ANALYZE SELECT * FROM t3
    WHERE date_trunc('day', a) BETWEEN '2020-01-01'::timestamp
      AND '2020-06-30'::timestamp;
```

```
EXPLAIN ANALYZE SELECT date_trunc('month', a), date_trunc('day', a)
    FROM t3 GROUP BY 1, 2;
```

```
-- build ndistinct statistics on the pair of expressions (per-expression
-- statistics are built automatically)
CREATE STATISTICS s3 (ndistinct) ON date_trunc('month', a), date_trunc('day', a) FROM
    t3;
```

```
ANALYZE t3;
```

```
-- now the row count estimates are more accurate:
EXPLAIN ANALYZE SELECT * FROM t3
    WHERE date_trunc('month', a) = '2020-01-01'::timestamp;
```

```
EXPLAIN ANALYZE SELECT * FROM t3
    WHERE date_trunc('day', a) BETWEEN '2020-01-01'::timestamp
      AND '2020-06-30'::timestamp;
```

```
EXPLAIN ANALYZE SELECT date_trunc('month', a), date_trunc('day', a)
FROM t3 GROUP BY 1, 2;
```

Without expression and ndistinct statistics, the planner has no information about the number of distinct values for the expressions, and has to rely on default estimates. The equality and range conditions are assumed to have 0.5% selectivity, and the number of distinct values in the expression is assumed to be the same as for the column (i.e. unique). This results in a significant underestimate of the row count in the first two queries. Moreover, the planner has no information about the relationship between the expressions, so it assumes the two `WHERE` and `GROUP BY` conditions are independent, and multiplies their selectivities together to arrive at a severe overestimate of the group count in the aggregate query. This is further exacerbated by the lack of accurate statistics for the expressions, forcing the planner to use a default ndistinct estimate for the expression derived from ndistinct for the column. With such statistics, the planner recognizes that the conditions are correlated, and arrives at much more accurate estimates.

Compatibility

There is no `CREATE STATISTICS` command in the SQL standard.

See Also

[ALTER STATISTICS](#), [DROP STATISTICS](#)

CREATE SUBSCRIPTION

CREATE SUBSCRIPTION — define a new subscription

Synopsis

```
CREATE SUBSCRIPTION subscription_name
    CONNECTION 'conninfo'
    PUBLICATION publication_name [, ...]
    [ WITH ( subscription_parameter [= value] [, ... ] ) ]
```

Description

CREATE SUBSCRIPTION adds a new logical-replication subscription. The user that creates a subscription becomes the owner of the subscription. The subscription name must be distinct from the name of any existing subscription in the current database.

A subscription represents a replication connection to the publisher. Hence, in addition to adding definitions in the local catalogs, this command normally creates a replication slot on the publisher.

A logical replication worker will be started to replicate data for the new subscription at the commit of the transaction where this command is run, unless the subscription is initially disabled.

To be able to create a subscription, you must have the privileges of the `pg_create_subscription` role, as well as CREATE privileges on the current database.

Additional information about subscriptions and logical replication as a whole is available at [Section 29.2](#) and [Chapter 29](#).

Parameters

subscription_name

The name of the new subscription.

CONNECTION '*conninfo*'

The libpq connection string defining how to connect to the publisher database. For details see [Section 35.1.1](#).

PUBLICATION *publication_name* [, ...]

Names of the publications on the publisher to subscribe to.

WITH (*subscription_parameter* [= *value*] [, ...])

This clause specifies optional parameters for a subscription.

The following parameters control what happens during subscription creation:

connect (boolean)

Specifies whether the CREATE SUBSCRIPTION command should connect to the publisher at all. The default is true. Setting this to false will force the values of create_slot, enabled and copy_data to false. (You cannot combine setting connect to false with setting create_slot, enabled, or copy_data to true.)

Since no connection is made when this option is false, no tables are subscribed. To initiate replication, you must manually create the replication slot, enable the failover if required, enable the subscription, and refresh the subscription. See [Section 29.2.3](#) for examples.

`create_slot` (boolean)

Specifies whether the command should create the replication slot on the publisher. The default is `true`.

If set to `false`, you are responsible for creating the publisher's slot in some other way. See [Section 29.2.3](#) for examples.

`enabled` (boolean)

Specifies whether the subscription should be actively replicating or whether it should just be set up but not started yet. The default is `true`.

`slot_name` (string)

Name of the publisher's replication slot to use. The default is to use the name of the subscription for the slot name.

Setting `slot_name` to `NONE` means there will be no replication slot associated with the subscription. Such subscriptions must also have both `enabled` and `create_slot` set to `false`. Use this when you will be creating the replication slot later manually. See [Section 29.2.3](#) for examples.

When setting `slot_name` to a valid name and `create_slot` to `false`, the `failover` property value of the named slot may differ from the counterpart `failover` parameter specified in the subscription. Always ensure the slot property `failover` matches the counterpart parameter of the subscription and vice versa. Otherwise, the slot on the publisher may behave differently from what these subscription options say: for example, the slot on the publisher could either be synced to the standbys even when the subscription's `failover` option is disabled or could be disabled for sync even when the subscription's `failover` option is enabled.

The following parameters control the subscription's replication behavior after it has been created:

`binary` (boolean)

Specifies whether the subscription will request the publisher to send the data in binary format (as opposed to text). The default is `false`. Any initial table synchronization copy (see `copy_data`) also uses the same format. Binary format can be faster than the text format, but it is less portable across machine architectures and Postgres Pro versions. Binary format is very data type specific; for example, it will not allow copying from a `smallint` column to an `integer` column, even though that would work fine in text format. Even when this option is enabled, only data types having binary send and receive functions will be transferred in binary. Note that the initial synchronization requires all data types to have binary send and receive functions, otherwise the synchronization will fail (see [CREATE TYPE](#) for more about send/receive functions).

When doing cross-version replication, it could be that the publisher has a binary send function for some data type, but the subscriber lacks a binary receive function for that type. In such a case, data transfer will fail, and the `binary` option cannot be used.

If the publisher is a Postgres Pro version before 16, then any initial table synchronization will use text format even if `binary = true`.

`copy_data` (boolean)

Specifies whether to copy pre-existing data in the publications that are being subscribed to when the replication starts. The default is `true`.

If the publications contain `WHERE` clauses, it will affect what data is copied. Refer to the [Notes](#) for details.

See [Notes](#) for details of how `copy_data = true` can interact with the `origin` parameter.

streaming (enum)

Specifies whether to enable streaming of in-progress transactions for this subscription. The default value is `off`, meaning all transactions are fully decoded on the publisher and only then sent to the subscriber as a whole.

If set to `on`, the incoming changes are written to temporary files and then applied only after the transaction is committed on the publisher and received by the subscriber.

If set to `parallel`, incoming changes are directly applied via one of the parallel apply workers, if available. If no parallel apply worker is free to handle streaming transactions then the changes are written to temporary files and applied after the transaction is committed. Note that if an error happens in a parallel apply worker, the finish LSN of the remote transaction might not be reported in the server log.

synchronous_commit (enum)

The value of this parameter overrides the [synchronous_commit](#) setting within this subscription's apply worker processes. The default value is `off`.

It is safe to use `off` for logical replication: If the subscriber loses transactions because of missing synchronization, the data will be sent again from the publisher.

A different setting might be appropriate when doing synchronous logical replication. The logical replication workers report the positions of writes and flushes to the publisher, and when using synchronous replication, the publisher will wait for the actual flush. This means that setting `synchronous_commit` for the subscriber to `off` when the subscription is used for synchronous replication might increase the latency for `COMMIT` on the publisher. In this scenario, it can be advantageous to set `synchronous_commit` to `local` or higher.

two_phase (boolean)

Specifies whether two-phase commit is enabled for this subscription. The default is `false`.

When two-phase commit is enabled, prepared transactions are sent to the subscriber at the time of `PREPARE TRANSACTION`, and are processed as two-phase transactions on the subscriber too. Otherwise, prepared transactions are sent to the subscriber only when committed, and are then processed immediately by the subscriber.

The implementation of two-phase commit requires that replication has successfully finished the initial table synchronization phase. So even when `two_phase` is enabled for a subscription, the internal two-phase state remains temporarily “pending” until the initialization phase completes. See column `subtwophasestate` of [pg_subscription](#) to know the actual two-phase state.

disable_on_error (boolean)

Specifies whether the subscription should be automatically disabled if any errors are detected by subscription workers during data replication from the publisher. The default is `false`.

password_required (boolean)

If set to `true`, connections to the publisher made as a result of this subscription must use password authentication and the password must be specified as a part of the connection string. This setting is ignored when the subscription is owned by a superuser. The default is `true`. Only superusers can set this value to `false`.

run_as_owner (boolean)

If `true`, all replication actions are performed as the subscription owner. If `false`, replication workers will perform actions on each table as the owner of that table. The latter configuration is generally much more secure; for details, see [Section 29.10](#). The default is `false`.

`origin (string)`

Specifies whether the subscription will request the publisher to only send changes that don't have an origin or send changes regardless of origin. Setting `origin` to `none` means that the subscription will request the publisher to only send changes that don't have an origin. Setting `origin` to `any` means that the publisher sends changes regardless of their origin. The default is `any`.

See [Notes](#) for details of how `copy_data = true` can interact with the `origin` parameter.

`failover (boolean)`

Specifies whether the replication slots associated with the subscription are enabled to be synced to the standbys so that logical replication can be resumed from the new primary after failover. The default is `false`.

When specifying a parameter of type `boolean`, the `= value` part can be omitted, which is equivalent to specifying `TRUE`.

Notes

See [Section 29.10](#) for details on how to configure access control between the subscription and the publication instance.

When creating a replication slot (the default behavior), `CREATE SUBSCRIPTION` cannot be executed inside a transaction block.

Creating a subscription that connects to the same database cluster (for example, to replicate between databases in the same cluster or to replicate within the same database) will only succeed if the replication slot is not created as part of the same command. Otherwise, the `CREATE SUBSCRIPTION` call will hang. To make this work, create the replication slot separately (using the function `pg_create_logical_replication_slot` with the plugin name `pgoutput`) and create the subscription using the parameter `create_slot = false`. See [Section 29.2.3](#) for examples. This is an implementation restriction that might be lifted in a future release.

If any table in the publication has a `WHERE` clause, rows for which the *expression* evaluates to false or null will not be published. If the subscription has several publications in which the same table has been published with different `WHERE` clauses, a row will be published if any of the expressions (referring to that publish operation) are satisfied. In the case of different `WHERE` clauses, if one of the publications has no `WHERE` clause (referring to that publish operation) or the publication is declared as [FOR ALL TABLES](#) or [FOR TABLES IN SCHEMA](#), rows are always published regardless of the definition of the other expressions. If the subscriber is a Postgres Pro version before 15, then any row filtering is ignored during the initial data synchronization phase. For this case, the user might want to consider deleting any initially copied data that would be incompatible with subsequent filtering. Because initial data synchronization does not take into account the publication `publish` parameter when copying existing table data, some rows may be copied that would not be replicated using DML. See [Section 29.2.2](#) for examples.

Subscriptions having several publications in which the same table has been published with different column lists are not supported.

We allow non-existent publications to be specified so that users can add those later. This means `pg_subscription` can have non-existent publications.

When using a subscription parameter combination of `copy_data = true` and `origin = NONE`, the initial sync table data is copied directly from the publisher, meaning that knowledge of the true origin of that data is not possible. If the publisher also has subscriptions then the copied table data might have originated from further upstream. This scenario is detected and a `WARNING` is logged to the user, but the warning is only an indication of a potential problem; it is the user's responsibility to make the necessary checks to ensure the copied data origins are really as wanted or not.

To find which tables might potentially include non-local origins (due to other subscriptions created on the publisher) try this SQL query:

```
# substitute <pub-names> below with your publication name(s) to be queried
SELECT DISTINCT PT.schemaname, PT.tablename
FROM pg_publication_tables PT
     JOIN pg_class C ON (C.relname = PT.tablename)
     JOIN pg_namespace N ON (N.nspname = PT.schemaname),
     pg_subscription_rel PS
WHERE C.relnamespace = N.oid AND
      (PS.srrelid = C.oid OR
       C.oid IN (SELECT relid FROM pg_partition_ancestors(PS.srrelid) UNION
                SELECT relid FROM pg_partition_tree(PS.srrelid))) AND
      PT.pubname IN (<pub-names>);
```

Examples

Create a subscription to a remote server that replicates tables in the publications `mypublication` and `insert_only` and starts replicating immediately on commit:

```
CREATE SUBSCRIPTION mysub
    CONNECTION 'host=192.168.1.50 port=5432 user=foo dbname=foodb'
    PUBLICATION mypublication, insert_only;
```

Create a subscription to a remote server that replicates tables in the `insert_only` publication and does not start replicating until enabled at a later time.

```
CREATE SUBSCRIPTION mysub
    CONNECTION 'host=192.168.1.50 port=5432 user=foo dbname=foodb'
    PUBLICATION insert_only
    WITH (enabled = false);
```

Compatibility

`CREATE SUBSCRIPTION` is a Postgres Pro extension.

CREATE TABLE

CREATE TABLE — define a new table

Synopsis

For sharded tables:

```
CREATE TABLE [ IF NOT EXISTS ] sharded_table_name ( [
    { column_name data_type [ COLLATE collation ] [ column_constraint [ ... ] ]
    | sharded_table_constraint
    | LIKE source_table [ like_option ... ] }
    [, ... ]
] )
[ USING method ]
[ TABLESPACE tablespace_name ]
[ WITH ( { distributed_by = 'column_name [, ... ]'
    [, num_parts = number_of_partitions ]
    [, colocate_with = 'colocation_table_name' ]
    [, partition_by = 'column_name',
        partition_bounds = 'array_of_partition_bound_exprs' ] |
        global = true
    [, storage_parameter [= value] [, ... ] }
)]
```

where *column_constraint* is:

```
[ CONSTRAINT constraint_name ]
{ NOT NULL |
  NULL |
  CHECK ( expression ) [ NO INHERIT ] |
  DEFAULT default_expr |
  UNIQUE index_parameters |
  PRIMARY KEY index_parameters |
  REFERENCES reftable [ ( refcolumn ) ] [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ]
    [ ON DELETE referential_action ] [ ON UPDATE referential_action ] }
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

and *sharded_table_constraint* is:

```
[ CONSTRAINT constraint_name ]
{ CHECK ( expression ) [ NO INHERIT ] |
  UNIQUE ( column_name [, ... ] ) index_parameters |
  PRIMARY KEY ( column_name [, ... ] ) index_parameters |
  EXCLUDE [ USING index_method ] ( exclude_element WITH operator
    [, ... ] ) index_parameters [ WHERE ( predicate ) ]
  FOREIGN KEY ( column_name [, ... ] ) REFERENCES reftable [ ( refcolumn [, ... ] ) ]
    [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ] [ ON DELETE referential_action ] [ ON
    UPDATE referential_action ] }
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

For other table types:

```
CREATE [ [ GLOBAL | LOCAL ] { TEMPORARY | TEMP } | UNLOGGED | CONSTANT ] TABLE [ IF NOT
EXISTS ] table_name ( [
    { column_name data_type [ STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN | DEFAULT } ]
    [ COMPRESSION compression_method ] [ COLLATE collation ] [ column_constraint [ ... ] ]
```

```

    | table_constraint
    | LIKE source_table [ like_option ... ] }
    [, ... ]
] )
[ INHERITS ( parent_table [, ... ] ) ]
[ PARTITION BY { RANGE | LIST | HASH } ( { column_name | ( expression ) }
  [ COLLATE collation ] [ opclass ] [, ... ] ) ]
[ USING method ]
[ WITH ( storage_parameter [= value] [, ... ] ) | WITHOUT OIDS ]
[ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
[ TABLESPACE tablespace_name ]

CREATE [ [ GLOBAL | LOCAL ] { TEMPORARY | TEMP } | UNLOGGED | CONSTANT ] TABLE [ IF NOT
  EXISTS ] table_name
  OF type_name [ (
    { column_name [ WITH OPTIONS ] [ column_constraint [ ... ] ]
      | table_constraint }
    [, ... ]
  ) ]
[ PARTITION BY { RANGE | LIST | HASH } ( { column_name | ( expression ) }
  [ COLLATE collation ] [ opclass ] [, ... ] ) ]
[ USING method ]
[ WITH ( storage_parameter [= value] [, ... ] ) | WITHOUT OIDS ]
[ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
[ TABLESPACE tablespace_name ]

CREATE [ [ GLOBAL | LOCAL ] { TEMPORARY | TEMP } | UNLOGGED ] TABLE [ IF NOT
  EXISTS ] table_name
  PARTITION OF parent_table [ (
    { column_name [ WITH OPTIONS ] [ column_constraint [ ... ] ]
      | table_constraint }
    [, ... ]
  ) ] { FOR VALUES partition_bound_spec | DEFAULT }
[ PARTITION BY { RANGE | LIST | HASH } ( { column_name | ( expression ) }
  [ COLLATE collation ] [ opclass ] [, ... ] ) ]
[ USING method ]
[ WITH ( storage_parameter [= value] [, ... ] ) | WITHOUT OIDS ]
[ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
[ TABLESPACE tablespace_name ]

where column_constraint is:

[ CONSTRAINT constraint_name ]
{ NOT NULL |
  NULL |
  CHECK ( expression ) [ NO INHERIT ] |
  DEFAULT default_expr |
  GENERATED ALWAYS AS ( generation_expr ) STORED |
  GENERATED { ALWAYS | BY DEFAULT } AS IDENTITY [ ( sequence_options ) ] |
  UNIQUE [ NULLS [ NOT ] DISTINCT ] index_parameters |
  PRIMARY KEY index_parameters |
  REFERENCES reftable [ ( refcolumn ) ] [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ]
    [ ON DELETE referential_action ] [ ON UPDATE referential_action ] }
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]

and table_constraint is:

[ CONSTRAINT constraint_name ]

```

```
{ CHECK ( expression ) [ NO INHERIT ] |
  UNIQUE [ NULLS [ NOT ] DISTINCT ] ( column_name [, ... ] ) index_parameters |
  PRIMARY KEY ( column_name [, ... ] ) index_parameters |
  EXCLUDE [ USING index_method ] ( exclude_element WITH operator
[, ... ] ) index_parameters [ WHERE ( predicate ) ] |
  FOREIGN KEY ( column_name [, ... ] ) REFERENCES reftable [ ( refcolumn [, ... ] ) ]
    [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ] [ ON DELETE referential_action ] [ ON
UPDATE referential_action ] }
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

and *like_option* is:

```
{ INCLUDING | EXCLUDING } { COMMENTS | COMPRESSION | CONSTRAINTS | DEFAULTS | GENERATED
| IDENTITY | INDEXES | STATISTICS | STORAGE | ALL }
```

and *partition_bound_spec* is:

```
IN ( partition_bound_expr [, ...] ) |
FROM ( { partition_bound_expr | MINVALUE | MAXVALUE } [, ...] )
  TO ( { partition_bound_expr | MINVALUE | MAXVALUE } [, ...] ) |
WITH ( MODULUS numeric_literal, REMAINDER numeric_literal )
```

index_parameters in UNIQUE, PRIMARY KEY, and EXCLUDE constraints are:

```
[ INCLUDE ( column_name [, ... ] ) ]
[ WITH ( storage_parameter [= value] [, ... ] ) ]
[ USING INDEX TABLESPACE tablespace_name ]
```

exclude_element in an EXCLUDE constraint is:

```
{ column_name | ( expression ) } [ COLLATE collation ] [ opclass [ ( opclass_parameter
= value [, ... ] ) ] ] [ ASC | DESC ] [ NULLS { FIRST | LAST } ]
```

referential_action in a FOREIGN KEY/REFERENCES constraint is:

```
{ NO ACTION | RESTRICT | CASCADE | SET NULL [ ( column_name [, ... ] ) ] | SET DEFAULT
[ ( column_name [, ... ] ) ] }
```

Description

CREATE TABLE will create a new, initially empty table in the current database. The table will be owned by the user issuing the command.

If a schema name is given (for example, CREATE TABLE myschema.mytable ...) then the table is created in the specified schema. Otherwise it is created in the current schema. Temporary tables exist in a special schema, so a schema name cannot be given when creating a temporary table. The name of the table must be distinct from the name of any other relation (table, sequence, index, view, materialized view, or foreign table) in the same schema.

CREATE TABLE also automatically creates a data type that represents the composite type corresponding to one row of the table. Therefore, tables cannot have the same name as any existing data type in the same schema.

The optional constraint clauses specify constraints (tests) that new or updated rows must satisfy for an insert or update operation to succeed. A constraint is an SQL object that helps define the set of valid values in the table in various ways.

There are two ways to define constraints: table constraints and column constraints. A column constraint is defined as part of a column definition. A table constraint definition is not tied to a particular column,

and it can encompass more than one column. Every column constraint can also be written as a table constraint; a column constraint is only a notational convenience for use when the constraint only affects one column.

To be able to create a table, you must have `USAGE` privilege on all column types or the type in the `OF` clause, respectively.

Parameters

TEMPORARY or TEMP

If specified, the table is created as a temporary table. Temporary tables are automatically dropped at the end of a session, or optionally at the end of the current transaction (see `ON COMMIT` below). The default `search_path` includes the temporary schema first and so identically named existing permanent tables are not chosen for new plans while the temporary table exists, unless they are referenced with schema-qualified names. Any indexes created on a temporary table are automatically temporary as well.

Unlike for permanent tables, we extend the physical file for a temporary table only when the table does not fit into `temp_buffers` cache anymore. Thus, the total and on-disk size of a temporary table can differ. Blocks are not allocated in advance, so we may run out of free space on disk when trying to evict a temporary buffer from cache. If the available disk space is smaller than `temp_buffers` size, an error occurs. This case is quite unusual, though.

The [autovacuum daemon](#) cannot access and therefore cannot vacuum or analyze temporary tables. For this reason, appropriate vacuum and analyze operations should be performed via session SQL commands. For example, if a temporary table is going to be used in complex queries, it is wise to run `ANALYZE` on the temporary table after it is populated.

Superusers can only use the `DROP TABLE` command with temporary relations of other sessions. Dropping such relations is not allowed when the `skip_temp_rel_lock` configuration parameter is enabled.

Optionally, `GLOBAL` or `LOCAL` can be written before `TEMPORARY` or `TEMP`. This presently makes no difference in Postgres Pro and is deprecated; see [Compatibility](#) below.

UNLOGGED

If specified, the table is created as an unlogged table. Data written to unlogged tables is not written to the write-ahead log (see [Chapter 28](#)), which makes them considerably faster than ordinary tables. However, they are not crash-safe: an unlogged table is automatically truncated after a crash or unclean shutdown. The contents of an unlogged table are also not replicated to standby servers. Any indexes created on an unlogged table are automatically unlogged as well.

If this is specified, any sequences created together with the unlogged table (for identity or serial columns) are also created as unlogged.

CONSTANT

If specified, the table is created as read-only. No data can be modified or added to constant tables, and they are not processed by [autovacuum](#). Constant tables cannot be changed to read-write mode, so there is no much sense to create them as constant; use [CREATE TABLE AS](#) or [ALTER TABLE](#) instead.

IF NOT EXISTS

Do not throw an error if a relation with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing relation is anything like the one that would have been created.

table_name

The name (optionally schema-qualified) of the table to be created.

OF *type_name*

Creates a *typed table*, which takes its structure from the specified composite type (name optionally schema-qualified). A typed table is tied to its type; for example the table will be dropped if the type is dropped (with `DROP TYPE ... CASCADE`).

When a typed table is created, then the data types of the columns are determined by the underlying composite type and are not specified by the `CREATE TABLE` command. But the `CREATE TABLE` command can add defaults and constraints to the table and can specify storage parameters.

column_name

The name of a column to be created in the new table.

data_type

The data type of the column. This can include array specifiers. For more information on the data types supported by Postgres Pro, refer to [Chapter 8](#).

`COLLATE collation`

The `COLLATE` clause assigns a collation to the column (which must be of a collatable data type). If not specified, the column data type's default collation is used.

`STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN | DEFAULT }`

This form sets the storage mode for the column. This controls whether this column is held inline or in a secondary TOAST table, and whether the data should be compressed or not. `PLAIN` must be used for fixed-length values such as `integer` and is inline, uncompressed. `MAIN` is for inline, compressible data. `EXTERNAL` is for external, uncompressed data, and `EXTENDED` is for external, compressed data. Writing `DEFAULT` sets the storage mode to the default mode for the column's data type. `EXTENDED` is the default for most data types that support non-`PLAIN` storage. Use of `EXTERNAL` will make substring operations on very large `text` and `bytea` values run faster, at the penalty of increased storage space. See [Section 66.2](#) for more information.

`COMPRESSION compression_method`

The `COMPRESSION` clause sets the compression method for the column. Compression is supported only for variable-width data types, and is used only when the column's storage mode is `main` or `extended`. (See [ALTER TABLE](#) for information on column storage modes.) Setting this property for a partitioned table has no direct effect, because such tables have no storage of their own, but the configured value will be inherited by newly-created partitions. The supported compression methods are `pglz` and `lz4`. (`lz4` is available only if `--with-lz4` was used when building Postgres Pro.) In addition, *compression_method* can be `default` to explicitly specify the default behavior, which is to consult the [default_toast_compression](#) setting at the time of data insertion to determine the method to use.

`INHERITS (parent_table [, ...])`

The optional `INHERITS` clause specifies a list of tables from which the new table automatically inherits all columns. Parent tables can be plain tables or foreign tables.

Use of `INHERITS` creates a persistent relationship between the new child table and its parent table(s). Schema modifications to the parent(s) normally propagate to children as well, and by default the data of the child table is included in scans of the parent(s).

If the same column name exists in more than one parent table, an error is reported unless the data types of the columns match in each of the parent tables. If there is no conflict, then the duplicate columns are merged to form a single column in the new table. If the column name list of the new table contains a column name that is also inherited, the data type must likewise match the inherited column(s), and the column definitions are merged into one. If the new table explicitly specifies a default value for the column, this default overrides any defaults from inherited declarations of the column. Otherwise, any parents that specify default values for the column must all specify the same default, or an error will be reported.

CHECK constraints are merged in essentially the same way as columns: if multiple parent tables and/or the new table definition contain identically-named CHECK constraints, these constraints must all have the same check expression, or an error will be reported. Constraints having the same name and expression will be merged into one copy. A constraint marked NO INHERIT in a parent will not be considered. Notice that an unnamed CHECK constraint in the new table will never be merged, since a unique name will always be chosen for it.

Column STORAGE settings are also copied from parent tables.

If a column in the parent table is an identity column, that property is not inherited. A column in the child table can be declared identity column if desired.

```
PARTITION BY { RANGE | LIST | HASH } ( { column_name | ( expression ) } [ opclass ] [, ...] )
```

The optional PARTITION BY clause specifies a strategy of partitioning the table. The table thus created is called a *partitioned* table. The parenthesized list of columns or expressions forms the *partition key* for the table. When using range or hash partitioning, the partition key can include multiple columns or expressions (up to 32, but this limit can be altered when building Postgres Pro), but for list partitioning, the partition key must consist of a single column or expression.

Range and list partitioning require a btree operator class, while hash partitioning requires a hash operator class. If no operator class is specified explicitly, the default operator class of the appropriate type will be used; if no default operator class exists, an error will be raised. When hash partitioning is used, the operator class used must implement support function 2 (see [Section 39.16.3](#) for details).

A partitioned table is divided into sub-tables (called partitions), which are created using separate CREATE TABLE commands. The partitioned table is itself empty. A data row inserted into the table is routed to a partition based on the value of columns or expressions in the partition key. If no existing partition matches the values in the new row, an error will be reported.

Partitioned tables do not support EXCLUDE constraints; however, you can define these constraints on individual partitions.

See [Section 5.12](#) for more discussion on table partitioning.

```
PARTITION OF parent_table { FOR VALUES partition_bound_spec | DEFAULT }
```

Creates the table as a *partition* of the specified parent table. The table can be created either as a partition for specific values using FOR VALUES or as a default partition using DEFAULT. Any indexes, constraints and user-defined row-level triggers that exist in the parent table are cloned on the new partition.

The *partition_bound_spec* must correspond to the partitioning method and partition key of the parent table, and must not overlap with any existing partition of that parent. The form with IN is used for list partitioning, the form with FROM and TO is used for range partitioning, and the form with WITH is used for hash partitioning.

partition_bound_expr is any variable-free expression (subqueries, window functions, aggregate functions, and set-returning functions are not allowed). Its data type must match the data type of the corresponding partition key column. The expression is evaluated once at table creation time, so it can even contain volatile expressions such as CURRENT_TIMESTAMP.

When creating a list partition, NULL can be specified to signify that the partition allows the partition key column to be null. However, there cannot be more than one such list partition for a given parent table. NULL cannot be specified for range partitions.

When creating a range partition, the lower bound specified with FROM is an inclusive bound, whereas the upper bound specified with TO is an exclusive bound. That is, the values specified in the FROM list are valid values of the corresponding partition key columns for this partition, whereas those in the TO list are not. Note that this statement must be understood according to the rules of row-wise comparison ([Section 9.25.5](#)). For example, given PARTITION BY RANGE (x,y), a partition bound FROM (1, 2) TO (3, 4) allows x=1 with any y>=2, x=2 with any non-null y, and x=3 with any y<4.

The special values `MINVALUE` and `MAXVALUE` may be used when creating a range partition to indicate that there is no lower or upper bound on the column's value. For example, a partition defined using `FROM (MINVALUE) TO (10)` allows any values less than 10, and a partition defined using `FROM (10) TO (MAXVALUE)` allows any values greater than or equal to 10.

When creating a range partition involving more than one column, it can also make sense to use `MAXVALUE` as part of the lower bound, and `MINVALUE` as part of the upper bound. For example, a partition defined using `FROM (0, MAXVALUE) TO (10, MAXVALUE)` allows any rows where the first partition key column is greater than 0 and less than or equal to 10. Similarly, a partition defined using `FROM ('a', MINVALUE) TO ('b', MINVALUE)` allows any rows where the first partition key column starts with "a".

Note that if `MINVALUE` or `MAXVALUE` is used for one column of a partitioning bound, the same value must be used for all subsequent columns. For example, `(10, MINVALUE, 0)` is not a valid bound; you should write `(10, MINVALUE, MINVALUE)`.

Also note that some element types, such as `timestamp`, have a notion of "infinity", which is just another value that can be stored. This is different from `MINVALUE` and `MAXVALUE`, which are not real values that can be stored, but rather they are ways of saying that the value is unbounded. `MAXVALUE` can be thought of as being greater than any other value, including "infinity" and `MINVALUE` as being less than any other value, including "minus infinity". Thus the range `FROM ('infinity') TO (MAXVALUE)` is not an empty range; it allows precisely one value to be stored — "infinity".

If `DEFAULT` is specified, the table will be created as the default partition of the parent table. This option is not available for hash-partitioned tables. A partition key value not fitting into any other partition of the given parent will be routed to the default partition.

When a table has an existing `DEFAULT` partition and a new partition is added to it, the default partition must be scanned to verify that it does not contain any rows which properly belong in the new partition. If the default partition contains a large number of rows, this may be slow. The scan will be skipped if the default partition is a foreign table or if it has a constraint which proves that it cannot contain rows which should be placed in the new partition.

When creating a hash partition, a modulus and remainder must be specified. The modulus must be a positive integer, and the remainder must be a non-negative integer less than the modulus. Typically, when initially setting up a hash-partitioned table, you should choose a modulus equal to the number of partitions and assign every table the same modulus and a different remainder (see examples, below). However, it is not required that every partition have the same modulus, only that every modulus which occurs among the partitions of a hash-partitioned table is a factor of the next larger modulus. This allows the number of partitions to be increased incrementally without needing to move all the data at once. For example, suppose you have a hash-partitioned table with 8 partitions, each of which has modulus 8, but find it necessary to increase the number of partitions to 16. You can detach one of the modulus-8 partitions, create two new modulus-16 partitions covering the same portion of the key space (one with a remainder equal to the remainder of the detached partition, and the other with a remainder equal to that value plus 8), and repopulate them with data. You can then repeat this -- perhaps at a later time -- for each modulus-8 partition until none remain. While this may still involve a large amount of data movement at each step, it is still better than having to create a whole new table and move all the data at once.

A partition must have the same column names and types as the partitioned table to which it belongs. Modifications to the column names or types of a partitioned table will automatically propagate to all partitions. `CHECK` constraints will be inherited automatically by every partition, but an individual partition may specify additional `CHECK` constraints; additional constraints with the same name and condition as in the parent will be merged with the parent constraint. Defaults may be specified separately for each partition. But note that a partition's default value is not applied when inserting a tuple through a partitioned table.

Rows inserted into a partitioned table will be automatically routed to the correct partition. If no suitable partition exists, an error will occur.

Operations such as `TRUNCATE` which normally affect a table and all of its inheritance children will cascade to all partitions, but may also be performed on an individual partition.

Note that creating a partition using `PARTITION OF` requires taking an `ACCESS EXCLUSIVE` lock on the parent partitioned table. Likewise, dropping a partition with `DROP TABLE` requires taking an `ACCESS EXCLUSIVE` lock on the parent table. It is possible to use `ALTER TABLE ATTACH/DETACH PARTITION` to perform these operations with a weaker lock, thus reducing interference with concurrent operations on the partitioned table.

`LIKE source_table [like_option ...]`

The `LIKE` clause specifies a table from which the new table automatically copies all column names, their data types, and their not-null constraints.

Unlike `INHERITS`, the new table and original table are completely decoupled after creation is complete. Changes to the original table will not be applied to the new table, and it is not possible to include data of the new table in scans of the original table.

Also unlike `INHERITS`, columns and constraints copied by `LIKE` are not merged with similarly named columns and constraints. If the same name is specified explicitly or in another `LIKE` clause, an error is signaled.

The optional `like_option` clauses specify which additional properties of the original table to copy. Specifying `INCLUDING` copies the property, specifying `EXCLUDING` omits the property. `EXCLUDING` is the default. If multiple specifications are made for the same kind of object, the last one is used. The available options are:

`INCLUDING COMMENTS`

Comments for the copied columns, constraints, and indexes will be copied. The default behavior is to exclude comments, resulting in the copied columns and constraints in the new table having no comments.

`INCLUDING COMPRESSION`

Compression method of the columns will be copied. The default behavior is to exclude compression methods, resulting in columns having the default compression method.

`INCLUDING CONSTRAINTS`

`CHECK` constraints will be copied. No distinction is made between column constraints and table constraints. Not-null constraints are always copied to the new table.

`INCLUDING DEFAULTS`

Default expressions for the copied column definitions will be copied. Otherwise, default expressions are not copied, resulting in the copied columns in the new table having null defaults. Note that copying defaults that call database-modification functions, such as `nextval`, may create a functional linkage between the original and new tables.

`INCLUDING GENERATED`

Any generation expressions of copied column definitions will be copied. By default, new columns will be regular base columns.

`INCLUDING IDENTITY`

Any identity specifications of copied column definitions will be copied. A new sequence is created for each identity column of the new table, separate from the sequences associated with the old table.

`INCLUDING INDEXES`

Indexes, `PRIMARY KEY`, `UNIQUE`, and `EXCLUDE` constraints on the original table will be created on the new table. Names for the new indexes and constraints are chosen according to the default

rules, regardless of how the originals were named. (This behavior avoids possible duplicate-name failures for the new indexes.)

INCLUDING STATISTICS

Extended statistics are copied to the new table.

INCLUDING STORAGE

`STORAGE` settings for the copied column definitions will be copied. The default behavior is to exclude `STORAGE` settings, resulting in the copied columns in the new table having type-specific default settings. For more on `STORAGE` settings, see [Section 66.2](#).

INCLUDING ALL

`INCLUDING ALL` is an abbreviated form selecting all the available individual options. (It could be useful to write individual `EXCLUDING` clauses after `INCLUDING ALL` to select all but some specific options.)

The `LIKE` clause can also be used to copy column definitions from views, foreign tables, or composite types. Inapplicable options (e.g., `INCLUDING INDEXES` from a view) are ignored.

CONSTRAINT *constraint_name*

An optional name for a column or table constraint. If the constraint is violated, the constraint name is present in error messages, so constraint names like `col must be positive` can be used to communicate helpful constraint information to client applications. (Double-quotes are needed to specify constraint names that contain spaces.) If a constraint name is not specified, the system generates a name.

NOT NULL

The column is not allowed to contain null values.

NULL

The column is allowed to contain null values. This is the default.

This clause is only provided for compatibility with non-standard SQL databases. Its use is discouraged in new applications.

CHECK (*expression*) [NO INHERIT]

The `CHECK` clause specifies an expression producing a Boolean result which new or updated rows must satisfy for an insert or update operation to succeed. Expressions evaluating to `TRUE` or `UNKNOWN` succeed. Should any row of an insert or update operation produce a `FALSE` result, an error exception is raised and the insert or update does not alter the database. A check constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint can reference multiple columns.

Currently, `CHECK` expressions cannot contain subqueries nor refer to variables other than columns of the current row (see [Section 5.5.1](#)). The system column `tableoid` may be referenced, but not any other system column.

A constraint marked with `NO INHERIT` will not propagate to child tables.

When a table has multiple `CHECK` constraints, they will be tested for each row in alphabetical order by name, after checking `NOT NULL` constraints. (PostgreSQL versions before 9.5 did not honor any particular firing order for `CHECK` constraints.)

DEFAULT *default_expr*

The `DEFAULT` clause assigns a default data value for the column whose column definition it appears within. The value is any variable-free expression (in particular, cross-references to other columns in

the current table are not allowed). Subqueries are not allowed either. The data type of the default expression must match the data type of the column.

The default expression will be used in any insert operation that does not specify a value for the column. If there is no default for a column, then the default is null.

`GENERATED ALWAYS AS (generation_expr) STORED`

This clause creates the column as a *generated column*. The column cannot be written to, and when read the result of the specified expression will be returned.

The keyword `STORED` is required to signify that the column will be computed on write and will be stored on disk.

The generation expression can refer to other columns in the table, but not other generated columns. Any functions and operators used must be immutable. References to other tables are not allowed.

`GENERATED { ALWAYS | BY DEFAULT } AS IDENTITY [(sequence_options)]`

This clause creates the column as an *identity column*. It will have an implicit sequence attached to it and in newly-inserted rows the column will automatically have values from the sequence assigned to it. Such a column is implicitly `NOT NULL`.

The clauses `ALWAYS` and `BY DEFAULT` determine how explicitly user-specified values are handled in `INSERT` and `UPDATE` commands.

In an `INSERT` command, if `ALWAYS` is selected, a user-specified value is only accepted if the `INSERT` statement specifies `OVERRIDING SYSTEM VALUE`. If `BY DEFAULT` is selected, then the user-specified value takes precedence. See [INSERT](#) for details. (In the `COPY` command, user-specified values are always used regardless of this setting.)

In an `UPDATE` command, if `ALWAYS` is selected, any update of the column to any value other than `DEFAULT` will be rejected. If `BY DEFAULT` is selected, the column can be updated normally. (There is no `OVERRIDING` clause for the `UPDATE` command.)

The optional *sequence_options* clause can be used to override the parameters of the sequence. The available options include those shown for [CREATE SEQUENCE](#), plus `SEQUENCE NAME name`, `LOGGED`, and `UNLOGGED`, which allow selection of the name and persistence level of the sequence. Without `SEQUENCE NAME`, the system chooses an unused name for the sequence. Without `LOGGED` or `UNLOGGED`, the sequence will have the same persistence level as the table.

`UNIQUE [NULLS [NOT] DISTINCT] (column constraint)`

`UNIQUE [NULLS [NOT] DISTINCT] (column_name [, ...]) [INCLUDE (column_name [, ...])] (table constraint)`

The `UNIQUE` constraint specifies that a group of one or more columns of a table can contain only unique values. The behavior of a unique table constraint is the same as that of a unique column constraint, with the additional capability to span multiple columns. The constraint therefore enforces that any two rows must differ in at least one of these columns.

For the purpose of a unique constraint, null values are not considered equal, unless `NULLS NOT DISTINCT` is specified.

Each unique constraint should name a set of columns that is different from the set of columns named by any other unique or primary key constraint defined for the table. (Otherwise, redundant unique constraints will be discarded.)

When establishing a unique constraint for a multi-level partition hierarchy, all the columns in the partition key of the target partitioned table, as well as those of all its descendant partitioned tables, must be included in the constraint definition.

Adding a unique constraint will automatically create a unique btree index on the column or group of columns used in the constraint. The created index has the same name as the unique constraint.

The optional `INCLUDE` clause adds to that index one or more columns that are simply “payload”: uniqueness is not enforced on them, and the index cannot be searched on the basis of those columns. However they can be retrieved by an index-only scan. Note that although the constraint is not enforced on included columns, it still depends on them. Consequently, some operations on such columns (e.g., `DROP COLUMN`) can cause cascaded constraint and index deletion.

PRIMARY KEY (column constraint)

`PRIMARY KEY (column_name [, ...]) [INCLUDE (column_name [, ...])] (table constraint)`

The `PRIMARY KEY` constraint specifies that a column or columns of a table can contain only unique (non-duplicate), nonnull values. Only one primary key can be specified for a table, whether as a column constraint or a table constraint.

The primary key constraint should name a set of columns that is different from the set of columns named by any unique constraint defined for the same table. (Otherwise, the unique constraint is redundant and will be discarded.)

`PRIMARY KEY` enforces the same data constraints as a combination of `UNIQUE` and `NOT NULL`. However, identifying a set of columns as the primary key also provides metadata about the design of the schema, since a primary key implies that other tables can rely on this set of columns as a unique identifier for rows.

When placed on a partitioned table, `PRIMARY KEY` constraints share the restrictions previously described for `UNIQUE` constraints.

Adding a `PRIMARY KEY` constraint will automatically create a unique btree index on the column or group of columns used in the constraint. That index has the same name as the primary key constraint.

The optional `INCLUDE` clause adds to that index one or more columns that are simply “payload”: uniqueness is not enforced on them, and the index cannot be searched on the basis of those columns. However they can be retrieved by an index-only scan. Note that although the constraint is not enforced on included columns, it still depends on them. Consequently, some operations on such columns (e.g., `DROP COLUMN`) can cause cascaded constraint and index deletion.

`EXCLUDE [USING index_method] (exclude_element WITH operator [, ...]) index_parameters [WHERE (predicate)]`

The `EXCLUDE` clause defines an exclusion constraint, which guarantees that if any two rows are compared on the specified column(s) or expression(s) using the specified operator(s), not all of these comparisons will return `TRUE`. If all of the specified operators test for equality, this is equivalent to a `UNIQUE` constraint, although an ordinary unique constraint will be faster. However, exclusion constraints can specify constraints that are more general than simple equality. For example, you can specify a constraint that no two rows in the table contain overlapping circles (see [Section 8.8](#)) by using the `&&` operator. The operator(s) are required to be commutative.

Exclusion constraints are implemented using an index that has the same name as the constraint, so each specified operator must be associated with an appropriate operator class (see [Section 11.10](#)) for the index access method `index_method`. Each `exclude_element` defines a column of the index, so it can optionally specify a collation, an operator class, operator class parameters, and/or ordering options; these are described fully under [CREATE INDEX](#).

The access method must support `amgettuple` (see [Chapter 63](#)); at present this means GIN cannot be used. Although it's allowed, there is little point in using B-tree or hash indexes with an exclusion constraint, because this does nothing that an ordinary unique constraint doesn't do better. So in practice the access method will always be GiST or SP-GiST.

The `predicate` allows you to specify an exclusion constraint on a subset of the table; internally this creates a partial index. Note that parentheses are required around the predicate.

```
REFERENCES reftable [ ( refcolumn ) ] [ MATCH matchtype ] [ ON DELETE referential_action ] [ ON UPDATE referential_action ] (column constraint)
FOREIGN KEY ( column_name [, ... ] ) REFERENCES reftable [ ( refcolumn [, ... ] ) ] [ MATCH matchtype ] [ ON DELETE referential_action ] [ ON UPDATE referential_action ]
(table constraint)
```

These clauses specify a foreign key constraint, which requires that a group of one or more columns of the new table must only contain values that match values in the referenced column(s) of some row of the referenced table. If the *refcolumn* list is omitted, the primary key of the *reftable* is used. Otherwise, the *refcolumn* list must refer to the columns of a non-deferrable unique or primary key constraint or be the columns of a non-partial unique index. The user must have REFERENCES permission on the referenced table (either the whole table, or the specific referenced columns). The addition of a foreign key constraint requires a SHARE ROW EXCLUSIVE lock on the referenced table. Note that foreign key constraints cannot be defined between temporary tables and permanent tables.

A value inserted into the referencing column(s) is matched against the values of the referenced table and referenced columns using the given match type. There are three match types: MATCH FULL, MATCH PARTIAL, and MATCH SIMPLE (which is the default). MATCH FULL will not allow one column of a multicolumn foreign key to be null unless all foreign key columns are null; if they are all null, the row is not required to have a match in the referenced table. MATCH SIMPLE allows any of the foreign key columns to be null; if any of them are null, the row is not required to have a match in the referenced table. MATCH PARTIAL is not yet implemented. (Of course, NOT NULL constraints can be applied to the referencing column(s) to prevent these cases from arising.)

In addition, when the data in the referenced columns is changed, certain actions are performed on the data in this table's columns. The ON DELETE clause specifies the action to perform when a referenced row in the referenced table is being deleted. Likewise, the ON UPDATE clause specifies the action to perform when a referenced column in the referenced table is being updated to a new value. If the row is updated, but the referenced column is not actually changed, no action is done. Referential actions other than the NO ACTION check cannot be deferred, even if the constraint is declared deferrable. There are the following possible actions for each clause:

NO ACTION

Produce an error indicating that the deletion or update would create a foreign key constraint violation. If the constraint is deferred, this error will be produced at constraint check time if there still exist any referencing rows. This is the default action.

RESTRICT

Produce an error indicating that the deletion or update would create a foreign key constraint violation. This is the same as NO ACTION except that the check is not deferrable.

CASCADE

Delete any rows referencing the deleted row, or update the values of the referencing column(s) to the new values of the referenced columns, respectively.

```
SET NULL [ ( column_name [, ... ] ) ]
```

Set all of the referencing columns, or a specified subset of the referencing columns, to null. A subset of columns can only be specified for ON DELETE actions.

```
SET DEFAULT [ ( column_name [, ... ] ) ]
```

Set all of the referencing columns, or a specified subset of the referencing columns, to their default values. A subset of columns can only be specified for ON DELETE actions. (There must be a row in the referenced table matching the default values, if they are not null, or the operation will fail.)

If the referenced column(s) are changed frequently, it might be wise to add an index to the referencing column(s) so that referential actions associated with the foreign key constraint can be performed more efficiently.

DEFERRABLE

NOT DEFERRABLE

This controls whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command. Checking of constraints that are deferrable can be postponed until the end of the transaction (using the [SET CONSTRAINTS](#) command). `NOT DEFERRABLE` is the default. Currently, only `UNIQUE`, `PRIMARY KEY`, `EXCLUDE`, and `REFERENCES` (foreign key) constraints accept this clause. `NOT NULL` and `CHECK` constraints are not deferrable. Note that deferrable constraints cannot be used as conflict arbitrators in an `INSERT` statement that includes an `ON CONFLICT DO UPDATE` clause.

INITIALLY IMMEDIATE

INITIALLY DEFERRED

If a constraint is deferrable, this clause specifies the default time to check the constraint. If the constraint is `INITIALLY IMMEDIATE`, it is checked after each statement. This is the default. If the constraint is `INITIALLY DEFERRED`, it is checked only at the end of the transaction. The constraint check time can be altered with the [SET CONSTRAINTS](#) command.

USING *method*

This optional clause specifies the table access method to use to store the contents for the new table; the method needs be an access method of type `TABLE`. See [Chapter 62](#) for more information. If this option is not specified, the default table access method is chosen for the new table. See [default_table_access_method](#) for more information.

When creating a partition, the table access method is the access method of its partitioned table, if set.

WITH (*storage_parameter* [= *value*] [, ...])

This clause specifies optional storage parameters for a table or index; see [Storage Parameters](#) below for more information. For backward-compatibility the `WITH` clause for a table can also include `oids=false` to specify that rows of the new table should not contain OIDs (object identifiers), `oids=true` is not supported anymore.

WITHOUT OIDS

This is backward-compatible syntax for declaring a table `WITHOUT OIDS`, creating a table `WITH OIDS` is not supported anymore.

ON COMMIT

The behavior of temporary tables at the end of a transaction block can be controlled using `ON COMMIT`. The three options are:

PRESERVE ROWS

No special action is taken at the ends of transactions. This is the default behavior.

DELETE ROWS

All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic `TRUNCATE` is done at each commit. When used on a partitioned table, this is not cascaded to its partitions.

DROP

The temporary table will be dropped at the end of the current transaction block. When used on a partitioned table, this action drops its partitions and when used on tables with inheritance children, it drops the dependent children.

TABLESPACE *tablespace_name*

The *tablespace_name* is the name of the tablespace in which the new table is to be created. If not specified, [default_tablespace](#) is consulted, or [temp_tablespaces](#) if the table is temporary. For parti-

tioned tables, since no storage is required for the table itself, the tablespace specified overrides `default_tablespace` as the default tablespace to use for any newly created partitions when no other tablespace is explicitly specified.

`USING INDEX TABLESPACE tablespace_name`

This clause allows selection of the tablespace in which the index associated with a `UNIQUE`, `PRIMARY KEY`, or `EXCLUDE` constraint will be created. If not specified, `default_tablespace` is consulted, or `temp_tablespaces` if the table is temporary.

Storage Parameters for Postgres Pro Shardman

Postgres Pro Shardman extends *storage parameters* of tables with its own *storage metaparameters*. They are not stored in the corresponding catalog entry, but are used to tell the Postgres Pro Shardman extension to perform some additional actions. Regular storage parameters are transparently passed to table partitions.

`distributed_by (text)`

This specifies the list of columns to use for the table partitioning. Only hash partitioning is currently supported, so this is effectively an equivalent of `PARTITION BY HASH`, but all the leaf partitions will be created immediately on all replication groups and the table will be registered in the Postgres Pro Shardman metadata.

`num_parts (integer)`

This sets the number of partitions that will be created for this table. This parameter is optional. If it is not specified, for a sharded table, the value of the global setting of `shardman.num_parts` will be used, for a colocated table, the value will be taken from the corresponding colocating table.

`colocate_with (text)`

This specifies the name of the table to colocate with. If set, Postgres Pro Shardman will try to place partitions of the created table with the same partition key on the same nodes as `colocation_table_name`. This parameter is optional.

`partition_by (text)`

This specifies the name of the column to use for the second-level table partitioning. Only range partitioning is currently supported. When this parameter is used, each table partition is created as a partitioned table. Subpartitions can be created immediately if `partition_bounds` parameter is set. This parameter is optional.

`partition_bounds (text)`

This sets bounds of second-level table partitions. Bounds should be a string representation of a two-dimensional array. Each array member is a pair of a lower and upper bound for partitions. If lower and upper bounds are both `NULL`, the default partition is created. Number of partitions is determined by the first array dimension. This parameter is optional.

`global (boolean)`

This defines that the table is global. If set, the table will be distributed on all replication groups and will be synchronized by triggers. This parameter is optional.

Storage Parameters for Not Sharded Tables

The `WITH` clause can specify *storage parameters* for tables, and for indexes associated with a `UNIQUE`, `PRIMARY KEY`, or `EXCLUDE` constraint. Storage parameters for indexes are documented in [CREATE INDEX](#). The storage parameters currently available for tables are listed below. For many of these parameters, as shown, there is an additional parameter with the same name prefixed with `toast.`, which controls the behavior of the table's secondary TOAST table, if any (see [Section 66.2](#) for more information about TOAST). If a table parameter value is set and the equivalent `toast.` parameter is not, the TOAST table

will use the table's parameter value. Specifying these parameters for partitioned tables is not supported, but you may specify them for individual leaf partitions.

`fillfactor (integer)`

The `fillfactor` for a table is a percentage between 10 and 100. 100 (complete packing) is the default. When a smaller `fillfactor` is specified, `INSERT` operations pack table pages only to the indicated percentage; the remaining space on each page is reserved for updating rows on that page. This gives `UPDATE` a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page, and makes [heap-only tuple updates](#) more likely. For a table whose entries are never updated, complete packing is the best choice, but in heavily updated tables smaller `fillfactors` are appropriate. This parameter cannot be set for TOAST tables.

`toast_tuple_target (integer)`

The `toast_tuple_target` specifies the minimum tuple length required before we try to compress and/or move long column values into TOAST tables, and is also the target length we try to reduce the length below once toasting begins. This affects columns marked as External (for move), Main (for compression), or Extended (for both) and applies only to new tuples. There is no effect on existing rows. By default this parameter is set to allow at least 4 tuples per block, which with the default block size will be 2040 bytes. Valid values are between 128 bytes and the (block size - header), by default 8160 bytes. Changing this value may not be useful for very short or very long rows. Note that the default setting is often close to optimal, and it is possible that setting this parameter could have negative effects in some cases. This parameter cannot be set for TOAST tables.

`parallel_workers (integer)`

This sets the number of workers that should be used to assist a parallel scan of this table. If not set, the system will determine a value based on the relation size. The actual number of workers chosen by the planner or by utility statements that use parallel scans may be less, for example due to the setting of [max_worker_processes](#).

`autovacuum_enabled, toast.autovacuum_enabled (boolean)`

Enables or disables the autovacuum daemon for a particular table. If true, the autovacuum daemon will perform automatic `VACUUM` and/or `ANALYZE` operations on this table following the rules discussed in [Section 24.1.6](#). If false, this table will not be autovacuumed, except to shrink `pg_xact` and `pg_multixact`. See [Section 24.1.5](#) for more about that. Note that the autovacuum daemon does not run at all (except to shrink `pg_xact` and `pg_multixact`) if the [autovacuum](#) parameter is false; setting individual tables' storage parameters does not override that. Therefore there is seldom much point in explicitly setting this storage parameter to true, only to false.

`vacuum_index_cleanup, toast.vacuum_index_cleanup (enum)`

Forces or disables index cleanup when `VACUUM` is run on this table. The default value is `AUTO`. With `OFF`, index cleanup is disabled, with `ON` it is enabled, and with `AUTO` a decision is made dynamically, each time `VACUUM` runs. The dynamic behavior allows `VACUUM` to avoid needlessly scanning indexes to remove very few dead tuples. Forcibly disabling all index cleanup can speed up `VACUUM` very significantly, but may also lead to severely bloated indexes if table modifications are frequent. The `INDEX_CLEANUP` parameter of [VACUUM](#), if specified, overrides the value of this option.

`vacuum_truncate, toast.vacuum_truncate (boolean)`

Enables or disables vacuum to try to truncate off any empty pages at the end of this table. The default value is `true`. If `true`, `VACUUM` and autovacuum do the truncation and the disk space for the truncated pages is returned to the operating system. Note that the truncation requires `ACCESS EXCLUSIVE` lock on the table. The `TRUNCATE` parameter of [VACUUM](#), if specified, overrides the value of this option.

`parallel_autovacuum_workers (integer)`

The maximum number of additional parallel autovacuum workers that can be launched for table processing. Must be less than or equal to [max_parallel_autovacuum_workers](#). If the value is 0, the

number of table indexes determines the number of parallel autovacuum workers. The default value is -1, which means no parallel vacuuming of the table.

`autovacuum_vacuum_threshold, toast.autovacuum_vacuum_threshold (integer)`

Per-table value for [autovacuum_vacuum_threshold](#) parameter.

`autovacuum_vacuum_scale_factor, toast.autovacuum_vacuum_scale_factor (floating point)`

Per-table value for [autovacuum_vacuum_scale_factor](#) parameter.

`autovacuum_vacuum_insert_threshold, toast.autovacuum_vacuum_insert_threshold (integer)`

Per-table value for [autovacuum_vacuum_insert_threshold](#) parameter. The special value of -1 may be used to disable insert vacuums on the table.

`autovacuum_vacuum_insert_scale_factor, toast.autovacuum_vacuum_insert_scale_factor (floating point)`

Per-table value for [autovacuum_vacuum_insert_scale_factor](#) parameter.

`autovacuum_analyze_threshold (integer)`

Per-table value for [autovacuum_analyze_threshold](#) parameter.

`autovacuum_analyze_scale_factor (floating point)`

Per-table value for [autovacuum_analyze_scale_factor](#) parameter.

`autovacuum_vacuum_cost_delay, toast.autovacuum_vacuum_cost_delay (floating point)`

Per-table value for [autovacuum_vacuum_cost_delay](#) parameter.

`autovacuum_vacuum_cost_limit, toast.autovacuum_vacuum_cost_limit (integer)`

Per-table value for [autovacuum_vacuum_cost_limit](#) parameter.

`autovacuum_freeze_min_age, toast.autovacuum_freeze_min_age (integer)`

Per-table value for [vacuum_freeze_min_age](#) parameter. Note that autovacuum will ignore per-table `autovacuum_freeze_min_age` parameters that are larger than half the system-wide [autovacuum_freeze_max_age](#) setting.

`autovacuum_freeze_max_age, toast.autovacuum_freeze_max_age (integer)`

Per-table value for [autovacuum_freeze_max_age](#) parameter. Note that autovacuum will ignore per-table `autovacuum_freeze_max_age` parameters that are larger than the system-wide setting (it can only be set smaller).

`autovacuum_freeze_table_age, toast.autovacuum_freeze_table_age (integer)`

Per-table value for [vacuum_freeze_table_age](#) parameter.

`autovacuum_multixact_freeze_min_age, toast.autovacuum_multixact_freeze_min_age (integer)`

Per-table value for [vacuum_multixact_freeze_min_age](#) parameter. Note that autovacuum will ignore per-table `autovacuum_multixact_freeze_min_age` parameters that are larger than half the system-wide [autovacuum_multixact_freeze_max_age](#) setting.

`autovacuum_multixact_freeze_max_age, toast.autovacuum_multixact_freeze_max_age (integer)`

Per-table value for [autovacuum_multixact_freeze_max_age](#) parameter. Note that autovacuum will ignore per-table `autovacuum_multixact_freeze_max_age` parameters that are larger than the system-wide setting (it can only be set smaller).

`autovacuum_multixact_freeze_table_age, toast.autovacuum_multixact_freeze_table_age (integer)`

Per-table value for `vacuum_multixact_freeze_table_age` parameter.

`log_autovacuum_min_duration, toast.log_autovacuum_min_duration (integer)`

Per-table value for `log_autovacuum_min_duration` parameter.

`user_catalog_table (boolean)`

Declare the table as an additional catalog table for purposes of logical replication. See [Section 50.6.2](#) for details. This parameter cannot be set for TOAST tables.

Notes

Postgres Pro automatically creates an index for each unique constraint and primary key constraint to enforce uniqueness. Thus, it is not necessary to create an index explicitly for primary key columns. (See [CREATE INDEX](#) for more information.)

Unique constraints and primary keys are not inherited in the current implementation. This makes the combination of inheritance and unique constraints rather dysfunctional.

A table cannot have more than 1600 columns. (In practice, the effective limit is usually lower because of tuple-length constraints.)

Compatibility

The `CREATE TABLE` command conforms to the SQL standard, with exceptions listed below.

Temporary Tables

Note that temporary table usage is highly limited in Postgres Pro Shardman. If a transaction referred a remote sever, it cannot refer a temporary table.

Although the syntax of `CREATE TEMPORARY TABLE` resembles that of the SQL standard, the effect is not the same. In the standard, temporary tables are defined just once and automatically exist (starting with empty contents) in every session that needs them. Postgres Pro instead requires each session to issue its own `CREATE TEMPORARY TABLE` command for each temporary table to be used. This allows different sessions to use the same temporary table name for different purposes, whereas the standard's approach constrains all instances of a given temporary table name to have the same table structure.

The standard's definition of the behavior of temporary tables is widely ignored. Postgres Pro's behavior on this point is similar to that of several other SQL databases.

The SQL standard also distinguishes between global and local temporary tables, where a local temporary table has a separate set of contents for each SQL module within each session, though its definition is still shared across sessions. Since Postgres Pro does not support SQL modules, this distinction is not relevant in Postgres Pro.

For compatibility's sake, Postgres Pro will accept the `GLOBAL` and `LOCAL` keywords in a temporary table declaration, but they currently have no effect. Use of these keywords is discouraged, since future versions of Postgres Pro might adopt a more standard-compliant interpretation of their meaning.

The `ON COMMIT` clause for temporary tables also resembles the SQL standard, but has some differences. If the `ON COMMIT` clause is omitted, SQL specifies that the default behavior is `ON COMMIT DELETE ROWS`. However, the default behavior in Postgres Pro is `ON COMMIT PRESERVE ROWS`. The `ON COMMIT DROP` option does not exist in SQL.

Non-Deferred Uniqueness Constraints

When a `UNIQUE` or `PRIMARY KEY` constraint is not deferrable, Postgres Pro checks for uniqueness immediately whenever a row is inserted or modified. The SQL standard says that uniqueness should be enforced only at the end of the statement; this makes a difference when, for example, a single command updates

multiple key values. To obtain standard-compliant behavior, declare the constraint as `DEFERRABLE` but not deferred (i.e., `INITIALLY IMMEDIATE`). Be aware that this can be significantly slower than immediate uniqueness checking.

Column Check Constraints

The SQL standard says that `CHECK` column constraints can only refer to the column they apply to; only `CHECK` table constraints can refer to multiple columns. Postgres Pro does not enforce this restriction; it treats column and table check constraints alike.

EXCLUDE Constraint

The `EXCLUDE` constraint type is a Postgres Pro extension.

Foreign Key Constraints

The ability to specify column lists in the foreign key actions `SET DEFAULT` and `SET NULL` is a Postgres Pro extension.

It is a Postgres Pro extension that a foreign key constraint may reference columns of a unique index instead of columns of a primary key or unique constraint.

NULL “Constraint”

The `NULL` “constraint” (actually a non-constraint) is a Postgres Pro extension to the SQL standard that is included for compatibility with some other database systems (and for symmetry with the `NOT NULL` constraint). Since it is the default for any column, its presence is simply noise.

Constraint Naming

The SQL standard says that table and domain constraints must have names that are unique across the schema containing the table or domain. Postgres Pro is laxer: it only requires constraint names to be unique across the constraints attached to a particular table or domain. However, this extra freedom does not exist for index-based constraints (`UNIQUE`, `PRIMARY KEY`, and `EXCLUDE` constraints), because the associated index is named the same as the constraint, and index names must be unique across all relations within the same schema.

Currently, Postgres Pro does not record names for not-null constraints at all, so they are not subject to the uniqueness restriction. This might change in a future release.

Inheritance

Multiple inheritance via the `INHERITS` clause is a Postgres Pro language extension. SQL:1999 and later define single inheritance using a different syntax and different semantics. SQL:1999-style inheritance is not yet supported by Postgres Pro.

Zero-Column Tables

Postgres Pro allows a table of no columns to be created (for example, `CREATE TABLE foo();`). This is an extension from the SQL standard, which does not allow zero-column tables. Zero-column tables are not in themselves very useful, but disallowing them creates odd special cases for `ALTER TABLE DROP COLUMN`, so it seems cleaner to ignore this spec restriction.

Multiple Identity Columns

Postgres Pro allows a table to have more than one identity column. The standard specifies that a table can have at most one identity column. This is relaxed mainly to give more flexibility for doing schema changes or migrations. Note that the `INSERT` command supports only one override clause that applies to the entire statement, so having multiple identity columns with different behaviors is not well supported.

Generated Columns

The option `STORED` is not standard but is also used by other SQL implementations. The SQL standard does not specify the storage of generated columns.

LIKE Clause

While a `LIKE` clause exists in the SQL standard, many of the options that Postgres Pro accepts for it are not in the standard, and some of the standard's options are not implemented by Postgres Pro.

WITH Clause

The `WITH` clause is a Postgres Pro extension; storage parameters are not in the standard.

Tablespaces

The Postgres Pro concept of tablespaces is not part of the standard. Hence, the clauses `TABLESPACE` and `USING INDEX TABLESPACE` are extensions.

Typed Tables

Typed tables implement a subset of the SQL standard. According to the standard, a typed table has columns corresponding to the underlying composite type as well as one other column that is the “self-referencing column”. Postgres Pro does not support self-referencing columns explicitly.

PARTITION BY Clause

The `PARTITION BY` clause is a Postgres Pro extension.

PARTITION OF Clause

The `PARTITION OF` clause is a Postgres Pro extension.

CREATE TABLE Limitations for Sharded Tables

The extended `CREATE TABLE` syntax imposes limitations on the general syntax of the command. For example, there is currently no support for:

- Generated columns.
- `REFERENCES` and `FOREIGN KEY` constraints between non-located sharded tables.
- `PARTITION BY` and `PARTITION OF` clauses.
- A foreign key on a global table can reference only another global table and a foreign key on a sharded table can reference a located sharded table or a global table. Note that when a foreign key on a sharded or a global table references a global table, only `NO ACTION` or `RESTRICT` referential actions are supported for the `ON UPDATE` action and only `NO ACTION`, `RESTRICT` or `CASCADE` are supported for the `ON DELETE` action.
- Columns of the `SERIAL8` type are implemented using an automatically created global sequence, so all global sequence properties also apply here.
- For `CREATE TABLE`, all limitations for `ALTER TABLE` apply.
- Using of non-builtin types (types with OIDs ≥ 10000) or non-base types or arrays are not allowed in 'distributed_by' columns.
- Only the global user can create sharded or global table.
- In a located table, the number and types of columns used for table partitioning must be the same as for the table to locate with.
- A temporary table cannot be created as sharded or global.
- Self-referencing sharded tables are allowed only if a foreign key is referencing the same partition of the sharded table.
- Global tables cannot inherit other tables. Other tables should not be inherited from sharded tables.

For tables created using `LIKE source_table` where `source_table` is a local table, the following limitations apply:

- Copying without the *like_option* clause or with `INCLUDING INDEXES` is only supported. Does not apply to global tables.
- With `INCLUDING INDEXES`, only unique indexes and indexes supporting the primary relation key are copied.
- Copying indexes for columns is not supported.
- `EXCLUDE` constraints are not supported.
- Local tables used in `CREATE TABLE LIKE` statement must only have columns of base types.
- Partial indexes are not supported.
- Standard collations are only supported.
- `NULLS NOT DISTINCT` constraint is not supported.

Examples

The following example is for a sharded table. In this example, the table `pgbench_branches` is created, as well as colocated tables `pgbench_accounts` and `pgbench_history`. Each partition of the `pgbench_history` table is additionally subpartitioned by range.

```
CREATE TABLE pgbench_branches (  
    bid integer NOT NULL PRIMARY KEY,  
    bbalance integer,  
    filler character(88)  
)  
WITH (distributed_by = 'bid',  
      num_parts = 8);  
CREATE TABLE pgbench_accounts (  
    aid integer NOT NULL,  
    bid integer,  
    abalance integer,  
    filler character(84),  
    PRIMARY KEY (bid, aid)  
)  
WITH (distributed_by = 'bid',  
      num_parts = 8,  
      colocate_with = 'pgbench_branches');  
CREATE TABLE public.pgbench_history (  
    tid integer,  
    bid integer,  
    aid integer,  
    delta integer,  
    mtime timestamp without time zone,  
    filler character(22)  
)  
WITH (distributed_by = 'bid',  
      colocate_with = 'pgbench_branches',  
      partition_by = 'mtime',  
      partition_bounds =  
          $${{minvalue, '2021-01-01 00:00'}},{ '2021-01-01 00:00', '2022-01-01 00:00'}},  
      {'2022-01-01 00:00', maxvalue}}$$  
);
```

These simple examples of `CREATE TABLE` illustrate [limitations](#) related to creation of colocated tables:

This command creates a table to colocate with:

```
CREATE TABLE teams_players (  
    team_id integer NOT NULL,
```

```
    player_id integer,
    scores int,
    PRIMARY KEY (team_id, player_id)
) WITH (distributed_by='team_id, player_id');
```

This command correctly creates a colocated table:

```
CREATE TABLE players_scores (
    player_id integer NOT NULL,
    team_id integer,
    interval tstzrange,
    scores integer,
    foreign key (team_id, player_id) references teams_players(team_id, player_id)
) WITH (distributed_by='team_id, player_id', colocate_with='teams_players');
```

And this command contains an error in the definition of a foreign key:

```
CREATE TABLE players_scores (
    player_id integer NOT NULL,
    team_id integer,
    interval tstzrange,
    scores integer,
    foreign key (team_id, player_id) references teams_players(team_id, player_id)
) WITH (distributed_by='player_id, team_id', colocate_with='teams_players');
ERROR:  foreign key should start with distributed_by columns
```

Consider another example:

```
CREATE TABLE teams (team_id integer primary key, team_name text) with
(distributed_by='team_id');
CREATE TABLE players_teams (
    player_id integer,
    team_id integer references teams(team_id),
    scores integer
) WITH (distributed_by='player_id', colocate_with='teams');
ERROR:  foreign key should start with distributed_by columns
```

For not sharded tables. Create table films and table distributors:

```
CREATE TABLE films (
    code          char(5) CONSTRAINT firstkey PRIMARY KEY,
    title         varchar(40) NOT NULL,
    did           integer NOT NULL,
    date_prod     date,
    kind          varchar(10),
    len           interval hour to minute
);

CREATE TABLE distributors (
    did          integer PRIMARY KEY GENERATED BY DEFAULT AS IDENTITY,
    name         varchar(40) NOT NULL CHECK (name <> '')
);
```

Create a table with a 2-dimensional array:

```
CREATE TABLE array_int (
    vector int[][]
);
```

Define a unique table constraint for the table films. Unique table constraints can be defined on one or more columns of the table:

```
CREATE TABLE films (
```

```

code          char(5),
title         varchar(40),
did           integer,
date_prod    date,
kind          varchar(10),
len           interval hour to minute,
CONSTRAINT production UNIQUE(date_prod)
);

```

Define a check column constraint:

```

CREATE TABLE distributors (
    did      integer CHECK (did > 100),
    name     varchar(40)
);

```

Define a check table constraint:

```

CREATE TABLE distributors (
    did      integer,
    name     varchar(40),
    CONSTRAINT con1 CHECK (did > 100 AND name <> '')
);

```

Define a primary key table constraint for the table `films`:

```

CREATE TABLE films (
    code      char(5),
    title     varchar(40),
    did       integer,
    date_prod date,
    kind      varchar(10),
    len       interval hour to minute,
    CONSTRAINT code_title PRIMARY KEY(code,title)
);

```

Define a primary key constraint for table `distributors`. The following two examples are equivalent, the first using the table constraint syntax, the second the column constraint syntax:

```

CREATE TABLE distributors (
    did      integer,
    name     varchar(40),
    PRIMARY KEY(did)
);

```

```

CREATE TABLE distributors (
    did      integer PRIMARY KEY,
    name     varchar(40)
);

```

Assign a literal constant default value for the column `name`, arrange for the default value of column `did` to be generated by selecting the next value of a sequence object, and make the default value of `modtime` be the time at which the row is inserted:

```

CREATE TABLE distributors (
    name      varchar(40) DEFAULT 'Luso Films',
    did       integer DEFAULT nextval('distributors_serial'),
    modtime   timestamp DEFAULT current_timestamp
);

```

Define two NOT NULL column constraints on the table `distributors`, one of which is explicitly given a name:

```
CREATE TABLE distributors (  
    did      integer CONSTRAINT no_null NOT NULL,  
    name     varchar(40) NOT NULL  
);
```

Define a unique constraint for the name column:

```
CREATE TABLE distributors (  
    did      integer,  
    name     varchar(40) UNIQUE  
);
```

The same, specified as a table constraint:

```
CREATE TABLE distributors (  
    did      integer,  
    name     varchar(40),  
    UNIQUE(name)  
);
```

Create the same table, specifying 70% fill factor for both the table and its unique index:

```
CREATE TABLE distributors (  
    did      integer,  
    name     varchar(40),  
    UNIQUE(name) WITH (fillfactor=70)  
)  
WITH (fillfactor=70);
```

Create table circles with an exclusion constraint that prevents any two circles from overlapping:

```
CREATE TABLE circles (  
    c circle,  
    EXCLUDE USING gist (c WITH &&)  
);
```

Create table cinemas in tablespace diskvol1:

```
CREATE TABLE cinemas (  
    id serial,  
    name text,  
    location text  
) TABLESPACE diskvol1;
```

Create a composite type and a typed table:

```
CREATE TYPE employee_type AS (name text, salary numeric);  
  
CREATE TABLE employees OF employee_type (  
    PRIMARY KEY (name),  
    salary WITH OPTIONS DEFAULT 1000  
);
```

Create a range partitioned table:

```
CREATE TABLE measurement (  
    logdate      date not null,  
    peaktemp     int,  
    unitsales    int  
) PARTITION BY RANGE (logdate);
```

Create a range partitioned table with multiple columns in the partition key:

```
CREATE TABLE measurement_year_month (  

```

```
    logdate          date not null,  
    peaktemp        int,  
    unitsales       int  
 ) PARTITION BY RANGE (EXTRACT(YEAR FROM logdate), EXTRACT(MONTH FROM logdate));
```

Create a list partitioned table:

```
CREATE TABLE cities (  
    city_id          bigserial not null,  
    name             text not null,  
    population       bigint  
 ) PARTITION BY LIST (left(lower(name), 1));
```

Create a hash partitioned table:

```
CREATE TABLE orders (  
    order_id         bigint not null,  
    cust_id          bigint not null,  
    status           text  
 ) PARTITION BY HASH (order_id);
```

Create partition of a range partitioned table:

```
CREATE TABLE measurement_y2016m07  
    PARTITION OF measurement (  
    unitsales DEFAULT 0  
 ) FOR VALUES FROM ('2016-07-01') TO ('2016-08-01');
```

Create a few partitions of a range partitioned table with multiple columns in the partition key:

```
CREATE TABLE measurement_ym_older  
    PARTITION OF measurement_year_month  
    FOR VALUES FROM (MINVALUE, MINVALUE) TO (2016, 11);  
  
CREATE TABLE measurement_ym_y2016m11  
    PARTITION OF measurement_year_month  
    FOR VALUES FROM (2016, 11) TO (2016, 12);  
  
CREATE TABLE measurement_ym_y2016m12  
    PARTITION OF measurement_year_month  
    FOR VALUES FROM (2016, 12) TO (2017, 01);  
  
CREATE TABLE measurement_ym_y2017m01  
    PARTITION OF measurement_year_month  
    FOR VALUES FROM (2017, 01) TO (2017, 02);
```

Create partition of a list partitioned table:

```
CREATE TABLE cities_ab  
    PARTITION OF cities (  
    CONSTRAINT city_id_nonzero CHECK (city_id != 0)  
 ) FOR VALUES IN ('a', 'b');
```

Create partition of a list partitioned table that is itself further partitioned and then add a partition to it:

```
CREATE TABLE cities_ab  
    PARTITION OF cities (  
    CONSTRAINT city_id_nonzero CHECK (city_id != 0)  
 ) FOR VALUES IN ('a', 'b') PARTITION BY RANGE (population);  
  
CREATE TABLE cities_ab_10000_to_100000  
    PARTITION OF cities_ab FOR VALUES FROM (10000) TO (100000);
```

Create partitions of a hash partitioned table:

```
CREATE TABLE orders_p1 PARTITION OF orders
  FOR VALUES WITH (MODULUS 4, REMAINDER 0);
CREATE TABLE orders_p2 PARTITION OF orders
  FOR VALUES WITH (MODULUS 4, REMAINDER 1);
CREATE TABLE orders_p3 PARTITION OF orders
  FOR VALUES WITH (MODULUS 4, REMAINDER 2);
CREATE TABLE orders_p4 PARTITION OF orders
  FOR VALUES WITH (MODULUS 4, REMAINDER 3);
```

Create a default partition:

```
CREATE TABLE cities_partdef
  PARTITION OF cities DEFAULT;
```

[ALTER TABLE](#), [DROP TABLE](#), [CREATE TABLE AS](#), [CREATE TABLESPACE](#), [CREATE TYPE](#)

CREATE TABLE AS

CREATE TABLE AS — define a new table from the results of a query

Synopsis

```
CREATE [ [ GLOBAL | LOCAL ] { TEMPORARY | TEMP } | UNLOGGED | CONSTANT ] TABLE [ IF NOT
EXISTS ] table_name
    [ ( column_name [, ...] ) ]
    [ USING method ]
    [ WITH ( storage_parameter [= value] [, ...] ) | WITHOUT OIDS ]
    [ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
    [ TABLESPACE tablespace_name ]
AS query
    [ WITH [ NO ] DATA ]
```

Description

CREATE TABLE AS creates a table and fills it with data computed by a SELECT command. The table columns have the names and data types associated with the output columns of the SELECT (except that you can override the column names by giving an explicit list of new column names).

CREATE TABLE AS bears some resemblance to creating a view, but it is really quite different: it creates a new table and evaluates the query just once to fill the new table initially. The new table will not track subsequent changes to the source tables of the query. In contrast, a view re-evaluates its defining SELECT statement whenever it is queried.

CREATE TABLE AS requires CREATE privilege on the schema used for the table.

Parameters

GLOBAL or LOCAL

Ignored for compatibility. Use of these keywords is deprecated; refer to [CREATE TABLE](#) for details.

TEMPORARY or TEMP

If specified, the table is created as a temporary table. Refer to [CREATE TABLE](#) for details.

UNLOGGED

If specified, the table is created as an unlogged table. Refer to [CREATE TABLE](#) for details.

CONSTANT

If specified, the table is created as read-only. No data can be modified or added to constant tables, and they are not processed by [autovacuum](#). Constant tables cannot be changed to read-write mode.

IF NOT EXISTS

Do not throw an error if a relation with the same name already exists; simply issue a notice and leave the table unmodified.

table_name

The name (optionally schema-qualified) of the table to be created.

column_name

The name of a column in the new table. If column names are not provided, they are taken from the output column names of the query.

USING *method*

This optional clause specifies the table access method to use to store the contents for the new table; the method needs be an access method of type `TABLE`. See [Chapter 62](#) for more information. If this option is not specified, the default table access method is chosen for the new table. See [default_table_access_method](#) for more information.

WITH (*storage_parameter* [= *value*] [, ...])

This clause specifies optional storage parameters for the new table; see [Storage Parameters](#) in the [CREATE TABLE](#) documentation for more information. For backward-compatibility the `WITH` clause for a table can also include `OIDS=FALSE` to specify that rows of the new table should contain no OIDs (object identifiers), `OIDS=TRUE` is not supported anymore.

WITHOUT OIDS

This is backward-compatible syntax for declaring a table `WITHOUT OIDS`, creating a table `WITH OIDS` is not supported anymore.

ON COMMIT

The behavior of temporary tables at the end of a transaction block can be controlled using `ON COMMIT`. The three options are:

PRESERVE ROWS

No special action is taken at the ends of transactions. This is the default behavior.

DELETE ROWS

All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic `TRUNCATE` is done at each commit.

DROP

The temporary table will be dropped at the end of the current transaction block.

TABLESPACE *tablespace_name*

The *tablespace_name* is the name of the tablespace in which the new table is to be created. If not specified, [default_tablespace](#) is consulted, or [temp_tablespaces](#) if the table is temporary.

query

A [SELECT](#), [TABLE](#), or [VALUES](#) command, or an [EXECUTE](#) command that runs a prepared `SELECT`, `TABLE`, or `VALUES` query.

WITH [NO] DATA

This clause specifies whether or not the data produced by the query should be copied into the new table. If not, only the table structure is copied. The default is to copy the data.

Notes

This command is functionally similar to [SELECT INTO](#), but it is preferred since it is less likely to be confused with other uses of the `SELECT INTO` syntax. Furthermore, `CREATE TABLE AS` offers a superset of the functionality offered by `SELECT INTO`.

Examples

Create a new table `films_recent` consisting of only recent entries from the table `films`:

```
CREATE TABLE films_recent AS
SELECT * FROM films WHERE date_prod >= '2002-01-01';
```

To copy a table completely, the short form using the `TABLE` command can also be used:

```
CREATE TABLE films2 AS
TABLE films;
```

Create a new temporary table `films_recent`, consisting of only recent entries from the table `films`, using a prepared statement. The new table will be dropped at commit:

```
PREPARE recentfilms(date) AS
SELECT * FROM films WHERE date_prod > $1;
CREATE TEMP TABLE films_recent ON COMMIT DROP AS
EXECUTE recentfilms('2002-01-01');
```

Compatibility

`CREATE TABLE AS` conforms to the SQL standard. The following are nonstandard extensions:

- The standard requires parentheses around the subquery clause; in Postgres Pro, these parentheses are optional.
- In the standard, the `WITH [NO] DATA` clause is required; in Postgres Pro it is optional.
- Postgres Pro handles temporary tables in a way rather different from the standard; see [CREATE TABLE](#) for details.
- The `WITH` clause is a Postgres Pro extension; storage parameters are not in the standard.
- The Postgres Pro concept of tablespaces is not part of the standard. Hence, the clause `TABLESPACE` is an extension.

CREATE TABLESPACE

CREATE TABLESPACE — define a new tablespace

Synopsis

For global tablespaces only:

```
CREATE TABLESPACE tablespace_name
    [ OWNER { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER } ]
    LOCATION 'template'
    [ WITH (global = true [ tablespace_option = value [, ... ] ] ) ]
```

Description

Note that Postgres Pro Shardman only supports global tablespaces.

Postgres Pro Shardman extension of the `CREATE TABLESPACE` syntax enables creation of a new cluster-wide tablespace. All tablespaces in a Postgres Pro Shardman cluster must be cluster-wide. The cluster-wide tablespace is created on each cluster node with the location derived from the `template` parameter.

A tablespace allows database administrators to define an alternative location on the file system where the data files containing database objects (such as tables and indexes) can reside. Only superusers and users with the privileges of the `pg_create_tablespace` role can create tablespaces, but they can assign ownership of tablespaces to non-superusers.

A user with appropriate privileges can pass *tablespace_name* to `CREATE DATABASE`, `CREATE TABLE`, `CREATE INDEX` or `ADD CONSTRAINT` to have the data files for these objects stored within the specified tablespace.

Warning

A tablespace cannot be used independently of the cluster in which it is defined; see [Section 22.7](#).

Parameters

tablespace_name

The name of a tablespace to be created. The name cannot begin with `pg_`, as such names are reserved for system tablespaces.

user_name

The name of the user who will own the tablespace. If omitted, defaults to the user executing the command.

directory

The directory that will be used for the tablespace. The directory must exist (`CREATE TABLESPACE` will not create it), should be empty, and must be owned by the Postgres Pro system user. The directory must be specified by an absolute path name.

global = *true*

Specifies that the created tablespace must be global.

tablespace_option

A tablespace parameter to be set or reset. Currently, the only available parameters are `seq_page_cost`, `random_page_cost`, `effective_io_concurrency`, `maintenance_io_concurrency` and

`compression`. Setting cost value for a particular tablespace will override the planner's usual estimate of the cost of reading pages from tables in that tablespace, and the executor's prefetching behavior, as established by the configuration parameters of the same name (see [seq_page_cost](#), [random_page_cost](#), [effective_io_concurrency](#), [maintenance_io_concurrency](#)). This may be useful if one tablespace is located on a disk which is faster or slower than the remainder of the I/O subsystem. Compression is discussed in section [Chapter 32](#).

Notes

`CREATE TABLESPACE` cannot be executed inside a transaction block.

Examples

To create a tablespace `dbspace` under the file system location `/data/dbs`, first create the directory using operating system facilities on all nodes and set the correct ownership (or ensure that `postgres` user has permissions to create it):

```
mkdir /data/dbs
chown postgres:postgres /data/dbs
```

Then issue the tablespace creation command

```
CREATE TABLESPACE dbspace LOCATION '/data/dbs/ts-{rgid}' WITH (global = true);
```

Compatibility

`CREATE TABLESPACE` is a Postgres Pro extension.

CREATE TEXT SEARCH CONFIGURATION

CREATE TEXT SEARCH CONFIGURATION — define a new text search configuration

Synopsis

```
CREATE TEXT SEARCH CONFIGURATION name (  
    PARSER = parser_name |  
    COPY = source_config  
)
```

Description

CREATE TEXT SEARCH CONFIGURATION creates a new text search configuration. A text search configuration specifies a text search parser that can divide a string into tokens, plus dictionaries that can be used to determine which tokens are of interest for searching.

If only the parser is specified, then the new text search configuration initially has no mappings from token types to dictionaries, and therefore will ignore all words. Subsequent ALTER TEXT SEARCH CONFIGURATION commands must be used to create mappings to make the configuration useful. Alternatively, an existing text search configuration can be copied.

If a schema name is given then the text search configuration is created in the specified schema. Otherwise it is created in the current schema.

The user who defines a text search configuration becomes its owner.

Refer to [Chapter 12](#) for further information.

Parameters

name

The name of the text search configuration to be created. The name can be schema-qualified.

parser_name

The name of the text search parser to use for this configuration.

source_config

The name of an existing text search configuration to copy.

Notes

The PARSER and COPY options are mutually exclusive, because when an existing configuration is copied, its parser selection is copied too.

Compatibility

There is no CREATE TEXT SEARCH CONFIGURATION statement in the SQL standard.

See Also

[ALTER TEXT SEARCH CONFIGURATION](#), [DROP TEXT SEARCH CONFIGURATION](#)

CREATE TEXT SEARCH DICTIONARY

CREATE TEXT SEARCH DICTIONARY — define a new text search dictionary

Synopsis

```
CREATE TEXT SEARCH DICTIONARY name (  
    TEMPLATE = template  
    [, option = value [, ... ]]  
)
```

Description

CREATE TEXT SEARCH DICTIONARY creates a new text search dictionary. A text search dictionary specifies a way of recognizing interesting or uninteresting words for searching. A dictionary depends on a text search template, which specifies the functions that actually perform the work. Typically the dictionary provides some options that control the detailed behavior of the template's functions.

If a schema name is given then the text search dictionary is created in the specified schema. Otherwise it is created in the current schema.

The user who defines a text search dictionary becomes its owner.

Refer to [Chapter 12](#) for further information.

Parameters

name

The name of the text search dictionary to be created. The name can be schema-qualified.

template

The name of the text search template that will define the basic behavior of this dictionary.

option

The name of a template-specific option to be set for this dictionary.

value

The value to use for a template-specific option. If the value is not a simple identifier or number, it must be quoted (but you can always quote it, if you wish).

The options can appear in any order.

Examples

The following example command creates a Snowball-based dictionary with a nonstandard list of stop words.

```
CREATE TEXT SEARCH DICTIONARY my_russian (  
    template = snowball,  
    language = russian,  
    stopwords = myrussian  
);
```

Compatibility

There is no CREATE TEXT SEARCH DICTIONARY statement in the SQL standard.

See Also

[ALTER TEXT SEARCH DICTIONARY](#), [DROP TEXT SEARCH DICTIONARY](#)

CREATE TEXT SEARCH PARSER

CREATE TEXT SEARCH PARSER — define a new text search parser

Synopsis

```
CREATE TEXT SEARCH PARSER name (  
    START = start_function ,  
    GETTOKEN = gettoken_function ,  
    END = end_function ,  
    LEXTYPES = lextypes_function  
    [, HEADLINE = headline_function ]  
)
```

Description

CREATE TEXT SEARCH PARSER creates a new text search parser. A text search parser defines a method for splitting a text string into tokens and assigning types (categories) to the tokens. A parser is not particularly useful by itself, but must be bound into a text search configuration along with some text search dictionaries to be used for searching.

If a schema name is given then the text search parser is created in the specified schema. Otherwise it is created in the current schema.

You must be a superuser to use CREATE TEXT SEARCH PARSER. (This restriction is made because an erroneous text search parser definition could confuse or even crash the server.)

Refer to [Chapter 12](#) for further information.

Parameters

name

The name of the text search parser to be created. The name can be schema-qualified.

start_function

The name of the start function for the parser.

gettoken_function

The name of the get-next-token function for the parser.

end_function

The name of the end function for the parser.

lextypes_function

The name of the lextypes function for the parser (a function that returns information about the set of token types it produces).

headline_function

The name of the headline function for the parser (a function that summarizes a set of tokens).

The function names can be schema-qualified if necessary. Argument types are not given, since the argument list for each type of function is predetermined. All except the headline function are required.

The arguments can appear in any order, not only the one shown above.

Compatibility

There is no `CREATE TEXT SEARCH PARSER` statement in the SQL standard.

See Also

[ALTER TEXT SEARCH PARSER](#), [DROP TEXT SEARCH PARSER](#)

CREATE TEXT SEARCH TEMPLATE

CREATE TEXT SEARCH TEMPLATE — define a new text search template

Synopsis

```
CREATE TEXT SEARCH TEMPLATE name (  
    [ INIT = init_function , ]  
    LEXIZE = lexize_function  
)
```

Description

CREATE TEXT SEARCH TEMPLATE creates a new text search template. Text search templates define the functions that implement text search dictionaries. A template is not useful by itself, but must be instantiated as a dictionary to be used. The dictionary typically specifies parameters to be given to the template functions.

If a schema name is given then the text search template is created in the specified schema. Otherwise it is created in the current schema.

You must be a superuser to use CREATE TEXT SEARCH TEMPLATE. This restriction is made because an erroneous text search template definition could confuse or even crash the server. The reason for separating templates from dictionaries is that a template encapsulates the “unsafe” aspects of defining a dictionary. The parameters that can be set when defining a dictionary are safe for unprivileged users to set, and so creating a dictionary need not be a privileged operation.

Refer to [Chapter 12](#) for further information.

Parameters

name

The name of the text search template to be created. The name can be schema-qualified.

init_function

The name of the init function for the template.

lexize_function

The name of the lexize function for the template.

The function names can be schema-qualified if necessary. Argument types are not given, since the argument list for each type of function is predetermined. The lexize function is required, but the init function is optional.

The arguments can appear in any order, not only the one shown above.

Compatibility

There is no CREATE TEXT SEARCH TEMPLATE statement in the SQL standard.

See Also

[ALTER TEXT SEARCH TEMPLATE](#), [DROP TEXT SEARCH TEMPLATE](#)

CREATE TRANSFORM

CREATE TRANSFORM — define a new transform

Synopsis

```
CREATE [ OR REPLACE ] TRANSFORM FOR type_name LANGUAGE lang_name (  
    FROM SQL WITH FUNCTION from_sql_function_name [ (argument_type [, ...]) ],  
    TO SQL WITH FUNCTION to_sql_function_name [ (argument_type [, ...]) ]  
);
```

Description

CREATE TRANSFORM defines a new transform. CREATE OR REPLACE TRANSFORM will either create a new transform, or replace an existing definition.

A transform specifies how to adapt a data type to a procedural language. For example, when writing a function in PL/Python using the `hstore` type, PL/Python has no prior knowledge how to present `hstore` values in the Python environment. Language implementations usually default to using the text representation, but that is inconvenient when, for example, an associative array or a list would be more appropriate.

A transform specifies two functions:

- A “from SQL” function that converts the type from the SQL environment to the language. This function will be invoked on the arguments of a function written in the language.
- A “to SQL” function that converts the type from the language to the SQL environment. This function will be invoked on the return value of a function written in the language.

It is not necessary to provide both of these functions. If one is not specified, the language-specific default behavior will be used if necessary. (To prevent a transformation in a certain direction from happening at all, you could also write a transform function that always errors out.)

To be able to create a transform, you must own and have `USAGE` privilege on the type, have `USAGE` privilege on the language, and own and have `EXECUTE` privilege on the from-SQL and to-SQL functions, if specified.

Parameters

type_name

The name of the data type of the transform.

lang_name

The name of the language of the transform.

from_sql_function_name[(*argument_type* [, ...])]

The name of the function for converting the type from the SQL environment to the language. It must take one argument of type `internal` and return type `internal`. The actual argument will be of the type for the transform, and the function should be coded as if it were. (But it is not allowed to declare an SQL-level function returning `internal` without at least one argument of type `internal`.) The actual return value will be something specific to the language implementation. If no argument list is specified, the function name must be unique in its schema.

to_sql_function_name[(*argument_type* [, ...])]

The name of the function for converting the type from the language to the SQL environment. It must take one argument of type `internal` and return the type that is the type for the transform. The actual argument value will be something specific to the language implementation. If no argument list is specified, the function name must be unique in its schema.

Notes

Use `DROP TRANSFORM` to remove transforms.

Examples

To create a transform for type `hstore` and language `plpython3u`, first set up the type and the language:

```
CREATE TYPE hstore ...;
```

```
CREATE EXTENSION plpython3u;
```

Then create the necessary functions:

```
CREATE FUNCTION hstore_to_plpython(val internal) RETURNS internal
LANGUAGE C STRICT IMMUTABLE
AS ...;
```

```
CREATE FUNCTION plpython_to_hstore(val internal) RETURNS hstore
LANGUAGE C STRICT IMMUTABLE
AS ...;
```

And finally create the transform to connect them all together:

```
CREATE TRANSFORM FOR hstore LANGUAGE plpython3u (
    FROM SQL WITH FUNCTION hstore_to_plpython(internal),
    TO SQL WITH FUNCTION plpython_to_hstore(internal)
);
```

In practice, these commands would be wrapped up in an extension.

The `contrib` section contains a number of extensions that provide transforms, which can serve as real-world examples.

Compatibility

This form of `CREATE TRANSFORM` is a Postgres Pro extension. There is a `CREATE TRANSFORM` command in the SQL standard, but it is for adapting data types to client languages. That usage is not supported by Postgres Pro.

See Also

[CREATE FUNCTION](#), [CREATE LANGUAGE](#), [CREATE TYPE](#), [DROP TRANSFORM](#)

CREATE TRIGGER

CREATE TRIGGER — define a new trigger

Synopsis

```
CREATE [ OR REPLACE ] [ CONSTRAINT ] TRIGGER name { BEFORE | AFTER | INSTEAD OF }
{ event [ OR ... ] }
ON table_name
[ FROM referenced_table_name ]
[ NOT DEFERRABLE | [ DEFERRABLE ] [ INITIALLY IMMEDIATE | INITIALLY DEFERRED ] ]
[ REFERENCING { { OLD | NEW } TABLE [ AS ] transition_relation_name } [ ... ] ]
[ FOR [ EACH ] { ROW | STATEMENT } ]
[ WHEN ( condition ) ]
EXECUTE { FUNCTION | PROCEDURE } function_name ( arguments )
```

where *event* can be one of:

```
INSERT
UPDATE [ OF column_name [, ... ] ]
DELETE
TRUNCATE
```

Description

CREATE TRIGGER creates a new trigger. CREATE OR REPLACE TRIGGER will either create a new trigger, or replace an existing trigger. The trigger will be associated with the specified table, view, or foreign table and will execute the specified function *function_name* when certain operations are performed on that table.

To replace the current definition of an existing trigger, use CREATE OR REPLACE TRIGGER, specifying the existing trigger's name and parent table. All other properties are replaced.

The trigger can be specified to fire before the operation is attempted on a row (before constraints are checked and the INSERT, UPDATE, or DELETE is attempted); or after the operation has completed (after constraints are checked and the INSERT, UPDATE, or DELETE has completed); or instead of the operation (in the case of inserts, updates or deletes on a view). If the trigger fires before or instead of the event, the trigger can skip the operation for the current row, or change the row being inserted (for INSERT and UPDATE operations only). If the trigger fires after the event, all changes, including the effects of other triggers, are “visible” to the trigger.

A trigger that is marked FOR EACH ROW is called once for every row that the operation modifies. For example, a DELETE that affects 10 rows will cause any ON DELETE triggers on the target relation to be called 10 separate times, once for each deleted row. In contrast, a trigger that is marked FOR EACH STATEMENT only executes once for any given operation, regardless of how many rows it modifies (in particular, an operation that modifies zero rows will still result in the execution of any applicable FOR EACH STATEMENT triggers).

Triggers that are specified to fire INSTEAD OF the trigger event must be marked FOR EACH ROW, and can only be defined on views. BEFORE and AFTER triggers on a view must be marked as FOR EACH STATEMENT.

In addition, triggers may be defined to fire for TRUNCATE, though only FOR EACH STATEMENT.

The following table summarizes which types of triggers may be used on tables, views, and foreign tables:

When	Event	Row-level	Statement-level
BEFORE	INSERT/UPDATE/DELETE	Tables and foreign tables	Tables, views, and foreign tables

When	Event	Row-level	Statement-level
	TRUNCATE	—	Tables and foreign tables
AFTER	INSERT/UPDATE/DELETE	Tables and foreign tables	Tables, views, and foreign tables
	TRUNCATE	—	Tables and foreign tables
INSTEAD OF	INSERT/UPDATE/DELETE	Views	—
	TRUNCATE	—	—

Also, a trigger definition can specify a Boolean `WHEN` condition, which will be tested to see whether the trigger should be fired. In row-level triggers the `WHEN` condition can examine the old and/or new values of columns of the row. Statement-level triggers can also have `WHEN` conditions, although the feature is not so useful for them since the condition cannot refer to any values in the table.

If multiple triggers of the same kind are defined for the same event, they will be fired in alphabetical order by name.

When the `CONSTRAINT` option is specified, this command creates a *constraint trigger*. This is the same as a regular trigger except that the timing of the trigger firing can be adjusted using `SET CONSTRAINTS`. Constraint triggers must be `AFTER ROW` triggers on plain tables (not foreign tables). They can be fired either at the end of the statement causing the triggering event, or at the end of the containing transaction; in the latter case they are said to be *deferred*. A pending deferred-trigger firing can also be forced to happen immediately by using `SET CONSTRAINTS`. Constraint triggers are expected to raise an exception when the constraints they implement are violated.

The `REFERENCING` option enables collection of *transition relations*, which are row sets that include all of the rows inserted, deleted, or modified by the current SQL statement. This feature lets the trigger see a global view of what the statement did, not just one row at a time. This option is only allowed for an `AFTER` trigger that is not a constraint trigger; also, if the trigger is an `UPDATE` trigger, it must not specify a *column_name* list. `OLD TABLE` may only be specified once, and only for a trigger that can fire on `UPDATE` or `DELETE`; it creates a transition relation containing the *before-images* of all rows updated or deleted by the statement. Similarly, `NEW TABLE` may only be specified once, and only for a trigger that can fire on `UPDATE` or `INSERT`; it creates a transition relation containing the *after-images* of all rows updated or inserted by the statement.

`SELECT` does not modify any rows so you cannot create `SELECT` triggers. Rules and views may provide workable solutions to problems that seem to need `SELECT` triggers.

Refer to [Chapter 40](#) for more information about triggers.

Parameters

name

The name to give the new trigger. This must be distinct from the name of any other trigger for the same table. The name cannot be schema-qualified — the trigger inherits the schema of its table. For a constraint trigger, this is also the name to use when modifying the trigger's behavior using `SET CONSTRAINTS`.

`BEFORE`

`AFTER`

`INSTEAD OF`

Determines whether the function is called before, after, or instead of the event. A constraint trigger can only be specified as `AFTER`.

event

One of `INSERT`, `UPDATE`, `DELETE`, or `TRUNCATE`; this specifies the event that will fire the trigger. Multiple events can be specified using `OR`, except when transition relations are requested.

For `UPDATE` events, it is possible to specify a list of columns using this syntax:

```
UPDATE OF column_name1 [, column_name2 ... ]
```

The trigger will only fire if at least one of the listed columns is mentioned as a target of the `UPDATE` command or if one of the listed columns is a generated column that depends on a column that is the target of the `UPDATE`.

`INSTEAD OF UPDATE` events do not allow a list of columns. A column list cannot be specified when requesting transition relations, either.

table_name

The name (optionally schema-qualified) of the table, view, or foreign table the trigger is for.

referenced_table_name

The (possibly schema-qualified) name of another table referenced by the constraint. This option is used for foreign-key constraints and is not recommended for general use. This can only be specified for constraint triggers.

`DEFERRABLE`

`NOT DEFERRABLE`

`INITIALLY IMMEDIATE`

`INITIALLY DEFERRED`

The default timing of the trigger. See the [CREATE TABLE](#) documentation for details of these constraint options. This can only be specified for constraint triggers.

`REFERENCING`

This keyword immediately precedes the declaration of one or two relation names that provide access to the transition relations of the triggering statement.

`OLD TABLE`

`NEW TABLE`

This clause indicates whether the following relation name is for the before-image transition relation or the after-image transition relation.

transition_relation_name

The (unqualified) name to be used within the trigger for this transition relation.

`FOR EACH ROW`

`FOR EACH STATEMENT`

This specifies whether the trigger function should be fired once for every row affected by the trigger event, or just once per SQL statement. If neither is specified, `FOR EACH STATEMENT` is the default. Constraint triggers can only be specified `FOR EACH ROW`.

condition

A Boolean expression that determines whether the trigger function will actually be executed. If `WHEN` is specified, the function will only be called if the *condition* returns `true`. In `FOR EACH ROW` triggers, the `WHEN` condition can refer to columns of the old and/or new row values by writing `OLD.column_name` or `NEW.column_name` respectively. Of course, `INSERT` triggers cannot refer to `OLD` and `DELETE` triggers cannot refer to `NEW`.

INSTEAD OF triggers do not support WHEN conditions.

Currently, WHEN expressions cannot contain subqueries.

Note that for constraint triggers, evaluation of the WHEN condition is not deferred, but occurs immediately after the row update operation is performed. If the condition does not evaluate to true then the trigger is not queued for deferred execution.

function_name

A user-supplied function that is declared as taking no arguments and returning type `trigger`, which is executed when the trigger fires.

In the syntax of `CREATE TRIGGER`, the keywords `FUNCTION` and `PROCEDURE` are equivalent, but the referenced function must in any case be a function, not a procedure. The use of the keyword `PROCEDURE` here is historical and deprecated.

arguments

An optional comma-separated list of arguments to be provided to the function when the trigger is executed. The arguments are literal string constants. Simple names and numeric constants can be written here, too, but they will all be converted to strings. Please check the description of the implementation language of the trigger function to find out how these arguments can be accessed within the function; it might be different from normal function arguments.

Notes

To create or replace a trigger on a table, the user must have the `TRIGGER` privilege on the table. The user must also have `EXECUTE` privilege on the trigger function.

Use `DROP TRIGGER` to remove a trigger.

Creating a row-level trigger on a partitioned table will cause an identical “clone” trigger to be created on each of its existing partitions; and any partitions created or attached later will have an identical trigger, too. If there is a conflictly-named trigger on a child partition already, an error occurs unless `CREATE OR REPLACE TRIGGER` is used, in which case that trigger is replaced with a clone trigger. When a partition is detached from its parent, its clone triggers are removed.

A column-specific trigger (one defined using the `UPDATE OF column_name` syntax) will fire when any of its columns are listed as targets in the `UPDATE` command's `SET` list. It is possible for a column's value to change even when the trigger is not fired, because changes made to the row's contents by `BEFORE UPDATE` triggers are not considered. Conversely, a command such as `UPDATE ... SET x = x ...` will fire a trigger on column `x`, even though the column's value did not change.

In a `BEFORE` trigger, the WHEN condition is evaluated just before the function is or would be executed, so using WHEN is not materially different from testing the same condition at the beginning of the trigger function. Note in particular that the `NEW` row seen by the condition is the current value, as possibly modified by earlier triggers. Also, a `BEFORE` trigger's WHEN condition is not allowed to examine the system columns of the `NEW` row (such as `ctid`), because those won't have been set yet.

In an `AFTER` trigger, the WHEN condition is evaluated just after the row update occurs, and it determines whether an event is queued to fire the trigger at the end of statement. So when an `AFTER` trigger's WHEN condition does not return true, it is not necessary to queue an event nor to re-fetch the row at end of statement. This can result in significant speedups in statements that modify many rows, if the trigger only needs to be fired for a few of the rows.

In some cases it is possible for a single SQL command to fire more than one kind of trigger. For instance an `INSERT` with an `ON CONFLICT DO UPDATE` clause may cause both insert and update operations, so it will fire both kinds of triggers as needed. The transition relations supplied to triggers are specific to their event type; thus an `INSERT` trigger will see only the inserted rows, while an `UPDATE` trigger will see only the updated rows.

Row updates or deletions caused by foreign-key enforcement actions, such as `ON UPDATE CASCADE` or `ON DELETE SET NULL`, are treated as part of the SQL command that caused them (note that such actions are never deferred). Relevant triggers on the affected table will be fired, so that this provides another way in which an SQL command might fire triggers not directly matching its type. In simple cases, triggers that request transition relations will see all changes caused in their table by a single original SQL command as a single transition relation. However, there are cases in which the presence of an `AFTER ROW` trigger that requests transition relations will cause the foreign-key enforcement actions triggered by a single SQL command to be split into multiple steps, each with its own transition relation(s). In such cases, any statement-level triggers that are present will be fired once per creation of a transition relation set, ensuring that the triggers see each affected row in a transition relation once and only once.

Statement-level triggers on a view are fired only if the action on the view is handled by a row-level `INSTEAD OF` trigger. If the action is handled by an `INSTEAD` rule, then whatever statements are emitted by the rule are executed in place of the original statement naming the view, so that the triggers that will be fired are those on tables named in the replacement statements. Similarly, if the view is automatically updatable, then the action is handled by automatically rewriting the statement into an action on the view's base table, so that the base table's statement-level triggers are the ones that are fired.

Modifying a partitioned table or a table with inheritance children fires statement-level triggers attached to the explicitly named table, but not statement-level triggers for its partitions or child tables. In contrast, row-level triggers are fired on the rows in affected partitions or child tables, even if they are not explicitly named in the query. If a statement-level trigger has been defined with transition relations named by a `REFERENCING` clause, then before and after images of rows are visible from all affected partitions or child tables. In the case of inheritance children, the row images include only columns that are present in the table that the trigger is attached to.

Currently, row-level triggers with transition relations cannot be defined on partitions or inheritance child tables. Also, triggers on partitioned tables may not be `INSTEAD OF`.

Currently, the `OR REPLACE` option is not supported for constraint triggers.

Replacing an existing trigger within a transaction that has already performed updating actions on the trigger's table is not recommended. Trigger firing decisions, or portions of firing decisions, that have already been made will not be reconsidered, so the effects could be surprising.

There are a few built-in trigger functions that can be used to solve common problems without having to write your own trigger code; see [Section 9.29](#).

Examples

Execute the function `check_account_update` whenever a row of the table `accounts` is about to be updated:

```
CREATE TRIGGER check_update
  BEFORE UPDATE ON accounts
  FOR EACH ROW
  EXECUTE FUNCTION check_account_update();
```

Modify that trigger definition to only execute the function if column `balance` is specified as a target in the `UPDATE` command:

```
CREATE OR REPLACE TRIGGER check_update
  BEFORE UPDATE OF balance ON accounts
  FOR EACH ROW
  EXECUTE FUNCTION check_account_update();
```

This form only executes the function if column `balance` has in fact changed value:

```
CREATE TRIGGER check_update
  BEFORE UPDATE ON accounts
  FOR EACH ROW
```

```
WHEN (OLD.balance IS DISTINCT FROM NEW.balance)
EXECUTE FUNCTION check_account_update();
```

Call a function to log updates of accounts, but only if something changed:

```
CREATE TRIGGER log_update
AFTER UPDATE ON accounts
FOR EACH ROW
WHEN (OLD.* IS DISTINCT FROM NEW.*)
EXECUTE FUNCTION log_account_update();
```

Execute the function `view_insert_row` for each row to insert rows into the tables underlying a view:

```
CREATE TRIGGER view_insert
INSTEAD OF INSERT ON my_view
FOR EACH ROW
EXECUTE FUNCTION view_insert_row();
```

Execute the function `check_transfer_balances_to_zero` for each statement to confirm that the transfer rows offset to a net of zero:

```
CREATE TRIGGER transfer_insert
AFTER INSERT ON transfer
REFERENCING NEW TABLE AS inserted
FOR EACH STATEMENT
EXECUTE FUNCTION check_transfer_balances_to_zero();
```

Execute the function `check_matching_pairs` for each row to confirm that changes are made to matching pairs at the same time (by the same statement):

```
CREATE TRIGGER paired_items_update
AFTER UPDATE ON paired_items
REFERENCING NEW TABLE AS newtab OLD TABLE AS oldtab
FOR EACH ROW
EXECUTE FUNCTION check_matching_pairs();
```

[Section 40.4](#) contains a complete example of a trigger function written in C.

Compatibility

The `CREATE TRIGGER` statement in Postgres Pro implements a subset of the SQL standard. The following functionalities are currently missing:

- While transition table names for `AFTER` triggers are specified using the `REFERENCING` clause in the standard way, the row variables used in `FOR EACH ROW` triggers may not be specified in a `REFERENCING` clause. They are available in a manner that is dependent on the language in which the trigger function is written, but is fixed for any one language. Some languages effectively behave as though there is a `REFERENCING` clause containing `OLD ROW AS OLD NEW ROW AS NEW`.
- The standard allows transition tables to be used with column-specific `UPDATE` triggers, but then the set of rows that should be visible in the transition tables depends on the trigger's column list. This is not currently implemented by Postgres Pro.
- Postgres Pro only allows the execution of a user-defined function for the triggered action. The standard allows the execution of a number of other SQL commands, such as `CREATE TABLE`, as the triggered action. This limitation is not hard to work around by creating a user-defined function that executes the desired commands.

SQL specifies that multiple triggers should be fired in time-of-creation order. Postgres Pro uses name order, which was judged to be more convenient.

SQL specifies that `BEFORE DELETE` triggers on cascaded deletes fire *after* the cascaded `DELETE` completes. The Postgres Pro behavior is for `BEFORE DELETE` to always fire before the delete action, even a cascading one. This is considered more consistent. There is also nonstandard behavior if `BEFORE` triggers

modify rows or prevent updates during an update that is caused by a referential action. This can lead to constraint violations or stored data that does not honor the referential constraint.

The ability to specify multiple actions for a single trigger using `OR` is a Postgres Pro extension of the SQL standard.

The ability to fire triggers for `TRUNCATE` is a Postgres Pro extension of the SQL standard, as is the ability to define statement-level triggers on views.

`CREATE CONSTRAINT TRIGGER` is a Postgres Pro extension of the SQL standard. So is the `OR REPLACE` option.

```
CREATE TYPE name
```

Description

CREATE TYPE registers a new data type for use in the current database. The user who defines a type becomes its owner.

If a schema name is given then the type is created in the specified schema. Otherwise it is created in the current schema. The type name must be distinct from the name of any existing type or domain in the same schema. (Because tables have associated data types, the type name must also be distinct from the name of any existing table in the same schema.)

There are five forms of CREATE TYPE, as shown in the syntax synopsis above. They respectively create a *composite type*, an *enum type*, a *range type*, a *base type*, or a *shell type*. The first four of these are

discussed in turn below. A shell type is simply a placeholder for a type to be defined later; it is created by issuing `CREATE TYPE` with no parameters except for the type name. Shell types are needed as forward references when creating range types and base types, as discussed in those sections.

Composite Types

The first form of `CREATE TYPE` creates a composite type. The composite type is specified by a list of attribute names and data types. An attribute's collation can be specified too, if its data type is collatable. A composite type is essentially the same as the row type of a table, but using `CREATE TYPE` avoids the need to create an actual table when all that is wanted is to define a type. A stand-alone composite type is useful, for example, as the argument or return type of a function.

To be able to create a composite type, you must have `USAGE` privilege on all attribute types.

Enumerated Types

The second form of `CREATE TYPE` creates an enumerated (enum) type, as described in [Section 8.7](#). Enum types take a list of quoted labels, each of which must be less than `NAMEDATALEN` bytes long (64 bytes in a standard Postgres Pro build). (It is possible to create an enumerated type with zero labels, but such a type cannot be used to hold values before at least one label is added using `ALTER TYPE`.)

Range Types

The third form of `CREATE TYPE` creates a new range type, as described in [Section 8.17](#).

The range type's *subtype* can be any type with an associated b-tree operator class (to determine the ordering of values for the range type). Normally the subtype's default b-tree operator class is used to determine ordering; to use a non-default operator class, specify its name with *subtype_opclass*. If the subtype is collatable, and you want to use a non-default collation in the range's ordering, specify the desired collation with the *collation* option.

The optional *canonical* function must take one argument of the range type being defined, and return a value of the same type. This is used to convert range values to a canonical form, when applicable. See [Section 8.17.8](#) for more information. Creating a *canonical* function is a bit tricky, since it must be defined before the range type can be declared. To do this, you must first create a shell type, which is a placeholder type that has no properties except a name and an owner. This is done by issuing the command `CREATE TYPE name`, with no additional parameters. Then the function can be declared using the shell type as argument and result, and finally the range type can be declared using the same name. This automatically replaces the shell type entry with a valid range type.

The optional *subtype_diff* function must take two values of the *subtype* type as argument, and return a double precision value representing the difference between the two given values. While this is optional, providing it allows much greater efficiency of GiST indexes on columns of the range type. See [Section 8.17.8](#) for more information.

The optional *multirange_type_name* parameter specifies the name of the corresponding multirange type. If not specified, this name is chosen automatically as follows. If the range type name contains the substring *range*, then the multirange type name is formed by replacement of the *range* substring with *multirange* in the range type name. Otherwise, the multirange type name is formed by appending a *_multirange* suffix to the range type name.

Base Types

The fourth form of `CREATE TYPE` creates a new base type (scalar type). To create a new base type, you must be a superuser. (This restriction is made because an erroneous type definition could confuse or even crash the server.)

The parameters can appear in any order, not only that illustrated above, and most are optional. You must register two or more functions (using `CREATE FUNCTION`) before defining the type. The support functions *input_function* and *output_function* are required, while the functions *receive_function*,

send_function, *type_modifier_input_function*, *type_modifier_output_function*, *analyze_function*, and *subscript_function* are optional. Generally these functions have to be coded in C or another low-level language.

The *input_function* converts the type's external textual representation to the internal representation used by the operators and functions defined for the type. *output_function* performs the reverse transformation. The input function can be declared as taking one argument of type *cstring*, or as taking three arguments of types *cstring*, *oid*, *integer*. The first argument is the input text as a C string, the second argument is the type's own OID (except for array types, which instead receive their element type's OID), and the third is the *typmod* of the destination column, if known (-1 will be passed if not). The input function must return a value of the data type itself. Usually, an input function should be declared *STRICT*; if it is not, it will be called with a NULL first parameter when reading a NULL input value. The function must still return NULL in this case, unless it raises an error. (This case is mainly meant to support domain input functions, which might need to reject NULL inputs.) The output function must be declared as taking one argument of the new data type. The output function must return type *cstring*. Output functions are not invoked for NULL values.

The optional *receive_function* converts the type's external binary representation to the internal representation. If this function is not supplied, the type cannot participate in binary input. The binary representation should be chosen to be cheap to convert to internal form, while being reasonably portable. (For example, the standard integer data types use network byte order as the external binary representation, while the internal representation is in the machine's native byte order.) The receive function should perform adequate checking to ensure that the value is valid. The receive function can be declared as taking one argument of type *internal*, or as taking three arguments of types *internal*, *oid*, *integer*. The first argument is a pointer to a *StringInfo* buffer holding the received byte string; the optional arguments are the same as for the text input function. The receive function must return a value of the data type itself. Usually, a receive function should be declared *STRICT*; if it is not, it will be called with a NULL first parameter when reading a NULL input value. The function must still return NULL in this case, unless it raises an error. (This case is mainly meant to support domain receive functions, which might need to reject NULL inputs.) Similarly, the optional *send_function* converts from the internal representation to the external binary representation. If this function is not supplied, the type cannot participate in binary output. The send function must be declared as taking one argument of the new data type. The send function must return type *bytea*. Send functions are not invoked for NULL values.

You should at this point be wondering how the input and output functions can be declared to have results or arguments of the new type, when they have to be created before the new type can be created. The answer is that the type should first be defined as a *shell type*, which is a placeholder type that has no properties except a name and an owner. This is done by issuing the command `CREATE TYPE name`, with no additional parameters. Then the C I/O functions can be defined referencing the shell type. Finally, `CREATE TYPE` with a full definition replaces the shell entry with a complete, valid type definition, after which the new type can be used normally.

The optional *type_modifier_input_function* and *type_modifier_output_function* are needed if the type supports modifiers, that is optional constraints attached to a type declaration, such as `char(5)` or `numeric(30,2)`. Postgres Pro allows user-defined types to take one or more simple constants or identifiers as modifiers. However, this information must be capable of being packed into a single non-negative integer value for storage in the system catalogs. The *type_modifier_input_function* is passed the declared modifier(s) in the form of a *cstring* array. It must check the values for validity (throwing an error if they are wrong), and if they are correct, return a single non-negative integer value that will be stored as the column "typmod". Type modifiers will be rejected if the type does not have a *type_modifier_input_function*. The *type_modifier_output_function* converts the internal integer typmod value back to the correct form for user display. It must return a *cstring* value that is the exact string to append to the type name; for example `numeric`'s function might return `(30,2)`. It is allowed to omit the *type_modifier_output_function*, in which case the default display format is just the stored typmod integer value enclosed in parentheses.

The optional *analyze_function* performs type-specific statistics collection for columns of the data type. By default, `ANALYZE` will attempt to gather statistics using the type's "equals" and "less-than" operators,

if there is a default b-tree operator class for the type. For non-scalar types this behavior is likely to be unsuitable, so it can be overridden by specifying a custom analysis function. The analysis function must be declared to take a single argument of type `internal`, and return a boolean result.

The optional `subscript_function` allows the data type to be subscripted in SQL commands. Specifying this function does not cause the type to be considered a “true” array type; for example, it will not be a candidate for the result type of `ARRAY[]` constructs. But if subscripting a value of the type is a natural notation for extracting data from it, then a `subscript_function` can be written to define what that means. The subscript function must be declared to take a single argument of type `internal`, and return an `internal` result, which is a pointer to a struct of methods (functions) that implement subscripting. The detailed API for subscript functions appears in [src/include/nodes/subscripting.h](#). Additional information appears in [Array Types](#) below.

While the details of the new type's internal representation are only known to the I/O functions and other functions you create to work with the type, there are several properties of the internal representation that must be declared to Postgres Pro. Foremost of these is `internallength`. Base data types can be fixed-length, in which case `internallength` is a positive integer, or variable-length, indicated by setting `internallength` to `VARIABLE`. (Internally, this is represented by setting `typlen` to -1.) The internal representation of all variable-length types must start with a 4-byte integer giving the total length of this value of the type. (Note that the length field is often encoded, as described in [Section 66.2](#); it's unwise to access it directly.)

The optional flag `PASSEDBYVALUE` indicates that values of this data type are passed by value, rather than by reference. Types passed by value must be fixed-length, and their internal representation cannot be larger than the size of the `Datum` type (4 bytes on some machines, 8 bytes on others).

The `alignment` parameter specifies the storage alignment required for the data type. The allowed values equate to alignment on 1, 2, 4, or 8 byte boundaries. Note that variable-length types must have an alignment of at least 4, since they necessarily contain an `int4` as their first component.

The `storage` parameter allows selection of storage strategies for variable-length data types. (Only `plain` is allowed for fixed-length types.) `plain` specifies that data of the type will always be stored in-line and not compressed. `extended` specifies that the system will first try to compress a long data value, and will move the value out of the main table row if it's still too long. `external` allows the value to be moved out of the main table, but the system will not try to compress it. `main` allows compression, but discourages moving the value out of the main table. (Data items with this storage strategy might still be moved out of the main table if there is no other way to make a row fit, but they will be kept in the main table preferentially over `extended` and `external` items.)

All `storage` values other than `plain` imply that the functions of the data type can handle values that have been *toasted*, as described in [Section 66.2](#) and [Section 39.13.1](#). The specific other value given merely determines the default TOAST storage strategy for columns of a toastable data type; users can pick other strategies for individual columns using `ALTER TABLE SET STORAGE`.

The `like_type` parameter provides an alternative method for specifying the basic representation properties of a data type: copy them from some existing type. The values of `internallength`, `passedbyvalue`, `alignment`, and `storage` are copied from the named type. (It is possible, though usually undesirable, to override some of these values by specifying them along with the `LIKE` clause.) Specifying representation this way is especially useful when the low-level implementation of the new type “piggybacks” on an existing type in some fashion.

The `category` and `preferred` parameters can be used to help control which implicit cast will be applied in ambiguous situations. Each data type belongs to a category named by a single ASCII character, and each type is either “preferred” or not within its category. The parser will prefer casting to preferred types (but only from other types within the same category) when this rule is helpful in resolving overloaded functions or operators. For more details see [Chapter 10](#). For types that have no implicit casts to or from any other types, it is sufficient to leave these settings at the defaults. However, for a group of related types that have implicit casts, it is often helpful to mark them all as belonging to a category and select one or two of the “most general” types as being preferred within the category. The `category` parameter

is especially useful when adding a user-defined type to an existing built-in category, such as the numeric or string types. However, it is also possible to create new entirely-user-defined type categories. Select any ASCII character other than an upper-case letter to name such a category.

A default value can be specified, in case a user wants columns of the data type to default to something other than the null value. Specify the default with the `DEFAULT` key word. (Such a default can be overridden by an explicit `DEFAULT` clause attached to a particular column.)

To indicate that a type is a fixed-length array type, specify the type of the array elements using the `ELEMENT` key word. For example, to define an array of 4-byte integers (`int4`), specify `ELEMENT = int4`. For more details, see [Array Types](#) below.

To indicate the delimiter to be used between values in the external representation of arrays of this type, *delimiter* can be set to a specific character. The default delimiter is the comma (`,`). Note that the delimiter is associated with the array element type, not the array type itself.

If the optional Boolean parameter *collatable* is true, column definitions and expressions of the type may carry collation information through use of the `COLLATE` clause. It is up to the implementations of the functions operating on the type to actually make use of the collation information; this does not happen automatically merely by marking the type collatable.

Array Types

Whenever a user-defined type is created, Postgres Pro automatically creates an associated array type, whose name consists of the element type's name prepended with an underscore, and truncated if necessary to keep it less than `NAMEDATALEN` bytes long. (If the name so generated collides with an existing type name, the process is repeated until a non-colliding name is found.) This implicitly-created array type is variable length and uses the built-in input and output functions `array_in` and `array_out`. Furthermore, this type is what the system uses for constructs such as `ARRAY[]` over the user-defined type. The array type tracks any changes in its element type's owner or schema, and is dropped if the element type is.

You might reasonably ask why there is an `ELEMENT` option, if the system makes the correct array type automatically. The main case where it's useful to use `ELEMENT` is when you are making a fixed-length type that happens to be internally an array of a number of identical things, and you want to allow these things to be accessed directly by subscripting, in addition to whatever operations you plan to provide for the type as a whole. For example, type `point` is represented as just two floating-point numbers, which can be accessed using `point[0]` and `point[1]`. Note that this facility only works for fixed-length types whose internal form is exactly a sequence of identical fixed-length fields. For historical reasons (i.e., this is clearly wrong but it's far too late to change it), subscripting of fixed-length array types starts from zero, rather than from one as for variable-length arrays.

Specifying the `SUBSCRIPT` option allows a data type to be subscripted, even though the system does not otherwise regard it as an array type. The behavior just described for fixed-length arrays is actually implemented by the `SUBSCRIPT` handler function `raw_array_subscript_handler`, which is used automatically if you specify `ELEMENT` for a fixed-length type without also writing `SUBSCRIPT`.

When specifying a custom `SUBSCRIPT` function, it is not necessary to specify `ELEMENT` unless the `SUBSCRIPT` handler function needs to consult `typelem` to find out what to return. Be aware that specifying `ELEMENT` causes the system to assume that the new type contains, or is somehow physically dependent on, the element type; thus for example changing properties of the element type won't be allowed if there are any columns of the dependent type.

Parameters

name

The name (optionally schema-qualified) of a type to be created.

attribute_name

The name of an attribute (column) for the composite type.

data_type

The name of an existing data type to become a column of the composite type.

collation

The name of an existing collation to be associated with a column of a composite type, or with a range type.

label

A string literal representing the textual label associated with one value of an enum type.

subtype

The name of the element type that the range type will represent ranges of.

subtype_operator_class

The name of a b-tree operator class for the subtype.

canonical_function

The name of the canonicalization function for the range type.

subtype_diff_function

The name of a difference function for the subtype.

multirange_type_name

The name of the corresponding multirange type.

input_function

The name of a function that converts data from the type's external textual form to its internal form.

output_function

The name of a function that converts data from the type's internal form to its external textual form.

receive_function

The name of a function that converts data from the type's external binary form to its internal form.

send_function

The name of a function that converts data from the type's internal form to its external binary form.

type_modifier_input_function

The name of a function that converts an array of modifier(s) for the type into internal form.

type_modifier_output_function

The name of a function that converts the internal form of the type's modifier(s) to external textual form.

analyze_function

The name of a function that performs statistical analysis for the data type.

subscript_function

The name of a function that defines what subscripting a value of the data type does.

internallength

A numeric constant that specifies the length in bytes of the new type's internal representation. The default assumption is that it is variable-length.

alignment

The storage alignment requirement of the data type. If specified, it must be `char`, `int2`, `int4`, or `double`; the default is `int4`.

storage

The storage strategy for the data type. If specified, must be `plain`, `external`, `extended`, or `main`; the default is `plain`.

like_type

The name of an existing data type that the new type will have the same representation as. The values of *internallength*, *passedbyvalue*, *alignment*, and *storage* are copied from that type, unless overridden by explicit specification elsewhere in this `CREATE TYPE` command.

category

The category code (a single ASCII character) for this type. The default is `'U'` for “user-defined type”. Other standard category codes can be found in [Table 54.67](#). You may also choose other ASCII characters in order to create custom categories.

preferred

True if this type is a preferred type within its type category, else false. The default is false. Be very careful about creating a new preferred type within an existing type category, as this could cause surprising changes in behavior.

default

The default value for the data type. If this is omitted, the default is null.

element

The type being created is an array; this specifies the type of the array elements.

delimiter

The delimiter character to be used between values in arrays made of this type.

collatable

True if this type's operations can use collation information. The default is false.

Notes

Because there are no restrictions on use of a data type once it's been created, creating a base type or range type is tantamount to granting public execute permission on the functions mentioned in the type definition. This is usually not an issue for the sorts of functions that are useful in a type definition. But you might want to think twice before designing a type in a way that would require “secret” information to be used while converting it to or from external form.

Before PostgreSQL version 8.3, the name of a generated array type was always exactly the element type's name with one underscore character (`_`) prepended. (Type names were therefore restricted in length to one fewer character than other names.) While this is still usually the case, the array type name may vary from this in case of maximum-length names or collisions with user type names that begin with underscore. Writing code that depends on this convention is therefore deprecated. Instead, use `pg_type.typarray` to locate the array type associated with a given type.

It may be advisable to avoid using type and table names that begin with underscore. While the server will change generated array type names to avoid collisions with user-given names, there is still risk of confusion, particularly with old client software that may assume that type names beginning with underscores always represent arrays.

Before PostgreSQL version 8.2, the shell-type creation syntax `CREATE TYPE name` did not exist. The way to create a new base type was to create its input function first. In this approach, Postgres Pro will first see the name of the new data type as the return type of the input function. The shell type is implicitly created in this situation, and then it can be referenced in the definitions of the remaining I/O functions. This approach still works, but is deprecated and might be disallowed in some future release. Also, to avoid accidentally cluttering the catalogs with shell types as a result of simple typos in function definitions, a shell type will only be made this way when the input function is written in C.

In Postgres Pro version 16 and later, it is desirable for base types' input functions to return “soft” errors using the new `errsave()/ereturn()` mechanism, rather than throwing `ereport()` exceptions as in previous versions.

Examples

This example creates a composite type and uses it in a function definition:

```
CREATE TYPE compfoo AS (f1 int, f2 text);

CREATE FUNCTION getfoo() RETURNS SETOF compfoo AS $$
    SELECT fooid, foename FROM foo
$$ LANGUAGE SQL;
```

This example creates an enumerated type and uses it in a table definition:

```
CREATE TYPE bug_status AS ENUM ('new', 'open', 'closed');

CREATE TABLE bug (
    id serial,
    description text,
    status bug_status
);
```

This example creates a range type:

```
CREATE TYPE float8_range AS RANGE (subtype = float8, subtype_diff = float8mi);
```

This example creates the base data type `box` and then uses the type in a table definition:

```
CREATE TYPE box;

CREATE FUNCTION my_box_in_function(cstring) RETURNS box AS ... ;
CREATE FUNCTION my_box_out_function(box) RETURNS cstring AS ... ;

CREATE TYPE box (
    INTERNALLENGTH = 16,
    INPUT = my_box_in_function,
    OUTPUT = my_box_out_function
);

CREATE TABLE myboxes (
    id integer,
    description box
);
```

If the internal structure of `box` were an array of four `float4` elements, we might instead use:

```
CREATE TYPE box (
    INTERNALLENGTH = 16,
    INPUT = my_box_in_function,
    OUTPUT = my_box_out_function,
    ELEMENT = float4
);
```

which would allow a box value's component numbers to be accessed by subscripting. Otherwise the type behaves the same as before.

This example creates a large object type and uses it in a table definition:

```
CREATE TYPE bigobj (  
    INPUT = lo_filein, OUTPUT = lo_fileout,  
    INTERNALLENGTH = VARIABLE  
);  
CREATE TABLE big_objs (  
    id integer,  
    obj bigobj  
);
```

More examples, including suitable input and output functions, are in [Section 39.13](#).

Compatibility

The first form of the `CREATE TYPE` command, which creates a composite type, conforms to the SQL standard. The other forms are Postgres Pro extensions. The `CREATE TYPE` statement in the SQL standard also defines other forms that are not implemented in Postgres Pro.

The ability to create a composite type with zero attributes is a Postgres Pro-specific deviation from the standard (analogous to the same case in `CREATE TABLE`).

See Also

[ALTER TYPE](#), [CREATE DOMAIN](#), [CREATE FUNCTION](#), [DROP TYPE](#)

CREATE USER

CREATE USER — define a new database role

Synopsis

```
CREATE USER name [ [ WITH ] option [ ... ] ]
```

where *option* can be:

```
SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| REPLICATION | NOREPLICATION
| BYPASSRLS | NOBYPASSRLS
| CONNECTION LIMIT connlimit
| [ ENCRYPTED ] PASSWORD 'password' | PASSWORD NULL
| VALID UNTIL 'timestamp'
| IN ROLE role_name [, ...]
| IN GROUP role_name [, ...]
| ROLE role_name [, ...]
| ADMIN role_name [, ...]
| USER role_name [, ...]
| SYSID uid
| PROFILE profile_name
```

Description

CREATE USER is now an alias for [CREATE ROLE](#). The only difference is that when the command is spelled CREATE USER, LOGIN is assumed by default, whereas NOLOGIN is assumed when the command is spelled CREATE ROLE.

Compatibility

The CREATE USER statement is a Postgres Pro extension. The SQL standard leaves the definition of users to the implementation.

[CREATE ROLE](#)

CREATE VIEW

CREATE VIEW — define a new view

Synopsis

```
CREATE [ OR REPLACE ] [ TEMP | TEMPORARY ] [ RECURSIVE ] VIEW name [ ( column_name
[ , ... ] ) ]
    [ WITH ( view_option_name [= view_option_value] [ , ... ] ) ]
    AS query
    [ WITH [ CASCADED | LOCAL ] CHECK OPTION ]
```

Description

CREATE VIEW defines a view of a query. The view is not physically materialized. Instead, the query is run every time the view is referenced in a query.

CREATE OR REPLACE VIEW is similar, but if a view of the same name already exists, it is replaced. The new query must generate the same columns that were generated by the existing view query (that is, the same column names in the same order and with the same data types), but it may add additional columns to the end of the list. The calculations giving rise to the output columns may be completely different.

If a schema name is given (for example, CREATE VIEW myschema.myview ...) then the view is created in the specified schema. Otherwise it is created in the current schema. Temporary views exist in a special schema, so a schema name cannot be given when creating a temporary view. The name of the view must be distinct from the name of any other relation (table, sequence, index, view, materialized view, or foreign table) in the same schema.

Parameters

TEMPORARY or TEMP

If specified, the view is created as a temporary view. Temporary views are automatically dropped at the end of the current session. Existing permanent relations with the same name are not visible to the current session while the temporary view exists, unless they are referenced with schema-qualified names.

If any of the tables referenced by the view are temporary, the view is created as a temporary view (whether TEMPORARY is specified or not).

RECURSIVE

Creates a recursive view. The syntax

```
CREATE RECURSIVE VIEW [ schema . ] view_name (column_names) AS SELECT ...;
```

is equivalent to

```
CREATE VIEW [ schema . ] view_name AS WITH RECURSIVE view_name (column_names) AS
    (SELECT ...) SELECT column_names FROM view_name;
```

A view column name list must be specified for a recursive view.

name

The name (optionally schema-qualified) of a view to be created.

column_name

An optional list of names to be used for columns of the view. If not given, the column names are deduced from the query.

```
WITH ( view_option_name [= view_option_value] [, ... ] )
```

This clause specifies optional parameters for a view; the following parameters are supported:

`check_option` (enum)

This parameter may be either `local` or `cascaded`, and is equivalent to specifying `WITH [CASCADED | LOCAL] CHECK OPTION` (see below).

`security_barrier` (boolean)

This should be used if the view is intended to provide row-level security. See [Section 42.5](#) for full details.

`security_invoker` (boolean)

This option causes the underlying base relations to be checked against the privileges of the user of the view rather than the view owner. See the notes below for full details.

All of the above options can be changed on existing views using [ALTER VIEW](#).

query

A [SELECT](#) or [VALUES](#) command which will provide the columns and rows of the view.

```
WITH [ CASCADED | LOCAL ] CHECK OPTION
```

This option controls the behavior of automatically updatable views. When this option is specified, `INSERT`, `UPDATE`, and `MERGE` commands on the view will be checked to ensure that new rows satisfy the view-defining condition (that is, the new rows are checked to ensure that they are visible through the view). If they are not, the update will be rejected. If the `CHECK OPTION` is not specified, `INSERT`, `UPDATE`, and `MERGE` commands on the view are allowed to create rows that are not visible through the view. The following check options are supported:

`LOCAL`

New rows are only checked against the conditions defined directly in the view itself. Any conditions defined on underlying base views are not checked (unless they also specify the `CHECK OPTION`).

`CASCADED`

New rows are checked against the conditions of the view and all underlying base views. If the `CHECK OPTION` is specified, and neither `LOCAL` nor `CASCADED` is specified, then `CASCADED` is assumed.

The `CHECK OPTION` may not be used with `RECURSIVE` views.

Note that the `CHECK OPTION` is only supported on views that are automatically updatable, and do not have `INSTEAD OF` triggers or `INSTEAD` rules. If an automatically updatable view is defined on top of a base view that has `INSTEAD OF` triggers, then the `LOCAL CHECK OPTION` may be used to check the conditions on the automatically updatable view, but the conditions on the base view with `INSTEAD OF` triggers will not be checked (a cascaded check option will not cascade down to a trigger-updatable view, and any check options defined directly on a trigger-updatable view will be ignored). If the view or any of its base relations has an `INSTEAD` rule that causes the `INSERT` or `UPDATE` command to be rewritten, then all check options will be ignored in the rewritten query, including any checks from automatically updatable views defined on top of the relation with the `INSTEAD` rule. `MERGE` is not supported if the view or any of its base relations have rules.

Notes

Use the [DROP VIEW](#) statement to drop views.

Be careful that the names and types of the view's columns will be assigned the way you want. For example:

```
CREATE VIEW vista AS SELECT 'Hello World';
```

is bad form because the column name defaults to `?column?`; also, the column data type defaults to `text`, which might not be what you wanted. Better style for a string literal in a view's result is something like:

```
CREATE VIEW vista AS SELECT text 'Hello World' AS hello;
```

By default, access to the underlying base relations referenced in the view is determined by the permissions of the view owner. In some cases, this can be used to provide secure but restricted access to the underlying tables. However, not all views are secure against tampering; see [Section 42.5](#) for details.

If the view has the `security_invoker` property set to `true`, access to the underlying base relations is determined by the permissions of the user executing the query, rather than the view owner. Thus, the user of a security invoker view must have the relevant permissions on the view and its underlying base relations.

If any of the underlying base relations is a security invoker view, it will be treated as if it had been accessed directly from the original query. Thus, a security invoker view will always check its underlying base relations using the permissions of the current user, even if it is accessed from a view without the `security_invoker` property.

If any of the underlying base relations has [row-level security](#) enabled, then by default, the row-level security policies of the view owner are applied, and access to any additional relations referred to by those policies is determined by the permissions of the view owner. However, if the view has `security_invoker` set to `true`, then the policies and permissions of the invoking user are used instead, as if the base relations had been referenced directly from the query using the view.

Functions called in the view are treated the same as if they had been called directly from the query using the view. Therefore, the user of a view must have permissions to call all functions used by the view. Functions in the view are executed with the privileges of the user executing the query or the function owner, depending on whether the functions are defined as `SECURITY INVOKER` or `SECURITY DEFINER`. Thus, for example, calling `CURRENT_USER` directly in a view will always return the invoking user, not the view owner. This is not affected by the view's `security_invoker` setting, and so a view with `security_invoker` set to `false` is *not* equivalent to a `SECURITY DEFINER` function and those concepts should not be confused.

The user creating or replacing a view must have `USAGE` privileges on any schemas referred to in the view query, in order to look up the referenced objects in those schemas. Note, however, that this lookup only happens when the view is created or replaced. Therefore, the user of the view only requires the `USAGE` privilege on the schema containing the view, not on the schemas referred to in the view query, even for a security invoker view.

When `CREATE OR REPLACE VIEW` is used on an existing view, only the view's defining `SELECT` rule, plus any `WITH (...)` parameters and its `CHECK OPTION` are changed. Other view properties, including ownership, permissions, and non-`SELECT` rules, remain unchanged. You must own the view to replace it (this includes being a member of the owning role).

Updatable Views

Simple views are automatically updatable: the system will allow `INSERT`, `UPDATE`, `DELETE`, and `MERGE` statements to be used on the view in the same way as on a regular table. A view is automatically updatable if it satisfies all of the following conditions:

- The view must have exactly one entry in its `FROM` list, which must be a table or another updatable view.
- The view definition must not contain `WITH`, `DISTINCT`, `GROUP BY`, `HAVING`, `LIMIT`, or `OFFSET` clauses at the top level.
- The view definition must not contain set operations (`UNION`, `INTERSECT` or `EXCEPT`) at the top level.

- The view's select list must not contain any aggregates, window functions or set-returning functions.

An automatically updatable view may contain a mix of updatable and non-updatable columns. A column is updatable if it is a simple reference to an updatable column of the underlying base relation; otherwise the column is read-only, and an error will be raised if an `INSERT`, `UPDATE`, or `MERGE` statement attempts to assign a value to it.

If the view is automatically updatable the system will convert any `INSERT`, `UPDATE`, `DELETE`, or `MERGE` statement on the view into the corresponding statement on the underlying base relation. `INSERT` statements that have an `ON CONFLICT UPDATE` clause are fully supported.

If an automatically updatable view contains a `WHERE` condition, the condition restricts which rows of the base relation are available to be modified by `UPDATE`, `DELETE`, and `MERGE` statements on the view. However, an `UPDATE` or `MERGE` is allowed to change a row so that it no longer satisfies the `WHERE` condition, and thus is no longer visible through the view. Similarly, an `INSERT` or `MERGE` command can potentially insert base-relation rows that do not satisfy the `WHERE` condition and thus are not visible through the view (`ON CONFLICT UPDATE` may similarly affect an existing row not visible through the view). The `CHECK OPTION` may be used to prevent `INSERT`, `UPDATE`, and `MERGE` commands from creating such rows that are not visible through the view.

If an automatically updatable view is marked with the `security_barrier` property then all the view's `WHERE` conditions (and any conditions using operators which are marked as `LEAKPROOF`) will always be evaluated before any conditions that a user of the view has added. See [Section 42.5](#) for full details. Note that, due to this, rows which are not ultimately returned (because they do not pass the user's `WHERE` conditions) may still end up being locked. `EXPLAIN` can be used to see which conditions are applied at the relation level (and therefore do not lock rows) and which are not.

A more complex view that does not satisfy all these conditions is read-only by default: the system will not allow an `INSERT`, `UPDATE`, `DELETE`, or `MERGE` on the view. You can get the effect of an updatable view by creating `INSTEAD OF` triggers on the view, which must convert attempted inserts, etc. on the view into appropriate actions on other tables. For more information see [CREATE TRIGGER](#). Another possibility is to create rules (see [CREATE RULE](#)), but in practice triggers are easier to understand and use correctly. Also note that `MERGE` is not supported on relations with rules.

Note that the user performing the insert, update or delete on the view must have the corresponding insert, update or delete privilege on the view. In addition, by default, the view's owner must have the relevant privileges on the underlying base relations, whereas the user performing the update does not need any permissions on the underlying base relations (see [Section 42.5](#)). However, if the view has `security_invoker` set to `true`, the user performing the update, rather than the view owner, must have the relevant privileges on the underlying base relations.

Examples

Create a view consisting of all comedy films:

```
CREATE VIEW comedies AS
  SELECT *
  FROM films
  WHERE kind = 'Comedy';
```

This will create a view containing the columns that are in the `film` table at the time of view creation. Though `*` was used to create the view, columns added later to the table will not be part of the view.

Create a view with `LOCAL CHECK OPTION`:

```
CREATE VIEW universal_comedies AS
  SELECT *
  FROM comedies
  WHERE classification = 'U'
  WITH LOCAL CHECK OPTION;
```

This will create a view based on the `comedies` view, showing only films with `kind = 'Comedy'` and `classification = 'U'`. Any attempt to `INSERT` or `UPDATE` a row in the view will be rejected if the new row doesn't have `classification = 'U'`, but the film `kind` will not be checked.

Create a view with `CASCADDED CHECK OPTION`:

```
CREATE VIEW pg_comedies AS
  SELECT *
  FROM comedies
  WHERE classification = 'PG'
  WITH CASCADDED CHECK OPTION;
```

This will create a view that checks both the `kind` and `classification` of new rows.

Create a view with a mix of updatable and non-updatable columns:

```
CREATE VIEW comedies AS
  SELECT f.*,
         country_code_to_name(f.country_code) AS country,
         (SELECT avg(r.rating)
          FROM user_ratings r
          WHERE r.film_id = f.id) AS avg_rating
  FROM films f
  WHERE f.kind = 'Comedy';
```

This view will support `INSERT`, `UPDATE` and `DELETE`. All the columns from the `films` table will be updatable, whereas the computed columns `country` and `avg_rating` will be read-only.

Create a recursive view consisting of the numbers from 1 to 100:

```
CREATE RECURSIVE VIEW public.nums_1_100 (n) AS
  VALUES (1)
  UNION ALL
  SELECT n+1 FROM nums_1_100 WHERE n < 100;
```

Notice that although the recursive view's name is schema-qualified in this `CREATE`, its internal self-reference is not schema-qualified. This is because the implicitly-created CTE's name cannot be schema-qualified.

Compatibility

`CREATE OR REPLACE VIEW` is a Postgres Pro language extension. So is the concept of a temporary view. The `WITH (...)` clause is an extension as well, as are security barrier views and security invoker views.

See Also

[ALTER VIEW](#), [DROP VIEW](#), [CREATE MATERIALIZED VIEW](#)

DEALLOCATE

DEALLOCATE — deallocate a prepared statement

Synopsis

```
DEALLOCATE [ PREPARE ] { name | ALL }
```

Description

DEALLOCATE is used to deallocate a previously prepared SQL statement. If you do not explicitly deallocate a prepared statement, it is deallocated when the session ends.

For more information on prepared statements, see [PREPARE](#).

Parameters

PREPARE

This key word is ignored.

name

The name of the prepared statement to deallocate.

ALL

Deallocate all prepared statements.

Compatibility

The SQL standard includes a DEALLOCATE statement, but it is only for use in embedded SQL.

See Also

[EXECUTE](#), [PREPARE](#)

DECLARE

DECLARE — define a cursor

Synopsis

```
DECLARE name [ BINARY ] [ ASENSITIVE | INSENSITIVE ] [ [ NO ] SCROLL ]  
CURSOR [ { WITH | WITHOUT } HOLD ] FOR query
```

Description

DECLARE allows a user to create cursors, which can be used to retrieve a small number of rows at a time out of a larger query. After the cursor is created, rows are fetched from it using [FETCH](#).

Note

This page describes usage of cursors at the SQL command level. If you are trying to use cursors inside a PL/pgSQL function, the rules are different — see [Section 44.7](#).

Parameters

name

The name of the cursor to be created. This must be different from any other active cursor name in the session.

BINARY

Causes the cursor to return data in binary rather than in text format.

ASENSITIVE

INSENSITIVE

Cursor sensitivity determines whether changes to the data underlying the cursor, done in the same transaction, after the cursor has been declared, are visible in the cursor. `INSENSITIVE` means they are not visible, `ASENSITIVE` means the behavior is implementation-dependent. A third behavior, `SENSITIVE`, meaning that such changes are visible in the cursor, is not available in Postgres Pro. In Postgres Pro, all cursors are insensitive; so these key words have no effect and are only accepted for compatibility with the SQL standard.

Specifying `INSENSITIVE` together with `FOR UPDATE` or `FOR SHARE` is an error.

SCROLL

NO SCROLL

`SCROLL` specifies that the cursor can be used to retrieve rows in a nonsequential fashion (e.g., backward). Depending upon the complexity of the query's execution plan, specifying `SCROLL` might impose a performance penalty on the query's execution time. `NO SCROLL` specifies that the cursor cannot be used to retrieve rows in a nonsequential fashion. The default is to allow scrolling in some cases; this is not the same as specifying `SCROLL`. See [Notes](#) below for details.

WITH HOLD

WITHOUT HOLD

`WITH HOLD` specifies that the cursor can continue to be used after the transaction that created it successfully commits. `WITHOUT HOLD` specifies that the cursor cannot be used outside of the transaction that created it. If neither `WITHOUT HOLD` nor `WITH HOLD` is specified, `WITHOUT HOLD` is the default.

query

A `SELECT` or `VALUES` command which will provide the rows to be returned by the cursor.

The key words `ASENSITIVE`, `BINARY`, `INSENSITIVE`, and `SCROLL` can appear in any order.

Notes

Normal cursors return data in text format, the same as a `SELECT` would produce. The `BINARY` option specifies that the cursor should return data in binary format. This reduces conversion effort for both the server and client, at the cost of more programmer effort to deal with platform-dependent binary data formats. As an example, if a query returns a value of one from an integer column, you would get a string of 1 with a default cursor, whereas with a binary cursor you would get a 4-byte field containing the internal representation of the value (in big-endian byte order).

Binary cursors should be used carefully. Many applications, including `psql`, are not prepared to handle binary cursors and expect data to come back in the text format.

Note

When the client application uses the “extended query” protocol to issue a `FETCH` command, the `Bind` protocol message specifies whether data is to be retrieved in text or binary format. This choice overrides the way that the cursor is defined. The concept of a binary cursor as such is thus obsolete when using extended query protocol — any cursor can be treated as either text or binary.

Unless `WITH HOLD` is specified, the cursor created by this command can only be used within the current transaction. Thus, `DECLARE` without `WITH HOLD` is useless outside a transaction block: the cursor would survive only to the completion of the statement. Therefore Postgres Pro reports an error if such a command is used outside a transaction block. Use `BEGIN` and `COMMIT` (or `ROLLBACK`) to define a transaction block.

If `WITH HOLD` is specified and the transaction that created the cursor successfully commits, the cursor can continue to be accessed by subsequent transactions in the same session. (But if the creating transaction is aborted, the cursor is removed.) A cursor created with `WITH HOLD` is closed when an explicit `CLOSE` command is issued on it, or the session ends. In the current implementation, the rows represented by a held cursor are copied into a temporary file or memory area so that they remain available for subsequent transactions.

`WITH HOLD` may not be specified when the query includes `FOR UPDATE` or `FOR SHARE`.

The `SCROLL` option should be specified when defining a cursor that will be used to fetch backwards. This is required by the SQL standard. However, for compatibility with earlier versions, Postgres Pro will allow backward fetches without `SCROLL`, if the cursor's query plan is simple enough that no extra overhead is needed to support it. However, application developers are advised not to rely on using backward fetches from a cursor that has not been created with `SCROLL`. If `NO SCROLL` is specified, then backward fetches are disallowed in any case.

Backward fetches are also disallowed when the query includes `FOR UPDATE` or `FOR SHARE`; therefore `SCROLL` may not be specified in this case.

Caution

Scrollable cursors may give unexpected results if they invoke any volatile functions (see [Section 39.7](#)). When a previously fetched row is re-fetched, the functions might be re-executed, perhaps leading to results different from the first time. It's best to specify `NO SCROLL` for a query involving volatile functions. If that is not practical, one workaround is to declare the cursor `SCROLL WITH HOLD` and commit the transaction before reading any rows from it. This will force the entire

output of the cursor to be materialized in temporary storage, so that volatile functions are executed exactly once for each row.

If the cursor's query includes `FOR UPDATE` or `FOR SHARE`, then returned rows are locked at the time they are first fetched, in the same way as for a regular [SELECT](#) command with these options. In addition, the returned rows will be the most up-to-date versions.

Caution

It is generally recommended to use `FOR UPDATE` if the cursor is intended to be used with `UPDATE ... WHERE CURRENT OF` or `DELETE ... WHERE CURRENT OF`. Using `FOR UPDATE` prevents other sessions from changing the rows between the time they are fetched and the time they are updated. Without `FOR UPDATE`, a subsequent `WHERE CURRENT OF` command will have no effect if the row was changed since the cursor was created.

Another reason to use `FOR UPDATE` is that without it, a subsequent `WHERE CURRENT OF` might fail if the cursor query does not meet the SQL standard's rules for being “simply updatable” (in particular, the cursor must reference just one table and not use grouping or `ORDER BY`). Cursors that are not simply updatable might work, or might not, depending on plan choice details; so in the worst case, an application might work in testing and then fail in production. If `FOR UPDATE` is specified, the cursor is guaranteed to be updatable.

The main reason not to use `FOR UPDATE` with `WHERE CURRENT OF` is if you need the cursor to be scrollable, or to be isolated from concurrent updates (that is, continue to show the old data). If this is a requirement, pay close heed to the caveats shown above.

The SQL standard only makes provisions for cursors in embedded SQL. The Postgres Pro server does not implement an `OPEN` statement for cursors; a cursor is considered to be open when it is declared. However, ECPG, the embedded SQL preprocessor for Postgres Pro, supports the standard SQL cursor conventions, including those involving `DECLARE` and `OPEN` statements.

The server data structure underlying an open cursor is called a *portal*. Portal names are exposed in the client protocol: a client can fetch rows directly from an open portal, if it knows the portal name. When creating a cursor with `DECLARE`, the portal name is the same as the cursor name.

You can see all available cursors by querying the [pg_cursors](#) system view.

Examples

To declare a cursor:

```
DECLARE liahona CURSOR FOR SELECT * FROM films;
```

See [FETCH](#) for more examples of cursor usage.

Compatibility

The SQL standard allows cursors only in embedded SQL and in modules. Postgres Pro permits cursors to be used interactively.

According to the SQL standard, changes made to insensitive cursors by `UPDATE ... WHERE CURRENT OF` and `DELETE ... WHERE CURRENT OF` statements are visible in that same cursor. Postgres Pro treats these statements like all other data changing statements in that they are not visible in insensitive cursors.

Binary cursors are a Postgres Pro extension.

DELETE

DELETE — delete rows of a table

Synopsis

```
[ WITH [ RECURSIVE ] with_query [, ...] ]  
DELETE FROM [ ONLY ] table_name [ * ] [ [ AS ] alias ]  
    [ USING from_item [, ...] ]  
    [ WHERE condition | WHERE CURRENT OF cursor_name ]  
    [ RETURNING { * | output_expression [ [ AS ] output_name ] } [, ...] ]
```

Description

DELETE deletes rows that satisfy the WHERE clause from the specified table. If the WHERE clause is absent, the effect is to delete all rows in the table. The result is a valid, but empty table.

Tip

TRUNCATE provides a faster mechanism to remove all rows from a table.

There are two ways to delete rows in a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the USING clause. Which technique is more appropriate depends on the specific circumstances.

The optional RETURNING clause causes DELETE to compute and return value(s) based on each row actually deleted. Any expression using the table's columns, and/or columns of other tables mentioned in USING, can be computed. The syntax of the RETURNING list is identical to that of the output list of SELECT.

You must have the DELETE privilege on the table to delete from it, as well as the SELECT privilege for any table in the USING clause or whose values are read in the *condition*.

Parameters

with_query

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the DELETE query. See [Section 7.8](#) and [SELECT](#) for details.

table_name

The name (optionally schema-qualified) of the table to delete rows from. If ONLY is specified before the table name, matching rows are deleted from the named table only. If ONLY is not specified, matching rows are also deleted from any tables inheriting from the named table. Optionally, * can be specified after the table name to explicitly indicate that descendant tables are included.

alias

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given DELETE FROM foo AS f, the remainder of the DELETE statement must refer to this table as f not foo.

from_item

A table expression allowing columns from other tables to appear in the WHERE condition. This uses the same syntax as the FROM clause of a SELECT statement; for example, an alias for the table name can be specified. Do not repeat the target table as a *from_item* unless you wish to set up a self-join (in which case it must appear with an alias in the *from_item*).

condition

An expression that returns a value of type `boolean`. Only rows for which this expression returns `true` will be deleted.

cursor_name

The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be deleted is the one most recently fetched from this cursor. The cursor must be a non-grouping query on the `DELETE`'s target table. Note that `WHERE CURRENT OF` cannot be specified together with a Boolean condition. See [DECLARE](#) for more information about using cursors with `WHERE CURRENT OF`.

output_expression

An expression to be computed and returned by the `DELETE` command after each row is deleted. The expression can use any column names of the table named by *table_name* or table(s) listed in `USING`. Write `*` to return all columns.

output_name

A name to use for a returned column.

Outputs

On successful completion, a `DELETE` command returns a command tag of the form

```
DELETE count
```

The *count* is the number of rows deleted. Note that the number may be less than the number of rows that matched the *condition* when deletes were suppressed by a `BEFORE DELETE` trigger. If *count* is 0, no rows were deleted by the query (this is not considered an error).

If the `DELETE` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) deleted by the command.

Notes

Postgres Pro lets you reference columns of other tables in the `WHERE` condition by specifying the other tables in the `USING` clause. For example, to delete all films produced by a given producer, one can do:

```
DELETE FROM films USING producers
WHERE producer_id = producers.id AND producers.name = 'foo';
```

What is essentially happening here is a join between `films` and `producers`, with all successfully joined `films` rows being marked for deletion. This syntax is not standard. A more standard way to do it is:

```
DELETE FROM films
WHERE producer_id IN (SELECT id FROM producers WHERE name = 'foo');
```

In some cases the join style is easier to write or faster to execute than the sub-select style.

Examples

Delete all films but musicals:

```
DELETE FROM films WHERE kind <> 'Musical';
```

Clear the table `films`:

```
DELETE FROM films;
```

Delete completed tasks, returning full details of the deleted rows:

```
DELETE FROM tasks WHERE status = 'DONE' RETURNING *;
```

Delete the row of `tasks` on which the cursor `c_tasks` is currently positioned:

```
DELETE FROM tasks WHERE CURRENT OF c_tasks;
```

While there is no `LIMIT` clause for `DELETE`, it is possible to get a similar effect using the same method described in [the documentation of `UPDATE`](#):

```
WITH delete_batch AS (  
  SELECT l.ctid FROM user_logs AS l  
    WHERE l.status = 'archived'  
    ORDER BY l.creation_date  
  FOR UPDATE  
  LIMIT 10000  
)  
DELETE FROM user_logs AS dl  
  USING delete_batch AS del  
  WHERE dl.ctid = del.ctid;
```

Compatibility

This command conforms to the SQL standard, except that the `USING` and `RETURNING` clauses are Postgres Pro extensions, as is the ability to use `WITH` with `DELETE`.

See Also

[TRUNCATE](#)

DISCARD

DISCARD — discard session state

Synopsis

```
DISCARD { ALL | PLANS | SEQUENCES | TEMPORARY | TEMP }
```

Description

`DISCARD` releases internal resources associated with a database session. This command is useful for partially or fully resetting the session's state. There are several subcommands to release different types of resources; the `DISCARD ALL` variant subsumes all the others, and also resets additional state.

Parameters

`PLANS`

Releases all cached query plans, forcing re-planning to occur the next time the associated prepared statement is used.

`SEQUENCES`

Discards all cached sequence-related state, including `currval()`/`lastval()` information and any pre-allocated sequence values that have not yet been returned by `nextval()`. (See [CREATE SEQUENCE](#) for a description of preallocated sequence values.)

`TEMPORARY` or `TEMP`

Drops all temporary tables created in the current session.

`ALL`

Releases all temporary resources associated with the current session and resets the session to its initial state. Currently, this has the same effect as executing the following sequence of statements:

```
CLOSE ALL;  
SET SESSION AUTHORIZATION DEFAULT;  
RESET ALL;  
DEALLOCATE ALL;  
UNLISTEN *;  
SELECT pg_advisory_unlock_all();  
DISCARD PLANS;  
DISCARD TEMP;  
DISCARD SEQUENCES;
```

Notes

`DISCARD ALL` cannot be executed inside a transaction block.

Compatibility

`DISCARD` is a Postgres Pro extension.

DO

DO — execute an anonymous code block

Synopsis

```
DO [ LANGUAGE lang_name ] code
```

Description

DO executes an anonymous code block, or in other words a transient anonymous function in a procedural language.

The code block is treated as though it were the body of a function with no parameters, returning `void`. It is parsed and executed a single time.

The optional `LANGUAGE` clause can be written either before or after the code block.

Parameters

code

The procedural language code to be executed. This must be specified as a string literal, just as in `CREATE FUNCTION`. Use of a dollar-quoted literal is recommended.

lang_name

The name of the procedural language the code is written in. If omitted, the default is `plpgsql`.

Notes

The procedural language to be used must already have been installed into the current database by means of `CREATE EXTENSION`. `plpgsql` is installed by default, but other languages are not.

The user must have `USAGE` privilege for the procedural language, or must be a superuser if the language is untrusted. This is the same privilege requirement as for creating a function in the language.

If `DO` is executed in a transaction block, then the procedure code cannot execute transaction control statements. Transaction control statements are only allowed if `DO` is executed in its own transaction.

Examples

Grant all privileges on all views in schema `public` to role `webuser`:

```
DO $$DECLARE r record;
BEGIN
    FOR r IN SELECT table_schema, table_name FROM information_schema.tables
              WHERE table_type = 'VIEW' AND table_schema = 'public'
    LOOP
        EXECUTE 'GRANT ALL ON ' || quote_ident(r.table_schema) || '.' ||
quote_ident(r.table_name) || ' TO webuser';
    END LOOP;
END$$;
```

Compatibility

There is no `DO` statement in the SQL standard.

See Also

[CREATE LANGUAGE](#)

DROP ACCESS METHOD

DROP ACCESS METHOD — remove an access method

Synopsis

```
DROP ACCESS METHOD [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP ACCESS METHOD removes an existing access method. Only superusers can drop access methods.

Parameters

IF EXISTS

Do not throw an error if the access method does not exist. A notice is issued in this case.

name

The name of an existing access method.

CASCADE

Automatically drop objects that depend on the access method (such as operator classes, operator families, and indexes), and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the access method if any objects depend on it. This is the default.

Examples

Drop the access method `heptree`:

```
DROP ACCESS METHOD heptree;
```

Compatibility

DROP ACCESS METHOD is a Postgres Pro extension.

See Also

[CREATE ACCESS METHOD](#)

DROP AGGREGATE

DROP AGGREGATE — remove an aggregate function

Synopsis

```
DROP AGGREGATE [ IF EXISTS ] name ( aggregate_signature ) [, ...] [ CASCADE |  
RESTRICT ]
```

where *aggregate_signature* is:

```
* |  
[ argmode ] [ argname ] argtype [ , ... ] |  
[ [ argmode ] [ argname ] argtype [ , ... ] ] ORDER BY [ argmode ] [ argname ] argtype  
[ , ... ]
```

Description

DROP AGGREGATE removes an existing aggregate function. To execute this command the current user must be the owner of the aggregate function.

Parameters

IF EXISTS

Do not throw an error if the aggregate does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing aggregate function.

argmode

The mode of an argument: IN or VARIADIC. If omitted, the default is IN.

argname

The name of an argument. Note that DROP AGGREGATE does not actually pay any attention to argument names, since only the argument data types are needed to determine the aggregate function's identity.

argtype

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write * in place of the list of argument specifications. To reference an ordered-set aggregate function, write ORDER BY between the direct and aggregated argument specifications.

CASCADE

Automatically drop objects that depend on the aggregate function (such as views using it), and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the aggregate function if any objects depend on it. This is the default.

Notes

Alternative syntaxes for referencing ordered-set aggregates are described under [ALTER AGGREGATE](#).

Examples

To remove the aggregate function `myavg` for type `integer`:

```
DROP AGGREGATE myavg(integer);
```

To remove the hypothetical-set aggregate function `myrank`, which takes an arbitrary list of ordering columns and a matching list of direct arguments:

```
DROP AGGREGATE myrank(VARIADIC "any" ORDER BY VARIADIC "any");
```

To remove multiple aggregate functions in one command:

```
DROP AGGREGATE myavg(integer), myavg(bigint);
```

Compatibility

There is no `DROP AGGREGATE` statement in the SQL standard.

See Also

[ALTER AGGREGATE](#), [CREATE AGGREGATE](#)

DROP CAST

DROP CAST — remove a cast

Synopsis

```
DROP CAST [ IF EXISTS ] (source_type AS target_type) [ CASCADE | RESTRICT ]
```

Description

DROP CAST removes a previously defined cast.

To be able to drop a cast, you must own the source or the target data type. These are the same privileges that are required to create a cast.

Parameters

IF EXISTS

Do not throw an error if the cast does not exist. A notice is issued in this case.

source_type

The name of the source data type of the cast.

target_type

The name of the target data type of the cast.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on casts.

Examples

To drop the cast from type `text` to type `int`:

```
DROP CAST (text AS int);
```

Compatibility

The DROP CAST command conforms to the SQL standard.

See Also

[CREATE CAST](#)

DROP COLLATION

DROP COLLATION — remove a collation

Synopsis

```
DROP COLLATION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP COLLATION removes a previously defined collation. To be able to drop a collation, you must own the collation.

Parameters

IF EXISTS

Do not throw an error if the collation does not exist. A notice is issued in this case.

name

The name of the collation. The collation name can be schema-qualified.

CASCADE

Automatically drop objects that depend on the collation, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the collation if any objects depend on it. This is the default.

Examples

To drop the collation named `german`:

```
DROP COLLATION german;
```

Compatibility

The DROP COLLATION command conforms to the SQL standard, apart from the IF EXISTS option, which is a Postgres Pro extension.

See Also

[ALTER COLLATION](#), [CREATE COLLATION](#)

DROP CONVERSION

DROP CONVERSION — remove a conversion

Synopsis

```
DROP CONVERSION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

`DROP CONVERSION` removes a previously defined conversion. To be able to drop a conversion, you must own the conversion.

Parameters

`IF EXISTS`

Do not throw an error if the conversion does not exist. A notice is issued in this case.

name

The name of the conversion. The conversion name can be schema-qualified.

`CASCADE`

`RESTRICT`

These key words do not have any effect, since there are no dependencies on conversions.

Examples

To drop the conversion named `myname`:

```
DROP CONVERSION myname;
```

Compatibility

There is no `DROP CONVERSION` statement in the SQL standard, but a `DROP TRANSLATION` statement that goes along with the `CREATE TRANSLATION` statement that is similar to the `CREATE CONVERSION` statement in Postgres Pro.

See Also

[ALTER CONVERSION](#), [CREATE CONVERSION](#)

DROP DATABASE

DROP DATABASE — remove a database

Synopsis

```
DROP DATABASE [ IF EXISTS ] name [ [ WITH ] ( option [, ...] ) ]
```

where *option* can be:

FORCE

Description

DROP DATABASE drops a database. It removes the catalog entries for the database and deletes the directory containing the data. It can only be executed by the database owner. It cannot be executed while you are connected to the target database. (Connect to `postgres` or any other database to issue this command.) Also, if anyone else is connected to the target database, this command will fail unless you use the `FORCE` option described below.

DROP DATABASE cannot be undone. Use it with care!

Parameters

IF EXISTS

Do not throw an error if the database does not exist. A notice is issued in this case.

name

The name of the database to remove.

FORCE

Attempt to terminate all existing connections to the target database. It doesn't terminate if prepared transactions, active logical replication slots or subscriptions are present in the target database.

This terminates background worker connections and connections that the current user has permission to terminate with `pg_terminate_backend`, described in [Section 9.28.2](#). If connections would remain, this command will fail.

Notes

DROP DATABASE cannot be executed inside a transaction block.

This command cannot be executed while connected to the target database. Thus, it might be more convenient to use the program [dropdb](#) instead, which is a wrapper around this command.

Compatibility

There is no DROP DATABASE statement in the SQL standard.

See Also

[CREATE DATABASE](#)

DROP DOMAIN

DROP DOMAIN — remove a domain

Synopsis

```
DROP DOMAIN [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP DOMAIN removes a domain. Only the owner of a domain can remove it.

Parameters

IF EXISTS

Do not throw an error if the domain does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing domain.

CASCADE

Automatically drop objects that depend on the domain (such as table columns), and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the domain if any objects depend on it. This is the default.

Examples

To remove the domain `box`:

```
DROP DOMAIN box;
```

Compatibility

This command conforms to the SQL standard, except for the IF EXISTS option, which is a Postgres Pro extension.

See Also

[CREATE DOMAIN](#), [ALTER DOMAIN](#)

DROP EVENT TRIGGER

DROP EVENT TRIGGER — remove an event trigger

Synopsis

```
DROP EVENT TRIGGER [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP EVENT TRIGGER removes an existing event trigger. To execute this command, the current user must be the owner of the event trigger.

Parameters

IF EXISTS

Do not throw an error if the event trigger does not exist. A notice is issued in this case.

name

The name of the event trigger to remove.

CASCADE

Automatically drop objects that depend on the trigger, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the trigger if any objects depend on it. This is the default.

Examples

Destroy the trigger `snitch`:

```
DROP EVENT TRIGGER snitch;
```

Compatibility

There is no DROP EVENT TRIGGER statement in the SQL standard.

See Also

[CREATE EVENT TRIGGER](#), [ALTER EVENT TRIGGER](#)

DROP EXTENSION

DROP EXTENSION — remove an extension

Synopsis

```
DROP EXTENSION [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP EXTENSION removes extensions from the database. Dropping an extension causes its member objects, and other explicitly dependent routines (see [ALTER ROUTINE](#), the `DEPENDS ON EXTENSION extension_name` action), to be dropped as well.

You must own the extension to use DROP EXTENSION.

Parameters

IF EXISTS

Do not throw an error if the extension does not exist. A notice is issued in this case.

name

The name of an installed extension.

CASCADE

Automatically drop objects that depend on the extension, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

This option prevents the specified extensions from being dropped if other objects, besides these extensions, their members, and their explicitly dependent routines, depend on them. This is the default.

Examples

To remove the extension `hstore` from the current database:

```
DROP EXTENSION hstore;
```

This command will fail if any of `hstore`'s objects are in use in the database, for example if any tables have columns of the `hstore` type. Add the `CASCADE` option to forcibly remove those dependent objects as well.

Compatibility

DROP EXTENSION is a Postgres Pro extension.

See Also

[CREATE EXTENSION](#), [ALTER EXTENSION](#)

DROP FUNCTION

DROP FUNCTION — remove a function

Synopsis

```
DROP FUNCTION [ IF EXISTS ] name [ ( [ argmode ] [ argname ] argtype [, ...] ) ]  
[ , ... ]  
[ CASCADE | RESTRICT ]
```

Description

DROP FUNCTION removes the definition of an existing function. To execute this command the user must be the owner of the function. The argument types to the function must be specified, since several different functions can exist with the same name and different argument lists.

Parameters

IF EXISTS

Do not throw an error if the function does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing function. If no argument list is specified, the name must be unique in its schema.

argmode

The mode of an argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that DROP FUNCTION does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

argname

The name of an argument. Note that DROP FUNCTION does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype

The data type(s) of the function's arguments (optionally schema-qualified), if any.

CASCADE

Automatically drop objects that depend on the function (such as operators or triggers), and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the function if any objects depend on it. This is the default.

Examples

This command removes the square root function:

```
DROP FUNCTION sqrt(integer);
```

Drop multiple functions in one command:

```
DROP FUNCTION sqrt(integer), sqrt(bigint);
```

If the function name is unique in its schema, it can be referred to without an argument list:

```
DROP FUNCTION update_employee_salaries;
```

Note that this is different from

```
DROP FUNCTION update_employee_salaries();
```

which refers to a function with zero arguments, whereas the first variant can refer to a function with any number of arguments, including zero, as long as the name is unique.

Compatibility

This command conforms to the SQL standard, with these Postgres Pro extensions:

- The standard only allows one function to be dropped per command.
- The `IF EXISTS` option
- The ability to specify argument modes and names

See Also

[CREATE FUNCTION](#), [ALTER FUNCTION](#), [DROP PROCEDURE](#), [DROP ROUTINE](#)

DROP GROUP

DROP GROUP — remove a database role

Synopsis

```
DROP GROUP [ IF EXISTS ] name [, ...]
```

Description

DROP GROUP is now an alias for [DROP ROLE](#).

Compatibility

There is no DROP GROUP statement in the SQL standard.

See Also

[DROP ROLE](#)

DROP INDEX

DROP INDEX — remove an index

Synopsis

```
DROP INDEX [ CONCURRENTLY ] [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP INDEX drops an existing index from the database system. To execute this command you must be the owner of the index.

Parameters

CONCURRENTLY

Drop the index without locking out concurrent selects, inserts, updates, and deletes on the index's table. A normal DROP INDEX acquires an ACCESS EXCLUSIVE lock on the table, blocking other accesses until the index drop can be completed. With this option, the command instead waits until conflicting transactions have completed.

There are several caveats to be aware of when using this option. Only one index name can be specified, and the CASCADE option is not supported. (Thus, an index that supports a UNIQUE or PRIMARY KEY constraint cannot be dropped this way.) Also, regular DROP INDEX commands can be performed within a transaction block, but DROP INDEX CONCURRENTLY cannot. Lastly, indexes on partitioned tables cannot be dropped using this option.

For temporary tables, DROP INDEX is always non-concurrent, as no other session can access them, and non-concurrent index drop is cheaper.

IF EXISTS

Do not throw an error if the index does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an index to remove.

CASCADE

Automatically drop objects that depend on the index, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the index if any objects depend on it. This is the default.

Examples

This command will remove the index `title_idx`:

```
DROP INDEX title_idx;
```

Compatibility

DROP INDEX is a Postgres Pro language extension. There are no provisions for indexes in the SQL standard.

See Also

[CREATE INDEX](#)

DROP LANGUAGE

DROP LANGUAGE — remove a procedural language

Synopsis

```
DROP [ PROCEDURAL ] LANGUAGE [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP LANGUAGE removes the definition of a previously registered procedural language. You must be a superuser or the owner of the language to use DROP LANGUAGE.

Note

As of PostgreSQL 9.1, most procedural languages have been made into “extensions”, and should therefore be removed with [DROP EXTENSION](#) not DROP LANGUAGE.

Parameters

IF EXISTS

Do not throw an error if the language does not exist. A notice is issued in this case.

name

The name of an existing procedural language.

CASCADE

Automatically drop objects that depend on the language (such as functions in the language), and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the language if any objects depend on it. This is the default.

Examples

This command removes the procedural language `plsample`:

```
DROP LANGUAGE plsample;
```

Compatibility

There is no DROP LANGUAGE statement in the SQL standard.

See Also

[ALTER LANGUAGE](#), [CREATE LANGUAGE](#)

DROP MATERIALIZED VIEW

DROP MATERIALIZED VIEW — remove a materialized view

Synopsis

```
DROP MATERIALIZED VIEW [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP MATERIALIZED VIEW drops an existing materialized view. To execute this command you must be the owner of the materialized view.

Parameters

IF EXISTS

Do not throw an error if the materialized view does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of the materialized view to remove.

CASCADE

Automatically drop objects that depend on the materialized view (such as other materialized views, or regular views), and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the materialized view if any objects depend on it. This is the default.

Examples

This command will remove the materialized view called `order_summary`:

```
DROP MATERIALIZED VIEW order_summary;
```

Compatibility

DROP MATERIALIZED VIEW is a Postgres Pro extension.

See Also

[CREATE MATERIALIZED VIEW](#), [ALTER MATERIALIZED VIEW](#), [REFRESH MATERIALIZED VIEW](#)

DROP OPERATOR

DROP OPERATOR — remove an operator

Synopsis

```
DROP OPERATOR [ IF EXISTS ] name ( { left_type | NONE } , right_type ) [, ...]  
[ CASCADE | RESTRICT ]
```

Description

DROP OPERATOR drops an existing operator from the database system. To execute this command you must be the owner of the operator.

Parameters

IF EXISTS

Do not throw an error if the operator does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing operator.

left_type

The data type of the operator's left operand; write NONE if the operator has no left operand.

right_type

The data type of the operator's right operand.

CASCADE

Automatically drop objects that depend on the operator (such as views using it), and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the operator if any objects depend on it. This is the default.

Examples

Remove the power operator a^b for type integer:

```
DROP OPERATOR ^ (integer, integer);
```

Remove the bitwise-complement prefix operator $\sim b$ for type bit:

```
DROP OPERATOR ~ (none, bit);
```

Remove multiple operators in one command:

```
DROP OPERATOR ~ (none, bit), ^ (integer, integer);
```

Compatibility

There is no DROP OPERATOR statement in the SQL standard.

See Also

[CREATE OPERATOR](#), [ALTER OPERATOR](#)

DROP OPERATOR CLASS

DROP OPERATOR CLASS — remove an operator class

Synopsis

```
DROP OPERATOR CLASS [ IF EXISTS ] name USING index_method [ CASCADE | RESTRICT ]
```

Description

DROP OPERATOR CLASS drops an existing operator class. To execute this command you must be the owner of the operator class.

DROP OPERATOR CLASS does not drop any of the operators or functions referenced by the class. If there are any indexes depending on the operator class, you will need to specify CASCADE for the drop to complete.

Parameters

IF EXISTS

Do not throw an error if the operator class does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing operator class.

index_method

The name of the index access method the operator class is for.

CASCADE

Automatically drop objects that depend on the operator class (such as indexes), and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the operator class if any objects depend on it. This is the default.

Notes

DROP OPERATOR CLASS will not drop the operator family containing the class, even if there is nothing else left in the family (in particular, in the case where the family was implicitly created by CREATE OPERATOR CLASS). An empty operator family is harmless, but for the sake of tidiness you might wish to remove the family with DROP OPERATOR FAMILY; or perhaps better, use DROP OPERATOR FAMILY in the first place.

Examples

Remove the B-tree operator class `widget_ops`:

```
DROP OPERATOR CLASS widget_ops USING btree;
```

This command will not succeed if there are any existing indexes that use the operator class. Add CASCADE to drop such indexes along with the operator class.

Compatibility

There is no DROP OPERATOR CLASS statement in the SQL standard.

See Also

[ALTER OPERATOR CLASS](#), [CREATE OPERATOR CLASS](#), [DROP OPERATOR FAMILY](#)

DROP OPERATOR FAMILY

DROP OPERATOR FAMILY — remove an operator family

Synopsis

```
DROP OPERATOR FAMILY [ IF EXISTS ] name USING index_method [ CASCADE | RESTRICT ]
```

Description

DROP OPERATOR FAMILY drops an existing operator family. To execute this command you must be the owner of the operator family.

DROP OPERATOR FAMILY includes dropping any operator classes contained in the family, but it does not drop any of the operators or functions referenced by the family. If there are any indexes depending on operator classes within the family, you will need to specify CASCADE for the drop to complete.

Parameters

IF EXISTS

Do not throw an error if the operator family does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing operator family.

index_method

The name of the index access method the operator family is for.

CASCADE

Automatically drop objects that depend on the operator family, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the operator family if any objects depend on it. This is the default.

Examples

Remove the B-tree operator family `float_ops`:

```
DROP OPERATOR FAMILY float_ops USING btree;
```

This command will not succeed if there are any existing indexes that use operator classes within the family. Add CASCADE to drop such indexes along with the operator family.

Compatibility

There is no DROP OPERATOR FAMILY statement in the SQL standard.

See Also

[ALTER OPERATOR FAMILY](#), [CREATE OPERATOR FAMILY](#), [ALTER OPERATOR CLASS](#), [CREATE OPERATOR CLASS](#), [DROP OPERATOR CLASS](#)

DROP OWNED

DROP OWNED — remove database objects owned by a database role

Synopsis

```
DROP OWNED BY { name | CURRENT_ROLE | CURRENT_USER | SESSION_USER } [, ...] [ CASCADE |  
RESTRICT ]
```

Description

DROP OWNED drops all the objects within the current database that are owned by one of the specified roles. Any privileges granted to the given roles on objects in the current database or on shared objects (databases, tablespaces, configuration parameters) will also be revoked.

Parameters

name

The name of a role whose objects will be dropped, and whose privileges will be revoked.

CASCADE

Automatically drop objects that depend on the affected objects, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the objects owned by a role if any other database objects depend on one of the affected objects. This is the default.

Notes

DROP OWNED is often used to prepare for the removal of one or more roles. Because DROP OWNED only affects the objects in the current database, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

Using the CASCADE option might make the command recurse to objects owned by other users.

The REASSIGN OWNED command is an alternative that reassigns the ownership of all the database objects owned by one or more roles. However, REASSIGN OWNED does not deal with privileges for other objects.

Databases and tablespaces owned by the role(s) will not be removed.

See [Section 21.4](#) for more discussion.

Compatibility

The DROP OWNED command is a Postgres Pro extension.

See Also

[REASSIGN OWNED](#), [DROP ROLE](#)

DROP PACKAGE

DROP PACKAGE — remove a package

Synopsis

```
DROP PACKAGE [ IF EXISTS ] package_name [, ...] [ CASCADE ]
```

Description

DROP PACKAGE removes packages from the database.

A package can only be dropped by its owner or a superuser. Note that the owner can drop the package (and thereby all contained objects) even if they do not own some of the objects within the package.

Parameters

IF EXISTS

Do not throw an error if the package does not exist. A notice is issued in this case.

package_name

The name of a package.

CASCADE

Automatically drop objects (tables, functions, etc.) that are contained in the package, and in turn all objects that depend on those objects (see [Section 5.15](#)).

Notes

Using the CASCADE option might make the command find objects to be removed in other packages besides the one(s) named. In this case, other packages are dropped as well.

Examples

To remove package `counter` from the database, along with everything it contains and all the dependent objects:

```
DROP PACKAGE counter CASCADE;
```

See Also

[CREATE PACKAGE](#)

DROP POLICY

DROP POLICY — remove a row-level security policy from a table

Synopsis

```
DROP POLICY [ IF EXISTS ] name ON table_name [ CASCADE | RESTRICT ]
```

Description

DROP POLICY removes the specified policy from the table. Note that if the last policy is removed for a table and the table still has row-level security enabled via ALTER TABLE, then the default-deny policy will be used. ALTER TABLE ... DISABLE ROW LEVEL SECURITY can be used to disable row-level security for a table, whether policies for the table exist or not.

Parameters

IF EXISTS

Do not throw an error if the policy does not exist. A notice is issued in this case.

name

The name of the policy to drop.

table_name

The name (optionally schema-qualified) of the table that the policy is on.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on policies.

Examples

To drop the policy called p1 on the table named my_table:

```
DROP POLICY p1 ON my_table;
```

Compatibility

DROP POLICY is a Postgres Pro extension.

See Also

[CREATE POLICY](#), [ALTER POLICY](#)

DROP PROCEDURE

DROP PROCEDURE — remove a procedure

Synopsis

```
DROP PROCEDURE [ IF EXISTS ] name [ ( [ argmode ] [ argname ] argtype [, ...] ) ]  
[ , ... ]  
[ CASCADE | RESTRICT ]
```

Description

`DROP PROCEDURE` removes the definition of one or more existing procedures. To execute this command the user must be the owner of the procedure(s). The argument types to the procedure(s) usually must be specified, since several different procedures can exist with the same name and different argument lists.

Parameters

`IF EXISTS`

Do not throw an error if the procedure does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing procedure.

argmode

The mode of an argument: `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN` (but see below).

argname

The name of an argument. Note that `DROP PROCEDURE` does not actually pay any attention to argument names, since only the argument data types are used to determine the procedure's identity.

argtype

The data type(s) of the procedure's arguments (optionally schema-qualified), if any. See below for details.

`CASCADE`

Automatically drop objects that depend on the procedure, and in turn all objects that depend on those objects (see [Section 5.15](#)).

`RESTRICT`

Refuse to drop the procedure if any objects depend on it. This is the default.

Notes

If there is only one procedure of the given name, the argument list can be omitted. Omit the parentheses too in this case.

In Postgres Pro, it's sufficient to list the input (including `INOUT`) arguments, because no two routines of the same name are allowed to share the same input-argument list. Moreover, the `DROP` command will not actually check that you wrote the types of `OUT` arguments correctly; so any arguments that are explicitly marked `OUT` are just noise. But writing them is recommendable for consistency with the corresponding `CREATE` command.

For compatibility with the SQL standard, it is also allowed to write all the argument data types (including those of `OUT` arguments) without any *argmode* markers. When this is done, the types of the procedure's

OUT argument(s) *will* be verified against the command. This provision creates an ambiguity, in that when the argument list contains no *argmode* markers, it's unclear which rule is intended. The `DROP` command will attempt the lookup both ways, and will throw an error if two different procedures are found. To avoid the risk of such ambiguity, it's recommendable to write `IN` markers explicitly rather than letting them be defaulted, thus forcing the traditional Postgres Pro interpretation to be used.

The lookup rules just explained are also used by other commands that act on existing procedures, such as `ALTER PROCEDURE` and `COMMENT ON PROCEDURE`.

Examples

If there is only one procedure `do_db_maintenance`, this command is sufficient to drop it:

```
DROP PROCEDURE do_db_maintenance;
```

Given this procedure definition:

```
CREATE PROCEDURE do_db_maintenance(IN target_schema text, OUT results text) ...
```

any one of these commands would work to drop it:

```
DROP PROCEDURE do_db_maintenance(IN target_schema text, OUT results text);
DROP PROCEDURE do_db_maintenance(IN text, OUT text);
DROP PROCEDURE do_db_maintenance(IN text);
DROP PROCEDURE do_db_maintenance(text);
DROP PROCEDURE do_db_maintenance(text, text); -- potentially ambiguous
```

However, the last example would be ambiguous if there is also, say,

```
CREATE PROCEDURE do_db_maintenance(IN target_schema text, IN options text) ...
```

Compatibility

This command conforms to the SQL standard, with these Postgres Pro extensions:

- The standard only allows one procedure to be dropped per command.
- The `IF EXISTS` option is an extension.
- The ability to specify argument modes and names is an extension, and the lookup rules differ when modes are given.

See Also

[CREATE PROCEDURE](#), [ALTER PROCEDURE](#), [DROP FUNCTION](#), [DROP ROUTINE](#)

DROP PROFILE

DROP PROFILE — remove an authentication profile

Synopsis

```
DROP PROFILE [ IF EXISTS ] name
```

Description

The `DROP PROFILE` command removes the specified profile. You must be a database superuser or have the privileges of the `pg_manage_profiles` role to use this command.

A profile cannot be removed if it is still referenced in any database of the cluster; if this is the case, an error is raised. Before dropping the profile, you must drop all the roles to which it is assigned, or assign another profile to them. Use the [ALTER ROLE](#) command if you need to reassign the profile.

Parameters

`IF EXISTS`

Do not throw an error if the profile does not exist. A notice is issued in this case.

name

The name of the profile to remove.

Examples

Drop the specified profile:

```
DROP PROFILE admin_profile;
```

See Also

[CREATE PROFILE](#), [ALTER PROFILE](#), [ALTER ROLE](#)

DROP PUBLICATION

DROP PUBLICATION — remove a publication

Synopsis

```
DROP PUBLICATION [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP PUBLICATION removes an existing publication from the database.

A publication can only be dropped by its owner or a superuser.

Parameters

IF EXISTS

Do not throw an error if the publication does not exist. A notice is issued in this case.

name

The name of an existing publication.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on publications.

Examples

Drop a publication:

```
DROP PUBLICATION mypublication;
```

Compatibility

DROP PUBLICATION is a Postgres Pro extension.

See Also

[CREATE PUBLICATION](#), [ALTER PUBLICATION](#)

DROP ROLE

DROP ROLE — remove a database role

Synopsis

```
DROP ROLE [ IF EXISTS ] name [, ...]
```

Description

`DROP ROLE` removes the specified role(s). To drop a superuser role, you must be a superuser yourself; to drop non-superuser roles, you must have `CREATEROLE` privilege and have been granted `ADMIN OPTION` on the role.

A role cannot be removed if it is still referenced in any database of the cluster; an error will be raised if so. Before dropping the role, you must drop all the objects it owns (or reassign their ownership) and revoke any privileges the role has been granted on other objects. The [REASSIGN OWNED](#) and [DROP OWNED](#) commands can be useful for this purpose; see [Section 21.4](#) for more discussion.

However, it is not necessary to remove role memberships involving the role; `DROP ROLE` automatically revokes any memberships of the target role in other roles, and of other roles in the target role. The other roles are not dropped nor otherwise affected.

Parameters

`IF EXISTS`

Do not throw an error if the role does not exist. A notice is issued in this case.

name

The name of the role to remove.

Notes

Postgres Pro includes a program [dropuser](#) that has the same functionality as this command (in fact, it calls this command) but can be run from the command shell.

Examples

To drop a role:

```
DROP ROLE jonathan;
```

Compatibility

The SQL standard defines `DROP ROLE`, but it allows only one role to be dropped at a time, and it specifies different privilege requirements than Postgres Pro uses.

See Also

[CREATE ROLE](#), [ALTER ROLE](#), [SET ROLE](#)

DROP ROUTINE

DROP ROUTINE — remove a routine

Synopsis

```
DROP ROUTINE [ IF EXISTS ] name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
[ , ... ]  
[ CASCADE | RESTRICT ]
```

Description

DROP ROUTINE removes the definition of one or more existing routines. The term “routine” includes aggregate functions, normal functions, and procedures. See under [DROP AGGREGATE](#), [DROP FUNCTION](#), and [DROP PROCEDURE](#) for the description of the parameters, more examples, and further details.

Notes

The lookup rules used by DROP ROUTINE are fundamentally the same as for DROP PROCEDURE; in particular, DROP ROUTINE shares that command's behavior of considering an argument list that has no *argmode* markers to be possibly using the SQL standard's definition that OUT arguments are included in the list. (DROP AGGREGATE and DROP FUNCTION do not do that.)

In some cases where the same name is shared by routines of different kinds, it is possible for DROP ROUTINE to fail with an ambiguity error when a more specific command (DROP FUNCTION, etc.) would work. Specifying the argument type list more carefully will also resolve such problems.

These lookup rules are also used by other commands that act on existing routines, such as ALTER ROUTINE and COMMENT ON ROUTINE.

Examples

To drop the routine `foo` for type `integer`:

```
DROP ROUTINE foo(integer);
```

This command will work independent of whether `foo` is an aggregate, function, or procedure.

Compatibility

This command conforms to the SQL standard, with these Postgres Pro extensions:

- The standard only allows one routine to be dropped per command.
- The `IF EXISTS` option is an extension.
- The ability to specify argument modes and names is an extension, and the lookup rules differ when modes are given.
- User-definable aggregate functions are an extension.

See Also

[DROP AGGREGATE](#), [DROP FUNCTION](#), [DROP PROCEDURE](#), [ALTER ROUTINE](#)

Note that there is no `CREATE ROUTINE` command.

DROP RULE

DROP RULE — remove a rewrite rule

Synopsis

```
DROP RULE [ IF EXISTS ] name ON table_name [ CASCADE | RESTRICT ]
```

Description

DROP RULE drops a rewrite rule.

Parameters

IF EXISTS

Do not throw an error if the rule does not exist. A notice is issued in this case.

name

The name of the rule to drop.

table_name

The name (optionally schema-qualified) of the table or view that the rule applies to.

CASCADE

Automatically drop objects that depend on the rule, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the rule if any objects depend on it. This is the default.

Examples

To drop the rewrite rule `newrule`:

```
DROP RULE newrule ON mytable;
```

Compatibility

DROP RULE is a Postgres Pro language extension, as is the entire query rewrite system.

See Also

[CREATE RULE](#), [ALTER RULE](#)

DROP SCHEMA

DROP SCHEMA — remove a schema

Synopsis

```
DROP SCHEMA [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP SCHEMA removes schemas from the database.

A schema can only be dropped by its owner or a superuser. Note that the owner can drop the schema (and thereby all contained objects) even if they do not own some of the objects within the schema.

Parameters

IF EXISTS

Do not throw an error if the schema does not exist. A notice is issued in this case.

name

The name of a schema.

CASCADE

Automatically drop objects (tables, functions, etc.) that are contained in the schema, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the schema if it contains any objects. This is the default.

Notes

Using the CASCADE option might make the command remove objects in other schemas besides the one(s) named.

Examples

To remove schema `mystuff` from the database, along with everything it contains:

```
DROP SCHEMA mystuff CASCADE;
```

Compatibility

DROP SCHEMA is fully conforming with the SQL standard, except that the standard only allows one schema to be dropped per command, and apart from the IF EXISTS option, which is a Postgres Pro extension.

See Also

[ALTER SCHEMA](#), [CREATE SCHEMA](#)

DROP SEQUENCE

DROP SEQUENCE — remove a sequence

Synopsis

```
DROP SEQUENCE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

`DROP SEQUENCE` removes sequence number generators. A sequence can only be dropped by its owner or a superuser.

Parameters

`IF EXISTS`

Do not throw an error if the sequence does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of a sequence.

`CASCADE`

Automatically drop objects that depend on the sequence, and in turn all objects that depend on those objects (see [Section 5.15](#)).

`RESTRICT`

Refuse to drop the sequence if any objects depend on it. This is the default.

Examples

To remove the sequence `serial`:

```
DROP SEQUENCE serial;
```

Compatibility

`DROP SEQUENCE` conforms to the SQL standard, except that the standard only allows one sequence to be dropped per command, and apart from the `IF EXISTS` option, which is a Postgres Pro extension.

See Also

[CREATE SEQUENCE](#), [ALTER SEQUENCE](#)

DROP SERVER

DROP SERVER — remove a foreign server descriptor

Synopsis

```
DROP SERVER [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP SERVER removes an existing foreign server descriptor. To execute this command, the current user must be the owner of the server.

Parameters

IF EXISTS

Do not throw an error if the server does not exist. A notice is issued in this case.

name

The name of an existing server.

CASCADE

Automatically drop objects that depend on the server (such as user mappings), and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the server if any objects depend on it. This is the default.

Examples

Drop a server `foo` if it exists:

```
DROP SERVER IF EXISTS foo;
```

Compatibility

DROP SERVER conforms to ISO/IEC 9075-9 (SQL/MED). The IF EXISTS clause is a Postgres Pro extension.

See Also

[CREATE SERVER](#), [ALTER SERVER](#)

DROP STATISTICS

DROP STATISTICS — remove extended statistics

Synopsis

```
DROP STATISTICS [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

`DROP STATISTICS` removes statistics object(s) from the database. Only the statistics object's owner, the schema owner, or a superuser can drop a statistics object.

Parameters

`IF EXISTS`

Do not throw an error if the statistics object does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of the statistics object to drop.

`CASCADE`

`RESTRICT`

These key words do not have any effect, since there are no dependencies on statistics.

Examples

To destroy two statistics objects in different schemas, without failing if they don't exist:

```
DROP STATISTICS IF EXISTS
    accounting.users_uid_creation,
    public.grants_user_role;
```

Compatibility

There is no `DROP STATISTICS` command in the SQL standard.

See Also

[ALTER STATISTICS](#), [CREATE STATISTICS](#)

DROP SUBSCRIPTION

DROP SUBSCRIPTION — remove a subscription

Synopsis

```
DROP SUBSCRIPTION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP SUBSCRIPTION removes a subscription from the database cluster.

To execute this command the user must be the owner of the subscription.

DROP SUBSCRIPTION cannot be executed inside a transaction block if the subscription is associated with a replication slot. (You can use [ALTER SUBSCRIPTION](#) to unset the slot.)

Parameters

name

The name of a subscription to be dropped.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on subscriptions.

Notes

When dropping a subscription that is associated with a replication slot on the remote host (the normal state), DROP SUBSCRIPTION will connect to the remote host and try to drop the replication slot (and any remaining table synchronization slots) as part of its operation. This is necessary so that the resources allocated for the subscription on the remote host are released. If this fails, either because the remote host is not reachable or because the remote replication slot cannot be dropped or does not exist or never existed, the DROP SUBSCRIPTION command will fail. To proceed in this situation, first disable the subscription by executing [ALTER SUBSCRIPTION ... DISABLE](#), and then disassociate it from the replication slot by executing [ALTER SUBSCRIPTION ... SET \(slot_name = NONE\)](#). After that, DROP SUBSCRIPTION will no longer attempt any actions on a remote host. Note that if the remote replication slot still exists, it (and any related table synchronization slots) should then be dropped manually; otherwise it/they will continue to reserve WAL and might eventually cause the disk to fill up. See also [Section 29.2.1](#).

If a subscription is associated with a replication slot, then DROP SUBSCRIPTION cannot be executed inside a transaction block.

Examples

Drop a subscription:

```
DROP SUBSCRIPTION mysub;
```

Compatibility

DROP SUBSCRIPTION is a Postgres Pro extension.

See Also

[CREATE SUBSCRIPTION](#), [ALTER SUBSCRIPTION](#)

DROP TABLE

DROP TABLE — remove a table

Synopsis

```
DROP TABLE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP TABLE removes tables from the database. Only the table owner, the schema owner, and superuser can drop a table. To empty a table of rows without destroying the table, use [DELETE](#) or [TRUNCATE](#).

DROP TABLE always removes any indexes, rules, triggers, and constraints that exist for the target table. However, to drop a table that is referenced by a view or a foreign-key constraint of another table, CASCADE must be specified. (CASCADE will remove a dependent view entirely, but in the foreign-key case it will only remove the foreign-key constraint, not the other table entirely.)

Parameters

IF EXISTS

Do not throw an error if the table does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of the table to drop.

CASCADE

Automatically drop objects that depend on the table (such as views), and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the table if any objects depend on it. This is the default.

Examples

To destroy two tables, `films` and `distributors`:

```
DROP TABLE films, distributors;
```

Compatibility

This command conforms to the SQL standard, except that the standard only allows one table to be dropped per command, and apart from the IF EXISTS option, which is a Postgres Pro extension.

See Also

[ALTER TABLE](#), [CREATE TABLE](#)

DROP TABLESPACE

DROP TABLESPACE — remove a tablespace

Synopsis

```
DROP TABLESPACE [ IF EXISTS ] name
```

Description

DROP TABLESPACE removes a tablespace from the system.

A tablespace can only be dropped by its owner or a superuser. The tablespace must be empty of all database objects before it can be dropped. It is possible that objects in other databases might still reside in the tablespace even if no objects in the current database are using the tablespace. Also, if the tablespace is listed in the [temp_tablespaces](#) setting of any active session, the DROP might fail due to temporary files residing in the tablespace.

Parameters

IF EXISTS

Do not throw an error if the tablespace does not exist. A notice is issued in this case.

name

The name of a tablespace.

Notes

DROP TABLESPACE cannot be executed inside a transaction block.

Examples

To remove tablespace `mystuff` from the system:

```
DROP TABLESPACE mystuff;
```

Compatibility

DROP TABLESPACE is a Postgres Pro extension.

See Also

[CREATE TABLESPACE](#), [ALTER TABLESPACE](#)

DROP TEXT SEARCH CONFIGURATION

DROP TEXT SEARCH CONFIGURATION — remove a text search configuration

Synopsis

```
DROP TEXT SEARCH CONFIGURATION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP TEXT SEARCH CONFIGURATION **drops** an existing text search configuration. To execute this command you must be the owner of the configuration.

Parameters

IF EXISTS

Do not throw an error if the text search configuration does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing text search configuration.

CASCADE

Automatically drop objects that depend on the text search configuration, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the text search configuration if any objects depend on it. This is the default.

Examples

Remove the text search configuration `my_english`:

```
DROP TEXT SEARCH CONFIGURATION my_english;
```

This command will not succeed if there are any existing indexes that reference the configuration in `to_tsvector` calls. Add `CASCADE` to drop such indexes along with the text search configuration.

Compatibility

There is no DROP TEXT SEARCH CONFIGURATION statement in the SQL standard.

See Also

[ALTER TEXT SEARCH CONFIGURATION](#), [CREATE TEXT SEARCH CONFIGURATION](#)

DROP TEXT SEARCH DICTIONARY

DROP TEXT SEARCH DICTIONARY — remove a text search dictionary

Synopsis

```
DROP TEXT SEARCH DICTIONARY [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP TEXT SEARCH DICTIONARY drops an existing text search dictionary. To execute this command you must be the owner of the dictionary.

Parameters

IF EXISTS

Do not throw an error if the text search dictionary does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing text search dictionary.

CASCADE

Automatically drop objects that depend on the text search dictionary, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the text search dictionary if any objects depend on it. This is the default.

Examples

Remove the text search dictionary `english`:

```
DROP TEXT SEARCH DICTIONARY english;
```

This command will not succeed if there are any existing text search configurations that use the dictionary. Add `CASCADE` to drop such configurations along with the dictionary.

Compatibility

There is no DROP TEXT SEARCH DICTIONARY statement in the SQL standard.

See Also

[ALTER TEXT SEARCH DICTIONARY](#), [CREATE TEXT SEARCH DICTIONARY](#)

DROP TEXT SEARCH PARSER

DROP TEXT SEARCH PARSER — remove a text search parser

Synopsis

```
DROP TEXT SEARCH PARSER [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP TEXT SEARCH PARSER drops an existing text search parser. You must be a superuser to use this command.

Parameters

IF EXISTS

Do not throw an error if the text search parser does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing text search parser.

CASCADE

Automatically drop objects that depend on the text search parser, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the text search parser if any objects depend on it. This is the default.

Examples

Remove the text search parser `my_parser`:

```
DROP TEXT SEARCH PARSER my_parser;
```

This command will not succeed if there are any existing text search configurations that use the parser. Add `CASCADE` to drop such configurations along with the parser.

Compatibility

There is no DROP TEXT SEARCH PARSER statement in the SQL standard.

See Also

[ALTER TEXT SEARCH PARSER](#), [CREATE TEXT SEARCH PARSER](#)

DROP TEXT SEARCH TEMPLATE

DROP TEXT SEARCH TEMPLATE — remove a text search template

Synopsis

```
DROP TEXT SEARCH TEMPLATE [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP TEXT SEARCH TEMPLATE drops an existing text search template. You must be a superuser to use this command.

Parameters

IF EXISTS

Do not throw an error if the text search template does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing text search template.

CASCADE

Automatically drop objects that depend on the text search template, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the text search template if any objects depend on it. This is the default.

Examples

Remove the text search template `thesaurus`:

```
DROP TEXT SEARCH TEMPLATE thesaurus;
```

This command will not succeed if there are any existing text search dictionaries that use the template. Add `CASCADE` to drop such dictionaries along with the template.

Compatibility

There is no DROP TEXT SEARCH TEMPLATE statement in the SQL standard.

See Also

[ALTER TEXT SEARCH TEMPLATE](#), [CREATE TEXT SEARCH TEMPLATE](#)

DROP TRANSFORM

DROP TRANSFORM — remove a transform

Synopsis

```
DROP TRANSFORM [ IF EXISTS ] FOR type_name LANGUAGE lang_name [ CASCADE | RESTRICT ]
```

Description

DROP TRANSFORM removes a previously defined transform.

To be able to drop a transform, you must own the type and the language. These are the same privileges that are required to create a transform.

Parameters

IF EXISTS

Do not throw an error if the transform does not exist. A notice is issued in this case.

type_name

The name of the data type of the transform.

lang_name

The name of the language of the transform.

CASCADE

Automatically drop objects that depend on the transform, and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the transform if any objects depend on it. This is the default.

Examples

To drop the transform for type `hstore` and language `plpython3u`:

```
DROP TRANSFORM FOR hstore LANGUAGE plpython3u;
```

Compatibility

This form of DROP TRANSFORM is a Postgres Pro extension. See [CREATE TRANSFORM](#) for details.

See Also

[CREATE TRANSFORM](#)

DROP TRIGGER

DROP TRIGGER — remove a trigger

Synopsis

```
DROP TRIGGER [ IF EXISTS ] name ON table_name [ CASCADE | RESTRICT ]
```

Description

`DROP TRIGGER` removes an existing trigger definition. To execute this command, the current user must be the owner of the table for which the trigger is defined.

Parameters

`IF EXISTS`

Do not throw an error if the trigger does not exist. A notice is issued in this case.

name

The name of the trigger to remove.

table_name

The name (optionally schema-qualified) of the table for which the trigger is defined.

`CASCADE`

Automatically drop objects that depend on the trigger, and in turn all objects that depend on those objects (see [Section 5.15](#)).

`RESTRICT`

Refuse to drop the trigger if any objects depend on it. This is the default.

Examples

Destroy the trigger `if_dist_exists` on the table `films`:

```
DROP TRIGGER if_dist_exists ON films;
```

Compatibility

The `DROP TRIGGER` statement in Postgres Pro is incompatible with the SQL standard. In the SQL standard, trigger names are not local to tables, so the command is simply `DROP TRIGGER name`.

See Also

[CREATE TRIGGER](#)

DROP TYPE

DROP TYPE — remove a data type

Synopsis

```
DROP TYPE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP TYPE removes a user-defined data type. Only the owner of a type can remove it.

Parameters

IF EXISTS

Do not throw an error if the type does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of the data type to remove.

CASCADE

Automatically drop objects that depend on the type (such as table columns, functions, and operators), and in turn all objects that depend on those objects (see [Section 5.15](#)).

RESTRICT

Refuse to drop the type if any objects depend on it. This is the default.

Examples

To remove the data type `box`:

```
DROP TYPE box;
```

Compatibility

This command is similar to the corresponding command in the SQL standard, apart from the `IF EXISTS` option, which is a Postgres Pro extension. But note that much of the `CREATE TYPE` command and the data type extension mechanisms in Postgres Pro differ from the SQL standard.

See Also

[ALTER TYPE](#), [CREATE TYPE](#)

DROP USER

DROP USER — remove a database role

Synopsis

```
DROP USER [ IF EXISTS ] name [, ...]
```

Description

DROP USER is simply an alternate spelling of [DROP ROLE](#).

Compatibility

The DROP USER statement is a Postgres Pro extension. The SQL standard leaves the definition of users to the implementation.

See Also

[DROP ROLE](#)

DROP VIEW

DROP VIEW — remove a view

Synopsis

```
DROP VIEW [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

`DROP VIEW` drops an existing view. To execute this command you must be the owner of the view.

Parameters

`IF EXISTS`

Do not throw an error if the view does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of the view to remove.

`CASCADE`

Automatically drop objects that depend on the view (such as other views), and in turn all objects that depend on those objects (see [Section 5.15](#)).

`RESTRICT`

Refuse to drop the view if any objects depend on it. This is the default.

Examples

This command will remove the view called `kinds`:

```
DROP VIEW kinds;
```

Compatibility

This command conforms to the SQL standard, except that the standard only allows one view to be dropped per command, and apart from the `IF EXISTS` option, which is a Postgres Pro extension.

See Also

[ALTER VIEW](#), [CREATE VIEW](#)

END

END — commit the current transaction

Synopsis

```
END [ AUTONOMOUS ] [ WORK | TRANSACTION ] [ AND [ NO ] CHAIN ]
```

Description

END commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs. This command is a Postgres Pro extension that is equivalent to [COMMIT](#).

Parameters

AUTONOMOUS

Optional key word that can be used when committing an autonomous transaction. For details on autonomous transactions, see [Chapter 16](#).

WORK

TRANSACTION

AUTONOMOUS

Optional key words. They have no effect.

AND CHAIN

If AND CHAIN is specified, a new transaction is immediately started with the same transaction characteristics (see [SET TRANSACTION](#)) as the just finished one. Otherwise, no new transaction is started.

Notes

Use [ROLLBACK](#) to abort a transaction.

Issuing END when not inside a transaction does no harm, but it will provoke a warning message.

Examples

To commit the current transaction and make all changes permanent:

```
END;
```

Compatibility

END is a Postgres Pro extension that provides functionality equivalent to [COMMIT](#), which is specified in the SQL standard.

See Also

[BEGIN](#), [COMMIT](#), [ROLLBACK](#)

EXECUTE

EXECUTE — execute a prepared statement

Synopsis

```
EXECUTE name [ ( parameter [, ...] ) ]
```

Description

EXECUTE is used to execute a previously prepared statement. Since prepared statements only exist for the duration of a session, the prepared statement must have been created by a `PREPARE` statement executed earlier in the current session.

If the `PREPARE` statement that created the statement specified some parameters, a compatible set of parameters must be passed to the `EXECUTE` statement, or else an error is raised. Note that (unlike functions) prepared statements are not overloaded based on the type or number of their parameters; the name of a prepared statement must be unique within a database session.

For more information on the creation and usage of prepared statements, see [PREPARE](#).

Parameters

name

The name of the prepared statement to execute.

parameter

The actual value of a parameter to the prepared statement. This must be an expression yielding a value that is compatible with the data type of this parameter, as was determined when the prepared statement was created.

Outputs

The command tag returned by `EXECUTE` is that of the prepared statement, and not `EXECUTE`.

Examples

Examples are given in [Examples](#) in the [PREPARE](#) documentation.

Compatibility

The SQL standard includes an `EXECUTE` statement, but it is only for use in embedded SQL. This version of the `EXECUTE` statement also uses a somewhat different syntax.

See Also

[DEALLOCATE](#), [PREPARE](#)

EXPLAIN

EXPLAIN — show the execution plan of a statement

Synopsis

```
EXPLAIN [ ( option [, ...] ) ] statement
```

where *option* can be one of:

```
ANALYZE [ boolean ]
VERBOSE [ boolean ]
COSTS [ boolean ]
SETTINGS [ boolean ]
GENERIC_PLAN [ boolean ]
BUFFERS [ boolean ]
SERIALIZE [ { NONE | TEXT | BINARY } ]
WAL [ boolean ]
TIMING [ boolean ]
SUMMARY [ boolean ]
MEMORY [ boolean ]
FORMAT { TEXT | XML | JSON | YAML }
```

Description

This command displays the execution plan that the Postgres Pro planner generates for the supplied statement. The execution plan shows how the table(s) referenced by the statement will be scanned — by plain sequential scan, index scan, etc. — and if multiple tables are referenced, what join algorithms will be used to bring together the required rows from each input table.

The most critical part of the display is the estimated statement execution cost, which is the planner's guess at how long it will take to run the statement (measured in cost units that are arbitrary, but conventionally mean disk page fetches). Actually two numbers are shown: the start-up cost before the first row can be returned, and the total cost to return all the rows. For most queries the total cost is what matters, but in contexts such as a subquery in `EXISTS`, the planner will choose the smallest start-up cost instead of the smallest total cost (since the executor will stop after getting one row, anyway). Also, if you limit the number of rows to return with a `LIMIT` clause, the planner makes an appropriate interpolation between the endpoint costs to estimate which plan is really the cheapest.

The `ANALYZE` option causes the statement to be actually executed, not only planned. Then actual run time statistics are added to the display, including the total elapsed time expended within each plan node (in milliseconds) and the total number of rows it actually returned. This is useful for seeing whether the planner's estimates are close to reality.

Important

Keep in mind that the statement is actually executed when the `ANALYZE` option is used. Although `EXPLAIN` will discard any output that a `SELECT` would return, other side effects of the statement will happen as usual. If you wish to use `EXPLAIN ANALYZE` on an `INSERT`, `UPDATE`, `DELETE`, `MERGE`, `CREATE TABLE AS`, or `EXECUTE` statement without letting the command affect your data, use this approach:

```
BEGIN;
EXPLAIN ANALYZE ...;
ROLLBACK;
```

Parameters

ANALYZE

Carry out the command and show actual run times and other statistics. This parameter defaults to `FALSE`.

VERBOSE

Display additional information regarding the plan. Specifically, include the output column list for each node in the plan tree, schema-qualify table and function names, always label variables in expressions with their range table alias, and always print the name of each trigger for which statistics are displayed. The query identifier will also be displayed if one has been computed, see [compute_query_id](#) for more details. This parameter defaults to `FALSE`.

COSTS

Include information on the estimated startup and total cost of each plan node, as well as the estimated number of rows and the estimated width of each row. This parameter defaults to `TRUE`.

SETTINGS

Include information on configuration parameters. Specifically, include options affecting query planning with value different from the built-in default value. This parameter defaults to `FALSE`.

GENERIC_PLAN

Allow the statement to contain parameter placeholders like `$1`, and generate a generic plan that does not depend on the values of those parameters. See [PREPARE](#) for details about generic plans and the types of statement that support parameters. This parameter cannot be used together with `ANALYZE`. It defaults to `FALSE`.

BUFFERS

Include information on buffer usage. Specifically, include the number of shared blocks hit, read, dirtied, and written, the number of local blocks hit, read, dirtied, and written, the number of temp blocks read and written, and the time spent reading and writing data file blocks, local blocks and temporary file blocks (in milliseconds) if [track_io_timing](#) is enabled. A *hit* means that a read was avoided because the block was found already in cache when needed. Shared blocks contain data from regular tables and indexes; local blocks contain data from temporary tables and indexes; while temporary blocks contain short-term working data used in sorts, hashes, Materialize plan nodes, and similar cases. The number of blocks *dirtied* indicates the number of previously unmodified blocks that were changed by this query; while the number of blocks *written* indicates the number of previously-dirtied blocks evicted from cache by this backend during query processing. The number of blocks shown for an upper-level node includes those used by all its child nodes. In text format, only non-zero values are printed. This parameter defaults to `FALSE`.

SERIALIZE

Include information on the cost of *serializing* the query's output data, that is converting it to text or binary format to send to the client. This can be a significant part of the time required for regular execution of the query, if the datatype output functions are expensive or if TOASTed values must be fetched from out-of-line storage. `EXPLAIN`'s default behavior, `SERIALIZE NONE`, does not perform these conversions. If `SERIALIZE TEXT` or `SERIALIZE BINARY` is specified, the appropriate conversions are performed, and the time spent doing so is measured (unless `TIMING OFF` is specified). If the `BUFFERS` option is also specified, then any buffer accesses involved in the conversions are counted too. In no case, however, will `EXPLAIN` actually send the resulting data to the client; hence network transmission costs cannot be investigated this way. Serialization may only be enabled when `ANALYZE` is also enabled. If `SERIALIZE` is written without an argument, `TEXT` is assumed.

WAL

Include information on WAL record generation. Specifically, include the number of records, number of full page images (fpi) and the amount of WAL generated in bytes. In text format, only non-zero

values are printed. This parameter may only be used when `ANALYZE` is also enabled. It defaults to `FALSE`.

TIMING

Include actual startup time and time spent in each node in the output. The overhead of repeatedly reading the system clock can slow down the query significantly on some systems, so it may be useful to set this parameter to `FALSE` when only actual row counts, and not exact times, are needed. Run time of the entire statement is always measured, even when node-level timing is turned off with this option. This parameter may only be used when `ANALYZE` is also enabled. It defaults to `TRUE`.

SUMMARY

Include summary information (e.g., totaled timing information) after the query plan. Summary information is included by default when `ANALYZE` is used but otherwise is not included by default, but can be enabled using this option. Planning time in `EXPLAIN EXECUTE` includes the time required to fetch the plan from the cache and the time required for re-planning, if necessary.

MEMORY

Include information on memory consumption by the query planning phase. Specifically, include the precise amount of storage used by planner in-memory structures, as well as total memory considering allocation overhead. This parameter defaults to `FALSE`.

FORMAT

Specify the output format, which can be `TEXT`, `XML`, `JSON`, or `YAML`. Non-text output contains the same information as the text output format, but is easier for programs to parse. This parameter defaults to `TEXT`.

boolean

Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to disable it. The *boolean* value can also be omitted, in which case `TRUE` is assumed.

statement

Any `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `MERGE`, `VALUES`, `EXECUTE`, `DECLARE`, `CREATE TABLE AS`, or `CREATE MATERIALIZED VIEW AS statement`, whose execution plan you wish to see.

Outputs

The command's result is a textual description of the plan selected for the *statement*, optionally annotated with execution statistics. [Section 14.1](#) describes the information provided.

Notes

In order to allow the Postgres Pro query planner to make reasonably informed decisions when optimizing queries, the `pg_statistic` data should be up-to-date for all tables used in the query. Normally the [auto-vacuum daemon](#) will take care of that automatically. But if a table has recently had substantial changes in its contents, you might need to do a manual `ANALYZE` rather than wait for autovacuum to catch up with the changes.

In order to measure the run-time cost of each node in the execution plan, the current implementation of `EXPLAIN ANALYZE` adds profiling overhead to query execution. As a result, running `EXPLAIN ANALYZE` on a query can sometimes take significantly longer than executing the query normally. The amount of overhead depends on the nature of the query, as well as the platform being used. The worst case occurs for plan nodes that in themselves require very little time per execution, and on machines that have relatively slow operating system calls for obtaining the time of day.

Examples

To show the plan for a simple query on a table with a single `integer` column and 10000 rows:

```
EXPLAIN SELECT * FROM foo;
```

QUERY PLAN

```
-----
Seq Scan on foo  (cost=0.00..155.00 rows=10000 width=4)
(1 row)
```

Here is the same query, with JSON output formatting:

```
EXPLAIN (FORMAT JSON) SELECT * FROM foo;
QUERY PLAN
```

```
-----
[
  {
    "Plan": {
      "Node Type": "Seq Scan",
      "Relation Name": "foo",
      "Alias": "foo",
      "Startup Cost": 0.00,
      "Total Cost": 155.00,
      "Plan Rows": 10000,
      "Plan Width": 4
    }
  }
]
(1 row)
```

If there is an index and we use a query with an indexable WHERE condition, EXPLAIN might show a different plan:

```
EXPLAIN SELECT * FROM foo WHERE i = 4;
```

QUERY PLAN

```
-----
Index Scan using fi on foo  (cost=0.00..5.98 rows=1 width=4)
Index Cond: (i = 4)
(2 rows)
```

Here is the same query, but in YAML format:

```
EXPLAIN (FORMAT YAML) SELECT * FROM foo WHERE i='4';
QUERY PLAN
```

```
-----
- Plan:
  Node Type: "Index Scan"
  Scan Direction: "Forward"
  Index Name: "fi"
  Relation Name: "foo"
  Alias: "foo"
  Startup Cost: 0.00
  Total Cost: 5.98
  Plan Rows: 1
  Plan Width: 4
  Index Cond: "(i = 4)"
(1 row)
```

XML format is left as an exercise for the reader.

Here is the same plan with cost estimates suppressed:

```
EXPLAIN (COSTS FALSE) SELECT * FROM foo WHERE i = 4;
```

QUERY PLAN

```
-----
Index Scan using fi on foo
  Index Cond: (i = 4)
(2 rows)
```

Here is an example of a query plan for a query using an aggregate function:

```
EXPLAIN SELECT sum(i) FROM foo WHERE i < 10;
```

QUERY PLAN

```
-----
Aggregate  (cost=23.93..23.93 rows=1 width=4)
->  Index Scan using fi on foo  (cost=0.00..23.92 rows=6 width=4)
     Index Cond: (i < 10)
(3 rows)
```

Here is an example of using `EXPLAIN EXECUTE` to display the execution plan for a prepared query:

```
PREPARE query(int, int) AS SELECT sum(bar) FROM test
  WHERE id > $1 AND id < $2
  GROUP BY foo;
```

```
EXPLAIN ANALYZE EXECUTE query(100, 200);
```

QUERY PLAN

```
-----
HashAggregate  (cost=10.77..10.87 rows=10 width=12) (actual time=0.043..0.044 rows=10
loops=1)
  Group Key: foo
  Batches: 1  Memory Usage: 24kB
->  Index Scan using test_pkey on test  (cost=0.29..10.27 rows=99 width=8) (actual
time=0.009..0.025 rows=99 loops=1)
     Index Cond: ((id > 100) AND (id < 200))
Planning Time: 0.244 ms
Execution Time: 0.073 ms
(7 rows)
```

Of course, the specific numbers shown here depend on the actual contents of the tables involved. Also note that the numbers, and even the selected query strategy, might vary between Postgres Pro releases due to planner improvements. In addition, the `ANALYZE` command uses random sampling to estimate data statistics; therefore, it is possible for cost estimates to change after a fresh run of `ANALYZE`, even if the actual distribution of data in the table has not changed.

Notice that the previous example showed a “custom” plan for the specific parameter values given in `EXECUTE`. We might also wish to see the generic plan for a parameterized query, which can be done with `GENERIC_PLAN`:

```
EXPLAIN (GENERIC_PLAN)
  SELECT sum(bar) FROM test
  WHERE id > $1 AND id < $2
  GROUP BY foo;
```

QUERY PLAN

```
-----
HashAggregate  (cost=26.79..26.89 rows=10 width=12)
  Group Key: foo
->  Index Scan using test_pkey on test  (cost=0.29..24.29 rows=500 width=8)
```

```
      Index Cond: ((id > $1) AND (id < $2))
(4 rows)
```

In this case the parser correctly inferred that `$1` and `$2` should have the same data type as `id`, so the lack of parameter type information from `PREPARE` was not a problem. In other cases it might be necessary to explicitly specify types for the parameter symbols, which can be done by casting them, for example:

```
EXPLAIN (GENERIC_PLAN)
  SELECT sum(bar) FROM test
     WHERE id > $1::integer AND id < $2::integer
     GROUP BY foo;
```

Compatibility

There is no `EXPLAIN` statement defined in the SQL standard.

The following syntax was used before Postgres Pro version 9.0 and is still supported:

```
EXPLAIN [ ANALYZE ] [ VERBOSE ] statement
```

Note that in this syntax, the options must be specified in exactly the order shown.

See Also

[ANALYZE](#)

FETCH

FETCH — retrieve rows from a query using a cursor

Synopsis

```
FETCH [ direction ] [ FROM | IN ] cursor_name
```

where *direction* can be one of:

```
NEXT  
PRIOR  
FIRST  
LAST  
ABSOLUTE count  
RELATIVE count  
count  
ALL  
FORWARD  
FORWARD count  
FORWARD ALL  
BACKWARD  
BACKWARD count  
BACKWARD ALL
```

Description

FETCH retrieves rows using a previously-created cursor.

A cursor has an associated position, which is used by FETCH. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result. When created, a cursor is positioned before the first row. After fetching some rows, the cursor is positioned on the row most recently retrieved. If FETCH runs off the end of the available rows then the cursor is left positioned after the last row, or before the first row if fetching backward. FETCH ALL or FETCH BACKWARD ALL will always leave the cursor positioned after the last row or before the first row.

The forms NEXT, PRIOR, FIRST, LAST, ABSOLUTE, RELATIVE fetch a single row after moving the cursor appropriately. If there is no such row, an empty result is returned, and the cursor is left positioned before the first row or after the last row as appropriate.

The forms using FORWARD and BACKWARD retrieve the indicated number of rows moving in the forward or backward direction, leaving the cursor positioned on the last-returned row (or after/before all rows, if the *count* exceeds the number of rows available).

RELATIVE 0, FORWARD 0, and BACKWARD 0 all request fetching the current row without moving the cursor, that is, re-fetching the most recently fetched row. This will succeed unless the cursor is positioned before the first row or after the last row; in which case, no row is returned.

Note

This page describes usage of cursors at the SQL command level. If you are trying to use cursors inside a PL/pgSQL function, the rules are different — see [Section 44.7.3](#).

Parameters

direction

direction defines the fetch direction and number of rows to fetch. It can be one of the following:

NEXT

Fetch the next row. This is the default if *direction* is omitted.

PRIOR

Fetch the prior row.

FIRST

Fetch the first row of the query (same as ABSOLUTE 1).

LAST

Fetch the last row of the query (same as ABSOLUTE -1).

ABSOLUTE *count*

Fetch the *count*'th row of the query, or the *abs(count)*'th row from the end if *count* is negative. Position before first row or after last row if *count* is out of range; in particular, ABSOLUTE 0 positions before the first row.

RELATIVE *count*

Fetch the *count*'th succeeding row, or the *abs(count)*'th prior row if *count* is negative. RELATIVE 0 re-fetches the current row, if any.

count

Fetch the next *count* rows (same as FORWARD *count*).

ALL

Fetch all remaining rows (same as FORWARD ALL).

FORWARD

Fetch the next row (same as NEXT).

FORWARD *count*

Fetch the next *count* rows. FORWARD 0 re-fetches the current row.

FORWARD ALL

Fetch all remaining rows.

BACKWARD

Fetch the prior row (same as PRIOR).

BACKWARD *count*

Fetch the prior *count* rows (scanning backwards). BACKWARD 0 re-fetches the current row.

BACKWARD ALL

Fetch all prior rows (scanning backwards).

count

count is a possibly-signed integer constant, determining the location or number of rows to fetch. For FORWARD and BACKWARD cases, specifying a negative *count* is equivalent to changing the sense of FORWARD and BACKWARD.

cursor_name

An open cursor's name.

Outputs

On successful completion, a `FETCH` command returns a command tag of the form

```
FETCH count
```

The *count* is the number of rows fetched (possibly zero). Note that in `psql`, the command tag will not actually be displayed, since `psql` displays the fetched rows instead.

Notes

The cursor should be declared with the `SCROLL` option if one intends to use any variants of `FETCH` other than `FETCH NEXT` or `FETCH FORWARD` with a positive count. For simple queries Postgres Pro will allow backwards fetch from cursors not declared with `SCROLL`, but this behavior is best not relied on. If the cursor is declared with `NO SCROLL`, no backward fetches are allowed.

`ABSOLUTE` fetches are not any faster than navigating to the desired row with a relative move: the underlying implementation must traverse all the intermediate rows anyway. Negative absolute fetches are even worse: the query must be read to the end to find the last row, and then traversed backward from there. However, rewinding to the start of the query (as with `FETCH ABSOLUTE 0`) is fast.

`DECLARE` is used to define a cursor. Use `MOVE` to change cursor position without retrieving data.

Examples

The following example traverses a table using a cursor:

```
BEGIN WORK;

-- Set up a cursor:
DECLARE liahona SCROLL CURSOR FOR SELECT * FROM films;

-- Fetch the first 5 rows in the cursor liahona:
FETCH FORWARD 5 FROM liahona;
```

code	title	did	date_prod	kind	len
BL101	The Third Man	101	1949-12-23	Drama	01:44
BL102	The African Queen	101	1951-08-11	Romantic	01:43
JL201	Une Femme est une Femme	102	1961-03-12	Romantic	01:25
P_301	Vertigo	103	1958-11-14	Action	02:08
P_302	Becket	103	1964-02-03	Drama	02:28

```
-- Fetch the previous row:
FETCH PRIOR FROM liahona;
```

code	title	did	date_prod	kind	len
P_301	Vertigo	103	1958-11-14	Action	02:08

```
-- Close the cursor and end the transaction:
CLOSE liahona;
COMMIT WORK;
```

Compatibility

The SQL standard defines `FETCH` for use in embedded SQL only. The variant of `FETCH` described here returns the data as if it were a `SELECT` result rather than placing it in host variables. Other than this point, `FETCH` is fully upward-compatible with the SQL standard.

The `FETCH` forms involving `FORWARD` and `BACKWARD`, as well as the forms `FETCH count` and `FETCH ALL`, in which `FORWARD` is implicit, are Postgres Pro extensions.

The SQL standard allows only `FROM` preceding the cursor name; the option to use `IN`, or to leave them out altogether, is an extension.

```
[ GROUP ] role_name
| PUBLIC
| CURRENT_ROLE
| CURRENT_USER
| SESSION_USER
```

Description

The GRANT command has two basic variants: one that grants privileges on a database object (table, column, view, foreign table, sequence, database, foreign-data wrapper, foreign server, function, procedure, procedural language, large object, configuration parameter, schema, tablespace, or type), and one that grants membership in a role. These variants are similar in many ways, but they are different enough to be described separately.

GRANT on Database Objects

This variant of the GRANT command gives specific privileges on a database object to one or more roles. These privileges are added to those already granted, if any.

The key word PUBLIC indicates that the privileges are to be granted to all roles, including those that might be created later. PUBLIC can be thought of as an implicitly defined group that always includes all roles. Any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to PUBLIC.

If WITH GRANT OPTION is specified, the recipient of the privilege can in turn grant it to others. Without a grant option, the recipient cannot do that. Grant options cannot be granted to PUBLIC.

If `GRANTED BY` is specified, the specified grantor must be the current user. This clause is currently present in this form only for SQL compatibility.

There is no need to grant privileges to the owner of an object (usually the user that created it), as the owner has all privileges by default. (The owner could, however, choose to revoke some of their own privileges for safety.)

The right to drop an object, or to alter its definition in any way, is not treated as a grantable privilege; it is inherent in the owner, and cannot be granted or revoked. (However, a similar effect can be obtained by granting or revoking membership in the role that owns the object; see below.) The owner implicitly has all grant options for the object, too.

The possible privileges are:

SELECT
INSERT
UPDATE
DELETE
TRUNCATE
REFERENCES
TRIGGER
CREATE
CONNECT
TEMPORARY
EXECUTE
USAGE
SET
ALTER SYSTEM
MAINTAIN

Specific types of privileges, as defined in [Section 5.8](#).

TEMP

Alternative spelling for `TEMPORARY`.

ALL PRIVILEGES

Grant all of the privileges available for the object's type. The `PRIVILEGES` key word is optional in Postgres Pro, though it is required by strict SQL.

The `FUNCTION` syntax works for plain functions, aggregate functions, and window functions, but not for procedures; use `PROCEDURE` for those. Alternatively, use `ROUTINE` to refer to a function, aggregate function, window function, or procedure regardless of its precise type.

There is also an option to grant privileges on all objects of the same type within one or more schemas. This functionality is currently supported only for tables, sequences, functions, and procedures. `ALL TABLES` also affects views and foreign tables, just like the specific-object `GRANT` command. `ALL FUNCTIONS` also affects aggregate and window functions, but not procedures, again just like the specific-object `GRANT` command. Use `ALL ROUTINES` to include procedures.

GRANT on Roles

This variant of the `GRANT` command grants membership in a role to one or more other roles, and the modification of membership options `SET`, `INHERIT`, and `ADMIN`; see [Section 21.3](#) for details. Membership in a role is significant because it potentially allows access to the privileges granted to a role to each of its members, and potentially also the ability to make changes to the role itself. However, the actual permissions conferred depend on the options associated with the grant. To modify that options of an existing membership, simply specify the membership with updated option values.

Each of the options described below can be set to either `TRUE` or `FALSE`. The keyword `OPTION` is accepted as a synonym for `TRUE`, so that `WITH ADMIN OPTION` is a synonym for `WITH ADMIN TRUE`. When altering an existing membership the omission of an option results in the current value being retained.

The `ADMIN` option allows the member to in turn grant membership in the role to others, and revoke membership in the role as well. Without the admin option, ordinary users cannot do that. A role is not considered to hold `WITH ADMIN OPTION` on itself. Database superusers can grant or revoke membership in any role to anyone. This option defaults to `FALSE`.

The `INHERIT` option controls the inheritance status of the new membership; see [Section 21.3](#) for details on inheritance. If it is set to `TRUE`, it causes the new member to inherit from the granted role. If set to `FALSE`, the new member does not inherit. If unspecified when creating a new role membership, this defaults to the inheritance attribute of the new member.

The `SET` option, if it is set to `TRUE`, allows the member to change to the granted role using the `SET ROLE` command. If a role is an indirect member of another role, it can use `SET ROLE` to change to that role only if there is a chain of grants each of which has `SET TRUE`. This option defaults to `TRUE`.

To create an object owned by another role or give ownership of an existing object to another role, you must have the ability to `SET ROLE` to that role; otherwise, commands such as `ALTER ... OWNER TO` or `CREATE DATABASE ... OWNER` will fail. However, a user who inherits the privileges of a role but does not have the ability to `SET ROLE` to that role may be able to obtain full access to the role by manipulating existing objects owned by that role (e.g. they could redefine an existing function to act as a Trojan horse). Therefore, if a role's privileges are to be inherited but should not be accessible via `SET ROLE`, it should not own any SQL objects.

If `GRANTED BY` is specified, the grant is recorded as having been done by the specified role. A user can only attribute a grant to another role if they possess the privileges of that role. The role recorded as the grantor must have `ADMIN OPTION` on the target role, unless it is the bootstrap superuser. When a grant is recorded as having a grantor other than the bootstrap superuser, it depends on the grantor continuing to possess `ADMIN OPTION` on the role; so, if `ADMIN OPTION` is revoked, dependent grants must be revoked as well.

Unlike the case with privileges, membership in a role cannot be granted to `PUBLIC`. Note also that this form of the command does not allow the noise word `GROUP` in *role_specification*.

Notes

The `REVOKE` command is used to revoke access privileges.

Since PostgreSQL 8.1, the concepts of users and groups have been unified into a single kind of entity called a role. It is therefore no longer necessary to use the keyword `GROUP` to identify whether a grantee is a user or a group. `GROUP` is still allowed in the command, but it is a noise word.

A user may perform `SELECT`, `INSERT`, etc. on a column if they hold that privilege for either the specific column or its whole table. Granting the privilege at the table level and then revoking it for one column will not do what one might wish: the table-level grant is unaffected by a column-level operation.

When a non-owner of an object attempts to `GRANT` privileges on the object, the command will fail outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command will proceed, but it will grant only those privileges for which the user has grant options. The `GRANT ALL PRIVILEGES` forms will issue a warning message if no grant options are held, while the other forms will issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since the owner is always treated as holding all grant options, the cases can never occur.)

It should be noted that database superusers can access all objects regardless of object privilege settings. This is comparable to the rights of `root` in a Unix system. As with `root`, it's unwise to operate as a superuser except when absolutely necessary.

If a superuser chooses to issue a `GRANT` or `REVOKE` command, the command is performed as though it were issued by the owner of the affected object. In particular, privileges granted via such a command will appear to have been granted by the object owner. (For role membership, the membership appears to have been granted by the bootstrap superuser.)

`GRANT` and `REVOKE` can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges `WITH GRANT OPTION` on the object. In this case the privileges will be recorded as having been granted by the role that actually owns the object or holds the privileges `WITH GRANT OPTION`. For example, if table `t1` is owned by role `g1`, of which role `u1` is a member, then `u1` can grant privileges on `t1` to `u2`, but those privileges will appear to have been granted directly by `g1`. Any other member of role `g1` could revoke them later.

If the role executing `GRANT` holds the required privileges indirectly via more than one role membership path, it is unspecified which containing role will be recorded as having done the grant. In such cases it is best practice to use `SET ROLE` to become the specific role you want to do the `GRANT` as.

Granting permission on a table does not automatically extend permissions to any sequences used by the table, including sequences tied to `SERIAL` columns. Permissions on sequences must be set separately.

See [Section 5.8](#) for more information about specific privilege types, as well as how to inspect objects' privileges.

Examples

Grant insert privilege to all users on table `films`:

```
GRANT INSERT ON films TO PUBLIC;
```

Grant all available privileges to user `manuel` on view `kinds`:

```
GRANT ALL PRIVILEGES ON kinds TO manuel;
```

Note that while the above will indeed grant all privileges if executed by a superuser or the owner of `kinds`, when executed by someone else it will only grant those permissions for which the someone else has grant options.

Grant membership in role `admins` to user `joe`:

```
GRANT admins TO joe;
```

Compatibility

According to the SQL standard, the `PRIVILEGES` key word in `ALL PRIVILEGES` is required. The SQL standard does not support setting the privileges on more than one object per command.

Postgres Pro allows an object owner to revoke their own ordinary privileges: for example, a table owner can make the table read-only to themselves by revoking their own `INSERT`, `UPDATE`, `DELETE`, and `TRUNCATE` privileges. This is not possible according to the SQL standard. The reason is that Postgres Pro treats the owner's privileges as having been granted by the owner to themselves; therefore they can revoke them too. In the SQL standard, the owner's privileges are granted by an assumed entity “`_SYSTEM`”. Not being “`_SYSTEM`”, the owner cannot revoke these rights.

According to the SQL standard, grant options can be granted to `PUBLIC`; Postgres Pro only supports granting grant options to roles.

The SQL standard allows the `GRANTED BY` option to specify only `CURRENT_USER` or `CURRENT_ROLE`. The other variants are Postgres Pro extensions.

The SQL standard provides for a `USAGE` privilege on other kinds of objects: character sets, collations, translations.

In the SQL standard, sequences only have a `USAGE` privilege, which controls the use of the `NEXT VALUE FOR` expression, which is equivalent to the function `nextval` in Postgres Pro. The sequence privileges `SELECT` and `UPDATE` are Postgres Pro extensions. The application of the sequence `USAGE` privilege to the `currval` function is also a Postgres Pro extension (as is the function itself).

Privileges on databases, tablespaces, schemas, languages, and configuration parameters are Postgres Pro extensions.

INSERT

INSERT — create new rows in a table

Synopsis

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
INSERT INTO table_name [ AS alias ] [ ( column_name [, ...] ) ]
    [ OVERRIDING { SYSTEM | USER } VALUE ]
    { DEFAULT VALUES | VALUES ( { expression | DEFAULT } [, ...] ) [, ...] | query }
    [ ON CONFLICT [ conflict_target ] conflict_action ]
    [ RETURNING { * | output_expression [ [ AS ] output_name ] } [, ...] ]
```

where *conflict_target* can be one of:

```
( { index_column_name | ( index_expression ) } [ COLLATE collation ] [ opclass ]
[, ...] ) [ WHERE index_predicate ]
ON CONSTRAINT constraint_name
```

and *conflict_action* is one of:

```
DO NOTHING
DO UPDATE SET { column_name = { expression | DEFAULT } |
                ( column_name [, ...] ) = [ ROW ] ( { expression | DEFAULT }
[, ...] ) |
                ( column_name [, ...] ) = ( sub-SELECT )
                } [, ...]
[ WHERE condition ]
```

Description

INSERT inserts new rows into a table. One can insert one or more rows specified by value expressions, or zero or more rows resulting from a query.

The target column names can be listed in any order. If no list of column names is given at all, the default is all the columns of the table in their declared order; or the first *N* column names, if there are only *N* columns supplied by the VALUES clause or *query*. The values supplied by the VALUES clause or *query* are associated with the explicit or implicit column list left-to-right.

Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or null if there is none.

If the expression for any column is not of the correct data type, automatic type conversion will be attempted.

INSERT into tables that lack unique indexes will not be blocked by concurrent activity. Tables with unique indexes might block if concurrent sessions perform actions that lock or modify rows matching the unique index values being inserted; the details are covered in [Section 63.5](#). ON CONFLICT can be used to specify an alternative action to raising a unique constraint or exclusion constraint violation error. (See [ON CONFLICT Clause](#) below.)

The optional RETURNING clause causes INSERT to compute and return value(s) based on each row actually inserted (or updated, if an ON CONFLICT DO UPDATE clause was used). This is primarily useful for obtaining values that were supplied by defaults, such as a serial sequence number. However, any expression using the table's columns is allowed. The syntax of the RETURNING list is identical to that of the output list of SELECT. Only rows that were successfully inserted or updated will be returned. For example, if a row was locked but not updated because an ON CONFLICT DO UPDATE ... WHERE clause *condition* was not satisfied, the row will not be returned.

You must have `INSERT` privilege on a table in order to insert into it. If `ON CONFLICT DO UPDATE` is present, `UPDATE` privilege on the table is also required.

If a column list is specified, you only need `INSERT` privilege on the listed columns. Similarly, when `ON CONFLICT DO UPDATE` is specified, you only need `UPDATE` privilege on the column(s) that are listed to be updated. However, `ON CONFLICT DO UPDATE` also requires `SELECT` privilege on any column whose values are read in the `ON CONFLICT DO UPDATE` expressions or *condition*.

Use of the `RETURNING` clause requires `SELECT` privilege on all columns mentioned in `RETURNING`. If you use the *query* clause to insert rows from a query, you of course need to have `SELECT` privilege on any table or column used in the query.

Parameters

Inserting

This section covers parameters that may be used when only inserting new rows. Parameters *exclusively* used with the `ON CONFLICT` clause are described separately.

with_query

The `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the `INSERT` query. See [Section 7.8](#) and [SELECT](#) for details.

It is possible for the *query* (`SELECT` statement) to also contain a `WITH` clause. In such a case both sets of *with_query* can be referenced within the *query*, but the second one takes precedence since it is more closely nested.

table_name

The name (optionally schema-qualified) of an existing table.

alias

A substitute name for *table_name*. When an alias is provided, it completely hides the actual name of the table. This is particularly useful when `ON CONFLICT DO UPDATE` targets a table named `excluded`, since that will otherwise be taken as the name of the special table representing the row proposed for insertion.

column_name

The name of a column in the table named by *table_name*. The column name can be qualified with a subfield name or array subscript, if needed. (Inserting into only some fields of a composite column leaves the other fields null.) When referencing a column with `ON CONFLICT DO UPDATE`, do not include the table's name in the specification of a target column. For example, `INSERT INTO table_name ... ON CONFLICT DO UPDATE SET table_name.col = 1` is invalid (this follows the general behavior for `UPDATE`).

`OVERRIDING SYSTEM VALUE`

If this clause is specified, then any values supplied for identity columns will override the default sequence-generated values.

For an identity column defined as `GENERATED ALWAYS`, it is an error to insert an explicit value (other than `DEFAULT`) without specifying either `OVERRIDING SYSTEM VALUE` or `OVERRIDING USER VALUE`. (For an identity column defined as `GENERATED BY DEFAULT`, `OVERRIDING SYSTEM VALUE` is the normal behavior and specifying it does nothing, but Postgres Pro allows it as an extension.)

`OVERRIDING USER VALUE`

If this clause is specified, then any values supplied for identity columns are ignored and the default sequence-generated values are applied.

This clause is useful for example when copying values between tables. Writing `INSERT INTO tbl2 OVERRIDING USER VALUE SELECT * FROM tbl1` will copy from `tbl1` all columns that are not identity columns in `tbl2` while values for the identity columns in `tbl2` will be generated by the sequences associated with `tbl2`.

DEFAULT VALUES

All columns will be filled with their default values, as if `DEFAULT` were explicitly specified for each column. (An `OVERRIDING` clause is not permitted in this form.)

expression

An expression or value to assign to the corresponding column.

DEFAULT

The corresponding column will be filled with its default value. An identity column will be filled with a new value generated by the associated sequence. For a generated column, specifying this is permitted but merely specifies the normal behavior of computing the column from its generation expression.

query

A query (`SELECT` statement) that supplies the rows to be inserted. Refer to the [SELECT](#) statement for a description of the syntax.

output_expression

An expression to be computed and returned by the `INSERT` command after each row is inserted or updated. The expression can use any column names of the table named by *table_name*. Write `*` to return all columns of the inserted or updated row(s).

output_name

A name to use for a returned column.

ON CONFLICT **Clause**

The optional `ON CONFLICT` clause specifies an alternative action to raising a unique violation or exclusion constraint violation error. For each individual row proposed for insertion, either the insertion proceeds, or, if an *arbiter* constraint or index specified by *conflict_target* is violated, the alternative *conflict_action* is taken. `ON CONFLICT DO NOTHING` simply avoids inserting a row as its alternative action. `ON CONFLICT DO UPDATE` updates the existing row that conflicts with the row proposed for insertion as its alternative action.

conflict_target can perform *unique index inference*. When performing inference, it consists of one or more *index_column_name* columns and/or *index_expression* expressions, and an optional *index_predicate*. All *table_name* unique indexes that, without regard to order, contain exactly the *conflict_target*-specified columns/expressions are inferred (chosen) as arbiter indexes. If an *index_predicate* is specified, it must, as a further requirement for inference, satisfy arbiter indexes. Note that this means a non-partial unique index (a unique index without a predicate) will be inferred (and thus used by `ON CONFLICT`) if such an index satisfying every other criteria is available. If an attempt at inference is unsuccessful, an error is raised.

`ON CONFLICT DO UPDATE` guarantees an atomic `INSERT` or `UPDATE` outcome; provided there is no independent error, one of those two outcomes is guaranteed, even under high concurrency. This is also known as *UPSERT* — “UPDATE or INSERT”.

conflict_target

Specifies which conflicts `ON CONFLICT` takes the alternative action on by choosing *arbiter indexes*. Either performs *unique index inference*, or names a constraint explicitly. For `ON CONFLICT DO NOTHING`, it is optional to specify a *conflict_target*; when omitted, conflicts with all usable constraints (and unique indexes) are handled. For `ON CONFLICT DO UPDATE`, a *conflict_target* *must* be provided.

conflict_action

conflict_action specifies an alternative `ON CONFLICT` action. It can be either `DO NOTHING`, or a `DO UPDATE` clause specifying the exact details of the `UPDATE` action to be performed in case of a conflict. The `SET` and `WHERE` clauses in `ON CONFLICT DO UPDATE` have access to the existing row using the table's name (or an alias), and to the row proposed for insertion using the special `excluded` table. `SELECT` privilege is required on any column in the target table where corresponding `excluded` columns are read.

Note that the effects of all per-row `BEFORE INSERT` triggers are reflected in `excluded` values, since those effects may have contributed to the row being excluded from insertion.

index_column_name

The name of a *table_name* column. Used to infer arbiter indexes. Follows `CREATE INDEX` format. `SELECT` privilege on *index_column_name* is required.

index_expression

Similar to *index_column_name*, but used to infer expressions on *table_name* columns appearing within index definitions (not simple columns). Follows `CREATE INDEX` format. `SELECT` privilege on any column appearing within *index_expression* is required.

collation

When specified, mandates that corresponding *index_column_name* or *index_expression* use a particular collation in order to be matched during inference. Typically this is omitted, as collations usually do not affect whether or not a constraint violation occurs. Follows `CREATE INDEX` format.

opclass

When specified, mandates that corresponding *index_column_name* or *index_expression* use particular operator class in order to be matched during inference. Typically this is omitted, as the *equality* semantics are often equivalent across a type's operator classes anyway, or because it's sufficient to trust that the defined unique indexes have the pertinent definition of equality. Follows `CREATE INDEX` format.

index_predicate

Used to allow inference of partial unique indexes. Any indexes that satisfy the predicate (which need not actually be partial indexes) can be inferred. Follows `CREATE INDEX` format. `SELECT` privilege on any column appearing within *index_predicate* is required.

constraint_name

Explicitly specifies an arbiter *constraint* by name, rather than inferring a constraint or index.

condition

An expression that returns a value of type `boolean`. Only rows for which this expression returns `true` will be updated, although all rows will be locked when the `ON CONFLICT DO UPDATE` action is taken. Note that *condition* is evaluated last, after a conflict has been identified as a candidate to update.

Note that exclusion constraints are not supported as arbiters with `ON CONFLICT DO UPDATE`. In all cases, only `NOT DEFERRABLE` constraints and unique indexes are supported as arbiters.

`INSERT` with an `ON CONFLICT DO UPDATE` clause is a “deterministic” statement. This means that the command will not be allowed to affect any single existing row more than once; a cardinality violation error will be raised when this situation arises. Rows proposed for insertion should not duplicate each other in terms of attributes constrained by an arbiter index or constraint.

Note that it is currently not supported for the `ON CONFLICT DO UPDATE` clause of an `INSERT` applied to a partitioned table to update the partition key of a conflicting row such that it requires the row be moved to a new partition.

Tip

It is often preferable to use unique index inference rather than naming a constraint directly using `ON CONFLICT ON CONSTRAINT constraint_name`. Inference will continue to work correctly when the underlying index is replaced by another more or less equivalent index in an overlapping way, for example when using `CREATE UNIQUE INDEX ... CONCURRENTLY` before dropping the index being replaced.

Outputs

On successful completion, an `INSERT` command returns a command tag of the form

```
INSERT oid count
```

The *count* is the number of rows inserted or updated. *oid* is always 0 (it used to be the OID assigned to the inserted row if *count* was exactly one and the target table was declared `WITH OIDS` and 0 otherwise, but creating a table `WITH OIDS` is not supported anymore).

If the `INSERT` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) inserted or updated by the command.

Notes

If the specified table is a partitioned table, each row is routed to the appropriate partition and inserted into it. If the specified table is a partition, an error will occur if one of the input rows violates the partition constraint.

You may also wish to consider using `MERGE`, since that allows mixing `INSERT`, `UPDATE`, and `DELETE` within a single statement. See [MERGE](#).

Examples

Insert a single row into table `films`:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, '1971-07-13', 'Comedy', '82 minutes');
```

In this example, the `len` column is omitted and therefore it will have the default value:

```
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

This example uses the `DEFAULT` clause for the date columns rather than specifying a value:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes');
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, DEFAULT, 'Drama');
```

To insert a row consisting entirely of default values:

```
INSERT INTO films DEFAULT VALUES;
```

To insert multiple rows using the multirow `VALUES` syntax:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES
('B6717', 'Tampopo', 110, '1985-02-10', 'Comedy'),
('HG120', 'The Dinner Game', 140, DEFAULT, 'Comedy');
```

This example inserts some rows into table `films` from a table `tmp_films` with the same column layout as `films`:

```
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod < '2004-05-07';
```

This example inserts into array columns:

```
-- Create an empty 3x3 gameboard for noughts-and-crosses
INSERT INTO tictactoe (game, board[1:3][1:3])
    VALUES (1, '{{" ", " ", " "},{ " ", " ", " "},{ " ", " ", " "}}');
-- The subscripts in the above example aren't really needed
INSERT INTO tictactoe (game, board)
    VALUES (2, '{{X, " ", " "},{ " ", O, " "},{ " ", X, " "}}');
```

Insert a single row into table distributors, returning the sequence number generated by the DEFAULT clause:

```
INSERT INTO distributors (did, dname) VALUES (DEFAULT, 'XYZ Widgets')
    RETURNING did;
```

Increment the sales count of the salesperson who manages the account for Acme Corporation, and record the whole updated row along with current time in a log table:

```
WITH upd AS (
    UPDATE employees SET sales_count = sales_count + 1 WHERE id =
        (SELECT sales_person FROM accounts WHERE name = 'Acme Corporation')
    RETURNING *
)
INSERT INTO employees_log SELECT *, current_timestamp FROM upd;
```

Insert or update new distributors as appropriate. Assumes a unique index has been defined that constrains values appearing in the did column. Note that the special excluded table is used to reference values originally proposed for insertion:

```
INSERT INTO distributors (did, dname)
    VALUES (5, 'Gizmo Transglobal'), (6, 'Associated Computing, Inc')
    ON CONFLICT (did) DO UPDATE SET dname = EXCLUDED.dname;
```

Insert a distributor, or do nothing for rows proposed for insertion when an existing, excluded row (a row with a matching constrained column or columns after before row insert triggers fire) exists. Example assumes a unique index has been defined that constrains values appearing in the did column:

```
INSERT INTO distributors (did, dname) VALUES (7, 'Redline GmbH')
    ON CONFLICT (did) DO NOTHING;
```

Insert or update new distributors as appropriate. Example assumes a unique index has been defined that constrains values appearing in the did column. WHERE clause is used to limit the rows actually updated (any existing row not updated will still be locked, though):

```
-- Don't update existing distributors based in a certain ZIP code
INSERT INTO distributors AS d (did, dname) VALUES (8, 'Anvil Distribution')
    ON CONFLICT (did) DO UPDATE
    SET dname = EXCLUDED.dname || ' (formerly ' || d.dname || ' )'
    WHERE d.zipcode <> '21201';

-- Name a constraint directly in the statement (uses associated
-- index to arbitrate taking the DO NOTHING action)
INSERT INTO distributors (did, dname) VALUES (9, 'Antwerp Design')
    ON CONFLICT ON CONSTRAINT distributors_pkey DO NOTHING;
```

Insert new distributor if possible; otherwise DO NOTHING. Example assumes a unique index has been defined that constrains values appearing in the did column on a subset of rows where the is_active Boolean column evaluates to true:

```
-- This statement could infer a partial unique index on "did"
-- with a predicate of "WHERE is_active", but it could also
```

```
-- just use a regular unique constraint on "did"
INSERT INTO distributors (did, dname) VALUES (10, 'Conrad International')
    ON CONFLICT (did) WHERE is_active DO NOTHING;
```

Compatibility

INSERT conforms to the SQL standard, except that the RETURNING clause is a Postgres Pro extension, as is the ability to use WITH with INSERT, and the ability to specify an alternative action with ON CONFLICT. Also, the case in which a column name list is omitted, but not all the columns are filled from the VALUES clause or *query*, is disallowed by the standard. If you prefer a more SQL standard conforming statement than ON CONFLICT, see [MERGE](#).

The SQL standard specifies that OVERRIDING SYSTEM VALUE can only be specified if an identity column that is generated always exists. Postgres Pro allows the clause in any case and ignores it if it is not applicable.

Possible limitations of the *query* clause are documented under [SELECT](#).

LISTEN

LISTEN — listen for a notification

Synopsis

```
LISTEN channel
```

Description

LISTEN registers the current session as a listener on the notification channel named *channel*. If the current session is already registered as a listener for this notification channel, nothing is done.

Whenever the command NOTIFY *channel* is invoked, either by this session or another one connected to the same database, all the sessions currently listening on that notification channel are notified, and each will in turn notify its connected client application.

A session can be unregistered for a given notification channel with the UNLISTEN command. A session's listen registrations are automatically cleared when the session ends.

The method a client application must use to detect notification events depends on which Postgres Pro application programming interface it uses. With the libpq library, the application issues LISTEN as an ordinary SQL command, and then must periodically call the function PQnotifies to find out whether any notification events have been received. Other interfaces such as libpgtcl provide higher-level methods for handling notify events; indeed, with libpgtcl the application programmer should not even issue LISTEN or UNLISTEN directly. See the documentation for the interface you are using for more details.

Parameters

channel

Name of a notification channel (any identifier).

Notes

LISTEN takes effect at transaction commit. If LISTEN or UNLISTEN is executed within a transaction that later rolls back, the set of notification channels being listened to is unchanged.

A transaction that has executed LISTEN cannot be prepared for two-phase commit.

There is a race condition when first setting up a listening session: if concurrently-committing transactions are sending notify events, exactly which of those will the newly listening session receive? The answer is that the session will receive all events committed after an instant during the transaction's commit step. But that is slightly later than any database state that the transaction could have observed in queries. This leads to the following rule for using LISTEN: first execute (and commit!) that command, then in a new transaction inspect the database state as needed by the application logic, then rely on notifications to find out about subsequent changes to the database state. The first few received notifications might refer to updates already observed in the initial database inspection, but this is usually harmless.

NOTIFY contains a more extensive discussion of the use of LISTEN and NOTIFY.

Examples

Configure and execute a listen/notify sequence from psql:

```
LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with PID 8448.
```

Compatibility

There is no `LISTEN` statement in the SQL standard.

LOAD

LOAD — load a shared library file

Synopsis

```
LOAD 'filename'
```

Description

This command loads a shared library file into the Postgres Pro server's address space. If the file has been loaded already, the command does nothing. Shared library files that contain C functions are automatically loaded whenever one of their functions is called. Therefore, an explicit `LOAD` is usually only needed to load a library that modifies the server's behavior through “hooks” rather than providing a set of functions.

The library file name is typically given as just a bare file name, which is sought in the server's library search path (set by [dynamic_library_path](#)). Alternatively it can be given as a full path name. In either case the platform's standard shared library file name extension may be omitted. See [Section 39.10.1](#) for more information on this topic.

Non-superusers can only apply `LOAD` to library files located in `$libdir/plugins/` — the specified *filename* must begin with exactly that string. (It is the database administrator's responsibility to ensure that only “safe” libraries are installed there.)

Compatibility

`LOAD` is a Postgres Pro extension.

[CREATE FUNCTION](#)

LOCK

LOCK — lock a table

Synopsis

For distributed systems (sharded and global tables):

```
LOCK [ TABLE ] [ ONLY ] name [ * ] [, ...] [ IN lockmode MODE ] [ NOWAIT ]
```

where *lockmode* is one of:

```
ACCESS SHARE | SHARE UPDATE EXCLUSIVE | SHARE | EXCLUSIVE | ACCESS EXCLUSIVE
```

For other system types:

```
LOCK [ TABLE ] [ ONLY ] name [ * ] [, ...] [ IN lockmode MODE ] [ NOWAIT ]
```

where *lockmode* is one of:

```
ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE EXCLUSIVE  
| SHARE | SHARE ROW EXCLUSIVE | EXCLUSIVE | ACCESS EXCLUSIVE
```

Description

`LOCK TABLE` obtains a table-level lock, waiting if necessary for any conflicting locks to be released. If `NOWAIT` is specified, `LOCK TABLE` does not wait to acquire the desired lock: if it cannot be acquired immediately, the command is aborted and an error is emitted. Once obtained, the lock is held for the remainder of the current transaction. (There is no `UNLOCK TABLE` command; locks are always released at transaction end.) For global and sharded tables the lock is on a table level (or one part of the table) for all cluster nodes.

Note that you cannot `LOCK` local and sharded or global tables simultaneously.

When a view is locked, all relations appearing in the view definition query are also locked recursively with the same lock mode.

When acquiring locks automatically for commands that reference tables, Postgres Pro always uses the least restrictive lock mode possible. `LOCK TABLE` provides for cases when you might need more restrictive locking. For example, suppose an application runs a transaction at the `READ COMMITTED` isolation level and needs to ensure that data in a table remains stable for the duration of the transaction. To achieve this you could obtain `SHARE` lock mode over the table before querying. This will prevent concurrent data changes and ensure subsequent reads of the table see a stable view of committed data, because `SHARE` lock mode conflicts with the `ROW EXCLUSIVE` lock acquired by writers, and your `LOCK TABLE name IN SHARE MODE` statement will wait until any concurrent holders of `ROW EXCLUSIVE` mode locks commit or roll back. Thus, once you obtain the lock, there are no uncommitted writes outstanding; furthermore none can begin until you release the lock.

To achieve a similar effect when running a transaction at the `REPEATABLE READ` or `SERIALIZABLE` isolation level, you have to execute the `LOCK TABLE` statement before executing any `SELECT` or data modification statement. A `REPEATABLE READ` or `SERIALIZABLE` transaction's view of data will be frozen when its first `SELECT` or data modification statement begins. A `LOCK TABLE` later in the transaction will still prevent concurrent writes — but it won't ensure that what the transaction reads corresponds to the latest committed values.

If a transaction of this sort is going to change the data in the table, then it should use `SHARE ROW EXCLUSIVE` lock mode instead of `SHARE` mode. This ensures that only one transaction of this type runs at a time. Without this, a deadlock is possible: two transactions might both acquire `SHARE` mode, and then be unable to also acquire `ROW EXCLUSIVE` mode to actually perform their updates. (Note that a transaction's

own locks never conflict, so a transaction can acquire `ROW EXCLUSIVE` mode when it holds `SHARE` mode — but not if anyone else holds `SHARE` mode.) To avoid deadlocks, make sure all transactions acquire locks on the same objects in the same order, and if multiple lock modes are involved for a single object, then transactions should always acquire the most restrictive mode first.

More information about the lock modes and locking strategies can be found in [Section 13.3](#).

Parameters

name

The name (optionally schema-qualified) of an existing table to lock. If `ONLY` is specified before the table name, only that table is locked. If `ONLY` is not specified, the table and all its descendant tables (if any) are locked. Optionally, `*` can be specified after the table name to explicitly indicate that descendant tables are included.

The command `LOCK TABLE a, b;` is equivalent to `LOCK TABLE a; LOCK TABLE b;`. The tables are locked one-by-one in the order specified in the `LOCK TABLE` command.

lockmode

The lock mode specifies which locks this lock conflicts with. Lock modes are described in [Section 13.3](#).

If no lock mode is specified, then `ACCESS EXCLUSIVE`, the most restrictive mode, is used.

`NOWAIT`

Specifies that `LOCK TABLE` should not wait for any conflicting locks to be released: if the specified lock(s) cannot be acquired immediately without waiting, the transaction is aborted.

Notes

To lock a table, the user must have the right privilege for the specified *lockmode*. If the user has `MAINTAIN`, `UPDATE`, `DELETE`, or `TRUNCATE` privileges on the table, any *lockmode* is permitted. If the user has `INSERT` privileges on the table, `ROW EXCLUSIVE MODE` (or a less-conflicting mode as described in [Section 13.3](#)) is permitted. If a user has `SELECT` privileges on the table, `ACCESS SHARE MODE` is permitted.

The user performing the lock on the view must have the corresponding privilege on the view. In addition, by default, the view's owner must have the relevant privileges on the underlying base relations, whereas the user performing the lock does not need any permissions on the underlying base relations. However, if the view has `security_invoker` set to `true` (see [CREATE VIEW](#)), the user performing the lock, rather than the view owner, must have the relevant privileges on the underlying base relations.

`LOCK TABLE` is useless outside a transaction block: the lock would remain held only to the completion of the statement. Therefore Postgres Pro reports an error if `LOCK` is used outside a transaction block. Use [BEGIN](#) and [COMMIT](#) (or [ROLLBACK](#)) to define a transaction block.

`LOCK TABLE` only deals with table-level locks, and so the mode names involving `ROW` are all misnomers. These mode names should generally be read as indicating the intention of the user to acquire row-level locks within the locked table. Also, `ROW EXCLUSIVE mode` is a shareable table lock. Keep in mind that all the lock modes have identical semantics so far as `LOCK TABLE` is concerned, differing only in the rules about which modes conflict with which. For information on how to acquire an actual row-level lock, see [Section 13.3.2](#) and [The Locking Clause](#) in the [SELECT](#) documentation.

Examples

Obtain a `SHARE` lock on a primary key table when going to perform inserts into a foreign key table:

```
BEGIN WORK;  
LOCK TABLE films IN SHARE MODE;  
SELECT id FROM films
```

```
WHERE name = 'Star Wars: Episode I - The Phantom Menace';
-- Do ROLLBACK if record was not returned
INSERT INTO films_user_comments VALUES
  (_id_, 'GREAT! I was waiting for it for so long!');
COMMIT WORK;
```

Take a `SHARE ROW EXCLUSIVE` lock on a primary key table when going to perform a delete operation:

```
BEGIN WORK;
LOCK TABLE films IN SHARE ROW EXCLUSIVE MODE;
DELETE FROM films_user_comments WHERE id IN
  (SELECT id FROM films WHERE rating < 5);
DELETE FROM films WHERE rating < 5;
COMMIT WORK;
```

Compatibility

There is no `LOCK TABLE` in the SQL standard, which instead uses `SET TRANSACTION` to specify concurrency levels on transactions. Postgres Pro supports that too; see [SET TRANSACTION](#) for details.

Except for `ACCESS SHARE`, `ACCESS EXCLUSIVE`, and `SHARE UPDATE EXCLUSIVE` lock modes, the Postgres Pro lock modes and the `LOCK TABLE` syntax are compatible with those present in Oracle.

MERGE

MERGE — conditionally insert, update, or delete rows of a table

Synopsis

```
[ WITH with_query [, ...] ]
MERGE INTO [ ONLY ] target_table_name [ * ] [ [ AS ] target_alias ]
USING data_source ON join_condition
when_clause [...]
[ RETURNING { * | output_expression [ [ AS ] output_name ] } [, ...] ]

where data_source is:

{ [ ONLY ] source_table_name [ * ] | ( source_query ) } [ [ AS ] source_alias ]

and when_clause is:

{ WHEN MATCHED [ AND condition ] THEN { merge_update | merge_delete | DO NOTHING } |
  WHEN NOT MATCHED BY SOURCE [ AND condition ] THEN { merge_update | merge_delete | DO
  NOTHING } |
  WHEN NOT MATCHED [ BY TARGET ] [ AND condition ] THEN { merge_insert | DO NOTHING } }

and merge_insert is:

INSERT [( column_name [, ...] )]
[ OVERRIDING { SYSTEM | USER } VALUE ]
{ VALUES ( { expression | DEFAULT } [, ...] ) | DEFAULT VALUES }

and merge_update is:

UPDATE SET { column_name = { expression | DEFAULT } |
            ( column_name [, ...] ) = [ ROW ] ( { expression | DEFAULT } [, ...] ) |
            ( column_name [, ...] ) = ( sub-SELECT )
            } [, ...]

and merge_delete is:

DELETE
```

Description

MERGE performs actions that modify rows in the target table identified as *target_table_name*, using the *data_source*. MERGE provides a single SQL statement that can conditionally INSERT, UPDATE or DELETE rows, a task that would otherwise require multiple procedural language statements.

First, the MERGE command performs a join from *data_source* to the target table producing zero or more candidate change rows. For each candidate change row, the status of MATCHED, NOT MATCHED BY SOURCE, or NOT MATCHED [BY TARGET] is set just once, after which WHEN clauses are evaluated in the order specified. For each candidate change row, the first clause to evaluate as true is executed. No more than one WHEN clause is executed for any candidate change row.

MERGE actions have the same effect as regular UPDATE, INSERT, or DELETE commands of the same names. The syntax of those commands is different, notably that there is no WHERE clause and no table name is specified. All actions refer to the target table, though modifications to other tables may be made using triggers.

When `DO NOTHING` is specified, the source row is skipped. Since actions are evaluated in their specified order, `DO NOTHING` can be handy to skip non-interesting source rows before more fine-grained handling.

The optional `RETURNING` clause causes `MERGE` to compute and return value(s) based on each row inserted, updated, or deleted. Any expression using the source or target table's columns, or the `merge_action()` function can be computed. When an `INSERT` or `UPDATE` action is performed, the new values of the target table's columns are used. When a `DELETE` is performed, the old values of the target table's columns are used. The syntax of the `RETURNING` list is identical to that of the output list of `SELECT`.

There is no separate `MERGE` privilege. If you specify an update action, you must have the `UPDATE` privilege on the column(s) of the target table that are referred to in the `SET` clause. If you specify an insert action, you must have the `INSERT` privilege on the target table. If you specify a delete action, you must have the `DELETE` privilege on the target table. If you specify a `DO NOTHING` action, you must have the `SELECT` privilege on at least one column of the target table. You will also need `SELECT` privilege on any column(s) of the `data_source` and of the target table referred to in any `condition` (including `join_condition`) or `expression`. Privileges are tested once at statement start and are checked whether or not particular `WHEN` clauses are executed.

`MERGE` is not supported if the target table is a materialized view, foreign table, or if it has any rules defined on it.

Parameters

with_query

The `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the `MERGE` query. See [Section 7.8](#) and [SELECT](#) for details. Note that `WITH RECURSIVE` is not supported by `MERGE`.

target_table_name

The name (optionally schema-qualified) of the target table or view to merge into. If `ONLY` is specified before a table name, matching rows are updated or deleted in the named table only. If `ONLY` is not specified, matching rows are also updated or deleted in any tables inheriting from the named table. Optionally, `*` can be specified after the table name to explicitly indicate that descendant tables are included. The `ONLY` keyword and `*` option do not affect insert actions, which always insert into the named table only.

If *target_table_name* is a view, it must either be automatically updatable with no `INSTEAD OF` triggers, or it must have `INSTEAD OF` triggers for every type of action (`INSERT`, `UPDATE`, and `DELETE`) specified in the `WHEN` clauses. Views with rules are not supported.

target_alias

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `MERGE INTO foo AS f`, the remainder of the `MERGE` statement must refer to this table as `f` not `foo`.

source_table_name

The name (optionally schema-qualified) of the source table, view, or transition table. If `ONLY` is specified before the table name, matching rows are included from the named table only. If `ONLY` is not specified, matching rows are also included from any tables inheriting from the named table. Optionally, `*` can be specified after the table name to explicitly indicate that descendant tables are included.

source_query

A query (`SELECT` statement or `VALUES` statement) that supplies the rows to be merged into the target table. Refer to the [SELECT](#) statement or [VALUES](#) statement for a description of the syntax.

source_alias

A substitute name for the data source. When an alias is provided, it completely hides the actual name of the table or the fact that a query was issued.

join_condition

join_condition is an expression resulting in a value of type `boolean` (similar to a `WHERE` clause) that specifies which rows in the *data_source* match rows in the target table.

Warning

Only columns from the target table that attempt to match *data_source* rows should appear in *join_condition*. *join_condition* subexpressions that only reference the target table's columns can affect which action is taken, often in surprising ways.

If both `WHEN NOT MATCHED BY SOURCE` and `WHEN NOT MATCHED [BY TARGET]` clauses are specified, the `MERGE` command will perform a `FULL` join between *data_source* and the target table. For this to work, at least one *join_condition* subexpression must use an operator that can support a hash join, or all of the subexpressions must use operators that can support a merge join.

when_clause

At least one `WHEN` clause is required.

The `WHEN` clause may specify `WHEN MATCHED`, `WHEN NOT MATCHED BY SOURCE`, or `WHEN NOT MATCHED [BY TARGET]`. Note that the SQL standard only defines `WHEN MATCHED` and `WHEN NOT MATCHED` (which is defined to mean no matching target row). `WHEN NOT MATCHED BY SOURCE` is an extension to the SQL standard, as is the option to append `BY TARGET` to `WHEN NOT MATCHED`, to make its meaning more explicit.

If the `WHEN` clause specifies `WHEN MATCHED` and the candidate change row matches a row in the *data_source* to a row in the target table, the `WHEN` clause is executed if the *condition* is absent or it evaluates to `true`.

If the `WHEN` clause specifies `WHEN NOT MATCHED BY SOURCE` and the candidate change row represents a row in the target table that does not match a row in the *data_source*, the `WHEN` clause is executed if the *condition* is absent or it evaluates to `true`.

If the `WHEN` clause specifies `WHEN NOT MATCHED [BY TARGET]` and the candidate change row represents a row in the *data_source* that does not match a row in the target table, the `WHEN` clause is executed if the *condition* is absent or it evaluates to `true`.

condition

An expression that returns a value of type `boolean`. If this expression for a `WHEN` clause returns `true`, then the action for that clause is executed for that row.

A condition on a `WHEN MATCHED` clause can refer to columns in both the source and the target relations. A condition on a `WHEN NOT MATCHED BY SOURCE` clause can only refer to columns from the target relation, since by definition there is no matching source row. A condition on a `WHEN NOT MATCHED [BY TARGET]` clause can only refer to columns from the source relation, since by definition there is no matching target row. Only the system attributes from the target table are accessible.

merge_insert

The specification of an `INSERT` action that inserts one row into the target table. The target column names can be listed in any order. If no list of column names is given at all, the default is all the columns of the table in their declared order.

Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or null if there is none.

If the target table is a partitioned table, each row is routed to the appropriate partition and inserted into it. If the target table is a partition, an error will occur if any input row violates the partition constraint.

Column names may not be specified more than once. `INSERT` actions cannot contain sub-selects.

Only one `VALUES` clause can be specified. The `VALUES` clause can only refer to columns from the source relation, since by definition there is no matching target row.

merge_update

The specification of an `UPDATE` action that updates the current row of the target table. Column names may not be specified more than once.

Neither a table name nor a `WHERE` clause are allowed.

merge_delete

Specifies a `DELETE` action that deletes the current row of the target table. Do not include the table name or any other clauses, as you would normally do with a `DELETE` command.

column_name

The name of a column in the target table. The column name can be qualified with a subfield name or array subscript, if needed. (Inserting into only some fields of a composite column leaves the other fields null.) Do not include the table's name in the specification of a target column.

OVERRIDING SYSTEM VALUE

Without this clause, it is an error to specify an explicit value (other than `DEFAULT`) for an identity column defined as `GENERATED ALWAYS`. This clause overrides that restriction.

OVERRIDING USER VALUE

If this clause is specified, then any values supplied for identity columns defined as `GENERATED BY DEFAULT` are ignored and the default sequence-generated values are applied.

DEFAULT VALUES

All columns will be filled with their default values. (An `OVERRIDING` clause is not permitted in this form.)

expression

An expression to assign to the column. If used in a `WHEN MATCHED` clause, the expression can use values from the original row in the target table, and values from the `data_source` row. If used in a `WHEN NOT MATCHED BY SOURCE` clause, the expression can only use values from the original row in the target table. If used in a `WHEN NOT MATCHED [BY TARGET]` clause, the expression can only use values from the `data_source` row.

DEFAULT

Set the column to its default value (which will be `NULL` if no specific default expression has been assigned to it).

sub-SELECT

A `SELECT` sub-query that produces as many output columns as are listed in the parenthesized column list preceding it. The sub-query must yield no more than one row when executed. If it yields one row, its column values are assigned to the target columns; if it yields no rows, `NULL` values are assigned to the target columns. If used in a `WHEN MATCHED` clause, the sub-query can refer to values from the

original row in the target table, and values from the `data_source` row. If used in a `WHEN NOT MATCHED BY SOURCE` clause, the sub-query can only refer to values from the original row in the target table.

output_expression

An expression to be computed and returned by the `MERGE` command after each row is changed (whether inserted, updated, or deleted). The expression can use any columns of the source or target tables, or the `merge_action()` function to return additional information about the action executed.

Writing `*` will return all columns from the source table, followed by all columns from the target table. Often this will lead to a lot of duplication, since it is common for the source and target tables to have a lot of the same columns. This can be avoided by qualifying the `*` with the name or alias of the source or target table.

output_name

A name to use for a returned column.

Outputs

On successful completion, a `MERGE` command returns a command tag of the form

`MERGE total_count`

The `total_count` is the total number of rows changed (whether inserted, updated, or deleted). If `total_count` is 0, no rows were changed in any way.

If the `MERGE` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) inserted, updated, or deleted by the command.

Notes

The following steps take place during the execution of `MERGE`.

1. Perform any `BEFORE STATEMENT` triggers for all actions specified, whether or not their `WHEN` clauses match.
2. Perform a join from source to target table. The resulting query will be optimized normally and will produce a set of candidate change rows. For each candidate change row,
 - a. Evaluate whether each row is `MATCHED`, `NOT MATCHED BY SOURCE`, or `NOT MATCHED [BY TARGET]`.
 - b. Test each `WHEN` condition in the order specified until one returns true.
 - c. When a condition returns true, perform the following actions:
 - i. Perform any `BEFORE ROW` triggers that fire for the action's event type.
 - ii. Perform the specified action, invoking any check constraints on the target table.
 - iii. Perform any `AFTER ROW` triggers that fire for the action's event type.If the target relation is a view with `INSTEAD OF ROW` triggers for the action's event type, they are used to perform the action instead.
3. Perform any `AFTER STATEMENT` triggers for actions specified, whether or not they actually occur. This is similar to the behavior of an `UPDATE` statement that modifies no rows.

In summary, statement triggers for an event type (say, `INSERT`) will be fired whenever we *specify* an action of that kind. In contrast, row-level triggers will fire only for the specific event type being *executed*. So a `MERGE` command might fire statement triggers for both `UPDATE` and `INSERT`, even though only `UPDATE` row triggers were fired.

You should ensure that the join produces at most one candidate change row for each target row. In other words, a target row shouldn't join to more than one data source row. If it does, then only one of the candidate change rows will be used to modify the target row; later attempts to modify the row will

cause an error. This can also occur if row triggers make changes to the target table and the rows so modified are then subsequently also modified by `MERGE`. If the repeated action is an `INSERT`, this will cause a uniqueness violation, while a repeated `UPDATE` or `DELETE` will cause a cardinality violation; the latter behavior is required by the SQL standard. This differs from historical PostgreSQL behavior of joins in `UPDATE` and `DELETE` statements where second and subsequent attempts to modify the same row are simply ignored.

If a `WHEN` clause omits an `AND` sub-clause, it becomes the final reachable clause of that kind (`MATCHED`, `NOT MATCHED BY SOURCE`, or `NOT MATCHED [BY TARGET]`). If a later `WHEN` clause of that kind is specified it would be provably unreachable and an error is raised. If no final reachable clause is specified of either kind, it is possible that no action will be taken for a candidate change row.

The order in which rows are generated from the data source is indeterminate by default. A *source_query* can be used to specify a consistent ordering, if required, which might be needed to avoid deadlocks between concurrent transactions.

When `MERGE` is run concurrently with other commands that modify the target table, the usual transaction isolation rules apply; see [Section 13.2](#) for an explanation on the behavior at each isolation level. You may also wish to consider using `INSERT ... ON CONFLICT` as an alternative statement which offers the ability to run an `UPDATE` if a concurrent `INSERT` occurs. There are a variety of differences and restrictions between the two statement types and they are not interchangeable.

Examples

Perform maintenance on `customer_accounts` based upon new `recent_transactions`.

```
MERGE INTO customer_account ca
USING recent_transactions t
ON t.customer_id = ca.customer_id
WHEN MATCHED THEN
    UPDATE SET balance = balance + transaction_value
WHEN NOT MATCHED THEN
    INSERT (customer_id, balance)
    VALUES (t.customer_id, t.transaction_value);
```

Notice that this would be exactly equivalent to the following statement because the `MATCHED` result does not change during execution.

```
MERGE INTO customer_account ca
USING (SELECT customer_id, transaction_value FROM recent_transactions) AS t
ON t.customer_id = ca.customer_id
WHEN MATCHED THEN
    UPDATE SET balance = balance + transaction_value
WHEN NOT MATCHED THEN
    INSERT (customer_id, balance)
    VALUES (t.customer_id, t.transaction_value);
```

Attempt to insert a new stock item along with the quantity of stock. If the item already exists, instead update the stock count of the existing item. Don't allow entries that have zero stock. Return details of all changes made.

```
MERGE INTO wines w
USING wine_stock_changes s
ON s.wine_name = w.wine_name
WHEN NOT MATCHED AND s.stock_delta > 0 THEN
    INSERT VALUES(s.wine_name, s.stock_delta)
WHEN MATCHED AND w.stock + s.stock_delta > 0 THEN
    UPDATE SET stock = w.stock + s.stock_delta
WHEN MATCHED THEN
    DELETE
```

```
RETURNING merge_action(), w.*;
```

The `wine_stock_changes` table might be, for example, a temporary table recently loaded into the database.

Update `wines` based on a replacement wine list, inserting rows for any new stock, updating modified stock entries, and deleting any wines not present in the new list.

```
MERGE INTO wines w
USING new_wine_list s
ON s.wine_name = w.wine_name
WHEN NOT MATCHED BY TARGET THEN
    INSERT VALUES(s.wine_name, s.stock)
WHEN MATCHED AND w.stock != s.stock THEN
    UPDATE SET stock = s.stock
WHEN NOT MATCHED BY SOURCE THEN
    DELETE;
```

Compatibility

This command conforms to the SQL standard.

The `WITH` clause, `BY SOURCE` and `BY TARGET` qualifiers to `WHEN NOT MATCHED, DO NOTHING` action, and `RETURNING` clause are extensions to the SQL standard.

MOVE

MOVE — position a cursor

Synopsis

```
MOVE [ direction ] [ FROM | IN ] cursor_name
```

where *direction* can be one of:

```
NEXT
PRIOR
FIRST
LAST
ABSOLUTE count
RELATIVE count
count
ALL
FORWARD
FORWARD count
FORWARD ALL
BACKWARD
BACKWARD count
BACKWARD ALL
```

Description

MOVE repositions a cursor without retrieving any data. MOVE works exactly like the FETCH command, except it only positions the cursor and does not return rows.

The parameters for the MOVE command are identical to those of the FETCH command; refer to [FETCH](#) for details on syntax and usage.

Outputs

On successful completion, a MOVE command returns a command tag of the form

```
MOVE count
```

The *count* is the number of rows that a FETCH command with the same parameters would have returned (possibly zero).

Examples

```
BEGIN WORK;
DECLARE liahona CURSOR FOR SELECT * FROM films;

-- Skip the first 5 rows:
MOVE FORWARD 5 IN liahona;
MOVE 5

-- Fetch the 6th row from the cursor liahona:
FETCH 1 FROM liahona;
  code | title  | did | date_prod | kind  | len
-----+-----+-----+-----+-----+-----
  P_303 | 48 Hrs | 103 | 1982-10-22 | Action | 01:37
(1 row)
```

```
-- Close the cursor liahona and end the transaction:  
CLOSE liahona;  
COMMIT WORK;
```

Compatibility

There is no `MOVE` statement in the SQL standard.

NOTIFY

NOTIFY — generate a notification

Synopsis

```
NOTIFY channel [ , payload ]
```

Description

The `NOTIFY` command sends a notification event together with an optional “payload” string to each client application that has previously executed `LISTEN channel` for the specified channel name in the current database. Notifications are visible to all users.

`NOTIFY` provides a simple interprocess communication mechanism for a collection of processes accessing the same Postgres Pro database. A payload string can be sent along with the notification, and higher-level mechanisms for passing structured data can be built by using tables in the database to pass additional data from notifier to listener(s).

The information passed to the client for a notification event includes the notification channel name, the notifying session's server process PID, and the payload string, which is an empty string if it has not been specified.

It is up to the database designer to define the channel names that will be used in a given database and what each one means. Commonly, the channel name is the same as the name of some table in the database, and the notify event essentially means, “I changed this table, take a look at it to see what's new”. But no such association is enforced by the `NOTIFY` and `LISTEN` commands. For example, a database designer could use several different channel names to signal different sorts of changes to a single table. Alternatively, the payload string could be used to differentiate various cases.

When `NOTIFY` is used to signal the occurrence of changes to a particular table, a useful programming technique is to put the `NOTIFY` in a statement trigger that is triggered by table updates. In this way, notification happens automatically when the table is changed, and the application programmer cannot accidentally forget to do it.

`NOTIFY` interacts with SQL transactions in some important ways. Firstly, if a `NOTIFY` is executed inside a transaction, the notify events are not delivered until and unless the transaction is committed. This is appropriate, since if the transaction is aborted, all the commands within it have had no effect, including `NOTIFY`. But it can be disconcerting if one is expecting the notification events to be delivered immediately. Secondly, if a listening session receives a notification signal while it is within a transaction, the notification event will not be delivered to its connected client until just after the transaction is completed (either committed or aborted). Again, the reasoning is that if a notification were delivered within a transaction that was later aborted, one would want the notification to be undone somehow — but the server cannot “take back” a notification once it has sent it to the client. So notification events are only delivered between transactions. The upshot of this is that applications using `NOTIFY` for real-time signaling should try to keep their transactions short.

If the same channel name is signaled multiple times with identical payload strings within the same transaction, only one instance of the notification event is delivered to listeners. On the other hand, notifications with distinct payload strings will always be delivered as distinct notifications. Similarly, notifications from different transactions will never get folded into one notification. Except for dropping later instances of duplicate notifications, `NOTIFY` guarantees that notifications from the same transaction get delivered in the order they were sent. It is also guaranteed that messages from different transactions are delivered in the order in which the transactions committed.

It is common for a client that executes `NOTIFY` to be listening on the same notification channel itself. In that case it will get back a notification event, just like all the other listening sessions. Depending on the application logic, this could result in useless work, for example, reading a database table to find the

same updates that that session just wrote out. It is possible to avoid such extra work by noticing whether the notifying session's server process PID (supplied in the notification event message) is the same as one's own session's PID (available from `libpq`). When they are the same, the notification event is one's own work bouncing back, and can be ignored.

Parameters

channel

Name of the notification channel to be signaled (any identifier).

payload

The “payload” string to be communicated along with the notification. This must be specified as a simple string literal. In the default configuration it must be shorter than 8000 bytes. (If binary data or large amounts of information need to be communicated, it's best to put it in a database table and send the key of the record.)

Notes

There is a queue that holds notifications that have been sent but not yet processed by all listening sessions. If this queue becomes full, transactions calling `NOTIFY` will fail at commit. The queue is quite large (8GB in a standard installation) and should be sufficiently sized for almost every use case. However, no cleanup can take place if a session executes `LISTEN` and then enters a transaction for a very long time. Once the queue is half full you will see warnings in the log file pointing you to the session that is preventing cleanup. In this case you should make sure that this session ends its current transaction so that cleanup can proceed.

The function `pg_notification_queue_usage` returns the fraction of the queue that is currently occupied by pending notifications. See [Section 9.27](#) for more information.

A transaction that has executed `NOTIFY` cannot be prepared for two-phase commit.

pg_notify

To send a notification you can also use the function `pg_notify(text, text)`. The function takes the channel name as the first argument and the payload as the second. The function is much easier to use than the `NOTIFY` command if you need to work with non-constant channel names and payloads.

Examples

Configure and execute a listen/notify sequence from `psql`:

```
LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with PID 8448.
NOTIFY virtual, 'This is the payload';
Asynchronous notification "virtual" with payload "This is the payload" received from
server process with PID 8448.

LISTEN foo;
SELECT pg_notify('fo' || 'o', 'pay' || 'load');
Asynchronous notification "foo" with payload "payload" received from server process
with PID 14728.
```

Compatibility

There is no `NOTIFY` statement in the SQL standard.

PREPARE

PREPARE — prepare a statement for execution

Synopsis

```
PREPARE name [ ( data_type [, ...] ) ] AS statement
```

Description

PREPARE creates a prepared statement. A prepared statement is a server-side object that can be used to optimize performance. When the PREPARE statement is executed, the specified statement is parsed, analyzed, and rewritten. When an EXECUTE command is subsequently issued, the prepared statement is planned and executed. This division of labor avoids repetitive parse analysis work, while allowing the execution plan to depend on the specific parameter values supplied.

Prepared statements can take parameters: values that are substituted into the statement when it is executed. When creating the prepared statement, refer to parameters by position, using \$1, \$2, etc. A corresponding list of parameter data types can optionally be specified. When a parameter's data type is not specified or is declared as `unknown`, the type is inferred from the context in which the parameter is first referenced (if possible). When executing the statement, specify the actual values for these parameters in the EXECUTE statement. Refer to [EXECUTE](#) for more information about that.

Prepared statements only last for the duration of the current database session. When the session ends, the prepared statement is forgotten, so it must be recreated before being used again. This also means that a single prepared statement cannot be used by multiple simultaneous database clients; however, each client can create their own prepared statement to use. Prepared statements can be manually cleaned up using the [DEALLOCATE](#) command.

Prepared statements potentially have the largest performance advantage when a single session is being used to execute a large number of similar statements. The performance difference will be particularly significant if the statements are complex to plan or rewrite, e.g., if the query involves a join of many tables or requires the application of several rules. If the statement is relatively simple to plan and rewrite but relatively expensive to execute, the performance advantage of prepared statements will be less noticeable.

Parameters

name

An arbitrary name given to this particular prepared statement. It must be unique within a single session and is subsequently used to execute or deallocate a previously prepared statement.

data_type

The data type of a parameter to the prepared statement. If the data type of a particular parameter is unspecified or is specified as `unknown`, it will be inferred from the context in which the parameter is first referenced. To refer to the parameters in the prepared statement itself, use \$1, \$2, etc.

statement

Any SELECT, INSERT, UPDATE, DELETE, MERGE, or VALUES statement.

Notes

A prepared statement can be executed with either a *generic plan* or a *custom plan*. A generic plan is the same across all executions, while a custom plan is generated for a specific execution using the parameter values given in that call. Use of a generic plan avoids planning overhead, but in some situations a custom plan will be much more efficient to execute because the planner can make use of knowledge of the

parameter values. (Of course, if the prepared statement has no parameters, then this is moot and a generic plan is always used.)

By default (that is, when [plan_cache_mode](#) is set to `auto`), the server will automatically choose whether to use a generic or custom plan for a prepared statement that has parameters. The current rule for this is that the first five executions are done with custom plans and the average estimated cost of those plans is calculated. Then a generic plan is created and its estimated cost is compared to the average custom-plan cost. Subsequent executions use the generic plan if its cost is not so much higher than the average custom-plan cost as to make repeated replanning seem preferable.

This heuristic can be overridden, forcing the server to use either generic or custom plans, by setting `plan_cache_mode` to `force_generic_plan` or `force_custom_plan` respectively. This setting is primarily useful if the generic plan's cost estimate is badly off for some reason, allowing it to be chosen even though its actual cost is much more than that of a custom plan.

By default, generic plans for only 64 most recent prepared statements are kept in memory; older statements have to be parsed and analyzed again if they are called later. This limit is enforced by the [plan_cache_lru_size](#) configuration parameter, which enables you to control the amount of memory used by prepared statements. If you would like to keep plans in memory for all prepared statements as long as possible, set this parameter to 0.

To examine the query plan Postgres Pro is using for a prepared statement, use [EXPLAIN](#), for example

```
EXPLAIN EXECUTE name(parameter_values);
```

If a generic plan is in use, it will contain parameter symbols $\$n$, while a custom plan will have the supplied parameter values substituted into it.

For more information on query planning and the statistics collected by Postgres Pro for that purpose, see the [ANALYZE](#) documentation.

Although the main point of a prepared statement is to avoid repeated parse analysis and planning of the statement, Postgres Pro will force re-analysis and re-planning of the statement before using it whenever database objects used in the statement have undergone definitional (DDL) changes or their planner statistics have been updated since the previous use of the prepared statement. Also, if the value of [search_path](#) changes from one use to the next, the statement will be re-parsed using the new `search_path`. (This latter behavior is new as of PostgreSQL 9.3.) These rules make use of a prepared statement semantically almost equivalent to re-submitting the same query text over and over, but with a performance benefit if no object definitions are changed, especially if the best plan remains the same across uses. An example of a case where the semantic equivalence is not perfect is that if the statement refers to a table by an unqualified name, and then a new table of the same name is created in a schema appearing earlier in the `search_path`, no automatic re-parse will occur since no object used in the statement changed. However, if some other change forces a re-parse, the new table will be referenced in subsequent uses.

You can see all prepared statements available in the session by querying the [pg_prepared_statements](#) system view.

Examples

Create a prepared statement for an `INSERT` statement, and then execute it:

```
PREPARE fooplan (int, text, bool, numeric) AS
  INSERT INTO foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

Create a prepared statement for a `SELECT` statement, and then execute it:

```
PREPARE usrrptplan (int) AS
  SELECT * FROM users u, logs l WHERE u.usrid=$1 AND u.usrid=l.usrid
  AND l.date = $2;
```

```
EXECUTE usrrptplan(1, current_date);
```

In this example, the data type of the second parameter is not specified, so it is inferred from the context in which \$2 is used.

Compatibility

The SQL standard includes a `PREPARE` statement, but it is only for use in embedded SQL. This version of the `PREPARE` statement also uses a somewhat different syntax.

[DEALLOCATE](#), [EXECUTE](#)

PREPARE TRANSACTION

PREPARE TRANSACTION — prepare the current transaction for two-phase commit

Synopsis

```
PREPARE TRANSACTION transaction_id
```

Description

PREPARE TRANSACTION prepares the current transaction for two-phase commit. After this command, the transaction is no longer associated with the current session; instead, its state is fully stored on disk, and there is a very high probability that it can be committed successfully, even if a database crash occurs before the commit is requested.

Once prepared, a transaction can later be committed or rolled back with `COMMIT PREPARED` or `ROLLBACK PREPARED`, respectively. Those commands can be issued from any session, not only the one that executed the original transaction.

From the point of view of the issuing session, PREPARE TRANSACTION is not unlike a ROLLBACK command: after executing it, there is no active current transaction, and the effects of the prepared transaction are no longer visible. (The effects will become visible again if the transaction is committed.)

If the PREPARE TRANSACTION command fails for any reason, it becomes a ROLLBACK: the current transaction is canceled.

Parameters

transaction_id

An arbitrary identifier that later identifies this transaction for `COMMIT PREPARED` or `ROLLBACK PREPARED`. The identifier must be written as a string literal, and must be less than 200 bytes long. It must not be the same as the identifier used for any currently prepared transaction.

Notes

PREPARE TRANSACTION is not intended for use in applications or interactive sessions. Its purpose is to allow an external transaction manager to perform atomic global transactions across multiple databases or other transactional resources. Unless you're writing a transaction manager, you probably shouldn't be using PREPARE TRANSACTION.

This command must be used inside a transaction block. Use `BEGIN` to start one.

It is not currently allowed to PREPARE a transaction that has executed any operations involving temporary tables or the session's temporary namespace, created any cursors `WITH HOLD`, or executed `LISTEN`, `UNLISTEN`, or `NOTIFY`. Those features are too tightly tied to the current session to be useful in a transaction to be prepared.

If the transaction modified any run-time parameters with `SET` (without the `LOCAL` option), those effects persist after PREPARE TRANSACTION, and will not be affected by any later `COMMIT PREPARED` or `ROLLBACK PREPARED`. Thus, in this one respect PREPARE TRANSACTION acts more like `COMMIT` than `ROLLBACK`.

All currently available prepared transactions are listed in the `pg_prepared_xacts` system view.

Caution

It is unwise to leave transactions in the prepared state for a long time. This will interfere with the ability of `VACUUM` to reclaim storage. Keep in mind also that the transaction continues to hold

whatever locks it held. The intended usage of the feature is that a prepared transaction will normally be committed or rolled back as soon as an external transaction manager has verified that other databases are also prepared to commit.

If you have not set up an external transaction manager to track prepared transactions and ensure they get closed out promptly, it is best to keep the prepared-transaction feature disabled by setting [max_prepared_transactions](#) to zero. This will prevent accidental creation of prepared transactions that might then be forgotten and eventually cause problems.

Examples

Prepare the current transaction for two-phase commit, using `foobar` as the transaction identifier:

```
PREPARE TRANSACTION 'foobar';
```

Compatibility

`PREPARE TRANSACTION` is a Postgres Pro extension. It is intended for use by external transaction management systems, some of which are covered by standards (such as X/Open XA), but the SQL side of those systems is not standardized.

REASSIGN OWNED

REASSIGN OWNED — change the ownership of database objects owned by a database role

Synopsis

```
REASSIGN OWNED BY { old_role | CURRENT_ROLE | CURRENT_USER | SESSION_USER } [, ...]
                TO { new_role | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
```

Description

REASSIGN OWNED instructs the system to change the ownership of database objects owned by any of the *old_roles* to *new_role*.

Parameters

old_role

The name of a role. The ownership of all the objects within the current database, and of all shared objects (databases, tablespaces), owned by this role will be reassigned to *new_role*.

new_role

The name of the role that will be made the new owner of the affected objects.

Notes

REASSIGN OWNED is often used to prepare for the removal of one or more roles. Because REASSIGN OWNED does not affect objects within other databases, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

REASSIGN OWNED requires membership on both the source role(s) and the target role.

The [DROP OWNED](#) command is an alternative that simply drops all the database objects owned by one or more roles.

The REASSIGN OWNED command does not affect any privileges granted to the *old_roles* on objects that are not owned by them. Likewise, it does not affect default privileges created with ALTER DEFAULT PRIVILEGES. Use DROP OWNED to revoke such privileges.

See [Section 21.4](#) for more discussion.

Compatibility

The REASSIGN OWNED command is a Postgres Pro extension.

[DROP OWNED](#), [DROP ROLE](#), [ALTER DATABASE](#)

REFRESH MATERIALIZED VIEW

REFRESH MATERIALIZED VIEW — replace the contents of a materialized view

Synopsis

```
REFRESH MATERIALIZED VIEW [ CONCURRENTLY ] name
[ WITH [ NO ] DATA ]
```

Description

REFRESH MATERIALIZED VIEW completely replaces the contents of a materialized view. To execute this command you must have the `MAINTAIN` privilege on the materialized view. The old contents are discarded. If `WITH DATA` is specified (or defaults) the backing query is executed to provide the new data, and the materialized view is left in a scannable state. If `WITH NO DATA` is specified no new data is generated and the materialized view is left in an unscannable state.

`CONCURRENTLY` and `WITH NO DATA` may not be specified together.

Parameters

`CONCURRENTLY`

Refresh the materialized view without locking out concurrent selects on the materialized view. Without this option a refresh which affects a lot of rows will tend to use fewer resources and complete more quickly, but could block other connections which are trying to read from the materialized view. This option may be faster in cases where a small number of rows are affected.

This option is only allowed if there is at least one `UNIQUE` index on the materialized view which uses only column names and includes all rows; that is, it must not be an expression index or include a `WHERE` clause.

This option can only be used when the materialized view is already populated.

Even with this option only one `REFRESH` at a time may run against any one materialized view.

name

The name (optionally schema-qualified) of the materialized view to refresh.

Notes

If there is an `ORDER BY` clause in the materialized view's defining query, the original contents of the materialized view will be ordered that way; but `REFRESH MATERIALIZED VIEW` does not guarantee to preserve that ordering.

While `REFRESH MATERIALIZED VIEW` is running, the [search_path](#) is temporarily changed to `pg_catalog`, `pg_temp`.

Examples

This command will replace the contents of the materialized view called `order_summary` using the query from the materialized view's definition, and leave it in a scannable state:

```
REFRESH MATERIALIZED VIEW order_summary;
```

This command will free storage associated with the materialized view `annual_statistics_basis` and leave it in an unscannable state:

```
REFRESH MATERIALIZED VIEW annual_statistics_basis WITH NO DATA;
```

Compatibility

REFRESH MATERIALIZED VIEW is a Postgres Pro extension.

[CREATE MATERIALIZED VIEW](#), [ALTER MATERIALIZED VIEW](#), [DROP MATERIALIZED VIEW](#)

REINDEX

REINDEX — rebuild indexes

Synopsis

```
REINDEX [ ( option [, ...] ) ] { INDEX | TABLE | SCHEMA } [ CONCURRENTLY ] name
REINDEX [ ( option [, ...] ) ] { DATABASE | SYSTEM } [ CONCURRENTLY ] [ name ]
```

where *option* can be one of:

```
CONCURRENTLY [ boolean ]
TABLESPACE new_tablespace
VERBOSE [ boolean ]
```

Description

REINDEX rebuilds an index using the data stored in the index's table, replacing the old copy of the index. There are several scenarios in which to use **REINDEX**:

- An index has become corrupted, and no longer contains valid data. Although in theory this should never happen, in practice indexes can become corrupted due to software bugs or hardware failures. **REINDEX** provides a recovery method.
- An index has become “bloated”, that is it contains many empty or nearly-empty pages. This can occur with B-tree indexes in Postgres Pro under certain uncommon access patterns. **REINDEX** provides a way to reduce the space consumption of the index by writing a new version of the index without the dead pages. See [Section 24.3](#) for more information.
- You have altered a storage parameter (such as `fillfactor`) for an index, and wish to ensure that the change has taken full effect.
- If an index build fails with the `CONCURRENTLY` option, this index is left as “invalid”. Such indexes are useless but it can be convenient to use **REINDEX** to rebuild them. Note that only **REINDEX INDEX** is able to perform a concurrent build on an invalid index.

Parameters

INDEX

Recreate the specified index. This form of **REINDEX** cannot be executed inside a transaction block when used with a partitioned index.

TABLE

Recreate all indexes of the specified table. If the table has a secondary “TOAST” table, that is reindexed as well. This form of **REINDEX** cannot be executed inside a transaction block when used with a partitioned table.

SCHEMA

Recreate all indexes of the specified schema. If a table of this schema has a secondary “TOAST” table, that is reindexed as well. Indexes on shared system catalogs are also processed. This form of **REINDEX** cannot be executed inside a transaction block.

DATABASE

Recreate all indexes within the current database, except system catalogs. Indexes on system catalogs are not processed. This form of **REINDEX** cannot be executed inside a transaction block.

SYSTEM

Recreate all indexes on system catalogs within the current database. Indexes on shared system catalogs are included. Indexes on user tables are not processed. This form of `REINDEX` cannot be executed inside a transaction block.

name

The name of the specific index, table, or database to be reindexed. Index and table names can be schema-qualified. Presently, `REINDEX DATABASE` and `REINDEX SYSTEM` can only reindex the current database. Their parameter is optional, and it must match the current database's name.

CONCURRENTLY

When this option is used, Postgres Pro will rebuild the index without taking any locks that prevent concurrent inserts, updates, or deletes on the table; whereas a standard index rebuild locks out writes (but not reads) on the table until it's done. There are several caveats to be aware of when using this option — see [Rebuilding Indexes Concurrently](#) below.

For temporary tables, `REINDEX` is always non-concurrent, as no other session can access them, and non-concurrent reindex is cheaper.

TABLESPACE

Specifies that indexes will be rebuilt on a new tablespace.

VERBOSE

Prints a progress report as each index is reindexed.

boolean

Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to disable it. The *boolean* value can also be omitted, in which case `TRUE` is assumed.

new_tablespace

The tablespace where indexes will be rebuilt.

Notes

If you suspect corruption of an index on a user table, you can simply rebuild that index, or all indexes on the table, using `REINDEX INDEX` or `REINDEX TABLE`.

Things are more difficult if you need to recover from corruption of an index on a system table. In this case it's important for the system to not have used any of the suspect indexes itself. (Indeed, in this sort of scenario you might find that server processes are crashing immediately at start-up, due to reliance on the corrupted indexes.) To recover safely, the server must be started with the `-P` option, which prevents it from using indexes for system catalog lookups.

One way to do this is to shut down the server and start a single-user Postgres Pro server with the `-P` option included on its command line. Then, `REINDEX DATABASE`, `REINDEX SYSTEM`, `REINDEX TABLE`, or `REINDEX INDEX` can be issued, depending on how much you want to reconstruct. If in doubt, use `REINDEX SYSTEM` to select reconstruction of all system indexes in the database. Then quit the single-user server session and restart the regular server. See the [postgres](#) reference page for more information about how to interact with the single-user server interface.

Alternatively, a regular server session can be started with `-P` included in its command line options. The method for doing this varies across clients, but in all libpq-based clients, it is possible to set the `PGOPTIONS` environment variable to `-P` before starting the client. Note that while this method does not

require locking out other clients, it might still be wise to prevent other users from connecting to the damaged database until repairs have been completed.

`REINDEX` is similar to a drop and recreate of the index in that the index contents are rebuilt from scratch. However, the locking considerations are rather different. `REINDEX` locks out writes but not reads of the index's parent table. It also takes an `ACCESS EXCLUSIVE` lock on the specific index being processed, which will block reads that attempt to use that index. In particular, the query planner tries to take an `ACCESS SHARE` lock on every index of the table, regardless of the query, and so `REINDEX` blocks virtually any queries except for some prepared queries whose plan has been cached and which don't use this very index. In contrast, `DROP INDEX` momentarily takes an `ACCESS EXCLUSIVE` lock on the parent table, blocking both writes and reads. The subsequent `CREATE INDEX` locks out writes but not reads; since the index is not there, no read will attempt to use it, meaning that there will be no blocking but reads might be forced into expensive sequential scans.

While `REINDEX` is running, the [search_path](#) is temporarily changed to `pg_catalog, pg_temp`.

Reindexing a single index or table requires having the `MAINTAIN` privilege on the table. Note that while `REINDEX` on a partitioned index or table requires having the `MAINTAIN` privilege on the partitioned table, such commands skip the privilege checks when processing the individual partitions. Reindexing a schema or database requires being the owner of that schema or database or having privileges of the [pg_maintain](#) role. Note specifically that it's thus possible for non-superusers to rebuild indexes of tables owned by other users. However, as a special exception, `REINDEX DATABASE`, `REINDEX SCHEMA`, and `REINDEX SYSTEM` will skip indexes on shared catalogs unless the user has the `MAINTAIN` privilege on the catalog.

Reindexing partitioned indexes or partitioned tables is supported with `REINDEX INDEX` or `REINDEX TABLE`, respectively. Each partition of the specified partitioned relation is reindexed in a separate transaction. Those commands cannot be used inside a transaction block when working on a partitioned table or index.

When using the `TABLESPACE` clause with `REINDEX` on a partitioned index or table, only the tablespace references of the leaf partitions are updated. As partitioned indexes are not updated, it is recommended to separately use `ALTER TABLE ONLY` on them so as any new partitions attached inherit the new tablespace. On failure, it may not have moved all the indexes to the new tablespace. Re-running the command will rebuild all the leaf partitions and move previously-unprocessed indexes to the new tablespace.

If `SCHEMA`, `DATABASE` or `SYSTEM` is used with `TABLESPACE`, system relations are skipped and a single `WARNING` will be generated. Indexes on TOAST tables are rebuilt, but not moved to the new tablespace.

Rebuilding Indexes Concurrently

Rebuilding an index can interfere with regular operation of a database. Normally Postgres Pro locks the table whose index is rebuilt against writes and performs the entire index build with a single scan of the table. Other transactions can still read the table, but if they try to insert, update, or delete rows in the table they will block until the index rebuild is finished. This could have a severe effect if the system is a live production database. Very large tables can take many hours to be indexed, and even for smaller tables, an index rebuild can lock out writers for periods that are unacceptably long for a production system.

Postgres Pro supports rebuilding indexes with minimum locking of writes. This method is invoked by specifying the `CONCURRENTLY` option of `REINDEX`. When this option is used, Postgres Pro must perform two scans of the table for each index that needs to be rebuilt and wait for termination of all existing transactions that could potentially use the index. This method requires more total work than a standard index rebuild and takes significantly longer to complete as it needs to wait for unfinished transactions that might modify the index. However, since it allows normal operations to continue while the index is being rebuilt, this method is useful for rebuilding indexes in a production environment. Of course, the extra CPU, memory and I/O load imposed by the index rebuild may slow down other operations.

The following steps occur in a concurrent reindex. Each step is run in a separate transaction. If there are multiple indexes to be rebuilt, then each step loops through all the indexes before moving to the next step.

1. A new transient index definition is added to the catalog `pg_index`. This definition will be used to replace the old index. A `SHARE UPDATE EXCLUSIVE` lock at session level is taken on the indexes being reindexed as well as their associated tables to prevent any schema modification while processing.
2. A first pass to build the index is done for each new index. Once the index is built, its flag `pg_index.indisready` is switched to “true” to make it ready for inserts, making it visible to other sessions once the transaction that performed the build is finished. This step is done in a separate transaction for each index.
3. Then a second pass is performed to add tuples that were added while the first pass was running. This step is also done in a separate transaction for each index.
4. All the constraints that refer to the index are changed to refer to the new index definition, and the names of the indexes are changed. At this point, `pg_index.indisvalid` is switched to “true” for the new index and to “false” for the old, and a cache invalidation is done causing all sessions that referenced the old index to be invalidated.
5. The old indexes have `pg_index.indisready` switched to “false” to prevent any new tuple insertions, after waiting for running queries that might reference the old index to complete.
6. The old indexes are dropped. The `SHARE UPDATE EXCLUSIVE` session locks for the indexes and the table are released.

If a problem arises while rebuilding the indexes, such as a uniqueness violation in a unique index, the `REINDEX` command will fail but leave behind an “invalid” new index in addition to the pre-existing one. This index will be ignored for querying purposes because it might be incomplete; however it will still consume update overhead. The `psql \d` command will report such an index as `INVALID`:

```
postgres=# \d tab
           Table "public.tab"
  Column | Type   | Modifiers
-----+-----+-----
 col    | integer |
Indexes:
    "idx" btree (col)
    "idx_ccnew" btree (col) INVALID
```

If the index marked `INVALID` is suffixed `ccnew`, then it corresponds to the transient index created during the concurrent operation, and the recommended recovery method is to drop it using `DROP INDEX`, then attempt `REINDEX CONCURRENTLY` again. If the invalid index is instead suffixed `ccold`, it corresponds to the original index which could not be dropped; the recommended recovery method is to just drop said index, since the rebuild proper has been successful.

Regular index builds permit other regular index builds on the same table to occur simultaneously, but only one concurrent index build can occur on a table at a time. In both cases, no other types of schema modification on the table are allowed meanwhile. Another difference is that a regular `REINDEX TABLE` or `REINDEX INDEX` command can be performed within a transaction block, but `REINDEX CONCURRENTLY` cannot.

Like any long-running transaction, `REINDEX` on a table can affect which tuples can be removed by concurrent `VACUUM` on any other table.

`REINDEX SYSTEM` does not support `CONCURRENTLY` since system catalogs cannot be reindexed concurrently.

Furthermore, indexes for exclusion constraints cannot be reindexed concurrently. If such an index is named directly in this command, an error is raised. If a table or database with exclusion constraint indexes is reindexed concurrently, those indexes will be skipped. (It is possible to reindex such indexes without the `CONCURRENTLY` option.)

Each backend running `REINDEX` will report its progress in the `pg_stat_progress_create_index` view. See [Section 27.4.4](#) for details.

Examples

Rebuild a single index:

```
REINDEX INDEX my_index;
```

Rebuild all the indexes on the table `my_table`:

```
REINDEX TABLE my_table;
```

Rebuild all indexes in a particular database, without trusting the system indexes to be valid already:

```
$ export PGOPTIONS="-P"
```

```
$ psql broken_db
```

```
...
```

```
broken_db=> REINDEX DATABASE broken_db;
```

```
broken_db=> \q
```

Rebuild indexes for a table, without blocking read and write operations on involved relations while reindexing is in progress:

```
REINDEX TABLE CONCURRENTLY my_broken_table;
```

Compatibility

There is no `REINDEX` command in the SQL standard.

See Also

[CREATE INDEX](#), [DROP INDEX](#), [reindexdb](#), [Section 27.4.4](#)

RELEASE SAVEPOINT

RELEASE SAVEPOINT — release a previously defined savepoint

Synopsis

```
RELEASE [ SAVEPOINT ] savepoint_name
```

Description

RELEASE SAVEPOINT releases the named savepoint and all active savepoints that were created after the named savepoint, and frees their resources. All changes made since the creation of the savepoint that didn't already get rolled back are merged into the transaction or savepoint that was active when the named savepoint was created. Changes made after RELEASE SAVEPOINT will also be part of this active transaction or savepoint.

Parameters

savepoint_name

The name of the savepoint to release.

Notes

Specifying a savepoint name that was not previously defined is an error.

It is not possible to release a savepoint when the transaction is in an aborted state; to do that, use [ROLLBACK TO SAVEPOINT](#).

If multiple savepoints have the same name, only the most recently defined unreleased one is released. Repeated commands will release progressively older savepoints.

Examples

To establish and later release a savepoint:

```
BEGIN;  
  INSERT INTO table1 VALUES (3);  
  SAVEPOINT my_savepoint;  
  INSERT INTO table1 VALUES (4);  
  RELEASE SAVEPOINT my_savepoint;  
COMMIT;
```

The above transaction will insert both 3 and 4.

A more complex example with multiple nested subtransactions:

```
BEGIN;  
  INSERT INTO table1 VALUES (1);  
  SAVEPOINT sp1;  
  INSERT INTO table1 VALUES (2);  
  SAVEPOINT sp2;  
  INSERT INTO table1 VALUES (3);  
  RELEASE SAVEPOINT sp2;  
  INSERT INTO table1 VALUES (4)); -- generates an error
```

In this example, the application requests the release of the savepoint `sp2`, which inserted 3. This changes the insert's transaction context to `sp1`. When the statement attempting to insert value 4 generates an error, the insertion of 2 and 4 are lost because they are in the same, now-rolled back savepoint, and value 3 is in the same transaction context. The application can now only choose one of these two commands, since all other commands will be ignored:

```
ROLLBACK;  
ROLLBACK TO SAVEPOINT sp1;
```

Choosing `ROLLBACK` will abort everything, including value 1, whereas `ROLLBACK TO SAVEPOINT sp1` will retain value 1 and allow the transaction to continue.

Compatibility

This command conforms to the SQL standard. The standard specifies that the key word `SAVEPOINT` is mandatory, but Postgres Pro allows it to be omitted.

RESET

RESET — restore the value of a run-time parameter to the default value

Synopsis

```
RESET configuration_parameter
RESET ALL
```

Description

RESET restores run-time parameters to their default values. RESET is an alternative spelling for

```
SET configuration_parameter TO DEFAULT
```

Refer to [SET](#) for details.

The default value is defined as the value that the parameter would have had, if no SET had ever been issued for it in the current session. The actual source of this value might be a compiled-in default, the configuration file, command-line options, or per-database or per-user default settings. This is subtly different from defining it as “the value that the parameter had at session start”, because if the value came from the configuration file, it will be reset to whatever is specified by the configuration file now. See [Chapter 19](#) for details.

The transactional behavior of RESET is the same as SET: its effects will be undone by transaction rollback.

Parameters

configuration_parameter

Name of a settable run-time parameter. Available parameters are documented in [Chapter 19](#) and on the [SET](#) reference page.

ALL

Resets all settable run-time parameters to default values.

Examples

Set the `timezone` configuration variable to its default value:

```
RESET timezone;
```

Compatibility

RESET is a Postgres Pro extension.

```

```
REVOKE [ { ADMIN | INHERIT | SET } OPTION FOR ]
role_name [, ...] FROM role_specification [, ...]
[ GRANTED BY role_specification ]
```

```
[ CASCADE | RESTRICT ]
```

where *role_specification* can be:

```
[ GROUP ] role_name  
| PUBLIC  
| CURRENT_ROLE  
| CURRENT_USER  
| SESSION_USER
```

Description

The **REVOKE** command revokes previously granted privileges from one or more roles. The key word **PUBLIC** refers to the implicitly defined group of all roles.

See the description of the **GRANT** command for the meaning of the privilege types.

Note that any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to **PUBLIC**. Thus, for example, revoking **SELECT** privilege from **PUBLIC** does not necessarily mean that all roles have lost **SELECT** privilege on the object: those who have it granted directly or via another role will still have it. Similarly, revoking **SELECT** from a user might not prevent that user from using **SELECT** if **PUBLIC** or another membership role still has **SELECT** rights.

If **GRANT OPTION FOR** is specified, only the grant option for the privilege is revoked, not the privilege itself. Otherwise, both the privilege and the grant option are revoked.

If a user holds a privilege with grant option and has granted it to other users then the privileges held by those other users are called dependent privileges. If the privilege or the grant option held by the first user is being revoked and dependent privileges exist, those dependent privileges are also revoked if **CASCADE** is specified; if it is not, the revoke action will fail. This recursive revocation only affects privileges that were granted through a chain of users that is traceable to the user that is the subject of this **REVOKE** command. Thus, the affected users might effectively keep the privilege if it was also granted through other users.

When revoking privileges on a table, the corresponding column privileges (if any) are automatically revoked on each column of the table, as well. On the other hand, if a role has been granted privileges on a table, then revoking the same privileges from individual columns will have no effect.

When revoking membership in a role, **GRANT OPTION** is instead called **ADMIN OPTION**, but the behavior is similar. Note that, in releases prior to Postgres Pro 16, dependent privileges were not tracked for grants of role membership, and thus **CASCADE** had no effect for role membership. This is no longer the case. Note also that this form of the command does not allow the noise word **GROUP** in *role_specification*.

Just as **ADMIN OPTION** can be removed from an existing role grant, it is also possible to revoke **INHERIT OPTION** or **SET OPTION**. This is equivalent to setting the value of the corresponding option to **FALSE**.

Notes

A user can only revoke privileges that were granted directly by that user. If, for example, user A has granted a privilege with grant option to user B, and user B has in turn granted it to user C, then user A cannot revoke the privilege directly from C. Instead, user A could revoke the grant option from user B and use the **CASCADE** option so that the privilege is in turn revoked from user C. For another example, if both A and B have granted the same privilege to C, A can revoke their own grant but not B's grant, so C will still effectively have the privilege.

When a non-owner of an object attempts to **REVOKE** privileges on the object, the command will fail outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command will proceed, but it will revoke only those privileges for which the user has grant options. The

`REVOKE ALL PRIVILEGES` forms will issue a warning message if no grant options are held, while the other forms will issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since the owner is always treated as holding all grant options, the cases can never occur.)

If a superuser chooses to issue a `GRANT` or `REVOKE` command, the command is performed as though it were issued by the owner of the affected object. (Since roles do not have owners, in the case of a `GRANT` of role membership, the command is performed as though it were issued by the bootstrap superuser.) Since all privileges ultimately come from the object owner (possibly indirectly via chains of grant options), it is possible for a superuser to revoke all privileges, but this might require use of `CASCADE` as stated above.

`REVOKE` can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges `WITH GRANT OPTION` on the object. In this case the command is performed as though it were issued by the containing role that actually owns the object or holds the privileges `WITH GRANT OPTION`. For example, if table `t1` is owned by role `g1`, of which role `u1` is a member, then `u1` can revoke privileges on `t1` that are recorded as being granted by `g1`. This would include grants made by `u1` as well as by other members of role `g1`.

If the role executing `REVOKE` holds privileges indirectly via more than one role membership path, it is unspecified which containing role will be used to perform the command. In such cases it is best practice to use `SET ROLE` to become the specific role you want to do the `REVOKE` as. Failure to do so might lead to revoking privileges other than the ones you intended, or not revoking anything at all.

See [Section 5.8](#) for more information about specific privilege types, as well as how to inspect objects' privileges.

Examples

Revoke insert privilege for the public on table `films`:

```
REVOKE INSERT ON films FROM PUBLIC;
```

Revoke all privileges from user `manuel` on view `kinds`:

```
REVOKE ALL PRIVILEGES ON kinds FROM manuel;
```

Note that this actually means “revoke all privileges that I granted”.

Revoke membership in role `admins` from user `joe`:

```
REVOKE admins FROM joe;
```

Compatibility

The compatibility notes of the [GRANT](#) command apply analogously to `REVOKE`. The keyword `RESTRICT` or `CASCADE` is required according to the standard, but Postgres Pro assumes `RESTRICT` by default.

[GRANT](#), [ALTER DEFAULT PRIVILEGES](#)

ROLLBACK

ROLLBACK — abort the current transaction

Synopsis

```
ROLLBACK [ AUTONOMOUS ] [ WORK | TRANSACTION ] [ AND [ NO ] CHAIN ]
```

Description

ROLLBACK rolls back the current transaction and causes all the updates made by the transaction to be discarded.

Parameters

AUTONOMOUS

Optional key word that can be used when aborting an autonomous transaction. For details on autonomous transactions, see [Chapter 16](#).

WORK

TRANSACTION

Optional key words. They have no effect.

AND CHAIN

If AND CHAIN is specified, a new (not aborted) transaction is immediately started with the same transaction characteristics (see [SET TRANSACTION](#)) as the just finished one. Otherwise, no new transaction is started.

Notes

Use [COMMIT](#) to successfully terminate a transaction.

Issuing ROLLBACK outside of a transaction block emits a warning and otherwise has no effect. ROLLBACK AND CHAIN outside of a transaction block is an error.

Examples

To abort all changes:

```
ROLLBACK;
```

Compatibility

The command ROLLBACK conforms to the SQL standard. The form ROLLBACK TRANSACTION is a Postgres Pro extension.

See Also

[BEGIN](#), [COMMIT](#), [ROLLBACK TO SAVEPOINT](#)

ROLLBACK PREPARED

ROLLBACK PREPARED — cancel a transaction that was earlier prepared for two-phase commit

Synopsis

```
ROLLBACK PREPARED transaction_id
```

Description

ROLLBACK PREPARED rolls back a transaction that is in prepared state.

Parameters

transaction_id

The transaction identifier of the transaction that is to be rolled back.

Notes

To roll back a prepared transaction, you must be either the same user that executed the transaction originally, or a superuser. But you do not have to be in the same session that executed the transaction.

This command cannot be executed inside a transaction block. The prepared transaction is rolled back immediately.

All currently available prepared transactions are listed in the [pg_prepared_xacts](#) system view.

Examples

Roll back the transaction identified by the transaction identifier `foobar`:

```
ROLLBACK PREPARED 'foobar';
```

Compatibility

ROLLBACK PREPARED is a Postgres Pro extension. It is intended for use by external transaction management systems, some of which are covered by standards (such as X/Open XA), but the SQL side of those systems is not standardized.

See Also

[PREPARE TRANSACTION](#), [COMMIT PREPARED](#)

ROLLBACK TO SAVEPOINT

ROLLBACK TO SAVEPOINT — roll back to a savepoint

Synopsis

```
ROLLBACK [ WORK | TRANSACTION ] TO [ SAVEPOINT ] savepoint_name
```

Description

Roll back all commands that were executed after the savepoint was established and then start a new subtransaction at the same transaction level. The savepoint remains valid and can be rolled back to again later, if needed.

ROLLBACK TO SAVEPOINT implicitly destroys all savepoints that were established after the named savepoint.

Parameters

savepoint_name

The savepoint to roll back to.

Notes

Use [RELEASE SAVEPOINT](#) to destroy a savepoint without discarding the effects of commands executed after it was established.

Specifying a savepoint name that has not been established is an error.

Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is affected by a `FETCH` or `MOVE` command inside a savepoint that is later rolled back, the cursor remains at the position that `FETCH` left it pointing to (that is, the cursor motion caused by `FETCH` is not rolled back). Closing a cursor is not undone by rolling back, either. However, other side-effects caused by the cursor's query (such as side-effects of volatile functions called by the query) *are* rolled back if they occur during a savepoint that is later rolled back. A cursor whose execution causes a transaction to abort is put in a cannot-execute state, so while the transaction can be restored using `ROLLBACK TO SAVEPOINT`, the cursor can no longer be used.

Examples

To undo the effects of the commands executed after `my_savepoint` was established:

```
ROLLBACK TO SAVEPOINT my_savepoint;
```

Cursor positions are not affected by savepoint rollback:

```
BEGIN;

DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;

SAVEPOINT foo;

FETCH 1 FROM foo;
  ?column?
-----
         1

ROLLBACK TO SAVEPOINT foo;
```

```
FETCH 1 FROM foo;  
?column?  
-----  
2
```

```
COMMIT;
```

Compatibility

The SQL standard specifies that the key word `SAVEPOINT` is mandatory, but Postgres Pro and Oracle allow it to be omitted. SQL allows only `WORK`, not `TRANSACTION`, as a noise word after `ROLLBACK`. Also, SQL has an optional clause `AND [NO] CHAIN` which is not currently supported by Postgres Pro. Otherwise, this command conforms to the SQL standard.

See Also

[BEGIN](#), [COMMIT](#), [RELEASE SAVEPOINT](#), [ROLLBACK](#), [SAVEPOINT](#)

SAVEPOINT

SAVEPOINT — define a new savepoint within the current transaction

Synopsis

```
SAVEPOINT savepoint_name
```

Description

SAVEPOINT establishes a new savepoint within the current transaction.

A savepoint is a special mark inside a transaction that allows all commands that are executed after it was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint.

Parameters

savepoint_name

The name to give to the new savepoint. If savepoints with the same name already exist, they will be inaccessible until newer identically-named savepoints are released.

Notes

Use `ROLLBACK TO` to rollback to a savepoint. Use `RELEASE SAVEPOINT` to destroy a savepoint, keeping the effects of commands executed after it was established.

Savepoints can only be established when inside a transaction block. There can be multiple savepoints defined within a transaction.

Examples

To establish a savepoint and later undo the effects of all commands executed after it was established:

```
BEGIN;  
  INSERT INTO table1 VALUES (1);  
  SAVEPOINT my_savepoint;  
  INSERT INTO table1 VALUES (2);  
  ROLLBACK TO SAVEPOINT my_savepoint;  
  INSERT INTO table1 VALUES (3);  
COMMIT;
```

The above transaction will insert the values 1 and 3, but not 2.

To establish and later destroy a savepoint:

```
BEGIN;  
  INSERT INTO table1 VALUES (3);  
  SAVEPOINT my_savepoint;  
  INSERT INTO table1 VALUES (4);  
  RELEASE SAVEPOINT my_savepoint;  
COMMIT;
```

The above transaction will insert both 3 and 4.

To use a single savepoint name:

```
BEGIN;  
  INSERT INTO table1 VALUES (1);  
  SAVEPOINT my_savepoint;  
  INSERT INTO table1 VALUES (2);
```

```
SAVEPOINT my_savepoint;
INSERT INTO table1 VALUES (3);

-- rollback to the second savepoint
ROLLBACK TO SAVEPOINT my_savepoint;
SELECT * FROM table1;           -- shows rows 1 and 2

-- release the second savepoint
RELEASE SAVEPOINT my_savepoint;

-- rollback to the first savepoint
ROLLBACK TO SAVEPOINT my_savepoint;
SELECT * FROM table1;           -- shows only row 1
COMMIT;
```

The above transaction shows row 3 being rolled back first, then row 2.

Compatibility

SQL requires a savepoint to be destroyed automatically when another savepoint with the same name is established. In Postgres Pro, the old savepoint is kept, though only the more recent one will be used when rolling back or releasing. (Releasing the newer savepoint with `RELEASE SAVEPOINT` will cause the older one to again become accessible to `ROLLBACK TO SAVEPOINT` and `RELEASE SAVEPOINT`.) Otherwise, `SAVEPOINT` is fully SQL conforming.

See Also

[BEGIN](#), [COMMIT](#), [RELEASE SAVEPOINT](#), [ROLLBACK](#), [ROLLBACK TO SAVEPOINT](#)

SECURITY LABEL

SECURITY LABEL — define or change a security label applied to an object

Synopsis

```
SECURITY LABEL [ FOR provider ] ON
{
    TABLE object_name |
    COLUMN table_name.column_name |
    AGGREGATE aggregate_name ( aggregate_signature ) |
    DATABASE object_name |
    DOMAIN object_name |
    EVENT TRIGGER object_name |
    FOREIGN TABLE object_name |
    FUNCTION function_name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ] |
    LARGE OBJECT large_object_oid |
    MATERIALIZED VIEW object_name |
    [ PROCEDURAL ] LANGUAGE object_name |
    PROCEDURE procedure_name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ] |
    PUBLICATION object_name |
    PROFILE object_name |
    ROLE object_name |
    ROUTINE routine_name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ] |
    SCHEMA object_name |
    SEQUENCE object_name |
    SUBSCRIPTION object_name |
    TABLESPACE object_name |
    TYPE object_name |
    VIEW object_name
} IS { string_literal | NULL }

where aggregate_signature is:

* |
[ argmode ] [ argname ] argtype [ , ... ] |
[ [ argmode ] [ argname ] argtype [ , ... ] ] ORDER BY [ argmode ] [ argname ] argtype
[ , ... ]
```

Description

SECURITY LABEL applies a security label to a database object. An arbitrary number of security labels, one per label provider, can be associated with a given database object. Label providers are loadable modules which register themselves by using the function `register_label_provider`.

Note

`register_label_provider` is not an SQL function; it can only be called from C code loaded into the backend.

The label provider determines whether a given label is valid and whether it is permissible to assign that label to a given object. The meaning of a given label is likewise at the discretion of the label provider. Postgres Pro places no restrictions on whether or how a label provider must interpret security labels; it merely provides a mechanism for storing them. In practice, this facility is intended to allow integration with label-based mandatory access control (MAC) systems such as SELinux. Such systems make all

access control decisions based on object labels, rather than traditional discretionary access control (DAC) concepts such as users and groups.

Parameters

object_name
table_name.column_name
aggregate_name
function_name
procedure_name
routine_name

The name of the object to be labeled. Names of objects that reside in schemas (tables, functions, etc.) can be schema-qualified.

provider

The name of the provider with which this label is to be associated. The named provider must be loaded and must consent to the proposed labeling operation. If exactly one provider is loaded, the provider name may be omitted for brevity.

argmode

The mode of a function, procedure, or aggregate argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that SECURITY LABEL does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

argname

The name of a function, procedure, or aggregate argument. Note that SECURITY LABEL does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype

The data type of a function, procedure, or aggregate argument.

large_object_oid

The OID of the large object.

PROCEDURAL

This is a noise word.

string_literal

The new setting of the security label, written as a string literal.

NULL

Write NULL to drop the security label.

Examples

The following example shows how the security label of a table could be set or changed:

```
SECURITY LABEL FOR selinux ON TABLE mytable IS 'system_u:object_r:sepgsql_table_t:s0';
```

To remove the label:

```
SECURITY LABEL FOR selinux ON TABLE mytable IS NULL;
```

Compatibility

There is no SECURITY LABEL command in the SQL standard.

SELECT

SELECT, TABLE, WITH — retrieve rows from a table or view

Synopsis

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
SELECT [ ALL | DISTINCT [ ON ( expression [, ...] ) ] ]
    [ { * | expression [ [ AS ] output_name ] } [, ...] ]
    [ FROM from_item [, ...] ]
    [ WHERE condition ]
    [ GROUP BY [ ALL | DISTINCT ] grouping_element [, ...] ]
    [ HAVING condition ]
    [ WINDOW window_name AS ( window_definition ) [, ...] ]
    [ { UNION | INTERSECT | EXCEPT } [ ALL | DISTINCT ] select ]
    [ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ]
[, ...] ]
    [ LIMIT { count | ALL } ]
    [ OFFSET start [ ROW | ROWS ] ]
    [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH TIES } ]
    [ FOR { UPDATE | NO KEY UPDATE | SHARE | KEY SHARE } [ OF from_reference [, ...] ]
[ NOWAIT | SKIP LOCKED ] [...]
```

where *from_item* can be one of:

```
    [ ONLY ] table_name [ * ] [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
        [ TABLESAMPLE sampling_method ( argument [, ...] ) [ REPEATABLE ( seed
) ] ]
    [ LATERAL ] ( select ) [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
    with_query_name [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
    [ LATERAL ] function_name ( [ argument [, ...] ] )
        [ WITH ORDINALITY ] [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
    [ LATERAL ] function_name ( [ argument [, ...] ] ) [ AS ] alias ( column_definition
[, ...] )
    [ LATERAL ] function_name ( [ argument [, ...] ] ) AS ( column_definition [, ...] )
    [ LATERAL ] ROWS FROM( function_name ( [ argument [, ...] ] ) [ AS
( column_definition [, ...] ) ] [, ...] )
        [ WITH ORDINALITY ] [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
    from_item join_type from_item { ON join_condition | USING ( join_column [, ...] )
[ AS join_using_alias ] }
    from_item NATURAL join_type from_item
    from_item CROSS JOIN from_item
```

and *grouping_element* can be one of:

```
( )
expression
( expression [, ...] )
ROLLUP ( { expression | ( expression [, ...] ) } [, ...] )
CUBE ( { expression | ( expression [, ...] ) } [, ...] )
GROUPING SETS ( grouping_element [, ...] )
```

and *with_query* is:

```
    with_query_name [ ( column_name [, ...] ) ] AS [ [ NOT ] MATERIALIZED ] ( select
| values | insert | update | delete | merge )
```

```
[ SEARCH { BREADTH | DEPTH } FIRST BY column_name [, ...]
SET search_seq_col_name ]
[ CYCLE column_name [, ...] SET cycle_mark_col_name [ TO cycle_mark_value
DEFAULT cycle_mark_default ] USING cycle_path_col_name ]

TABLE [ ONLY ] table_name [ * ]
```

Description

SELECT retrieves rows from zero or more tables. The general processing of SELECT is as follows:

1. All queries in the WITH list are computed. These effectively serve as temporary tables that can be referenced in the FROM list. A WITH query that is referenced more than once in FROM is computed only once, unless specified otherwise with NOT MATERIALIZED. (See [WITH Clause](#) below.)
2. All elements in the FROM list are computed. (Each element in the FROM list is a real or virtual table.) If more than one element is specified in the FROM list, they are cross-joined together. (See [FROM Clause](#) below.)
3. If the WHERE clause is specified, all rows that do not satisfy the condition are eliminated from the output. (See [WHERE Clause](#) below.)
4. If the GROUP BY clause is specified, or if there are aggregate function calls, the output is combined into groups of rows that match on one or more values, and the results of aggregate functions are computed. If the HAVING clause is present, it eliminates groups that do not satisfy the given condition. (See [GROUP BY Clause](#) and [HAVING Clause](#) below.) Although query output columns are nominally computed in the next step, they can also be referenced (by name or ordinal number) in the GROUP BY clause.
5. The actual output rows are computed using the SELECT output expressions for each selected row or row group. (See [SELECT List](#) below.)
6. SELECT DISTINCT eliminates duplicate rows from the result. SELECT DISTINCT ON eliminates rows that match on all the specified expressions. SELECT ALL (the default) will return all candidate rows, including duplicates. (See [DISTINCT Clause](#) below.)
7. Using the operators UNION, INTERSECT, and EXCEPT, the output of more than one SELECT statement can be combined to form a single result set. The UNION operator returns all rows that are in one or both of the result sets. The INTERSECT operator returns all rows that are strictly in both result sets. The EXCEPT operator returns the rows that are in the first result set but not in the second. In all three cases, duplicate rows are eliminated unless ALL is specified. The noise word DISTINCT can be added to explicitly specify eliminating duplicate rows. Notice that DISTINCT is the default behavior here, even though ALL is the default for SELECT itself. (See [UNION Clause](#), [INTERSECT Clause](#), and [EXCEPT Clause](#) below.)
8. If the ORDER BY clause is specified, the returned rows are sorted in the specified order. If ORDER BY is not given, the rows are returned in whatever order the system finds fastest to produce. (See [ORDER BY Clause](#) below.)
9. If the LIMIT (or FETCH FIRST) or OFFSET clause is specified, the SELECT statement only returns a subset of the result rows. (See [LIMIT Clause](#) below.)
10. If FOR UPDATE, FOR NO KEY UPDATE, FOR SHARE or FOR KEY SHARE is specified, the SELECT statement locks the selected rows against concurrent updates. (See [The Locking Clause](#) below.)

You must have SELECT privilege on each column used in a SELECT command. The use of FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE or FOR KEY SHARE requires UPDATE privilege as well (for at least one column of each table so selected).

Parameters

WITH Clause

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the primary query. The subqueries effectively act as temporary tables or views for the duration of the primary

query. Each subquery can be a `SELECT`, `TABLE`, `VALUES`, `INSERT`, `UPDATE`, `DELETE`, or `MERGE` statement. When writing a data-modifying statement (`INSERT`, `UPDATE`, `DELETE`, or `MERGE`) in `WITH`, it is usual to include a `RETURNING` clause. It is the output of `RETURNING`, *not* the underlying table that the statement modifies, that forms the temporary table that is read by the primary query. If `RETURNING` is omitted, the statement is still executed, but it produces no output so it cannot be referenced as a table by the primary query.

A name (without schema qualification) must be specified for each `WITH` query. Optionally, a list of column names can be specified; if this is omitted, the column names are inferred from the subquery.

If `RECURSIVE` is specified, it allows a `SELECT` subquery to reference itself by name. Such a subquery must have the form

```
non_recursive_term UNION [ ALL | DISTINCT ] recursive_term
```

where the recursive self-reference must appear on the right-hand side of the `UNION`. Only one recursive self-reference is permitted per query. Recursive data-modifying statements are not supported, but you can use the results of a recursive `SELECT` query in a data-modifying statement. See [Section 7.8](#) for an example.

Another effect of `RECURSIVE` is that `WITH` queries need not be ordered: a query can reference another one that is later in the list. (However, circular references, or mutual recursion, are not implemented.) Without `RECURSIVE`, `WITH` queries can only reference sibling `WITH` queries that are earlier in the `WITH` list.

When there are multiple queries in the `WITH` clause, `RECURSIVE` should be written only once, immediately after `WITH`. It applies to all queries in the `WITH` clause, though it has no effect on queries that do not use recursion or forward references.

The optional `SEARCH` clause computes a *search sequence column* that can be used for ordering the results of a recursive query in either breadth-first or depth-first order. The supplied column name list specifies the row key that is to be used for keeping track of visited rows. A column named `search_seq_col_name` will be added to the result column list of the `WITH` query. This column can be ordered by in the outer query to achieve the respective ordering. See [Section 7.8.2.1](#) for examples.

The optional `CYCLE` clause is used to detect cycles in recursive queries. The supplied column name list specifies the row key that is to be used for keeping track of visited rows. A column named `cycle_mark_col_name` will be added to the result column list of the `WITH` query. This column will be set to `cycle_mark_value` when a cycle has been detected, else to `cycle_mark_default`. Furthermore, processing of the recursive union will stop when a cycle has been detected. `cycle_mark_value` and `cycle_mark_default` must be constants and they must be coercible to a common data type, and the data type must have an inequality operator. (The SQL standard requires that they be Boolean constants or character strings, but Postgres Pro does not require that.) By default, `TRUE` and `FALSE` (of type `boolean`) are used. Furthermore, a column named `cycle_path_col_name` will be added to the result column list of the `WITH` query. This column is used internally for tracking visited rows. See [Section 7.8.2.2](#) for examples.

Both the `SEARCH` and the `CYCLE` clause are only valid for recursive `WITH` queries. The `with_query` must be a `UNION` (or `UNION ALL`) of two `SELECT` (or equivalent) commands (no nested `UNIONS`). If both clauses are used, the column added by the `SEARCH` clause appears before the columns added by the `CYCLE` clause.

The primary query and the `WITH` queries are all (notionally) executed at the same time. This implies that the effects of a data-modifying statement in `WITH` cannot be seen from other parts of the query, other than by reading its `RETURNING` output. If two such data-modifying statements attempt to modify the same row, the results are unspecified.

A key property of `WITH` queries is that they are normally evaluated only once per execution of the primary query, even if the primary query refers to them more than once. In particular, data-modifying statements are guaranteed to be executed once and only once, regardless of whether the primary query reads all or any of their output.

However, a `WITH` query can be marked `NOT MATERIALIZED` to remove this guarantee. In that case, the `WITH` query can be folded into the primary query much as though it were a simple sub-`SELECT` in the

primary query's `FROM` clause. This results in duplicate computations if the primary query refers to that `WITH` query more than once; but if each such use requires only a few rows of the `WITH` query's total output, `NOT MATERIALIZED` can provide a net savings by allowing the queries to be optimized jointly. `NOT MATERIALIZED` is ignored if it is attached to a `WITH` query that is recursive or is not side-effect-free (i.e., is not a plain `SELECT` containing no volatile functions).

By default, a side-effect-free `WITH` query is folded into the primary query if it is used exactly once in the primary query's `FROM` clause. This allows joint optimization of the two query levels in situations where that should be semantically invisible. However, such folding can be prevented by marking the `WITH` query as `MATERIALIZED`. That might be useful, for example, if the `WITH` query is being used as an optimization fence to prevent the planner from choosing a bad plan. Postgres Pro versions before v12 never did such folding, so queries written for older versions might rely on `WITH` to act as an optimization fence.

See [Section 7.8](#) for additional information.

FROM Clause

The `FROM` clause specifies one or more source tables for the `SELECT`. If multiple sources are specified, the result is the Cartesian product (cross join) of all the sources. But usually qualification conditions are added (via `WHERE`) to restrict the returned rows to a small subset of the Cartesian product.

The `FROM` clause can contain the following elements:

table_name

The name (optionally schema-qualified) of an existing table or view. If `ONLY` is specified before the table name, only that table is scanned. If `ONLY` is not specified, the table and all its descendant tables (if any) are scanned. Optionally, `*` can be specified after the table name to explicitly indicate that descendant tables are included.

alias

A substitute name for the `FROM` item containing the alias. An alias is used for brevity or to eliminate ambiguity for self-joins (where the same table is scanned multiple times). When an alias is provided, it completely hides the actual name of the table or function; for example given `FROM foo AS f`, the remainder of the `SELECT` must refer to this `FROM` item as `f` not `foo`. If an alias is written, a column alias list can also be written to provide substitute names for one or more columns of the table.

`TABLESAMPLE sampling_method (argument [, ...]) [REPEATABLE (seed)]`

A `TABLESAMPLE` clause after a *table_name* indicates that the specified *sampling_method* should be used to retrieve a subset of the rows in that table. This sampling precedes the application of any other filters such as `WHERE` clauses. The standard Postgres Pro distribution includes two sampling methods, `BERNOULLI` and `SYSTEM`, and other sampling methods can be installed in the database via extensions.

The `BERNOULLI` and `SYSTEM` sampling methods each accept a single *argument* which is the fraction of the table to sample, expressed as a percentage between 0 and 100. This argument can be any real-valued expression. (Other sampling methods might accept more or different arguments.) These two methods each return a randomly-chosen sample of the table that will contain approximately the specified percentage of the table's rows. The `BERNOULLI` method scans the whole table and selects or ignores individual rows independently with the specified probability. The `SYSTEM` method does block-level sampling with each block having the specified chance of being selected; all rows in each selected block are returned. The `SYSTEM` method is significantly faster than the `BERNOULLI` method when small sampling percentages are specified, but it may return a less-random sample of the table as a result of clustering effects.

The optional `REPEATABLE` clause specifies a *seed* number or expression to use for generating random numbers within the sampling method. The seed value can be any non-null floating-point value. Two queries that specify the same seed and *argument* values will select the same sample of the table, if the table has not been changed meanwhile. But different seed values will usually produce different samples. If `REPEATABLE` is not given then a new random sample is selected for each query, based

upon a system-generated seed. Note that some add-on sampling methods do not accept `REPEATABLE`, and will always produce new samples on each use.

select

A sub-`SELECT` can appear in the `FROM` clause. This acts as though its output were created as a temporary table for the duration of this single `SELECT` command. Note that the sub-`SELECT` must be surrounded by parentheses, and an alias can be provided in the same way as for a table. A `VALUES` command can also be used here.

with_query_name

A `WITH` query is referenced by writing its name, just as though the query's name were a table name. (In fact, the `WITH` query hides any real table of the same name for the purposes of the primary query. If necessary, you can refer to a real table of the same name by schema-qualifying the table's name.) An alias can be provided in the same way as for a table.

function_name

Function calls can appear in the `FROM` clause. (This is especially useful for functions that return result sets, but any function can be used.) This acts as though the function's output were created as a temporary table for the duration of this single `SELECT` command. If the function's result type is composite (including the case of a function with multiple `OUT` parameters), each attribute becomes a separate column in the implicit table.

When the optional `WITH ORDINALITY` clause is added to the function call, an additional column of type `bigint` will be appended to the function's result column(s). This column numbers the rows of the function's result set, starting from 1. By default, this column is named `ordinality`.

An alias can be provided in the same way as for a table. If an alias is written, a column alias list can also be written to provide substitute names for one or more attributes of the function's composite return type, including the ordinality column if present.

Multiple function calls can be combined into a single `FROM`-clause item by surrounding them with `ROWS FROM(...)`. The output of such an item is the concatenation of the first row from each function, then the second row from each function, etc. If some of the functions produce fewer rows than others, null values are substituted for the missing data, so that the total number of rows returned is always the same as for the function that produced the most rows.

If the function has been defined as returning the `record` data type, then an alias or the key word `AS` must be present, followed by a column definition list in the form (`column_name data_type` [, ...]). The column definition list must match the actual number and types of columns returned by the function.

When using the `ROWS FROM(...)` syntax, if one of the functions requires a column definition list, it's preferred to put the column definition list after the function call inside `ROWS FROM(...)`. A column definition list can be placed after the `ROWS FROM(...)` construct only if there's just a single function and no `WITH ORDINALITY` clause.

To use `ORDINALITY` together with a column definition list, you must use the `ROWS FROM(...)` syntax and put the column definition list inside `ROWS FROM(...)`.

join_type

One of

- [`INNER`] `JOIN`
- `LEFT` [`OUTER`] `JOIN`
- `RIGHT` [`OUTER`] `JOIN`
- `FULL` [`OUTER`] `JOIN`

For the `INNER` and `OUTER` join types, a join condition must be specified, namely exactly one of `ON join_condition`, `USING (join_column [, ...])`, or `NATURAL`. See below for the meaning.

A `JOIN` clause combines two `FROM` items, which for convenience we will refer to as “tables”, though in reality they can be any type of `FROM` item. Use parentheses if necessary to determine the order of nesting. In the absence of parentheses, `JOINS` nest left-to-right. In any case `JOIN` binds more tightly than the commas separating `FROM`-list items. All the `JOIN` options are just a notational convenience, since they do nothing you couldn't do with plain `FROM` and `WHERE`.

`LEFT OUTER JOIN` returns all rows in the qualified Cartesian product (i.e., all combined rows that pass its join condition), plus one copy of each row in the left-hand table for which there was no right-hand row that passed the join condition. This left-hand row is extended to the full width of the joined table by inserting null values for the right-hand columns. Note that only the `JOIN` clause's own condition is considered while deciding which rows have matches. Outer conditions are applied afterwards.

Conversely, `RIGHT OUTER JOIN` returns all the joined rows, plus one row for each unmatched right-hand row (extended with nulls on the left). This is just a notational convenience, since you could convert it to a `LEFT OUTER JOIN` by switching the left and right tables.

`FULL OUTER JOIN` returns all the joined rows, plus one row for each unmatched left-hand row (extended with nulls on the right), plus one row for each unmatched right-hand row (extended with nulls on the left).

`ON join_condition`

join_condition is an expression resulting in a value of type `boolean` (similar to a `WHERE` clause) that specifies which rows in a join are considered to match.

`USING (join_column [, ...]) [AS join_using_alias]`

A clause of the form `USING (a, b, ...)` is shorthand for `ON left_table.a = right_table.a AND left_table.b = right_table.b` Also, `USING` implies that only one of each pair of equivalent columns will be included in the join output, not both.

If a *join_using_alias* name is specified, it provides a table alias for the join columns. Only the join columns listed in the `USING` clause are addressable by this name. Unlike a regular *alias*, this does not hide the names of the joined tables from the rest of the query. Also unlike a regular *alias*, you cannot write a column alias list — the output names of the join columns are the same as they appear in the `USING` list.

`NATURAL`

`NATURAL` is shorthand for a `USING` list that mentions all columns in the two tables that have matching names. If there are no common column names, `NATURAL` is equivalent to `ON TRUE`.

`CROSS JOIN`

`CROSS JOIN` is equivalent to `INNER JOIN ON (TRUE)`, that is, no rows are removed by qualification. They produce a simple Cartesian product, the same result as you get from listing the two tables at the top level of `FROM`, but restricted by the join condition (if any).

`LATERAL`

The `LATERAL` key word can precede a sub-`SELECT FROM` item. This allows the sub-`SELECT` to refer to columns of `FROM` items that appear before it in the `FROM` list. (Without `LATERAL`, each sub-`SELECT` is evaluated independently and so cannot cross-reference any other `FROM` item.)

`LATERAL` can also precede a function-call `FROM` item, but in this case it is a noise word, because the function expression can refer to earlier `FROM` items in any case.

A `LATERAL` item can appear at top level in the `FROM` list, or within a `JOIN` tree. In the latter case it can also refer to any items that are on the left-hand side of a `JOIN` that it is on the right-hand side of.

When a `FROM` item contains `LATERAL` cross-references, evaluation proceeds as follows: for each row of the `FROM` item providing the cross-referenced column(s), or set of rows of multiple `FROM` items providing the columns, the `LATERAL` item is evaluated using that row or row set's values of the columns. The resulting row(s) are joined as usual with the rows they were computed from. This is repeated for each row or set of rows from the column source table(s).

The column source table(s) must be `INNER` or `LEFT` joined to the `LATERAL` item, else there would not be a well-defined set of rows from which to compute each set of rows for the `LATERAL` item. Thus, although a construct such as `X RIGHT JOIN LATERAL Y` is syntactically valid, it is not actually allowed for `Y` to reference `X`.

WHERE Clause

The optional `WHERE` clause has the general form

```
WHERE condition
```

where *condition* is any expression that evaluates to a result of type `boolean`. Any row that does not satisfy this condition will be eliminated from the output. A row satisfies the condition if it returns true when the actual row values are substituted for any variable references.

GROUP BY Clause

The optional `GROUP BY` clause has the general form

```
GROUP BY [ ALL | DISTINCT ] grouping_element [, ...]
```

`GROUP BY` will condense into a single row all selected rows that share the same values for the grouped expressions. An *expression* used inside a *grouping_element* can be an input column name, or the name or ordinal number of an output column (`SELECT` list item), or an arbitrary expression formed from input-column values. In case of ambiguity, a `GROUP BY` name will be interpreted as an input-column name rather than an output column name.

If any of `GROUPING SETS`, `ROLLUP` or `CUBE` are present as grouping elements, then the `GROUP BY` clause as a whole defines some number of independent *grouping sets*. The effect of this is equivalent to constructing a `UNION ALL` between subqueries with the individual grouping sets as their `GROUP BY` clauses. The optional `DISTINCT` clause removes duplicate sets before processing; it does *not* transform the `UNION ALL` into a `UNION DISTINCT`. For further details on the handling of grouping sets see [Section 7.2.4](#).

Aggregate functions, if any are used, are computed across all rows making up each group, producing a separate value for each group. (If there are aggregate functions but no `GROUP BY` clause, the query is treated as having a single group comprising all the selected rows.) The set of rows fed to each aggregate function can be further filtered by attaching a `FILTER` clause to the aggregate function call; see [Section 4.2.7](#) for more information. When a `FILTER` clause is present, only those rows matching it are included in the input to that aggregate function.

When `GROUP BY` is present, or any aggregate functions are present, it is not valid for the `SELECT` list expressions to refer to ungrouped columns except within aggregate functions or when the ungrouped column is functionally dependent on the grouped columns, since there would otherwise be more than one possible value to return for an ungrouped column. A functional dependency exists if the grouped columns (or a subset thereof) are the primary key of the table containing the ungrouped column.

Keep in mind that all aggregate functions are evaluated before evaluating any “scalar” expressions in the `HAVING` clause or `SELECT` list. This means that, for example, a `CASE` expression cannot be used to skip evaluation of an aggregate function; see [Section 4.2.14](#).

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified with `GROUP BY`.

HAVING Clause

The optional `HAVING` clause has the general form

HAVING *condition*

where *condition* is the same as specified for the WHERE clause.

HAVING eliminates group rows that do not satisfy the condition. HAVING is different from WHERE: WHERE filters individual rows before the application of GROUP BY, while HAVING filters group rows created by GROUP BY. Each column referenced in *condition* must unambiguously reference a grouping column, unless the reference appears within an aggregate function or the ungrouped column is functionally dependent on the grouping columns.

The presence of HAVING turns a query into a grouped query even if there is no GROUP BY clause. This is the same as what happens when the query contains aggregate functions but no GROUP BY clause. All the selected rows are considered to form a single group, and the SELECT list and HAVING clause can only reference table columns from within aggregate functions. Such a query will emit a single row if the HAVING condition is true, zero rows if it is not true.

Currently, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE and FOR KEY SHARE cannot be specified with HAVING.

WINDOW Clause

The optional WINDOW clause has the general form

```
WINDOW window_name AS ( window_definition ) [, ...]
```

where *window_name* is a name that can be referenced from OVER clauses or subsequent window definitions, and *window_definition* is

```
[ existing_window_name ]  
[ PARTITION BY expression [, ...] ]  
[ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ]  
  [, ...] ]  
[ frame_clause ]
```

If an *existing_window_name* is specified it must refer to an earlier entry in the WINDOW list; the new window copies its partitioning clause from that entry, as well as its ordering clause if any. In this case the new window cannot specify its own PARTITION BY clause, and it can specify ORDER BY only if the copied window does not have one. The new window always uses its own frame clause; the copied window must not specify a frame clause.

The elements of the PARTITION BY list are interpreted in much the same fashion as elements of a GROUP BY clause, except that they are always simple expressions and never the name or number of an output column. Another difference is that these expressions can contain aggregate function calls, which are not allowed in a regular GROUP BY clause. They are allowed here because windowing occurs after grouping and aggregation.

Similarly, the elements of the ORDER BY list are interpreted in much the same fashion as elements of a statement-level ORDER BY clause, except that the expressions are always taken as simple expressions and never the name or number of an output column.

The optional *frame_clause* defines the *window frame* for window functions that depend on the frame (not all do). The window frame is a set of related rows for each row of the query (called the *current row*). The *frame_clause* can be one of

```
{ RANGE | ROWS | GROUPS } frame_start [ frame_exclusion ]  
{ RANGE | ROWS | GROUPS } BETWEEN frame_start AND frame_end [ frame_exclusion ]
```

where *frame_start* and *frame_end* can be one of

```
UNBOUNDED PRECEDING  
offset PRECEDING  
CURRENT ROW  
offset FOLLOWING
```

UNBOUNDED FOLLOWING

and *frame_exclusion* can be one of

EXCLUDE CURRENT ROW
EXCLUDE GROUP
EXCLUDE TIES
EXCLUDE NO OTHERS

If *frame_end* is omitted it defaults to CURRENT ROW. Restrictions are that *frame_start* cannot be UNBOUNDED FOLLOWING, *frame_end* cannot be UNBOUNDED PRECEDING, and the *frame_end* choice cannot appear earlier in the above list of *frame_start* and *frame_end* options than the *frame_start* choice does — for example RANGE BETWEEN CURRENT ROW AND *offset* PRECEDING is not allowed.

The default framing option is RANGE UNBOUNDED PRECEDING, which is the same as RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW; it sets the frame to be all rows from the partition start up through the current row's last *peer* (a row that the window's ORDER BY clause considers equivalent to the current row; all rows are peers if there is no ORDER BY). In general, UNBOUNDED PRECEDING means that the frame starts with the first row of the partition, and similarly UNBOUNDED FOLLOWING means that the frame ends with the last row of the partition, regardless of RANGE, ROWS or GROUPS mode. In ROWS mode, CURRENT ROW means that the frame starts or ends with the current row; but in RANGE or GROUPS mode it means that the frame starts or ends with the current row's first or last peer in the ORDER BY ordering. The *offset* PRECEDING and *offset* FOLLOWING options vary in meaning depending on the frame mode. In ROWS mode, the *offset* is an integer indicating that the frame starts or ends that many rows before or after the current row. In GROUPS mode, the *offset* is an integer indicating that the frame starts or ends that many peer groups before or after the current row's peer group, where a *peer group* is a group of rows that are equivalent according to the window's ORDER BY clause. In RANGE mode, use of an *offset* option requires that there be exactly one ORDER BY column in the window definition. Then the frame contains those rows whose ordering column value is no more than *offset* less than (for PRECEDING) or more than (for FOLLOWING) the current row's ordering column value. In these cases the data type of the *offset* expression depends on the data type of the ordering column. For numeric ordering columns it is typically of the same type as the ordering column, but for datetime ordering columns it is an interval. In all these cases, the value of the *offset* must be non-null and non-negative. Also, while the *offset* does not have to be a simple constant, it cannot contain variables, aggregate functions, or window functions.

The *frame_exclusion* option allows rows around the current row to be excluded from the frame, even if they would be included according to the frame start and frame end options. EXCLUDE CURRENT ROW excludes the current row from the frame. EXCLUDE GROUP excludes the current row and its ordering peers from the frame. EXCLUDE TIES excludes any peers of the current row from the frame, but not the current row itself. EXCLUDE NO OTHERS simply specifies explicitly the default behavior of not excluding the current row or its peers.

Beware that the ROWS mode can produce unpredictable results if the ORDER BY ordering does not order the rows uniquely. The RANGE and GROUPS modes are designed to ensure that rows that are peers in the ORDER BY ordering are treated alike: all rows of a given peer group will be in the frame or excluded from it.

The purpose of a WINDOW clause is to specify the behavior of *window functions* appearing in the query's SELECT list or ORDER BY clause. These functions can reference the WINDOW clause entries by name in their OVER clauses. A WINDOW clause entry does not have to be referenced anywhere, however; if it is not used in the query it is simply ignored. It is possible to use window functions without any WINDOW clause at all, since a window function call can specify its window definition directly in its OVER clause. However, the WINDOW clause saves typing when the same window definition is needed for more than one window function.

Currently, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE and FOR KEY SHARE cannot be specified with WINDOW.

Window functions are described in detail in [Section 3.5](#), [Section 4.2.8](#), and [Section 7.2.5](#).

SELECT List

The `SELECT` list (between the key words `SELECT` and `FROM`) specifies expressions that form the output rows of the `SELECT` statement. The expressions can (and usually do) refer to columns computed in the `FROM` clause.

Just as in a table, every output column of a `SELECT` has a name. In a simple `SELECT` this name is just used to label the column for display, but when the `SELECT` is a sub-query of a larger query, the name is seen by the larger query as the column name of the virtual table produced by the sub-query. To specify the name to use for an output column, write `AS output_name` after the column's expression. (You can omit `AS`, but only if the desired output name does not match any Postgres Pro keyword (see [Appendix C](#)). For protection against possible future keyword additions, it is recommended that you always either write `AS` or double-quote the output name.) If you do not specify a column name, a name is chosen automatically by Postgres Pro. If the column's expression is a simple column reference then the chosen name is the same as that column's name. In more complex cases a function or type name may be used, or the system may fall back on a generated name such as `?column?`.

An output column's name can be used to refer to the column's value in `ORDER BY` and `GROUP BY` clauses, but not in the `WHERE` or `HAVING` clauses; there you must write out the expression instead.

Instead of an expression, `*` can be written in the output list as a shorthand for all the columns of the selected rows. Also, you can write `table_name.*` as a shorthand for the columns coming from just that table. In these cases it is not possible to specify new names with `AS`; the output column names will be the same as the table columns' names.

According to the SQL standard, the expressions in the output list should be computed before applying `DISTINCT`, `ORDER BY`, or `LIMIT`. This is obviously necessary when using `DISTINCT`, since otherwise it's not clear what values are being made distinct. However, in many cases it is convenient if output expressions are computed after `ORDER BY` and `LIMIT`; particularly if the output list contains any volatile or expensive functions. With that behavior, the order of function evaluations is more intuitive and there will not be evaluations corresponding to rows that never appear in the output. Postgres Pro will effectively evaluate output expressions after sorting and limiting, so long as those expressions are not referenced in `DISTINCT`, `ORDER BY` or `GROUP BY`. (As a counterexample, `SELECT f(x) FROM tab ORDER BY 1` clearly must evaluate `f(x)` before sorting.) Output expressions that contain set-returning functions are effectively evaluated after sorting and before limiting, so that `LIMIT` will act to cut off the output from a set-returning function.

Note

Postgres Pro versions before 9.6 did not provide any guarantees about the timing of evaluation of output expressions versus sorting and limiting; it depended on the form of the chosen query plan.

DISTINCT Clause

If `SELECT DISTINCT` is specified, all duplicate rows are removed from the result set (one row is kept from each group of duplicates). `SELECT ALL` specifies the opposite: all rows are kept; that is the default.

`SELECT DISTINCT ON (expression [, ...])` keeps only the first row of each set of rows where the given expressions evaluate to equal. The `DISTINCT ON` expressions are interpreted using the same rules as for `ORDER BY` (see above). Note that the “first row” of each set is unpredictable unless `ORDER BY` is used to ensure that the desired row appears first. For example:

```
SELECT DISTINCT ON (location) location, time, report
FROM weather_reports
ORDER BY location, time DESC;
```

retrieves the most recent weather report for each location. But if we had not used `ORDER BY` to force descending order of time values for each location, we'd have gotten a report from an unpredictable time for each location.

The `DISTINCT ON` expression(s) must match the leftmost `ORDER BY` expression(s). The `ORDER BY` clause will normally contain additional expression(s) that determine the desired precedence of rows within each `DISTINCT ON` group.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified with `DISTINCT`.

UNION Clause

The `UNION` clause has this general form:

```
select_statement UNION [ ALL | DISTINCT ] select_statement
```

select_statement is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` clause. (`ORDER BY` and `LIMIT` can be attached to a subexpression if it is enclosed in parentheses. Without parentheses, these clauses will be taken to apply to the result of the `UNION`, not to its right-hand input expression.)

The `UNION` operator computes the set union of the rows returned by the involved `SELECT` statements. A row is in the set union of two result sets if it appears in at least one of the result sets. The two `SELECT` statements that represent the direct operands of the `UNION` must produce the same number of columns, and corresponding columns must be of compatible data types.

The result of `UNION` does not contain any duplicate rows unless the `ALL` option is specified. `ALL` prevents elimination of duplicates. (Therefore, `UNION ALL` is usually significantly quicker than `UNION`; use `ALL` when you can.) `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `UNION` operators in the same `SELECT` statement are evaluated left to right, unless otherwise indicated by parentheses.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified either for a `UNION` result or for any input of a `UNION`.

INTERSECT Clause

The `INTERSECT` clause has this general form:

```
select_statement INTERSECT [ ALL | DISTINCT ] select_statement
```

select_statement is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` clause.

The `INTERSECT` operator computes the set intersection of the rows returned by the involved `SELECT` statements. A row is in the intersection of two result sets if it appears in both result sets.

The result of `INTERSECT` does not contain any duplicate rows unless the `ALL` option is specified. With `ALL`, a row that has m duplicates in the left table and n duplicates in the right table will appear $\min(m, n)$ times in the result set. `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `INTERSECT` operators in the same `SELECT` statement are evaluated left to right, unless parentheses dictate otherwise. `INTERSECT` binds more tightly than `UNION`. That is, `A UNION B INTERSECT C` will be read as `A UNION (B INTERSECT C)`.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified either for an `INTERSECT` result or for any input of an `INTERSECT`.

EXCEPT Clause

The `EXCEPT` clause has this general form:

```
select_statement EXCEPT [ ALL | DISTINCT ] select_statement
```

select_statement is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` clause.

The `EXCEPT` operator computes the set of rows that are in the result of the left `SELECT` statement but not in the result of the right one.

The result of `EXCEPT` does not contain any duplicate rows unless the `ALL` option is specified. With `ALL`, a row that has m duplicates in the left table and n duplicates in the right table will appear $\max(m-n, 0)$ times in the result set. `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `EXCEPT` operators in the same `SELECT` statement are evaluated left to right, unless parentheses dictate otherwise. `EXCEPT` binds at the same level as `UNION`.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified either for an `EXCEPT` result or for any input of an `EXCEPT`.

ORDER BY Clause

The optional `ORDER BY` clause has this general form:

```
ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ] [, ...]
```

The `ORDER BY` clause causes the result rows to be sorted according to the specified expression(s). If two rows are equal according to the leftmost expression, they are compared according to the next expression and so on. If they are equal according to all specified expressions, they are returned in an implementation-dependent order.

Each *expression* can be the name or ordinal number of an output column (`SELECT` list item), or it can be an arbitrary expression formed from input-column values.

The ordinal number refers to the ordinal (left-to-right) position of the output column. This feature makes it possible to define an ordering on the basis of a column that does not have a unique name. This is never absolutely necessary because it is always possible to assign a name to an output column using the `AS` clause.

It is also possible to use arbitrary expressions in the `ORDER BY` clause, including columns that do not appear in the `SELECT` output list. Thus the following statement is valid:

```
SELECT name FROM distributors ORDER BY code;
```

A limitation of this feature is that an `ORDER BY` clause applying to the result of a `UNION`, `INTERSECT`, or `EXCEPT` clause can only specify an output column name or number, not an expression.

If an `ORDER BY` expression is a simple name that matches both an output column name and an input column name, `ORDER BY` will interpret it as the output column name. This is the opposite of the choice that `GROUP BY` will make in the same situation. This inconsistency is made to be compatible with the SQL standard.

Optionally one can add the key word `ASC` (ascending) or `DESC` (descending) after any expression in the `ORDER BY` clause. If not specified, `ASC` is assumed by default. Alternatively, a specific ordering operator name can be specified in the `USING` clause. An ordering operator must be a less-than or greater-than member of some B-tree operator family. `ASC` is usually equivalent to `USING <` and `DESC` is usually equivalent to `USING >`. (But the creator of a user-defined data type can define exactly what the default sort ordering is, and it might correspond to operators with other names.)

If `NULLS LAST` is specified, null values sort after all non-null values; if `NULLS FIRST` is specified, null values sort before all non-null values. If neither is specified, the default behavior is `NULLS LAST` when `ASC` is specified or implied, and `NULLS FIRST` when `DESC` is specified (thus, the default is to act as though nulls are larger than non-nulls). When `USING` is specified, the default nulls ordering depends on whether the operator is a less-than or greater-than operator.

Note that ordering options apply only to the expression they follow; for example `ORDER BY x, y DESC` does not mean the same thing as `ORDER BY x DESC, y DESC`.

Character-string data is sorted according to the collation that applies to the column being sorted. That can be overridden at need by including a `COLLATE` clause in the *expression*, for example `ORDER BY mycolumn COLLATE "en_US"`. For more information see [Section 4.2.10](#) and [Section 23.2](#).

LIMIT Clause

The `LIMIT` clause consists of two independent sub-clauses:

```
LIMIT { count | ALL }  
OFFSET start
```

The parameter *count* specifies the maximum number of rows to return, while *start* specifies the number of rows to skip before starting to return rows. When both are specified, *start* rows are skipped before starting to count the *count* rows to be returned.

If the *count* expression evaluates to `NULL`, it is treated as `LIMIT ALL`, i.e., no limit. If *start* evaluates to `NULL`, it is treated the same as `OFFSET 0`.

SQL:2008 introduced a different syntax to achieve the same result, which Postgres Pro also supports. It is:

```
OFFSET start { ROW | ROWS }  
FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH TIES }
```

In this syntax, the *start* or *count* value is required by the standard to be a literal constant, a parameter, or a variable name; as a Postgres Pro extension, other expressions are allowed, but will generally need to be enclosed in parentheses to avoid ambiguity. If *count* is omitted in a `FETCH` clause, it defaults to 1. The `WITH TIES` option is used to return any additional rows that tie for the last place in the result set according to the `ORDER BY` clause; `ORDER BY` is mandatory in this case, and `SKIP LOCKED` is not allowed. `ROW` and `ROWS` as well as `FIRST` and `NEXT` are noise words that don't influence the effects of these clauses. According to the standard, the `OFFSET` clause must come before the `FETCH` clause if both are present; but Postgres Pro is laxer and allows either order.

When using `LIMIT`, it is a good idea to use an `ORDER BY` clause that constrains the result rows into a unique order. Otherwise you will get an unpredictable subset of the query's rows — you might be asking for the tenth through twentieth rows, but tenth through twentieth in what ordering? You don't know what ordering unless you specify `ORDER BY`.

The query planner takes `LIMIT` into account when generating a query plan, so you are very likely to get different plans (yielding different row orders) depending on what you use for `LIMIT` and `OFFSET`. Thus, using different `LIMIT/OFFSET` values to select different subsets of a query result *will give inconsistent results* unless you enforce a predictable result ordering with `ORDER BY`. This is not a bug; it is an inherent consequence of the fact that SQL does not promise to deliver the results of a query in any particular order unless `ORDER BY` is used to constrain the order.

It is even possible for repeated executions of the same `LIMIT` query to return different subsets of the rows of a table, if there is not an `ORDER BY` to enforce selection of a deterministic subset. Again, this is not a bug; determinism of the results is simply not guaranteed in such a case.

The Locking Clause

`FOR UPDATE`, `FOR NO KEY UPDATE`, `FOR SHARE` and `FOR KEY SHARE` are *locking clauses*; they affect how `SELECT` locks rows as they are obtained from the table.

The locking clause has the general form

```
FOR lock_strength [ OF from_reference [, ...] ] [ NOWAIT | SKIP LOCKED ]
```

where *lock_strength* can be one of

```
UPDATE  
NO KEY UPDATE  
SHARE  
KEY SHARE
```

from_reference must be a table *alias* or non-hidden *table_name* referenced in the `FROM` clause. For more information on each row-level lock mode, refer to [Section 13.3.2](#).

To prevent the operation from waiting for other transactions to commit, use either the `NOWAIT` or `SKIP LOCKED` option. With `NOWAIT`, the statement reports an error, rather than waiting, if a selected row cannot be locked immediately. With `SKIP LOCKED`, any selected rows that cannot be immediately locked are skipped. Skipping locked rows provides an inconsistent view of the data, so this is not suitable for general purpose work, but can be used to avoid lock contention with multiple consumers accessing a queue-like table. Note that `NOWAIT` and `SKIP LOCKED` apply only to the row-level lock(s) — the required `ROW SHARE` table-level lock is still taken in the ordinary way (see [Chapter 13](#)). You can use `LOCK` with the `NOWAIT` option first, if you need to acquire the table-level lock without waiting.

If specific tables are named in a locking clause, then only rows coming from those tables are locked; any other tables used in the `SELECT` are simply read as usual. A locking clause without a table list affects all tables used in the statement. If a locking clause is applied to a view or sub-query, it affects all tables used in the view or sub-query. However, these clauses do not apply to `WITH` queries referenced by the primary query. If you want row locking to occur within a `WITH` query, specify a locking clause within the `WITH` query.

Multiple locking clauses can be written if it is necessary to specify different locking behavior for different tables. If the same table is mentioned (or implicitly affected) by more than one locking clause, then it is processed as if it was only specified by the strongest one. Similarly, a table is processed as `NOWAIT` if that is specified in any of the clauses affecting it. Otherwise, it is processed as `SKIP LOCKED` if that is specified in any of the clauses affecting it.

The locking clauses cannot be used in contexts where returned rows cannot be clearly identified with individual table rows; for example they cannot be used with aggregation.

When a locking clause appears at the top level of a `SELECT` query, the rows that are locked are exactly those that are returned by the query; in the case of a join query, the rows locked are those that contribute to returned join rows. In addition, rows that satisfied the query conditions as of the query snapshot will be locked, although they will not be returned if they were updated after the snapshot and no longer satisfy the query conditions. If a `LIMIT` is used, locking stops once enough rows have been returned to satisfy the limit (but note that rows skipped over by `OFFSET` will get locked). Similarly, if a locking clause is used in a cursor's query, only rows actually fetched or stepped past by the cursor will be locked.

When a locking clause appears in a sub-`SELECT`, the rows locked are those returned to the outer query by the sub-query. This might involve fewer rows than inspection of the sub-query alone would suggest, since conditions from the outer query might be used to optimize execution of the sub-query. For example,

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss WHERE col1 = 5;
```

will lock only rows having `col1 = 5`, even though that condition is not textually within the sub-query.

Previous releases failed to preserve a lock which is upgraded by a later savepoint. For example, this code:

```
BEGIN;
SELECT * FROM mytable WHERE key = 1 FOR UPDATE;
SAVEPOINT s;
UPDATE mytable SET ... WHERE key = 1;
ROLLBACK TO s;
```

would fail to preserve the `FOR UPDATE` lock after the `ROLLBACK TO`. This has been fixed in release 9.3.

Caution

It is possible for a `SELECT` command running at the `READ COMMITTED` transaction isolation level and using `ORDER BY` and a locking clause to return rows out of order. This is because `ORDER BY` is applied first. The command sorts the result, but might then block trying to obtain a lock on one or more of the rows. Once the `SELECT` unblocks, some of the ordering column values might have been

modified, leading to those rows appearing to be out of order (though they are in order in terms of the original column values). This can be worked around at need by placing the `FOR UPDATE/SHARE` clause in a sub-query, for example

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss ORDER BY column1;
```

Note that this will result in locking all rows of `mytable`, whereas `FOR UPDATE` at the top level would lock only the actually returned rows. This can make for a significant performance difference, particularly if the `ORDER BY` is combined with `LIMIT` or other restrictions. So this technique is recommended only if concurrent updates of the ordering columns are expected and a strictly sorted result is required.

At the `REPEATABLE READ` or `SERIALIZABLE` transaction isolation level this would cause a serialization failure (with an `SQLSTATE` of `'40001'`), so there is no possibility of receiving rows out of order under these isolation levels.

TABLE Command

The command

```
TABLE name
```

is equivalent to

```
SELECT * FROM name
```

It can be used as a top-level command or as a space-saving syntax variant in parts of complex queries. Only the `WITH`, `UNION`, `INTERSECT`, `EXCEPT`, `ORDER BY`, `LIMIT`, `OFFSET`, `FETCH` and `FOR` locking clauses can be used with `TABLE`; the `WHERE` clause and any form of aggregation cannot be used.

Examples

To join the table `films` with the table `distributors`:

```
SELECT f.title, f.did, d.name, f.date_prod, f.kind
FROM distributors d JOIN films f USING (did);
```

title	did	name	date_prod	kind
The Third Man	101	British Lion	1949-12-23	Drama
The African Queen	101	British Lion	1951-08-11	Romantic
...				

To sum the column `len` of all films and group the results by `kind`:

```
SELECT kind, sum(len) AS total FROM films GROUP BY kind;
```

kind	total
Action	07:34
Comedy	02:58
Drama	14:28
Musical	06:42
Romantic	04:38

To sum the column `len` of all films, group the results by `kind` and show those group totals that are less than 5 hours:

```
SELECT kind, sum(len) AS total
FROM films
GROUP BY kind
HAVING sum(len) < interval '5 hours';
```

SELECT

kind	total
Comedy	02:58
Romantic	04:38

The following two examples are identical ways of sorting the individual results according to the contents of the second column (name):

```
SELECT * FROM distributors ORDER BY name;
SELECT * FROM distributors ORDER BY 2;
```

did	name
109	20th Century Fox
110	Bavaria Atelier
101	British Lion
107	Columbia
102	Jean Luc Godard
113	Luso films
104	Mosfilm
103	Paramount
106	Toho
105	United Artists
111	Walt Disney
112	Warner Bros.
108	Westward

The next example shows how to obtain the union of the tables `distributors` and `actors`, restricting the results to those that begin with the letter W in each table. Only distinct rows are wanted, so the key word `ALL` is omitted.

distributors:	actors:
did name	id name
108 Westward	1 Woody Allen
111 Walt Disney	2 Warren Beatty
112 Warner Bros.	3 Walter Matthau
...	...

```
SELECT distributors.name
FROM distributors
WHERE distributors.name LIKE 'W%'
UNION
SELECT actors.name
FROM actors
WHERE actors.name LIKE 'W%';
```

name
Walt Disney
Walter Matthau
Warner Bros.
Warren Beatty
Westward
Woody Allen

This example shows how to use a function in the `FROM` clause, both with and without a column definition list:

```
CREATE FUNCTION distributors(int) RETURNS SETOF distributors AS $$
```

SELECT

```
SELECT * FROM distributors WHERE did = $1;
$$ LANGUAGE SQL;
```

```
SELECT * FROM distributors(111);
 did |    name
-----+-----
 111 | Walt Disney
```

```
CREATE FUNCTION distributors_2(int) RETURNS SETOF record AS $$
    SELECT * FROM distributors WHERE did = $1;
$$ LANGUAGE SQL;
```

```
SELECT * FROM distributors_2(111) AS (f1 int, f2 text);
 f1 |    f2
-----+-----
 111 | Walt Disney
```

Here is an example of a function with an ordinality column added:

```
SELECT * FROM unnest(ARRAY['a','b','c','d','e','f']) WITH ORDINALITY;
unnest | ordinality
-----+-----
 a     |          1
 b     |          2
 c     |          3
 d     |          4
 e     |          5
 f     |          6
(6 rows)
```

This example shows how to use a simple `WITH` clause:

```
WITH t AS (
    SELECT random() as x FROM generate_series(1, 3)
)
SELECT * FROM t
UNION ALL
SELECT * FROM t;
      x
-----
0.534150459803641
0.520092216785997
0.0735620250925422
0.534150459803641
0.520092216785997
0.0735620250925422
```

Notice that the `WITH` query was evaluated only once, so that we got two sets of the same three random values.

This example uses `WITH RECURSIVE` to find all subordinates (direct or indirect) of the employee Mary, and their level of indirectness, from a table that shows only direct subordinates:

```
WITH RECURSIVE employee_recursive(distance, employee_name, manager_name) AS (
    SELECT 1, employee_name, manager_name
    FROM employee
    WHERE manager_name = 'Mary'
    UNION ALL
    SELECT er.distance + 1, e.employee_name, e.manager_name
    FROM employee_recursive er, employee e
    WHERE er.employee_name = e.manager_name
```

```
)  
SELECT distance, employee_name FROM employee_recursive;
```

Notice the typical form of recursive queries: an initial condition, followed by `UNION`, followed by the recursive part of the query. Be sure that the recursive part of the query will eventually return no tuples, or else the query will loop indefinitely. (See [Section 7.8](#) for more examples.)

This example uses `LATERAL` to apply a set-returning function `get_product_names()` for each row of the `manufacturers` table:

```
SELECT m.name AS mname, pname  
FROM manufacturers m, LATERAL get_product_names(m.id) pname;
```

Manufacturers not currently having any products would not appear in the result, since it is an inner join. If we wished to include the names of such manufacturers in the result, we could do:

```
SELECT m.name AS mname, pname  
FROM manufacturers m LEFT JOIN LATERAL get_product_names(m.id) pname ON true;
```

Compatibility

Of course, the `SELECT` statement is compatible with the SQL standard. But there are some extensions and some missing features.

Omitted `FROM` Clauses

Postgres Pro allows one to omit the `FROM` clause. It has a straightforward use to compute the results of simple expressions:

```
SELECT 2+2;
```

```
?column?  
-----  
4
```

Some other SQL databases cannot do this except by introducing a dummy one-row table from which to do the `SELECT`.

Empty `SELECT` Lists

The list of output expressions after `SELECT` can be empty, producing a zero-column result table. This is not valid syntax according to the SQL standard. Postgres Pro allows it to be consistent with allowing zero-column tables. However, an empty list is not allowed when `DISTINCT` is used.

Omitting the `AS` Key Word

In the SQL standard, the optional key word `AS` can be omitted before an output column name whenever the new column name is a valid column name (that is, not the same as any reserved keyword). Postgres Pro is slightly more restrictive: `AS` is required if the new column name matches any keyword at all, reserved or not. Recommended practice is to use `AS` or double-quote output column names, to prevent any possible conflict against future keyword additions.

In `FROM` items, both the standard and Postgres Pro allow `AS` to be omitted before an alias that is an unreserved keyword. But this is impractical for output column names, because of syntactic ambiguities.

Omitting Sub-`SELECT` Aliases in `FROM`

According to the SQL standard, a sub-`SELECT` in the `FROM` list must have an alias. In Postgres Pro, this alias may be omitted.

`ONLY` and Inheritance

The SQL standard requires parentheses around the table name when writing `ONLY`, for example `SELECT * FROM ONLY (tab1), ONLY (tab2) WHERE ...`. Postgres Pro considers these parentheses to be optional.

Postgres Pro allows a trailing `*` to be written to explicitly specify the non-ONLY behavior of including child tables. The standard does not allow this.

(These points apply equally to all SQL commands supporting the ONLY option.)

`TABLESAMPLE` **Clause Restrictions**

The `TABLESAMPLE` clause is currently accepted only on regular tables and materialized views. According to the SQL standard it should be possible to apply it to any `FROM` item.

Function Calls in `FROM`

Postgres Pro allows a function call to be written directly as a member of the `FROM` list. In the SQL standard it would be necessary to wrap such a function call in a sub-`SELECT`; that is, the syntax `FROM func(...) alias` is approximately equivalent to `FROM LATERAL (SELECT func(...)) alias`. Note that `LATERAL` is considered to be implicit; this is because the standard requires `LATERAL` semantics for an `UNNEST()` item in `FROM`. Postgres Pro treats `UNNEST()` the same as other set-returning functions.

Namespace Available to `GROUP BY` **and** `ORDER BY`

In the SQL-92 standard, an `ORDER BY` clause can only use output column names or numbers, while a `GROUP BY` clause can only use expressions based on input column names. Postgres Pro extends each of these clauses to allow the other choice as well (but it uses the standard's interpretation if there is ambiguity). Postgres Pro also allows both clauses to specify arbitrary expressions. Note that names appearing in an expression will always be taken as input-column names, not as output-column names.

SQL:1999 and later use a slightly different definition which is not entirely upward compatible with SQL-92. In most cases, however, Postgres Pro will interpret an `ORDER BY` or `GROUP BY` expression the same way SQL:1999 does.

Functional Dependencies

Postgres Pro recognizes functional dependency (allowing columns to be omitted from `GROUP BY`) only when a table's primary key is included in the `GROUP BY` list. The SQL standard specifies additional conditions that should be recognized.

`LIMIT` **and** `OFFSET`

The clauses `LIMIT` and `OFFSET` are Postgres Pro-specific syntax, also used by MySQL. The SQL:2008 standard has introduced the clauses `OFFSET ... FETCH {FIRST|NEXT} ...` for the same functionality, as shown above in [LIMIT Clause](#). This syntax is also used by IBM DB2. (Applications written for Oracle frequently use a workaround involving the automatically generated `rownum` column, which is not available in Postgres Pro, to implement the effects of these clauses.)

`FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, `FOR KEY SHARE`

Although `FOR UPDATE` appears in the SQL standard, the standard allows it only as an option of `DECLARE CURSOR`. Postgres Pro allows it in any `SELECT` query as well as in sub-`SELECT`s, but this is an extension. The `FOR NO KEY UPDATE`, `FOR SHARE` and `FOR KEY SHARE` variants, as well as the `NOWAIT` and `SKIP LOCKED` options, do not appear in the standard.

Data-Modifying Statements in `WITH`

Postgres Pro allows `INSERT`, `UPDATE`, `DELETE`, and `MERGE` to be used as `WITH` queries. This is not found in the SQL standard.

Nonstandard Clauses

`DISTINCT ON (...)` is an extension of the SQL standard.

`ROWS FROM(...)` is an extension of the SQL standard.

The `MATERIALIZED` and `NOT MATERIALIZED` options of `WITH` are extensions of the SQL standard.

SELECT INTO

SELECT INTO — define a new table from the results of a query

Synopsis

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
SELECT [ ALL | DISTINCT [ ON ( expression [, ...] ) ] ]
    [ { * | expression [ [ AS ] output_name ] } [, ...] ]
    INTO [ TEMPORARY | TEMP | UNLOGGED | CONSTANT ] [ TABLE ] new_table
    [ FROM from_item [, ...] ]
    [ WHERE condition ]
    [ GROUP BY expression [, ...] ]
    [ HAVING condition ]
    [ WINDOW window_name AS ( window_definition ) [, ...] ]
    [ { UNION | INTERSECT | EXCEPT } [ ALL | DISTINCT ] select ]
    [ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ]
    [, ...] ]
    [ LIMIT { count | ALL } ]
    [ OFFSET start [ ROW | ROWS ] ]
    [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY ]
    [ FOR { UPDATE | SHARE } [ OF table_name [, ...] ] [ NOWAIT ] [...] ]
```

Description

SELECT INTO creates a new table and fills it with data computed by a query. The data is not returned to the client, as it is with a normal SELECT. The new table's columns have the names and data types associated with the output columns of the SELECT.

Parameters

TEMPORARY or TEMP

If specified, the table is created as a temporary table. Refer to [CREATE TABLE](#) for details.

UNLOGGED

If specified, the table is created as an unlogged table. Refer to [CREATE TABLE](#) for details.

CONSTANT

If specified, the table is created as read-only. Refer to [CREATE TABLE](#) for details.

new_table

The name (optionally schema-qualified) of the table to be created.

All other parameters are described in detail under [SELECT](#).

Notes

CREATE TABLE AS is functionally similar to SELECT INTO. CREATE TABLE AS is the recommended syntax, since this form of SELECT INTO is not available in ECPG or PL/pgSQL, because they interpret the INTO clause differently. Furthermore, CREATE TABLE AS offers a superset of the functionality provided by SELECT INTO.

In contrast to CREATE TABLE AS, SELECT INTO does not allow specifying properties like a table's access method with USING *method* or the table's tablespace with TABLESPACE *tablespace_name*. Use CREATE TABLE AS if necessary. Therefore, the default table access method is chosen for the new table. See [default_table_access_method](#) for more information.

Examples

Create a new table `films_recent` consisting of only recent entries from the table `films`:

```
SELECT * INTO films_recent FROM films WHERE date_prod >= '2002-01-01';
```

Compatibility

The SQL standard uses `SELECT INTO` to represent selecting values into scalar variables of a host program, rather than creating a new table. This indeed is the usage found in ECPG (see [Chapter 37](#)) and PL/pgSQL (see [Chapter 44](#)). The Postgres Pro usage of `SELECT INTO` to represent table creation is historical. Some other SQL implementations also use `SELECT INTO` in this way (but most SQL implementations support `CREATE TABLE AS` instead). Apart from such compatibility considerations, it is best to use `CREATE TABLE AS` for this purpose in new code.

[CREATE TABLE AS](#)

SET

SET — change a run-time parameter

Synopsis

```
SET [ SESSION | LOCAL ] configuration_parameter { TO | = } { value | 'value' |  
  DEFAULT }  
SET [ SESSION | LOCAL ] TIME ZONE { value | 'value' | LOCAL | DEFAULT }
```

Description

The `SET` command changes run-time configuration parameters. Many of the run-time parameters listed in [Chapter 19](#) can be changed on-the-fly with `SET`. (Some parameters can only be changed by superusers and users who have been granted `SET` privilege on that parameter. There are also parameters that cannot be changed after server or session start.) `SET` only affects the value used by the current session.

If `SET` (or equivalently `SET SESSION`) is issued within a transaction that is later aborted, the effects of the `SET` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `SET`.

The effects of `SET LOCAL` last only till the end of the current transaction, whether committed or not. A special case is `SET` followed by `SET LOCAL` within a single transaction: the `SET LOCAL` value will be seen until the end of the transaction, but afterwards (if the transaction is committed) the `SET` value will take effect.

The effects of `SET` or `SET LOCAL` are also canceled by rolling back to a savepoint that is earlier than the command.

If `SET LOCAL` is used within a function that has a `SET` option for the same variable (see [CREATE FUNCTION](#)), the effects of the `SET LOCAL` command disappear at function exit; that is, the value in effect when the function was called is restored anyway. This allows `SET LOCAL` to be used for dynamic or repeated changes of a parameter within a function, while still having the convenience of using the `SET` option to save and restore the caller's value. However, a regular `SET` command overrides any surrounding function's `SET` option; its effects will persist unless rolled back.

Note

In PostgreSQL versions 8.0 through 8.2, the effects of a `SET LOCAL` would be canceled by releasing an earlier savepoint, or by successful exit from a PL/pgSQL exception block. This behavior has been changed because it was deemed unintuitive.

Parameters

`SESSION`

Specifies that the command takes effect for the current session. (This is the default if neither `SESSION` nor `LOCAL` appears.)

`LOCAL`

Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Issuing this outside of a transaction block emits a warning and otherwise has no effect.

configuration_parameter

Name of a settable run-time parameter. Available parameters are documented in [Chapter 19](#) and below.

value

New value of parameter. Values can be specified as string constants, identifiers, numbers, or comma-separated lists of these, as appropriate for the particular parameter. `DEFAULT` can be written to specify resetting the parameter to its default value (that is, whatever value it would have had if no `SET` had been executed in the current session).

Besides the configuration parameters documented in [Chapter 19](#), there are a few that can only be adjusted using the `SET` command or that have a special syntax:

SCHEMA

`SET SCHEMA 'value'` is an alias for `SET search_path TO value`. Only one schema can be specified using this syntax.

NAMES

`SET NAMES value` is an alias for `SET client_encoding TO value`.

SEED

Sets the internal seed for the random number generator (the function `random`). Allowed values are floating-point numbers between -1 and 1 inclusive.

The seed can also be set by invoking the function `setseed`:

```
SELECT setseed(value);
```

TIME ZONE

`SET TIME ZONE 'value'` is an alias for `SET timezone TO 'value'`. The syntax `SET TIME ZONE` allows special syntax for the time zone specification. Here are examples of valid values:

`'America/Los_Angeles'`

The time zone for Berkeley, California.

`'Europe/Rome'`

The time zone for Italy.

`-7`

The time zone 7 hours west from UTC (equivalent to PDT). Positive values are east from UTC.

`INTERVAL '-08:00' HOUR TO MINUTE`

The time zone 8 hours west from UTC (equivalent to PST).

LOCAL

DEFAULT

Set the time zone to your local time zone (that is, the server's default value of `timezone`).

Timezone settings given as numbers or intervals are internally translated to POSIX timezone syntax. For example, after `SET TIME ZONE -7`, `SHOW TIME ZONE` would report `<-07>+07`.

Time zone abbreviations are not supported by `SET`; see [Section 8.5.3](#) for more information about time zones.

Notes

The function `set_config` provides equivalent functionality; see [Section 9.28.1](#). Also, it is possible to `UPDATE` the `pg_settings` system view to perform the equivalent of `SET`.

Examples

Set the schema search path:

```
SET search_path TO my_schema, public;
```

Set the style of date to traditional POSTGRES with “day before month” input convention:

```
SET datestyle TO postgres, dmy;
```

Set the time zone for Berkeley, California:

```
SET TIME ZONE 'America/Los_Angeles';
```

Set the time zone for Italy:

```
SET TIME ZONE 'Europe/Rome';
```

Compatibility

`SET TIME ZONE` extends syntax defined in the SQL standard. The standard allows only numeric time zone offsets while Postgres Pro allows more flexible time-zone specifications. All other `SET` features are Postgres Pro extensions.

See Also

[RESET](#), [SHOW](#)

SET CONSTRAINTS

SET CONSTRAINTS — set constraint check timing for the current transaction

Synopsis

```
SET CONSTRAINTS { ALL | name [, ...] } { DEFERRED | IMMEDIATE }
```

Description

SET CONSTRAINTS sets the behavior of constraint checking within the current transaction. IMMEDIATE constraints are checked at the end of each statement. DEFERRED constraints are not checked until transaction commit. Each constraint has its own IMMEDIATE or DEFERRED mode.

Upon creation, a constraint is given one of three characteristics: DEFERRABLE INITIALLY DEFERRED, DEFERRABLE INITIALLY IMMEDIATE, or NOT DEFERRABLE. The third class is always IMMEDIATE and is not affected by the SET CONSTRAINTS command. The first two classes start every transaction in the indicated mode, but their behavior can be changed within a transaction by SET CONSTRAINTS.

SET CONSTRAINTS with a list of constraint names changes the mode of just those constraints (which must all be deferrable). Each constraint name can be schema-qualified. The current schema search path is used to find the first matching name if no schema name is specified. SET CONSTRAINTS ALL changes the mode of all deferrable constraints.

When SET CONSTRAINTS changes the mode of a constraint from DEFERRED to IMMEDIATE, the new mode takes effect retroactively: any outstanding data modifications that would have been checked at the end of the transaction are instead checked during the execution of the SET CONSTRAINTS command. If any such constraint is violated, the SET CONSTRAINTS fails (and does not change the constraint mode). Thus, SET CONSTRAINTS can be used to force checking of constraints to occur at a specific point in a transaction.

Currently, only UNIQUE, PRIMARY KEY, REFERENCES (foreign key), and EXCLUDE constraints are affected by this setting. NOT NULL and CHECK constraints are always checked immediately when a row is inserted or modified (*not* at the end of the statement). Uniqueness and exclusion constraints that have not been declared DEFERRABLE are also checked immediately.

The firing of triggers that are declared as “constraint triggers” is also controlled by this setting — they fire at the same time that the associated constraint should be checked.

Notes

Because Postgres Pro does not require constraint names to be unique within a schema (but only per-table), it is possible that there is more than one match for a specified constraint name. In this case SET CONSTRAINTS will act on all matches. For a non-schema-qualified name, once a match or matches have been found in some schema in the search path, schemas appearing later in the path are not searched.

This command only alters the behavior of constraints within the current transaction. Issuing this outside of a transaction block emits a warning and otherwise has no effect.

Compatibility

This command complies with the behavior defined in the SQL standard, except for the limitation that, in Postgres Pro, it does not apply to NOT NULL and CHECK constraints. Also, Postgres Pro checks non-deferrable uniqueness constraints immediately, not at end of statement as the standard would suggest.

SET ROLE

SET ROLE — set the current user identifier of the current session

Synopsis

```
SET [ SESSION | LOCAL ] ROLE role_name
SET [ SESSION | LOCAL ] ROLE NONE
RESET ROLE
```

Description

This command sets the current user identifier of the current SQL session to be *role_name*. The role name can be written as either an identifier or a string literal. After SET ROLE, permissions checking for SQL commands is carried out as though the named role were the one that had logged in originally. Note that SET ROLE and SET SESSION AUTHORIZATION are exceptions; permissions checks for those continue to use the current session user and the initial session user (the *authenticated user*), respectively.

The current session user must have the SET option for the specified *role_name*, either directly or indirectly via a chain of memberships with the SET option. (If the session user is a superuser, any role can be selected.)

The SESSION and LOCAL modifiers act the same as for the regular SET command.

SET ROLE NONE sets the current user identifier to the current session user identifier, as returned by session_user. RESET ROLE sets the current user identifier to the connection-time setting specified by the [command-line options](#), ALTER ROLE, or ALTER DATABASE, if any such settings exist. Otherwise, RESET ROLE sets the current user identifier to the current session user identifier. These forms can be executed by any user.

Notes

Using this command, it is possible to either add privileges or restrict one's privileges. If the session user role has been granted memberships WITH INHERIT TRUE, it automatically has all the privileges of every such role. In this case, SET ROLE effectively drops all the privileges except for those which the target role directly possesses or inherits. On the other hand, if the session user role has been granted memberships WITH INHERIT FALSE, the privileges of the granted roles can't be accessed by default. However, if the role was granted WITH SET TRUE, the session user can use SET ROLE to drop the privileges assigned directly to the session user and instead acquire the privileges available to the named role. If the role was granted WITH INHERIT FALSE, SET FALSE then the privileges of that role cannot be exercised either with or without SET ROLE.

SET ROLE has effects comparable to SET SESSION AUTHORIZATION, but the privilege checks involved are quite different. Also, SET SESSION AUTHORIZATION determines which roles are allowable for later SET ROLE commands, whereas changing roles with SET ROLE does not change the set of roles allowed to a later SET ROLE.

SET ROLE does not process session variables as specified by the role's ALTER ROLE settings; this only happens during login.

SET ROLE cannot be used within a SECURITY DEFINER function.

Examples

```
SELECT SESSION_USER, CURRENT_USER;
```

```
session_user | current_user
-----+-----
```

```
peter          | peter

SET ROLE 'paul';

SELECT SESSION_USER, CURRENT_USER;

 session_user | current_user
-----+-----
peter        | paul
```

Compatibility

Postgres Pro allows identifier syntax ("*rolename*"), while the SQL standard requires the role name to be written as a string literal. SQL does not allow this command during a transaction; Postgres Pro does not make this restriction because there is no reason to. The `SESSION` and `LOCAL` modifiers are a Postgres Pro extension, as is the `RESET` syntax.

See Also

[SET SESSION AUTHORIZATION](#)

SET SESSION AUTHORIZATION

SET SESSION AUTHORIZATION — set the session user identifier and the current user identifier of the current session

Synopsis

```
SET [ SESSION | LOCAL ] SESSION AUTHORIZATION user_name
SET [ SESSION | LOCAL ] SESSION AUTHORIZATION DEFAULT
RESET SESSION AUTHORIZATION
```

Description

This command sets the session user identifier and the current user identifier of the current SQL session to be *user_name*. The user name can be written as either an identifier or a string literal. Using this command, it is possible, for example, to temporarily become an unprivileged user and later switch back to being a superuser.

The session user identifier is initially set to be the (possibly authenticated) user name provided by the client. The current user identifier is normally equal to the session user identifier, but might change temporarily in the context of SECURITY DEFINER functions and similar mechanisms; it can also be changed by SET ROLE. The current user identifier is relevant for permission checking.

The session user identifier can be changed only if the initial session user (the *authenticated user*) has the superuser privilege. Otherwise, the command is accepted only if it specifies the authenticated user name.

The SESSION and LOCAL modifiers act the same as for the regular SET command.

The DEFAULT and RESET forms reset the session and current user identifiers to be the originally authenticated user name. These forms can be executed by any user.

Notes

SET SESSION AUTHORIZATION cannot be used within a SECURITY DEFINER function.

Examples

```
SELECT SESSION_USER, CURRENT_USER;
```

```
 session_user | current_user
-----+-----
peter        | peter
```

```
SET SESSION AUTHORIZATION 'paul';
```

```
SELECT SESSION_USER, CURRENT_USER;
```

```
 session_user | current_user
-----+-----
paul         | paul
```

Compatibility

The SQL standard allows some other expressions to appear in place of the literal *user_name*, but these options are not important in practice. Postgres Pro allows identifier syntax ("*username*"), which SQL does not. SQL does not allow this command during a transaction; Postgres Pro does not make this restriction because there is no reason to. The SESSION and LOCAL modifiers are a Postgres Pro extension, as is the RESET syntax.

The privileges necessary to execute this command are left implementation-defined by the standard.

[SET ROLE](#)

SET TRANSACTION

SET TRANSACTION — set the characteristics of the current transaction

Synopsis

```
SET TRANSACTION transaction_mode [, ...]
SET TRANSACTION SNAPSHOT snapshot_id
SET SESSION CHARACTERISTICS AS TRANSACTION transaction_mode [, ...]
```

where *transaction_mode* is one of:

```
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ
UNCOMMITTED }
READ WRITE | READ ONLY
[ NOT ] DEFERRABLE
```

Description

The `SET TRANSACTION` command sets the characteristics of the current transaction. It has no effect on any subsequent transactions. `SET SESSION CHARACTERISTICS` sets the default transaction characteristics for subsequent transactions of a session. These defaults can be overridden by `SET TRANSACTION` for an individual transaction.

The available transaction characteristics are the transaction isolation level, the transaction access mode (read/write or read-only), and the deferrable mode. In addition, a snapshot can be selected, though only for the current transaction, not as a session default.

The isolation level of a transaction determines what data the transaction can see when other transactions are running concurrently:

`READ COMMITTED`

A statement can only see rows committed before it began. This is the default.

`REPEATABLE READ`

All statements of the current transaction can only see rows committed before the first query or data-modification statement was executed in this transaction.

`SERIALIZABLE`

All statements of the current transaction can only see rows committed before the first query or data-modification statement was executed in this transaction. If a pattern of reads and writes among concurrent serializable transactions would create a situation which could not have occurred for any serial (one-at-a-time) execution of those transactions, one of them will be rolled back with a `serialization_failure` error.

The SQL standard defines one additional level, `READ UNCOMMITTED`. In Postgres Pro `READ UNCOMMITTED` is treated as `READ COMMITTED`.

The transaction isolation level cannot be changed after the first query or data-modification statement (`SELECT`, `INSERT`, `DELETE`, `UPDATE`, `MERGE`, `FETCH`, or `COPY`) of a transaction has been executed. See [Chapter 13](#) for more information about transaction isolation and concurrency control.

The transaction access mode determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: `INSERT`, `UPDATE`, `DELETE`, `MERGE`, and `COPY FROM` if the table they would write to is not a temporary table; all `CREATE`, `ALTER`, and `DROP` commands; `COMMENT`, `GRANT`, `REVOKE`, `TRUNCATE`; and `EXPLAIN ANALYZE` and `EXECUTE` if the command they would execute is among those listed. This is a high-level notion of read-only that does not prevent all writes to disk.

The `DEFERRABLE` transaction property has no effect unless the transaction is also `SERIALIZABLE` and `READ ONLY`. When all three of these properties are selected for a transaction, the transaction may block when first acquiring its snapshot, after which it is able to run without the normal overhead of a `SERIALIZABLE` transaction and without any risk of contributing to or being canceled by a serialization failure. This mode is well suited for long-running reports or backups.

The `SET TRANSACTION SNAPSHOT` command allows a new transaction to run with the same *snapshot* as an existing transaction. The pre-existing transaction must have exported its snapshot with the `pg_export_snapshot` function (see [Section 9.28.5](#)). That function returns a snapshot identifier, which must be given to `SET TRANSACTION SNAPSHOT` to specify which snapshot is to be imported. The identifier must be written as a string literal in this command, for example `'00000003-0000001B-1'`. `SET TRANSACTION SNAPSHOT` can only be executed at the start of a transaction, before the first query or data-modification statement (`SELECT`, `INSERT`, `DELETE`, `UPDATE`, `MERGE`, `FETCH`, or `COPY`) of the transaction. Furthermore, the transaction must already be set to `SERIALIZABLE` or `REPEATABLE READ` isolation level (otherwise, the snapshot would be discarded immediately, since `READ COMMITTED` mode takes a new snapshot for each command). If the importing transaction uses `SERIALIZABLE` isolation level, then the transaction that exported the snapshot must also use that isolation level. Also, a non-read-only serializable transaction cannot import a snapshot from a read-only transaction.

Notes

If `SET TRANSACTION` is executed without a prior `START TRANSACTION` or `BEGIN`, it emits a warning and otherwise has no effect.

It is possible to dispense with `SET TRANSACTION` by instead specifying the desired *transaction_modes* in `BEGIN` or `START TRANSACTION`. But that option is not available for `SET TRANSACTION SNAPSHOT`.

The session default transaction modes can also be set or examined via the configuration parameters [default_transaction_isolation](#), [default_transaction_read_only](#), and [default_transaction_deferrable](#). (In fact `SET SESSION CHARACTERISTICS` is just a verbose equivalent for setting these variables with `SET`.) This means the defaults can be set in the configuration file, via `ALTER DATABASE`, etc. Consult [Chapter 19](#) for more information.

The current transaction's modes can similarly be set or examined via the configuration parameters [transaction_isolation](#), [transaction_read_only](#), and [transaction_deferrable](#). Setting one of these parameters acts the same as the corresponding `SET TRANSACTION` option, with the same restrictions on when it can be done. However, these parameters cannot be set in the configuration file, or from any source other than live SQL.

Examples

To begin a new transaction with the same snapshot as an already existing transaction, first export the snapshot from the existing transaction. That will return the snapshot identifier, for example:

```
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
SELECT pg_export_snapshot();
pg_export_snapshot
-----
00000003-0000001B-1
(1 row)
```

Then give the snapshot identifier in a `SET TRANSACTION SNAPSHOT` command at the beginning of the newly opened transaction:

```
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
SET TRANSACTION SNAPSHOT '00000003-0000001B-1';
```

Compatibility

These commands are defined in the SQL standard, except for the `DEFERRABLE` transaction mode and the `SET TRANSACTION SNAPSHOT` form, which are Postgres Pro extensions.

`SERIALIZABLE` is the default transaction isolation level in the standard. In Postgres Pro the default is ordinarily `READ COMMITTED`, but you can change it as mentioned above.

In the SQL standard, there is one other transaction characteristic that can be set with these commands: the size of the diagnostics area. This concept is specific to embedded SQL, and therefore is not implemented in the Postgres Pro server.

The SQL standard requires commas between successive *transaction_modes*, but for historical reasons Postgres Pro allows the commas to be omitted.

SHOW

SHOW — show the value of a run-time parameter

Synopsis

```
SHOW name
SHOW ALL
```

Description

SHOW will display the current setting of run-time parameters. These variables can be set using the SET statement, by editing the `postgresql.conf` configuration file, through the `PGOPTIONS` environmental variable (when using libpq or a libpq-based application), or through command-line flags when starting the `postgres` server. See [Chapter 19](#) for details.

Parameters

name

The name of a run-time parameter. Available parameters are documented in [Chapter 19](#) and on the [SET](#) reference page. In addition, there are a few parameters that can be shown but not set:

SERVER_VERSION

Shows the server's version number.

SERVER_ENCODING

Shows the server-side character set encoding. At present, this parameter can be shown but not set, because the encoding is determined at database creation time.

IS_SUPERUSER

True if the current role has superuser privileges.

ALL

Show the values of all configuration parameters, with descriptions.

Notes

The function `current_setting` produces equivalent output; see [Section 9.28.1](#). Also, the `pg_settings` system view produces the same information.

Examples

Show the current setting of the parameter `DateStyle`:

```
SHOW DateStyle;
DateStyle
-----
ISO, MDY
(1 row)
```

Show the current setting of the parameter `geqo`:

```
SHOW geqo;
geqo
-----
on
(1 row)
```

Show all settings:

```
SHOW ALL;
```

name	setting	description
allow_system_table_mods	off	Allows modifications of the structure of ...
.	.	.
xmloption	content	Sets whether XML data in implicit parsing ...
zero_damaged_pages	off	Continues processing past damaged page headers.

(196 rows)

Compatibility

The SHOW command is a Postgres Pro extension.

See Also

[SET](#), [RESET](#)

START TRANSACTION

START TRANSACTION — start a transaction block

Synopsis

```
START [ AUTONOMOUS ] TRANSACTION [ transaction_mode [, ...] ]
```

where *transaction_mode* is one of:

```
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ  
UNCOMMITTED }  
READ WRITE | READ ONLY  
[ NOT ] DEFERRABLE
```

Description

This command begins a new transaction block. If the isolation level, read/write mode, or deferrable mode is specified, the new transaction has those characteristics, as if [SET TRANSACTION](#) was executed. This is the same as the [BEGIN](#) command.

If you specify an optional `AUTONOMOUS` keyword, an autonomous transaction is started. Autonomous transactions can be started only within another transaction. For details, see [Chapter 16](#).

Parameters

Refer to [SET TRANSACTION](#) for information on the meaning of the parameters to this statement.

Compatibility

In the standard, it is not necessary to issue `START TRANSACTION` to start a transaction block: any SQL command implicitly begins a block. Postgres Pro's behavior can be seen as implicitly issuing a `COMMIT` after each command that does not follow `START TRANSACTION` (or `BEGIN`), and it is therefore often called “autocommit”. Other relational database systems might offer an autocommit feature as a convenience.

The `DEFERRABLE transaction_mode` is a Postgres Pro language extension.

The SQL standard requires commas between successive *transaction_modes*, but for historical reasons Postgres Pro allows the commas to be omitted.

See also the compatibility section of [SET TRANSACTION](#).

See Also

[BEGIN](#), [COMMIT](#), [ROLLBACK](#), [SAVEPOINT](#), [SET TRANSACTION](#)

TRUNCATE

TRUNCATE — empty a table or set of tables

Synopsis

```
TRUNCATE [ TABLE ] [ ONLY ] name [ * ] [, ... ]  
        [ RESTART IDENTITY | CONTINUE IDENTITY ] [ CASCADE | RESTRICT ]
```

Description

TRUNCATE quickly removes all rows from a set of tables. It has the same effect as an unqualified DELETE on each table, but since it does not actually scan the tables it is faster. Furthermore, it reclaims disk space immediately, rather than requiring a subsequent VACUUM operation. This is most useful on large tables.

Parameters

name

The name (optionally schema-qualified) of a table to truncate. If ONLY is specified before the table name, only that table is truncated. If ONLY is not specified, the table and all its descendant tables (if any) are truncated. Optionally, * can be specified after the table name to explicitly indicate that descendant tables are included.

RESTART IDENTITY

Automatically restart sequences owned by columns of the truncated table(s).

CONTINUE IDENTITY

Do not change the values of sequences. This is the default.

CASCADE

Automatically truncate all tables that have foreign-key references to any of the named tables, or to any tables added to the group due to CASCADE.

RESTRICT

Refuse to truncate if any of the tables have foreign-key references from tables that are not listed in the command. This is the default.

Notes

You must have the TRUNCATE privilege on a table to truncate it.

TRUNCATE acquires an ACCESS EXCLUSIVE lock on each table it operates on, which blocks all other concurrent operations on the table. When RESTART IDENTITY is specified, any sequences that are to be restarted are likewise locked exclusively. If concurrent access to a table is required, then the DELETE command should be used instead.

TRUNCATE cannot be used on a table that has foreign-key references from other tables, unless all such tables are also truncated in the same command. Checking validity in such cases would require table scans, and the whole point is not to do one. The CASCADE option can be used to automatically include all dependent tables — but be very careful when using this option, or else you might lose data you did not intend to! Note in particular that when the table to be truncated is a partition, siblings partitions are left untouched, but cascading occurs to all referencing tables and all their partitions with no distinction.

TRUNCATE will not fire any ON DELETE triggers that might exist for the tables. But it will fire ON TRUNCATE triggers. If ON TRUNCATE triggers are defined for any of the tables, then all BEFORE TRUNCATE triggers are

fired before any truncation happens, and all `AFTER TRUNCATE` triggers are fired after the last truncation is performed and any sequences are reset. The triggers will fire in the order that the tables are to be processed (first those listed in the command, and then any that were added due to cascading).

`TRUNCATE` is not MVCC-safe. After truncation, the table will appear empty to concurrent transactions, if they are using a snapshot taken before the truncation occurred. See [Section 13.6](#) for more details.

`TRUNCATE` is transaction-safe with respect to the data in the tables: the truncation will be safely rolled back if the surrounding transaction does not commit.

When `RESTART IDENTITY` is specified, the implied `ALTER SEQUENCE RESTART` operations are also done transactionally; that is, they will be rolled back if the surrounding transaction does not commit. Be aware that if any additional sequence operations are done on the restarted sequences before the transaction rolls back, the effects of these operations on the sequences will be rolled back, but not their effects on `currval()`; that is, after the transaction `currval()` will continue to reflect the last sequence value obtained inside the failed transaction, even though the sequence itself may no longer be consistent with that. This is similar to the usual behavior of `currval()` after a failed transaction.

`TRUNCATE` can be used for foreign tables if supported by the foreign data wrapper, for instance, see [postgres_fdw](#).

Examples

Truncate the tables `bigtable` and `fattable`:

```
TRUNCATE bigtable, fattable;
```

The same, and also reset any associated sequence generators:

```
TRUNCATE bigtable, fattable RESTART IDENTITY;
```

Truncate the table `othertable`, and cascade to any tables that reference `othertable` via foreign-key constraints:

```
TRUNCATE othertable CASCADE;
```

Compatibility

The SQL:2008 standard includes a `TRUNCATE` command with the syntax `TRUNCATE TABLE tablename`. The clauses `CONTINUE IDENTITY/RESTART IDENTITY` also appear in that standard, but have slightly different though related meanings. Some of the concurrency behavior of this command is left implementation-defined by the standard, so the above notes should be considered and compared with other implementations if necessary.

See Also

[DELETE](#)

UNLISTEN

UNLISTEN — stop listening for a notification

Synopsis

```
UNLISTEN { channel | * }
```

Description

UNLISTEN is used to remove an existing registration for NOTIFY events. UNLISTEN cancels any existing registration of the current Postgres Pro session as a listener on the notification channel named *channel*. The special wildcard * cancels all listener registrations for the current session.

[NOTIFY](#) contains a more extensive discussion of the use of LISTEN and NOTIFY.

Parameters

channel

Name of a notification channel (any identifier).

*

All current listen registrations for this session are cleared.

Notes

You can unlisten something you were not listening for; no warning or error will appear.

At the end of each session, UNLISTEN * is automatically executed.

A transaction that has executed UNLISTEN cannot be prepared for two-phase commit.

Examples

To make a registration:

```
LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with PID 8448.
```

Once UNLISTEN has been executed, further NOTIFY messages will be ignored:

```
UNLISTEN virtual;
NOTIFY virtual;
-- no NOTIFY event is received
```

Compatibility

There is no UNLISTEN command in the SQL standard.

See Also

[LISTEN](#), [NOTIFY](#)

UPDATE

UPDATE — update rows of a table

Synopsis

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
UPDATE [ ONLY ] table_name [ * ] [ [ AS ] alias ]
    SET { column_name = { expression | DEFAULT } |
        ( column_name [, ...] ) = [ ROW ] ( { expression | DEFAULT } [, ...] ) |
        ( column_name [, ...] ) = ( sub-SELECT )
    } [, ...]
[ FROM from_item [, ...] ]
[ WHERE condition | WHERE CURRENT OF cursor_name ]
[ RETURNING { * | output_expression [ [ AS ] output_name ] } [, ...] ]
```

Description

UPDATE changes the values of the specified columns in all rows that satisfy the condition. Only the columns to be modified need be mentioned in the SET clause; columns not explicitly modified retain their previous values.

There are two ways to modify a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the FROM clause. Which technique is more appropriate depends on the specific circumstances.

The optional RETURNING clause causes UPDATE to compute and return value(s) based on each row actually updated. Any expression using the table's columns, and/or columns of other tables mentioned in FROM, can be computed. The new (post-update) values of the table's columns are used. The syntax of the RETURNING list is identical to that of the output list of SELECT.

You must have the UPDATE privilege on the table, or at least on the column(s) that are listed to be updated. You must also have the SELECT privilege on any column whose values are read in the *expressions* or *condition*.

Parameters

with_query

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the UPDATE query. See [Section 7.8](#) and [SELECT](#) for details.

table_name

The name (optionally schema-qualified) of the table to update. If ONLY is specified before the table name, matching rows are updated in the named table only. If ONLY is not specified, matching rows are also updated in any tables inheriting from the named table. Optionally, * can be specified after the table name to explicitly indicate that descendant tables are included.

alias

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given UPDATE foo AS f, the remainder of the UPDATE statement must refer to this table as f not foo.

column_name

The name of a column in the table named by *table_name*. The column name can be qualified with a subfield name or array subscript, if needed. Do not include the table's name in the specification of a target column — for example, UPDATE table_name SET table_name.col = 1 is invalid.

expression

An expression to assign to the column. The expression can use the old values of this and other columns in the table.

DEFAULT

Set the column to its default value (which will be NULL if no specific default expression has been assigned to it). An identity column will be set to a new value generated by the associated sequence. For a generated column, specifying this is permitted but merely specifies the normal behavior of computing the column from its generation expression.

sub-SELECT

A `SELECT` sub-query that produces as many output columns as are listed in the parenthesized column list preceding it. The sub-query must yield no more than one row when executed. If it yields one row, its column values are assigned to the target columns; if it yields no rows, NULL values are assigned to the target columns. The sub-query can refer to old values of the current row of the table being updated.

from_item

A table expression allowing columns from other tables to appear in the `WHERE` condition and update expressions. This uses the same syntax as the `FROM` clause of a `SELECT` statement; for example, an alias for the table name can be specified. Do not repeat the target table as a *from_item* unless you intend a self-join (in which case it must appear with an alias in the *from_item*).

condition

An expression that returns a value of type `boolean`. Only rows for which this expression returns `true` will be updated.

cursor_name

The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be updated is the one most recently fetched from this cursor. The cursor must be a non-grouping query on the `UPDATE`'s target table. Note that `WHERE CURRENT OF` cannot be specified together with a Boolean condition. See [DECLARE](#) for more information about using cursors with `WHERE CURRENT OF`.

output_expression

An expression to be computed and returned by the `UPDATE` command after each row is updated. The expression can use any column names of the table named by *table_name* or table(s) listed in `FROM`. Write `*` to return all columns.

output_name

A name to use for a returned column.

Outputs

On successful completion, an `UPDATE` command returns a command tag of the form

```
UPDATE count
```

The *count* is the number of rows updated, including matched rows whose values did not change. Note that the number may be less than the number of rows that matched the *condition* when updates were suppressed by a `BEFORE UPDATE` trigger. If *count* is 0, no rows were updated by the query (this is not considered an error).

If the `UPDATE` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) updated by the command.

Notes

When a `FROM` clause is present, what essentially happens is that the target table is joined to the tables mentioned in the *from_item* list, and each output row of the join represents an update operation for the target table. When using `FROM` you should ensure that the join produces at most one output row for each row to be modified. In other words, a target row shouldn't join to more than one row from the other table(s). If it does, then only one of the join rows will be used to update the target row, but which one will be used is not readily predictable.

Because of this indeterminacy, referencing other tables only within sub-selects is safer, though often harder to read and slower than using a join.

In the case of a partitioned table, updating a row might cause it to no longer satisfy the partition constraint of the containing partition. In that case, if there is some other partition in the partition tree for which this row satisfies its partition constraint, then the row is moved to that partition. If there is no such partition, an error will occur. Behind the scenes, the row movement is actually a `DELETE` and `INSERT` operation.

There is a possibility that a concurrent `UPDATE` or `DELETE` on the row being moved will get a serialization failure error. Suppose session 1 is performing an `UPDATE` on a partition key, and meanwhile a concurrent session 2 for which this row is visible performs an `UPDATE` or `DELETE` operation on this row. In such case, session 2's `UPDATE` or `DELETE` will detect the row movement and raise a serialization failure error (which always returns with an `SQLSTATE` code '40001'). Applications may wish to retry the transaction if this occurs. In the usual case where the table is not partitioned, or where there is no row movement, session 2 would have identified the newly updated row and carried out the `UPDATE/DELETE` on this new row version.

Note that while rows can be moved from local partitions to a foreign-table partition (provided the foreign data wrapper supports tuple routing), they cannot be moved from a foreign-table partition to another partition.

An attempt of moving a row from one partition to another will fail if a foreign key is found to directly reference an ancestor of the source partition that is not the same as the ancestor that's mentioned in the `UPDATE` query.

Examples

Change the word `Drama` to `Dramatic` in the column `kind` of the table `films`:

```
UPDATE films SET kind = 'Dramatic' WHERE kind = 'Drama';
```

Adjust temperature entries and reset precipitation to its default value in one row of the table `weather`:

```
UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp = DEFAULT
WHERE city = 'San Francisco' AND date = '2003-07-03';
```

Perform the same operation and return the updated entries:

```
UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp = DEFAULT
WHERE city = 'San Francisco' AND date = '2003-07-03'
RETURNING temp_lo, temp_hi, prcp;
```

Use the alternative column-list syntax to do the same update:

```
UPDATE weather SET (temp_lo, temp_hi, prcp) = (temp_lo+1, temp_lo+15, DEFAULT)
WHERE city = 'San Francisco' AND date = '2003-07-03';
```

Increment the sales count of the salesperson who manages the account for Acme Corporation, using the `FROM` clause syntax:

```
UPDATE employees SET sales_count = sales_count + 1 FROM accounts
WHERE accounts.name = 'Acme Corporation'
AND employees.id = accounts.sales_person;
```

Perform the same operation, using a sub-select in the `WHERE` clause:

```
UPDATE employees SET sales_count = sales_count + 1 WHERE id =
  (SELECT sales_person FROM accounts WHERE name = 'Acme Corporation');
```

Update contact names in an accounts table to match the currently assigned salespeople:

```
UPDATE accounts SET (contact_first_name, contact_last_name) =
  (SELECT first_name, last_name FROM employees
   WHERE employees.id = accounts.sales_person);
```

A similar result could be accomplished with a join:

```
UPDATE accounts SET contact_first_name = first_name,
                    contact_last_name = last_name
  FROM employees WHERE employees.id = accounts.sales_person;
```

However, the second query may give unexpected results if `employees.id` is not a unique key, whereas the first query is guaranteed to raise an error if there are multiple `id` matches. Also, if there is no match for a particular `accounts.sales_person` entry, the first query will set the corresponding name fields to `NULL`, whereas the second query will not update that row at all.

Update statistics in a summary table to match the current data:

```
UPDATE summary s SET (sum_x, sum_y, avg_x, avg_y) =
  (SELECT sum(x), sum(y), avg(x), avg(y) FROM data d
   WHERE d.group_id = s.group_id);
```

Attempt to insert a new stock item along with the quantity of stock. If the item already exists, instead update the stock count of the existing item. To do this without failing the entire transaction, use savepoints:

```
BEGIN;
-- other operations
SAVEPOINT sp1;
INSERT INTO wines VALUES('Chateau Lafite 2003', '24');
-- Assume the above fails because of a unique key violation,
-- so now we issue these commands:
ROLLBACK TO sp1;
UPDATE wines SET stock = stock + 24 WHERE winename = 'Chateau Lafite 2003';
-- continue with other operations, and eventually
COMMIT;
```

Change the `kind` column of the table `films` in the row on which the cursor `c_films` is currently positioned:

```
UPDATE films SET kind = 'Dramatic' WHERE CURRENT OF c_films;
```

Updates affecting many rows can have negative effects on system performance, such as table bloat, increased replica lag, and increased lock contention. In such situations it can make sense to perform the operation in smaller batches, possibly with a `VACUUM` operation on the table between batches. While there is no `LIMIT` clause for `UPDATE`, it is possible to get a similar effect through the use of a [Common Table Expression](#) and a self-join. With the standard Postgres Pro table access method, a self-join on the system column `ctid` is very efficient:

```
WITH exceeded_max_retries AS (
  SELECT w.ctid FROM work_item AS w
    WHERE w.status = 'active' AND w.num_retries > 10
    ORDER BY w.retry_timestamp
    FOR UPDATE
    LIMIT 5000
)
UPDATE work_item SET status = 'failed'
  FROM exceeded_max_retries AS emr
```

```
WHERE work_item.ctid = emr.ctid;
```

This command will need to be repeated until no rows remain to be updated. Use of an `ORDER BY` clause allows the command to prioritize which rows will be updated; it can also prevent deadlock with other update operations if they use the same ordering. If lock contention is a concern, then `SKIP LOCKED` can be added to the CTE to prevent multiple commands from updating the same row. However, then a final `UPDATE` without `SKIP LOCKED` or `LIMIT` will be needed to ensure that no matching rows were overlooked.

Compatibility

This command conforms to the SQL standard, except that the `FROM` and `RETURNING` clauses are Postgres Pro extensions, as is the ability to use `WITH` with `UPDATE`.

Some other database systems offer a `FROM` option in which the target table is supposed to be listed again within `FROM`. That is not how Postgres Pro interprets `FROM`. Be careful when porting applications that use this extension.

According to the standard, the source value for a parenthesized sub-list of target column names can be any row-valued expression yielding the correct number of columns. Postgres Pro only allows the source value to be a [row constructor](#) or a sub-`SELECT`. An individual column's updated value can be specified as `DEFAULT` in the row-constructor case, but not inside a sub-`SELECT`.

VACUUM

VACUUM — garbage-collect and optionally analyze a database

Synopsis

```
VACUUM [ ( option [, ...] ) ] [ table_and_columns [, ...] ]
```

where *option* can be one of:

```
FULL [ boolean ]
FREEZE [ boolean ]
VERBOSE [ boolean ]
ANALYZE [ boolean ]
DISABLE_PAGE_SKIPPING [ boolean ]
SKIP_LOCKED [ boolean ]
INDEX_CLEANUP { AUTO | ON | OFF }
PROCESS_MAIN [ boolean ]
PROCESS_TOAST [ boolean ]
TRUNCATE [ boolean ]
PARALLEL integer
SKIP_DATABASE_STATS [ boolean ]
ONLY_DATABASE_STATS [ boolean ]
BUFFER_USAGE_LIMIT size
```

and *table_and_columns* is:

```
table_name [ ( column_name [, ...] ) ]
```

Description

VACUUM reclaims storage occupied by dead tuples. In normal Postgres Pro operation, tuples that are deleted or obsoleted by an update are not physically removed from their table; they remain present until a VACUUM is done. Therefore it's necessary to do VACUUM periodically, especially on frequently-updated tables.

Without a *table_and_columns* list, VACUUM processes every table and materialized view in the current database that the current user has permission to vacuum. With a list, VACUUM processes only those table(s).

VACUUM ANALYZE performs a VACUUM and then an ANALYZE for each selected table. This is a handy combination form for routine maintenance scripts. See [ANALYZE](#) for more details about its processing.

Plain VACUUM (without FULL) simply reclaims space and makes it available for re-use. This form of the command can operate in parallel with normal reading and writing of the table, as an exclusive lock is not obtained. However, extra space is not returned to the operating system (in most cases); it's just kept available for re-use within the same table. It also allows us to leverage multiple CPUs in order to process indexes. This feature is known as *parallel vacuum*. To disable this feature, one can use PARALLEL option and specify parallel workers as zero. VACUUM FULL rewrites the entire contents of the table into a new disk file with no extra space, allowing unused space to be returned to the operating system. This form is much slower and requires an ACCESS EXCLUSIVE lock on each table while it is being processed.

Parameters

FULL

Selects “full” vacuum, which can reclaim more space, but takes much longer and exclusively locks the table. This method also requires extra disk space, since it writes a new copy of the table and

doesn't release the old copy until the operation is complete. Usually this should only be used when a significant amount of space needs to be reclaimed from within the table.

FREEZE

Selects aggressive “freezing” of tuples. Specifying `FREEZE` is equivalent to performing `VACUUM` with the `vacuum_freeze_min_age` and `vacuum_freeze_table_age` parameters set to zero. Aggressive freezing is always performed when the table is rewritten, so this option is redundant when `FULL` is specified.

VERBOSE

Prints a detailed vacuum activity report for each table.

ANALYZE

Updates statistics used by the planner to determine the most efficient way to execute a query.

DISABLE_PAGE_SKIPPING

Normally, `VACUUM` will skip pages based on the [visibility map](#). Pages where all tuples are known to be frozen can always be skipped, and those where all tuples are known to be visible to all transactions may be skipped except when performing an aggressive vacuum. Furthermore, except when performing an aggressive vacuum, some pages may be skipped in order to avoid waiting for other sessions to finish using them. This option disables all page-skipping behavior, and is intended to be used only when the contents of the visibility map are suspect, which should happen only if there is a hardware or software issue causing database corruption.

SKIP_LOCKED

Specifies that `VACUUM` should not wait for any conflicting locks to be released when beginning work on a relation: if a relation cannot be locked immediately without waiting, the relation is skipped. Note that even with this option, `VACUUM` may still block when opening the relation's indexes. Additionally, `VACUUM ANALYZE` may still block when acquiring sample rows from partitions, table inheritance children, and some types of foreign tables. Also, while `VACUUM` ordinarily processes all partitions of specified partitioned tables, this option will cause `VACUUM` to skip all partitions if there is a conflicting lock on the partitioned table.

INDEX_CLEANUP

Normally, `VACUUM` will skip index vacuuming when there are very few dead tuples in the table. The cost of processing all of the table's indexes is expected to greatly exceed the benefit of removing dead index tuples when this happens. This option can be used to force `VACUUM` to process indexes when there are more than zero dead tuples. The default is `AUTO`, which allows `VACUUM` to skip index vacuuming when appropriate. If `INDEX_CLEANUP` is set to `ON`, `VACUUM` will conservatively remove all dead tuples from indexes. This may be useful for backwards compatibility with earlier releases of PostgreSQL where this was the standard behavior.

`INDEX_CLEANUP` can also be set to `OFF` to force `VACUUM` to *always* skip index vacuuming, even when there are many dead tuples in the table. This may be useful when it is necessary to make `VACUUM` run as quickly as possible to avoid imminent transaction ID wraparound (see [Section 24.1.5](#)). However, the wraparound failsafe mechanism controlled by `vacuum_failsafe_age` will generally trigger automatically to avoid transaction ID wraparound failure, and should be preferred. If index cleanup is not performed regularly, performance may suffer, because as the table is modified indexes will accumulate dead tuples and the table itself will accumulate dead line pointers that cannot be removed until index cleanup is completed.

This option has no effect for tables that have no index and is ignored if the `FULL` option is used. It also has no effect on the transaction ID wraparound failsafe mechanism. When triggered it will skip index vacuuming, even when `INDEX_CLEANUP` is set to `ON`.

PROCESS_MAIN

Specifies that `VACUUM` should attempt to process the main relation. This is usually the desired behavior and is the default. Setting this option to false may be useful when it is only necessary to vacuum a relation's corresponding `TOAST` table.

PROCESS_TOAST

Specifies that `VACUUM` should attempt to process the corresponding `TOAST` table for each relation, if one exists. This is usually the desired behavior and is the default. Setting this option to false may be useful when it is only necessary to vacuum the main relation. This option is required when the `FULL` option is used.

TRUNCATE

Specifies that `VACUUM` should attempt to truncate off any empty pages at the end of the table and allow the disk space for the truncated pages to be returned to the operating system. This is normally the desired behavior and is the default unless the `vacuum_truncate` option has been set to false for the table to be vacuumed. Setting this option to false may be useful to avoid `ACCESS EXCLUSIVE` lock on the table that the truncation requires. This option is ignored if the `FULL` option is used.

PARALLEL

Perform index vacuum and index cleanup phases of `VACUUM` in parallel using *integer* background workers (for the details of each vacuum phase, please refer to [Table 27.53](#)). The number of workers used to perform the operation is equal to the number of indexes on the relation that support parallel vacuum which is limited by the number of workers specified with `PARALLEL` option if any which is further limited by [max_parallel_maintenance_workers](#). An index can participate in parallel vacuum if and only if the size of the index is more than [min_parallel_index_scan_size](#). Please note that it is not guaranteed that the number of parallel workers specified in *integer* will be used during execution. It is possible for a vacuum to run with fewer workers than specified, or even with no workers at all. Only one worker can be used per index. So parallel workers are launched only when there are at least 2 indexes in the table. Workers for vacuum are launched before the start of each phase and exit at the end of the phase. These behaviors might change in a future release. This option can't be used with the `FULL` option.

SKIP_DATABASE_STATS

Specifies that `VACUUM` should skip updating the database-wide statistics about oldest unfrozen XIDs. Normally `VACUUM` will update these statistics once at the end of the command. However, this can take awhile in a database with a very large number of tables, and it will accomplish nothing unless the table that had contained the oldest unfrozen XID was among those vacuumed. Moreover, if multiple `VACUUM` commands are issued in parallel, only one of them can update the database-wide statistics at a time. Therefore, if an application intends to issue a series of many `VACUUM` commands, it can be helpful to set this option in all but the last such command; or set it in all the commands and separately issue `VACUUM (ONLY_DATABASE_STATS)` afterwards.

ONLY_DATABASE_STATS

Specifies that `VACUUM` should do nothing except update the database-wide statistics about oldest unfrozen XIDs. When this option is specified, the *table_and_columns* list must be empty, and no other option may be enabled except `VERBOSE`.

BUFFER_USAGE_LIMIT

Specifies the [Buffer Access Strategy](#) ring buffer size for `VACUUM`. This size is used to calculate the number of shared buffers which will be reused as part of this strategy. 0 disables use of a Buffer Access Strategy. If `ANALYZE` is also specified, the `BUFFER_USAGE_LIMIT` value is used for both the vacuum and analyze stages. This option can't be used with the `FULL` option except if `ANALYZE` is also specified. When this option is not specified, `VACUUM` uses the value from [vacuum_buffer_usage_limit](#). Higher settings can allow `VACUUM` to run more quickly, but having too large a setting may cause too

many other useful pages to be evicted from shared buffers. The minimum value is 128 kB and the maximum value is 16 GB.

boolean

Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to disable it. The *boolean* value can also be omitted, in which case `TRUE` is assumed.

integer

Specifies a non-negative integer value passed to the selected option.

size

Specifies an amount of memory in kilobytes. Sizes may also be specified as a string containing the numerical size followed by any one of the following memory units: `B` (bytes), `kB` (kilobytes), `MB` (megabytes), `GB` (gigabytes), or `TB` (terabytes).

table_name

The name (optionally schema-qualified) of a specific table or materialized view to vacuum. If the specified table is a partitioned table, all of its leaf partitions are vacuumed.

column_name

The name of a specific column to analyze. Defaults to all columns. If a column list is specified, `ANALYZE` must also be specified.

Outputs

When `VERBOSE` is specified, `VACUUM` emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

Notes

To vacuum a table, one must ordinarily have the `MAINTAIN` privilege on the table. However, database owners are allowed to vacuum all tables in their databases, except shared catalogs. `VACUUM` will skip over any tables that the calling user does not have permission to vacuum.

While `VACUUM` is running, the [search_path](#) is temporarily changed to `pg_catalog`, `pg_temp`.

`VACUUM` cannot be executed inside a transaction block.

For tables with GIN indexes, `VACUUM` (in any form) also completes any pending index insertions, by moving pending index entries to the appropriate places in the main GIN index structure. See [Section 65.4.4.1](#) for details.

We recommend that all databases be vacuumed regularly in order to remove dead rows. Postgres Pro includes an “autovacuum” facility which can automate routine vacuum maintenance. For more information about automatic and manual vacuuming, see [Section 24.1](#).

The `FULL` option is not recommended for routine use, but might be useful in special cases. An example is when you have deleted or updated most of the rows in a table and would like the table to physically shrink to occupy less disk space and allow faster table scans. `VACUUM FULL` will usually shrink the table more than a plain `VACUUM` would.

The `PARALLEL` option is used only for vacuum purposes. If this option is specified with the `ANALYZE` option, it does not affect `ANALYZE`.

`VACUUM` causes a substantial increase in I/O traffic, which might cause poor performance for other active sessions. Therefore, it is sometimes advisable to use the cost-based vacuum delay feature. For parallel vacuum, each worker sleeps in proportion to the work done by that worker. See [Section 19.4.4](#) for details.

Each backend running `VACUUM` without the `FULL` option will report its progress in the `pg_stat_progress_vacuum` view. Backends running `VACUUM FULL` will instead report their progress in the `pg_stat_progress_cluster` view. See [Section 27.4.5](#) and [Section 27.4.2](#) for details.

Examples

To clean a single table `onek`, analyze it for the optimizer and print a detailed vacuum activity report:

```
VACUUM (VERBOSE, ANALYZE) onek;
```

Compatibility

There is no `VACUUM` statement in the SQL standard.

The following syntax was used before PostgreSQL version 9.0 and is still supported:

```
VACUUM [ FULL ] [ FREEZE ] [ VERBOSE ] [ ANALYZE ] [ table_and_columns [, ...] ]
```

Note that in this syntax, the options must be specified in exactly the order shown.

VALUES

VALUES — compute a set of rows

Synopsis

```
VALUES ( expression [, ...] ) [, ...]  
  [ ORDER BY sort_expression [ ASC | DESC | USING operator ] [, ...] ]  
  [ LIMIT { count | ALL } ]  
  [ OFFSET start [ ROW | ROWS ] ]  
  [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY ]
```

Description

VALUES computes a row value or set of row values specified by value expressions. It is most commonly used to generate a “constant table” within a larger command, but it can be used on its own.

When more than one row is specified, all the rows must have the same number of elements. The data types of the resulting table's columns are determined by combining the explicit or inferred types of the expressions appearing in that column, using the same rules as for UNION (see [Section 10.5](#)).

Within larger commands, VALUES is syntactically allowed anywhere that SELECT is. Because it is treated like a SELECT by the grammar, it is possible to use the ORDER BY, LIMIT (or equivalently FETCH FIRST), and OFFSET clauses with a VALUES command.

Parameters

expression

A constant or expression to compute and insert at the indicated place in the resulting table (set of rows). In a VALUES list appearing at the top level of an INSERT, an *expression* can be replaced by DEFAULT to indicate that the destination column's default value should be inserted. DEFAULT cannot be used when VALUES appears in other contexts.

sort_expression

An expression or integer constant indicating how to sort the result rows. This expression can refer to the columns of the VALUES result as column1, column2, etc. For more details see [ORDER BY Clause](#) in the [SELECT](#) documentation.

operator

A sorting operator. For details see [ORDER BY Clause](#) in the [SELECT](#) documentation.

count

The maximum number of rows to return. For details see [LIMIT Clause](#) in the [SELECT](#) documentation.

start

The number of rows to skip before starting to return rows. For details see [LIMIT Clause](#) in the [SELECT](#) documentation.

Notes

VALUES lists with very large numbers of rows should be avoided, as you might encounter out-of-memory failures or poor performance. VALUES appearing within INSERT is a special case (because the desired column types are known from the INSERT's target table, and need not be inferred by scanning the VALUES list), so it can handle larger lists than are practical in other contexts.

Examples

A bare VALUES command:

```
VALUES (1, 'one'), (2, 'two'), (3, 'three');
```

This will return a table of two columns and three rows. It's effectively equivalent to:

```
SELECT 1 AS column1, 'one' AS column2
UNION ALL
SELECT 2, 'two'
UNION ALL
SELECT 3, 'three';
```

More usually, VALUES is used within a larger SQL command. The most common use is in INSERT:

```
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

In the context of INSERT, entries of a VALUES list can be DEFAULT to indicate that the column default should be used here instead of specifying a value:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes'),
('T_601', 'Yojimbo', 106, DEFAULT, 'Drama', DEFAULT);
```

VALUES can also be used where a sub-SELECT might be written, for example in a FROM clause:

```
SELECT f.*
FROM films f, (VALUES('MGM', 'Horror'), ('UA', 'Sci-Fi')) AS t (studio, kind)
WHERE f.studio = t.studio AND f.kind = t.kind;
```

```
UPDATE employees SET salary = salary * v.increase
FROM (VALUES(1, 200000, 1.2), (2, 400000, 1.4)) AS v (depno, target, increase)
WHERE employees.depno = v.depno AND employees.sales >= v.target;
```

Note that an AS clause is required when VALUES is used in a FROM clause, just as is true for SELECT. It is not required that the AS clause specify names for all the columns, but it's good practice to do so. (The default column names for VALUES are column1, column2, etc. in Postgres Pro, but these names might be different in other database systems.)

When VALUES is used in INSERT, the values are all automatically coerced to the data type of the corresponding destination column. When it's used in other contexts, it might be necessary to specify the correct data type. If the entries are all quoted literal constants, coercing the first is sufficient to determine the assumed type for all:

```
SELECT * FROM machines
WHERE ip_address IN (VALUES('192.168.0.1'::inet), ('192.168.0.10'), ('192.168.1.43'));
```

Tip

For simple IN tests, it's better to rely on the [list-of-scalars](#) form of IN than to write a VALUES query as shown above. The list of scalars method requires less writing and is often more efficient.

Compatibility

VALUES conforms to the SQL standard. LIMIT and OFFSET are Postgres Pro extensions; see also under [SELECT](#).

[INSERT](#), [SELECT](#)

Postgres Pro Client Applications

This part contains reference information for Postgres Pro client applications and utilities. Not all of these commands are of general utility; some might require special privileges. The common feature of these applications is that they can be run on any host, independent of where the database server resides.

When specified on the command line, user and database names have their case preserved — the presence of spaces or special characters might require quoting. Table names and other identifiers do not have their case preserved, except where documented, and might require quoting.

clusterdb

clusterdb — cluster a Postgres Pro database

Synopsis

```
clusterdb [connection-option...] [option...] [ --table | -t table ] ... [ dbname | -a | --all ]
```

Description

clusterdb is a utility for recluster tables in a Postgres Pro database. It finds tables that have previously been clustered, and clusters them again on the same index that was last used. Tables that have never been clustered are not affected.

clusterdb is a wrapper around the SQL command [CLUSTER](#). There is no effective difference between clustering databases via this utility and via other methods for accessing the server.

Options

clusterdb accepts the following command-line arguments:

-a
--all

Cluster all databases.

[-d] dbname
[--dbname=] dbname

Specifies the name of the database to be clustered, when -a/--all is not used. If this is not specified, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used. The dbname can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

-e
--echo

Echo the commands that clusterdb generates and sends to the server.

-q
--quiet

Do not display progress messages.

-t table
--table=table

Cluster table only. Multiple tables can be clustered by writing multiple -t switches.

-v
--verbose

Print detailed information during processing.

-V
--version

Print the clusterdb version and exit.

-?
--help

Show help about clusterdb command line arguments, and exit.

clusterdb also accepts the following command-line arguments for connection parameters:

`-h host`
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`
`--username=username`

User name to connect as.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force clusterdb to prompt for a password before connecting to a database.

This option is never essential, since clusterdb will automatically prompt for a password if the server demands password authentication. However, clusterdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--maintenance-db=dbname`

When the `-a/--all` is used, connect to this database to gather the list of databases to cluster. If not specified, the `postgres` database will be used, or if that does not exist, `template1` will be used. This can be a [connection string](#). If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

Environment

PGDATABASE
PGHOST
PGPORT
PGUSER

Default connection parameters

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 35.15](#)).

Diagnostics

In case of difficulty, see [CLUSTER](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Examples

To cluster the database `test`:

```
$ clusterdb test
```

To cluster a single table `foo` in a database named `xyzzzy`:

```
$ clusterdb --table=foo xyzzzy
```

See Also

[CLUSTER](#)

createdb

createdb — create a new Postgres Pro database

Synopsis

```
createdb [connection-option...] [option...] [dbname [description]]
```

Description

createdb creates a new Postgres Pro database.

Note

Note createdb only works for local DBs.

Normally, the database user who executes this command becomes the owner of the new database. However, a different owner can be specified via the `-O` option, if the executing user has appropriate privileges.

createdb is a wrapper around the SQL command `CREATE DATABASE`. There is no effective difference between creating databases via this utility and via other methods for accessing the server.

Options

createdb accepts the following command-line arguments:

dbname

Specifies the name of the database to be created. The name must be unique among all Postgres Pro databases in this cluster. The default is to create a database with the same name as the current system user.

description

Specifies a comment to be associated with the newly created database.

`-D tablespace`

`--tablespace=tablespace`

Specifies the default tablespace for the database. (This name is processed as a double-quoted identifier.)

`-e`

`--echo`

Echo the commands that createdb generates and sends to the server.

`-E encoding`

`--encoding=encoding`

Specifies the character encoding scheme to be used in this database. The character sets supported by the Postgres Pro server are described in [Section 23.3.1](#).

`-l locale`

`--locale=locale`

Specifies the locale to be used in this database. This is equivalent to specifying `--lc-collate`, `--lc-ctype`, and `--icu-locale` to the same value. Some locales are only valid for ICU and must be set with `--icu-locale`.

`--lc-collate=locale`

Specifies the LC_COLLATE setting to be used in this database.

`--lc-ctype=locale`

Specifies the LC_CTYPE setting to be used in this database.

`--builtin-locale=locale`

Specifies the locale name when the builtin provider is used. Locale support is described in [Section 23.1](#).

`--icu-locale=locale`

Specifies the ICU locale ID to be used in this database, if the ICU locale provider is selected.

`--icu-rules=rules`

Specifies additional collation rules to customize the behavior of the default collation of this database. This is supported for ICU only.

`--locale-provider={builtin|libc|icu}`

Specifies the locale provider for the database's default collation.

`-O owner`

`--owner=owner`

Specifies the database user who will own the new database. (This name is processed as a double-quoted identifier.)

`-S strategy`

`--strategy=strategy`

Specifies the database creation strategy. See [CREATE DATABASE STRATEGY](#) for more details.

`-T template`

`--template=template`

Specifies the template database from which to build this database. (This name is processed as a double-quoted identifier.)

`-V`

`--version`

Print the createdb version and exit.

`-?`

`--help`

Show help about createdb command line arguments, and exit.

The options `-D`, `-l`, `-E`, `-O`, and `-T` correspond to options of the underlying SQL command [CREATE DATABASE](#); see there for more information about them.

createdb also accepts the following command-line arguments for connection parameters:

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`

`--port=port`

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username=username
```

User name to connect as.

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force createdb to prompt for a password before connecting to a database.

This option is never essential, since createdb will automatically prompt for a password if the server demands password authentication. However, createdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

```
--maintenance-db=dbname
```

Specifies the name of the database to connect to when creating the new database. If not specified, the `postgres` database will be used; if that does not exist (or if it is the name of the new database being created), `template1` will be used. This can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

Environment

`PGDATABASE`

If set, the name of the database to create, unless overridden on the command line.

`PGHOST`
`PGPORT`
`PGUSER`

Default connection parameters. `PGUSER` also determines the name of the database to create, if it is not specified on the command line or by `PGDATABASE`.

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 35.15](#)).

Diagnostics

In case of difficulty, see [CREATE DATABASE](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Examples

To create the database `demo` using the default database server:

```
$ createdb demo
```

To create the database `demo` using the server on host `eden`, port 5000, using the `template0` template database, here is the command-line command and the underlying SQL command:

```
$ createdb -p 5000 -h eden -T template0 -e demo  
CREATE DATABASE demo TEMPLATE template0;
```

[dropdb](#), [CREATE DATABASE](#)

createuser

createuser — define a new Postgres Pro user account

Synopsis

```
createuser [connection-option...] [option...] [username]
```

Description

createuser creates a new Postgres Pro user (or more precisely, a role). Only superusers and users with `CREATEROLE` privilege can create new users, so createuser must be invoked by someone who can connect as a superuser or a user with `CREATEROLE` privilege.

Note

Note createuser cannot create global users.

If you wish to create a role with the `SUPERUSER`, `REPLICATION`, or `BYPASSRLS` privilege, you must connect as a superuser, not merely with `CREATEROLE` privilege. Being a superuser implies the ability to bypass all access permission checks within the database, so superuser access should not be granted lightly. `CREATEROLE` also conveys [very extensive privileges](#).

createuser is a wrapper around the SQL command `CREATE ROLE`. There is no effective difference between creating users via this utility and via other methods for accessing the server.

Options

createuser accepts the following command-line arguments:

username

Specifies the name of the Postgres Pro user to be created. This name must be different from all existing roles in this Postgres Pro installation.

`-a role`

`--with-admin=role`

Specifies an existing role that will be automatically added as a member of the new role with admin option, giving it the right to grant membership in the new role to others. Multiple existing roles can be specified by writing multiple `-a` switches.

`-c number`

`--connection-limit=number`

Set a maximum number of connections for the new user. The default is to set no limit.

`-d`

`--createdb`

The new user will be allowed to create databases.

`-D`

`--no-createdb`

The new user will not be allowed to create databases. This is the default.

`-e`

`--echo`

Echo the commands that createuser generates and sends to the server.

`-E`
`--encrypted`

This option is obsolete but still accepted for backward compatibility.

`-g role`
`--member-of=role`
`--role=role` (deprecated)

Specifies the new role should be automatically added as a member of the specified existing role. Multiple existing roles can be specified by writing multiple `-g` switches.

`-i`
`--inherit`

The new role will automatically inherit privileges of roles it is a member of. This is the default.

`-I`
`--no-inherit`

The new role will not automatically inherit privileges of roles it is a member of.

`--interactive`

Prompt for the user name if none is specified on the command line, and also prompt for whichever of the options `-d/-D`, `-r/-R`, `-s/-S` is not specified on the command line. (This was the default behavior up to PostgreSQL 9.1.)

`-l`
`--login`

The new user will be allowed to log in (that is, the user name can be used as the initial session user identifier). This is the default.

`-L`
`--no-login`

The new user will not be allowed to log in. (A role without login privilege is still useful as a means of managing database permissions.)

`-m role`
`--with-member=role`

Specifies an existing role that will be automatically added as a member of the new role. Multiple existing roles can be specified by writing multiple `-m` switches.

`-P`
`--pwprompt`

If given, `createuser` will issue a prompt for the password of the new user. This is not necessary if you do not plan on using password authentication.

`-r`
`--createrole`

The new user will be allowed to create, alter, drop, comment on, change the security label for other roles; that is, this user will have `CREATEROLE` privilege. See [role creation](#) for more details about what capabilities are conferred by this privilege.

`-R`
`--no-createrole`

The new user will not be allowed to create new roles. This is the default.

`-s`
`--superuser`
The new user will be a superuser.

`-S`
`--no-superuser`
The new user will not be a superuser. This is the default.

`-v timestamp`
`--valid-until=timestamp`
Set a date and time after which the role's password is no longer valid. The default is to set no password expiry date.

`-V`
`--version`
Print the createuser version and exit.

`--bypassrls`
The new user will bypass every row-level security (RLS) policy.

`--no-bypassrls`
The new user will not bypass row-level security (RLS) policies. This is the default.

`--profile=profile`
The new role will be assigned the profile that enforces password management policy. All restrictions of this profile will apply to the role.

`--replication`
The new user will have the `REPLICATION` privilege, which is described more fully in the documentation for [CREATE ROLE](#).

`--no-replication`
The new user will not have the `REPLICATION` privilege, which is described more fully in the documentation for [CREATE ROLE](#). This is the default.

`-?`
`--help`
Show help about createuser command line arguments, and exit.

createuser also accepts the following command-line arguments for connection parameters:

`-h host`
`--host=host`
Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`
`--port=port`
Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`
`--username=username`
User name to connect as (not the user name to create).

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force createuser to prompt for a password (for connecting to the server, not for the password of the new user).

This option is never essential, since createuser will automatically prompt for a password if the server demands password authentication. However, createuser will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

Environment

`PGHOST`
`PGPORT`
`PGUSER`

Default connection parameters

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 35.15](#)).

Diagnostics

In case of difficulty, see [CREATE ROLE](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Examples

To create a user `joe` on the default database server:

```
$ createuser joe
```

To create a user `joe` on the default database server with prompting for some additional attributes:

```
$ createuser --interactive joe
Shall the new role be a superuser? (y/n) n
Shall the new role be allowed to create databases? (y/n) n
Shall the new role be allowed to create more new roles? (y/n) n
```

To create the same user `joe` using the server on host `eden`, port 5000, with attributes explicitly specified, taking a look at the underlying command:

```
$ createuser -h eden -p 5000 -S -D -R -e joe
CREATE ROLE joe NOSUPERUSER NOCREATEDB NOCREATEROLE INHERIT LOGIN;
```

To create the user `joe` as a superuser, and assign a password immediately:

```
$ createuser -P -s -e joe
Enter password for new role: xyzzy
Enter it again: xyzzy
```

```
CREATE ROLE joe PASSWORD 'md5b5f5ba1a423792b526f799ae4eb3d59e' SUPERUSER CREATEDB  
CREATEROLE INHERIT LOGIN;
```

In the above example, the new password isn't actually echoed when typed, but we show what was typed for clarity. As you see, the password is encrypted before it is sent to the client.

[dropuser](#), [CREATE ROLE](#), [createrole_self_grant](#)

dropdb

dropdb — remove a Postgres Pro database

Synopsis

```
dropdb [connection-option...] [option...] dbname
```

Description

dropdb destroys an existing Postgres Pro database. The user who executes this command must be a database superuser or the owner of the database.

dropdb is a wrapper around the SQL command [DROP DATABASE](#). There is no effective difference between dropping databases via this utility and via other methods for accessing the server.

Options

dropdb accepts the following command-line arguments:

dbname

Specifies the name of the database to be removed.

-e

--echo

Echo the commands that dropdb generates and sends to the server.

-f

--force

Attempt to terminate all existing connections to the target database before dropping it. See [DROP DATABASE](#) for more information on this option.

-i

--interactive

Issues a verification prompt before doing anything destructive.

-V

--version

Print the dropdb version and exit.

--if-exists

Do not throw an error if the database does not exist. A notice is issued in this case.

-?

--help

Show help about dropdb command line arguments, and exit.

dropdb also accepts the following command-line arguments for connection parameters:

-h *host*

--host=*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`
`--username=username`

User name to connect as.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force dropdb to prompt for a password before connecting to a database.

This option is never essential, since dropdb will automatically prompt for a password if the server demands password authentication. However, dropdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to in order to drop the target database. If not specified, the `postgres` database will be used; if that does not exist (or is the database being dropped), `template1` will be used. This can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

Environment

PGHOST
PGPORT
PGUSER

Default connection parameters

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 35.15](#)).

Diagnostics

In case of difficulty, see [DROP DATABASE](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Examples

To destroy the database `demo` on the default database server:

```
$ dropdb demo
```

To destroy the database `demo` using the server on host `eden`, port 5000, with verification and a peek at the underlying command:

```
$ dropdb -p 5000 -h eden -i -e demo
Database "demo" will be permanently deleted.
Are you sure? (y/n) y
DROP DATABASE demo;
```

See Also

[createdb](#), [DROP DATABASE](#)

dropuser

dropuser — remove a Postgres Pro user account

Synopsis

```
dropuser [connection-option...] [option...] [username]
```

Description

dropuser removes an existing Postgres Pro user. Superusers can use this command to remove any role; otherwise, only non-superuser roles can be removed, and only by a user who possesses the `CREATEROLE` privilege and has been granted `ADMIN OPTION` on the target role.

dropuser is a wrapper around the SQL command `DROP ROLE`. There is no effective difference between dropping users via this utility and via other methods for accessing the server.

Options

dropuser accepts the following command-line arguments:

username

Specifies the name of the Postgres Pro user to be removed. You will be prompted for a name if none is specified on the command line and the `-i/--interactive` option is used.

`-e`

`--echo`

Echo the commands that dropuser generates and sends to the server.

`-i`

`--interactive`

Prompt for confirmation before actually removing the user, and prompt for the user name if none is specified on the command line.

`-V`

`--version`

Print the dropuser version and exit.

`--if-exists`

Do not throw an error if the user does not exist. A notice is issued in this case.

`-?`

`--help`

Show help about dropuser command line arguments, and exit.

dropuser also accepts the following command-line arguments for connection parameters:

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username=username
```

User name to connect as (not the user name to drop).

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force dropuser to prompt for a password before connecting to a database.

This option is never essential, since dropuser will automatically prompt for a password if the server demands password authentication. However, dropuser will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

Environment

```
PGHOST
PGPORT
PGUSER
```

Default connection parameters

```
PG_COLOR
```

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 35.15](#)).

Diagnostics

In case of difficulty, see [DROP ROLE](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Examples

To remove user `joe` from the default database server:

```
$ dropuser joe
```

To remove user `joe` using the server on host `eden`, port 5000, with verification and a peek at the underlying command:

```
$ dropuser -p 5000 -h eden -i -e joe
Role "joe" will be permanently removed.
Are you sure? (y/n) y
DROP ROLE joe;
```

[createuser](#), [DROP ROLE](#)

ecpg

ecpg — embedded SQL C preprocessor

Synopsis

`ecpg [option...] file...`

Description

`ecpg` is the embedded SQL preprocessor for C programs. It converts C programs with embedded SQL statements to normal C code by replacing the SQL invocations with special function calls. The output files can then be processed with any C compiler tool chain.

`ecpg` will convert each input file given on the command line to the corresponding C output file. If an input file name does not have any extension, `.pgc` is assumed. The file's extension will be replaced by `.c` to construct the output file name. But the output file name can be overridden using the `-o` option.

If an input file name is just `-`, `ecpg` reads the program from standard input (and writes to standard output, unless that is overridden with `-o`).

This reference page does not describe the embedded SQL language. See [Chapter 37](#) for more information on that topic.

Options

`ecpg` accepts the following command-line arguments:

- `-c`
Automatically generate certain C code from SQL code. Currently, this works for `EXEC SQL TYPE`.
- `-C mode`
Set a compatibility mode. *mode* can be `INFORMIX`, `INFORMIX_SE`, or `ORACLE`.
- `-D symbol[=value]`
Define a preprocessor symbol, equivalently to the `EXEC SQL DEFINE` directive. If no *value* is specified, the symbol is defined with the value `1`.
- `-h`
Process header files. When this option is specified, the output file extension becomes `.h` not `.c`, and the default input file extension is `.pgh` not `.pgc`. Also, the `-c` option is forced on.
- `-i`
Parse system include files as well.
- `-I directory`
Specify an additional include path, used to find files included via `EXEC SQL INCLUDE`. Defaults are `.` (current directory), `/usr/local/include`, the Postgres Pro include directory which is defined at compile time (default: `/usr/local/pgsql/include`), and `/usr/include`, in that order.
- `-o filename`
Specifies that `ecpg` should write all its output to the given *filename*. Write `-o -` to send all output to standard output.
- `-r option`
Selects run-time behavior. *Option* can be one of the following:

no_indicator

Do not use indicators but instead use special values to represent null values. Historically there have been databases using this approach.

prepare

Prepare all statements before using them. Libecpg will keep a cache of prepared statements and reuse a statement if it gets executed again. If the cache runs full, libecpg will free the least used statement.

questionmarks

Allow question mark as placeholder for compatibility reasons. This used to be the default long ago.

-t

Turn on autocommit of transactions. In this mode, each SQL command is automatically committed unless it is inside an explicit transaction block. In the default mode, commands are committed only when EXEC SQL COMMIT is issued.

-v

Print additional information including the version and the "include" path.

--version

Print the ecpg version and exit.

-?**--help**

Show help about ecpg command line arguments, and exit.

Notes

When compiling the preprocessed C code files, the compiler needs to be able to find the ECPG header files in the Postgres Pro include directory. Therefore, you might have to use the `-I` option when invoking the compiler (e.g., `-I/usr/local/pgsql/include`).

Programs using C code with embedded SQL have to be linked against the `libecpg` library, for example using the linker options `-L/usr/local/pgsql/lib -lecpg`.

The value of either of these directories that is appropriate for the installation can be found out using [pg_config](#).

Examples

If you have an embedded SQL C source file named `prog1.pgc`, you can create an executable program using the following sequence of commands:

```
ecpg prog1.pgc
cc -I/usr/local/pgsql/include -c prog1.c
cc -o prog1 prog1.o -L/usr/local/pgsql/lib -lecpg
```

pg_amcheck

pg_amcheck — checks for corruption in one or more Postgres Pro databases

Synopsis

```
pg_amcheck [option...] [dbname]
```

Description

pg_amcheck supports running [amcheck](#)'s corruption checking functions against one or more databases, with options to select which schemas, tables and indexes to check, which kinds of checking to perform, and whether to perform the checks in parallel, and if so, the number of parallel connections to establish and use.

Only ordinary and toast table relations, materialized views, sequences, and btree indexes are currently supported. Other relation types are silently skipped.

If *dbname* is specified, it should be the name of a single database to check, and no other database selection options should be present. Otherwise, if any database selection options are present, all matching databases will be checked. If no such options are present, the default database will be checked. Database selection options include `--all`, `--database` and `--exclude-database`. They also include `--relation`, `--exclude-relation`, `--table`, `--exclude-table`, `--index`, and `--exclude-index`, but only when such options are used with a three-part pattern (e.g. `mydb*.myschema*.myrel*`). Finally, they include `--schema` and `--exclude-schema` when such options are used with a two-part pattern (e.g. `mydb*.myschema*`).

dbname can also be a [connection string](#).

Options

The following command-line options control what is checked:

```
-a  
--all
```

Check all databases, except for any excluded via `--exclude-database`.

```
-d pattern  
--database=pattern
```

Check databases matching the specified *pattern*, except for any excluded by `--exclude-database`. This option can be specified more than once.

```
-D pattern  
--exclude-database=pattern
```

Exclude databases matching the given *pattern*. This option can be specified more than once.

```
-i pattern  
--index=pattern
```

Check indexes matching the specified *pattern*, unless they are otherwise excluded. This option can be specified more than once.

This is similar to the `--relation` option, except that it applies only to indexes, not to other relation types.

```
-I pattern  
--exclude-index=pattern
```

Exclude indexes matching the specified *pattern*. This option can be specified more than once.

This is similar to the `--exclude-relation` option, except that it applies only to indexes, not other relation types.

```
-r pattern  
--relation=pattern
```

Check relations matching the specified *pattern*, unless they are otherwise excluded. This option can be specified more than once.

Patterns may be unqualified, e.g. `myrel*`, or they may be schema-qualified, e.g. `myschema*.myrel*` or database-qualified and schema-qualified, e.g. `mydb*.myschema*.myrel*`. A database-qualified pattern will add matching databases to the list of databases to be checked.

```
-R pattern  
--exclude-relation=pattern
```

Exclude relations matching the specified *pattern*. This option can be specified more than once.

As with `--relation`, the *pattern* may be unqualified, schema-qualified, or database- and schema-qualified.

```
-s pattern  
--schema=pattern
```

Check tables and indexes in schemas matching the specified *pattern*, unless they are otherwise excluded. This option can be specified more than once.

To select only tables in schemas matching a particular pattern, consider using something like `--table=SCHEMAPAT.* --no-dependent-indexes`. To select only indexes, consider using something like `--index=SCHEMAPAT.*`.

A schema pattern may be database-qualified. For example, you may write `--schema=mydb*.myschema*` to select schemas matching `myschema*` in databases matching `mydb*`.

```
-S pattern  
--exclude-schema=pattern
```

Exclude tables and indexes in schemas matching the specified *pattern*. This option can be specified more than once.

As with `--schema`, the pattern may be database-qualified.

```
-t pattern  
--table=pattern
```

Check tables matching the specified *pattern*, unless they are otherwise excluded. This option can be specified more than once.

This is similar to the `--relation` option, except that it applies only to tables, materialized views, and sequences, not to indexes.

```
-T pattern  
--exclude-table=pattern
```

Exclude tables matching the specified *pattern*. This option can be specified more than once.

This is similar to the `--exclude-relation` option, except that it applies only to tables, materialized views, and sequences, not to indexes.

```
--no-dependent-indexes
```

By default, if a table is checked, any btree indexes of that table will also be checked, even if they are not explicitly selected by an option such as `--index` or `--relation`. This option suppresses that behavior.

`--no-dependent-toast`

By default, if a table is checked, its toast table, if any, will also be checked, even if it is not explicitly selected by an option such as `--table` or `--relation`. This option suppresses that behavior.

`--no-strict-names`

By default, if an argument to `--database`, `--table`, `--index`, or `--relation` matches no objects, it is a fatal error. This option downgrades that error to a warning.

The following command-line options control checking of tables:

`--exclude-toast-pointers`

By default, whenever a toast pointer is encountered in a table, a lookup is performed to ensure that it references apparently-valid entries in the toast table. These checks can be quite slow, and this option can be used to skip them.

`--on-error-stop`

After reporting all corruptions on the first page of a table where corruption is found, stop processing that table relation and move on to the next table or index.

Note that index checking always stops after the first corrupt page. This option only has meaning relative to table relations.

`--skip=option`

If `all-frozen` is given, table corruption checks will skip over pages in all tables that are marked as all frozen.

If `all-visible` is given, table corruption checks will skip over pages in all tables that are marked as all visible.

By default, no pages are skipped. This can be specified as `none`, but since this is the default, it need not be mentioned.

`--startblock=block`

Start checking at the specified block number. An error will occur if the table relation being checked has fewer than this number of blocks. This option does not apply to indexes, and is probably only useful when checking a single table relation. See `--endblock` for further caveats.

`--endblock=block`

End checking at the specified block number. An error will occur if the table relation being checked has fewer than this number of blocks. This option does not apply to indexes, and is probably only useful when checking a single table relation. If both a regular table and a toast table are checked, this option will apply to both, but higher-numbered toast blocks may still be accessed while validating toast pointers, unless that is suppressed using `--exclude-toast-pointers`.

The following command-line options control checking of B-tree indexes:

`--checkunique`

For each index with unique constraint checked, verify that no more than one among duplicate entries is visible in the index using [amcheck's](#) `checkunique` option.

`--heapallindexed`

For each index checked, verify the presence of all heap tuples as index tuples in the index using [amcheck's](#) `heapallindexed` option.

`--parent-check`

For each btree index checked, use [amcheck's](#) `bt_index_parent_check` function, which performs additional checks of parent/child relationships during index checking.

The default is to use `amcheck`'s `bt_index_check` function, but note that use of the `--rootdescend` option implicitly selects `bt_index_parent_check`.

`--rootdescend`

For each index checked, re-find tuples on the leaf level by performing a new search from the root page for each tuple using `amcheck`'s `rootdescend` option.

Use of this option implicitly also selects the `--parent-check` option.

This form of verification was originally written to help in the development of btree index features. It may be of limited use or even of no use in helping detect the kinds of corruption that occur in practice. It may also cause corruption checking to take considerably longer and consume considerably more resources on the server.

Warning

The extra checks performed against B-tree indexes when the `--parent-check` option or the `--rootdescend` option is specified require relatively strong relation-level locks. These checks are the only checks that will block concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands.

The following command-line options control the connection to the server:

`-h hostname`

`--host=hostname`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U`

`--username=username`

User name to connect as.

`-w`

`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`

`--password`

Force `pg_amcheck` to prompt for a password before connecting to a database.

This option is never essential, since `pg_amcheck` will automatically prompt for a password if the server demands password authentication. However, `pg_amcheck` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--maintenance-db=dbname`

Specifies a database or [connection string](#) to be used to discover the list of databases to be checked. If neither `--all` nor any option including a database pattern is used, no such connection is required and

this option does nothing. Otherwise, any connection string parameters other than the database name which are included in the value for this option will also be used when connecting to the databases being checked. If this option is omitted, the default is `postgres` or, if that fails, `template1`.

Other options are also available:

`-e`
`--echo`

Echo to stdout all SQL sent to the server.

`-j num`
`--jobs=num`

Use *num* concurrent connections to the server, or one per object to be checked, whichever is less.

The default is to use a single connection.

`-P`
`--progress`

Show progress information. Progress information includes the number of relations for which checking has been completed, and the total size of those relations. It also includes the total number of relations that will eventually be checked, and the estimated size of those relations.

`-v`
`--verbose`

Print more messages. In particular, this will print a message for each relation being checked, and will increase the level of detail shown for server errors.

`-V`
`--version`

Print the `pg_amcheck` version and exit.

`--install-missing`
`--install-missing=schema`

Install any missing extensions that are required to check the database(s). If not yet installed, each extension's objects will be installed into the given *schema*, or if not specified into schema `pg_catalog`.

At present, the only required extension is [amcheck](#).

`-?`
`--help`

Show help about `pg_amcheck` command line arguments, and exit.

Environment

`pg_amcheck`, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 35.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

`pg_amcheck` is designed to work with Postgres Pro 14.0 and later.

pgbench

pgbench — run a benchmark test on Postgres Pro

Synopsis

```
pgbench -i [option...] [dbname]
```

```
pgbench [option...] [dbname]
```

Description

pgbench is a simple program for running benchmark tests on Postgres Pro. It runs the same sequence of SQL commands over and over, possibly in multiple concurrent database sessions, and then calculates the average transaction rate (transactions per second). By default, pgbench tests a scenario that is loosely based on TPC-B, involving five `SELECT`, `UPDATE`, and `INSERT` commands per transaction. However, it is easy to test other cases by writing your own transaction script files.

Typical output from pgbench looks like:

```
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 10
query mode: simple
number of clients: 10
number of threads: 1
maximum number of tries: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
number of failed transactions: 0 (0.000%)
latency average = 11.013 ms
latency stddev = 7.351 ms
initial connection time = 45.758 ms
tps = 896.967014 (without initial connection time)
```

The first seven lines report some of the most important parameter settings. The sixth line reports the maximum number of tries for transactions with serialization or deadlock errors (see [Failures and Serialization/Deadlock Retries](#) for more information). The eighth line reports the number of transactions completed and intended (the latter being just the product of number of clients and number of transactions per client); these will be equal unless the run failed before completion or some SQL command(s) failed. (In `-T` mode, only the actual number of transactions is printed.) The next line reports the number of failed transactions due to serialization or deadlock errors (see [Failures and Serialization/Deadlock Retries](#) for more information). The last line reports the number of transactions per second.

The default TPC-B-like transaction test requires specific tables to be set up beforehand. pgbench should be invoked with the `-i` (initialize) option to create and populate these tables. (When you are testing a custom script, you don't need this step, but will instead need to do whatever setup your test needs.) Initialization looks like:

```
pgbench -i [ other-options ] dbname
```

where *dbname* is the name of the already-created database to test in. (You may also need `-h`, `-p`, and/or `-U` options to specify how to connect to the database server.)

Caution

pgbench -i creates four tables `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`, destroying any existing tables of these names. Be very careful to use another database if you have tables having these names!

At the default “scale factor” of 1, the tables initially contain this many rows:

table	# of rows
-----	-----
pgbench_branches	1
pgbench_tellers	10
pgbench_accounts	100000
pgbench_history	0

You can (and, for most purposes, probably should) increase the number of rows by using the `-s` (scale factor) option. The `-F` (fillfactor) option might also be used at this point.

Once you have done the necessary setup, you can run your benchmark with a command that doesn't include `-i`, that is

```
pgbench [ options ] dbname
```

In nearly all cases, you'll need some options to make a useful test. The most important options are `-c` (number of clients), `-t` (number of transactions), `-T` (time limit), and `-f` (specify a custom script file). See below for a full list.

Options

The following is divided into three subsections. Different options are used during database initialization and while running benchmarks, but some options are useful in both cases.

Initialization Options

pgbench accepts the following command-line initialization arguments:

```
[-d] dbname  
[--dbname=] dbname
```

Specifies the name of the database to test in. If this is not specified, the environment variable `PGDATABASE` is used. If that is not set, the user name specified for the connection is used.

```
-i  
--initialize
```

Required to invoke initialization mode.

```
-I init_steps  
--init-steps=init_steps
```

Perform just a selected set of the normal initialization steps. *init_steps* specifies the initialization steps to be performed, using one character per step. Each step is invoked in the specified order. The default is `dtgvp`. The available steps are:

d (Drop)

Drop any existing pgbench tables.

t (create Tables)

Create the tables used by the standard pgbench scenario, namely `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`.

g or G (Generate data, client-side or server-side)

Generate data and load it into the standard tables, replacing any data already present.

With `g` (client-side data generation), data is generated in `pgbench` client and then sent to the server. This uses the client/server bandwidth extensively through a `COPY`. `pgbench` uses the `FREEZE`

option to load data into ordinary (non-partition) tables with version 14 or later of Postgres Pro to speed up subsequent `VACUUM`. Using `g` causes logging to print one message every 100,000 rows while generating data for all tables.

With `G` (server-side data generation), only small queries are sent from the `pgbench` client and then data is actually generated in the server. No significant bandwidth is required for this variant, but the server will do more work. Using `G` causes logging not to print any progress message while generating data.

The default initialization behavior uses client-side data generation (equivalent to `g`).

`v` (Vacuum)

Invoke `VACUUM` on the standard tables.

`p` (create Primary keys)

Create primary key indexes on the standard tables.

`f` (create Foreign keys)

Create foreign key constraints between the standard tables. (Note that this step is not performed by default.)

`-F fillfactor`

`--fillfactor=fillfactor`

Create the `pgbench_accounts`, `pgbench_tellers` and `pgbench_branches` tables with the given fillfactor. Default is 100.

`-n`

`--no-vacuum`

Perform no vacuuming during initialization. (This option suppresses the `v` initialization step, even if it was specified in `-I`.)

`-q`

`--quiet`

Switch logging to quiet mode, producing only one progress message per 5 seconds. The default logging prints one message each 100,000 rows, which often outputs many lines per second (especially on good hardware).

This setting has no effect if `G` is specified in `-I`.

`-s scale_factor`

`--scale=scale_factor`

Multiply the number of rows generated by the scale factor. For example, `-s 100` will create 10,000,000 rows in the `pgbench_accounts` table. Default is 1. When the scale is 20,000 or larger, the columns used to hold account identifiers (`aid` columns) will switch to using larger integers (`bigint`), in order to be big enough to hold the range of account identifiers.

`--foreign-keys`

Create foreign key constraints between the standard tables. (This option adds the `f` step to the initialization step sequence, if it is not already present.)

`--index-tablespace=index_tablespace`

Create indexes in the specified tablespace, rather than the default tablespace.

`--partition-method=NAME`

Create a partitioned `pgbench_accounts` table with *NAME* method. Expected values are `range` or `hash`. This option requires that `--partitions` is set to non-zero. If unspecified, default is `range`.

`--partitions=NUM`

Create a partitioned `pgbench_accounts` table with *NUM* partitions of nearly equal size for the scaled number of accounts. Default is 0, meaning no partitioning.

`--tablespace=tablespace`

Create tables in the specified tablespace, rather than the default tablespace.

`--unlogged-tables`

Create all tables as unlogged tables, rather than permanent tables.

Benchmarking Options

`pgbench` accepts the following command-line benchmarking arguments:

`-b scriptname[@weight]`

`--builtin=scriptname[@weight]`

Add the specified built-in script to the list of scripts to be executed. Available built-in scripts are: `tpcb-like`, `simple-update` and `select-only`. Unambiguous prefixes of built-in names are accepted. With the special name `list`, show the list of built-in scripts and exit immediately.

Optionally, write an integer weight after `@` to adjust the probability of selecting this script versus other ones. The default weight is 1. See below for details.

`-c clients`

`--client=clients`

Number of clients simulated, that is, number of concurrent database sessions. Default is 1.

`-C`

`--connect`

Establish a new connection for each transaction, rather than doing it just once per client session. This is useful to measure the connection overhead.

`-D varname=value`

`--define=varname=value`

Define a variable for use by a custom script (see below). Multiple `-D` options are allowed.

`-f filename[@weight]`

`--file=filename[@weight]`

Add a transaction script read from *filename* to the list of scripts to be executed.

Optionally, write an integer weight after `@` to adjust the probability of selecting this script versus other ones. The default weight is 1. (To use a script file name that includes an `@` character, append a weight so that there is no ambiguity, for example `filen@me@1`.) See below for details.

`-j threads`

`--jobs=threads`

Number of worker threads within `pgbench`. Using more than one thread can be helpful on multi-CPU machines. Clients are distributed as evenly as possible among available threads. Default is 1.

-l
--log

Write information about each transaction to a log file. See below for details.

-L *limit*
--latency-limit=*limit*

Transactions that last more than *limit* milliseconds are counted and reported separately, as *late*.

When throttling is used (`--rate=...`), transactions that lag behind schedule by more than *limit* ms, and thus have no hope of meeting the latency limit, are not sent to the server at all. They are counted and reported separately as *skipped*.

When the `--max-tries` option is used, a transaction which fails due to a serialization anomaly or from a deadlock will not be retried if the total time of all its tries is greater than *limit* ms. To limit only the time of tries and not their number, use `--max-tries=0`. By default, the option `--max-tries` is set to 1 and transactions with serialization/deadlock errors are not retried. See [Failures and Serialization/Deadlock Retries](#) for more information about retrying such transactions.

-M *querymode*
--protocol=*querymode*

Protocol to use for submitting queries to the server:

- `simple`: use simple query protocol.
- `extended`: use extended query protocol.
- `prepared`: use extended query protocol with prepared statements.

In the `prepared` mode, `pgbench` reuses the parse analysis result starting from the second query iteration, so `pgbench` runs faster than in other modes.

The default is simple query protocol. (See [Chapter 56](#) for more information.)

-n
--no-vacuum

Perform no vacuuming before running the test. This option is *necessary* if you are running a custom test scenario that does not include the standard tables `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`.

-N
--skip-some-updates

Run built-in simple-update script. Shorthand for `-b simple-update`.

-P *sec*
--progress=*sec*

Show progress report every *sec* seconds. The report includes the time since the beginning of the run, the TPS since the last report, and the transaction latency average, standard deviation, and the number of failed transactions since the last report. Under throttling (`-R`), the latency is computed with respect to the transaction scheduled start time, not the actual transaction beginning time, thus it also includes the average schedule lag time. When `--max-tries` is used to enable transaction retries after serialization/deadlock errors, the report includes the number of retried transactions and the sum of all retries.

-r
--report-per-command

Report the following statistics for each command after the benchmark finishes: the average per-statement latency (execution time from the perspective of the client), the number of failures, and the number of retries after serialization or deadlock errors in this command. The report displays retry statistics only if the `--max-tries` option is not equal to 1.

`-R rate`
`--rate=rate`

Execute transactions targeting the specified rate instead of running as fast as possible (the default). The rate is given in transactions per second. If the targeted rate is above the maximum possible rate, the rate limit won't impact the results.

The rate is targeted by starting transactions along a Poisson-distributed schedule time line. The expected start time schedule moves forward based on when the client first started, not when the previous transaction ended. That approach means that when transactions go past their original scheduled end time, it is possible for later ones to catch up again.

When throttling is active, the transaction latency reported at the end of the run is calculated from the scheduled start times, so it includes the time each transaction had to wait for the previous transaction to finish. The wait time is called the schedule lag time, and its average and maximum are also reported separately. The transaction latency with respect to the actual transaction start time, i.e., the time spent executing the transaction in the database, can be computed by subtracting the schedule lag time from the reported latency.

If `--latency-limit` is used together with `--rate`, a transaction can lag behind so much that it is already over the latency limit when the previous transaction ends, because the latency is calculated from the scheduled start time. Such transactions are not sent to the server, but are skipped altogether and counted separately.

A high schedule lag time is an indication that the system cannot process transactions at the specified rate, with the chosen number of clients and threads. When the average transaction execution time is longer than the scheduled interval between each transaction, each successive transaction will fall further behind, and the schedule lag time will keep increasing the longer the test run is. When that happens, you will have to reduce the specified transaction rate.

`-s scale_factor`
`--scale=scale_factor`

Report the specified scale factor in pgbench's output. With the built-in tests, this is not necessary; the correct scale factor will be detected by counting the number of rows in the `pgbench_branches` table. However, when testing only custom benchmarks (`-f` option), the scale factor will be reported as 1 unless this option is used.

`-S`
`--select-only`

Run built-in select-only script. Shorthand for `-b select-only`.

`-t transactions`
`--transactions=transactions`

Number of transactions each client runs. Default is 10.

`-T seconds`
`--time=seconds`

Run the test for this many seconds, rather than a fixed number of transactions per client. `-t` and `-T` are mutually exclusive.

`-v`
`--vacuum-all`

Vacuum all four standard tables before running the test. With neither `-n` nor `-v`, pgbench will vacuum the `pgbench_tellers` and `pgbench_branches` tables, and will truncate `pgbench_history`.

`--aggregate-interval=seconds`

Length of aggregation interval (in seconds). May be used only with `-l` option. With this option, the log contains per-interval summary data, as described below.

`--exit-on-abort`

Exit immediately when any client is aborted due to some error. Without this option, even when a client is aborted, other clients could continue their run as specified by `-t` or `-T` option, and `pgbench` will print an incomplete results in this case.

Note that serialization failures or deadlock failures do not abort the client, so they are not affected by this option. See [Failures and Serialization/Deadlock Retries](#) for more information.

`--failures-detailed`

Report failures in per-transaction and aggregation logs, as well as in the main and per-script reports, grouped by the following types:

- serialization failures;
- deadlock failures;

See [Failures and Serialization/Deadlock Retries](#) for more information.

`--log-prefix=prefix`

Set the filename prefix for the log files created by `--log`. The default is `pgbench_log`.

`--max-tries=number_of_tries`

Enable retries for transactions with serialization/deadlock errors and set the maximum number of these tries. This option can be combined with the `--latency-limit` option which limits the total time of all transaction tries; moreover, you cannot use an unlimited number of tries (`--max-tries=0`) without `--latency-limit` or `--time`. The default value is 1 and transactions with serialization/deadlock errors are not retried. See [Failures and Serialization/Deadlock Retries](#) for more information about retrying such transactions.

`--progress-timestamp`

When showing progress (option `-P`), use a timestamp (Unix epoch) instead of the number of seconds since the beginning of the run. The unit is in seconds, with millisecond precision after the dot. This helps compare logs generated by various tools.

`--random-seed=seed`

Set random generator seed. Seeds the system random number generator, which then produces a sequence of initial generator states, one for each thread. Values for *seed* may be: `time` (the default, the seed is based on the current time), `rand` (use a strong random source, failing if none is available), or an unsigned decimal integer value. The random generator is invoked explicitly from a `pgbench` script (`random...` functions) or implicitly (for instance option `--rate` uses it to schedule transactions). When explicitly set, the value used for seeding is shown on the terminal. Any value allowed for *seed* may also be provided through the environment variable `PGBENCH_RANDOM_SEED`. To ensure that the provided seed impacts all possible uses, put this option first or use the environment variable.

Setting the seed explicitly allows to reproduce a `pgbench` run exactly, as far as random numbers are concerned. As the random state is managed per thread, this means the exact same `pgbench` run for an identical invocation if there is one client per thread and there are no external or data dependencies. From a statistical viewpoint reproducing runs exactly is a bad idea because it can hide the performance variability or improve performance unduly, e.g., by hitting the same pages as a previous run. However, it may also be of great help for debugging, for instance re-running a tricky case which leads to an error. Use wisely.

`--sampling-rate=rate`

Sampling rate, used when writing data into the log, to reduce the amount of log generated. If this option is given, only the specified fraction of transactions are logged. 1.0 means all transactions will be logged, 0.05 means only 5% of the transactions will be logged.

Remember to take the sampling rate into account when processing the log file. For example, when computing TPS values, you need to multiply the numbers accordingly (e.g., with 0.01 sample rate, you'll only get 1/100 of the actual TPS).

`--show-script=scriptname`

Show the actual code of builtin script *scriptname* on stderr, and exit immediately.

`--verbose-errors`

Print messages about all errors and failures (errors without retrying) including which limit for retries was exceeded and how far it was exceeded for the serialization/deadlock failures. (Note that in this case the output can be significantly increased.) See [Failures and Serialization/Deadlock Retries](#) for more information.

Common Options

pgbench also accepts the following common command-line arguments for connection parameters and other common settings:

`--debug`

Print debugging output.

`-h hostname`

`--host=hostname`

The database server's host name

`-p port`

`--port=port`

The database server's port number

`-U login`

`--username=login`

The user name to connect as

`-V`

`--version`

Print the pgbench version and exit.

`-?`

`--help`

Show help about pgbench command line arguments, and exit.

Exit Status

A successful run will exit with status 0. Exit status 1 indicates static problems such as invalid command-line options or internal errors which are supposed to never occur. Early errors that occur when starting benchmark such as initial connection failures also exit with status 1. Errors during the run such as database errors or problems in the script will result in exit status 2. In the latter case, pgbench will print partial results if `--exit-on-abort` option is not specified.

Environment

PGDATABASE

PGHOST

PGPORT

PGUSER

Default connection parameters.

This utility, like most other Postgres Pro utilities, uses the environment variables supported by libpq (see [Section 35.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

What Is the “Transaction” Actually Performed in pgbench?

pgbench executes test scripts chosen randomly from a specified list. The scripts may include built-in scripts specified with `-b` and user-provided scripts specified with `-f`. Each script may be given a relative weight specified after an `@` so as to change its selection probability. The default weight is 1. Scripts with a weight of 0 are ignored.

The default built-in transaction script (also invoked with `-b tpcb-like`) issues seven commands per transaction over randomly chosen `aid`, `tid`, `bid` and `delta`. The scenario is inspired by the TPC-B benchmark, but is not actually TPC-B, hence the name.

1. `BEGIN;`
2. `UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;`
3. `SELECT abalance FROM pgbench_accounts WHERE aid = :aid;`
4. `UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;`
5. `UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid = :bid;`
6. `INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES (:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);`
7. `END;`

If you select the `simple-update` built-in (also `-N`), steps 4 and 5 aren't included in the transaction. This will avoid update contention on these tables, but it makes the test case even less like TPC-B.

If you select the `select-only` built-in (also `-S`), only the `SELECT` is issued.

Custom Scripts

pgbench has support for running custom benchmark scenarios by replacing the default transaction script (described above) with a transaction script read from a file (`-f` option). In this case a “transaction” counts as one execution of a script file.

A script file contains one or more SQL commands terminated by semicolons. Empty lines and lines beginning with `--` are ignored. Script files can also contain “meta commands”, which are interpreted by pgbench itself, as described below.

Note

Before Postgres Pro 9.6, SQL commands in script files were terminated by newlines, and so they could not be continued across lines. Now a semicolon is *required* to separate consecutive SQL commands (though an SQL command does not need one if it is followed by a meta command). If you need to create a script file that works with both old and new versions of pgbench, be sure to write each SQL command on a single line ending with a semicolon.

It is assumed that pgbench scripts do not contain incomplete blocks of SQL transactions. If at runtime the client reaches the end of the script without completing the last transaction block, it will be aborted.

There is a simple variable-substitution facility for script files. Variable names must consist of letters (including non-Latin letters), digits, and underscores, with the first character not being a digit. Variables can be set by the command-line `-D` option, explained above, or by the meta commands explained below. In addition to any variables preset by `-D` command-line options, there are a few variables that are preset automatically, listed in [Table 312](#). A value specified for these variables using `-D` takes precedence over the automatic presets. Once set, a variable's value can be inserted into an SQL command by writing `:variablename`. When running more than one client session, each session has its own set of variables. `pgbench` supports up to 255 variable uses in one statement.

Table 312. `pgbench` Automatic Variables

Variable	Description
<code>client_id</code>	unique number identifying the client session (starts from zero)
<code>default_seed</code>	seed used in hash and pseudorandom permutation functions by default
<code>random_seed</code>	random generator seed (unless overwritten with <code>-D</code>)
<code>scale</code>	current scale factor

Script file meta commands begin with a backslash (`\`) and normally extend to the end of the line, although they can be continued to additional lines by writing backslash-return. Arguments to a meta command are separated by white space. These meta commands are supported:

```
\gset [prefix] \aset [prefix]
```

These commands may be used to end SQL queries, taking the place of the terminating semicolon (`;`).

When the `\gset` command is used, the preceding SQL query is expected to return one row, the columns of which are stored into variables named after column names, and prefixed with *prefix* if provided.

When the `\aset` command is used, all combined SQL queries (separated by `\;`) have their columns stored into variables named after column names, and prefixed with *prefix* if provided. If a query returns no row, no assignment is made and the variable can be tested for existence to detect this. If a query returns more than one row, the last value is kept.

`\gset` and `\aset` cannot be used in pipeline mode, since the query results are not yet available by the time the commands would need them.

The following example puts the final account balance from the first query into variable *abalance*, and fills variables *p_two* and *p_three* with integers from the third query. The result of the second query is discarded. The result of the two last combined queries are stored in variables *four* and *five*.

```
UPDATE pgbench_accounts
SET abalance = abalance + :delta
WHERE aid = :aid
RETURNING abalance \gset
-- compound of two queries
SELECT 1 \;
SELECT 2 AS two, 3 AS three \gset p_
SELECT 4 AS four \; SELECT 5 AS five \aset
```

```
\if expression
\elif expression
\else
\endif
```

This group of commands implements nestable conditional blocks, similarly to `psql`'s `\if expression`. Conditional expressions are identical to those with `\set`, with non-zero values interpreted as true.

```
\set varname expression
```

Sets variable *varname* to a value calculated from *expression*. The expression may contain the `NULL` constant, Boolean constants `TRUE` and `FALSE`, integer constants such as `5432`, double constants such as `3.14159`, references to variables `:variablename`, [operators](#) with their usual SQL precedence and associativity, [function calls](#), SQL [CASE generic conditional expressions](#) and parentheses.

Functions and most operators return `NULL` on `NULL` input.

For conditional purposes, non zero numerical values are `TRUE`, zero numerical values and `NULL` are `FALSE`.

Too large or small integer and double constants, as well as integer arithmetic operators (`+`, `-`, `*` and `/`) raise errors on overflows.

When no final `ELSE` clause is provided to a `CASE`, the default value is `NULL`.

Examples:

```
\set ntellers 10 * :scale
\set aid (1021 * random(1, 100000 * :scale)) % \
        (100000 * :scale) + 1
\set divx CASE WHEN :x <> 0 THEN :y/:x ELSE NULL END
```

```
\sleep number [ us | ms | s ]
```

Causes script execution to sleep for the specified duration in microseconds (`us`), milliseconds (`ms`) or seconds (`s`). If the unit is omitted then seconds are the default. *number* can be either an integer constant or a `:variablename` reference to a variable having an integer value.

Example:

```
\sleep 10 ms
```

```
\setshell varname command [ argument ... ]
```

Sets variable *varname* to the result of the shell command *command* with the given *argument(s)*. The command must return an integer value through its standard output.

command and each *argument* can be either a text constant or a `:variablename` reference to a variable. If you want to use an *argument* starting with a colon, write an additional colon at the beginning of *argument*.

Example:

```
\setshell variable_to_be_assigned command
literal_argument :variable ::literal_starting_with_colon
```

```
\shell command [ argument ... ]
```

Same as `\setshell`, but the result of the command is discarded.

Example:

```
\shell command literal_argument :variable ::literal_starting_with_colon
```

```
\startpipeline
```

```
\syncpipeline
```

```
\endpipeline
```

This group of commands implements pipelining of SQL statements. A pipeline must begin with a `\startpipeline` and end with an `\endpipeline`. In between there may be any number of `\syncpipeline` commands, which sends a [sync message](#) without ending the ongoing pipeline and

flushing the send buffer. In pipeline mode, statements are sent to the server without waiting for the results of previous statements. See [Section 35.5](#) for more details. Pipeline mode requires the use of extended query protocol.

Built-in Operators

The arithmetic, bitwise, comparison and logical operators listed in [Table 313](#) are built into pgbench and may be used in expressions appearing in `\set`. The operators are listed in increasing precedence order. Except as noted, operators taking two numeric inputs will produce a double value if either input is double, otherwise they produce an integer result.

Table 313. pgbench Operators

Operator Description Example(s)
<i>boolean OR boolean → boolean</i> Logical OR <code>5 or 0 → TRUE</code>
<i>boolean AND boolean → boolean</i> Logical AND <code>3 and 0 → FALSE</code>
<i>NOT boolean → boolean</i> Logical NOT <code>not false → TRUE</code>
<i>boolean IS [NOT] (NULL TRUE FALSE) → boolean</i> Boolean value tests <code>1 is null → FALSE</code>
<i>value ISNULL NOTNULL → boolean</i> Nullness tests <code>1 notnull → TRUE</code>
<i>number = number → boolean</i> Equal <code>5 = 4 → FALSE</code>
<i>number <> number → boolean</i> Not equal <code>5 <> 4 → TRUE</code>
<i>number != number → boolean</i> Not equal <code>5 != 5 → FALSE</code>
<i>number < number → boolean</i> Less than <code>5 < 4 → FALSE</code>
<i>number <= number → boolean</i> Less than or equal to <code>5 <= 4 → FALSE</code>
<i>number > number → boolean</i> Greater than <code>5 > 4 → TRUE</code>

Operator	Description	Example(s)
$number \geq number \rightarrow boolean$	Greater than or equal to	$5 \geq 4 \rightarrow TRUE$
$integer \mid integer \rightarrow integer$	Bitwise OR	$1 \mid 2 \rightarrow 3$
$integer \# integer \rightarrow integer$	Bitwise XOR	$1 \# 3 \rightarrow 2$
$integer \& integer \rightarrow integer$	Bitwise AND	$1 \& 3 \rightarrow 1$
$\sim integer \rightarrow integer$	Bitwise NOT	$\sim 1 \rightarrow -2$
$integer \ll integer \rightarrow integer$	Bitwise shift left	$1 \ll 2 \rightarrow 4$
$integer \gg integer \rightarrow integer$	Bitwise shift right	$8 \gg 2 \rightarrow 2$
$number + number \rightarrow number$	Addition	$5 + 4 \rightarrow 9$
$number - number \rightarrow number$	Subtraction	$3 - 2.0 \rightarrow 1.0$
$number * number \rightarrow number$	Multiplication	$5 * 4 \rightarrow 20$
$number / number \rightarrow number$	Division (truncates the result towards zero if both inputs are integers)	$5 / 3 \rightarrow 1$
$integer \% integer \rightarrow integer$	Modulo (remainder)	$3 \% 2 \rightarrow 1$
$- number \rightarrow number$	Negation	$- 2.0 \rightarrow -2.0$

Built-In Functions

The functions listed in [Table 314](#) are built into pgbench and may be used in expressions appearing in `\set`.

Table 314. pgbench Functions

Function	Description	Example(s)
<code>abs (number)</code>	→ same type as input Absolute value	<code>abs (-17) → 17</code>
<code>debug (number)</code>	→ same type as input Prints the argument to stderr, and returns the argument.	<code>debug (5432.1) → 5432.1</code>
<code>double (number)</code>	→ double Casts to double.	<code>double (5432) → 5432.0</code>
<code>exp (number)</code>	→ double Exponential (e raised to the given power)	<code>exp (1.0) → 2.718281828459045</code>
<code>greatest (number [, ...])</code>	→ double if any argument is double, else integer Selects the largest value among the arguments.	<code>greatest (5, 4, 3, 2) → 5</code>
<code>hash (value [, seed])</code>	→ integer This is an alias for <code>hash_murmur2</code> .	<code>hash (10, 5432) → -5817877081768721676</code>
<code>hash_fnv1a (value [, seed])</code>	→ integer Computes FNV-1a hash .	<code>hash_fnv1a (10, 5432) → -7793829335365542153</code>
<code>hash_murmur2 (value [, seed])</code>	→ integer Computes MurmurHash2 hash .	<code>hash_murmur2 (10, 5432) → -5817877081768721676</code>
<code>int (number)</code>	→ integer Casts to integer.	<code>int (5.4 + 3.8) → 9</code>
<code>least (number [, ...])</code>	→ double if any argument is double, else integer Selects the smallest value among the arguments.	<code>least (5, 4, 3, 2.1) → 2.1</code>
<code>ln (number)</code>	→ double Natural logarithm	<code>ln (2.718281828459045) → 1.0</code>
<code>mod (integer, integer)</code>	→ integer Modulo (remainder)	<code>mod (54, 32) → 22</code>
<code>permute (i, size [, seed])</code>	→ integer Permuted value of <i>i</i> , in the range <code>[0, size)</code> . This is the new position of <i>i</i> (modulo <i>size</i>) in a pseudorandom permutation of the integers <code>0...size-1</code> , parameterized by <i>seed</i> , see below.	<code>permute (0, 4) → an integer between 0 and 3</code>
<code>pi ()</code>	→ double	

Function	Description	Example(s)
	Approximate value of π	<code>pi()</code> \rightarrow 3.14159265358979323846
	<code>pow(x, y)</code> \rightarrow double <code>power(x, y)</code> \rightarrow double x raised to the power of y	<code>pow(2.0, 10)</code> \rightarrow 1024.0
	<code>random(lb, ub)</code> \rightarrow integer Computes a uniformly-distributed random integer in $[lb, ub]$.	<code>random(1, 10)</code> \rightarrow an integer between 1 and 10
	<code>random_exponential(lb, ub, parameter)</code> \rightarrow integer Computes an exponentially-distributed random integer in $[lb, ub]$, see below.	<code>random_exponential(1, 10, 3.0)</code> \rightarrow an integer between 1 and 10
	<code>random_gaussian(lb, ub, parameter)</code> \rightarrow integer Computes a Gaussian-distributed random integer in $[lb, ub]$, see below.	<code>random_gaussian(1, 10, 2.5)</code> \rightarrow an integer between 1 and 10
	<code>random_zipfian(lb, ub, parameter)</code> \rightarrow integer Computes a Zipfian-distributed random integer in $[lb, ub]$, see below.	<code>random_zipfian(1, 10, 1.5)</code> \rightarrow an integer between 1 and 10
	<code>sqrt(number)</code> \rightarrow double Square root	<code>sqrt(2.0)</code> \rightarrow 1.414213562

The `random` function generates values using a uniform distribution, that is all the values are drawn within the specified range with equal probability. The `random_exponential`, `random_gaussian` and `random_zipfian` functions require an additional double parameter which determines the precise shape of the distribution.

- For an exponential distribution, *parameter* controls the distribution by truncating a quickly-decreasing exponential distribution at *parameter*, and then projecting onto integers between the bounds. To be precise, with

$$f(x) = \exp(-\text{parameter} * (x - \min) / (\max - \min + 1)) / (1 - \exp(-\text{parameter}))$$

Then value *i* between *min* and *max* inclusive is drawn with probability: $f(i) - f(i + 1)$.

Intuitively, the larger the *parameter*, the more frequently values close to *min* are accessed, and the less frequently values close to *max* are accessed. The closer to 0 *parameter* is, the flatter (more uniform) the access distribution. A crude approximation of the distribution is that the most frequent 1% values in the range, close to *min*, are drawn *parameter*% of the time. The *parameter* value must be strictly positive.

- For a Gaussian distribution, the interval is mapped onto a standard normal distribution (the classical bell-shaped Gaussian curve) truncated at $-\text{parameter}$ on the left and $+\text{parameter}$ on the right. Values in the middle of the interval are more likely to be drawn. To be precise, if $\text{PHI}(x)$ is the cumulative distribution function of the standard normal distribution, with mean *mu* defined as $(\max + \min) / 2.0$, with

$$f(x) = \text{PHI}(2.0 * \text{parameter} * (x - \mu) / (\max - \min + 1)) / (2.0 * \text{PHI}(\text{parameter}) - 1)$$

then value i between min and max inclusive is drawn with probability: $f(i + 0.5) - f(i - 0.5)$. Intuitively, the larger the *parameter*, the more frequently values close to the middle of the interval are drawn, and the less frequently values close to the *min* and *max* bounds. About 67% of values are drawn from the middle $1.0 / parameter$, that is a relative $0.5 / parameter$ around the mean, and 95% in the middle $2.0 / parameter$, that is a relative $1.0 / parameter$ around the mean; for instance, if *parameter* is 4.0, 67% of values are drawn from the middle quarter ($1.0 / 4.0$) of the interval (i.e., from $3.0 / 8.0$ to $5.0 / 8.0$) and 95% from the middle half ($2.0 / 4.0$) of the interval (second and third quartiles). The minimum allowed *parameter* value is 2.0.

- `random_zipfian` generates a bounded Zipfian distribution. *parameter* defines how skewed the distribution is. The larger the *parameter*, the more frequently values closer to the beginning of the interval are drawn. The distribution is such that, assuming the range starts from 1, the ratio of the probability of drawing k versus drawing $k+1$ is $((k+1)/k)**parameter$. For example, `random_zipfian(1, ..., 2.5)` produces the value 1 about $(2/1)**2.5 = 5.66$ times more frequently than 2, which itself is produced $(3/2)**2.5 = 2.76$ times more frequently than 3, and so on.

pgbench's implementation is based on "Non-Uniform Random Variate Generation", Luc Devroye, p. 550-551, Springer 1986. Due to limitations of that algorithm, the *parameter* value is restricted to the range [1.001, 1000].

Note

When designing a benchmark which selects rows non-uniformly, be aware that the rows chosen may be correlated with other data such as IDs from a sequence or the physical row ordering, which may skew performance measurements.

To avoid this, you may wish to use the `permute` function, or some other additional step with similar effect, to shuffle the selected rows and remove such correlations.

Hash functions `hash`, `hash_murmur2` and `hash_fnv1a` accept an input value and an optional seed parameter. In case the seed isn't provided the value of `:default_seed` is used, which is initialized randomly unless set by the command-line `-D` option.

`permute` accepts an input value, a size, and an optional seed parameter. It generates a pseudorandom permutation of integers in the range $[0, size)$, and returns the index of the input value in the permuted values. The permutation chosen is parameterized by the seed, which defaults to `:default_seed`, if not specified. Unlike the hash functions, `permute` ensures that there are no collisions or holes in the output values. Input values outside the interval are interpreted modulo the size. The function raises an error if the size is not positive. `permute` can be used to scatter the distribution of non-uniform random functions such as `random_zipfian` or `random_exponential` so that values drawn more often are not trivially correlated. For instance, the following pgbench script simulates a possible real world workload typical for social media and blogging platforms where a few accounts generate excessive load:

```
\set size 1000000
\set r random_zipfian(1, :size, 1.07)
\set k 1 + permute(:r, :size)
```

In some cases several distinct distributions are needed which don't correlate with each other and this is when the optional seed parameter comes in handy:

```
\set k1 1 + permute(:r, :size, :default_seed + 123)
\set k2 1 + permute(:r, :size, :default_seed + 321)
```

A similar behavior can also be approximated with `hash`:

```
\set size 1000000
\set r random_zipfian(1, 100 * :size, 1.07)
\set k 1 + abs(hash(:r)) % :size
```

However, since `hash` generates collisions, some values will not be reachable and others will be more frequent than expected from the original distribution.

As an example, the full definition of the built-in TPC-B-like transaction is:

```
\set aid random(1, 100000 * :scale)
\set bid random(1, 1 * :scale)
\set tid random(1, 10 * :scale)
\set delta random(-5000, 5000)
BEGIN;
UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;
SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;
UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid = :bid;
INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES
(:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
END;
```

This script allows each iteration of the transaction to reference different, randomly-chosen rows. (This example also shows why it's important for each client session to have its own variables — otherwise they'd not be independently touching different rows.)

Per-Transaction Logging

With the `-l` option (but without the `--aggregate-interval` option), `pgbench` writes information about each transaction to a log file. The log file will be named *prefix.nnn*, where *prefix* defaults to `pgbench_log`, and *nnn* is the PID of the `pgbench` process. The prefix can be changed by using the `--log-prefix` option. If the `-j` option is 2 or higher, so that there are multiple worker threads, each will have its own log file. The first worker will use the same name for its log file as in the standard single worker case. The additional log files for the other workers will be named *prefix.nnn.mmm*, where *mmm* is a sequential number for each worker starting with 1.

Each line in a log file describes one transaction. It contains the following space-separated fields:

client_id

identifies the client session that ran the transaction

transaction_no

counts how many transactions have been run by that session

time

transaction's elapsed time, in microseconds

script_no

identifies the script file that was used for the transaction (useful when multiple scripts are specified with `-f` or `-b`)

time_epoch

transaction's completion time, as a Unix-epoch time stamp

time_us

fractional-second part of transaction's completion time, in microseconds

schedule_lag

transaction start delay, that is the difference between the transaction's scheduled start time and the time it actually started, in microseconds (present only if `--rate` is specified)

retries

count of retries after serialization or deadlock errors during the transaction (present only if `--max-tries` is not equal to one)

When both `--rate` and `--latency-limit` are used, the *time* for a skipped transaction will be reported as `skipped`. If the transaction ends with a failure, its *time* will be reported as `failed`. If you use the `--failures-detailed` option, the *time* of the failed transaction will be reported as `serialization` or `deadlock` depending on the type of failure (see [Failures and Serialization/Deadlock Retries](#) for more information).

Here is a snippet of a log file generated in a single-client run:

```
0 199 2241 0 1175850568 995598
0 200 2465 0 1175850568 998079
0 201 2513 0 1175850569 608
0 202 2038 0 1175850569 2663
```

Another example with `--rate=100` and `--latency-limit=5` (note the additional *schedule_lag* column):

```
0 81 4621 0 1412881037 912698 3005
0 82 6173 0 1412881037 914578 4304
0 83 skipped 0 1412881037 914578 5217
0 83 skipped 0 1412881037 914578 5099
0 83 4722 0 1412881037 916203 3108
0 84 4142 0 1412881037 918023 2333
0 85 2465 0 1412881037 919759 740
```

In this example, transaction 82 was late, because its latency (6.173 ms) was over the 5 ms limit. The next two transactions were skipped, because they were already late before they were even started.

The following example shows a snippet of a log file with failures and retries, with the maximum number of tries set to 10 (note the additional *retries* column):

```
3 0 47423 0 1499414498 34501 3
3 1 8333 0 1499414498 42848 0
3 2 8358 0 1499414498 51219 0
4 0 72345 0 1499414498 59433 6
1 3 41718 0 1499414498 67879 4
1 4 8416 0 1499414498 76311 0
3 3 33235 0 1499414498 84469 3
0 0 failed 0 1499414498 84905 9
2 0 failed 0 1499414498 86248 9
3 4 8307 0 1499414498 92788 0
```

If the `--failures-detailed` option is used, the type of failure is reported in the *time* like this:

```
3 0 47423 0 1499414498 34501 3
3 1 8333 0 1499414498 42848 0
3 2 8358 0 1499414498 51219 0
4 0 72345 0 1499414498 59433 6
1 3 41718 0 1499414498 67879 4
1 4 8416 0 1499414498 76311 0
3 3 33235 0 1499414498 84469 3
0 0 serialization 0 1499414498 84905 9
2 0 serialization 0 1499414498 86248 9
3 4 8307 0 1499414498 92788 0
```

When running a long test on hardware that can handle a lot of transactions, the log files can become very large. The `--sampling-rate` option can be used to log only a random sample of transactions.

Aggregated Logging

With the `--aggregate-interval` option, a different format is used for the log files. Each log line describes one aggregation interval. It contains the following space-separated fields:

interval_start

start time of the interval, as a Unix-epoch time stamp

num_transactions

number of transactions within the interval

sum_latency

sum of transaction latencies

sum_latency_2

sum of squares of transaction latencies

min_latency

minimum transaction latency

max_latency

maximum transaction latency

sum_lag

sum of transaction start delays (zero unless `--rate` is specified)

sum_lag_2

sum of squares of transaction start delays (zero unless `--rate` is specified)

min_lag

minimum transaction start delay (zero unless `--rate` is specified)

max_lag

maximum transaction start delay (zero unless `--rate` is specified)

skipped

number of transactions skipped because they would have started too late (zero unless `--rate` and `--latency-limit` are specified)

retried

number of retried transactions (zero unless `--max-tries` is not equal to one)

retries

number of retries after serialization or deadlock errors (zero unless `--max-tries` is not equal to one)

serialization_failures

number of transactions that got a serialization error and were not retried afterwards (zero unless `--failures-detailed` is specified)

deadlock_failures

number of transactions that got a deadlock error and were not retried afterwards (zero unless `--failures-detailed` is specified)

Here is some example output generated with this option:

```
pgbench --aggregate-interval=10 --time=20 --client=10 --log --rate=1000 --latency-limit=10 --failures-detailed --max-tries=10 test
```

```
1650260552 5178 26171317 177284491527 1136 44462 2647617 7321113867 0 9866 64 7564
28340 4148 0
1650260562 4808 25573984 220121792172 1171 62083 3037380 9666800914 0 9998 598 7392
26621 4527 0
```

Notice that while the plain (unaggregated) log format shows which script was used for each transaction, the aggregated format does not. Therefore if you need per-script data, you need to aggregate the data on your own.

Per-Statement Report

With the `-r` option, pgbench collects the following statistics for each statement:

- `latency` — elapsed transaction time for each statement. pgbench reports an average value of all successful runs of the statement.
- The number of failures in this statement. See [Failures and Serialization/Deadlock Retries](#) for more information.
- The number of retries after a serialization or a deadlock error in this statement. See [Failures and Serialization/Deadlock Retries](#) for more information.

The report displays retry statistics only if the `--max-tries` option is not equal to 1.

All values are computed for each statement executed by every client and are reported after the benchmark has finished.

For the default script, the output will look similar to this:

```
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 1
query mode: simple
number of clients: 10
number of threads: 1
maximum number of tries: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
number of failed transactions: 0 (0.000%)
number of transactions above the 50.0 ms latency limit: 1311/10000 (13.110 %)
latency average = 28.488 ms
latency stddev = 21.009 ms
initial connection time = 69.068 ms
tps = 346.224794 (without initial connection time)
statement latencies in milliseconds and failures:
  0.012  0  \set aid random(1, 100000 * :scale)
  0.002  0  \set bid random(1, 1 * :scale)
  0.002  0  \set tid random(1, 10 * :scale)
  0.002  0  \set delta random(-5000, 5000)
  0.319  0  BEGIN;
  0.834  0  UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;
  0.641  0  SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
 11.126  0  UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;
 12.961  0  UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid = :bid;
  0.634  0  INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES
(:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
 1.957  0  END;
```

Another example of output for the default script using serializable default transaction isolation level (PGOPTIONS='-c default_transaction_isolation=serializable' pgbench ...):

```
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 1
query mode: simple
number of clients: 10
number of threads: 1
```

```
maximum number of tries: 10
number of transactions per client: 1000
number of transactions actually processed: 6317/10000
number of failed transactions: 3683 (36.830%)
number of transactions retried: 7667 (76.670%)
total number of retries: 45339
number of transactions above the 50.0 ms latency limit: 106/6317 (1.678 %)
latency average = 17.016 ms
latency stddev = 13.283 ms
initial connection time = 45.017 ms
tps = 186.792667 (without initial connection time)
statement latencies in milliseconds, failures and retries:
 0.006      0      0  \set aid random(1, 100000 * :scale)
 0.001      0      0  \set bid random(1, 1 * :scale)
 0.001      0      0  \set tid random(1, 10 * :scale)
 0.001      0      0  \set delta random(-5000, 5000)
 0.385      0      0  BEGIN;
 0.773      0      1  UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE
aid = :aid;
 0.624      0      0  SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
 1.098     320     3762  UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid
= :tid;
 0.582    3363    41576  UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE
bid = :bid;
 0.465      0      0  INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES
(:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
 1.933      0      0  END;
```

If multiple script files are specified, all statistics are reported separately for each script file.

Note that collecting the additional timing information needed for per-statement latency computation adds some overhead. This will slow average execution speed and lower the computed TPS. The amount of slowdown varies significantly depending on platform and hardware. Comparing average TPS values with and without latency reporting enabled is a good way to measure if the timing overhead is significant.

Failures and Serialization/Deadlock Retries

When executing pgbench, there are three main types of errors:

- Errors of the main program. They are the most serious and always result in an immediate exit from pgbench with the corresponding error message. They include:
 - errors at the beginning of pgbench (e.g. an invalid option value);
 - errors in the initialization mode (e.g. the query to create tables for built-in scripts fails);
 - errors before starting threads (e.g. could not connect to the database server, syntax error in the meta command, thread creation failure);
 - internal pgbench errors (which are supposed to never occur...).
- Errors when the thread manages its clients (e.g. the client could not start a connection to the database server / the socket for connecting the client to the database server has become invalid). In such cases all clients of this thread stop while other threads continue to work. However, `--exit-on-abort` is specified, all of the threads stop immediately in this case.
- Direct client errors. They lead to immediate exit from pgbench with the corresponding error message in the case of an internal pgbench error (which are supposed to never occur...) or when `--exit-on-abort` is specified. Otherwise in the worst case they only lead to the abortion of the failed client while other clients continue their run (but some client errors are handled without an abortion of the client and reported separately, see below). Later in this section it is assumed that the discussed errors are only the direct client errors and they are not internal pgbench errors.

A client's run is aborted in case of a serious error; for example, the connection with the database server was lost or the end of script was reached without completing the last transaction. In addition, if execution of an SQL or meta command fails for reasons other than serialization or deadlock errors, the client is aborted. Otherwise, if an SQL command fails with serialization or deadlock errors, the client is not aborted. In such cases, the current transaction is rolled back, which also includes setting the client variables as they were before the run of this transaction (it is assumed that one transaction script contains only one transaction; see [What Is the "Transaction" Actually Performed in pgbench?](#) for more information). Transactions with serialization or deadlock errors are repeated after rollbacks until they complete successfully or reach the maximum number of tries (specified by the `--max-tries` option) / the maximum time of retries (specified by the `--latency-limit` option) / the end of benchmark (specified by the `--time` option). If the last trial run fails, this transaction will be reported as failed but the client is not aborted and continues to work.

Note

Without specifying the `--max-tries` option, a transaction will never be retried after a serialization or deadlock error because its default value is 1. Use an unlimited number of tries (`--max-tries=0`) and the `--latency-limit` option to limit only the maximum time of tries. You can also use the `--time` option to limit the benchmark duration under an unlimited number of tries.

Be careful when repeating scripts that contain multiple transactions: the script is always retried completely, so successful transactions can be performed several times.

Be careful when repeating transactions with shell commands. Unlike the results of SQL commands, the results of shell commands are not rolled back, except for the variable value of the `\setshell` command.

The latency of a successful transaction includes the entire time of transaction execution with rollbacks and retries. The latency is measured only for successful transactions and commands but not for failed transactions or commands.

The main report contains the number of failed transactions. If the `--max-tries` option is not equal to 1, the main report also contains statistics related to retries: the total number of retried transactions and total number of retries. The per-script report inherits all these fields from the main report. The per-statement report displays retry statistics only if the `--max-tries` option is not equal to 1.

If you want to group failures by basic types in per-transaction and aggregation logs, as well as in the main and per-script reports, use the `--failures-detailed` option. If you also want to distinguish all errors and failures (errors without retrying) by type including which limit for retries was exceeded and how much it was exceeded by for the serialization/deadlock failures, use the `--verbose-errors` option.

Table Access Methods

You may specify the [Table Access Method](#) for the pgbench tables. The environment variable `PGOPTIONS` specifies database configuration options that are passed to Postgres Pro via the command line (See [Section 19.1.4](#)). For example, a hypothetical default Table Access Method for the tables that pgbench creates called `wuzza` can be specified with:

```
PGOPTIONS='-c default_table_access_method=wuzza'
```

Good Practices

It is very easy to use pgbench to produce completely meaningless numbers. Here are some guidelines to help you get useful results.

In the first place, *never* believe any test that runs for only a few seconds. Use the `-t` or `-T` option to make the run last at least a few minutes, so as to average out noise. In some cases you could need hours to get numbers that are reproducible. It's a good idea to try the test run a few times, to find out if your numbers are reproducible or not.

For the default TPC-B-like test scenario, the initialization scale factor (`-s`) should be at least as large as the largest number of clients you intend to test (`-c`); else you'll mostly be measuring update contention. There are only `-s` rows in the `pgbench_branches` table, and every transaction wants to update one of them, so `-c` values in excess of `-s` will undoubtedly result in lots of transactions blocked waiting for other transactions.

The default test scenario is also quite sensitive to how long it's been since the tables were initialized: accumulation of dead rows and dead space in the tables changes the results. To understand the results you must keep track of the total number of updates and when vacuuming happens. If `autovacuum` is enabled it can result in unpredictable changes in measured performance.

A limitation of `pgbench` is that it can itself become the bottleneck when trying to test a large number of client sessions. This can be alleviated by running `pgbench` on a different machine from the database server, although low network latency will be essential. It might even be useful to run several `pgbench` instances concurrently, on several client machines, against the same database server.

Security

If untrusted users have access to a database that has not adopted a [secure schema usage pattern](#), do not run `pgbench` in that database. `pgbench` uses unqualified names and does not manipulate the search path.

pg_combinebackup

`pg_combinebackup` — reconstruct a full backup from an incremental backup and dependent backups

Synopsis

`pg_combinebackup` [*option...*] [*backup_directory...*]

Description

`pg_combinebackup` is used to reconstruct a synthetic full backup from an incremental backup and the earlier backups upon which it depends.

Specify all of the required backups on the command line from oldest to newest. That is, the first backup directory should be the path to the full backup, and the last should be the path to the final incremental backup that you wish to restore. The reconstructed backup will be written to the output directory specified by the `-o` option.

`pg_combinebackup` will attempt to verify that the backups you specify form a legal backup chain from which a correct full backup can be reconstructed. However, it is not designed to help you keep track of which backups depend on which other backups. If you remove one or more of the previous backups upon which your incremental backup relies, you will not be able to restore it. Moreover, `pg_combinebackup` only attempts to verify that the backups have the correct relationship to each other, not that each individual backup is intact; for that, use [pg_verifybackup](#).

Since the output of `pg_combinebackup` is a synthetic full backup, it can be used as an input to a future invocation of `pg_combinebackup`. The synthetic full backup would be specified on the command line in lieu of the chain of backups from which it was reconstructed.

Options

`-d`
`--debug`

Print lots of debug logging output on `stderr`.

`-n`
`--dry-run`

The `-n/--dry-run` option instructs `pg_combinebackup` to figure out what would be done without actually creating the target directory or any output files. It is particularly useful in combination with `--debug`.

`-N`
`--no-sync`

By default, `pg_combinebackup` will wait for all files to be written safely to disk. This option causes `pg_combinebackup` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the output backup corrupt. Generally, this option is useful for testing but should not be used when creating a production installation.

`-o outputdir`
`--output=outputdir`

Specifies the output directory to which the synthetic full backup should be written. Currently, this argument is required.

`-T olddir=newdir`
`--tablespace-mapping=olddir=newdir`

Relocates the tablespace in directory `olddir` to `newdir` during the backup. `olddir` is the absolute path of the tablespace as it exists in the final backup specified on the command line, and `newdir`

is the absolute path to use for the tablespace in the reconstructed backup. If either path needs to contain an equal sign (=), precede that with a backslash. This option can be specified multiple times for multiple tablespaces.

`--clone`

Use efficient file cloning (also known as “reflinks” on some systems) instead of copying files to the new data directory, which can result in near-instantaneous copying of the data files.

If a backup manifest is not available or does not contain checksum of the right type, file cloning will be used to copy the file, but the file will be also read block-by-block for the checksum calculation.

File cloning is only supported on some operating systems and file systems. If it is selected but not supported, the `pg_combinebackup` run will error. At present, it is supported on Linux (kernel 4.5 or later) with Btrfs and XFS (on file systems created with reflink support), and on macOS with APFS.

`--copy`

Perform regular file copy. This is the default. (See also `--copy-file-range` and `--clone`.)

`--copy-file-range`

Use the `copy_file_range` system call for efficient copying. On some file systems this gives results similar to `--clone`, sharing physical disk blocks, while on others it may still copy blocks, but do so via an optimized path. At present, it is supported on Linux and FreeBSD.

If a backup manifest is not available or does not contain checksum of the right type, `copy_file_range` will be used to copy the file, but the file will be also read block-by-block for the checksum calculation.

`--manifest-checksums=algorithm`

`pg_combinebackup` writes a backup manifest in the output directory. This option specifies the checksum algorithm that should be applied to each file included in the backup manifest. Currently, the available algorithms are `NONE`, `CRC32C`, `SHA224`, `SHA256`, `SHA384`, and `SHA512`. The default is `CRC32C`.

`--no-manifest`

Disables generation of a backup manifest. If this option is not specified, a backup manifest for the reconstructed backup will be written to the output directory.

`--sync-method=method`

When set to `fsync`, which is the default, `pg_combinebackup` will recursively open and synchronize all files in the backup directory. When the plain format is used, the search for files will follow symbolic links for the WAL directory and each configured tablespace.

On Linux, `syncfs` may be used instead to ask the operating system to synchronize the whole file system that contains the backup directory. When the plain format is used, `pg_combinebackup` will also synchronize the file systems that contain the WAL files and each tablespace. See [recovery_init_sync_method](#) for information about the caveats to be aware of when using `syncfs`.

This option has no effect when `--no-sync` is used.

`-V`

`--version`

Prints the `pg_combinebackup` version and exits.

`-?`

`--help`

Shows help about `pg_combinebackup` command line arguments, and exits.

Limitations

`pg_combinebackup` does not recompute page checksums when writing the output directory. Therefore, if any of the backups used for reconstruction were taken with checksums disabled, but the final backup was taken with checksums enabled, the resulting directory may contain pages with invalid checksums.

To avoid this problem, taking a new full backup after changing the checksum state of the cluster using [pg_checksums](#) is recommended. Otherwise, you can disable and then optionally reenable checksums on the directory produced by `pg_combinebackup` in order to correct the problem.

Environment

This utility, like most other PostgreSQL utilities, uses the environment variables supported by libpq (see [Section 35.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

pg_config

pg_config — retrieve information about the installed version of Postgres Pro

Synopsis

```
pg_config [option...]
```

Description

The `pg_config` utility prints configuration parameters of the currently installed version of Postgres Pro. It is intended, for example, to be used by software packages that want to interface to Postgres Pro to facilitate finding the required header files and libraries.

Options

To use `pg_config`, supply one or more of the following options:

`--bindir`

Print the location of user executables. Use this, for example, to find the `psql` program. This is normally also the location where the `pg_config` program resides.

`--docdir`

Print the location of documentation files.

`--htmldir`

Print the location of HTML documentation files.

`--includedir`

Print the location of C header files of the client interfaces.

`--pkgincludedir`

Print the location of other C header files.

`--includedir-server`

Print the location of C header files for server programming.

`--libdir`

Print the location of object code libraries.

`--pkglibdir`

Print the location of dynamically loadable modules, or where the server would search for them. (Other architecture-dependent data files might also be installed in this directory.)

`--localedir`

Print the location of locale support files. (This will be an empty string if locale support was not configured when Postgres Pro was built.)

`--mandir`

Print the location of manual pages.

`--sharedir`

Print the location of architecture-independent support files.

`--sysconfdir`

Print the location of system-wide configuration files.

`--pgxs`

Print the location of extension makefiles.

`--configure`

Print the options that were given to the `configure` script when Postgres Pro was configured for building. This can be used to reproduce the identical configuration, or to find out with what options a binary package was built. (Note however that binary packages often contain vendor-specific custom patches.) See also the examples below.

`--cc`

Print the value of the `CC` variable that was used for building Postgres Pro. This shows the C compiler used.

`--cppflags`

Print the value of the `CPPFLAGS` variable that was used for building Postgres Pro. This shows C compiler switches needed at preprocessing time (typically, `-I` switches).

`--cflags`

Print the value of the `CFLAGS` variable that was used for building Postgres Pro. This shows C compiler switches.

`--cflags_sl`

Print the value of the `CFLAGS_SL` variable that was used for building Postgres Pro. This shows extra C compiler switches used for building shared libraries.

`--ldflags`

Print the value of the `LDFLAGS` variable that was used for building Postgres Pro. This shows linker switches.

`--ldflags_ex`

Print the value of the `LDFLAGS_EX` variable that was used for building Postgres Pro. This shows linker switches used for building executables only.

`--ldflags_sl`

Print the value of the `LDFLAGS_SL` variable that was used for building Postgres Pro. This shows linker switches used for building shared libraries only.

`--libs`

Print the value of the `LIBS` variable that was used for building Postgres Pro. This normally contains `-l` switches for external libraries linked into Postgres Pro.

`--version`

Print the PostgreSQL version on which Postgres Pro is based.

`--pgpro-version`

Print the version of Postgres Pro.

`--pgpro-edition`

Print the edition of Postgres Pro.

-?
--help

Show help about pg_config command line arguments, and exit.

If more than one option is given, the information is printed in that order, one item per line. If no options are given, all available information is printed, with labels.

Notes

The options `--docdir`, `--pkgincludedir`, `--localedir`, `--mandir`, `--sharedir`, `--sysconfdir`, `--cc`, `--cppflags`, `--cflags`, `--cflags_sl`, `--ldflags`, `--ldflags_sl`, and `--libs` were added in PostgreSQL 8.1. The option `--htmldir` was added in PostgreSQL 8.4. The option `--ldflags_ex` was added in PostgreSQL 9.0.

Example

To reproduce the build configuration of the current Postgres Pro installation, run the following command:

```
eval `./configure `pg_config --configure`
```

The output of `pg_config --configure` contains shell quotation marks so arguments with spaces are represented correctly. Therefore, using `eval` is required for proper results.

pg_dump

`pg_dump` — extract a Postgres Pro database into a script file or other archive file

Synopsis

```
pg_dump [connection-option...] [option...] [dbname]
```

Description

`pg_dump` is a utility for backing up a Postgres Pro database. It makes consistent backups even if the database is being used concurrently. `pg_dump` does not block other users accessing the database (readers or writers).

Note

Note `pg_dump` does not work with the distributed systems.

`pg_dump` only dumps a single database. To back up an entire cluster, or to back up global objects that are common to all databases in a cluster (such as roles and tablespaces), use [pg_dumpall](#).

Dumps can be output in script or archive file formats. Script dumps are plain-text files containing the SQL commands required to reconstruct the database to the state it was in at the time it was saved. To restore from such a script, feed it to [psql](#). Script files can be used to reconstruct the database even on other machines and other architectures; with some modifications, even on other SQL database products.

The alternative archive file formats must be used with [pg_restore](#) to rebuild the database. They allow `pg_restore` to be selective about what is restored, or even to reorder the items prior to being restored. The archive file formats are designed to be portable across architectures.

When used with one of the archive file formats and combined with `pg_restore`, `pg_dump` provides a flexible archival and transfer mechanism. `pg_dump` can be used to backup an entire database, then `pg_restore` can be used to examine the archive and/or select which parts of the database are to be restored. The most flexible output file formats are the “custom” format (`-Fc`) and the “directory” format (`-Fd`). They allow for selection and reordering of all archived items, support parallel restoration, and are compressed by default. The “directory” format is the only format that supports parallel dumps.

While running `pg_dump`, one should examine the output for any warnings (printed on standard error), especially in light of the limitations listed below.

Options

The following command-line options control the content and format of the output.

dbname

Specifies the name of the database to be dumped. If this is not specified, the environment variable `PGDATABASE` is used. If that is not set, the user name specified for the connection is used.

`-a`

`--data-only`

Dump only the data, not the schema (data definitions). Table data, large objects, and sequence values are dumped.

This option is similar to, but for historical reasons not identical to, specifying `--section=data`.

`-b`
`--large-objects`
`--blobs` (deprecated)

Include large objects in the dump. This is the default behavior except when `--schema`, `--table`, or `--schema-only` is specified. The `-b` switch is therefore only useful to add large objects to dumps where a specific schema or table has been requested. Note that large objects are considered data and therefore will be included when `--data-only` is used, but not when `--schema-only` is.

`-B`
`--no-large-objects`
`--no-blobs` (deprecated)

Exclude large objects in the dump.

When both `-b` and `-B` are given, the behavior is to output large objects, when data is being dumped, see the `-b` documentation.

`-c`
`--clean`

Output commands to `DROP` all the dumped database objects prior to outputting the commands for creating them. This option is useful when the restore is to overwrite an existing database. If any of the objects do not exist in the destination database, ignorable error messages will be reported during restore, unless `--if-exists` is also specified.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

`-C`
`--create`

Begin the output with a command to create the database itself and reconnect to the created database. (With a script of this form, it doesn't matter which database in the destination installation you connect to before running the script.) If `--clean` is also specified, the script drops and recreates the target database before reconnecting to it.

With `--create`, the output also includes the database's comment if any, and any configuration variable settings that are specific to this database, that is, any `ALTER DATABASE ... SET ...` and `ALTER ROLE ... IN DATABASE ... SET ...` commands that mention this database. Access privileges for the database itself are also dumped, unless `--no-acl` is specified.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

`-e pattern`
`--extension=pattern`

Dump only extensions matching *pattern*. When this option is not specified, all non-system extensions in the target database will be dumped. Multiple extensions can be selected by writing multiple `-e` switches. The *pattern* parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see [Patterns](#)), so multiple extensions can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards.

Any configuration relation registered by `pg_extension_config_dump` is included in the dump if its extension is specified by `--extension`.

Note

When `-e` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected extension(s) might depend upon. Therefore, there is no guarantee that the results of a specific-extension dump can be successfully restored by themselves into a clean database.

`-E encoding`
`--encoding=encoding`

Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the `PGCLIENTENCODING` environment variable to the desired dump encoding.) The supported encodings are described in [Section 23.3.1](#).

`-f file`
`--file=file`

Send output to the specified file. This parameter can be omitted for file based output formats, in which case the standard output is used. It must be given for the directory output format however, where it specifies the target directory instead of a file. In this case the directory is created by `pg_dump` and must not exist before.

`-F format`
`--format=format`

Selects the format of the output. *format* can be one of the following:

`p`
`plain`

Output a plain-text SQL script file (the default).

`c`
`custom`

Output a custom-format archive suitable for input into `pg_restore`. Together with the directory output format, this is the most flexible output format in that it allows manual selection and re-ordering of archived items during restore. This format is also compressed by default.

`d`
`directory`

Output a directory-format archive suitable for input into `pg_restore`. This will create a directory with one file for each table and large object being dumped, plus a so-called Table of Contents file describing the dumped objects in a machine-readable format that `pg_restore` can read. A directory format archive can be manipulated with standard Unix tools; for example, files in an uncompressed archive can be compressed with the `gzip`, `lz4`, or `zstd` tools. This format is compressed by default using `gzip` and also supports parallel dumps.

`t`
`tar`

Output a `tar`-format archive suitable for input into `pg_restore`. The `tar` format is compatible with the directory format: extracting a `tar`-format archive produces a valid directory-format archive. However, the `tar` format does not support compression. Also, when using `tar` format the relative order of table data items cannot be changed during restore.

`-j njobs`
`--jobs=njobs`

Run the dump in parallel by dumping *njobs* tables simultaneously. This option may reduce the time needed to perform the dump but it also increases the load on the database server. You can only use this option with the directory output format because this is the only output format where multiple processes can write their data at the same time.

`pg_dump` will open `njobs + 1` connections to the database, so make sure your `max_connections` setting is high enough to accommodate all connections.

Requesting exclusive locks on database objects while running a parallel dump could cause the dump to fail. The reason is that the `pg_dump` leader process requests shared locks ([ACCESS SHARE](#)) on the objects that the worker processes are going to dump later in order to make sure that nobody deletes them and makes them go away while the dump is running. If another client then requests an exclusive lock on a table, that lock will not be granted but will be queued waiting for the shared lock of the leader process to be released. Consequently any other access to the table will not be granted either and will queue after the exclusive lock request. This includes the worker process trying to dump the table. Without any precautions this would be a classic deadlock situation. To detect this conflict, the `pg_dump` worker process requests another shared lock using the `NOWAIT` option. If the worker process is not granted this shared lock, somebody else must have requested an exclusive lock in the meantime and there is no way to continue with the dump, so `pg_dump` has no choice but to abort the dump.

To perform a parallel dump, the database server needs to support synchronized snapshots, a feature that was introduced in PostgreSQL 9.2 for primary servers and 10 for standbys. With this feature, database clients can ensure they see the same data set even though they use different connections. `pg_dump -j` uses multiple database connections; it connects to the database once with the leader process and once again for each worker job. Without the synchronized snapshot feature, the different worker jobs wouldn't be guaranteed to see the same data in each connection, which could lead to an inconsistent backup.

```
-n pattern
--schema=pattern
```

Dump only schemas matching *pattern*; this selects both the schema itself, and all its contained objects. When this option is not specified, all non-system schemas in the target database will be dumped. Multiple schemas can be selected by writing multiple `-n` switches. The *pattern* parameter is interpreted as a pattern according to the same rules used by `psql's \d` commands (see [Patterns](#)), so multiple schemas can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see [Examples](#) below.

Note

When `-n` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected schema(s) might depend upon. Therefore, there is no guarantee that the results of a specific-schema dump can be successfully restored by themselves into a clean database.

Note

Non-schema objects such as large objects are not dumped when `-n` is specified. You can add large objects back to the dump with the `--large-objects` switch.

```
-N pattern
--exclude-schema=pattern
```

Do not dump any schemas matching *pattern*. The pattern is interpreted according to the same rules as for `-n`. `-N` can be given more than once to exclude schemas matching any of several patterns.

When both `-n` and `-N` are given, the behavior is to dump just the schemas that match at least one `-n` switch but no `-N` switches. If `-N` appears without `-n`, then schemas matching `-N` are excluded from what is otherwise a normal dump.

`-O`
`--no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_dump` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

`-R`
`--no-reconnect`

This option is obsolete but still accepted for backwards compatibility.

`-s`
`--schema-only`

Dump only the object definitions (schema), not data.

This option is the inverse of `--data-only`. It is similar to, but for historical reasons not identical to, specifying `--section=pre-data --section=post-data`.

(Do not confuse this with the `--schema` option, which uses the word “schema” in a different meaning.)

To exclude table data for only a subset of tables in the database, see `--exclude-table-data`.

`-S username`
`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used. (Usually, it's better to leave this out, and instead start the resulting script as superuser.)

`-t pattern`
`--table=pattern`

Dump only tables with names matching *pattern*. Multiple tables can be selected by writing multiple `-t` switches. The *pattern* parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see [Patterns](#)), so multiple tables can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see [Examples](#) below.

As well as tables, this option can be used to dump the definition of matching views, materialized views, foreign tables, and sequences. It will not dump the contents of views or materialized views, and the contents of foreign tables will only be dumped if the corresponding foreign server is specified with `--include-foreign-data`.

The `-n` and `-N` switches have no effect when `-t` is used, because tables selected by `-t` will be dumped regardless of those switches, and non-table objects will not be dumped.

Note

When `-t` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that the results of a specific-table dump can be successfully restored by themselves into a clean database.

`-T pattern`
`--exclude-table=pattern`

Do not dump any tables matching *pattern*. The pattern is interpreted according to the same rules as for `-t`. `-T` can be given more than once to exclude tables matching any of several patterns.

When both `-t` and `-T` are given, the behavior is to dump just the tables that match at least one `-t` switch but no `-T` switches. If `-T` appears without `-t`, then tables matching `-T` are excluded from what is otherwise a normal dump.

`-v`
`--verbose`

Specifies verbose mode. This will cause `pg_dump` to output detailed object comments and start/stop times to the dump file, and progress messages to standard error. Repeating the option causes additional debug-level messages to appear on standard error.

`-V`
`--version`

Print the `pg_dump` version and exit.

`-x`
`--no-privileges`
`--no-acl`

Prevent dumping of access privileges (grant/revoke commands).

`-Z level`
`-Z method[:detail]`
`--compress=level`
`--compress=method[:detail]`

Specify the compression method and/or the compression level to use. The compression method can be set to `gzip`, `lz4`, `zstd`, or `none` for no compression. A compression detail string can optionally be specified. If the detail string is an integer, it specifies the compression level. Otherwise, it should be a comma-separated list of items, each of the form `keyword` or `keyword=value`. Currently, the supported keywords are `level` and `long`.

If no compression level is specified, the default compression level will be used. If only a level is specified without mentioning an algorithm, `gzip` compression will be used if the level is greater than 0, and no compression will be used if the level is 0.

For the custom and directory archive formats, this specifies compression of individual table-data segments, and the default is to compress using `gzip` at a moderate level. For plain text output, setting a nonzero compression level causes the entire output file to be compressed, as though it had been fed through `gzip`, `lz4`, or `zstd`; but the default is not to compress. With `zstd` compression, `long` mode may improve the compression ratio, at the cost of increased memory use.

The tar archive format currently does not support compression at all.

`--binary-upgrade`

This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

`--column-inserts`
`--attribute-inserts`

Dump data as `INSERT` commands with explicit column names (`INSERT INTO table (column, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can

be loaded into non-Postgres Pro databases. Any error during restoring will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents.

`--disable-dollar-quoting`

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

`--disable-triggers`

This option is relevant only when creating a data-only dump. It instructs `pg_dump` to include commands to temporarily disable triggers on the target tables while the data is restored. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data restore.

Presently, the commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably be careful to start the resulting script as a superuser.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

`--enable-large-mem-buffers`

Dump large `bytea` values exceeding 0.5 GB (up to 1 GB) and records with several `text` values exceeding 1 GB in total (up to 2 GB). This option cannot be used with `--inserts`, `--column-inserts`, or `--rows-per-insert`.

`--enable-row-security`

This option is relevant only when dumping the contents of a table which has row security. By default, `pg_dump` will set `row_security` to off, to ensure that all data is dumped from the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs `pg_dump` to set `row_security` to on instead, allowing the user to dump the parts of the contents of the table that they have access to.

Note that if you use this option currently, you probably also want the dump be in `INSERT` format, as the `COPY FROM` during restore does not support row security.

`--exclude-extension=pattern`

Do not dump any extensions matching *pattern*. The pattern is interpreted according to the same rules as for `-e`. `--exclude-extension` can be given more than once to exclude extensions matching any of several patterns.

When both `-e` and `--exclude-extension` are given, the behavior is to dump just the extensions that match at least one `-e` switch but no `--exclude-extension` switches. If `--exclude-extension` appears without `-e`, then extensions matching `--exclude-extension` are excluded from what is otherwise a normal dump.

`--exclude-table-and-children=pattern`

This is the same as the `-T/--exclude-table` option, except that it also excludes any partitions or inheritance child tables of the table(s) matching the *pattern*.

`--exclude-table-data=pattern`

Do not dump data for any tables matching *pattern*. The pattern is interpreted according to the same rules as for `-t`. `--exclude-table-data` can be given more than once to exclude tables matching any of several patterns. This option is useful when you need the definition of a particular table even though you do not need the data in it.

To exclude data for all tables in the database, see `--schema-only`.

`--exclude-table-data-and-children=pattern`

This is the same as the `--exclude-table-data` option, except that it also excludes data of any partitions or inheritance child tables of the table(s) matching the *pattern*.

`--extra-float-digits=ndigits`

Use the specified value of `extra_float_digits` when dumping floating-point data, instead of the maximum available precision. Routine dumps made for backup purposes should not use this option.

`--filter=filename`

Specify a filename from which to read patterns for objects to include or exclude from the dump. The patterns are interpreted according to the same rules as the corresponding options: `-t/--table`, `--table-and-children`, `-T/--exclude-table`, and `--exclude-table-and-children` for tables, `-n/--schema` and `-N/--exclude-schema` for schemas, `--include-foreign-data` for data on foreign servers, `--exclude-table-data` and `--exclude-table-data-and-children` for table data, and `-e/--extension` and `--exclude-extension` for extensions. To read from `STDIN`, use `-` as the filename. The `--filter` option can be specified in conjunction with the above listed options for including or excluding objects, and can also be specified more than once for multiple filter files.

The file lists one object pattern per row, with the following format:

```
{ include | exclude } { extension | foreign_data | table | table_and_children |
table_data | table_data_and_children | schema } PATTERN
```

The first keyword specifies whether the objects matched by the pattern are to be included or excluded. The second keyword specifies the type of object to be filtered using the pattern:

- **extension:** extensions. This works like the `-e/--extension` or `--exclude-extension` option.
- **foreign_data:** data on foreign servers. This works like the `--include-foreign-data` option. This keyword can only be used with the `include` keyword.
- **table:** tables. This works like the `-t/--table` or `-T/--exclude-table` option.
- **table_and_children:** tables including any partitions or inheritance child tables. This works like the `--table-and-children` or `--exclude-table-and-children` option.
- **table_data:** table data of any tables matching *pattern*. This works like the `--exclude-table-data` option. This keyword can only be used with the `exclude` keyword.
- **table_data_and_children:** table data of any tables matching *pattern* as well as any partitions or inheritance children of the table(s). This works like the `--exclude-table-data-and-children` option. This keyword can only be used with the `exclude` keyword.
- **schema:** schemas. This works like the `-n/--schema` or `-N/--exclude-schema` option.

Lines starting with `#` are considered comments and ignored. Comments can be placed after an object pattern row as well. Blank lines are also ignored. See [Patterns](#) for how to perform quoting in patterns.

Example files are listed below in the [Examples](#) section.

`--if-exists`

Use `DROP ... IF EXISTS` commands to drop objects in `--clean` mode. This suppresses “does not exist” errors that might otherwise be reported. This option is not valid unless `--clean` is also specified.

`--include-foreign-data=foreignserver`

Dump the data for any foreign table with a foreign server matching *foreignserver* pattern. Multiple foreign servers can be selected by writing multiple `--include-foreign-data` switches. Also, the *foreignserver* parameter is interpreted as a pattern according to the same rules used by `psql's \d` commands (see [Patterns](#)), so multiple foreign servers can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent

the shell from expanding the wildcards; see [Examples](#) below. The only exception is that an empty pattern is disallowed.

Note

Using wildcards in `--include-foreign-data` may result in access to unexpected foreign servers. Also, to use this option securely, make sure that the named server must have a trusted owner.

Note

When `--include-foreign-data` is specified, `pg_dump` does not check that the foreign table is writable. Therefore, there is no guarantee that the results of a foreign table dump can be successfully restored.

`--inserts`

Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-Postgres Pro databases. Any error during restoring will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents. Note that the restore might fail altogether if you have rearranged column order. The `--column-inserts` option is safe against column order changes, though even slower.

`--load-via-partition-root`

When dumping data for a table partition, make the `COPY` or `INSERT` statements target the root of the partitioning hierarchy that contains it, rather than the partition itself. This causes the appropriate partition to be re-determined for each row when the data is loaded. This may be useful when restoring data on a server where rows do not always fall into the same partitions as they did on the original server. That could happen, for example, if the partitioning column is of type `text` and the two systems have different definitions of the collation used to sort the partitioning column.

`--lock-wait-timeout=timeout`

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead fail if unable to lock a table within the specified *timeout*. The timeout may be specified in any of the formats accepted by `SET statement_timeout`. (Allowed formats vary depending on the server version you are dumping from, but an integer number of milliseconds is accepted by all versions.)

`--no-comments`

Do not dump comments.

`--no-publications`

Do not dump publications.

`--no-security-labels`

Do not dump security labels.

`--no-subscriptions`

Do not dump subscriptions.

`--no-sync`

By default, `pg_dump` will wait for all files to be written safely to disk. This option causes `pg_dump` to return without waiting, which is faster, but means that a subsequent operating system crash can

leave the dump corrupt. Generally, this option is useful for testing but should not be used when dumping data from production installation.

`--no-table-access-method`

Do not output commands to select table access methods. With this option, all objects will be created with whichever table access method is the default during restore.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

`--no-tablespaces`

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

`--no-toast-compression`

Do not output commands to set TOAST compression methods. With this option, all columns will be restored with the default compression setting.

`--no-unlogged-table-data`

Do not dump the contents of unlogged tables and sequences. This option has no effect on whether or not the table and sequence definitions (schema) are dumped; it only suppresses dumping the table and sequence data. Data in unlogged tables and sequences is always excluded when dumping from a standby server.

`--on-conflict-do-nothing`

Add `ON CONFLICT DO NOTHING` to `INSERT` commands. This option is not valid unless `--inserts`, `--column-inserts` or `--rows-per-insert` is also specified.

`--privileges-only`

Dump only access privileges (`GRANT/REVOKE` commands) and output commands executed by the security officer for schemas and their objects.

`--quote-all-identifiers`

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose PostgreSQL major version is different from `pg_dump`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dump` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

`--rows-per-insert=nrows`

Dump data as `INSERT` commands (rather than `COPY`). Controls the maximum number of rows per `INSERT` command. The value specified must be a number greater than zero. Any error during restoring will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents.

`--section=sectionname`

Only dump the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections. The default is to dump all sections.

The data section contains actual table data, large-object contents, and sequence values. Post-data items include definitions of indexes, triggers, rules, and constraints other than validated check constraints. Pre-data items include all other data definition items.

`--serializable-deferrable`

Use a `serializable` transaction for the dump, to ensure that the snapshot used is consistent with later database states; but do this by waiting for a point in the transaction stream at which no anomalies can be present, so that there isn't a risk of the dump failing or causing other transactions to roll back with a `serialization_failure`. See [Chapter 13](#) for more information about transaction isolation and concurrency control.

This option is not beneficial for a dump which is intended only for disaster recovery. It could be useful for a dump used to load a copy of the database for reporting or other read-only load sharing while the original database continues to be updated. Without it the dump may reflect a state which is not consistent with any serial execution of the transactions eventually committed. For example, if batch processing techniques are used, a batch may show as closed in the dump without all of the items which are in the batch appearing.

This option will make no difference if there are no read-write transactions active when `pg_dump` is started. If read-write transactions are active, the start of the dump may be delayed for an indeterminate length of time. Once running, performance with or without the switch is the same.

`--snapshot=snapshotname`

Use the specified synchronized snapshot when making a dump of the database (see [Table 9.98](#) for more details).

This option is useful when needing to synchronize the dump with a logical replication slot (see [Chapter 50](#)) or with a concurrent session.

In the case of a parallel dump, the snapshot name defined by this option is used rather than taking a new snapshot.

`--strict-names`

Require that each extension (`-e/--extension`), schema (`-n/--schema`) and table (`-t/--table`) pattern match at least one extension/schema/table in the database to be dumped. This also applies to filters used with `--filter`. Note that if none of the extension/schema/table patterns find matches, `pg_dump` will generate an error even without `--strict-names`.

This option has no effect on `--exclude-extension`, `-N/--exclude-schema`, `-T/--exclude-table`, or `--exclude-table-data`. An exclude pattern failing to match any objects is not considered an error.

`--sync-method=method`

When set to `fsync`, which is the default, `pg_dump --format=directory` will recursively open and synchronize all files in the archive directory.

On Linux, `syncfs` may be used instead to ask the operating system to synchronize the whole file system that contains the archive directory. See [recovery_init_sync_method](#) for information about the caveats to be aware of when using `syncfs`.

This option has no effect when `--no-sync` is used or `--format` is not set to `directory`.

`--table-and-children=pattern`

This is the same as the `-t/--table` option, except that it also includes any partitions or inheritance child tables of the table(s) matching the *pattern*.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, might not restore properly. Also, a dump using `SET SESSION AUTHORIZATION` will certainly require superuser privileges to restore correctly, whereas `ALTER OWNER` requires lesser privileges.

-?
--help

Show help about pg_dump command line arguments, and exit.

The following command-line options control the database connection parameters.

-d *dbname*
--dbname=*dbname*

Specifies the name of the database to connect to. This is equivalent to specifying *dbname* as the first non-option argument on the command line. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

-h *host*
--host=*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

-p *port*
--port=*port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.

-U *username*
--username=*username*

User name to connect as.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force pg_dump to prompt for a password before connecting to a database.

This option is never essential, since pg_dump will automatically prompt for a password if the server demands password authentication. However, pg_dump will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

--role=*rolename*

Specifies a role name to be used to create the dump. This option causes pg_dump to issue a SET ROLE *rolename* command after connecting to the database. It is useful when the authenticated user (specified by -U) lacks privileges needed by pg_dump, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

Environment

PGDATABASE
PGHOST
PGOPTIONS
PGPORT
PGUSER

Default connection parameters.

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 35.15](#)).

Diagnostics

`pg_dump` internally executes `SELECT` statements. If you have problems running `pg_dump`, make sure you are able to select information from the database using, for example, `psql`. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

The database activity of `pg_dump` is normally collected by the cumulative statistics system. If this is undesirable, you can set parameter `track_counts` to `false` via `PGOPTIONS` or the `ALTER USER` command.

Notes

If your database cluster has any local additions to the `template1` database, be careful to restore the output of `pg_dump` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

When a data-only dump is chosen and the option `--disable-triggers` is used, `pg_dump` emits commands to disable triggers on user tables before inserting the data, and then commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.

The dump file produced by `pg_dump` does not contain the statistics used by the optimizer to make query planning decisions. Therefore, it is wise to run `ANALYZE` after restoring from a dump file to ensure optimal performance; see [Section 24.1.3](#) and [Section 24.1.6](#) for more information.

Because `pg_dump` is used to transfer data to newer versions of Postgres Pro, the output of `pg_dump` can be expected to load into Postgres Pro server versions newer than `pg_dump`'s version. `pg_dump` can also dump from Postgres Pro servers older than its own version. (Currently, servers back to version 9.2 are supported.) However, `pg_dump` cannot dump from Postgres Pro servers newer than its own major version; it will refuse to even try, rather than risk making an invalid dump. Also, it is not guaranteed that `pg_dump`'s output can be loaded into a server of an older major version — not even if the dump was taken from a server of that version. Loading a dump file into an older server may require manual editing of the dump file to remove syntax not understood by the older server. Use of the `--quote-all-identifiers` option is recommended in cross-version cases, as it can prevent problems arising from varying reserved-word lists in different PostgreSQL versions.

When dumping logical replication subscriptions, `pg_dump` will generate `CREATE SUBSCRIPTION` commands that use the `connect = false` option, so that restoring the subscription does not make remote connections for creating a replication slot or for initial table copy. That way, the dump can be restored without requiring network access to the remote servers. It is then up to the user to reactivate the subscriptions in a suitable way. If the involved hosts have changed, the connection information might have to be changed. It might also be appropriate to truncate the target tables before initiating a new full table copy. If users intend to copy initial data during refresh they must create the slot with `two_phase = false`. After the initial sync, the `two_phase` option will be automatically enabled by the subscriber if the subscription had been originally created with `two_phase = true` option.

It is generally recommended to use the `-X (--no-psqlrc)` option when restoring a database from a plain-text `pg_dump` script to ensure a clean restore process and prevent potential conflicts with non-default `psql` configurations.

Examples

To dump a database called `mydb` into an SQL-script file:

```
$ pg_dump mydb > db.sql
```

To reload such a script into a (freshly created) database named `newdb`:

```
$ psql -X -d newdb -f db.sql
```

To dump a database into a custom-format archive file:

```
$ pg_dump -Fc mydb > db.dump
```

To dump a database into a directory-format archive:

```
$ pg_dump -Fd mydb -f dumpdir
```

To dump a database into a directory-format archive in parallel with 5 worker jobs:

```
$ pg_dump -Fd mydb -j 5 -f dumpdir
```

To reload an archive file into a (freshly created) database named `newdb`:

```
$ pg_restore -d newdb db.dump
```

To reload an archive file into the same database it was dumped from, discarding the current contents of that database:

```
$ pg_restore -d postgres --clean --create db.dump
```

To dump a single table named `mytab`:

```
$ pg_dump -t mytab mydb > db.sql
```

To dump all tables whose names start with `emp` in the `detroit` schema, except for the table named `employee_log`:

```
$ pg_dump -t 'detroit.emp*' -T detroit.employee_log mydb > db.sql
```

To dump all schemas whose names start with `east` or `west` and end in `gsm`, excluding any schemas whose names contain the word `test`:

```
$ pg_dump -n 'east*gsm' -n 'west*gsm' -N '*test*' mydb > db.sql
```

The same, using regular expression notation to consolidate the switches:

```
$ pg_dump -n '(east|west)*gsm' -N '*test*' mydb > db.sql
```

To dump all database objects except for tables whose names begin with `ts_`:

```
$ pg_dump -T 'ts_*' mydb > db.sql
```

To specify an upper-case or mixed-case name in `-t` and related switches, you need to double-quote the name; else it will be folded to lower case (see [Patterns](#)). But double quotes are special to the shell, so in turn they must be quoted. Thus, to dump a single table with a mixed-case name, you need something like

```
$ pg_dump -t "\"MixedCaseName\"" mydb > mytab.sql
```

To dump all tables whose names start with `mytable`, except for table `mytable2`, specify a filter file `filter.txt` like:

```
include table mytable*
exclude table mytable2
```

```
$ pg_dump --filter=filter.txt mydb > db.sql
```

[pg_dumpall](#), [pg_restore](#), [psql](#)

pg_dumpall

pg_dumpall — extract a Postgres Pro database cluster into a script file

Synopsis

```
pg_dumpall [connection-option...] [option...]
```

Description

pg_dumpall is a utility for writing out (“dumping”) all Postgres Pro databases of a cluster into one script file. The script file contains SQL commands that can be used as input to [psql](#) to restore the databases. It does this by calling [pg_dump](#) for each database in the cluster. pg_dumpall also dumps global objects that are common to all databases, namely database roles, tablespaces, and privilege grants for configuration parameters. (pg_dump does not save these objects.)

Note

Note pg_dumpall does not work with the distributed systems.

Since pg_dumpall reads tables from all databases you will most likely have to connect as a database superuser in order to produce a complete dump. Also you will need superuser privileges to execute the saved script in order to be allowed to add roles and create databases.

The SQL script will be written to the standard output. Use the `-f/--file` option or shell operators to redirect it into a file.

pg_dumpall needs to connect several times to the Postgres Pro server (once per database). If you use password authentication it will ask for a password each time. It is convenient to have a `~/.pgpass` file in such cases. See [Section 35.16](#) for more information.

Options

The following command-line options control the content and format of the output.

`-a`
`--data-only`

Dump only the data, not the schema (data definitions).

`-c`
`--clean`

Emit SQL commands to `DROP` all the dumped databases, roles, and tablespaces before recreating them. This option is useful when the restore is to overwrite an existing cluster. If any of the objects do not exist in the destination cluster, ignorable error messages will be reported during restore, unless `--if-exists` is also specified.

`-E encoding`
`--encoding=encoding`

Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the `PGCLIENTENCODING` environment variable to the desired dump encoding.)

`-f filename`
`--file=filename`

Send output to the specified file. If this is omitted, the standard output is used.

`--filter=filename`

Specify a filename from which to read patterns for databases excluded from the dump. The patterns are interpreted according to the same rules as `--exclude-database`. To read from `STDIN`, use `-` as the filename. The `--filter` option can be specified in conjunction with `--exclude-database` for excluding databases, and can also be specified more than once for multiple filter files.

The file lists one database pattern per row, with the following format:

```
exclude database PATTERN
```

Lines starting with `#` are considered comments and ignored. Comments can be placed after an object pattern row as well. Blank lines are also ignored. See [Patterns](#) for how to perform quoting in patterns.

`-g`

`--globals-only`

Dump only global objects (roles and tablespaces), no databases.

`-O`

`--no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_dumpall` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created schema elements. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`.

`-r`

`--roles-only`

Dump only roles, no databases or tablespaces.

`-s`

`--schema-only`

Dump only the object definitions (schema), not data.

`-S username`

`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used. (Usually, it's better to leave this out, and instead start the resulting script as superuser.)

`-t`

`--tablespaces-only`

Dump only tablespaces, no databases or roles.

`-v`

`--verbose`

Specifies verbose mode. This will cause `pg_dumpall` to output start/stop times to the dump file, and progress messages to standard error. Repeating the option causes additional debug-level messages to appear on standard error. The option is also passed down to `pg_dump`.

`-V`

`--version`

Print the `pg_dumpall` version and exit.

`-x`

`--no-privileges`

`--no-acl`

Prevent dumping of access privileges (grant/revoke commands).

`--binary-upgrade`

This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

`--column-inserts`

`--attribute-inserts`

Dump data as `INSERT` commands with explicit column names (`INSERT INTO table (column, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-Postgres Pro databases.

`--disable-dollar-quoting`

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

`--disable-triggers`

This option is relevant only when creating a data-only dump. It instructs `pg_dumpall` to include commands to temporarily disable triggers on the target tables while the data is restored. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data restore.

Presently, the commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-s`, or preferably be careful to start the resulting script as a superuser.

`--enable-large-mem-buffers`

Dump large bytea values exceeding 0.5 GB (up to 1 GB) and records with several text values exceeding 1 GB in total (up to 2 GB). This option cannot be used with `--inserts`, `--column-inserts`, or `--rows-per-insert`.

`--exclude-database=pattern`

Do not dump databases whose name matches *pattern*. Multiple patterns can be excluded by writing multiple `--exclude-database` switches. The *pattern* parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see [Patterns](#)), so multiple databases can also be excluded by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent shell wildcard expansion.

`--extra-float-digits=ndigits`

Use the specified value of `extra_float_digits` when dumping floating-point data, instead of the maximum available precision. Routine dumps made for backup purposes should not use this option.

`--if-exists`

Use `DROP ... IF EXISTS` commands to drop objects in `--clean` mode. This suppresses “does not exist” errors that might otherwise be reported. This option is not valid unless `--clean` is also specified.

`--inserts`

Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-Postgres Pro databases. Note that the restore might fail altogether if you have rearranged column order. The `--column-inserts` option is safer, though even slower.

`--load-via-partition-root`

When dumping data for a table partition, make the `COPY` or `INSERT` statements target the root of the partitioning hierarchy that contains it, rather than the partition itself. This causes the appropriate

partition to be re-determined for each row when the data is loaded. This may be useful when restoring data on a server where rows do not always fall into the same partitions as they did on the original server. That could happen, for example, if the partitioning column is of type text and the two systems have different definitions of the collation used to sort the partitioning column.

`--lock-wait-timeout=timeout`

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead, fail if unable to lock a table within the specified *timeout*. The timeout may be specified in any of the formats accepted by `SET statement_timeout`.

`--no-comments`

Do not dump comments.

`--no-publications`

Do not dump publications.

`--no-role-passwords`

Do not dump passwords for roles. When restored, roles will have a null password, and password authentication will always fail until the password is set. Since password values aren't needed when this option is specified, the role information is read from the catalog view `pg_roles` instead of `pg_authid`. Therefore, this option also helps if access to `pg_authid` is restricted by some security policy.

`--no-security-labels`

Do not dump security labels.

`--no-subscriptions`

Do not dump subscriptions.

`--no-sync`

By default, `pg_dumpall` will wait for all files to be written safely to disk. This option causes `pg_dumpall` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the dump corrupt. Generally, this option is useful for testing but should not be used when dumping data from production installation.

`--no-table-access-method`

Do not output commands to select table access methods. With this option, all objects will be created with whichever table access method is the default during restore.

`--no-tablespaces`

Do not output commands to create tablespaces nor select tablespaces for objects. With this option, all objects will be created in whichever tablespace is the default during restore.

`--no-toast-compression`

Do not output commands to set TOAST compression methods. With this option, all columns will be restored with the default compression setting.

`--no-unlogged-table-data`

Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data.

`--on-conflict-do-nothing`

Add `ON CONFLICT DO NOTHING` to `INSERT` commands. This option is not valid unless `--inserts` or `--column-inserts` is also specified.

`--quote-all-identifiers`

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose PostgreSQL major version is different from `pg_dumpall`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dumpall` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

`--rows-per-insert=nrows`

Dump data as `INSERT` commands (rather than `COPY`). Controls the maximum number of rows per `INSERT` command. The value specified must be a number greater than zero. Any error during restoring will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, might not restore properly.

`-?`

`--help`

Show help about `pg_dumpall` command line arguments, and exit.

The following command-line options control the database connection parameters.

`-d connstr`

`--dbname=connstr`

Specifies parameters used to connect to the server, as a [connection string](#); these will override any conflicting command line options.

The option is called `--dbname` for consistency with other client applications, but because `pg_dumpall` needs to connect to many databases, the database name in the connection string will be ignored. Use the `-l` option to specify the name of the database used for the initial connection, which will dump global objects and discover what other databases should be dumped.

`-h host`

`--host=host`

Specifies the host name of the machine on which the database server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-l dbname`

`--database=dbname`

Specifies the name of the database to connect to for dumping global objects and discovering what other databases should be dumped. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U username`

`--username=username`

User name to connect as.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force `pg_dumpall` to prompt for a password before connecting to a database.

This option is never essential, since `pg_dumpall` will automatically prompt for a password if the server demands password authentication. However, `pg_dumpall` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

Note that the password prompt will occur again for each database to be dumped. Usually, it's better to set up a `~/.pgpass` file than to rely on manual password entry.

`--role=rolename`

Specifies a role name to be used to create the dump. This option causes `pg_dumpall` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_dumpall`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

Environment

`PGHOST`
`PGOPTIONS`
`PGPORT`
`PGUSER`

Default connection parameters

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 35.15](#)).

Notes

Since `pg_dumpall` calls `pg_dump` internally, some diagnostic messages will refer to `pg_dump`.

The `--clean` option can be useful even when your intention is to restore the dump script into a fresh cluster. Use of `--clean` authorizes the script to drop and re-create the built-in `postgres` and `template1` databases, ensuring that those databases will retain the same properties (for instance, locale and encoding) that they had in the source cluster. Without the option, those databases will retain their existing database-level properties, as well as any pre-existing contents.

Once restored, it is wise to run `ANALYZE` on each database so the optimizer has useful statistics. You can also run `vacuumdb -a -z` to analyze all databases.

The dump script should not be expected to run completely without errors. In particular, because the script will issue `CREATE ROLE` for every role existing in the source cluster, it is certain to get a “role already exists” error for the bootstrap superuser, unless the destination cluster was initialized with a different bootstrap superuser name. This error is harmless and should be ignored. Use of the `--clean`

option is likely to produce additional harmless error messages about non-existent objects, although you can minimize those by adding `--if-exists`.

`pg_dumpall` requires all needed tablespace directories to exist before the restore; otherwise, database creation will fail for databases in non-default locations.

It is generally recommended to use the `-X` (`--no-psqlrc`) option when restoring a database from a `pg_dumpall` script to ensure a clean restore process and prevent potential conflicts with non-default `psql` configurations. Additionally, because the `pg_dumpall` script may include `psql` meta-commands, it may be incompatible with clients other than `psql`.

Examples

To dump all databases:

```
$ pg_dumpall > db.out
```

To restore database(s) from this file, you can use:

```
$ psql -X -f db.out -d postgres
```

It is not important which database you connect to here since the script file created by `pg_dumpall` will contain the appropriate commands to create and connect to the saved databases. An exception is that if you specified `--clean`, you must connect to the `postgres` database initially; the script will attempt to drop other databases immediately, and that will fail for the database you are connected to.

See Also

Check [pg_dump](#) for details on possible error conditions.

pg_isready

pg_isready — check the connection status of a Postgres Pro server

Synopsis

```
pg_isready [connection-option...] [option...]
```

Description

pg_isready is a utility for checking the connection status of a Postgres Pro database server. The exit status specifies the result of the connection check.

Options

```
-d dbname  
--dbname=dbname
```

Specifies the name of the database to connect to. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

```
-h hostname  
--host=hostname
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix-domain socket.

```
-p port  
--port=port
```

Specifies the TCP port or the local Unix-domain socket file extension on which the server is listening for connections. Defaults to the value of the `PGPORT` environment variable or, if not set, to the port specified at compile time, usually 5432.

```
-q  
--quiet
```

Do not display status message. This is useful when scripting.

```
-t seconds  
--timeout=seconds
```

The maximum number of seconds to wait when attempting connection before returning that the server is not responding. Setting to 0 disables. The default is 3 seconds.

```
-U username  
--username=username
```

Connect to the database as the user *username* instead of the default.

```
-V  
--version
```

Print the pg_isready version and exit.

```
-?  
--help
```

Show help about pg_isready command line arguments, and exit.

Exit Status

`pg_isready` returns 0 to the shell if the server is accepting connections normally, 1 if the server is rejecting connections (for example during startup), 2 if there was no response to the connection attempt, and 3 if no attempt was made (for example due to invalid parameters).

Environment

`pg_isready`, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 35.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

It is not necessary to supply correct user name, password, or database name values to obtain the server status; however, if incorrect values are provided, the server will log a failed connection attempt.

Examples

Standard Usage:

```
$ pg_isready
/tmp:5432 - accepting connections
$ echo $?
0
```

Running with connection parameters to a Postgres Pro cluster in startup:

```
$ pg_isready -h localhost -p 5433
localhost:5433 - rejecting connections
$ echo $?
1
```

Running with connection parameters to a non-responsive Postgres Pro cluster:

```
$ pg_isready -h someremotehost
someremotehost:5432 - no response
$ echo $?
2
```

pg_receivewal

pg_receivewal — stream write-ahead logs from a Postgres Pro server

Synopsis

```
pg_receivewal [option...]
```

Description

pg_receivewal is used to stream the write-ahead log from a running Postgres Pro cluster. The write-ahead log is streamed using the streaming replication protocol, and is written to a local directory of files. This directory can be used as the archive location for doing a restore using point-in-time recovery (see [Section 25.1](#)).

pg_receivewal streams the write-ahead log in real time as it's being generated on the server, and does not wait for segments to complete like [archive command](#) and [archive library](#) do. For this reason, it is not necessary to set [archive_timeout](#) when using pg_receivewal.

Unlike the WAL receiver of a Postgres Pro standby server, pg_receivewal by default flushes WAL data only when a WAL file is closed. The option `--synchronous` must be specified to flush WAL data in real time. Since pg_receivewal does not apply WAL, you should not allow it to become a synchronous standby when [synchronous_commit](#) equals `remote_apply`. If it does, it will appear to be a standby that never catches up, and will cause transaction commits to block. To avoid this, you should either configure an appropriate value for [synchronous_standby_names](#), or specify `application_name` for pg_receivewal that does not match it, or change the value of `synchronous_commit` to something other than `remote_apply`.

The write-ahead log is streamed over a regular Postgres Pro connection and uses the replication protocol. The connection must be made with a user having `REPLICATION` permissions (see [Section 21.2](#)) or a superuser, and `pg_hba.conf` must permit the replication connection. The server must also be configured with [max_wal_senders](#) set high enough to leave at least one session available for the stream.

The starting point of the write-ahead log streaming is calculated when pg_receivewal starts:

1. First, scan the directory where the WAL segment files are written and find the newest completed segment file, using as the starting point the beginning of the next WAL segment file.
2. If a starting point cannot be calculated with the previous method, and if a replication slot is used, an extra `READ_REPLICATION_SLOT` command is issued to retrieve the slot's `restart_lsn` to use as the starting point. This option is only available when streaming write-ahead logs from Postgres Pro 15 and up.
3. If a starting point cannot be calculated with the previous method, the latest WAL flush location is used as reported by the server from an `IDENTIFY_SYSTEM` command.

If the connection is lost, or if it cannot be initially established, with a non-fatal error, pg_receivewal will retry the connection indefinitely, and reestablish streaming as soon as possible. To avoid this behavior, use the `-n` parameter.

In the absence of fatal errors, pg_receivewal will run until terminated by the SIGINT (**Control+C**) or SIGTERM signal.

Options

```
-D directory  
--directory=directory
```

Directory to write the output to.

This parameter is required.

`-E lsn`

`--endpos=lsn`

Automatically stop replication and exit with normal exit status 0 when receiving reaches the specified LSN.

If there is a record with LSN exactly equal to *lsn*, the record will be processed.

`--if-not-exists`

Do not error out when `--create-slot` is specified and a slot with the specified name already exists.

`-n`

`--no-loop`

Don't loop on connection errors. Instead, exit right away with an error.

`--no-sync`

This option causes `pg_receivewal` to not force WAL data to be flushed to disk. This is faster, but means that a subsequent operating system crash can leave the WAL segments corrupt. Generally, this option is useful for testing but should not be used when doing WAL archiving on a production deployment.

This option is incompatible with `--synchronous`.

`-s interval`

`--status-interval=interval`

Specifies the number of seconds between status packets sent back to the server. This allows for easier monitoring of the progress from server. A value of zero disables the periodic status updates completely, although an update will still be sent when requested by the server, to avoid timeout disconnect. The default value is 10 seconds.

`-S slotname`

`--slot=slotname`

Require `pg_receivewal` to use an existing replication slot (see [Section 26.2.6](#)). When this option is used, `pg_receivewal` will report a flush position to the server, indicating when each segment has been synchronized to disk so that the server can remove that segment if it is not otherwise needed.

When the replication client of `pg_receivewal` is configured on the server as a synchronous standby, then using a replication slot will report the flush position to the server, but only when a WAL file is closed. Therefore, that configuration will cause transactions on the primary to wait for a long time and effectively not work satisfactorily. The option `--synchronous` (see below) must be specified in addition to make this work correctly.

`--synchronous`

Flush the WAL data to disk immediately after it has been received. Also send a status packet back to the server immediately after flushing, regardless of `--status-interval`.

This option should be specified if the replication client of `pg_receivewal` is configured on the server as a synchronous standby, to ensure that timely feedback is sent to the server.

`-v`

`--verbose`

Enables verbose mode.

`-Z level`

`-Z method[:detail]`

`--compress=level`

`--compress=method[:detail]`

Enables compression of write-ahead logs.

The compression method can be set to `gzip`, `lz4` (if Postgres Pro was compiled with `--with-lz4`) or `none` for no compression. A compression detail string can optionally be specified. If the detail string is an integer, it specifies the compression level. Otherwise, it should be a comma-separated list of items, each of the form *keyword* or *keyword=value*. Currently, the only supported keyword is `level`.

If no compression level is specified, the default compression level will be used. If only a level is specified without mentioning an algorithm, `gzip` compression will be used if the level is greater than 0, and no compression will be used if the level is 0.

The suffix `.gz` will automatically be added to all filenames when using `gzip`, and the suffix `.lz4` is added when using `lz4`.

The following command-line options control the database connection parameters.

```
-d connstr
--dbname=connstr
```

Specifies parameters used to connect to the server, as a [connection string](#); these will override any conflicting command line options.

This option is called `--dbname` for consistency with other client applications, but because `pg_receivewal` doesn't connect to any particular database in the cluster, any database name included in the connection string will be ignored by the server. However, a database name supplied that way overrides the default database name (`replication`) for purposes of looking up the replication connection's password in `~/.pgpass`. Similarly, middleware or proxies used in connecting to Postgres Pro might utilize the name for purposes such as connection routing.

```
-h host
--host=host
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

```
-p port
--port=port
```

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

```
-U username
--username=username
```

User name to connect as.

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force `pg_receivewal` to prompt for a password before connecting to a database.

This option is never essential, since `pg_receivewal` will automatically prompt for a password if the server demands password authentication. However, `pg_receivewal` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`pg_receivewal` can perform one of the two following actions in order to control physical replication slots:

`--create-slot`

Create a new physical replication slot with the name specified in `--slot`, then exit.

`--drop-slot`

Drop the replication slot with the name specified in `--slot`, then exit.

Other options are also available:

`-V`

`--version`

Print the `pg_receivewal` version and exit.

`-?`

`--help`

Show help about `pg_receivewal` command line arguments, and exit.

Exit Status

`pg_receivewal` will exit with status 0 when terminated by the SIGINT or SIGTERM signal. (That is the normal way to end it. Hence it is not an error.) For fatal errors or other signals, the exit status will be nonzero.

Environment

This utility, like most other Postgres Pro utilities, uses the environment variables supported by libpq (see [Section 35.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

When using `pg_receivewal` instead of [archive_command](#) or [archive_library](#) as the main WAL backup method, it is strongly recommended to use replication slots. Otherwise, the server is free to recycle or remove write-ahead log files before they are backed up, because it does not have any information, either from [archive_command](#) or [archive_library](#) or the replication slots, about how far the WAL stream has been archived. Note, however, that a replication slot will fill up the server's disk space if the receiver does not keep up with fetching the WAL data.

`pg_receivewal` will preserve group permissions on the received WAL files if group permissions are enabled on the source cluster.

Examples

To stream the write-ahead log from the server at `mydbserver` and store it in the local directory `/usr/local/pgsql/archive`:

```
$ pg_receivewal -h mydbserver -D /usr/local/pgsql/archive
```

pg_recvlogical

pg_recvlogical — control Postgres Pro logical decoding streams

Synopsis

```
pg_recvlogical [option...]
```

Description

pg_recvlogical controls logical decoding replication slots and streams data from such replication slots.

It creates a replication-mode connection, so it is subject to the same constraints as [pg_receivewal](#), plus those for logical replication (see [Chapter 50](#)).

pg_recvlogical has no equivalent to the logical decoding SQL interface's peek and get modes. It sends replay confirmations for data lazily as it receives it and on clean exit. To examine pending data on a slot without consuming it, use [pg_logical_slot_peek_changes](#).

In the absence of fatal errors, pg_recvlogical will run until terminated by the SIGINT (**Control+C**) or SIGTERM signal.

Options

At least one of the following options must be specified to select an action:

`--create-slot`

Create a new logical replication slot with the name specified by `--slot`, using the output plugin specified by `--plugin`, for the database specified by `--dbname`.

The `--two-phase` can be specified with `--create-slot` to enable decoding of prepared transactions.

`--drop-slot`

Drop the replication slot with the name specified by `--slot`, then exit.

`--start`

Begin streaming changes from the logical replication slot specified by `--slot`, continuing until terminated by a signal. If the server side change stream ends with a server shutdown or disconnect, retry in a loop unless `--no-loop` is specified.

The stream format is determined by the output plugin specified when the slot was created.

The connection must be to the same database used to create the slot.

`--create-slot` and `--start` can be specified together. `--drop-slot` cannot be combined with another action.

The following command-line options control the location and format of the output and other replication behavior:

`-E lsn`

`--endpos=lsn`

In `--start` mode, automatically stop replication and exit with normal exit status 0 when receiving reaches the specified LSN. If specified when not in `--start` mode, an error is raised.

If there's a record with LSN exactly equal to `lsn`, the record will be output.

The `--endpos` option is not aware of transaction boundaries and may truncate output partway through a transaction. Any partially output transaction will not be consumed and will be replayed again when the slot is next read from. Individual messages are never truncated.

`-f filename`
`--file=filename`

Write received and decoded transaction data into this file. Use `-` for stdout.

`-F interval_seconds`
`--fsync-interval=interval_seconds`

Specifies how often `pg_recvlogical` should issue `fsync()` calls to ensure the output file is safely flushed to disk.

The server will occasionally request the client to perform a flush and report the flush position to the server. This setting is in addition to that, to perform flushes more frequently.

Specifying an interval of 0 disables issuing `fsync()` calls altogether, while still reporting progress to the server. In this case, data could be lost in the event of a crash.

`-I lsn`
`--startpos=lsn`

In `--start` mode, start replication from the given LSN. For details on the effect of this, see the documentation in [Chapter 50](#) and [Section 56.4](#). Ignored in other modes.

`--if-not-exists`

Do not error out when `--create-slot` is specified and a slot with the specified name already exists.

`-n`
`--no-loop`

When the connection to the server is lost, do not retry in a loop, just exit.

`-o name[=value]`
`--option=name[=value]`

Pass the option *name* to the output plugin with, if specified, the option value *value*. Which options exist and their effects depends on the used output plugin.

`-P plugin`
`--plugin=plugin`

When creating a slot, use the specified logical decoding output plugin. See [Chapter 50](#). This option has no effect if the slot already exists.

`-s interval_seconds`
`--status-interval=interval_seconds`

This option has the same effect as the option of the same name in [pg_receivewal](#). See the description there.

`-S slot_name`
`--slot=slot_name`

In `--start` mode, use the existing logical replication slot named *slot_name*. In `--create-slot` mode, create the slot with this name. In `--drop-slot` mode, delete the slot with this name.

`-t`
`--two-phase`

Enables decoding of prepared transactions. This option may only be specified with `--create-slot`.

`-v`
`--verbose`

Enables verbose mode.

The following command-line options control the database connection parameters.

`-d dbname`
`--dbname=dbname`

The database to connect to. See the description of the actions for what this means in detail. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options. Defaults to the user name.

`-h hostname-or-ip`
`--host=hostname-or-ip`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-p port`
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U user`
`--username=user`

User name to connect as. Defaults to current operating system user name.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force `pg_recvlogical` to prompt for a password before connecting to a database.

This option is never essential, since `pg_recvlogical` will automatically prompt for a password if the server demands password authentication. However, `pg_recvlogical` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

The following additional options are available:

`-V`
`--version`

Print the `pg_recvlogical` version and exit.

`-?`
`--help`

Show help about `pg_recvlogical` command line arguments, and exit.

Exit Status

`pg_recvlogical` will exit with status 0 when terminated by the `SIGINT` or `SIGTERM` signal. (That is the normal way to end it. Hence it is not an error.) For fatal errors or other signals, the exit status will be nonzero.

Environment

This utility, like most other Postgres Pro utilities, uses the environment variables supported by libpq (see [Section 35.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

`pg_recvlogical` will preserve group permissions on the received WAL files if group permissions are enabled on the source cluster.

Examples

See [Section 50.1](#) for an example.

[pg_receivewal](#)

pg_restore

pg_restore — restore a Postgres Pro database from an archive file created by pg_dump

Synopsis

```
pg_restore [connection-option...] [option...] [filename]
```

Description

pg_restore is a utility for restoring a Postgres Pro database from an archive created by [pg_dump](#) in one of the non-plain-text formats. It will issue the commands necessary to reconstruct the database to the state it was in at the time it was saved. The archive files also allow pg_restore to be selective about what is restored, or even to reorder the items prior to being restored. The archive files are designed to be portable across architectures.

pg_restore can operate in two modes. If a database name is specified, pg_restore connects to that database and restores archive contents directly into the database. Otherwise, a script containing the SQL commands necessary to rebuild the database is created and written to a file or standard output. This script output is equivalent to the plain text output format of pg_dump. Some of the options controlling the output are therefore analogous to pg_dump options.

Obviously, pg_restore cannot restore information that is not present in the archive file. For instance, if the archive was made using the “dump data as INSERT commands” option, pg_restore will not be able to load the data using COPY statements.

Options

pg_restore accepts the following command line arguments.

filename

Specifies the location of the archive file (or directory, for a directory-format archive) to be restored. If not specified, the standard input is used.

-a

--data-only

Restore only the data, not the schema (data definitions). Table data, large objects, and sequence values are restored, if present in the archive.

This option is similar to, but for historical reasons not identical to, specifying --section=data.

-c

--clean

Before restoring database objects, issue commands to DROP all the objects that will be restored. This option is useful for overwriting an existing database. If any of the objects do not exist in the destination database, ignorable error messages will be reported, unless --if-exists is also specified.

-C

--create

Create the database before restoring into it. If --clean is also specified, drop and recreate the target database before connecting to it.

With --create, pg_restore also restores the database's comment if any, and any configuration variable settings that are specific to this database, that is, any ALTER DATABASE ... SET ... and ALTER

ROLE ... IN DATABASE ... SET ... commands that mention this database. Access privileges for the database itself are also restored, unless `--no-acl` is specified.

When this option is used, the database named with `-d` is used only to issue the initial `DROP DATABASE` and `CREATE DATABASE` commands. All data is restored into the database name that appears in the archive.

`-d dbname`
`--dbname=dbname`

Connect to database *dbname* and restore directly into the database. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

`-e`
`--exit-on-error`

Exit if an error is encountered while sending SQL commands to the database. The default is to continue and to display a count of errors at the end of the restoration.

`-f filename`
`--file=filename`

Specify output file for generated script, or for the listing when used with `-l`. Use `-` for stdout.

`--filter=filename`

Specify a filename from which to read patterns for objects excluded or included from restore. The patterns are interpreted according to the same rules as `-n/--schema` for including objects in schemas, `-N/--exclude-schema` for excluding objects in schemas, `-P/--function` for restoring named functions, `-I/--index` for restoring named indexes, `-t/--table` for restoring named tables or `-T/--trigger` for restoring triggers. To read from `STDIN`, use `-` as the filename. The `--filter` option can be specified in conjunction with the above listed options for including or excluding objects, and can also be specified more than once for multiple filter files.

The file lists one database pattern per row, with the following format:

```
{ include | exclude } { function | index | schema | table | trigger } PATTERN
```

The first keyword specifies whether the objects matched by the pattern are to be included or excluded. The second keyword specifies the type of object to be filtered using the pattern:

- **function:** functions, works like the `-P/--function` option. This keyword can only be used with the **include** keyword.
- **index:** indexes, works like the `-I/--indexes` option. This keyword can only be used with the **include** keyword.
- **schema:** schemas, works like the `-n/--schema` and `-N/--exclude-schema` options.
- **table:** tables, works like the `-t/--table` option. This keyword can only be used with the **include** keyword.
- **trigger:** triggers, works like the `-T/--trigger` option. This keyword can only be used with the **include** keyword.

Lines starting with `#` are considered comments and ignored. Comments can be placed after an object pattern row as well. Blank lines are also ignored. See [Patterns](#) for how to perform quoting in patterns.

`-F format`
`--format=format`

Specify format of the archive. It is not necessary to specify the format, since `pg_restore` will determine the format automatically. If specified, it can be one of the following:

`c`
`custom`

The archive is in the custom format of `pg_dump`.

`d`
`directory`

The archive is a directory archive.

`t`
`tar`

The archive is a `tar` archive.

`-I index`
`--index=index`

Restore definition of named index only. Multiple indexes may be specified with multiple `-I` switches.

`-j number-of-jobs`
`--jobs=number-of-jobs`

Run the most time-consuming steps of `pg_restore` — those that load data, create indexes, or create constraints — concurrently, using up to *number-of-jobs* concurrent sessions. This option can dramatically reduce the time to restore a large database to a server running on a multiprocessor machine. This option is ignored when emitting a script rather than connecting directly to a database server.

Each job is one process or one thread, depending on the operating system, and uses a separate connection to the server.

The optimal value for this option depends on the hardware setup of the server, of the client, and of the network. Factors include the number of CPU cores and the disk setup. A good place to start is the number of CPU cores on the server, but values larger than that can also lead to faster restore times in many cases. Of course, values that are too high will lead to decreased performance because of thrashing.

Only the custom and directory archive formats are supported with this option. The input must be a regular file or directory (not, for example, a pipe or standard input). Also, multiple jobs cannot be used together with the option `--single-transaction`.

`-l`
`--list`

List the table of contents of the archive. The output of this operation can be used as input to the `-L` option. Note that if filtering switches such as `-n` or `-t` are used with `-l`, they will restrict the items listed.

`-L list-file`
`--use-list=list-file`

Restore only those archive elements that are listed in *list-file*, and restore them in the order they appear in the file. Note that if filtering switches such as `-n` or `-t` are used with `-L`, they will further restrict the items restored.

list-file is normally created by editing the output of a previous `-l` operation. Lines can be moved or removed, and can also be commented out by placing a semicolon (;) at the start of the line. See below for examples.

`-n schema`
`--schema=schema`

Restore only objects that are in the named schema. Multiple schemas may be specified with multiple `-n` switches. This can be combined with the `-t` option to restore just a specific table.

`-N schema`
`--exclude-schema=schema`

Do not restore objects that are in the named schema. Multiple schemas to be excluded may be specified with multiple `-N` switches.

When both `-n` and `-N` are given for the same schema name, the `-N` switch wins and the schema is excluded.

`-O`
`--no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_restore` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created schema elements. These statements will fail unless the initial connection to the database is made by a superuser (or the same user that owns all of the objects in the script). With `-O`, any user name can be used for the initial connection, and this user will own all the created objects.

`-P function-name(argtype [, ...])`
`--function=function-name(argtype [, ...])`

Restore the named function only. Be careful to spell the function name and arguments exactly as they appear in the dump file's table of contents. Multiple functions may be specified with multiple `-P` switches.

`-R`
`--no-reconnect`

This option is obsolete but still accepted for backwards compatibility.

`-s`
`--schema-only`

Restore only the schema (data definitions), not data, to the extent that schema entries are present in the archive.

This option is the inverse of `--data-only`. It is similar to, but for historical reasons not identical to, specifying `--section=pre-data --section=post-data`.

(Do not confuse this with the `--schema` option, which uses the word “schema” in a different meaning.)

`-S username`
`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used.

`-t table`
`--table=table`

Restore definition and/or data of only the named table. For this purpose, “table” includes views, materialized views, sequences, and foreign tables. Multiple tables can be selected by writing multiple `-t` switches. This option can be combined with the `-n` option to specify table(s) in a particular schema.

Note

When `-t` is specified, `pg_restore` makes no attempt to restore any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that a specific-table restore into a clean database will succeed.

Note

This flag does not behave identically to the `-t` flag of `pg_dump`. There is not currently any provision for wild-card matching in `pg_restore`, nor can you include a schema name within its `-t`. And, while `pg_dump`'s `-t` flag will also dump subsidiary objects (such as indexes) of the selected table(s), `pg_restore`'s `-t` flag does not include such subsidiary objects.

Note

In versions prior to Postgres Pro 9.6, this flag matched only tables, not any other type of relation.

`-T trigger`
`--trigger=trigger`

Restore named trigger only. Multiple triggers may be specified with multiple `-T` switches.

`-v`
`--verbose`

Specifies verbose mode. This will cause `pg_restore` to output detailed object comments and start/stop times to the output file, and progress messages to standard error. Repeating the option causes additional debug-level messages to appear on standard error.

`-V`
`--version`

Print the `pg_restore` version and exit.

`-x`
`--no-privileges`
`--no-acl`

Prevent restoration of access privileges (grant/revoke commands).

`-1`
`--single-transaction`

Execute the restore as a single transaction (that is, wrap the emitted commands in `BEGIN/COMMIT`). This ensures that either all the commands complete successfully, or no changes are applied. This option implies `--exit-on-error`.

`--disable-triggers`

This option is relevant only when performing a data-only restore. It instructs `pg_restore` to execute commands to temporarily disable triggers on the target tables while the data is restored. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data restore.

Presently, the commands emitted for `--disable-triggers` must be done as superuser. So you should also specify a superuser name with `-s` or, preferably, run `pg_restore` as a Postgres Pro superuser.

`--enable-row-security`

This option is relevant only when restoring the contents of a table which has row security. By default, `pg_restore` will set [row_security](#) to off, to ensure that all data is restored in to the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs `pg_restore` to set [row_security](#) to on instead, allowing the user to attempt to restore the

contents of the table with row security enabled. This might still fail if the user does not have the right to insert the rows from the dump into the table.

Note that this option currently also requires the dump be in `INSERT` format, as `COPY FROM` does not support row security.

`--if-exists`

Use `DROP ... IF EXISTS` commands to drop objects in `--clean` mode. This suppresses “does not exist” errors that might otherwise be reported. This option is not valid unless `--clean` is also specified.

`--no-comments`

Do not output commands to restore comments, even if the archive contains them.

`--no-data-for-failed-tables`

By default, table data is restored even if the creation command for the table failed (e.g., because it already exists). With this option, data for such a table is skipped. This behavior is useful if the target database already contains the desired table contents. For example, auxiliary tables for Postgres Pro extensions such as PostGIS might already be loaded in the target database; specifying this option prevents duplicate or obsolete data from being loaded into them.

This option is effective only when restoring directly into a database, not when producing SQL script output.

`--no-publications`

Do not output commands to restore publications, even if the archive contains them.

`--no-security-labels`

Do not output commands to restore security labels, even if the archive contains them.

`--no-subscriptions`

Do not output commands to restore subscriptions, even if the archive contains them.

`--no-table-access-method`

Do not output commands to select table access methods. With this option, all objects will be created with whichever table access method is the default during restore.

`--no-tablespaces`

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

`--section=sectionname`

Only restore the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections. The default is to restore all sections.

The data section contains actual table data as well as large-object definitions. Post-data items consist of definitions of indexes, triggers, rules and constraints other than validated check constraints. Pre-data items consist of all other data definition items.

`--strict-names`

Require that each schema (`-n/--schema`) and table (`-t/--table`) qualifier match at least one schema/table in the backup file.

`--transaction-size=N`

Execute the restore as a series of transactions, each processing up to *N* database objects. This option implies `--exit-on-error`.

`--transaction-size` offers an intermediate choice between the default behavior (one transaction per SQL command) and `-1/--single-transaction` (one transaction for all restored objects). While `--single-transaction` has the least overhead, it may be impractical for large databases because the transaction will take a lock on each restored object, possibly exhausting the server's lock table space. Using `--transaction-size` with a size of a few thousand objects offers nearly the same performance benefits while capping the amount of lock table space needed.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, might not restore properly.

`-?`

`--help`

Show help about `pg_restore` command line arguments, and exit.

`pg_restore` also accepts the following command line arguments for connection parameters:

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U username`

`--username=username`

User name to connect as.

`-w`

`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`

`--password`

Force `pg_restore` to prompt for a password before connecting to a database.

This option is never essential, since `pg_restore` will automatically prompt for a password if the server demands password authentication. However, `pg_restore` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--role=rolename`

Specifies a role name to be used to perform the restore. This option causes `pg_restore` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_restore`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows restores to be performed without violating the policy.

Environment

PGHOST
PGOPTIONS
PGPORT
PGUSER

Default connection parameters

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 35.15](#)). However, it does not read `PGDATABASE` when a database name is not supplied.

Diagnostics

When a direct database connection is specified using the `-d` option, `pg_restore` internally executes SQL statements. If you have problems running `pg_restore`, make sure you are able to select information from the database using, for example, `psql`. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Notes

If your installation has any local additions to the `template1` database, be careful to load the output of `pg_restore` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

The limitations of `pg_restore` are detailed below.

- When restoring data to a pre-existing table and the option `--disable-triggers` is used, `pg_restore` emits commands to disable triggers on user tables before inserting the data, then emits commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.
- `pg_restore` cannot restore large objects selectively; for instance, only those for a specific table. If an archive contains large objects, then all large objects will be restored, or none of them if they are excluded via `-L`, `-t`, or other options.

See also the [pg_dump](#) documentation for details on limitations of `pg_dump`.

Once restored, it is wise to run `ANALYZE` on each restored table so the optimizer has useful statistics; see [Section 24.1.3](#) and [Section 24.1.6](#) for more information.

Examples

Assume we have dumped a database called `mydb` into a custom-format dump file:

```
$ pg_dump -Fc mydb > db.dump
```

To drop the database and recreate it from the dump:

```
$ dropdb mydb
$ pg_restore -C -d postgres db.dump
```

The database named in the `-d` switch can be any database existing in the cluster; `pg_restore` only uses it to issue the `CREATE DATABASE` command for `mydb`. With `-C`, data is always restored into the database name that appears in the dump file.

To restore the dump into a new database called `newdb`:

```
$ createdb -T template0 newdb
$ pg_restore -d newdb db.dump
```

Notice we don't use `-C`, and instead connect directly to the database to be restored into. Also note that we clone the new database from `template0` not `template1`, to ensure it is initially empty.

To reorder database items, it is first necessary to dump the table of contents of the archive:

```
$ pg_restore -l db.dump > db.list
```

The listing file consists of a header and one line for each item, e.g.:

```
;
; Archive created at Mon Sep 14 13:55:39 2009
;   dbname: DBDEMOS
;   TOC Entries: 81
;   Compression: 9
;   Dump Version: 1.10-0
;   Format: CUSTOM
;   Integer: 4 bytes
;   Offset: 8 bytes
;   Dumped from database version: 8.3.5
;   Dumped by pg_dump version: 8.3.8
;
;
; Selected TOC Entries:
;
3; 2615 2200 SCHEMA - public pasha
1861; 0 0 COMMENT - SCHEMA public pasha
1862; 0 0 ACL - public pasha
317; 1247 17715 TYPE public composite pasha
319; 1247 25899 DOMAIN public domain0 pasha
```

Semicolons start a comment, and the numbers at the start of lines refer to the internal archive ID assigned to each item.

Lines in the file can be commented out, deleted, and reordered. For example:

```
10; 145433 TABLE map_resolutions postgres
;2; 145344 TABLE species postgres
;4; 145359 TABLE nt_header postgres
6; 145402 TABLE species_records postgres
;8; 145416 TABLE ss_old postgres
```

could be used as input to `pg_restore` and would only restore items 10 and 6, in that order:

```
$ pg_restore -L db.list db.dump
```

pg-wrapper

pg-wrapper — manage Postgres Pro symbolic links

Synopsis

```
pg-wrapper links { update | remove }
```

Description

pg-wrapper is a shell script provided in the Postgres Pro distribution to manage Postgres Pro symbolic links for the provided programs and adjust the handling of SQL man pages on Linux systems. Since Postgres Pro is installed into `/opt/pgpro/sdm-17`, this is required to make client and server programs available in the standard system `PATH` and find the new SQL man pages. This setup is not performed automatically at installation time to avoid possible conflicts with other PostgreSQL-based products you may have installed, unless you have opted for using the `postgrespro-sdm-17` quick-install package.

pg-wrapper is provided as part of the `postgrespro-sdm-17-client` package. Once this package is installed, you can find pg-wrapper in the `install-dir/bin` directory, where `install-dir` is `/opt/pgpro/sdm-17`.

pg-wrapper must be run as root.

Options

pg-wrapper accepts the following command-line arguments:

```
links {update | remove}
```

Manage Postgres Pro symbolic links and SQL man pages:

- `update` — create or replace symbolic links for server and client programs provided with Postgres Pro, as well as add SQL man pages to the man page configuration file.
- `remove` — remove symbolic links and SQL man page support for the current Postgres Pro version.

Notes

If you are installing Postgres Pro from the `postgrespro-sdm-17` package, pg-wrapper is invoked automatically.

If you are installing individual Postgres Pro packages, you can run this script manually to create symbolic links to the provided client and server programs, as well as add SQL man pages to the man page configuration file.

For parallel installations with other PostgreSQL-based products, pg-wrapper behavior depends on whether the `update-alternatives` utility is supported by your system and the already installed PostgreSQL-based product:

- If `update-alternatives` is supported, pg-wrapper adds symbolic links to Postgres Pro programs into the alternative system, in accordance with their priority, as well as adds SQL man pages to the man page configuration file. For details on how to change the alternatives system priorities, see the man page for `update-alternatives` on your system.

If SQL man pages are already installed from a different product, the pages unique for the new installation will be displayed, while the previous installation will keep its priority for all the coinciding man pages. For the new SQL documentation to be displayed for all pages, you have to modify the system configuration, for example, change the `MANPATH` value.

- If `update-alternatives` is not supported, pg-wrapper updates the system configuration only if there are no conflicts with any programs or man pages already installed. Otherwise, pg-wrapper does not

create or update any program links and skips SQL man page integration. In this case, you can either continue using the already available program versions and SQL man pages, or modify the `PATH` and `MANPATH` settings manually.

For details on binary installation specifics on Linux, see [Section 17.1](#).

pg_verifybackup

pg_verifybackup — verify the integrity of a base backup of a Postgres Pro cluster

Synopsis

```
pg_verifybackup [option...]
```

Description

pg_verifybackup is used to check the integrity of a database cluster backup taken using pg_basebackup against a backup_manifest generated by the server at the time of the backup. The backup must be stored in the "plain" format; a "tar" format backup can be checked after extracting it.

It is important to note that the validation which is performed by pg_verifybackup does not and cannot include every check which will be performed by a running server when attempting to make use of the backup. Even if you use this tool, you should still perform test restores and verify that the resulting databases work as expected and that they appear to contain the correct data. However, pg_verifybackup can detect many problems that commonly occur due to storage problems or user error.

Backup verification proceeds in four stages. First, pg_verifybackup reads the backup_manifest file. If that file does not exist, cannot be read, is malformed, fails to match the system identifier with pg_control of the backup directory or fails verification against its own internal checksum, pg_verifybackup will terminate with a fatal error.

Second, pg_verifybackup will attempt to verify that the data files currently stored on disk are exactly the same as the data files which the server intended to send, with some exceptions that are described below. Extra and missing files will be detected, with a few exceptions. This step will ignore the presence or absence of, or any modifications to, postgresql.auto.conf, standby.signal, and recovery.signal, because it is expected that these files may have been created or modified as part of the process of taking the backup. It also won't complain about a backup_manifest file in the target directory or about anything inside pg_wal, even though these files won't be listed in the backup manifest. Only files are checked; the presence or absence of directories is not verified, except indirectly: if a directory is missing, any files it should have contained will necessarily also be missing.

Next, pg_verifybackup will checksum all the files, compare the checksums against the values in the manifest, and emit errors for any files for which the computed checksum does not match the checksum stored in the manifest. This step is not performed for any files which produced errors in the previous step, since they are already known to have problems. Files which were ignored in the previous step are also ignored in this step.

Finally, pg_verifybackup will use the manifest to verify that the write-ahead log records which will be needed to recover the backup are present and that they can be read and parsed. The backup_manifest contains information about which write-ahead log records will be needed, and pg_verifybackup will use that information to invoke pg_waldump to parse those write-ahead log records. The --quiet flag will be used, so that pg_waldump will only report errors, without producing any other output. While this level of verification is sufficient to detect obvious problems such as a missing file or one whose internal checksums do not match, they aren't extensive enough to detect every possible problem that might occur when attempting to recover. For instance, a server bug that produces write-ahead log records that have the correct checksums but specify nonsensical actions can't be detected by this method.

Note that if extra WAL files which are not required to recover the backup are present, they will not be checked by this tool, although a separate invocation of pg_waldump could be used for that purpose. Also note that WAL verification is version-specific: you must use the version of pg_verifybackup, and thus of pg_waldump, which pertains to the backup being checked. In contrast, the data file integrity checks should work with any version of the server that generates a backup_manifest file.

Options

pg_verifybackup accepts the following command-line arguments:

`-e`
`--exit-on-error`

Exit as soon as a problem with the backup is detected. If this option is not specified, `pg_verifybackup` will continue checking the backup even after a problem has been detected, and will report all problems detected as errors.

`-i path`
`--ignore=path`

Ignore the specified file or directory, which should be expressed as a relative path name, when comparing the list of data files actually present in the backup to those listed in the `backup_manifest` file. If a directory is specified, this option affects the entire subtree rooted at that location. Complaints about extra files, missing files, file size differences, or checksum mismatches will be suppressed if the relative path name matches the specified path name. This option can be specified multiple times.

`-m path`
`--manifest-path=path`

Use the manifest file at the specified path, rather than one located in the root of the backup directory.

`-n`
`--no-parse-wal`

Don't attempt to parse write-ahead log data that will be needed to recover from this backup.

`-P`
`--progress`

Enable progress reporting. Turning this on will deliver a progress report while verifying checksums.

This option cannot be used together with the option `--quiet`.

`-q`
`--quiet`

Don't print anything when a backup is successfully verified.

`-s`
`--skip-checksums`

Do not verify data file checksums. The presence or absence of files and the sizes of those files will still be checked. This is much faster, because the files themselves do not need to be read.

`-w path`
`--wal-directory=path`

Try to parse WAL files stored in the specified directory, rather than in `pg_wal`. This may be useful if the backup is stored in a separate location from the WAL archive.

Other options are also available:

`-V`
`--version`

Print the `pg_verifybackup` version and exit.

`-?`
`--help`

Show help about `pg_verifybackup` command line arguments, and exit.

Examples

To create a base backup of the server at `mydbserver` and verify the integrity of the backup:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/data
$ pg_verifybackup /usr/local/pgsql/data
```

To create a base backup of the server at `mydbserver`, move the manifest somewhere outside the backup directory, and verify the backup:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/backup1234
$ mv /usr/local/pgsql/backup1234/backup_manifest /my/secure/location/
  backup_manifest.1234
$ pg_verifybackup -m /my/secure/location/backup_manifest.1234 /usr/local/pgsql/
  backup1234
```

To verify a backup while ignoring a file that was added manually to the backup directory, and also skipping checksum verification:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/data
$ edit /usr/local/pgsql/data/note.to.self
$ pg_verifybackup --ignore=note.to.self --skip-checksums /usr/local/pgsql/data
```

psql

psql — Postgres Pro interactive terminal

Synopsis

```
psql [option...] [dbname [username]]
```

Description

psql is a terminal-based front-end to Postgres Pro. It enables you to type in queries interactively, issue them to Postgres Pro, and see the query results. Alternatively, input can be from a file or from command line arguments. In addition, psql provides a number of meta-commands and various shell-like features to facilitate writing scripts and automating a wide variety of tasks.

Options

```
-a  
--echo-all
```

Print all nonempty input lines to standard output as they are read. (This does not apply to lines read interactively.) This is equivalent to setting the variable `ECHO` to `all`.

```
-A  
--no-align
```

Switches to unaligned output mode. (The default output mode is `aligned`.) This is equivalent to `\pset format unaligned`.

```
-b  
--echo-errors
```

Print failed SQL commands to standard error output. This is equivalent to setting the variable `ECHO` to `errors`.

```
-c command  
--command=command
```

Specifies that psql is to execute the given command string, *command*. This option can be repeated and combined in any order with the `-f` option. When either `-c` or `-f` is specified, psql does not read commands from standard input; instead it terminates after processing all the `-c` and `-f` options in sequence.

command must be either a command string that is completely parsable by the server (i.e., it contains no psql-specific features), or a single backslash command. Thus you cannot mix SQL and psql meta-commands within a `-c` option. To achieve that, you could use repeated `-c` options or pipe the string into psql, for example:

```
psql -c '\x' -c 'SELECT * FROM foo;'
```

or

```
echo '\x \ SELECT * FROM foo;' | psql
```

(`\` is the separator meta-command.)

Each SQL command string passed to `-c` is sent to the server as a single request. Because of this, the server executes it as a single transaction even if the string contains multiple SQL commands, unless there are explicit `BEGIN/COMMIT` commands included in the string to divide it into multiple transactions. (See [Section 56.2.2.1](#) for more details about how the server handles multi-query strings.)

If having several commands executed in one transaction is not desired, use repeated `-c` commands or feed multiple commands to psql's standard input, either using echo as illustrated above, or via a shell here-document, for example:

```
psql <<EOF
\x
SELECT * FROM foo;
EOF
```

`--csv`

Switches to CSV (Comma-Separated Values) output mode. This is equivalent to `\pset format csv`.

`-d dbname`

`--dbname=dbname`

Specifies the name of the database to connect to. This is equivalent to specifying `dbname` as the first non-option argument on the command line. The `dbname` can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

`-e`

`--echo-queries`

Copy all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable `ECHO` to `queries`.

`-E`

`--echo-hidden`

Echo the actual queries generated by `\d` and other backslash commands. You can use this to study psql's internal operations. This is equivalent to setting the variable `ECHO_HIDDEN` to `on`.

`-f filename`

`--file=filename`

Read commands from the file `filename`, rather than standard input. This option can be repeated and combined in any order with the `-c` option. When either `-c` or `-f` is specified, psql does not read commands from standard input; instead it terminates after processing all the `-c` and `-f` options in sequence. Except for that, this option is largely equivalent to the meta-command `\i`.

If `filename` is `-` (hyphen), then standard input is read until an EOF indication or `\q` meta-command. This can be used to intersperse interactive input with input from files. Note however that Readline is not used in this case (much as if `-n` had been specified).

Using this option is subtly different from writing `psql < filename`. In general, both will do what you expect, but using `-f` enables some nice features such as error messages with line numbers. There is also a slight chance that using this option will reduce the start-up overhead. On the other hand, the variant using the shell's input redirection is (in theory) guaranteed to yield exactly the same output you would have received had you entered everything by hand.

`-F separator`

`--field-separator=separator`

Use `separator` as the field separator for unaligned output. This is equivalent to `\pset fieldsep` or `\f`.

`-h hostname`

`--host=hostname`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix-domain socket.

-H
--html

Switches to HTML output mode. This is equivalent to `\pset format html` or the `\H` command.

-l
--list

List all available databases, then exit. Other non-connection options are ignored. This is similar to the meta-command `\list`.

When this option is used, `psql` will connect to the database `postgres`, unless a different database is named on the command line (option `-d` or non-option argument, possibly via a service entry, but not via an environment variable).

-L *filename*
--log-file=*filename*

Write all query output into file *filename*, in addition to the normal output destination.

-n
--no-readline

Do not use Readline for line editing and do not use the command history (see [the section called “Command-Line Editing”](#) below).

-o *filename*
--output=*filename*

Put all query output into file *filename*. This is equivalent to the command `\o`.

-p *port*
--port=*port*

Specifies the TCP port or the local Unix-domain socket file extension on which the server is listening for connections. Defaults to the value of the `PGPORT` environment variable or, if not set, to the port specified at compile time, usually 5432.

-P *assignment*
--pset=*assignment*

Specifies printing options, in the style of `\pset`. Note that here you have to separate name and value with an equal sign instead of a space. For example, to set the output format to LaTeX, you could write `-P format=latex`.

-q
--quiet

Specifies that `psql` should do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this happens. This is useful with the `-c` option. This is equivalent to setting the variable `QUIET` to `on`.

-R *separator*
--record-separator=*separator*

Use *separator* as the record separator for unaligned output. This is equivalent to `\pset recordsep`.

-s
--single-step

Run in single-step mode. That means the user is prompted before each command is sent to the server, with the option to cancel execution as well. Use this to debug scripts.

-S
--single-line

Runs in single-line mode where a newline terminates an SQL command, as a semicolon does.

Note

This mode is provided for those who insist on it, but you are not necessarily encouraged to use it. In particular, if you mix SQL and meta-commands on a line the order of execution might not always be clear to the inexperienced user.

-t
--tuples-only

Turn off printing of column names and result row count footers, etc. This is equivalent to `\t` or `\pset tuples_only`.

-T *table_options*
--table-attr=*table_options*

Specifies options to be placed within the HTML `table` tag. See `\pset tableattr` for details.

-U *username*
--username=*username*

Connect to the database as the user *username* instead of the default. (You must have permission to do so, of course.)

-v *assignment*
--set=*assignment*
--variable=*assignment*

Perform a variable assignment, like the `\set` meta-command. Note that you must separate name and value, if any, by an equal sign on the command line. To unset a variable, leave off the equal sign. To set a variable with an empty value, use the equal sign but leave off the value. These assignments are done during command line processing, so variables that reflect connection state will get overwritten later.

-V
--version

Print the psql version and exit.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available from other sources such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

Note that this option will remain set for the entire session, and so it affects uses of the meta-command `\connect` as well as the initial connection attempt.

-W
--password

Force psql to prompt for a password before connecting to a database, even if the password will not be used.

If the server requires password authentication and a password is not available from other sources such as a `.pgpass` file, psql will prompt for a password in any case. However, psql will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

Note that this option will remain set for the entire session, and so it affects uses of the meta-command `\connect` as well as the initial connection attempt.

`-x`
`--expanded`

Turn on the expanded table formatting mode. This is equivalent to `\x` or `\pset expanded`.

`-X`
`--no-psqlrc`

Do not read the start-up file (neither the system-wide `psqlrc` file nor the user's `~/.psqlrc` file).

`-z`
`--field-separator-zero`

Set the field separator for unaligned output to a zero byte. This is equivalent to `\pset fieldsep_zero`.

`-0`
`--record-separator-zero`

Set the record separator for unaligned output to a zero byte. This is useful for interfacing, for example, with `xargs -0`. This is equivalent to `\pset recordsep_zero`.

`-1`
`--single-transaction`

This option can only be used in combination with one or more `-c` and/or `-f` options. It causes `psql` to issue a `BEGIN` command before the first such option and a `COMMIT` command after the last one, thereby wrapping all the commands into a single transaction. If any of the commands fails and the variable `ON_ERROR_STOP` was set, a `ROLLBACK` command is sent instead. This ensures that either all the commands complete successfully, or no changes are applied.

If the commands themselves contain `BEGIN`, `COMMIT`, or `ROLLBACK`, this option will not have the desired effects. Also, if an individual command cannot be executed inside a transaction block, specifying this option will cause the whole transaction to fail.

`-?`
`--help[=topic]`

Show help about `psql` and exit. The optional *topic* parameter (defaulting to `options`) selects which part of `psql` is explained: `commands` describes `psql`'s backslash commands; `options` describes the command-line options that can be passed to `psql`; and `variables` shows help about `psql` configuration variables.

Exit Status

`psql` returns 0 to the shell if it finished normally, 1 if a fatal error of its own occurs (e.g., out of memory, file not found), 2 if the connection to the server went bad and the session was not interactive, and 3 if an error occurred in a script and the variable `ON_ERROR_STOP` was set.

Usage

Connecting to a Database

`psql` is a regular Postgres Pro client application. In order to connect to a database you need to know the name of your target database, the host name and port number of the server, and what database user name you want to connect as. `psql` can be told about those parameters via command line options, namely `-d`, `-h`, `-p`, and `-U` respectively. If an argument is found that does not belong to any option it will be interpreted as the database name (or the database user name, if the database name is already given). Not all of these options are required; there are useful defaults. If you omit the host name, `psql` will connect via a Unix-domain socket to a server on the local host, or via TCP/IP to `localhost` on Windows. The default

port number is determined at compile time. Since the database server uses the same default, you will not have to specify the port in most cases. The default database user name is your operating-system user name. Once the database user name is determined, it is used as the default database name. Note that you cannot just connect to any database under any database user name. Your database administrator should have informed you about your access rights.

When the defaults aren't quite right, you can save yourself some typing by setting the environment variables `PGDATABASE`, `PGHOST`, `PGPORT` and/or `PGUSER` to appropriate values. (For additional environment variables, see [Section 35.15](#).) It is also convenient to have a `~/.pgpass` file to avoid regularly having to type in passwords. See [Section 35.16](#) for more information.

An alternative way to specify connection parameters is in a *conninfo* string or a URI, which is used instead of a database name. This mechanism give you very wide control over the connection. For example:

```
$ psql "service=myservice sslmode=require"
$ psql postgresql://dbmaster:5433/mydb?sslmode=require
```

This way you can also use LDAP for connection parameter lookup as described in [Section 35.18](#). See [Section 35.1.2](#) for more information on all the available connection options.

If the connection could not be made for any reason (e.g., insufficient privileges, server is not running on the targeted host, etc.), `psql` will return an error and terminate.

If both standard input and standard output are a terminal, then `psql` sets the client encoding to “auto”, which will detect the appropriate client encoding from the locale settings (`LC_CTYPE` environment variable on Unix systems). If this doesn't work out as expected, the client encoding can be overridden using the environment variable `PGCLIENTENCODING`.

Entering SQL Commands

In normal operation, `psql` provides a prompt with the name of the database to which `psql` is currently connected, followed by the string `=>`. For example:

```
$ psql testdb
psql (17.5.1)
Type "help" for help.

testdb=>
```

At the prompt, the user can type in SQL commands. Ordinarily, input lines are sent to the server when a command-terminating semicolon is reached. An end of line does not terminate a command. Thus commands can be spread over several lines for clarity. If the command was sent and executed without error, the results of the command are displayed on the screen.

If untrusted users have access to a database that has not adopted a [secure schema usage pattern](#), begin your session by removing publicly-writable schemas from `search_path`. One can add `options=-csearch_path=` to the connection string or issue `SELECT pg_catalog.set_config('search_path', '', false)` before other SQL commands. This consideration is not specific to `psql`; it applies to every interface for executing arbitrary SQL commands.

Whenever a command is executed, `psql` also polls for asynchronous notification events generated by [LISTEN](#) and [NOTIFY](#).

While C-style block comments are passed to the server for processing and removal, SQL-standard comments are removed by `psql`.

Meta-Commands

Anything you enter in `psql` that begins with an unquoted backslash is a `psql` meta-command that is processed by `psql` itself. These commands make `psql` more useful for administration or scripting. Meta-commands are often called slash or backslash commands.

The format of a psql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace in an argument you can quote it with single quotes. To include a single quote in an argument, write two single quotes within single-quoted text. Anything contained in single quotes is furthermore subject to C-like substitutions for `\n` (new line), `\t` (tab), `\b` (backspace), `\r` (carriage return), `\f` (form feed), `\digits` (octal), and `\xdigits` (hexadecimal). A backslash preceding any other character within single-quoted text quotes that single character, whatever it is.

If an unquoted colon (`:`) followed by a psql variable name appears within an argument, it is replaced by the variable's value, as described in [SQL Interpolation](#) below. The forms `:'variable_name'` and `:"variable_name"` described there work as well. The `: {?variable_name}` syntax allows testing whether a variable is defined. It is substituted by `TRUE` or `FALSE`. Escaping the colon with a backslash protects it from substitution.

Within an argument, text that is enclosed in backquotes (```) is taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) replaces the backquoted text. Within the text enclosed in backquotes, no special quoting or other processing occurs, except that appearances of `:variable_name` where `variable_name` is a psql variable name are replaced by the variable's value. Also, appearances of `:'variable_name'` are replaced by the variable's value suitably quoted to become a single shell command argument. (The latter form is almost always preferable, unless you are very sure of what is in the variable.) Because carriage return and line feed characters cannot be safely quoted on all platforms, the `:'variable_name'` form prints an error message and does not substitute the variable value when such characters appear in the value.

Some commands take an SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (`"`) protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, `FOO"BAR"BAZ` is interpreted as `fooBARbaz`, and `"A weird" name"` becomes `A weird name`.

Parsing for arguments stops at the end of the line, or when another unquoted backslash is found. An unquoted backslash is taken as the beginning of a new meta-command. The special sequence `\\` (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and psql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

Many of the meta-commands act on the *current query buffer*. This is simply a buffer holding whatever SQL command text has been typed but not yet sent to the server for execution. This will include previous input lines as well as any text appearing before the meta-command on the same line.

The following meta-commands are defined:

`\a`

If the current table output format is unaligned, it is switched to aligned. If it is not unaligned, it is set to unaligned. This command is kept for backwards compatibility. See `\pset` for a more general solution.

`\bind [parameter] ...`

Sets query parameters for the next query execution, with the specified parameters passed for any parameter placeholders (`$1` etc.).

Example:

```
INSERT INTO tbl1 VALUES ($1, $2) \bind 'first value' 'second value' \g
```

This also works for query-execution commands besides `\g`, such as `\gx` and `\gset`.

This command causes the extended query protocol (see [Section 56.1.2](#)) to be used, unlike normal psql operation, which uses the simple query protocol. So this command can be useful to test the

extended query protocol from psql. (The extended query protocol is used even if the query has no parameters and this command specifies zero parameters.) This command affects only the next query executed; all subsequent queries will use the simple query protocol by default.

```
\c or \connect [ -reuse-previous=on/off ] [ dbname [ username ] [ host ] [ port ] |
conninfo ]
```

Establishes a new connection to a Postgres Pro server. The connection parameters to use can be specified either using a positional syntax (one or more of database name, user, host, and port), or using a *conninfo* connection string as detailed in [Section 35.1.1](#). If no arguments are given, a new connection is made using the same parameters as before.

Specifying any of *dbname*, *username*, *host* or *port* as `-` is equivalent to omitting that parameter.

The new connection can re-use connection parameters from the previous connection; not only database name, user, host, and port, but other settings such as *sslmode*. By default, parameters are re-used in the positional syntax, but not when a *conninfo* string is given. Passing a first argument of `-reuse-previous=on` or `-reuse-previous=off` overrides that default. If parameters are re-used, then any parameter not explicitly specified as a positional parameter or in the *conninfo* string is taken from the existing connection's parameters. An exception is that if the *host* setting is changed from its previous value using the positional syntax, any *hostaddr* setting present in the existing connection's parameters is dropped. Also, any password used for the existing connection will be re-used only if the user, host, and port settings are not changed. When the command neither specifies nor reuses a particular parameter, the libpq default is used.

If the new connection is successfully made, the previous connection is closed. If the connection attempt fails (wrong user name, access denied, etc.), the previous connection will be kept if psql is in interactive mode. But when executing a non-interactive script, the old connection is closed and an error is reported. That may or may not terminate the script; if it does not, all database-accessing commands will fail until another `\connect` command is successfully executed. This distinction was chosen as a user convenience against typos on the one hand, and a safety mechanism that scripts are not accidentally acting on the wrong database on the other hand. Note that whenever a `\connect` command attempts to re-use parameters, the values re-used are those of the last successful connection, not of any failed attempts made subsequently. However, in the case of a non-interactive `\connect` failure, no parameters are allowed to be re-used later, since the script would likely be expecting the values from the failed `\connect` to be re-used.

Examples:

```
=> \c mydb myuser host.dom 6432
=> \c service=foo
=> \c "host=localhost port=5432 dbname=mydb connect_timeout=10 sslmode=disable"
=> \c -reuse-previous=on sslmode=require      -- changes only sslmode
=> \c postgresql://tom@localhost/mydb?application_name=myapp
```

```
\C [ title ]
```

Sets the title of any tables being printed as the result of a query or unset any such title. This command is equivalent to `\pset title title`. (The name of this command derives from “caption”, as it was previously only used to set the caption in an HTML table.)

```
\cd [ directory ]
```

Changes the current working directory to *directory*. Without argument, changes to the current user's home directory.

Tip

To print your current working directory, use `\! pwd`.

`\conninfo`

Outputs information about the current database connection.

```
\copy { table [ ( column_list ) ] } from { 'filename' | program 'command' | stdin |
pstdin } [ [ with ] ( option [, ...] ) ] [ where condition ]
\copy { table [ ( column_list ) ] | ( query ) } to { 'filename' | program 'command' |
stdout | pstdout } [ [ with ] ( option [, ...] ) ]
```

Performs a frontend (client) copy. This is an operation that runs an SQL `COPY` command, but instead of the server reading or writing the specified file, psql reads or writes the file and routes the data between the server and the local file system. This means that file accessibility and privileges are those of the local user, not the server, and no SQL superuser privileges are required.

When `program` is specified, `command` is executed by psql and the data passed from or to `command` is routed between the server and the client. Again, the execution privileges are those of the local user, not the server, and no SQL superuser privileges are required.

For `\copy ... from stdin`, data rows are read from the same source that issued the command, continuing until `\.` is read or the stream reaches EOF. This option is useful for populating tables in-line within an SQL script file. For `\copy ... to stdout`, output is sent to the same place as psql command output, and the `COPY count` command status is not printed (since it might be confused with a data row). To read/write psql's standard input or output regardless of the current command source or `\o` option, write `from pstdin` or `to pstdout`.

The syntax of this command is similar to that of the SQL `COPY` command. All options other than the data source/destination are as specified for `COPY`. Because of this, special parsing rules apply to the `\copy` meta-command. Unlike most other meta-commands, the entire remainder of the line is always taken to be the arguments of `\copy`, and neither variable interpolation nor backquote expansion are performed in the arguments.

Tip

Another way to obtain the same result as `\copy ... to` is to use the SQL `COPY ... TO STDOUT` command and terminate it with `\g filename` or `\g |program`. Unlike `\copy`, this method allows the command to span multiple lines; also, variable interpolation and backquote expansion can be used.

Tip

These operations are not as efficient as the SQL `COPY` command with a file or program data source or destination, because all data must pass through the client/server connection. For large amounts of data the SQL command might be preferable. Also, because of this pass-through method, `\copy ... from` in CSV mode will erroneously treat a `\.` data value alone on a line as an end-of-input marker.

`\copyright`

Shows the copyright and distribution terms of Postgres Pro.

```
\crosstabview [ colV [ colH [ colD [ sortcolH ] ] ] ]
```

Executes the current query buffer (like `\g`) and shows the results in a crosstab grid. The query must return at least three columns. The output column identified by `colV` becomes a vertical header and the output column identified by `colH` becomes a horizontal header. `colD` identifies the output column to display within the grid. `sortcolH` identifies an optional sort column for the horizontal header.

Each column specification can be a column number (starting at 1) or a column name. The usual SQL case folding and quoting rules apply to column names. If omitted, *colV* is taken as column 1 and *colH* as column 2. *colH* must differ from *colV*. If *colD* is not specified, then there must be exactly three columns in the query result, and the column that is neither *colV* nor *colH* is taken to be *colD*.

The vertical header, displayed as the leftmost column, contains the values found in column *colV*, in the same order as in the query results, but with duplicates removed.

The horizontal header, displayed as the first row, contains the values found in column *colH*, with duplicates removed. By default, these appear in the same order as in the query results. But if the optional *sortcolH* argument is given, it identifies a column whose values must be integer numbers, and the values from *colH* will appear in the horizontal header sorted according to the corresponding *sortcolH* values.

Inside the crosstab grid, for each distinct value *x* of *colH* and each distinct value *y* of *colV*, the cell located at the intersection (*x*, *y*) contains the value of the *colD* column in the query result row for which the value of *colH* is *x* and the value of *colV* is *y*. If there is no such row, the cell is empty. If there are multiple such rows, an error is reported.

`\d[S+] [pattern]`

For each relation (table, view, materialized view, index, sequence, or foreign table) or composite type matching the *pattern*, show all columns, their types, the tablespace (if not the default) and any special attributes such as `NOT NULL` or defaults. Associated indexes, constraints, rules, and triggers are also shown. For foreign tables, the associated foreign server is shown as well. (“Matching the pattern” is defined in [Patterns](#) below.)

For some types of relation, `\d` shows additional information for each column: column values for sequences, indexed expressions for indexes, and foreign data wrapper options for foreign tables.

The command form `\d+` is identical, except that more information is displayed: any comments associated with the columns of the table are shown, as is the presence of OIDs in the table, the view definition if the relation is a view, a non-default [replica identity](#) setting and the [access method](#) name if the relation has an access method.

By default, only user-created objects are shown; supply a *pattern* or the *s* modifier to include system objects.

Note

If `\d` is used without a *pattern* argument, it is equivalent to `\dtvmsE` which will show a list of all visible tables, views, materialized views, sequences and foreign tables. This is purely a convenience measure.

`\da[S] [pattern]`

Lists aggregate functions, together with their return type and the data types they operate on. If *pattern* is specified, only aggregates whose names match the pattern are shown. By default, only user-created objects are shown; supply a *pattern* or the *s* modifier to include system objects.

`\dA[+] [pattern]`

Lists access methods. If *pattern* is specified, only access methods whose names match the pattern are shown. If *+* is appended to the command name, each access method is listed with its associated handler function and description.

`\dAc[+] [access-method-pattern [input-type-pattern]`

Lists operator classes (see [Section 39.16.1](#)). If *access-method-pattern* is specified, only operator classes associated with access methods whose names match that pattern are listed. If *input-type-*

pattern is specified, only operator classes associated with input types whose names match that pattern are listed. If + is appended to the command name, each operator class is listed with its associated operator family and owner.

`\dAf[+] [access-method-pattern [input-type-pattern]]`

Lists operator families (see [Section 39.16.5](#)). If *access-method-pattern* is specified, only operator families associated with access methods whose names match that pattern are listed. If *input-type-pattern* is specified, only operator families associated with input types whose names match that pattern are listed. If + is appended to the command name, each operator family is listed with its owner.

`\dAo[+] [access-method-pattern [operator-family-pattern]]`

Lists operators associated with operator families (see [Section 39.16.2](#)). If *access-method-pattern* is specified, only members of operator families associated with access methods whose names match that pattern are listed. If *operator-family-pattern* is specified, only members of operator families whose names match that pattern are listed. If + is appended to the command name, each operator is listed with its sort operator family (if it is an ordering operator).

`\dAp[+] [access-method-pattern [operator-family-pattern]]`

Lists support functions associated with operator families (see [Section 39.16.3](#)). If *access-method-pattern* is specified, only functions of operator families associated with access methods whose names match that pattern are listed. If *operator-family-pattern* is specified, only functions of operator families whose names match that pattern are listed. If + is appended to the command name, functions are displayed verbosely, with their actual parameter lists.

`\db[+] [pattern]`

Lists tablespaces. If *pattern* is specified, only tablespaces whose names match the pattern are shown. If + is appended to the command name, each tablespace is listed with its associated options, on-disk size, permissions and description.

`\dc[S+] [pattern]`

Lists conversions between character-set encodings. If *pattern* is specified, only conversions whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If + is appended to the command name, each object is listed with its associated description.

`\dconfig[+] [pattern]`

Lists server configuration parameters and their values. If *pattern* is specified, only parameters whose names match the pattern are listed. Without a *pattern*, only parameters that are set to non-default values are listed. (Use `\dconfig *` to see all parameters.) If + is appended to the command name, each parameter is listed with its data type, context in which the parameter can be set, and access privileges (if non-default access privileges have been granted).

`\dC[+] [pattern]`

Lists type casts. If *pattern* is specified, only casts whose source or target types match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

`\dd[S] [pattern]`

Shows the descriptions of objects of type `constraint`, `operator class`, `operator family`, `rule`, and `trigger`. All other comments may be viewed by the respective backslash commands for those object types.

`\dd` displays descriptions for objects matching the *pattern*, or of visible objects of the appropriate type if no argument is given. But in either case, only objects that have a description are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects.

Descriptions for objects can be created with the [COMMENT](#) SQL command.

`\d[S+] [pattern]`

Lists domains. If *pattern* is specified, only domains whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If *+* is appended to the command name, each object is listed with its associated permissions and description.

`\ddp [pattern]`

Lists default access privilege settings. An entry is shown for each role (and schema, if applicable) for which the default privilege settings have been changed from the built-in defaults. If *pattern* is specified, only entries whose role name or schema name matches the pattern are listed.

The [ALTER DEFAULT PRIVILEGES](#) command is used to set default access privileges. The meaning of the privilege display is explained in [Section 5.8](#).

`\dE[S+] [pattern]`

`\di[S+] [pattern]`

`\dm[S+] [pattern]`

`\ds[S+] [pattern]`

`\dt[S+] [pattern]`

`\dv[S+] [pattern]`

In this group of commands, the letters *E*, *i*, *m*, *s*, *t*, and *v* stand for foreign table, index, materialized view, sequence, table, and view, respectively. You can specify any or all of these letters, in any order, to obtain a listing of objects of these types. For example, `\dti` lists tables and indexes. If *+* is appended to the command name, each object is listed with its persistence status (permanent, temporary, or unlogged), physical size on disk, and associated description if any. If *pattern* is specified, only objects whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects.

`\des[+] [pattern]`

Lists foreign servers (mnemonic: “external servers”). If *pattern* is specified, only those servers whose name matches the pattern are listed. If the form `\des+` is used, a full description of each server is shown, including the server's access privileges, type, version, options, and description.

`\det[+] [pattern]`

Lists foreign tables (mnemonic: “external tables”). If *pattern* is specified, only entries whose table name or schema name matches the pattern are listed. If the form `\det+` is used, generic options and the foreign table description are also displayed.

`\deu[+] [pattern]`

Lists user mappings (mnemonic: “external users”). If *pattern* is specified, only those mappings whose user names match the pattern are listed. If the form `\deu+` is used, additional information about each mapping is shown.

Caution

`\deu+` might also display the user name and password of the remote user, so care should be taken not to disclose them.

`\dew[+] [pattern]`

Lists foreign-data wrappers (mnemonic: “external wrappers”). If *pattern* is specified, only those foreign-data wrappers whose name matches the pattern are listed. If the form `\dew+` is used, the access privileges, options, and description of the foreign-data wrapper are also shown.

`\df[anptwS+] [pattern [arg_pattern ...]]`

Lists functions, together with their result data types, argument data types, and function types, which are classified as “agg” (aggregate), “normal”, “procedure”, “trigger”, or “window”. To display only functions of specific type(s), add the corresponding letters *a*, *n*, *p*, *t*, or *w* to the command. If *pattern* is specified, only functions whose names match the pattern are shown. Any additional arguments are type-name patterns, which are matched to the type names of the first, second, and so on arguments of the function. (Matching functions can have more arguments than what you specify. To prevent that, write a dash - as the last *arg_pattern*.) By default, only user-created objects are shown; supply a pattern or the *S* modifier to include system objects. If the form `\df+` is used, additional information about each function is shown, including volatility, parallel safety, owner, security classification, access privileges, language, internal name (for C and internal functions only), and description. Source code for a specific function can be seen using `\sf`.

`\dF[+] [pattern]`

Lists text search configurations. If *pattern* is specified, only configurations whose names match the pattern are shown. If the form `\dF+` is used, a full description of each configuration is shown, including the underlying text search parser and the dictionary list for each parser token type.

`\dFd[+] [pattern]`

Lists text search dictionaries. If *pattern* is specified, only dictionaries whose names match the pattern are shown. If the form `\dFd+` is used, additional information is shown about each selected dictionary, including the underlying text search template and the option values.

`\dFp[+] [pattern]`

Lists text search parsers. If *pattern* is specified, only parsers whose names match the pattern are shown. If the form `\dFp+` is used, a full description of each parser is shown, including the underlying functions and the list of recognized token types.

`\dFt[+] [pattern]`

Lists text search templates. If *pattern* is specified, only templates whose names match the pattern are shown. If the form `\dFt+` is used, additional information is shown about each template, including the underlying function names.

`\dg[S+] [pattern]`

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to `\du`.) By default, only user-created roles are shown; supply the *S* modifier to include system roles. If *pattern* is specified, only those roles whose names match the pattern are listed. If the form `\dg+` is used, additional information is shown about each role; currently this adds the comment for each role.

`\dl[+]`

This is an alias for `\lo_list`, which shows a list of large objects. If *+* is appended to the command name, each large object is listed with its associated permissions, if any.

`\dL[S+] [pattern]`

Lists procedural languages. If *pattern* is specified, only languages whose names match the pattern are listed. By default, only user-created languages are shown; supply the *S* modifier to include system objects. If *+* is appended to the command name, each language is listed with its call handler, validator, access privileges, and whether it is a system object.

`\dn[S+] [pattern]`

Lists schemas (namespaces). If *pattern* is specified, only schemas whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *S* modifier to include system objects. If *+* is appended to the command name, each object is listed with its associated permissions, description, and the security officer, if any.

```
\do[S+] [ pattern [ arg_pattern [ arg_pattern ] ] ]
```

Lists operators with their operand and result types. If *pattern* is specified, only operators whose names match the pattern are listed. If one *arg_pattern* is specified, only prefix operators whose right argument's type name matches that pattern are listed. If two *arg_patterns* are specified, only binary operators whose argument type names match those patterns are listed. (Alternatively, write `-` for the unused argument of a unary operator.) By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects. If `+` is appended to the command name, additional information about each operator is shown, currently just the name of the underlying function.

```
\do[S+] [ pattern ]
```

Lists collations. If *pattern* is specified, only collations whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects. If `+` is appended to the command name, each collation is listed with its associated description, if any. Note that only collations usable with the current database's encoding are shown, so the results may vary in different databases of the same installation.

```
\dp[S] [ pattern ]
```

Lists tables, views and sequences with their associated access privileges. If *pattern* is specified, only tables, views and sequences whose names match the pattern are listed. By default only user-created objects are shown; supply a pattern or the `s` modifier to include system objects.

The [GRANT](#) and [REVOKE](#) commands are used to set access privileges. The meaning of the privilege display is explained in [Section 5.8](#).

```
\dP[itn+] [ pattern ]
```

Lists partitioned relations. If *pattern* is specified, only entries whose name matches the pattern are listed. The modifiers `t` (tables) and `i` (indexes) can be appended to the command, filtering the kind of relations to list. By default, partitioned tables and indexes are listed.

If the modifier `n` ("nested") is used, or a pattern is specified, then non-root partitioned relations are included, and a column is shown displaying the parent of each partitioned relation.

If `+` is appended to the command name, the sum of the sizes of each relation's partitions is also displayed, along with the relation's description. If `n` is combined with `+`, two sizes are shown: one including the total size of directly-attached leaf partitions, and another showing the total size of all partitions, including indirectly attached sub-partitions.

```
\drds [ role-pattern [ database-pattern ] ]
```

Lists defined configuration settings. These settings can be role-specific, database-specific, or both. *role-pattern* and *database-pattern* are used to select specific roles and databases to list, respectively. If omitted, or if `*` is specified, all settings are listed, including those not role-specific or database-specific, respectively.

The [ALTER ROLE](#) and [ALTER DATABASE](#) commands are used to define per-role and per-database configuration settings.

```
\drg[S] [ pattern ]
```

Lists information about each granted role membership, including assigned options (`ADMIN`, `INHERIT` and/or `SET`) and grantor. See the [GRANT](#) command for information about role memberships.

By default, only grants to user-created roles are shown; supply the `s` modifier to include system roles. If *pattern* is specified, only grants to those roles whose names match the pattern are listed.

```
\dRp[+] [ pattern ]
```

Lists replication publications. If *pattern* is specified, only those publications whose names match the pattern are listed. If `+` is appended to the command name, the tables and schemas associated with each publication are shown as well.

`\dRs[+] [pattern]`

Lists replication subscriptions. If *pattern* is specified, only those subscriptions whose names match the pattern are listed. If + is appended to the command name, additional properties of the subscriptions are shown.

`\duP [pattern]`

Lists profiles. If *pattern* is specified, only those profiles whose names match the pattern are listed. This command is only available for superusers.

`\dT[S+] [pattern]`

Lists data types. If *pattern* is specified, only types whose names match the pattern are listed. If + is appended to the command name, each type is listed with its internal name and size, its allowed values if it is an `enum` type, and its associated permissions. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects.

`\du[S+] [pattern]`

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to `\dg`.) By default, only user-created roles are shown; supply the *s* modifier to include system roles. If *pattern* is specified, only those roles whose names match the pattern are listed. If the form `\du+` is used, additional information is shown about each role; currently this adds the comment for each role.

`\dx[+] [pattern]`

Lists installed extensions. If *pattern* is specified, only those extensions whose names match the pattern are listed. If the form `\dx+` is used, all the objects belonging to each matching extension are listed.

`\dX [pattern]`

Lists extended statistics. If *pattern* is specified, only those extended statistics whose names match the pattern are listed.

The status of each kind of extended statistics is shown in a column named after its statistic kind (e.g. `Ndistinct`). `defined` means that it was requested when creating the statistics, and `NULL` means it wasn't requested. You can use `pg_stats_ext` if you'd like to know whether `ANALYZE` was run and statistics are available to the planner.

`\dy[+] [pattern]`

Lists event triggers. If *pattern* is specified, only those event triggers whose names match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

`\e or \edit [filename] [line_number]`

If *filename* is specified, the file is edited; after the editor exits, the file's content is copied into the current query buffer. If no *filename* is given, the current query buffer is copied to a temporary file which is then edited in the same fashion. Or, if the current query buffer is empty, the most recently executed query is copied to a temporary file and edited in the same fashion.

If you edit a file or the previous query, and you quit the editor without modifying the file, the query buffer is cleared. Otherwise, the new contents of the query buffer are re-parsed according to the normal rules of psql, treating the whole buffer as a single line. Any complete queries are immediately executed; that is, if the query buffer contains or ends with a semicolon, everything up to that point is executed and removed from the query buffer. Whatever remains in the query buffer is redisplayed. Type semicolon or `\g` to send it, or `\r` to cancel it by clearing the query buffer.

Treating the buffer as a single line primarily affects meta-commands: whatever is in the buffer after a meta-command will be taken as argument(s) to the meta-command, even if it spans multiple lines. (Thus you cannot make meta-command-using scripts this way. Use `\i` for that.)

If a line number is specified, psql will position the cursor on the specified line of the file or query buffer. Note that if a single all-digits argument is given, psql assumes it is a line number, not a file name.

Tip

See [Environment](#), below, for how to configure and customize your editor.

```
\echo text [ ... ]
```

Prints the evaluated arguments to standard output, separated by spaces and followed by a newline. This can be useful to intersperse information in the output of scripts. For example:

```
=> \echo `date`  
Tue Oct 26 21:40:57 CEST 1999
```

If the first argument is an unquoted `-n` the trailing newline is not written (nor is the first argument).

Tip

If you use the `\o` command to redirect your query output you might wish to use `\qecho` instead of this command. See also `\warn`.

```
\ef [ function_description [ line_number ] ]
```

This command fetches and edits the definition of the named function or procedure, in the form of a `CREATE OR REPLACE FUNCTION` or `CREATE OR REPLACE PROCEDURE` command. Editing is done in the same way as for `\edit`. If you quit the editor without saving, the statement is discarded. If you save and exit the editor, the updated command is executed immediately if you added a semicolon to it. Otherwise it is redisplayed; type semicolon or `\g` to send it, or `\r` to cancel.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If no function is specified, a blank `CREATE FUNCTION` template is presented for editing.

If a line number is specified, psql will position the cursor on the specified line of the function body. (Note that the function body typically does not begin on the first line of the file.)

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\ef`, and neither variable interpolation nor backquote expansion are performed in the arguments.

Tip

See [Environment](#), below, for how to configure and customize your editor.

```
\encoding [ encoding ]
```

Sets the client character set encoding. Without an argument, this command shows the current encoding.

```
\errverbose
```

Repeats the most recent server error message at maximum verbosity, as though `VERBOSITY` were set to `verbose` and `SHOW_CONTEXT` were set to `always`.

```
\ev [ view_name [ line_number ] ]
```

This command fetches and edits the definition of the named view, in the form of a `CREATE OR REPLACE VIEW` command. Editing is done in the same way as for `\edit`. If you quit the editor without saving, the statement is discarded. If you save and exit the editor, the updated command is executed immediately if you added a semicolon to it. Otherwise it is redisplayed; type semicolon or `\g` to send it, or `\r` to cancel.

If no view is specified, a blank `CREATE VIEW` template is presented for editing.

If a line number is specified, psql will position the cursor on the specified line of the view definition.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\ev`, and neither variable interpolation nor backquote expansion are performed in the arguments.

```
\f [ string ]
```

Sets the field separator for unaligned query output. The default is the vertical bar (`|`). It is equivalent to `\pset fieldsep`.

```
\g [ (option=value [...]) ] [ filename ]  
\g [ (option=value [...]) ] [ |command ]
```

Sends the current query buffer to the server for execution.

If parentheses appear after `\g`, they surround a space-separated list of `option=value` formatting-option clauses, which are interpreted in the same way as `\pset option value` commands, but take effect only for the duration of this query. In this list, spaces are not allowed around `=` signs, but are required between option clauses. If `=value` is omitted, the named `option` is changed in the same way as for `\pset option` with no explicit `value`.

If a `filename` or `|command` argument is given, the query's output is written to the named file or piped to the given shell command, instead of displaying it as usual. The file or command is written to only if the query successfully returns zero or more tuples, not if the query fails or is a non-data-returning SQL command.

If the current query buffer is empty, the most recently sent query is re-executed instead. Except for that behavior, `\g` without any arguments is essentially equivalent to a semicolon. With arguments, `\g` provides a “one-shot” alternative to the `\o` command, and additionally allows one-shot adjustments of the output formatting options normally set by `\pset`.

When the last argument begins with `|`, the entire remainder of the line is taken to be the `command` to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.

```
\gdesc
```

Shows the description (that is, the column names and data types) of the result of the current query buffer. The query is not actually executed; however, if it contains some type of syntax error, that error will be reported in the normal way.

If the current query buffer is empty, the most recently sent query is described instead.

```
\getenv psql_var env_var
```

Gets the value of the environment variable `env_var` and assigns it to the psql variable `psql_var`. If `env_var` is not defined in the psql process's environment, `psql_var` is not changed. Example:

```
=> \getenv home HOME  
=> \echo :home  
/home/postgres
```

\gexec

Sends the current query buffer to the server, then treats each column of each row of the query's output (if any) as an SQL statement to be executed. For example, to create an index on each column of `my_table`:

```
=> SELECT format('create index on my_table(%I)', attname)
-> FROM pg_attribute
-> WHERE attrelid = 'my_table'::regclass AND attnum > 0
-> ORDER BY attnum
-> \gexec
CREATE INDEX
CREATE INDEX
CREATE INDEX
CREATE INDEX
```

The generated queries are executed in the order in which the rows are returned, and left-to-right within each row if there is more than one column. NULL fields are ignored. The generated queries are sent literally to the server for processing, so they cannot be psql meta-commands nor contain psql variable references. If any individual query fails, execution of the remaining queries continues unless `ON_ERROR_STOP` is set. Execution of each query is subject to `ECHO` processing. (Setting `ECHO` to all or queries is often advisable when using `\gexec`.) Query logging, single-step mode, timing, and other query execution features apply to each generated query as well.

If the current query buffer is empty, the most recently sent query is re-executed instead.

\gset [*prefix*]

Sends the current query buffer to the server and stores the query's output into psql variables (see [Variables](#) below). The query to be executed must return exactly one row. Each column of the row is stored into a separate variable, named the same as the column. For example:

```
=> SELECT 'hello' AS var1, 10 AS var2
-> \gset
=> \echo :var1 :var2
hello 10
```

If you specify a *prefix*, that string is prepended to the query's column names to create the variable names to use:

```
=> SELECT 'hello' AS var1, 10 AS var2
-> \gset result_
=> \echo :result_var1 :result_var2
hello 10
```

If a column result is NULL, the corresponding variable is unset rather than being set.

If the query fails or does not return one row, no variables are changed.

If the current query buffer is empty, the most recently sent query is re-executed instead.

\gx [(*option=value* [...])] [*filename*]
\gx [(*option=value* [...])] [|*command*]

`\gx` is equivalent to `\g`, except that it forces expanded output mode for this query, as if `expanded=on` were included in the list of `\pset` options. See also `\x`.

\h or **\help** [*command*]

Gives syntax help on the specified SQL command. If *command* is not specified, then psql will list all the commands for which syntax help is available. If *command* is an asterisk (*), then syntax help on all SQL commands is shown.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\help`, and neither variable interpolation nor backquote expansion are performed in the arguments.

Note

To simplify typing, commands that consists of several words do not have to be quoted. Thus it is fine to type `\help alter table`.

`\H` or `\html`

Turns on HTML query output format. If the HTML format is already on, it is switched back to the default aligned text format. This command is for compatibility and convenience, but see `\pset` about setting other output options.

`\i` or `\include filename [name=value] [value] [...]`

Reads input from the file *filename* and executes it as though it had been typed on the keyboard.

If *filename* is `-` (hyphen), then standard input is read until an EOF indication or `\q` meta-command. This can be used to intersperse interactive input with input from files. Note that Readline behavior will be used only if it is active at the outermost level.

When the optional arguments are passed, psql parses them for variable substitution. If *name=value* is passed, a named variable is created. If only the *value* is specified, it is saved as a positional variable named `PSQL_ARG1`, `PSQL_ARG2`, `PSQL_ARG3`, etc. These parameter variables are temporary and will be deleted after the script execution. Example:

```
\i expfile.sql filename=myfile.dmp lines=12
```

You can mix named and positional parameters, for example:

```
\i expfile.sql filename=myfile.dmp lines=12 1 100
```

In the above example, four variables will be available in the `expfile.sql` script:

- `filename` with the value `myfile.dmp`
- `lines` with the value `12`
- `PSQL_ARG1` with the value `1`
- `PSQL_ARG2` with the value `100`

If there are other psql variables with the same name, the temporary variable overrides the existing one for the time of script execution. If a script calls another one, both of them have their own sets of temporary variables, and the caller's variables cannot be used by another script (though they are not deleted yet).

Note

If you want to see the lines on the screen as they are read you must set the variable `ECHO` to `all`.

```
\if expression
\elif expression
\else
\endif
```

This group of commands implements nestable conditional blocks. A conditional block must begin with an `\if` and end with an `\endif`. In between there may be any number of `\elif` clauses, which

may optionally be followed by a single `\else` clause. Ordinary queries and other types of backslash commands may (and usually do) appear between the commands forming a conditional block.

The `\if` and `\elif` commands read their argument(s) and evaluate them as a Boolean expression. If the expression yields `true` then processing continues normally; otherwise, lines are skipped until a matching `\elif`, `\else`, or `\endif` is reached. Once an `\if` or `\elif` test has succeeded, the arguments of later `\elif` commands in the same block are not evaluated but are treated as false. Lines following an `\else` are processed only if no earlier matching `\if` or `\elif` succeeded.

The *expression* argument of an `\if` or `\elif` command is subject to variable interpolation and backquote expansion, just like any other backslash command argument. After that it is evaluated like the value of an on/off option variable. So a valid value is any unambiguous case-insensitive match for one of: `true`, `false`, `1`, `0`, `on`, `off`, `yes`, `no`. For example, `t`, `T`, and `tR` will all be considered to be `true`.

Expressions that do not properly evaluate to true or false will generate a warning and be treated as false.

Lines being skipped are parsed normally to identify queries and backslash commands, but queries are not sent to the server, and backslash commands other than conditionals (`\if`, `\elif`, `\else`, `\endif`) are ignored. Conditional commands are checked only for valid nesting. Variable references in skipped lines are not expanded, and backquote expansion is not performed either.

All the backslash commands of a given conditional block must appear in the same source file. If EOF is reached on the main input file or an `\include`-ed file before all local `\if`-blocks have been closed, then psql will raise an error.

Here is an example:

```
-- check for the existence of two separate records in the database and store
-- the results in separate psql variables
SELECT
    EXISTS(SELECT 1 FROM customer WHERE customer_id = 123) as is_customer,
    EXISTS(SELECT 1 FROM employee WHERE employee_id = 456) as is_employee
\gset
\if :is_customer
    SELECT * FROM customer WHERE customer_id = 123;
\elif :is_employee
    \echo 'is not a customer but is an employee'
    SELECT * FROM employee WHERE employee_id = 456;
\else
    \if yes
        \echo 'not a customer or employee'
    \else
        \echo 'this will never print'
    \endif
\endif
\ir or \include_relative filename
```

The `\ir` command is similar to `\i`, but resolves relative file names differently. When executing in interactive mode, the two commands behave identically. However, when invoked from a script, `\ir` interprets file names relative to the directory in which the script is located, rather than the current working directory.

```
\l[+] or \list[+] [ pattern ]
```

List the databases in the server and show their names, owners, character set encodings, and access privileges. If *pattern* is specified, only databases whose names match the pattern are listed. If `+` is appended to the command name, database sizes, default tablespaces, and descriptions are also displayed. (Size information is only available for databases that the current user can connect to.)

```
\lo_export loid filename
```

Reads the large object with OID *loid* from the database and writes it to *filename*. Note that this is subtly different from the server function `lo_export`, which acts with the permissions of the user that the database server runs as and on the server's file system.

Tip

Use `\lo_list` to find out the large object's OID.

```
\lo_import filename [ comment ]
```

Stores the file into a Postgres Pro large object. Optionally, it associates the given comment with the object. Example:

```
foo=> \lo_import '/home/peter/pictures/photo.xcf' 'a picture of me'
lo_import 152801
```

The response indicates that the large object received object ID 152801, which can be used to access the newly-created large object in the future. For the sake of readability, it is recommended to always associate a human-readable comment with every object. Both OIDs and comments can be viewed with the `\lo_list` command.

Note that this command is subtly different from the server-side `lo_import` because it acts as the local user on the local file system, rather than the server's user and file system.

```
\lo_list[+]
```

Shows a list of all Postgres Pro large objects currently stored in the database, along with any comments provided for them. If `+` is appended to the command name, each large object is listed with its associated permissions, if any.

```
\lo_unlink loid
```

Deletes the large object with OID *loid* from the database.

Tip

Use `\lo_list` to find out the large object's OID.

```
\o or \out [ filename ]
```

```
\o or \out [ |command ]
```

Arranges to save future query results to the file *filename* or pipe future results to the shell command *command*. If no argument is specified, the query output is reset to the standard output.

If the argument begins with `|`, then the entire remainder of the line is taken to be the *command* to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.

“Query results” includes all tables, command responses, and notices obtained from the database server, as well as output of various backslash commands that query the database (such as `\d`); but not error messages.

Tip

To intersperse text output in between query results, use `\qecho`.

`\p` or `\print`

Print the current query buffer to the standard output. If the current query buffer is empty, the most recently executed query is printed instead.

`\password [username]`

Changes the password of the specified user (by default, the current user). This command prompts for the new password, encrypts it, and sends it to the server as an `ALTER ROLE` command. This makes sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

`\prompt [text] name`

Prompts the user to supply text, which is assigned to the variable *name*. An optional prompt string, *text*, can be specified. (For multiword prompts, surround the text with single quotes.)

By default, `\prompt` uses the terminal for input and output. However, if the `-f` command line switch was used, `\prompt` uses standard input and standard output.

`\pset [option [value]]`

This command sets options affecting the output of query result tables. *option* indicates which option is to be set. The semantics of *value* vary depending on the selected option. For some options, omitting *value* causes the option to be toggled or unset, as described under the particular option. If no such behavior is mentioned, then omitting *value* just results in the current setting being displayed.

`\pset` without any arguments displays the current status of all printing options.

Adjustable printing options are:

`border`

The *value* must be a number. In general, the higher the number the more borders and lines the tables will have, but details depend on the particular format. In HTML format, this will translate directly into the `border=...` attribute. In most other formats only values 0 (no border), 1 (internal dividing lines), and 2 (table frame) make sense, and values above 2 will be treated the same as `border = 2`. The `latex` and `latex-longtable` formats additionally allow a value of 3 to add dividing lines between data rows.

`columns`

Sets the target width for the `wrapped` format, and also the width limit for determining whether output is wide enough to require the pager or switch to the vertical display in expanded auto mode. Zero (the default) causes the target width to be controlled by the environment variable `COLUMNS`, or the detected screen width if `COLUMNS` is not set. In addition, if `columns` is zero then the `wrapped` format only affects screen output. If `columns` is nonzero then file and pipe output is wrapped to that width as well.

`csv_fieldsep`

Specifies the field separator to be used in CSV output format. If the separator character appears in a field's value, that field is output within double quotes, following standard CSV rules. The default is a comma.

`expanded` (or `x`)

If *value* is specified it must be either `on` or `off`, which will enable or disable expanded mode, or `auto`. If *value* is omitted the command toggles between the on and off settings. When expanded mode is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data wouldn't fit on the screen in the normal "horizontal" mode. In the auto setting, the expanded mode is used whenever the query output

has more than one column and is wider than the screen; otherwise, the regular mode is used. The auto setting is only effective in the aligned and wrapped formats. In other formats, it always behaves as if the expanded mode is off.

fieldsep

Specifies the field separator to be used in unaligned output format. That way one can create, for example, tab-separated output, which other programs might prefer. To set a tab as field separator, type `\pset fieldsep '\t'`. The default field separator is `'|'` (a vertical bar).

fieldsep_zero

Sets the field separator to use in unaligned output format to a zero byte.

footer

If *value* is specified it must be either `on` or `off` which will enable or disable display of the table footer (the `(n rows)` count). If *value* is omitted the command toggles footer display on or off.

format

Sets the output format to one of `aligned`, `asciidoc`, `csv`, `html`, `latex`, `latex-longtable`, `troff-ms`, `unaligned`, or `wrapped`. Unique abbreviations are allowed.

`aligned` format is the standard, human-readable, nicely formatted text output; this is the default.

`unaligned` format writes all columns of a row on one line, separated by the currently active field separator. This is useful for creating output that might be intended to be read in by other programs, for example, tab-separated or comma-separated format. However, the field separator character is not treated specially if it appears in a column's value; so CSV format may be better suited for such purposes.

`csv` format writes column values separated by commas, applying the quoting rules described in [RFC 4180](#). This output is compatible with the CSV format of the server's `COPY` command. A header line with column names is generated unless the `tuples_only` parameter is `on`. Titles and footers are not printed. Each row is terminated by the system-dependent end-of-line character, which is typically a single newline (`\n`) for Unix-like systems or a carriage return and newline sequence (`\r\n`) for Microsoft Windows. Field separator characters other than comma can be selected with `\pset csv_fieldsep`.

`wrapped` format is like `aligned` but wraps wide data values across lines to make the output fit in the target column width. The target width is determined as described under the `columns` option. Note that `psql` will not attempt to wrap column header titles; therefore, `wrapped` format behaves the same as `aligned` if the total width needed for column headers exceeds the target.

The `asciidoc`, `html`, `latex`, `latex-longtable`, and `troff-ms` formats put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! This might not be necessary in HTML, but in LaTeX you must have a complete document wrapper. The `latex` format uses LaTeX's `tabular` environment. The `latex-longtable` format requires the LaTeX `longtable` and `booktabs` packages.

linestyle

Sets the border line drawing style to one of `ascii`, `old-ascii`, or `unicode`. Unique abbreviations are allowed. (That would mean one letter is enough.) The default setting is `ascii`. This option only affects the `aligned` and `wrapped` output formats.

`ascii` style uses plain ASCII characters. Newlines in data are shown using a `+` symbol in the right-hand margin. When the `wrapped` format wraps data from one line to the next without a newline character, a dot (`.`) is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

`old-ascii` style uses plain ASCII characters, using the formatting style used in PostgreSQL 8.4 and earlier. Newlines in data are shown using a `:` symbol in place of the left-hand column separator. When the data is wrapped from one line to the next without a newline character, a `;` symbol is used in place of the left-hand column separator.

`unicode` style uses Unicode box-drawing characters. Newlines in data are shown using a carriage return symbol in the right-hand margin. When the data is wrapped from one line to the next without a newline character, an ellipsis symbol is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

When the `border` setting is greater than zero, the `linestyle` option also determines the characters with which the border lines are drawn. Plain ASCII characters work everywhere, but Unicode characters look nicer on displays that recognize them.

`null`

Sets the string to be printed in place of a null value. The default is to print nothing, which can easily be mistaken for an empty string. For example, one might prefer `\pset null '(null)'`.

`numericlocale`

If *value* is specified it must be either `on` or `off` which will enable or disable display of a locale-specific character to separate groups of digits to the left of the decimal marker. If *value* is omitted the command toggles between regular and locale-specific numeric output.

`pager`

Controls use of a pager program for query and psql help output. When the `pager` option is `off`, the pager program is not used. When the `pager` option is `on`, the pager is used when appropriate, i.e., when the output is to a terminal and will not fit on the screen. The `pager` option can also be set to `always`, which causes the pager to be used for all terminal output regardless of whether it fits on the screen. `\pset pager` without a *value* toggles pager use on and off.

If the environment variable `PSQL_PAGER` or `PAGER` is set, output to be paged is piped to the specified program. Otherwise a platform-dependent default program (such as `more`) is used.

When using the `\watch` command to execute a query repeatedly, the environment variable `PSQL_WATCH_PAGER` is used to find the pager program instead, on Unix systems. This is configured separately because it may confuse traditional pagers, but can be used to send output to tools that understand psql's output format (such as `pspg --stream`).

`pager_min_lines`

If `pager_min_lines` is set to a number greater than the page height, the pager program will not be called unless there are at least this many lines of output to show. The default setting is 0.

`recordsep`

Specifies the record (line) separator to use in unaligned output format. The default is a newline character.

`recordsep_zero`

Sets the record separator to use in unaligned output format to a zero byte.

`tableattr` (or `T`)

In HTML format, this specifies attributes to be placed inside the `table` tag. This could for example be `cellpadding` or `bgcolor`. Note that you probably don't want to specify `border` here, as that is already taken care of by `\pset border`. If no *value* is given, the table attributes are unset.

In `latex-longtable` format, this controls the proportional width of each column containing a left-aligned data type. It is specified as a whitespace-separated list of values, e.g., `'0.2 0.2 0.6'`. Unspecified output columns use the last specified value.

title (or C)

Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no *value* is given, the title is unset.

tuples_only (or t)

If *value* is specified it must be either `on` or `off` which will enable or disable tuples-only mode. If *value* is omitted the command toggles between regular and tuples-only output. Regular output includes extra information such as column headers, titles, and various footers. In tuples-only mode, only actual table data is shown.

unicode_border_linestyle

Sets the border drawing style for the `unicode` line style to one of `single` or `double`.

unicode_column_linestyle

Sets the column drawing style for the `unicode` line style to one of `single` or `double`.

unicode_header_linestyle

Sets the header drawing style for the `unicode` line style to one of `single` or `double`.

xheader_width

Sets the maximum width of the header for expanded output to one of `full` (the default value), `column`, `page`, or an *integer value*.

`full`: the expanded header is not truncated, and will be as wide as the widest output line.

`column`: truncate the header line to the width of the first column.

`page`: truncate the header line to the terminal width.

integer value: specify the exact maximum width of the header line.

Illustrations of how these different formats look can be seen in [Examples](#), below.

Tip

There are various shortcut commands for `\pset`. See `\a`, `\C`, `\f`, `\H`, `\t`, `\T`, and `\x`.

\q or \quit

Quits the psql program. In a script file, only execution of that script is terminated.

\qecho text [...]

This command is identical to `\echo` except that the output will be written to the query output channel, as set by `\o`.

\r or \reset

Resets (clears) the query buffer.

\s [filename]

Print psql's command line history to *filename*. If *filename* is omitted, the history is written to the standard output (using the pager if appropriate). This command is not available if psql was built without Readline support.

```
\set [ name [ value [ ... ] ] ]
```

Sets the psql variable *name* to *value*, or if more than one value is given, to the concatenation of all of them. If only one argument is given, the variable is set to an empty-string value. To unset a variable, use the `\unset` command.

`\set` without any arguments displays the names and values of all currently-set psql variables.

Valid variable names can contain letters, digits, and underscores. See [Variables](#) below for details. Variable names are case-sensitive.

Certain variables are special, in that they control psql's behavior or are automatically set to reflect connection state. These variables are documented in [Variables](#), below.

Note

This command is unrelated to the SQL command `SET`.

```
\setenv name [ value ]
```

Sets the environment variable *name* to *value*, or if the *value* is not supplied, unsets the environment variable. Example:

```
testdb=> \setenv PAGER less
testdb=> \setenv LESS -imx4F
```

```
\sf[+] function_description
```

This command fetches and shows the definition of the named function or procedure, in the form of a `CREATE OR REPLACE FUNCTION` or `CREATE OR REPLACE PROCEDURE` command. The definition is printed to the current query output channel, as set by `\o`.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If `+` is appended to the command name, then the output lines are numbered, with the first line of the function body being line 1.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\sf`, and neither variable interpolation nor backquote expansion are performed in the arguments.

```
\sv[+] view_name
```

This command fetches and shows the definition of the named view, in the form of a `CREATE OR REPLACE VIEW` command. The definition is printed to the current query output channel, as set by `\o`.

If `+` is appended to the command name, then the output lines are numbered from 1.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\sv`, and neither variable interpolation nor backquote expansion are performed in the arguments.

```
\t
```

Toggles the display of output column name headings and row count footer. This command is equivalent to `\pset tuples_only` and is provided for convenience.

```
\T table_options
```

Specifies attributes to be placed within the `table` tag in HTML output format. This command is equivalent to `\pset tableattr table_options`.

`\timing [on | off]`

With a parameter, turns displaying of how long each SQL statement takes on or off. Without a parameter, toggles the display between on and off. The display is in milliseconds; intervals longer than 1 second are also shown in minutes:seconds format, with hours and days fields added if needed.

`\unset name`

Unsets (deletes) the psql variable *name*.

Most variables that control psql's behavior cannot be unset; instead, an `\unset` command is interpreted as setting them to their default values. See [Variables](#) below.

`\w or \write filename`

`\w or \write |command`

Writes the current query buffer to the file *filename* or pipes it to the shell command *command*. If the current query buffer is empty, the most recently executed query is written instead.

If the argument begins with `|`, then the entire remainder of the line is taken to be the *command* to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.

`\warn text [...]`

This command is identical to `\echo` except that the output will be written to psql's standard error channel, rather than standard output.

`\watch [i[nterval]=seconds] [c[ount]=times] [m[in_rows]=rows] [seconds]`

Repeatedly execute the current query buffer (as `\g` does) until interrupted, or the query fails, or the execution count limit (if given) is reached, or the query no longer returns the minimum number of rows. Wait the specified number of seconds (default 2) between executions. For backwards compatibility, *seconds* can be specified with or without an *interval=* prefix. Each query result is displayed with a header that includes the `\pset title` string (if any), the time as of query start, and the delay interval.

If the current query buffer is empty, the most recently sent query is re-executed instead.

`\x [on | off | auto]`

Sets or toggles expanded table formatting mode. As such it is equivalent to `\pset expanded`.

`\z[S] [pattern]`

Lists tables, views and sequences with their associated access privileges. If a *pattern* is specified, only tables, views and sequences whose names match the pattern are listed. By default only user-created objects are shown; supply a pattern or the *S* modifier to include system objects.

This is an alias for `\dp` ("display privileges").

`\! [command]`

With no argument, escapes to a sub-shell; psql resumes when the sub-shell exits. With an argument, executes the shell command *command*.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\!`, and neither variable interpolation nor backquote expansion are performed in the arguments. The rest of the line is simply passed literally to the shell.

`\? [topic]`

Shows help information. The optional *topic* parameter (defaulting to *commands*) selects which part of psql is explained: *commands* describes psql's backslash commands; *options* describes the com-

mand-line options that can be passed to psql; and `variables` shows help about psql configuration variables.

`\;`

Backslash-semicolon is not a meta-command in the same way as the preceding commands; rather, it simply causes a semicolon to be added to the query buffer without any further processing.

Normally, psql will dispatch an SQL command to the server as soon as it reaches the command-ending semicolon, even if more input remains on the current line. Thus for example entering

```
select 1; select 2; select 3;
```

will result in the three SQL commands being individually sent to the server, with each one's results being displayed before continuing to the next command. However, a semicolon entered as `\;` will not trigger command processing, so that the command before it and the one after are effectively combined and sent to the server in one request. So for example

```
select 1\; select 2\; select 3;
```

results in sending the three SQL commands to the server in a single request, when the non-backslashed semicolon is reached. The server executes such a request as a single transaction, unless there are explicit `BEGIN/COMMIT` commands included in the string to divide it into multiple transactions. (See [Section 56.2.2.1](#) for more details about how the server handles multi-query strings.)

Patterns

The various `\d` commands accept a *pattern* parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, `\dt FOO` will display the table named `foo`. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, `\dt "FOO" "BAR"` will display the table named `FOO"BAR` (not `foo"bar`). Unlike the normal rules for SQL names, you can put double quotes around just part of a pattern, for instance `\dt FOO"FOO"BAR` will display the table named `fooFOObar`.

Whenever the *pattern* parameter is omitted completely, the `\d` commands display all objects that are visible in the current schema search path — this is equivalent to using `*` as the pattern. (An object is said to be *visible* if its containing schema is in the search path and no object of the same kind and name appears earlier in the search path. This is equivalent to the statement that the object can be referenced by name without explicit schema qualification.) To see all objects in the database regardless of visibility, use `*.*` as the pattern.

Within a pattern, `*` matches any sequence of characters (including no characters) and `?` matches any single character. (This notation is comparable to Unix shell file name patterns.) For example, `\dt int*` displays tables whose names begin with `int`. But within double quotes, `*` and `?` lose these special meanings and are just matched literally.

A relation pattern that contains a dot (`.`) is interpreted as a schema name pattern followed by an object name pattern. For example, `\dt foo*.*bar*` displays all tables whose table name includes `bar` that are in schemas whose schema name starts with `foo`. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally. A relation pattern that contains two dots (`..`) is interpreted as a database name followed by a schema name pattern followed by an object name pattern. The database name portion will not be treated as a pattern and must match the name of the currently connected database, else an error will be raised.

A schema pattern that contains a dot (`.`) is interpreted as a database name followed by a schema name pattern. For example, `\dn mydb.*foo*` displays all schemas whose schema name includes `foo`. The data-

base name portion will not be treated as a pattern and must match the name of the currently connected database, else an error will be raised.

Advanced users can use regular-expression notations such as character classes, for example `[0-9]` to match any digit. All regular expression special characters work as specified in [Section 9.7.3](#), except for `.` which is taken as a separator as mentioned above, `*` which is translated to the regular-expression notation `.*`, `?` which is translated to `.`, and `$` which is matched literally. You can emulate these pattern characters at need by writing `?` for `.`, `(R+|)` for `R*`, or `(R|)` for `R?`. `$` is not needed as a regular-expression character since the pattern must match the whole name, unlike the usual interpretation of regular expressions (in other words, `$` is automatically appended to your pattern). Write `*` at the beginning and/or end if you don't wish the pattern to be anchored. Note that within double quotes, all regular expression special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (i.e., the argument of `\do`).

Advanced Features

Variables

psql provides variable substitution features similar to common Unix command shells. Variables are simply name/value pairs, where the value can be any string of any length. The name must consist of letters (including non-Latin letters), digits, and underscores.

To set a variable, use the psql meta-command `\set`. For example,

```
testdb=> \set foo bar
```

sets the variable `foo` to the value `bar`. To retrieve the content of the variable, precede the name with a colon, for example:

```
testdb=> \echo :foo
bar
```

This works in both regular SQL commands and meta-commands; there is more detail in [SQL Interpolation](#), below.

If you call `\set` without a second argument, the variable is set to an empty-string value. To unset (i.e., delete) a variable, use the command `\unset`. To show the values of all variables, call `\set` without any argument.

Note

The arguments of `\set` are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as `\set :foo 'something'` and get “soft links” or “variable variables” of Perl or PHP fame, respectively. Unfortunately (or fortunately?), there is no way to do anything useful with these constructs. On the other hand, `\set bar :foo` is a perfectly valid way to copy a variable.

A number of these variables are treated specially by psql. They represent certain option settings that can be changed at run time by altering the value of the variable, or in some cases represent changeable state of psql. By convention, all specially treated variables' names consist of all upper-case ASCII letters (and possibly digits and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

Variables that control psql's behavior generally cannot be unset or set to invalid values. An `\unset` command is allowed but is interpreted as setting the variable to its default value. A `\set` command without a second argument is interpreted as setting the variable to `on`, for control variables that accept that value, and is rejected for others. Also, control variables that accept the values `on` and `off` will also accept other common spellings of Boolean values, such as `true` and `false`.

The specially treated variables are:

AUTOCOMMIT

When `on` (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a `BEGIN` or `START TRANSACTION` SQL command. When `off` or `unset`, SQL commands are not committed until you explicitly issue `COMMIT` or `END`. The autocommit-off mode works by issuing an implicit `BEGIN` for you, just before any command that is not already in a transaction block and is not itself a `BEGIN` or other transaction-control command, nor a command that cannot be executed inside a transaction block (such as `VACUUM`).

Note

In autocommit-off mode, you must explicitly abandon any failed transaction by entering `ABORT` or `ROLLBACK`. Also keep in mind that if you exit the session without committing, your work will be lost.

Note

The autocommit-on mode is Postgres Pro's traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you might wish to set it in the system-wide `psqlrc` file or your `~/.psqlrc` file.

COMP_KEYWORD_CASE

Determines which letter case to use when completing an SQL key word. If set to `lower` or `upper`, the completed word will be in lower or upper case, respectively. If set to `preserve-lower` or `preserve-upper` (the default), the completed word will be in the case of the word already entered, but words being completed without anything entered will be in lower or upper case, respectively.

DBNAME

The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be changed or unset.

ECHO

If set to `all`, all nonempty input lines are printed to standard output as they are read. (This does not apply to lines read interactively.) To select this behavior on program start-up, use the switch `-a`. If set to `queries`, `psql` prints each query to standard output as it is sent to the server. The switch to select this behavior is `-e`. If set to `errors`, then only failed queries are displayed on standard error output. The switch for this behavior is `-b`. If set to `none` (the default), then no queries are displayed.

ECHO_HIDDEN

When this variable is set to `on` and a backslash command queries the database, the query is first shown. This feature helps you to study Postgres Pro internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch `-E`.) If you set this variable to the value `noexec`, the queries are just shown but are not actually sent to the server and executed. The default value is `off`.

ENCODING

The current client character set encoding. This is set every time you connect to a database (including program start-up), and when you change the encoding with `\encoding`, but it can be changed or unset.

ERROR

`true` if the last SQL query failed, `false` if it succeeded. See also `SQLSTATE`.

FETCH_COUNT

If this variable is set to an integer value greater than zero, the results of `SELECT` queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query might fail after having already displayed some rows.

Tip

Although you can use any output format with this feature, the default `aligned` format tends to look bad because each group of `FETCH_COUNT` rows will be formatted separately, leading to varying column widths across the row groups. The other output formats work better.

HIDE_TABLEAM

If this variable is set to `true`, a table's access method details are not displayed. This is mainly useful for regression tests.

HIDE_TOAST_COMPRESSION

If this variable is set to `true`, column compression method details are not displayed. This is mainly useful for regression tests.

HISTCONTROL

If this variable is set to `ignoreSpace`, lines which begin with a space are not entered into the history list. If set to a value of `ignoreDups`, lines matching the previous history line are not entered. A value of `ignoreBoth` combines the two options. If set to `none` (the default), all lines read in interactive mode are saved on the history list.

Note

This feature was shamelessly plagiarized from Bash.

HISTFILE

The file name that will be used to store the history list. If unset, the file name is taken from the `PSQL_HISTORY` environment variable. If that is not set either, the default is `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows. For example, putting:

```
\set HISTFILE ~/.psql_history-:DBNAME
```

in `~/.psqlrc` will cause `psql` to maintain a separate history for each database.

Note

This feature was shamelessly plagiarized from Bash.

HISTSIZE

The maximum number of commands to store in the command history (default 500). If set to a negative value, no limit is applied.

Note

This feature was shamelessly plagiarized from Bash.

HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be changed or unset.

IGNOREEOF

If set to 1 or less, sending an EOF character (usually **Control+D**) to an interactive session of psql will terminate the application. If set to a larger numeric value, that many consecutive EOF characters must be typed to make an interactive session terminate. If the variable is set to a non-numeric value, it is interpreted as 10. The default is 0.

Note

This feature was shamelessly plagiarized from Bash.

LASTOID

The value of the last affected OID, as returned from an `INSERT` or `\lo_import` command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed. Postgres Pro servers since version 12 do not support OID system columns anymore, thus `LASTOID` will always be 0 following `INSERT` when targeting such servers.

LAST_ERROR_MESSAGE**LAST_ERROR_SQLSTATE**

The primary error message and associated `SQLSTATE` code for the most recent failed query in the current psql session, or an empty string and 00000 if no error has occurred in the current session.

ON_ERROR_ROLLBACK

When set to `on`, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When set to `interactive`, such errors are only ignored in interactive sessions, and not when reading script files. When set to `off` (the default), a statement in a transaction block that generates an error aborts the entire transaction. The error rollback mode works by issuing an implicit `SAVEPOINT` for you, just before each command that is in a transaction block, and then rolling back to the savepoint if the command fails.

ON_ERROR_STOP

By default, command processing continues after an error. When this variable is set to `on`, processing will instead stop immediately. In interactive mode, psql will return to the command prompt; otherwise, psql will exit, returning error code 3 to distinguish this case from fatal error conditions, which are reported using error code 1. In either case, any currently running scripts (the top-level script, if any, and any other scripts which it may have in invoked) will be terminated immediately. If the top-level command string contained multiple SQL commands, processing will stop with the current command.

PORT

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be changed or unset.

PROMPT1**PROMPT2****PROMPT3**

These specify what the prompts psql issues should look like. See [Prompting](#) below.

QUIET

Setting this variable to `on` is equivalent to the command line option `-q`. It is probably not too useful in interactive mode.

ROW_COUNT

The number of rows returned or affected by the last SQL query, or 0 if the query failed or did not report a row count.

SERVER_VERSION_NAME**SERVER_VERSION_NUM**

The server's version number as a string, for example 9.6.2, 10.1 or 11beta1, and in numeric form, for example 90602 or 100001. These are set every time you connect to a database (including program start-up), but can be changed or unset.

SHELL_ERROR

true if the last shell command failed, false if it succeeded. This applies to shell commands invoked via the \!, \g, \o, \w, and \copy meta-commands, as well as backquote (`) expansion. Note that for \o, this variable is updated when the output pipe is closed by the next \o command. See also SHELL_EXIT_CODE.

SHELL_EXIT_CODE

The exit status returned by the last shell command. 0-127 represent program exit codes, 128-255 indicate termination by a signal, and -1 indicates failure to launch a program or to collect its exit status. This applies to shell commands invoked via the \!, \g, \o, \w, and \copy meta-commands, as well as backquote (`) expansion. Note that for \o, this variable is updated when the output pipe is closed by the next \o command. See also SHELL_ERROR.

SHOW_ALL_RESULTS

When this variable is set to off, only the last result of a combined query (\;) is shown instead of all of them. The default is on. The off behavior is for compatibility with older versions of psql.

SHOW_CONTEXT

This variable can be set to the values never, errors, or always to control whether CONTEXT fields are displayed in messages from the server. The default is errors (meaning that context will be shown in error messages, but not in notice or warning messages). This setting has no effect when VERBOSITY is set to terse or sqlstate. (See also \errverbose, for use when you want a verbose version of the error you just got.)

SINGLELINE

Setting this variable to on is equivalent to the command line option -S.

SINGLESTEP

Setting this variable to on is equivalent to the command line option -s.

SQLSTATE

The error code (see [Appendix A](#)) associated with the last SQL query's failure, or 00000 if it succeeded.

USER

The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be changed or unset.

VERBOSITY

This variable can be set to the values default, verbose, terse, or sqlstate to control the verbosity of error reports. (See also \errverbose, for use when you want a verbose version of the error you just got.)

```
VERSION
VERSION_NAME
VERSION_NUM
```

These variables are set at program start-up to reflect psql's version, respectively as a verbose string, a short string (e.g., 9.6.2, 10.1, or 11beta1), and a number (e.g., 90602 or 100001). They can be changed or unset.

SQL Interpolation

A key feature of psql variables is that you can substitute (“interpolate”) them into regular SQL statements, as well as the arguments of meta-commands. Furthermore, psql provides facilities for ensuring that variable values used as SQL literals and identifiers are properly quoted. The syntax for interpolating a value without any quoting is to prepend the variable name with a colon (:). For example,

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :foo;
```

would query the table `my_table`. Note that this may be unsafe: the value of the variable is copied literally, so it can contain unbalanced quotes, or even backslash commands. You must make sure that it makes sense where you put it.

When a value is to be used as an SQL literal or identifier, it is safest to arrange for it to be quoted. To quote the value of a variable as an SQL literal, write a colon followed by the variable name in single quotes. To quote the value as an SQL identifier, write a colon followed by the variable name in double quotes. These constructs deal correctly with quotes and other special characters embedded within the variable value. The previous example would be more safely written this way:

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :"foo";
```

Variable interpolation will not be performed within quoted SQL literals and identifiers. Therefore, a construction such as `':foo'` doesn't work to produce a quoted literal from a variable's value (and it would be unsafe if it did work, since it wouldn't correctly handle quotes embedded in the value).

One example use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then interpolate the variable's value as a quoted string:

```
testdb=> \set content `cat my_file.txt`
testdb=> INSERT INTO my_table VALUES (: 'content');
```

(Note that this still won't work if `my_file.txt` contains NUL bytes. psql does not support embedded NUL bytes in variable values.)

Since colons can legally appear in SQL commands, an apparent attempt at interpolation (that is, `:name`, `:'name'`, or `:"name"`) is not replaced unless the named variable is currently set. In any case, you can escape a colon with a backslash to protect it from substitution.

The `: {?name}` special syntax returns TRUE or FALSE depending on whether the variable exists or not, and is thus always substituted, unless the colon is backslash-escaped.

The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntaxes for array slices and type casts are Postgres Pro extensions, which can sometimes conflict with the standard usage. The colon-quote syntax for escaping a variable's value as an SQL literal or identifier is a psql extension.

Prompting

The prompts psql issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when psql requests a new command. Prompt 2 is issued when more input is expected during command entry, for example because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you are running an SQL `COPY FROM STDIN` command and you need to type in a row value on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

%M

The full host name (with domain name) of the database server, or [local] if the connection is over a Unix domain socket, or [local:/dir/name], if the Unix domain socket is not at the compiled in default location.

%m

The host name of the database server, truncated at the first dot, or [local] if the connection is over a Unix domain socket.

%>

The port number at which the database server is listening.

%n

The database session user name. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)

%/

The name of the current database.

%~

Like %/, but the output is ~ (tilde) if the database is your default database.

%#

If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)

%p

The process ID of the backend currently connected to.

%R

In prompt 1 normally =, but @ if the session is in an inactive branch of a conditional block, or ^ if in single-line mode, or ! if the session is disconnected from the database (which can happen if `\connect` fails). In prompt 2 %R is replaced by a character that depends on why psql expects more input: - if the command simply wasn't terminated yet, but * if there is an unfinished `/* ... */` comment, a single quote if there is an unfinished quoted string, a double quote if there is an unfinished quoted identifier, a dollar sign if there is an unfinished dollar-quoted string, or (if there is an unmatched left parenthesis. In prompt 3 %R doesn't produce anything.

%x

Transaction status: an empty string when not in a transaction block, or * when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).

%l

The line number inside the current statement, starting from 1.

%*digits*

The character with the indicated octal code is substituted.

`%:name:`

The value of the psql variable *name*. See [Variables](#), above, for details.

`%`command``

The output of *command*, similar to ordinary “back-tick” substitution.

`%[... %]`

Prompts can contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with `%[` and `%)`. Multiple pairs of these can occur within the prompt. For example:

```
testdb=> \set PROMPT1 '%[%033[1;33;40m%]n@%/%R%[%033[0m%]## '
```

results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals.

`%w`

Whitespace of the same width as the most recent output of `PROMPT1`. This can be used as a `PROMPT2` setting, so that multi-line statements are aligned with the first line, but there is no visible secondary prompt.

To insert a percent sign into your prompt, write `%%`. The default prompts are `'%/%R%x%# '` for prompts 1 and 2, and `'>> '` for prompt 3.

Note

This feature was shamelessly plagiarized from `tcsh`.

Command-Line Editing

psql uses the Readline or libedit library, if available, for convenient line editing and retrieval. The command history is automatically saved when psql exits and is reloaded when psql starts up. Type up-arrow or control-P to retrieve previous lines.

You can also use tab completion to fill in partially-typed keywords and SQL object names in many (by no means all) contexts. For example, at the start of a command, typing `ins` and pressing TAB will fill in `insert into`. Then, typing a few characters of a table or schema name and pressing TAB will fill in the unfinished name, or offer a menu of possible completions when there's more than one. (Depending on the library in use, you may need to press TAB more than once to get a menu.)

Tab completion for SQL object names requires sending queries to the server to find possible matches. In some contexts this can interfere with other operations. For example, after `BEGIN` it will be too late to issue `SET TRANSACTION ISOLATION LEVEL` if a tab-completion query is issued in between. If you do not want tab completion at all, you can turn it off permanently by putting this in a file named `.inputrc` in your home directory:

```
$if psql
set disable-completion on
$endif
```

(This is not a psql but a Readline feature. Read its documentation for further details.)

The `-n` (`--no-readline`) command line option can also be useful to disable use of Readline for a single run of psql. This prevents tab completion, use or recording of command line history, and editing of multi-line commands. It is particularly useful when you need to copy-and-paste text that contains TAB characters.

Environment

COLUMNS

If `\pset columns` is zero, controls the width for the `wrapped` format and width for determining if wide output requires the pager or should be switched to the vertical format in expanded auto mode.

PGDATABASE

PGHOST

PGPORT

PGUSER

Default connection parameters (see [Section 35.15](#)).

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

PSQL_EDITOR

EDITOR

VISUAL

Editor used by the `\e`, `\ef`, and `\ev` commands. These variables are examined in the order listed; the first that is set is used. If none of them is set, the default is to use `vi` on Unix systems or `notepad.exe` on Windows systems.

PSQL_EDITOR_LINENUMBER_ARG

When `\e`, `\ef`, or `\ev` is used with a line number argument, this variable specifies the command-line argument used to pass the starting line number to the user's editor. For editors such as Emacs or `vi`, this is a plus sign. Include a trailing space in the value of the variable if there needs to be space between the option name and the line number. Examples:

```
PSQL_EDITOR_LINENUMBER_ARG='+'
```

```
PSQL_EDITOR_LINENUMBER_ARG='--line '
```

The default is `+` on Unix systems (corresponding to the default editor `vi`, and useful for many other common editors); but there is no default on Windows systems.

PSQL_HISTORY

Alternative location for the command history file. Tilde (`~`) expansion is performed.

PSQL_PAGER

PAGER

If a query's results do not fit on the screen, they are piped through this command. Typical values are `more` or `less`. Use of the pager can be disabled by setting `PSQL_PAGER` or `PAGER` to an empty string, or by adjusting the pager-related options of the `\pset` command. These variables are examined in the order listed; the first that is set is used. If neither of them is set, the default is to use `more` on most platforms, but `less` on Cygwin.

PSQL_WATCH_PAGER

When a query is executed repeatedly with the `\watch` command, a pager is not used by default. This behavior can be changed by setting `PSQL_WATCH_PAGER` to a pager command, on Unix systems. The `pspg` pager (not part of PostgreSQL but available in many open source software distributions) can display the output of `\watch` if started with the option `--stream`.

PSQLRC

Alternative location of the user's `.psqlrc` file. Tilde (`~`) expansion is performed.

SHELL

Command executed by the `\!` command.

TMPDIR

Directory for storing temporary files. The default is `/tmp`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 35.15](#)).

Files

psqlrc and `~/.psqlrc`

Unless it is passed an `-x` option, `psql` attempts to read and execute commands from the system-wide startup file (`psqlrc`) and then the user's personal startup file (`~/.psqlrc`), after connecting to the database but before accepting normal commands. These files can be used to set up the client and/or the server to taste, typically with `\set` and `SET` commands.

The system-wide startup file is named `psqlrc`. By default it is sought in the installation's "system configuration" directory, which is most reliably identified by running `pg_config --sysconfdir`. Typically this directory will be `./etc/` relative to the directory containing the Postgres Pro executables. The directory to look in can be set explicitly via the `PGSYSCONFDIR` environment variable.

The user's personal startup file is named `.psqlrc` and is sought in the invoking user's home directory. On Windows the personal startup file is instead named `%APPDATA%\postgresql\psqlrc.conf`. In either case, this default file path can be overridden by setting the `PSQLRC` environment variable.

Both the system-wide startup file and the user's personal startup file can be made `psql`-version-specific by appending a dash and the Postgres Pro major or minor release identifier to the file name, for example `~/.psqlrc-17` or `~/.psqlrc-17.5.1`. The most specific version-matching file will be read in preference to a non-version-specific file. These version suffixes are added after determining the file path as explained above.

`.psql_history`

The command-line history is stored in the file `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows.

The location of the history file can be set explicitly via the `HISTFILE` `psql` variable or the `PSQL_HISTORY` environment variable.

Notes

- `psql` works best with servers of the same or an older major version. Backslash commands are particularly likely to fail if the server is of a newer version than `psql` itself. However, backslash commands of the `\d` family should work with servers of versions back to 9.2, though not necessarily with servers newer than `psql` itself. The general functionality of running SQL commands and displaying query results should also work with servers of a newer major version, but this cannot be guaranteed in all cases.

If you want to use `psql` to connect to several servers of different major versions, it is recommended that you use the newest version of `psql`. Alternatively, you can keep around a copy of `psql` from each major version and be sure to use the version that matches the respective server. But in practice, this additional complication should not be necessary.

- Before Postgres Pro 9.6, the `-c` option implied `-x` (`--no-psqlrc`); this is no longer the case.
- Before PostgreSQL 8.4, `psql` allowed the first argument of a single-letter backslash command to start directly after the command, without intervening whitespace. Now, some whitespace is required.

Notes for Windows Users

psql is built as a “console application”. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within psql. If psql detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

- Set the code page by entering `cmd.exe /c chcp 1252`. (1252 is a code page that is appropriate for German; replace it with your value.) If you are using Cygwin, you can put this command in `/etc/profile`.
- Set the console font to `Lucida Console`, because the raster font does not work with the ANSI code page.

By default, psql works in the UTF-8 encoding and uses Windows Unicode API for console output. The console code page must be set to 65001 to ensure the correct display of all characters supported by your Windows console font.

Postgres Pro Windows installer ships the `less.exe` pager with UTF-8 support and provides a shortcut that opens the console window with `Lucida Console` font and `codepage 65001` settings. If you use a different pager, make sure it also supports UTF-8.

You can override the default psql encoding by setting the `PGCLIENTENCODING` environment variable.

Examples

The first example shows how to spread a command over several lines of input. Notice the changing prompt:

```
testdb=> CREATE TABLE my_table (  
testdb(>   first integer not null default 0,  
testdb(>   second text)  
testdb-> ;  
CREATE TABLE
```

Now look at the table definition again:

```
testdb=> \d my_table  
          Table "public.my_table"  
Column | Type   | Collation | Nullable | Default  
-----+-----+-----+-----+-----  
first  | integer |           | not null | 0  
second | text    |           |          |
```

Now we change the prompt to something more interesting:

```
testdb=> \set PROMPT1 '%n%m %~%R%# '  
peter@localhost testdb=>
```

Let's assume you have filled the table with data and want to take a look at it:

```
peter@localhost testdb=> SELECT * FROM my_table;  
 first | second  
-----+-----  
    1  | one  
    2  | two  
    3  | three  
    4  | four  
(4 rows)
```

You can display tables in different ways by using the `\pset` command:

```
peter@localhost testdb=> \pset border 2  
Border style is 2.
```

```
peter@localhost testdb=> SELECT * FROM my_table;
```

```
+-----+-----+
| first | second |
+-----+-----+
|      1 | one     |
|      2 | two     |
|      3 | three   |
|      4 | four    |
+-----+-----+
(4 rows)
```

```
peter@localhost testdb=> \pset border 0
```

```
Border style is 0.
```

```
peter@localhost testdb=> SELECT * FROM my_table;
```

```
first second
-----
1 one
2 two
3 three
4 four
(4 rows)
```

```
peter@localhost testdb=> \pset border 1
```

```
Border style is 1.
```

```
peter@localhost testdb=> \pset format csv
```

```
Output format is csv.
```

```
peter@localhost testdb=> \pset tuples_only
```

```
Tuples only is on.
```

```
peter@localhost testdb=> SELECT second, first FROM my_table;
```

```
one,1
two,2
three,3
four,4
```

```
peter@localhost testdb=> \pset format unaligned
```

```
Output format is unaligned.
```

```
peter@localhost testdb=> \pset fieldsep '\t'
```

```
Field separator is "\t".
```

```
peter@localhost testdb=> SELECT second, first FROM my_table;
```

```
one      1
two      2
three    3
four     4
```

Alternatively, use the short commands:

```
peter@localhost testdb=> \a \t \x
```

```
Output format is aligned.
```

```
Tuples only is off.
```

```
Expanded display is on.
```

```
peter@localhost testdb=> SELECT * FROM my_table;
```

```
-[ RECORD 1 ]-
first  | 1
second | one
-[ RECORD 2 ]-
first  | 2
second | two
-[ RECORD 3 ]-
first  | 3
second | three
```

```
-[ RECORD 4 ]-
first  | 4
second | four
```

Also, these output format options can be set for just one query by using `\g`:

```
peter@localhost testdb=> SELECT * FROM my_table
peter@localhost testdb-> \g (format=aligned tuples_only=off expanded=on)
-[ RECORD 1 ]-
first  | 1
second | one
-[ RECORD 2 ]-
first  | 2
second | two
-[ RECORD 3 ]-
first  | 3
second | three
-[ RECORD 4 ]-
first  | 4
second | four
```

Here is an example of using the `\df` command to find only functions with names matching `int*pl` and whose second argument is of type `bigint`:

```
testdb=> \df int*pl * bigint
                                List of functions
 Schema | Name      | Result data type | Argument data types | Type
-----+-----+-----+-----+-----
pg_catalog | int28pl | bigint          | smallint, bigint   | func
pg_catalog | int48pl | bigint          | integer, bigint    | func
pg_catalog | int8pl  | bigint          | bigint, bigint     | func
(3 rows)
```

When suitable, query results can be shown in a crosstab representation with the `\crosstabview` command:

```
testdb=> SELECT first, second, first > 2 AS gt2 FROM my_table;
 first | second | gt2
-----+-----+-----
      1 | one    | f
      2 | two    | f
      3 | three  | t
      4 | four   | t
(4 rows)
```

```
testdb=> \crosstabview first second
 first | one | two | three | four
-----+-----+-----+-----+-----
      1 | f   |     |       |
      2 |     | f   |       |
      3 |     |     | t     |
      4 |     |     |       | t
(4 rows)
```

This second example shows a multiplication table with rows sorted in reverse numerical order and columns with an independent, ascending numerical order.

```
testdb=> SELECT t1.first as "A", t2.first+100 AS "B", t1.first*(t2.first+100) as "AxB",
testdb-> row_number() over(order by t2.first) AS ord
testdb-> FROM my_table t1 CROSS JOIN my_table t2 ORDER BY 1 DESC
testdb-> \crosstabview "A" "B" "AxB" ord
```

A	101	102	103	104
4	404	408	412	416
3	303	306	309	312
2	202	204	206	208
1	101	102	103	104

(4 rows)

reindexdb

reindexdb — reindex a Postgres Pro database

Synopsis

```
reindexdb [connection-option...] [option...] [ -S | --schema schema ] ... [ -t | --table table ] ... [ -i  
| --index index ] ... [ -s | --system ] [ dbname | -a | --all ]
```

Description

reindexdb is a utility for rebuilding indexes in a Postgres Pro database.

reindexdb is a wrapper around the SQL command [REINDEX](#). There is no effective difference between reindexing databases via this utility and via other methods for accessing the server.

Options

reindexdb accepts the following command-line arguments:

-a
--all

Reindex all databases.

--concurrently

Use the `CONCURRENTLY` option. See [REINDEX](#), where all the caveats of this option are explained in detail.

[-d] *dbname*
[--dbname=] *dbname*

Specifies the name of the database to be reindexed, when `-a/--all` is not used. If this is not specified, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

-e
--echo

Echo the commands that reindexdb generates and sends to the server.

-i *index*
--index=*index*

Recreate *index* only. Multiple indexes can be recreated by writing multiple `-i` switches.

-j *njobs*
--jobs=*njobs*

Execute the reindex commands in parallel by running *njobs* commands simultaneously. This option may reduce the processing time but it also increases the load on the database server.

reindexdb will open *njobs* connections to the database, so make sure your [max_connections](#) setting is high enough to accommodate all connections.

Note that this option is incompatible with the `--system` option.

-q
--quiet

Do not display progress messages.

`-s`
`--system`

Reindex database's system catalogs only.

`-S schema`
`--schema=schema`

Reindex *schema* only. Multiple schemas can be reindexed by writing multiple `-S` switches.

`-t table`
`--table=table`

Reindex *table* only. Multiple tables can be reindexed by writing multiple `-t` switches.

`--tablespace=tablespace`

Specifies the tablespace where indexes are rebuilt. (This name is processed as a double-quoted identifier.)

`-v`
`--verbose`

Print detailed information during processing.

`-V`
`--version`

Print the reindexdb version and exit.

`-?`
`--help`

Show help about reindexdb command line arguments, and exit.

reindexdb also accepts the following command-line arguments for connection parameters:

`-h host`
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`
`--username=username`

User name to connect as.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force reindexdb to prompt for a password before connecting to a database.

This option is never essential, since `reindexdb` will automatically prompt for a password if the server demands password authentication. However, `reindexdb` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--maintenance-db=dbname`

When the `-a/--all` is used, connect to this database to gather the list of databases to reindex. If not specified, the `postgres` database will be used, or if that does not exist, `template1` will be used. This can be a [connection string](#). If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

Environment

PGDATABASE
PGHOST
PGPORT
PGUSER

Default connection parameters

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 35.15](#)).

Diagnostics

In case of difficulty, see [REINDEX](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Examples

To reindex the database `test`:

```
$ reindexdb test
```

To reindex the table `foo` and the index `bar` in a database named `abcd`:

```
$ reindexdb --table=foo --index=bar abcd
```

[REINDEX](#)

vacuumdb

vacuumdb — garbage-collect and analyze a Postgres Pro database

Synopsis

```
vacuumdb [connection-option...] [option...] [ -t | --table table [( column [,...] )] ] ... [ dbname | -a | --all ]
```

```
vacuumdb [connection-option...] [option...] [ -n | --schema schema ] ... [ dbname | -a | --all ]
```

```
vacuumdb [connection-option...] [option...] [ -N | --exclude-schema schema ] ... [ dbname | -a | --all ]
```

Description

vacuumdb is a utility for cleaning a Postgres Pro database. vacuumdb will also generate internal statistics used by the Postgres Pro query optimizer.

vacuumdb is a wrapper around the SQL command [VACUUM](#). There is no effective difference between vacuuming and analyzing databases via this utility and via other methods for accessing the server.

Options

vacuumdb accepts the following command-line arguments:

-a
--all

Vacuum all databases.

--buffer-usage-limit *size*

Specifies the [Buffer Access Strategy](#) ring buffer size for a given invocation of vacuumdb. This size is used to calculate the number of shared buffers which will be reused as part of this strategy. See [VACUUM](#).

[-d] *dbname*
[--dbname=] *dbname*

Specifies the name of the database to be cleaned or analyzed, when -a/--all is not used. If this is not specified, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

--disable-page-skipping

Disable skipping pages based on the contents of the visibility map.

-e
--echo

Echo the commands that vacuumdb generates and sends to the server.

-f
--full

Perform “full” vacuuming.

-F
--freeze

Aggressively “freeze” tuples.

`--force-index-cleanup`

Always remove index entries pointing to dead tuples.

`-j njobs`

`--jobs=njobs`

Execute the vacuum or analyze commands in parallel by running *njobs* commands simultaneously. This option may reduce the processing time but it also increases the load on the database server.

`vacuumdb` will open *njobs* connections to the database, so make sure your [max_connections](#) setting is high enough to accommodate all connections.

Note that using this mode together with the `-f` (FULL) option might cause deadlock failures if certain system catalogs are processed in parallel.

`--min-mxid-age mxid_age`

Only execute the vacuum or analyze commands on tables with a multixact ID age of at least *mxid_age*. This setting is useful for prioritizing tables to process to prevent multixact ID wraparound (see [Section 24.1.5.1](#)).

For the purposes of this option, the multixact ID age of a relation is the greatest of the ages of the main relation and its associated TOAST table, if one exists. Since the commands issued by `vacuumdb` will also process the TOAST table for the relation if necessary, it does not need to be considered separately.

`--min-xid-age xid_age`

Only execute the vacuum or analyze commands on tables with a transaction ID age of at least *xid_age*. This setting is useful for prioritizing tables to process to prevent transaction ID wraparound (see [Section 24.1.5](#)).

For the purposes of this option, the transaction ID age of a relation is the greatest of the ages of the main relation and its associated TOAST table, if one exists. Since the commands issued by `vacuumdb` will also process the TOAST table for the relation if necessary, it does not need to be considered separately.

`-n schema`

`--schema=schema`

Clean or analyze all tables in *schema* only. Multiple schemas can be vacuumed by writing multiple `-n` switches.

`-N schema`

`--exclude-schema=schema`

Do not clean or analyze any tables in *schema*. Multiple schemas can be excluded by writing multiple `-N` switches.

`--no-index-cleanup`

Do not remove index entries pointing to dead tuples.

`--no-process-main`

Skip the main relation.

`--no-process-toast`

Skip the TOAST table associated with the table to vacuum, if any.

`--no-truncate`

Do not truncate empty pages at the end of the table.

`-P parallel_workers`
`--parallel=parallel_workers`

Specify the number of parallel workers for *parallel vacuum*. This allows the vacuum to leverage multiple CPUs to process indexes. See [VACUUM](#).

`-q`
`--quiet`

Do not display progress messages.

`--skip-locked`

Skip relations that cannot be immediately locked for processing.

`-t table [(column [,...])]`
`--table=table [(column [,...])]`

Clean or analyze *table* only. Column names can be specified only in conjunction with the `--analyze` or `--analyze-only` options. Multiple tables can be vacuumed by writing multiple `-t` switches.

Tip

If you specify columns, you probably have to escape the parentheses from the shell. (See examples below.)

`-v`
`--verbose`

Print detailed information during processing.

`-V`
`--version`

Print the vacuumdb version and exit.

`-z`
`--analyze`

Also calculate statistics for use by the optimizer.

`-Z`
`--analyze-only`

Only calculate statistics for use by the optimizer (no vacuum).

`--analyze-in-stages`

Only calculate statistics for use by the optimizer (no vacuum), like `--analyze-only`. Run three stages of analyze; the first stage uses the lowest possible statistics target (see [default_statistics_target](#)) to produce usable statistics faster, and subsequent stages build the full statistics.

This option is only useful to analyze a database that currently has no statistics or has wholly incorrect ones, such as if it is newly populated from a restored dump or by `pg_upgrade`. Be aware that running with this option in a database with existing statistics may cause the query optimizer choices to become transiently worse due to the low statistics targets of the early stages.

`-?`
`--help`

Show help about vacuumdb command line arguments, and exit.

vacuumdb also accepts the following command-line arguments for connection parameters:

`-h host`
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`
`--username=username`

User name to connect as.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force vacuumdb to prompt for a password before connecting to a database.

This option is never essential, since vacuumdb will automatically prompt for a password if the server demands password authentication. However, vacuumdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

`--maintenance-db=dbname`

When the `-a/--all` is used, connect to this database to gather the list of databases to vacuum. If not specified, the `postgres` database will be used, or if that does not exist, `template1` will be used. This can be a [connection string](#). If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

Environment

PGDATABASE
PGHOST
PGPORT
PGUSER

Default connection parameters

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 35.15](#)).

Diagnostics

In case of difficulty, see [VACUUM](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Examples

To clean the database `test`:

```
$ vacuumdb test
```

To clean and analyze for the optimizer a database named `bigdb`:

```
$ vacuumdb --analyze bigdb
```

To clean a single table `foo` in a database named `xyzyy`, and analyze a single column `bar` of the table for the optimizer:

```
$ vacuumdb --analyze --verbose --table='foo(bar)' xyzyy
```

To clean all tables in the `foo` and `bar` schemas in a database named `xyzyy`:

```
$ vacuumdb --schema='foo' --schema='bar' xyzyy
```

Postgres Pro Server Applications

This part contains reference information for Postgres Pro server applications and support utilities. These commands can only be run usefully on the host where the database server resides. Other utility programs are listed in [Postgres Pro Client Applications](#).

initdb

initdb — create a new Postgres Pro database cluster

Synopsis

```
initdb [option...] [ --pgdata | -D ] directory
```

Description

initdb creates a new Postgres Pro *database cluster*.

Creating a database cluster consists of creating the *directories* in which the cluster data will live, generating the shared catalog tables (tables that belong to the whole cluster rather than to any particular database), and creating the `postgres`, `template1`, and `template0` databases. The `postgres` database is a default database meant for use by users, utilities and third party applications. `template1` and `template0` are meant as source databases to be copied by later `CREATE DATABASE` commands. `template0` should never be modified, but you can add objects to `template1`, which by default will be copied into databases created later. See [Section 22.4](#) for more details.

Although `initdb` will attempt to create the specified data directory, it might not have permission if the parent directory of the desired data directory is root-owned. To initialize in such a setup, create an empty data directory as root, then use `chown` to assign ownership of that directory to the database user account, then `su` to become the database user to run `initdb`.

`initdb` must be run as the user that will own the server process, because the server needs to have access to the files and directories that `initdb` creates. Since the server cannot be run as root, you must not run `initdb` as root either. (It will in fact refuse to do so.)

For security reasons the new cluster created by `initdb` will only be accessible by the cluster owner by default. The `--allow-group-access` option allows any user in the same group as the cluster owner to read files in the cluster. This is useful for performing backups as a non-privileged user.

`initdb` initializes the database cluster's default locale and character set encoding. These can also be set separately for each database when it is created. `initdb` determines those settings for the template databases, which will serve as the default for all other databases.

By default, `initdb` takes the locale settings from the environment, and determines the encoding from the locale settings. If the locale provider is not specified, it is set automatically based on the `lc_collate` value for the cluster: `libc` is used for the C or POSIX locales, and `icu` is used for other locales.

To choose a different locale for the cluster, use the option `--locale`. There are also individual options `--lc-*` and `--icu-locale` (see below) to set values for the individual locale categories. Note that inconsistent settings for different locale categories can give nonsensical results, so this should be used with care.

Alternatively, `initdb` can use the ICU library to provide locale services by specifying `--locale-provider=icu`. The server must be built with ICU support. To choose the specific ICU locale ID to apply, use the option `--icu-locale`. Note that for implementation reasons and to support legacy code, `initdb` will still select and initialize `libc` locale settings when the ICU locale provider is used.

When `initdb` runs, it will print out the locale settings it has chosen. If you have complex requirements or specified multiple options, it is advisable to check that the result matches what was intended.

More details about locale settings can be found in [Section 23.1](#).

To alter the default encoding, use the `--encoding`. More details can be found in [Section 23.3](#).

Options

`-A authmethod`

`--auth=authmethod`

This option specifies the default authentication method for local users used in `pg_hba.conf` (host and local lines). See [Section 20.1](#) for an overview of valid values.

`initdb` will prepopulate `pg_hba.conf` entries using the specified authentication method for non-replication as well as replication connections.

Do not use `trust` unless you trust all local users on your system. `trust` is the default for ease of installation.

`--auth-host=authmethod`

This option specifies the authentication method for local users via TCP/IP connections used in `pg_hba.conf` (host lines).

`--auth-local=authmethod`

This option specifies the authentication method for local users via Unix-domain socket connections used in `pg_hba.conf` (local lines).

`-D directory`

`--pgdata=directory`

This option specifies the directory where the database cluster should be stored. This is the only information required by `initdb`, but you can avoid writing it by setting the `PGDATA` environment variable, which can be convenient since the database server (`postgres`) can find the data directory later by the same variable.

`-E encoding`

`--encoding=encoding`

Selects the encoding of the template databases. This will also be the default encoding of any database you create later, unless you override it then. The character sets supported by the Postgres Pro server are described in [Section 23.3.1](#).

By default, the template database encoding is derived from the locale. If `--no-locale` is specified (or equivalently, if the locale is `C` or `POSIX`), then the default is `UTF8` for the ICU provider and `SQL_ASCII` for the `libc` provider.

`-g`

`--allow-group-access`

Allows users in the same group as the cluster owner to read all cluster files created by `initdb`. This option is ignored on Windows as it does not support POSIX-style group permissions.

`--icu-locale=locale`

Specifies the ICU locale when the ICU provider is used. Locale support is described in [Section 23.1](#).

`--icu-rules=rules`

Specifies additional collation rules to customize the behavior of the default collation. This is supported for ICU only.

`-k`

`--data-checksums`

Use checksums on data pages to help detect corruption by the I/O system that would otherwise be silent. Enabling checksums may incur a noticeable performance penalty. If set, checksums are calculated for all objects, in all databases. All checksum failures will be reported in the `pg_stat_data-base` view. See [Section 28.2](#) for details.

By default, Postgres Pro clusters are initialized with checksums enabled. To change this behavior, provide the `--no-data-checksums` option.

`--no-data-checksums`

Disable checksums on data pages.

By default, Postgres Pro clusters are initialized with checksums enabled.

`--locale=locale`

Sets the default locale for the database cluster. If this option is not specified, the locale is inherited from the environment that `initdb` runs in. Locale support is described in [Section 23.1](#).

If `--locale-provider` is builtin, `--locale` or `--builtin-locale` must be specified and set to `C` or `C.UTF-8`.

`--lc-collate=locale`

`--lc-ctype=locale`

`--lc-messages=locale`

`--lc-monetary=locale`

`--lc-numeric=locale`

`--lc-time=locale`

Like `--locale`, but only sets the locale in the specified category. The `--lc-collate` option overrides the `--locale` setting, regardless of whether the collation provider is specified.

`--no-locale`

Equivalent to `--locale=C`.

`--builtin-locale=locale`

Specifies the locale name when the builtin provider is used. Locale support is described in [Section 23.1](#).

`--locale-provider={builtin|libc|icu}`

This option sets the locale provider for databases created in the new cluster. It can be overridden in the `CREATE DATABASE` command when new databases are subsequently created. See [Section 23.1.4](#).

`--pwfile=filename`

Makes `initdb` read the bootstrap superuser's password from a file. The first line of the file is taken as the password.

`--no-tune`

By default, the use of `pgpro_tune` is enabled in `initdb`. Use this option to disable it.

`--tune=options`

Sets parameters for `pgpro_tune`. See [their description](#) for further information.

`-T config`

`--text-search-config=config`

Sets the default text search configuration. See [default_text_search_config](#) for further information.

`-U username`

`--username=username`

Sets the user name of the *bootstrap superuser*. This defaults to the name of the operating-system user running `initdb`.

-W
--pwprompt

Makes `initdb` prompt for a password to give the bootstrap superuser. If you don't plan on using password authentication, this is not important. Otherwise you won't be able to use password authentication until you have a password set up.

-X *directory*
--waldir=*directory*

This option specifies the directory where the write-ahead log should be stored.

--wal-segsize=*size*

Set the *WAL segment size*, in megabytes. This is the size of each individual file in the WAL log. The default size is 16 megabytes. The value must be a power of 2 between 1 and 1024 (megabytes). This option can only be set during initialization, and cannot be changed later.

It may be useful to adjust this size to control the granularity of WAL log shipping or archiving. Also, in databases with a high volume of WAL, the sheer number of WAL files per directory can become a performance and management problem. Increasing the WAL file size will reduce the number of WAL files.

Other, less commonly used, options are also available:

-c *name=value*
--set *name=value*

Forcibly set the server parameter *name* to *value* during `initdb`, and also install that setting in the generated `postgresql.conf` file, so that it will apply during future server runs. This option can be given more than once to set several parameters. It is primarily useful when the environment is such that the server will not start at all using the default parameters.

-d
--debug

Print debugging output from the bootstrap backend and a few other messages of lesser interest for the general public. The bootstrap backend is the program `initdb` uses to create the catalog tables. This option generates a tremendous amount of extremely boring output.

--discard-caches

Run the bootstrap backend with the `debug_discard_caches=1` option. This takes a very long time and is only of use for deep debugging.

-L *directory*

Specifies where `initdb` should find its input files to initialize the database cluster. This is normally not necessary. You will be told if you need to specify their location explicitly.

-n
--no-clean

By default, when `initdb` determines that an error prevented it from completely creating the database cluster, it removes any files it might have created before discovering that it cannot finish the job. This option inhibits tidying-up and is thus useful for debugging.

-N
--no-sync

By default, `initdb` will wait for all files to be written safely to disk. This option causes `initdb` to return without waiting, which is faster, but means that a subsequent operating system crash can

leave the data directory corrupt. Generally, this option is useful for testing, but should not be used when creating a production installation.

`--no-instructions`

By default, `initdb` will write instructions for how to start the cluster at the end of its output. This option causes those instructions to be left out. This is primarily intended for use by tools that wrap `initdb` in platform-specific behavior, where those instructions are likely to be incorrect.

`-s`

`--show`

Show internal settings and exit, without doing anything else. This can be used to debug the `initdb` installation.

`--sync-method=method`

When set to `fsync`, which is the default, `initdb` will recursively open and synchronize all files in the data directory. The search for files will follow symbolic links for the WAL directory and each configured tablespace.

On Linux, `syncfs` may be used instead to ask the operating system to synchronize the whole file systems that contain the data directory, the WAL files, and each tablespace. See [recovery_init_sync_method](#) for information about the caveats to be aware of when using `syncfs`.

This option has no effect when `--no-sync` is used.

`-S`

`--sync-only`

Safely write all database files to disk and exit. This does not perform any of the normal `initdb` operations. Generally, this option is useful for ensuring reliable recovery after changing `fsync` from `off` to `on`.

Other options for testing 64-bit XIDs:

`-m START_MX_ID`

`--multixact-id=START_MX_ID`

Specifies the initial multixact ID value in the decimal format for a new database instance to test database upgrades, default value is 0.

`-o START_MX_OFFSET`

`--multixact-offset=START_MX_OFFSET`

Specifies the initial multixact offset value in the decimal format for a new database instance to test database upgrades, default value is 0.

`-x START_XID`

`--xid=START_XID`

Specifies the initial XID value in the decimal format for a new database instance to test database upgrades, default value is 0.

Other options:

`-V`

`--version`

Print the `initdb` version and exit.

`-?`

`--help`

Show help about `initdb` command line arguments, and exit.

Environment

PGDATA

Specifies the directory where the database cluster is to be stored; can be overridden using the `-D` option.

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

PGPRO_TUNE

Specifies whether to use [pgpro_tune](#) without modifying command-line options directly. If set to `disable`, this environment variable has the same effect as passing `--no-tune`, disabling the use of `pgpro_tune`. If set to any other value, and neither `--tune` nor `--no-tune` is explicitly specified on the command line, the behavior is the same as if `--tune` is specified with the value of `PGPRO_TUNE`.

TZ

Specifies the default time zone of the created database cluster. The value should be a full time zone name (see [Section 8.5.3](#)).

Notes

`initdb` can also be invoked via `pg_ctl initdb`.

See Also

[pg_ctl](#), [postgres](#), [Section 20.1](#)

pg_archivecleanup

pg_archivecleanup — clean up Postgres Pro WAL archive files

Synopsis

```
pg_archivecleanup [option...] archivelocation oldestkeptwalfile
```

Description

pg_archivecleanup is designed to be used as an `archive_cleanup_command` to clean up WAL file archives when running as a standby server (see [Section 26.2](#)). pg_archivecleanup can also be used as a standalone program to clean WAL file archives.

To configure a standby server to use pg_archivecleanup, put this into its `postgresql.conf` configuration file:

```
archive_cleanup_command = 'pg_archivecleanup archivelocation %r'
```

where *archivelocation* is the directory from which WAL segment files should be removed.

When used within [archive_cleanup_command](#), all WAL files logically preceding the value of the `%r` argument will be removed from *archivelocation*. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the *archivelocation* is a transient staging area for this particular standby server, but *not* when the *archivelocation* is intended as a long-term WAL archive area, or when multiple standby servers are recovering from the same archive location.

When used as a standalone program all WAL files logically preceding the *oldestkeptwalfile* will be removed from *archivelocation*. In this mode, if you specify a `.partial` or `.backup` file name, then only the file prefix will be used as the *oldestkeptwalfile*. This treatment of `.backup` file name allows you to remove all WAL files archived prior to a specific base backup without error. For example, the following example will remove all files older than WAL file name `00000001000000037000000010`:

```
pg_archivecleanup -d archive 00000001000000037000000010.00000020.backup
```

```
pg_archivecleanup: keep WAL file "archive/00000001000000037000000010" and later
pg_archivecleanup: removing file "archive/0000000100000003700000000F"
pg_archivecleanup: removing file "archive/0000000100000003700000000E"
```

pg_archivecleanup assumes that *archivelocation* is a directory readable and writable by the server-owning user.

Options

pg_archivecleanup accepts the following command-line arguments:

`-b`

`--clean-backup-history`

Remove backup history files as well.

`-d`

`--debug`

Print lots of debug logging output on `stderr`.

`-n`

`--dry-run`

Print the names of the files that would have been removed on `stdout` (performs a dry run).

`-V`
`--version`

Print the `pg_archivecleanup` version and exit.

`-x extension`
`--strip-extension=extension`

Provide an extension that will be stripped from all file names before deciding if they should be deleted. This is typically useful for cleaning up archives that have been compressed during storage, and therefore have had an extension added by the compression program. For example: `-x .gz`.

`-?`
`--help`

Show help about `pg_archivecleanup` command line arguments, and exit.

Environment

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

`pg_archivecleanup` is designed to work with PostgreSQL 8.0 and later when used as a standalone utility, or with PostgreSQL 9.0 and later when used as an archive cleanup command.

`pg_archivecleanup` is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

Examples

On Linux or Unix systems, you might use:

```
archive_cleanup_command = 'pg_archivecleanup -d /mnt/standby/archive %r 2>>cleanup.log'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby. This will:

- produce debugging output in `cleanup.log`
- remove no-longer-needed files from the archive directory

pg_checksums

pg_checksums — enable, disable or check data checksums in a Postgres Pro database cluster

Synopsis

```
pg_checksums [option...] [[ -D | --pgdata ]datadir]
```

Description

pg_checksums checks, enables or disables data checksums in a Postgres Pro cluster. The server must be shut down cleanly before running pg_checksums. When verifying checksums, the exit status is zero if there are no checksum errors, and nonzero if at least one checksum failure is detected. When enabling or disabling checksums, the exit status is nonzero if the operation failed.

When verifying checksums, every file in the cluster is scanned. When enabling checksums, each relation file block with a changed checksum is rewritten in-place. Disabling checksums only updates the file pg_control.

Options

The following command-line options are available:

`-D directory`
`--pgdata=directory`

Specifies the directory where the database cluster is stored.

`-c`
`--check`

Checks checksums. This is the default mode if nothing else is specified.

`-d`
`--disable`

Disables checksums.

`-e`
`--enable`

Enables checksums.

`-f filenode`
`--filenode=filenode`

Only validate checksums in the relation with filenode *filenode*.

`-N`
`--no-sync`

By default, pg_checksums will wait for all files to be written safely to disk. This option causes pg_checksums to return without waiting, which is faster, but means that a subsequent operating system crash can leave the updated data directory corrupt. Generally, this option is useful for testing but should not be used on a production installation. This option has no effect when using `--check`.

`-P`
`--progress`

Enable progress reporting. Turning this on will deliver a progress report while checking or enabling checksums.

`--sync-method=method`

When set to `fsync`, which is the default, `pg_checksums` will recursively open and synchronize all files in the data directory. The search for files will follow symbolic links for the WAL directory and each configured tablespace.

On Linux, `syncfs` may be used instead to ask the operating system to synchronize the whole file systems that contain the data directory, the WAL files, and each tablespace. See [recovery_init_sync_method](#) for information about the caveats to be aware of when using `syncfs`.

This option has no effect when `--no-sync` is used.

`-v`

`--verbose`

Enable verbose output. Lists all checked files.

`-V`

`--version`

Print the `pg_checksums` version and exit.

`-?`

`--help`

Show help about `pg_checksums` command line arguments, and exit.

Environment

`PGDATA`

Specifies the directory where the database cluster is stored; can be overridden using the `-D` option.

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

Enabling checksums in a large cluster can potentially take a long time. During this operation, the cluster or other programs that write to the data directory must not be started or else data loss may occur.

When using a replication setup with tools which perform direct copies of relation file blocks (for example [pg_rewind](#)), enabling or disabling checksums can lead to page corruptions in the shape of incorrect checksums if the operation is not done consistently across all nodes. When enabling or disabling checksums in a replication setup, it is thus recommended to stop all the clusters before switching them all consistently. Destroying all standbys, performing the operation on the primary and finally recreating the standbys from scratch is also safe.

If `pg_checksums` is aborted or killed while enabling or disabling checksums, the cluster's data checksum configuration remains unchanged, and `pg_checksums` can be re-run to perform the same operation.

pg_createsubscriber

pg_createsubscriber — convert a physical replica into a new logical replica

Synopsis

```
pg_createsubscriber [option...] { -d | --database }dbname { -D | --pgdata }datadir { -P | --publisher-server }connstr
```

Description

pg_createsubscriber creates a new logical replica from a physical standby server. All tables in the specified database are included in the [logical replication](#) setup. A pair of publication and subscription objects are created for each database. It must be run at the target server.

After a successful run, the state of the target server is analogous to a fresh logical replication setup. The main difference between the logical replication setup and pg_createsubscriber is how the data synchronization is done. pg_createsubscriber does not copy the initial table data. It does only the synchronization phase, which ensures each table is brought up to a synchronized state.

pg_createsubscriber targets large database systems because in logical replication setup, most of the time is spent doing the initial data copy. Furthermore, a side effect of this long time spent synchronizing data is usually a large amount of changes to be applied (that were produced during the initial data copy), which increases even more the time when the logical replica will be available. For smaller databases, it is recommended to set up logical replication with initial data synchronization. For details, see the `CREATE SUBSCRIPTION copy_data` option.

Options

pg_createsubscriber accepts the following command-line arguments:

`-d dbname`

`--database=dbname`

The name of the database in which to create a subscription. Multiple databases can be selected by writing multiple `-d` switches.

`-D directory`

`--pgdata=directory`

The target directory that contains a cluster directory from a physical replica.

`-n`

`--dry-run`

Do everything except actually modifying the target directory.

`-p port`

`--subscriber-port=port`

The port number on which the target server is listening for connections. Defaults to running the target server on port 50432 to avoid unintended client connections.

`-P connstr`

`--publisher-server=connstr`

The connection string to the publisher. For details see [Section 35.1.1](#).

`-s dir`

`--socketdir=dir`

The directory to use for postmaster sockets on target server. The default is current directory.

`-t seconds`

`--recovery-timeout=seconds`

The maximum number of seconds to wait for recovery to end. Setting to 0 disables. The default is 0.

`-U username`

`--subscriber-username=username`

The user name to connect as on target server. Defaults to the current operating system user name.

`-v`

`--verbose`

Enables verbose mode. This will cause `pg_createsubscriber` to output progress messages and detailed information about each step to standard error. Repeating the option causes additional debug-level messages to appear on standard error.

`--config-file=filename`

Use the specified main server configuration file for the target data directory. `pg_createsubscriber` internally uses the `pg_ctl` command to start and stop the target server. It allows you to specify the actual `postgresql.conf` configuration file if it is stored outside the data directory.

`--publication=name`

The publication name to set up the logical replication. Multiple publications can be specified by writing multiple `--publication` switches. The number of publication names must match the number of specified databases, otherwise an error is reported. The order of the multiple publication name switches must match the order of database switches. If this option is not specified, a generated name is assigned to the publication name.

`--replication-slot=name`

The replication slot name to set up the logical replication. Multiple replication slots can be specified by writing multiple `--replication-slot` switches. The number of replication slot names must match the number of specified databases, otherwise an error is reported. The order of the multiple replication slot name switches must match the order of database switches. If this option is not specified, the subscription name is assigned to the replication slot name.

`--subscription=name`

The subscription name to set up the logical replication. Multiple subscriptions can be specified by writing multiple `--subscription` switches. The number of subscription names must match the number of specified databases, otherwise an error is reported. The order of the multiple subscription name switches must match the order of database switches. If this option is not specified, a generated name is assigned to the subscription name.

`-V`

`--version`

Print the `pg_createsubscriber` version and exit.

`-?`

`--help`

Show help about `pg_createsubscriber` command line arguments, and exit.

Notes

Prerequisites

There are some prerequisites for `pg_createsubscriber` to convert the target server into a logical replica. If these are not met, an error will be reported. The source and target servers must have the same major version as the `pg_createsubscriber`. The given target data directory must have the same system identifier

as the source data directory. The given database user for the target data directory must have privileges for creating `subscriptions` and using `pg_replication_origin_advance()`.

The target server must be used as a physical standby. The target server must have `max_replication_slots` and `max_logical_replication_workers` configured to a value greater than or equal to the number of specified databases. The target server must have `max_worker_processes` configured to a value greater than the number of specified databases. The target server must accept local connections.

The source server must accept connections from the target server. The source server must not be in recovery. The source server must have `wal_level` as `logical`. The source server must have `max_replication_slots` configured to a value greater than or equal to the number of specified databases plus existing replication slots. The source server must have `max_wal_senders` configured to a value greater than or equal to the number of specified databases and existing WAL sender processes.

Warnings

If `pg_createsubscriber` fails after the target server was promoted, then the data directory is likely not in a state that can be recovered. In such case, creating a new standby server is recommended.

`pg_createsubscriber` usually starts the target server with different connection settings during transformation. Hence, connections to the target server should fail.

Since DDL commands are not replicated by logical replication, avoid executing DDL commands that change the database schema while running `pg_createsubscriber`. If the target server has already been converted to logical replica, the DDL commands might not be replicated, which might cause an error.

If `pg_createsubscriber` fails while processing, objects (publications, replication slots) created on the source server are removed. The removal might fail if the target server cannot connect to the source server. In such a case, a warning message will inform the objects left. If the target server is running, it will be stopped.

If the replication is using `primary_slot_name`, it will be removed from the source server after the logical replication setup.

If the target server is a synchronous replica, transaction commits on the primary might wait for replication while running `pg_createsubscriber`.

`pg_createsubscriber` sets up logical replication with two-phase commit disabled. This means that any prepared transactions will be replicated at the time of `COMMIT PREPARED`, without advance preparation. Once setup is complete, you can manually drop and re-create the subscription(s) with the `two_phase` option enabled.

`pg_createsubscriber` changes the system identifier using `pg_resetwal`. It would avoid situations in which the target server might use WAL files from the source server. If the target server has a standby, replication will break and a fresh standby should be created.

How It Works

The basic idea is to have a replication start point from the source server and set up a logical replication to start from this point:

1. Start the target server with the specified command-line options. If the target server is already running, `pg_createsubscriber` will terminate with an error.
2. Check if the target server can be converted. There are also a few checks on the source server. If any of the prerequisites are not met, `pg_createsubscriber` will terminate with an error.
3. Create a publication and replication slot for each specified database on the source server. Each publication is created using `FOR ALL TABLES`. If the `--publication` option is not specified, the publication has the following name pattern: `"pg_createsubscriber_%u_%x"` (parameter: database *oid*, random *int*). If the `--replication-slot` option is not specified, the replication slot has the following name pattern: `"pg_createsubscriber_%u_%x"` (parameters: database *oid*, random *int*).

These replication slots will be used by the subscriptions in a future step. The last replication slot LSN is used as a stopping point in the [recovery_target_lsn](#) parameter and by the subscriptions as a replication start point. It guarantees that no transaction will be lost.

4. Write recovery parameters into the target data directory and restart the target server. It specifies an LSN ([recovery_target_lsn](#)) of the write-ahead log location up to which recovery will proceed. It also specifies `promote` as the action that the server should take once the recovery target is reached. Additional [recovery parameters](#) are added to avoid unexpected behavior during the recovery process such as end of the recovery as soon as a consistent state is reached (WAL should be applied until the replication start location) and multiple recovery targets that can cause a failure. This step finishes once the server ends standby mode and is accepting read-write transactions. If `--recovery-timeout` option is set, `pg_createsubscriber` terminates if recovery does not end until the given number of seconds.
5. Create a subscription for each specified database on the target server. If the `--subscription` option is not specified, the subscription has the following name pattern: `"pg_createsubscriber_%u_%x"` (parameters: database *oid*, random *int*). It does not copy existing data from the source server. It does not create a replication slot. Instead, it uses the replication slot that was created in a previous step. The subscription is created but it is not enabled yet. The reason is the replication progress must be set to the replication start point before starting the replication.
6. Drop publications on the target server that were replicated because they were created before the replication start location. It has no use on the subscriber.
7. Set the replication progress to the replication start point for each subscription. When the target server starts the recovery process, it catches up to the replication start point. This is the exact LSN to be used as a initial replication location for each subscription. The replication origin name is obtained since the subscription was created. The replication origin name and the replication start point are used in `pg_replication_origin_advance()` to set up the initial replication location.
8. Enable the subscription for each specified database on the target server. The subscription starts applying transactions from the replication start point.
9. If the standby server was using [primary_slot_name](#), it has no use from now on so drop it.
10. If the standby server contains [failover replication slots](#), they cannot be synchronized anymore, so drop them.
11. Update the system identifier on the target server. The [pg_resetwal](#) is run to modify the system identifier. The target server is stopped as a `pg_resetwal` requirement.

Examples

To create a logical replica for databases `hr` and `finance` from a physical replica at `foo`:

```
$ pg_createsubscriber -D /usr/local/pgsql/data -P "host=foo" -d hr -d finance
```

pg_ctl

pg_ctl — initialize, start, stop, or control a Postgres Pro server

Synopsis

```
pg_ctl init[db] [-D datadir] [-s] [-o initdb-options]  
  
pg_ctl start [-D datadir] [-l filename] [-W] [-t seconds] [-s] [-o options] [-p path] [-c]  
  
pg_ctl stop [-D datadir] [-m s[mart] | f[ast] | i[mmediate]] [-W] [-t seconds] [-s]  
  
pg_ctl restart [-D datadir] [-m s[mart] | f[ast] | i[mmediate]] [-W] [-t seconds] [-s] [-o options]  
[-c]  
  
pg_ctl reload [-D datadir] [-s]  
  
pg_ctl status [-D datadir]  
  
pg_ctl promote [-D datadir] [-W] [-t seconds] [-s]  
  
pg_ctl logrotate [-D datadir] [-s]  
  
pg_ctl kill signal_name process_id
```

On Microsoft Windows, also:

```
pg_ctl register [-D datadir] [-N servicename] [-U username] [-P password] [-S a[uto] | d[emand]] [-e source] [-W] [-t seconds] [-s] [-o options]  
  
pg_ctl unregister [-N servicename]
```

Description

pg_ctl is a utility for initializing a Postgres Pro database cluster, starting, stopping, or restarting the Postgres Pro database server ([postgres](#)), or displaying the status of a running server. Although the server can be started manually, pg_ctl encapsulates tasks such as redirecting log output and properly detaching from the terminal and process group. It also provides convenient options for controlled shutdown.

The `init` or `initdb` mode creates a new Postgres Pro database cluster, that is, a collection of databases that will be managed by a single server instance. This mode invokes the `initdb` command. See [initdb](#) for details.

`start` mode launches a new server. The server is started in the background, and its standard input is attached to `/dev/null` (or `nul` on Windows). On Unix-like systems, by default, the server's standard output and standard error are sent to pg_ctl's standard output (not standard error). The standard output of pg_ctl should then be redirected to a file or piped to another process such as a log rotating program like `rotatelogs`; otherwise `postgres` will write its output to the controlling terminal (from the background) and will not leave the shell's process group. On Windows, by default the server's standard output and standard error are sent to the terminal. These default behaviors can be changed by using `-l` to append the server's output to a log file. Use of either `-l` or output redirection is recommended.

`stop` mode shuts down the server that is running in the specified data directory. Three different shutdown methods can be selected with the `-m` option. “Smart” mode disallows new connections, then waits for all existing clients to disconnect. If the server is in hot standby, recovery and streaming replication will be terminated once all clients have disconnected. “Fast” mode (the default) does not wait for clients to disconnect. All active transactions are rolled back and clients are forcibly disconnected, then the server is shut down. “Immediate” mode will abort all server processes immediately, without a clean shutdown. This choice will lead to a crash-recovery cycle during the next server start.

restart mode effectively executes a stop followed by a start. This allows changing the `postgres` command-line options, or changing configuration-file options that cannot be changed without restarting the server. If relative paths were used on the command line during server start, `restart` might fail unless `pg_ctl` is executed in the same current directory as it was during server start.

reload mode simply sends the `postgres` server process a `SIGHUP` signal, causing it to reread its configuration files (`postgresql.conf`, `pg_hba.conf`, etc.). This allows changing configuration-file options that do not require a full server restart to take effect.

status mode checks whether a server is running in the specified data directory. If it is, the server's PID and the command line options that were used to invoke it are displayed. If the server is not running, `pg_ctl` returns an exit status of 3. If an accessible data directory is not specified, `pg_ctl` returns an exit status of 4.

promote mode commands the standby server that is running in the specified data directory to end standby mode and begin read-write operations.

logrotate mode rotates the server log file. For details on how to use this mode with external log rotation tools, see [Section 24.4](#).

kill mode sends a signal to a specified process. This is primarily valuable on Microsoft Windows which does not have a built-in kill command. Use `--help` to see a list of supported signal names.

register mode registers the Postgres Pro server as a system service on Microsoft Windows. The `-s` option allows selection of service start type, either “auto” (start service automatically on system startup) or “demand” (start service on demand).

unregister mode unregisters a system service on Microsoft Windows. This undoes the effects of the `register` command.

Options

`-c`
`--core-files`

Attempt to allow server crashes to produce core files, on platforms where this is possible, by lifting any soft resource limit placed on core files. This is useful in debugging or diagnosing problems by allowing a stack trace to be obtained from a failed server process.

`-D datadir`
`--pgdata=datadir`

Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-l filename`
`--log=filename`

Append the server log output to *filename*. If the file does not exist, it is created. The umask is set to 077, so access to the log file is disallowed to other users by default.

`-m mode`
`--mode=mode`

Specifies the shutdown mode. *mode* can be `smart`, `fast`, or `immediate`, or the first letter of one of these three. If this option is omitted, `fast` is the default.

`-o options`
`--options=options`

Specifies options to be passed directly to the `postgres` command. `-o` can be specified multiple times, with all the given options being passed through.

The *options* should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

`-o initdb-options`
`--options=initdb-options`

Specifies options to be passed directly to the `initdb` command. `-o` can be specified multiple times, with all the given options being passed through.

The *initdb-options* should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

`-p path`

Specifies the location of the `postgres` executable. By default the `postgres` executable is taken from the same directory as `pg_ctl`, or failing that, the hard-wired installation directory. It is not necessary to use this option unless you are doing something unusual and get errors that the `postgres` executable was not found.

In `init` mode, this option analogously specifies the location of the `initdb` executable.

`-s`
`--silent`

Print only errors, no informational messages.

`-t seconds`
`--timeout=seconds`

Specifies the maximum number of seconds to wait when waiting for an operation to complete (see option `-w`). Defaults to the value of the `PGCTLTIMEOUT` environment variable or, if not set, to 60 seconds.

`-V`
`--version`

Print the `pg_ctl` version and exit.

`-w`
`--wait`

Wait for the operation to complete. This is supported for the modes `start`, `stop`, `restart`, `promote`, and `register`, and is the default for those modes.

When waiting, `pg_ctl` repeatedly checks the server's PID file, sleeping for a short amount of time between checks. Startup is considered complete when the PID file indicates that the server is ready to accept connections. Shutdown is considered complete when the server removes the PID file. `pg_ctl` returns an exit code based on the success of the startup or shutdown.

If the operation does not complete within the timeout (see option `-t`), then `pg_ctl` exits with a nonzero exit status. But note that the operation might continue in the background and eventually succeed.

`-W`
`--no-wait`

Do not wait for the operation to complete. This is the opposite of the option `-w`.

If waiting is disabled, the requested action is triggered, but there is no feedback about its success. In that case, the server log file or an external monitoring system would have to be used to check the progress and success of the operation.

In prior releases of Postgres Pro, this was the default except for the `stop` mode.

-?
--help

Show help about pg_ctl command line arguments, and exit.

If an option is specified that is valid, but not relevant to the selected operating mode, pg_ctl ignores it.

Options for Windows

-e *source*

Name of the event source for pg_ctl to use for logging to the event log when running as a Windows service. The default is `Postgres Pro`. Note that this only controls messages sent from pg_ctl itself; once started, the server will use the event source specified by its [event_source](#) parameter. Should the server fail very early in startup, before that parameter has been set, it might also log using the default event source name `Postgres Pro`.

-N *servicename*

Name of the system service to register. This name will be used as both the service name and the display name. The default is `Postgres Pro`.

-P *password*

Password for the user to run the service as.

-S *start-type*

Start type of the system service. *start-type* can be `auto`, or `demand`, or the first letter of one of these two. If this option is omitted, `auto` is the default.

-U *username*

User name for the user to run the service as. For domain users, use the format `DOMAIN\username`.

Environment

PGCTLTIMEOUT

Default limit on the number of seconds to wait when waiting for startup or shutdown to complete. If not set, the default is 60 seconds.

PGDATA

Default data directory location.

Most pg_ctl modes require knowing the data directory location; therefore, the `-D` option is required unless PGDATA is set.

For additional variables that affect the server, see [postgres](#).

Files

postmaster.pid

pg_ctl examines this file in the data directory to determine whether the server is currently running.

postmaster.opts

If this file exists in the data directory, pg_ctl (in `restart` mode) will pass the contents of the file as options to postgres, unless overridden by the `-o` option. The contents of this file are also displayed in `status` mode.

Examples

Starting the Server

To start the server, waiting until the server is accepting connections:

```
$ pg_ctl start
```

To start the server using port 5433, and running without `fsync`, use:

```
$ pg_ctl -o "-F -p 5433" start
```

Stopping the Server

To stop the server, use:

```
$ pg_ctl stop
```

The `-m` option allows control over *how* the server shuts down:

```
$ pg_ctl stop -m smart
```

Restarting the Server

Restarting the server is almost equivalent to stopping the server and starting it again, except that by default, `pg_ctl` saves and reuses the command line options that were passed to the previously-running instance. To restart the server using the same options as before, use:

```
$ pg_ctl restart
```

But if `-o` is specified, that replaces any previous options. To restart using port 5433, disabling `fsync` upon restart:

```
$ pg_ctl -o "-F -p 5433" restart
```

Showing the Server Status

Here is sample status output from `pg_ctl`:

```
$ pg_ctl status
```

```
pg_ctl: server is running (PID: 13718)
/usr/local/pgsql/bin/postgres "-D" "/usr/local/pgsql/data" "-p" "5433" "-B" "128"
```

The second line is the command that would be invoked in restart mode.

pgpro_tune

pgpro_tune — a command-line tool for automatic tuning

Synopsis

```
pgpro_tune [option...] [ -D | --pgdata ] directory preset_name
```

Description

The pgpro_tune utility is a command-line tool for automatic tuning. Optimal values for different configuration parameters of Postgres Pro Shardman depend on the hardware configuration. The pgpro_tune utility collects information about the system and transforms it into a set of parameters written into the configuration file. Note that it must be aware of the Shardman server topology to work properly.

Usage

The use of pgpro_tune is enabled in initdb by default. There are two initdb options for this tool: `--no-tune` disables its usage, `--tune=OPTIONS` allows passing additional options for the pgpro_tune run.

First pgpro_tune runs the default preset. Additional presets may be provided by using `-P` or `--preset=NAME` option, or specifying the preset name as the last command-line argument. To disable the default preset, use the `--no-default` option.

Additional options may be passed via `-O` or `--options=OPTIONS` parameter for any preset, but for the default preset `--default-options=OPTIONS` should be used.

Additional environment variables can be set for presets with the `--set NAME=VALUE` parameter. These values will be the same both for the default preset and all custom presets.

By default, the presets are placed in the `share` directory, but you can specify their location manually in the `--preset-dir=NAME` parameter.

By default, pgpro_tune works with the `postgresql.conf` configuration file located in the data directory. The data directory can be specified with `-D` or `--pgdata=DATADIR`, or provided with environment variable `PGDATA`. When running pgpro_tune from initdb, the tool will use the data directory of initdb.

Configuration file can also be specified with `--config-file=FILENAME`.

The pgpro_tune tool writes its changes into a separate block at the end of the configuration file, which is commented as added by pgpro_tune. For details, see [the example of the preset](#).

Options

`--config-file=filename`

Specifies the main configuration file name.

`-D datadir`

`--pgdata=datadir`

Specifies the directory where the database cluster should be stored.

`--default-options=options`

Specifies parameters for the default preset.

`--no-default`

Disables the default preset. Note that in this case another preset must be specified anyway either with the `-P` option or as the last parameter with the preset name.

`-O preset-options`

`--options=preset-options`

Specifies options to be passed directly to the preset that was previously specified in the `-P` parameter or to the preset indicated as the last command-line parameter, if `-P` was not used.

`-P name`

`--preset=name`

Specifies the preset name. If several names are indicated, presets are executed in turn, taking into account the output of the previous preset.

Note

The preset name may be specified either with this option or as the last parameter. Using both will cause an error.

`--preset-dir=name`

Specifies the directory containing presets. By default, presets are located in the `share` directory.

`--set name=value`

Sets the environment variable for presets.

`--show`

Shows all available presets from the directory specified in the `--preset-dir` option, if it is set, or from the default directory otherwise.

`-V`

`--version`

Print the `pgpro_tune` version and exit.

`-?`

`--help`

Show help about `pgpro_tune` command line arguments, and exit.

Environment variables

`pgpro_tune` sets the following environment variables before running presets.

- `EDITION` — the Postgres Pro edition.
- `ENABLE_CRASH_INFO` — if set, Postgres Pro was built with the `--enable-crash-info` option.
- `ENABLE_NLS` — if set, Postgres Pro was built with the `--enable-nls` option.
- `ENABLE_PGPRO_TUNE` — if set, Postgres Pro was built with the `--enable-pgpro-tune` option.
- `MEMMB` — the RAM size in megabytes.
- `MVER` — Postgres Pro major version.
- `NCPU` — the number of CPUs.
- `USE_BONJOUR` — if set, Postgres Pro was built with the `--with-bonjour` option.
- `USE_BSD_AUTH` — if set, Postgres Pro was built with the `--with-bsd-auth` option.
- `USE_ICU` — if set, Postgres Pro was built the `--with-icu` option.
- `USE_LDAP` — if set, Postgres Pro was built with the `--with-ldap` option.
- `USE_LIBUNWIND` — if set, Postgres Pro was built with the `--with-libunwind` option.

- `USE_LIBXML` — if set, Postgres Pro was built with the `--with-libxml` option.
- `USE_LIBXSLT` — if set, Postgres Pro was built with the `--with-libxslt` option.
- `USE_LLVM` — if set, Postgres Pro was built with the `--with-llvm` option.
- `USE_LZ4` — if set, Postgres Pro was built with the `--with-lz4` option.
- `USE_OPENSSL` — if set, Postgres Pro was built with the `--with-openssl` option.
- `USE_PAM` — if set, Postgres Pro was built with the `--with-pam` option.
- `USE_SYSTEMD` — if set, Postgres Pro was built with the `--with-systemd` option.
- `USE_ZSTD` — if set, Postgres Pro was built with the `--with-zstd` option.

Writing presets

A preset is an executable, usually a shell script, that transforms the information passed through environment variables into the set of configuration parameters.

The expected output of the preset is the set of specifically formatted lines. The first non-whitespace character is the indicator of the line content interpretation for `pgpro_tune`. The indicator should be one of the following:

- `#` for the comment action, the rest of the output line will be written into the configuration file after `'#'`.
- `=` for the replace action, the rest of the output line should contain a pair of parameters `NAME` and `VALUE` (both `NAME=VALUE` and `NAME VALUE` are acceptable). Line `NAME = VALUE` will be written into the configuration file. The text after `VALUE` will be added as a comment.
- `+=` or `+=` for the add action, the rest of the output line should contain a pair of parameters `NAME` and `VALUE`. `VALUE` will be added to the previous effective value of the parameter `NAME` at the back (`+=`) or at the front (`+=`). If there is no effective value, the `ADD` action works like the replace action. The text after `VALUE` will be added as a comment.
- `--` for the withdraw action, the rest of the output line should contain a pair of parameters `NAME` and `VALUE`. If the `NAME` parameter has the effective value containing `VALUE`, it will be removed and the rest of the effective value will remain the same. The text after `VALUE` will be added as a comment. If there is no effective value, nothing happens.

Example of the preset

Suppose you have the following configuration file called `test.conf`:

```
work_mem = 4MB # Default value
shared_preload_libraries = 'plantuner'
search_path = '"$user",wrong_schema,public'
```

And the following preset called `test.tune`:

```
echo "# Adding new configuration parameters."
#Replace configuration parameter value by a new one
echo "work_mem = 8MB"
#Append to the start of existing value
echo "shared_preload_libraries += pg_stat_statements"
#Append to the end of existing value
echo "shared_preload_libraries += pg_prewarm"
#Withdraw from existing value
echo "search_path -= 'wrong_schema'"
```

Run the following command to use this preset:

```
pgpro_tune --config-file=/path/to/test.conf -P/path/to/test.tune --no-default
```

This command will result in the following changes of the configuration file:

```
#-----
# The following settings were added by pgpro_tune.
# pgpro_tune was run with the following options:
# --no-default --config-file=/path/to/test/conf -P/path/to/test/tune --no-default
# At YYYY-MM-DD HH:MM:SS
#-----
# Adding new configuration parameters.
work_mem = 8MB
shared_preload_libraries = 'pg_stat_statements, plantuner'
shared_preload_libraries = 'pg_stat_statements, plantuner, pg_prewarm'
search_path = '"$user", public'
#-----
# End of settings added by pgpro_tune at YYYY-MM-DD HH-MM-SS
#-----
```

pg_resetwal

`pg_resetwal` — reset the write-ahead log and other control information of a Postgres Pro database cluster

Synopsis

```
pg_resetwal [ -f | --force ] [ -n | --dry-run ] [option...] [ -D | --pgdata ] datadir
```

Description

`pg_resetwal` clears the write-ahead log (WAL) and optionally resets some other control information stored in the `pg_control` file. This function is sometimes needed if these files have become corrupted. It should be used only as a last resort, when the server will not start due to such corruption.

Some options, such as `--wal-segsize` (see below), can also be used to modify certain global settings of a database cluster without the need to rerun `initdb`. This can be done safely on an otherwise sound database cluster, if none of the dangerous modes mentioned below are used.

If `pg_resetwal` is used on a data directory where the server has been cleanly shut down and the control file is sound, then it will have no effect on the contents of the database system, except that no longer used WAL files are cleared away. Any other use is potentially dangerous and must be done with great care. `pg_resetwal` will require the `-f` (force) option to be specified before working on a data directory in an unclean shutdown state or with a corrupted control file.

After running this command on a data directory with corrupted WAL or a corrupted control file, it should be possible to start the server, but bear in mind that the database might contain inconsistent data due to partially-committed transactions. You should immediately dump your data, run `initdb`, and restore. After restore, check for inconsistencies and repair as needed.

If `pg_resetwal` complains that it cannot determine valid data for `pg_control`, you can force it to proceed anyway by specifying the `-f` (force) option. In this case plausible values will be substituted for the missing data. Most of the fields can be expected to match, but manual assistance might be needed for the next OID, next transaction ID, next multitransaction ID and offset, and WAL starting location fields. These fields can be set using the options discussed below. If you are not able to determine correct values for all these fields, `-f` can still be used, but the recovered database must be treated with even more suspicion than usual: an immediate dump and restore is imperative. *Do not* execute any data-modifying operations in the database before you dump, as any such action is likely to make the corruption worse.

This utility can only be run by the user who installed the server, because it requires read/write access to the data directory.

Options

```
datadir
-D datadir
--pgdata=datadir
```

Specifies the location of the database directory. For safety reasons, you must specify the data directory on the command line. `pg_resetwal` does not use the environment variable `PGDATA`.

```
-f
--force
```

Force `pg_resetwal` to proceed even in situations where it could be dangerous, as explained above. Specifically, this option is required to proceed if the server had not been cleanly shut down or if `pg_resetwal` cannot determine valid data for `pg_control`.

`-n`
`--dry-run`

The `-n/--dry-run` option instructs `pg_resetwal` to print the values reconstructed from `pg_control` and values about to be changed, and then exit without modifying anything. This is mainly a debugging tool, but can be useful as a sanity check before allowing `pg_resetwal` to proceed for real.

`-V`
`--version`

Display version information, then exit.

`-?`
`--help`

Show help, then exit.

The following options are only needed when `pg_resetwal` is unable to determine appropriate values by reading `pg_control`. Safe values can be determined as described below. For values that take numeric arguments, hexadecimal values can be specified by using the prefix `0x`. Note that these instructions only apply with the standard block size of 8 kB.

`-c xid,xid`
`--commit-timestamp-ids=xid,xid`

Manually set the oldest and newest transaction IDs for which the commit time can be retrieved.

A safe value for the oldest transaction ID for which the commit time can be retrieved (first part) can be determined by looking for the numerically smallest file name in the directory `pg_commit_ts` under the data directory. Conversely, a safe value for the newest transaction ID for which the commit time can be retrieved (second part) can be determined by looking for the numerically greatest file name in the same directory. The file names are in hexadecimal.

`-l walfile`
`--next-wal-file=walfile`

Manually set the WAL starting location by specifying the name of the next WAL segment file.

The name of next WAL segment file should be larger than any WAL segment file name currently existing in the directory `pg_wal` under the data directory. These names are also in hexadecimal and have three parts. The first part is the “timeline ID” and should usually be kept the same. For example, if `000000010000000320000004A` is the largest entry in `pg_wal`, use `-l 000000010000000320000004B` or higher.

Note that when using nondefault WAL segment sizes, the numbers in the WAL file names are different from the LSNs that are reported by system functions and system views. This option takes a WAL file name, not an LSN.

Note

`pg_resetwal` itself looks at the files in `pg_wal` and chooses a default `-l` setting beyond the last existing file name. Therefore, manual adjustment of `-l` should only be needed if you are aware of WAL segment files that are not currently present in `pg_wal`, such as entries in an offline archive; or if the contents of `pg_wal` have been lost entirely.

`-m mxid,mxid`
`--multixact-ids=mxid,mxid`

Manually set the next and oldest multitransaction ID.

A safe value for the next multitransaction ID (first part) can be determined by looking for the numerically largest file name in the directory `pg_multixact/offsets` under the data directory, adding one, and then multiplying by 2097152 (0x200000). Conversely, a safe value for the oldest multitransaction ID (second part of `-m`) can be determined by looking for the numerically smallest file name in the same directory and multiplying by 2097152. The file names are in hexadecimal, so the easiest way to do this is to specify the option value in hexadecimal and append four zeroes.

```
-o oid
--next-oid=oid
```

Manually set the next OID.

There is no comparably easy way to determine a next OID that's beyond the largest one in the database, but fortunately it is not critical to get the next-OID setting right.

```
-O mxoff
--multixact-offset=mxoff
```

Manually set the next multitransaction offset.

A safe value can be determined by looking for the numerically largest file name in the directory `pg_multixact/members` under the data directory, adding one, and then multiplying by 1851392 (0x1c4000). The file names are in hexadecimal. There is no simple recipe such as the ones for other options of appending zeroes.

```
--wal-segsize=wal_segment_size
```

Set the new WAL segment size, in megabytes. The value must be set to a power of 2 between 1 and 1024 (megabytes). See the same option of [initdb](#) for more information.

This option can also be used to change the WAL segment size of an existing database cluster, avoiding the need to `re-initdb`.

Note

While `pg_resetwal` will set the WAL starting address beyond the latest existing WAL segment file, some segment size changes can cause previous WAL file names to be reused. It is recommended to use `-l` together with this option to manually set the WAL starting address if WAL file name overlap will cause problems with your archiving strategy.

```
-u xid
--oldest-transaction-id=xid
```

Manually set the oldest unfrozen transaction ID.

A safe value can be determined by looking for the numerically smallest file name in the directory `pg_xact` under the data directory and then multiplying by 67108864 (0x4000000). Note that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal too. For example, if `0007` is the smallest entry in `pg_xact`, `-u 0x700000` will work (five trailing zeroes provide the proper multiplier).

```
-x xid
--next-transaction-id=xid
```

Manually set the next transaction ID.

A safe value can be determined by looking for the numerically largest file name in the directory `pg_xact` under the data directory, adding one, and then multiplying by 67108864 (0x4000000). Note that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal too. For example, if `0011` is the largest entry in `pg_xact`, `-x 0x1200000` will work (five trailing zeroes provide the proper multiplier).

Environment

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

This command must not be used when the server is running. `pg_resetwal` will refuse to start up if it finds a server lock file in the data directory. If the server crashed then a lock file might have been left behind; in that case you can remove the lock file to allow `pg_resetwal` to run. But before you do so, make doubly certain that there is no server process still alive.

`pg_resetwal` works only with servers of the same major version.

pg_rewind

`pg_rewind` — synchronize a Postgres Pro data directory with another data directory that was forked from it

Synopsis

```
pg_rewind [option...] { -D | --target-pgdata } directory { --source-pgdata=directory | --source-server=connstr }
```

Description

`pg_rewind` is a tool for synchronizing a Postgres Pro cluster with another copy of the same cluster, after the clusters' timelines have diverged. A typical scenario is to bring an old primary server back online after failover as a standby that follows the new primary.

After a successful rewind, the state of the target data directory is analogous to a base backup of the source data directory. Unlike taking a new base backup or using a tool like `rsync`, `pg_rewind` does not require comparing or copying unchanged relation blocks in the cluster. Only changed blocks from existing relation files are copied; all other files, including new relation files, configuration files, and WAL segments, are copied in full. As such the rewind operation is significantly faster than other approaches when the database is large and only a small fraction of blocks differ between the clusters.

`pg_rewind` examines the timeline histories of the source and target clusters to determine the point where they diverged, and expects to find WAL in the target cluster's `pg_wal` directory reaching all the way back to the point of divergence. The point of divergence can be found either on the target timeline, the source timeline, or their common ancestor. In the typical failover scenario where the target cluster was shut down soon after the divergence, this is not a problem, but if the target cluster ran for a long time after the divergence, its old WAL files might no longer be present. In this case, you can manually copy them from the WAL archive to the `pg_wal` directory, or run `pg_rewind` with the `-c` option to automatically retrieve them from the WAL archive. The use of `pg_rewind` is not limited to failover, e.g., a standby server can be promoted, run some write transactions, and then rewound to become a standby again.

After running `pg_rewind`, WAL replay needs to complete for the data directory to be in a consistent state. When the target server is started again it will enter archive recovery and replay all WAL generated in the source server from the last checkpoint before the point of divergence. If some of the WAL was no longer available in the source server when `pg_rewind` was run, and therefore could not be copied by the `pg_rewind` session, it must be made available when the target server is started. This can be done by creating a `recovery.signal` file in the target data directory and by configuring a suitable [restore_command](#) in `postgresql.conf`.

`pg_rewind` requires that the target server either has the [wal_log_hints](#) option enabled in `postgresql.conf` or data checksums enabled when the cluster was initialized with `initdb`. While `wal_log_hints` is currently off by default, the checksums are enabled. [full_page_writes](#) must also be set to `on`, and it is enabled by default.

Warning: Failures While Rewinding

If `pg_rewind` fails while processing, then the data folder of the target is likely not in a state that can be recovered. In such a case, taking a new fresh backup is recommended.

As `pg_rewind` copies configuration files entirely from the source, it may be required to correct the configuration used for recovery before restarting the target server, especially if the target is reintroduced as a standby of the source. If you restart the server after the rewind operation has finished but without configuring recovery, the target may again diverge from the primary.

`pg_rewind` will fail immediately if it finds files it cannot write directly to. This can happen for example when the source and the target server use the same file mapping for read-only SSL keys

and certificates. If such files are present on the target server it is recommended to remove them before running `pg_rewind`. After doing the rewind, some of those files may have been copied from the source, in which case it may be necessary to remove the data copied and restore back the set of links used before the rewind.

Options

`pg_rewind` accepts the following command-line arguments:

`-D directory`

`--target-pgdata=directory`

This option specifies the target data directory that is synchronized with the source. The target server must be shut down cleanly before running `pg_rewind`

`--source-pgdata=directory`

Specifies the file system path to the data directory of the source server to synchronize the target with. This option requires the source server to be cleanly shut down.

`--source-server=connstr`

Specifies a libpq connection string to connect to the source Postgres Pro server to synchronize the target with. The connection must be a normal (non-replication) connection with a role having sufficient permissions to execute the functions used by `pg_rewind` on the source server (see Notes section for details) or a superuser role. This option requires the source server to be running and accepting connections.

`-R`

`--write-recovery-conf`

Create `standby.signal` and append connection settings to `postgresql.auto.conf` in the output directory. `--source-server` is mandatory with this option.

`-n`

`--dry-run`

Do everything except actually modifying the target directory.

`-N`

`--no-sync`

By default, `pg_rewind` will wait for all files to be written safely to disk. This option causes `pg_rewind` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the data directory corrupt. Generally, this option is useful for testing but should not be used on a production installation.

`-P`

`--progress`

Enables progress reporting. Turning this on will deliver an approximate progress report while copying data from the source cluster.

`-c`

`--restore-target-wal`

Use `restore_command` defined in the target cluster configuration to retrieve WAL files from the WAL archive if these files are no longer available in the `pg_wal` directory.

`--config-file=filename`

Use the specified main server configuration file for the target cluster. This affects `pg_rewind` when it uses internally the `postgres` command for the rewind operation on this cluster (when retrieving

`restore_command` with the option `-c/--restore-target-wal` and when forcing a completion of crash recovery).

`--debug`

Print verbose debugging output that is mostly useful for developers debugging `pg_rewind`.

`--no-ensure-shutdown`

`pg_rewind` requires that the target server is cleanly shut down before rewinding. By default, if the target server is not shut down cleanly, `pg_rewind` starts the target server in single-user mode to complete crash recovery first, and stops it. By passing this option, `pg_rewind` skips this and errors out immediately if the server is not cleanly shut down. Users are expected to handle the situation themselves in that case.

`--sync-method=method`

When set to `fsync`, which is the default, `pg_rewind` will recursively open and synchronize all files in the data directory. The search for files will follow symbolic links for the WAL directory and each configured tablespace.

On Linux, `syncfs` may be used instead to ask the operating system to synchronize the whole file systems that contain the data directory, the WAL files, and each tablespace. See [recovery_init_sync_method](#) for information about the caveats to be aware of when using `syncfs`.

This option has no effect when `--no-sync` is used.

`--biha`

Set the `biha` node to the `CSTATE_FORMING` state for the subsequent status of the node to be set automatically depending on the current status of the cluster. This option is used when restoring the node of the built-in high-availability cluster from the `NODE_ERROR` state.

Important

The `--biha` option is essential for saving `biha` configuration files. Using `pg_rewind` in a BiHA cluster without the `--biha` option may cause cluster configuration inconsistency.

`-V`

`--version`

Display version information, then exit.

`-?`

`--help`

Show help, then exit.

Environment

When `--source-server` option is used, `pg_rewind` also uses the environment variables supported by `libpq` (see [Section 35.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

When executing `pg_rewind` using an online cluster as source, a role having sufficient permissions to execute the functions used by `pg_rewind` on the source cluster can be used instead of a superuser. Here is how to create such a role, named `rewind_user` here:

```
CREATE USER rewind_user LOGIN;
GRANT EXECUTE ON function pg_catalog.pg_ls_dir(text, boolean, boolean) TO rewind_user;
GRANT EXECUTE ON function pg_catalog.pg_stat_file(text, boolean) TO rewind_user;
GRANT EXECUTE ON function pg_catalog.pg_read_binary_file(text) TO rewind_user;
GRANT EXECUTE ON function pg_catalog.pg_read_binary_file(text, bigint, bigint, boolean)
    TO rewind_user;
```

How It Works

The basic idea is to copy all file system-level changes from the source cluster to the target cluster:

1. Scan the WAL log of the target cluster, starting from the last checkpoint before the point where the source cluster's timeline history forked off from the target cluster. For each WAL record, record each data block that was touched. This yields a list of all the data blocks that were changed in the target cluster, after the source cluster forked off. If some of the WAL files are no longer available, try re-running `pg_rewind` with the `-c` option to search for the missing files in the WAL archive.
2. Copy all those changed blocks from the source cluster to the target cluster, either using direct file system access (`--source-pgdata`) or SQL (`--source-server`). Relation files are now in a state equivalent to the moment of the last completed checkpoint prior to the point at which the WAL timelines of the source and target diverged plus the current state on the source of any blocks changed on the target after that divergence.
3. Copy all other files, including new relation files, WAL segments, `pg_xact`, and configuration files from the source cluster to the target cluster. Similarly to base backups, the contents of the directories `pg_dynshmem/`, `pg_notify/`, `pg_replslot/`, `pg_serial/`, `pg_snapshots/`, `pg_stat_tmp/`, and `pg_subtrans/` are omitted from the data copied from the source cluster. The files `backup_label`, `tablespace_map`, `pg_internal.init`, `postmaster.opts`, `postmaster.pid` and `.DS_Store` as well as any file or directory beginning with `pgsql_tmp`, are omitted.
4. Create a `backup_label` file to begin WAL replay at the checkpoint created at failover and configure the `pg_control` file with a minimum consistency LSN defined as the result of `pg_current_wal_insert_lsn()` when rewinding from a live source or the last checkpoint LSN when rewinding from a stopped source.
5. When starting the target, Postgres Pro replays all the required WAL, resulting in a data directory in a consistent state.

pg-setup

pg-setup — set up a new Postgres Pro database cluster and manage the corresponding service

Synopsis

```
pg-setup initdb [initdb_options]
```

```
pg-setup find-free-port
```

```
pg-setup set-server-port port
```

```
pg-setup set parameter value
```

```
pg-setup service service_option
```

Description

pg-setup is a shell script provided in the Postgres Pro distribution to automate database cluster setup on Linux systems. This script is provided as part of the `postgrespro-sdm-17-server` package. Once Postgres Pro is installed, you can find pg-setup in the `install-dir/bin` directory, where `install-dir` is `/opt/pgpro/sdm-17`.

pg-setup must be run as root, but performs database administration operations as user `postgres`. You can run this script with different options to:

- initialize the database cluster
- configure the database cluster for a specific Postgres Pro product
- check for available ports and change the port used by Postgres Pro server
- enable/disable automatic startup of Postgres Pro service
- start, stop, or restart Postgres Pro service

Options

pg-setup accepts the following command-line arguments:

```
initdb [initdb_options]
```

Initialize the database cluster on behalf of the `postgres` user.

By default, the database cluster, configured for your Postgres Pro distribution, is initialized in the `/var/lib/pgpro/sdm-17/data` directory, with checksums enabled, `auth-local` parameter set to `peer`, and `auth-host` parameter set to `md5`. Localization settings are inherited from the `LANG` environment variable for the current session. All the `LC_*` environment variables are ignored. Optionally, you can provide `initdb` options to customize the installation.

If the default database is created using pg-setup, the path to its data directory is stored in the `/etc/default/postgrespro-shardman-17` file, so all the subsequent pg-setup commands, as well as any commands that manage Postgres Pro service, affect this database only. You cannot manage several databases using pg-setup.

For systems where more than one database server and/or application will run, you may need to adjust the configuration since pg-setup chooses the configuration settings depending on hardware characteristics, assuming that the system will use only one database server.

```
find-free-port
```

Search for a free port on your system. This option is useful if you are going to install more than one server instance, or the default 5432 port is used by another program.

`set-server-port port`

Specify the port number on which the server will listen for connections. Use this option to avoid conflicts if you are installing more than one server instance on the same system.

Default: 5432

`set name value`

Set the specified configuration parameter to the provided *value* in the `postgresql.conf` file. If this parameter has been already defined by the `ALTER SYSTEM` command, its previous value is removed from the `postgresql.auto.conf` file.

`service service_option`

Manage Postgres Pro service using one of the following options:

- `enable` — enable automatic service startup upon system restart.
- `disable` — disable automatic service startup upon system restart.
- `start` — start the service.
- `stop` — stop the service.
- `condrestart` — restart the service if it is running when `pg-setup` is invoked.
- `status` — return the Postgres Pro service status.

Notes

If you are installing Postgres Pro from the `postgrespro-sdm-17` package, `pg-setup` is invoked automatically with the default settings. As a result, the database cluster is initialized and the default database is created in the `/var/lib/pgpro/sdm-17/data` directory, Postgres Pro service autostart is enabled, and the service is started.

If you are installing Postgres Pro server directly from the `postgrespro-sdm-17-server` package, you can run this script manually to initialize the database cluster or manage the Postgres Pro service.

For details on binary installation specifics on Linux, see [Section 17.1](#).

pg_test_fsync

`pg_test_fsync` — determine fastest `wal_sync_method` for Postgres Pro

Synopsis

```
pg_test_fsync [option...]
```

Description

`pg_test_fsync` is intended to give you a reasonable idea of what the fastest [wal_sync_method](#) is on your specific system, as well as supplying diagnostic information in the event of an identified I/O problem. However, differences shown by `pg_test_fsync` might not make any significant difference in real database throughput, especially since many database servers are not speed-limited by their write-ahead logs. `pg_test_fsync` reports average file sync operation time in microseconds for each `wal_sync_method`, which can also be used to inform efforts to optimize the value of [commit_delay](#).

Options

`pg_test_fsync` accepts the following command-line options:

- `-f`
`--filename`
Specifies the file name to write test data in. This file should be in the same file system that the `pg_wal` directory is or will be placed in. (`pg_wal` contains the WAL files.) The default is `pg_test_fsync.out` in the current directory.
- `-s`
`--secs-per-test`
Specifies the number of seconds for each test. The more time per test, the greater the test's accuracy, but the longer it takes to run. The default is 5 seconds, which allows the program to complete in under 2 minutes.
- `-V`
`--version`
Print the `pg_test_fsync` version and exit.
- `-?`
`--help`
Show help about `pg_test_fsync` command line arguments, and exit.

Environment

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

pg_test_timing

pg_test_timing — measure timing overhead

Synopsis

pg_test_timing [*option...*]

Description

pg_test_timing is a tool to measure the timing overhead on your system and confirm that the system time never moves backwards. Systems that are slow to collect timing data can give less accurate EXPLAIN ANALYZE results.

Options

pg_test_timing accepts the following command-line options:

-d *duration*

--duration=*duration*

Specifies the test duration, in seconds. Longer durations give slightly better accuracy, and are more likely to discover problems with the system clock moving backwards. The default test duration is 3 seconds.

-V

--version

Print the pg_test_timing version and exit.

-?

--help

Show help about pg_test_timing command line arguments, and exit.

Usage

Interpreting Results

Good results will show most (>90%) individual timing calls take less than one microsecond. Average per loop overhead will be even lower, below 100 nanoseconds. This example from an Intel i7-860 system using a TSC clock source shows excellent performance:

Testing timing overhead for 3 seconds.

Per loop time including overhead: 35.96 ns

Histogram of timing durations:

< us	% of total	count
1	96.40465	80435604
2	3.59518	2999652
4	0.00015	126
8	0.00002	13
16	0.00000	2

Note that different units are used for the per loop time than the histogram. The loop can have resolution within a few nanoseconds (ns), while the individual timing calls can only resolve down to one microsecond (us).

Measuring Executor Timing Overhead

When the query executor is running a statement using EXPLAIN ANALYZE, individual operations are timed as well as showing a summary. The overhead of your system can be checked by counting rows with the psql program:

```
CREATE TABLE t AS SELECT * FROM generate_series(1,100000);
\timing
SELECT COUNT(*) FROM t;
EXPLAIN ANALYZE SELECT COUNT(*) FROM t;
```

The i7-860 system measured runs the count query in 9.8 ms while the `EXPLAIN ANALYZE` version takes 16.6 ms, each processing just over 100,000 rows. That 6.8 ms difference means the timing overhead per row is 68 ns, about twice what `pg_test_timing` estimated it would be. Even that relatively small amount of overhead is making the fully timed count statement take almost 70% longer. On more substantial queries, the timing overhead would be less problematic.

Changing Time Sources

On some newer Linux systems, it's possible to change the clock source used to collect timing data at any time. A second example shows the slowdown possible from switching to the slower `acpi_pm` time source, on the same system used for the fast results above:

```
# cat /sys/devices/system/clocksource/clocksource0/available_clocksource
tsc hpet acpi_pm
# echo acpi_pm > /sys/devices/system/clocksource/clocksource0/current_clocksource
# pg_test_timing
Per loop time including overhead: 722.92 ns
Histogram of timing durations:
  < us    % of total    count
    1      27.84870    1155682
    2      72.05956    2990371
    4       0.07810     3241
    8       0.01357      563
   16       0.00007       3
```

In this configuration, the sample `EXPLAIN ANALYZE` above takes 115.9 ms. That's 1061 ns of timing overhead, again a small multiple of what's measured directly by this utility. That much timing overhead means the actual query itself is only taking a tiny fraction of the accounted for time, most of it is being consumed in overhead instead. In this configuration, any `EXPLAIN ANALYZE` totals involving many timed operations would be inflated significantly by timing overhead.

FreeBSD also allows changing the time source on the fly, and it logs information about the timer selected during boot:

```
# dmesg | grep "Timecounter"
Timecounter "ACPI-fast" frequency 3579545 Hz quality 900
Timecounter "i8254" frequency 1193182 Hz quality 0
Timecounters tick every 10.000 msec
Timecounter "TSC" frequency 2531787134 Hz quality 800
# sysctl kern.timecounter.hardware=TSC
kern.timecounter.hardware: ACPI-fast -> TSC
```

Other systems may only allow setting the time source on boot. On older Linux systems the "clock" kernel setting is the only way to make this sort of change. And even on some more recent ones, the only option you'll see for a clock source is "jiffies". Jiffies are the older Linux software clock implementation, which can have good resolution when it's backed by fast enough timing hardware, as in this example:

```
$ cat /sys/devices/system/clocksource/clocksource0/available_clocksource
jiffies
$ dmesg | grep time.c
time.c: Using 3.579545 MHz WALL PM GTOD PIT/TSC timer.
time.c: Detected 2400.153 MHz processor.
$ pg_test_timing
Testing timing overhead for 3 seconds.
Per timing duration including loop overhead: 97.75 ns
Histogram of timing durations:
```

< us	% of total	count
1	90.23734	27694571
2	9.75277	2993204
4	0.00981	3010
8	0.00007	22
16	0.00000	1
32	0.00000	1

Clock Hardware and Timing Accuracy

Collecting accurate timing information is normally done on computers using hardware clocks with various levels of accuracy. With some hardware the operating systems can pass the system clock time almost directly to programs. A system clock can also be derived from a chip that simply provides timing interrupts, periodic ticks at some known time interval. In either case, operating system kernels provide a clock source that hides these details. But the accuracy of that clock source and how quickly it can return results varies based on the underlying hardware.

Inaccurate time keeping can result in system instability. Test any change to the clock source very carefully. Operating system defaults are sometimes made to favor reliability over best accuracy. And if you are using a virtual machine, look into the recommended time sources compatible with it. Virtual hardware faces additional difficulties when emulating timers, and there are often per operating system settings suggested by vendors.

The Time Stamp Counter (TSC) clock source is the most accurate one available on current generation CPUs. It's the preferred way to track the system time when it's supported by the operating system and the TSC clock is reliable. There are several ways that TSC can fail to provide an accurate timing source, making it unreliable. Older systems can have a TSC clock that varies based on the CPU temperature, making it unusable for timing. Trying to use TSC on some older multicore CPUs can give a reported time that's inconsistent among multiple cores. This can result in the time going backwards, a problem this program checks for. And even the newest systems can fail to provide accurate TSC timing with very aggressive power saving configurations.

Newer operating systems may check for the known TSC problems and switch to a slower, more stable clock source when they are seen. If your system supports TSC time but doesn't default to that, it may be disabled for a good reason. And some operating systems may not detect all the possible problems correctly, or will allow using TSC even in situations where it's known to be inaccurate.

The High Precision Event Timer (HPET) is the preferred timer on systems where it's available and TSC is not accurate. The timer chip itself is programmable to allow up to 100 nanosecond resolution, but you may not see that much accuracy in your system clock.

Advanced Configuration and Power Interface (ACPI) provides a Power Management (PM) Timer, which Linux refers to as the `acpi_pm`. The clock derived from `acpi_pm` will at best provide 300 nanosecond resolution.

Timers used on older PC hardware include the 8254 Programmable Interval Timer (PIT), the real-time clock (RTC), the Advanced Programmable Interrupt Controller (APIC) timer, and the Cyclone timer. These timers aim for millisecond resolution.

[EXPLAIN](#)

pg_waldump

`pg_waldump` — display a human-readable rendering of the write-ahead log of a Postgres Pro database cluster

Synopsis

```
pg_waldump [option...] [timestamp-option...] [startseg [endseg]]
```

Description

`pg_waldump` displays the write-ahead log (WAL) and prints timestamps for WAL records. This utility is mainly useful for debugging or educational purposes.

This utility can only be run by the user who installed the server, because it requires read-only access to the data directory.

Options

The following command-line options control the location and format of the output:

startseg

Start reading at the specified WAL segment file. This implicitly determines the path in which files will be searched for, and the timeline to use.

endseg

Stop after reading the specified WAL segment file.

`-b`

`--bkp-details`

Output detailed information about backup blocks.

`-B block`

`--block=block`

Only display records that modify the given block. The relation must also be provided with `--relation` or `-R`.

`-e end`

`--end=end`

Stop reading at the specified WAL location, instead of reading to the end of the log stream.

`-f`

`--follow`

After reaching the end of valid WAL, keep polling once per second for new WAL to appear.

`-F fork`

`--fork=fork`

Only display records that modify blocks in the given fork. The valid values are `main` for the main fork, `fsm` for the free space map, `vm` for the visibility map, and `init` for the init fork.

`-n limit`

`--limit=limit`

Display the specified number of records, then stop.

`-p path`
`--path=path`

Specifies a directory to search for WAL segment files or a directory with a `pg_wal` subdirectory that contains such files. The default is to search in the current directory, the `pg_wal` subdirectory of the current directory, and the `pg_wal` subdirectory of `PGDATA`.

`-q`
`--quiet`

Do not print any output, except for errors. This option can be useful when you want to know whether a range of WAL records can be successfully parsed but don't care about the record contents.

`-r rmgr`
`--rmgr=rmgr`

Only display records generated by the specified resource manager. You can specify the option multiple times to select multiple resource managers. If `list` is passed as name, print a list of valid resource manager names, and exit.

Extensions may define custom resource managers, but `pg_waldump` does not load the extension module and therefore does not recognize custom resource managers by name. Instead, you can specify the custom resource managers as `custom###` where `###` is the three-digit resource manager ID. Names of this form will always be considered valid.

`-R tblspc/db/rel`
`--relation=tblspc/db/rel`

Only display records that modify blocks in the given relation. The relation is specified with tablespace OID, database OID, and relfilenode separated by slashes, for example `1234/12345/12345`. This is the same format used for relations in the program's output.

`-s start`
`--start=start`

WAL location at which to start reading. The default is to start reading the first valid WAL record found in the earliest file found.

`-t timeline`
`--timeline=timeline`

Timeline from which to read WAL records. The default is to use the value in `startseg`, if that is specified; otherwise, the default is 1. The value can be specified in decimal or hexadecimal, for example `17` or `0x11`.

`-V`
`--version`

Print the `pg_waldump` version and exit.

`-w`
`--fullpage`

Only display records that include full page images.

`-x xid`
`--xid=xid`

Only display records marked with the given transaction ID.

`-z`
`--stats[=record]`

Display summary statistics (number and size of records and full-page images) instead of individual records. Optionally generate statistics per-record instead of per-rmgr.

If `pg_waldump` is terminated by signal SIGINT (**Control+C**), the summary of the statistics computed is displayed up to the termination point. This operation is not supported on Windows.

`--save-fullpage=save_path`

Save full page images found in the WAL records to the `save_path` directory. The images saved are subject to the same filtering and limiting criteria as the records displayed.

The full page images are saved with the following file name format: `TIMELINE-LSN.RELTABLESPACE.DATOID.RELNODE.BLKNO_FORK`. The file names are composed of the following parts:

Component	Description
TIMELINE	The timeline of the WAL segment file where the record is located formatted as one 8-character hexadecimal number <code>%08X</code>
LSN	The LSN of the record with this image, formatted as two 8-character hexadecimal numbers <code>%08X-%08X</code>
RELTABLESPACE	tablespace OID of the block
DATOID	database OID of the block
RELNODE	filenode of the block
BLKNO	block number of the block
FORK	The name of the fork the full page image came from, such as <code>main</code> , <code>fsm</code> , <code>vm</code> , or <code>init</code> .

`-?`

`--help`

Show help about `pg_waldump` command line arguments, and exit.

The following command-line options enable printing timestamps for various types of WAL records. You can use these options together with `startseg`, `endseg`, `-s`, and `-e` options.

`-E`

`--end-timestamp`

Print the timestamp of the last WAL record of the specified type found in the log segment file. When using this option, you must also specify the `-s` option.

By default, `pg_waldump` prints timestamps only for COMMIT records. You can specify other record types using the `--timestamp-filter` option.

`-S`

`--start-timestamp`

Print the timestamp of the first WAL record of the specified type found in the log segment file. This option is required if you are going to use `-E` or `--timestamp-filter` options.

By default, `pg_waldump` prints timestamps only for COMMIT records. You can specify other record types using the `--timestamp-filter` option.

`--timestamp-filter=argument [, ...]`

Specify WAL record types for which to print timestamps. When using this option, you must also specify the `-s` option.

The `--timestamp-filter` option can take the following arguments, in the comma-separated format:

- `XLOG_RESTORE_POINT` — named restore points created with the `pg_create_restore_point()` function.

- `XLOG_XACT_COMMIT` — commit records for transactions. These records are caused by the [COMMIT](#) command.
- `XLOG_XACT_COMMIT_PREPARED` — commit records for transactions that were earlier prepared for a two-phase commit. These records are caused by the [COMMIT PREPARED](#) command.
- `XLOG_XACT_ABORT` — abort records for transactions. These records are caused by the [ROLLBACK](#) command.
- `XLOG_XACT_ABORT_PREPARED` — abort records for transactions that were earlier prepared for a two-phase commit. These records are caused by the [ROLLBACK PREPARED](#) command.

By default, `pg_waldump` prints timestamps only for COMMIT records.

Environment

`PGDATA`

Data directory; see also the `-p` option.

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

Can give wrong results when the server is running.

Only the specified timeline is displayed (or the default, if none is specified). Records in other timelines are ignored.

`pg_waldump` cannot read WAL files with suffix `.partial`. If those files need to be read, `.partial` suffix needs to be removed from the file name.

[Section 28.7](#)

pg_walsummary

pg_walsummary — print contents of WAL summary files

Synopsis

```
pg_walsummary [option...] [file...]
```

Description

pg_walsummary is used to print the contents of WAL summary files. These binary files are found with the `pg_wal/summaries` subdirectory of the data directory, and can be converted to text using this tool. This is not ordinarily necessary, since WAL summary files primarily exist to support incremental backup, but it may be useful for debugging purposes.

A WAL summary file is indexed by tablespace OID, relation OID, and relation fork. For each relation fork, it stores the list of blocks that were modified by WAL within the range summarized in the file. It can also store a "limit block," which is 0 if the relation fork was created or truncated within the relevant WAL range, and otherwise the shortest length to which the relation fork was truncated. If the relation fork was not created, deleted, or truncated within the relevant WAL range, the limit block is undefined or infinite and will not be printed by this tool.

Options

```
-i  
--individual
```

By default, `pg_walsummary` prints one line of output for each range of one or more consecutive modified blocks. This can make the output a lot briefer, since a relation where all blocks from 0 through 999 were modified will produce only one line of output rather than 1000 separate lines. This option requests a separate line of output for every modified block.

```
-q  
--quiet
```

Do not print any output, except for errors. This can be useful when you want to know whether a WAL summary file can be successfully parsed but don't care about the contents.

```
-V  
--version
```

Display version information, then exit.

```
-?  
--help
```

Shows help about `pg_walsummary` command line arguments, and exits.

Environment

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

postgres

postgres — Postgres Pro database server

Synopsis

postgres [*option...*]

Description

postgres is the Postgres Pro database server. In order for a client application to access a database it connects (over a network or locally) to a running postgres instance. The postgres instance then starts a separate server process to handle the connection.

One postgres instance always manages the data of exactly one database cluster. A database cluster is a collection of databases that is stored at a common file system location (the “data area”). More than one postgres instance can run on a system at one time, so long as they use different data areas and different communication ports (see below). When postgres starts it needs to know the location of the data area. The location must be specified by the `-D` option or the `PGDATA` environment variable; there is no default. Typically, `-D` or `PGDATA` points directly to the data area directory created by [initdb](#). Other possible file layouts are discussed in [Section 19.2](#).

By default postgres starts in the foreground and prints log messages to the standard error stream. In practical applications postgres should be started as a background process, perhaps at boot time.

The postgres command can also be called in single-user mode. The primary use for this mode is during bootstrapping by [initdb](#). Sometimes it is used for debugging or disaster recovery; note that running a single-user server is not truly suitable for debugging the server, since no realistic interprocess communication and locking will happen. When invoked in single-user mode from the shell, the user can enter queries and the results will be printed to the screen, but in a form that is more useful for developers than end users. In the single-user mode, the session user will be set to the user with ID 1, and implicit superuser powers are granted to this user. This user does not actually have to exist, so the single-user mode can be used to manually recover from certain kinds of accidental damage to the system catalogs.

Options

postgres accepts the following command-line arguments. For a detailed discussion of the options consult [Chapter 19](#). You can save typing most of these options by setting up a configuration file. Some (safe) options can also be set from the connecting client in an application-dependent way to apply only for that session. For example, if the environment variable `PGOPTIONS` is set, then libpq-based clients will pass that string to the server, which will interpret it as postgres command-line options.

General Purpose

`-B nbuffers`

Sets the number of shared buffers for use by the server processes. The default value of this parameter is chosen automatically by [initdb](#). Specifying this option is equivalent to setting the [shared_buffers](#) configuration parameter.

`-c name=value`

Sets a named run-time parameter. The configuration parameters supported by Postgres Pro are described in [Chapter 19](#). Most of the other command line options are in fact short forms of such a parameter assignment. `-c` can appear multiple times to set multiple parameters.

`-C name`

Prints the value of the named run-time parameter, and exits. (See the `-c` option above for details.) This returns values from `postgresql.conf`, modified by any parameters supplied in this invocation. It does not reflect parameters supplied when the cluster was started.

This can be used on a running server for most parameters. However, the server must be shut down for some runtime-computed parameters (e.g., [shared_memory_size](#), [shared_memory_size_in_huge_pages](#), and [wal_segment_size](#)).

This option is meant for other programs that interact with a server instance, such as [pg_ctl](#), to query configuration parameter values. User-facing applications should instead use [SHOW](#) or the `pg_settings` view.

`-d debug-level`

Sets the debug level. The higher this value is set, the more debugging output is written to the server log. Values are from 1 to 5. It is also possible to pass `-d 0` for a specific session, which will prevent the server log level of the parent `postgres` process from being propagated to this session.

`-D datadir`

Specifies the file system location of the database configuration files. See [Section 19.2](#) for details.

`-e`

Sets the default date style to “European”, that is `DMY` ordering of input date fields. This also causes the day to be printed before the month in certain date output formats. See [Section 8.5](#) for more information.

`-F`

Disables `fsync` calls for improved performance, at the risk of data corruption in the event of a system crash. Specifying this option is equivalent to disabling the [fsync](#) configuration parameter. Read the detailed documentation before using this!

`-h hostname`

Specifies the IP host name or address on which `postgres` is to listen for TCP/IP connections from client applications. The value can also be a comma-separated list of addresses, or `*` to specify listening on all available interfaces. An empty value specifies not listening on any IP addresses, in which case only Unix-domain sockets can be used to connect to the server. Defaults to listening only on localhost. Specifying this option is equivalent to setting the [listen_addresses](#) configuration parameter.

`-i`

Allows remote clients to connect via TCP/IP (Internet domain) connections. Without this option, only local connections are accepted. This option is equivalent to setting `listen_addresses` to `*` in `postgresql.conf` or via `-h`.

This option is deprecated since it does not allow access to the full functionality of [listen_addresses](#). It's usually better to set `listen_addresses` directly.

`-k directory`

Specifies the directory of the Unix-domain socket on which `postgres` is to listen for connections from client applications. The value can also be a comma-separated list of directories. An empty value specifies not listening on any Unix-domain sockets, in which case only TCP/IP sockets can be used to connect to the server. The default value is normally `/tmp`, but that can be changed at build time. Specifying this option is equivalent to setting the [unix_socket_directories](#) configuration parameter.

`-l`

Enables secure connections using SSL. Postgres Pro must have been compiled with support for SSL for this option to be available. For more information on using SSL, refer to [Section 18.9](#).

`-N max-connections`

Sets the maximum number of client connections that this server will accept. The default value of this parameter is chosen automatically by `initdb`. Specifying this option is equivalent to setting the [max_connections](#) configuration parameter.

`-p port`

Specifies the TCP/IP port or local Unix domain socket file extension on which `postgres` is to listen for connections from client applications. Defaults to the value of the `PGPORT` environment variable, or if `PGPORT` is not set, then defaults to the value established during compilation (normally 5432). If you specify a port other than the default port, then all client applications must specify the same port using either command-line options or `PGPORT`.

`-s`

Print time information and other statistics at the end of each command. This is useful for benchmarking or for use in tuning the number of buffers.

`-S work-mem`

Specifies the base amount of memory to be used by sorts and hash tables before resorting to temporary disk files. See the description of the `work_mem` configuration parameter in [Section 19.4.1](#).

`-V`

`--version`

Print the postgres version and exit.

`--name=value`

Sets a named run-time parameter; a shorter form of `-c`.

`--describe-config`

This option dumps out the server's internal configuration variables, descriptions, and defaults in tab-delimited `COPY` format. It is designed primarily for use by administration tools.

`-?`

`--help`

Show help about postgres command line arguments, and exit.

Semi-Internal Options

The options described here are used mainly for debugging purposes, and in some cases to assist with recovery of severely damaged databases. There should be no reason to use them in a production database setup. They are listed here only for use by Postgres Pro system developers. Furthermore, these options might change or be removed in a future release without notice.

`-f { s | i | o | b | t | n | m | h }`

Forbids the use of particular scan and join methods: `s` and `i` disable sequential and index scans respectively, `o`, `b` and `t` disable index-only scans, bitmap index scans, and TID scans respectively, while `n`, `m`, and `h` disable nested-loop, merge and hash joins respectively.

Neither sequential scans nor nested-loop joins can be disabled completely; the `-fs` and `-fn` options simply discourage the optimizer from using those plan types if it has any other alternative.

`-O`

Allows the structure of system tables to be modified. This is used by `initdb`.

`-P`

Ignore system indexes when reading system tables, but still update the indexes when modifying the tables. This is useful when recovering from damaged system indexes.

`-t pa[rser] | pl[anner] | e[xecutor]`

Print timing statistics for each query relating to each of the major system modules. This option cannot be used together with the `-s` option.

-T

This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate, by sending them SIGQUIT signals. With this option, SIGABRT will be sent instead, resulting in production of core dump files.

-v *protocol*

Specifies the version number of the frontend/backend protocol to be used for a particular session. This option is for internal use only.

-W *seconds*

A delay of this many seconds occurs when a new server process is started, after it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger.

-Z

Verifies that the current postgres binary is compatible with the specified cluster. If the architecture type or any compilation options that affect cluster compatibility do not match, returns an exit status of 1 and provides an error message specifying the first detected incompatibility. Otherwise, reports success and exits without starting the cluster.

You must provide the path to the data directory of the cluster to check.

The cluster and the binary must have the same byte order and architecture type for this option to work correctly.

Tip

If the binary appears to be incompatible with the specified cluster, run [pgpro_controldata](#) with the `-P` or `-C` command-line argument to view all parameters of the cluster that affect the compatibility.

Options for Single-User Mode

The following options only apply to the single-user mode (see [Single-User Mode](#) below).

--single

Selects the single-user mode. This must be the first argument on the command line.

database

Specifies the name of the database to be accessed. This must be the last argument on the command line. If it is omitted it defaults to the user name.

-E

Echo all commands to standard output before executing them.

-j

Use semicolon followed by two newlines, rather than just newline, as the command entry terminator.

-r *filename*

Send all server log output to *filename*. This option is only honored when supplied as a command-line option.

Environment

PGCLIENTENCODING

Default character encoding used by clients. (The clients can override this individually.) This value can also be set in the configuration file.

PGDATA

Default data directory location

PGDATESTYLE

Default value of the [DateStyle](#) run-time parameter. (The use of this environment variable is deprecated.)

PGPORT

Default port number (preferably set in the configuration file)

Diagnostics

A failure message mentioning `semget` or `shmget` probably indicates you need to configure your kernel to provide adequate shared memory and semaphores. For more discussion see [Section 18.4](#). You might be able to postpone reconfiguring your kernel by decreasing [shared_buffers](#) to reduce the shared memory consumption of Postgres Pro, and/or by reducing [max_connections](#) to reduce the semaphore consumption.

A failure message suggesting that another server is already running should be checked carefully, for example by using the command

```
$ ps ax | grep postgres
```

or

```
$ ps -ef | grep postgres
```

depending on your system. If you are certain that no conflicting server is running, you can remove the lock file mentioned in the message and try again.

A failure message indicating inability to bind to a port might indicate that that port is already in use by some non-Postgres Pro process. You might also get this error if you terminate `postgres` and immediately restart it using the same port; in this case, you must simply wait a few seconds until the operating system closes the port before trying again. Finally, you might get this error if you specify a port number that your operating system considers to be reserved. For example, many versions of Unix consider port numbers under 1024 to be “trusted” and only permit the Unix superuser to access them.

Notes

The utility command [pg_ctl](#) can be used to start and shut down the `postgres` server safely and comfortably.

If at all possible, *do not* use `SIGKILL` to kill the main `postgres` server. Doing so will prevent `postgres` from freeing the system resources (e.g., shared memory and semaphores) that it holds before terminating. This might cause problems for starting a fresh `postgres` run.

To terminate the `postgres` server normally, the signals `SIGTERM`, `SIGINT`, or `SIGQUIT` can be used. The first will wait for all clients to terminate before quitting, the second will forcefully disconnect all clients, and the third will quit immediately without proper shutdown, resulting in a recovery run during restart.

The `SIGHUP` signal will reload the server configuration files. It is also possible to send `SIGHUP` to an individual server process, but that is usually not sensible.

To cancel a running query, send the `SIGINT` signal to the process running that command. To terminate a backend process cleanly, send `SIGTERM` to that process. See also `pg_cancel_backend` and `pg_terminate_backend` in [Section 9.28.2](#) for the SQL-callable equivalents of these two actions.

The `postgres` server uses `SIGQUIT` to tell subordinate server processes to terminate without normal cleanup. This signal *should not* be used by users. It is also unwise to send `SIGKILL` to a server process — the main `postgres` process will interpret this as a crash and will force all the sibling processes to quit as part of its standard crash-recovery procedure.

Bugs

The `--` options will not work on FreeBSD or OpenBSD. Use `-c` instead. This is a bug in the affected operating systems; a future release of Postgres Pro will provide a workaround if this is not fixed.

Single-User Mode

To start a single-user mode server, use a command like

```
postgres --single -D /usr/local/pgsql/data other-options my_database
```

Provide the correct path to the database directory with `-D`, or make sure that the environment variable `PGDATA` is set. Also specify the name of the particular database you want to work in.

Normally, the single-user mode server treats newline as the command entry terminator; there is no intelligence about semicolons, as there is in `psql`. To continue a command across multiple lines, you must type backslash just before each newline except the last one. The backslash and adjacent newline are both dropped from the input command. Note that this will happen even when within a string literal or comment.

But if you use the `-j` command line switch, a single newline does not terminate command entry; instead, the sequence semicolon-newline-newline does. That is, type a semicolon immediately followed by a completely empty line. Backslash-newline is not treated specially in this mode. Again, there is no intelligence about such a sequence appearing within a string literal or comment.

In either input mode, if you type a semicolon that is not just before or part of a command entry terminator, it is considered a command separator. When you do type a command entry terminator, the multiple statements you've entered will be executed as a single transaction.

To quit the session, type EOF (**Control+D**, usually). If you've entered any text since the last command entry terminator, then EOF will be taken as a command entry terminator, and another EOF will be needed to exit.

Note that the single-user mode server does not provide sophisticated line-editing features (no command history, for example). Single-user mode also does not do any background processing, such as automatic checkpoints or replication.

Examples

To start `postgres` in the background using default values, type:

```
$ nohup postgres >logfile 2>&1 </dev/null &
```

To start `postgres` with a specific port, e.g., 1234:

```
$ postgres -p 1234
```

To connect to this server using `psql`, specify this port with the `-p` option:

```
$ psql -p 1234
```

or set the environment variable `PGPORT`:

```
$ export PGPORT=1234
$ psql
```

Named run-time parameters can be set in either of these styles:

```
$ postgres -c work_mem=1234  
$ postgres --work-mem=1234
```

Either form overrides whatever setting might exist for `work_mem` in `postgresql.conf`. Notice that underscores in parameter names can be written as either underscore or dash on the command line. Except for short-term experiments, it's probably better practice to edit the setting in `postgresql.conf` than to rely on a command-line switch to set a parameter.

Description

shardmanctl is an utility for managing a Shardman cluster.

For any command that uses the node name as an argument, the node name can be specified either by its hostname or IP address.

The `backup` command is used to backup a Postgres Pro Shardman cluster. A backup consists of a directory with base backups of all replication groups and WAL files needed for recovery. etcd metadata is saved to the `etcd_dump` file. The `backup_info` file is created during a backup and contains the backup description.

The `cleanup` command is used for cleanup after failure of the `nodes add` command or of the [shardmanctl rebalance](#) command. Final changes to the etcd store are done at the end of the command execution. This simplifies the `cleanup` process. During cleanup, incomplete clover definitions and definitions of the corresponding replication groups are removed from the etcd metadata. Definitions of the corresponding foreign servers are removed from the DBMS metadata of the remaining replication groups. Since the `cleanup` process can be destructive, by default, the tool operates in the report-only mode: it only shows actions to be done during the actual cleanup. To perform the actual cleanup, add the `-p` flag. For usage details of the command, see [the section called “Performing Cleanup”](#).

The `daemon check` command is used to verify that shardmand daemon is running on the nodes specified by `--nodes` option and is configured for the same cluster as `shardmanctl`. For usage details of the command, see [the section called “Checking shardmand Service on Nodes”](#).

The `init` command is used to register a new Postgres Pro Shardman cluster in the etcd store or to reinitialize the existing cluster defining a new cluster configuration and removing all data and nodes. In the `init` mode, `shardmanctl` reads the cluster specification, processes it and saves to the etcd store as parts of two JSON documents: `ClusterSpec` — as part of `shardman/cluster0/data/cluster` and `LadleSpec` — as part of `shardman/cluster0/data/ladle` (`cluster0` is the default cluster name used by Postgres Pro Shardman utilities). Common options related to the etcd store, such as `--store-endpoints`, are also saved to the etcd store and pushed down to all Postgres Pro Shardman services started by `shardmand`. For the description of the Postgres Pro Shardman initialization file format, see [Section 19.21.2](#). For usage details of the command, see [the section called “Registering a Postgres Pro Shardman Cluster”](#).

The `config generate` command is used to create a default `sdmspec.json` template. By default, data is returned to the standard output. To write the result to a file, use flag `-f filename`. For the description of the Shardman initialization file format, see [Section 19.21.2](#).

The `config verify` command is used to check a correctness of the input Postgres Pro Shardman initialization file. By default, the configuration is read from standard input. To read the configuration from a file, use flag `-f filename`. For the description of the Postgres Pro Shardman initialization file format, see [Section 19.21.2](#).

The `config get` command is used to output the current full cluster specification or a configuration of the specified revision. The command takes the current cluster configuration from the cluster store. For the description of the Postgres Pro Shardman initialization file format, see [Section 19.21.2](#).

The `config update` command is used to update the BiHA cluster or full Postgres Pro Shardman configuration. The new configuration is applied to all replication groups and is saved in `shardman/cluster0/data/cluster` etcd key. Note that `config update` can cause a DBMS restart.

The `forall` command is used to execute an SQL statement on all replication groups in a Postgres Pro Shardman cluster.

The `getconnstr` command is used to get the libpq connection string for connecting to a cluster as administrator.

The `load` command is used to upload data from a text file to a distributed table or to upload a database schema from a PostgreSQL database to Postgres Pro Shardman. When loading data from a file, `text` and `csv` formats are supported. If a file is compressed with `gzip`, it will be automatically decoded while reading. To read data from `stdin`, specify `--file=-`. The data loading process can be optimized by specifying the number of parallel workers (`key -j`).

The `nodes add` command is used to add new nodes to a Shardman cluster. With the default `cross` placement policy, nodes are added to a cluster by `clovers`. Each node in a clover runs the primary DBMS instance and perhaps several replicas of other nodes in the clover. The number of replicas is determined by the [Repfactor](#) configuration parameter. So, each clover consists of `Repfactor + 1` nodes and can stand loss of `Repfactor` nodes.

With `manual` placement policy, each new node is added as a replication group consisting of one primary server. After adding primary nodes, you can add replicas to the new replication group by calling the `shard add` command.

`shardmanctl` performs the `nodes add` operation in several steps:

1. Acquires a global metadata lock.
2. For each specified node, checks that Postgres Pro Shardman is running on it and that it sees the current cluster configuration.

3. Calculates the services to be present on each node and saves this information in etcd as part of the `shardman/cluster0/data/ladle Layout` object.
4. Generates the configuration for new BiHA clusters (also called *replication groups*) and initializes them.
5. Registers the added replication groups in the `shardman/cluster0/data/ladle etcd` key.
6. Waits for shardmand to start all the necessary services, checks that new replication groups are accessible and have correct configuration.
7. Creates an auxiliary broadcaster that holds locks on each existing replication group in the cluster.
8. For each new replication group, copies all schemas and `shardman` schema data from a randomly selected existing replication group to the new one, ensures that the Postgres Pro Shardman extension is installed on the new replication group, and recalculates OIDs used in the extension configuration tables.
9. On each existing replication group, defines foreign servers referencing the new replication group and recreates definitions of foreign servers on the new replication group.
10. Recreates all partitions of sharded tables as foreign tables referencing data from old replication groups and has the changes registered in the etcd storage.
11. For each new replication group, copies the global table data from existing replication groups to the new one.
12. Rebalances partitions of sharded tables. The rebalancing process for each sharded table iteratively determines the replication group with the maximum and minimum number of partitions and creates a task to move one partition to the replication group with the minimum number of partitions. This process is repeated while `max - min > 1`. To move partitions, we use logical replication. Partitions of colocated tables are moved together with partitions of the distributed tables to which they refer. You can skip this step using the `--no-rebalance`.

For usage details of the command, see [the section called “Adding Nodes to a Postgres Pro Shardman Cluster”](#).

The `nodes rm` command is used to remove nodes from a Shardman cluster. In the manual-topology mode, this command only removes the specified nodes from the cluster and if a node is the last in the replication group, the entire group gets removed. In the cross-replication mode, this command removes clovers containing the specified nodes from the cluster. The last clover in the cluster cannot be removed. Any data (such as partitions of sharded relations) on removed replication groups is migrated to the remaining replication groups using logical replication, and all references to the removed replication groups (including definitions of foreign servers) are removed from the metadata of the remaining replication groups. Finally, the metadata in etcd is updated. For usage details of the command, see [the section called “Removing Nodes from a Postgres Pro Shardman cluster”](#).

The `probackup` command is used to backup and restore the Shardman cluster using `pg_probackup` backup utility. For usage details of the command, see [the section called “probackup Command”](#).

The `rebalance` command is used to evenly rebalance sharded tables in a cluster. This can be useful, for example, if you did not perform rebalance when adding nodes to the cluster. If the `--force` option is not provided, then tables with manually moved partitions will be skipped.

The `cleanup` command with flag `--after-rebalance` is used to perform cleanup after failure of a `rebalance` command. On each node, it cleans up subscriptions and publications left from the `rebalance` command and drops tables that store data of partially-transferred partitions of sharded tables.

The `cluster repfactor set` command is used to set the value of the replication factor for the Postgres Pro Shardman cluster. This command can only be used in `manual` topology cluster mode. The value of the new replication factor is passed through the command line flag `--value repfactor`.

The `cluster start` command is used to start all stopped PostgreSQL instances with the `cluster stop` command. For the command to work, `shardmand` must be running.

The `cluster stop` command is used to stop all PostgreSQL instances for the Postgres Pro Shardman cluster. At the same time, the shardmand daemons continue to work.

The `cluster topology` command is used to visualize the topology of a cluster. By default, the topology is returned in a table view. If you want to get a JSON or text representation, then use the flag `--format json|text`.

The `recover` command is used to restore a Postgres Pro Shardman cluster from a backup created by the `backup` command.

The `restart` command is used to restart a Postgres Pro Shardman cluster, including all shardmand instances. If PostgreSQL instances were previously stopped using the `cluster stop` command, they will be started. The command returns control after all primary nodes in the cluster have been restarted.

The `set` command is used to set one or more parameters for DBMS instances of the Postgres Pro Shardman cluster. Parameters are passed as arguments to the command line, each of them looks like `param=value`. The command is actually an alternative to `shardmanctl config update -p` to update database settings.

The `status` command is used to display health status of Postgres Pro Shardman cluster subsystems. It can show status of several components: store, metadata, shardmand, replication groups, primary nodes, dictionary, status from `biha.status_v`, and restart of the required parameters. If only some subsystems are of interest, option `--filter` may be used. Also `status` supports sorting its messages by `status`, `node` or `replication group` and printing the result to stdout as a table (`table`), text (`text`) or JSON (`json`) with `table` as the default. For usage details of the command, see [the section called “Getting the Status of Cluster Subsystems”](#).

The `store dump` command gets all the keys and their values from the etcd store and outputs them into the `--file`, where `-` value is used for outputting to stdout (default). It is intended to be used for debugging, so some harmless errors may be produced during execution, yet all the available information will be dumped. Only keys for the current cluster (with current cluster prefix like `shardman/cluster0/`) will be dumped. For usage details of the command, see [the section called “Dumping All Keys from the Store to Debug Error Configuration”](#).

The `store get` command gets a particular value from the store by its key name. It is expected to be a JSON value, so if it is not (which is not prohibited), some harmless errors may be produced. The key to retrieve from store can be specified with `--key` option; several keys have *aliases* — short names for easy use. To get a key by its alias, use `--alias` option with one of the available aliases (use `--help` or examples below for reference). Also aliases `shardspec` and `spec` can be used to manipulate initial cluster and BiHA configuration explicitly, without retrieving it from the full cluster specification. It is recommended to use existing aliases instead of full key names since there are some additional checks in alias processing, which help to achieve safer results. By default, a key is printed to stdout (explicitly — with `--file=-` option), but can be output to any desired file. For usage details of the command, see [the section called “Getting the Current Shard Specification”](#).

The `store keys` command shows all the keys in the store for the current cluster (with cluster prefix) and its aliases. Aliases `shardspec` and `spec` are not shown since they are parts of other keys. For usage details of the command, see [the section called “Getting the Cluster and Ladle Key Names For the Current Cluster”](#).

The `store set` command creates or rewrites one particular key in the store. It is not expected to be a JSON value for a random key, but if it is one of the keys that have aliases with a known mapping (like `ladle` or `cluster`), the command will not accept incorrect JSON structures. Just like `store get` command, `store set` accepts a key name via `--key` or `--alias` option and the input source file as `--file` (stdin is specified with `-` value). For usage details of the command, see [the section called “Setting a New Spec for the Cluster”](#).

The `store lock` command shows the current cluster meta lock information. In case lock does not exist returns `Lock not found`. Displays cluster id, command that acquired locks, host name and lock time.

You can specify `--format` to output in `json` format or in `text` format (by default). For usage details of the command, see [the section called “Output Current Cluster Meta Lock Information”](#).

The `upgrade` command is used to update the version of Postgresql shardman extension on all cluster nodes. Before upgrading extensions, you need to install new packages and run the `restart` command. As a result of `upgrade`, utilities will upgrade shardman and all the other extensions on the server.

Sometimes after running the `upgrade` command or some user's manual manipulations, dictionary errors may appear in the output of the `status` command. One of the reasons for these errors is that the value of the `srvoptions` field of the `pg_foreign_server` table differs from what the system expects. To solve this specific issue, use the `config update fdw` command, which will return `srvoptions` to the expected state.

Note

Most of the described `shardmanctl` commands take a global metadata lock.

Backup and Restore-related Commands

backup Command

To backup a Postgres Pro Shardman cluster, you can run the following command:

```
shardmanctl [common_options] backup --datadir directory [--use-ssh]
```

You must pass the directory to write the output to through the `--datadir` option. You can limit the number of running concurrent tasks (`pg_receivewal` or `pg_basebackup` commands) by passing the limit through the `--maxtasks` option.

If `--use-ssh` is specified [shardmanctl recover](#) command will use `scp` command to restore data. It allows to use backup repository on the local host.

probackup Command

Syntax:

```
shardmanctl [common_options] probackup
    [init|archive-command|backup|checkdb|delete|merge|restore|set-config|show|
validate|show-config]
    [--log-to-console] [--help]
    [subcommand_options]
```

Creates a backup of a Shardman cluster and restores the Postgres Pro Shardman cluster from a backup using `pg_probackup`.

List of subcommands:

`init`

Initializes a new repository folder for the Postgres Pro Shardman cluster backup and creates a configuration file on all nodes for connection to the backup storage if `--storage-type` is `S3`.

`archive-command`

Adds `archive_command` to each replication group (or to a single one if the `--shard` option is specified) and enables or disables it in the Postgres Pro Shardman cluster.

`backup`

Creates a backup of the Postgres Pro Shardman cluster.

checkdb

Verifies the Postgres Pro Shardman cluster correctness by detecting physical and logical corruption.

delete

Deletes a backup of the Postgres Pro Shardman cluster with the specified `backup_id`.

merge

Merges the backups that belong to a common incremental backup chain. The full backup merges the backups with their first incremental backup. The incremental backup merges the backups with their parent full backup, along with all the incremental backups between them. Once the merge is complete, the full backup covers all the merged data, and the incremental backups are removed as redundant. In this version, you cannot run the `merge` command using the S3 interface.

restore

Restores the Postgres Pro Shardman cluster from the selected backup.

show

Shows the list of backups of the Postgres Pro Shardman cluster.

validate

Checks the selected Postgres Pro Shardman cluster backup for integrity.

show-config

Displays all the current `pg_probackup` configuration settings, including those that are specified in the `pg_probackup.conf` configuration file located in the `backup_dir/backups/shard_name` directory and those that were provided on a command line.

set-config

Adds the specified settings to the `pg_probackup.conf` or modifies those previously added.

The following options can be used with all `probackup` subcommands:

--log-to-console

Outputs a full `probackup` log to the console. By default, for each replication group the `probackup` log file is written to the backup directory (see `--backup-path` below) as the `<backup-directory>/backup/log/pg_probackup-<repgroup-name>.log` file. The log rotation file size is 20MB. If this value is reached, the log file is rotated once a `shardmanctl probackup validate` or `shardmanctl probackup backup` command is launched.

--help

Shows subcommand help.

init**Syntax:**

```
shardmanctl [common_options] probackup init
-B|--backup-path path
-E|--etcd-path path
[--remote-port port]
[--remote-user username]
[--ssh-key path]
[-t|--timeout seconds]
[-m|--maxtasks number_of_tasks]
[--storage-type mount|remote|S3]
[--s3-config-only]
```

```
[--s3-config-path path]  
[--s3-host S3_host]  
[--s3-port S3_port]  
[--s3-access-key S3_access_key]  
[--s3-secret-key S3_secret_key]  
[--s3-bucket S3_bucket]  
[--s3-region S3_region]  
[--s3-buffer-size size]  
[--s3-retries number_of_retries]  
[--s3-timeout time]  
[--s3-https]  
[-y|--yes]
```

Initializes a new repository folder for the Postgres Pro Shardman cluster backup.

```
-B path  
--backup-path path
```

Required if `--s3-config-only` is not used. Specifies the path to the backup catalog where Postgres Pro Shardman cluster backups should be stored.

```
-E path  
--etcd-path path
```

Required if `--s3-config-only` is not used. Specifies the path to the catalog where the etcd dumps should be stored.

```
--remote-port port
```

Specifies the remote ssh port for replication group instances.

Default: 22.

```
--remote-user username
```

Specifies the remote ssh user for replication group instances.

Default: postgres.

```
--ssh-key path
```

Specifies the ssh private key for execution of remote ssh commands.

Default: `$HOME/.ssh/id_rsa`.

```
--storage-type mount|remote|S3
```

Type of the backup storage. If the value is `remote`, SSH is used to copy data files to the remote backup directory. But this behavior is different if a directory mounted to all nodes or an S3-compatible object storage is used to store backups. To specify these kinds of storage, the value of the `--storage-type` option is set to `mount` or `S3`, respectively.

Default: `remote`.

```
--s3-config-path path
```

Specifies the path where the S3 configuration file will be created on all Postgres Pro Shardman nodes.

Default: `<shardman-data-dir>/s3.config`.

```
--s3-config-only
```

Create only S3 configuration files on all nodes and skip backup repository initialization. This flag is useful if the value of `--storage-type` is `S3`.

`--s3-host host`

Specifies the S3 host to connect to S3-compatible storage.

`--s3-port port`

Specifies the S3 port to connect to S3-compatible storage.

`--s3-access-key access-key`

Specifies the S3 access key to connect to S3-compatible storage.

`--s3-secret-key access-key`

Specifies the S3 secret key to connect to the S3-compatible storage.

`--s3-bucket bucket`

Specifies the bucket in the S3-compatible object storage for storing backups.

`--s3-region bucket`

Specifies the region in the S3-compatible object storage.

`--s3-buffer-size size`

Size of the read/write buffer for `pg_probackup` to communicate with the S3-compatible object storage, in MiB.

Default: 16.

`--s3-retries number_of_retries`

Maximum number of attempts for `pg_probackup` to execute an S3 request in case of failures.

Default: 5.

`--s3-timeout time`

Maximum allowable amount of time for `pg_probackup` to transfer data of size `--s3-buffer-size` to/from the S3-compatible object storage, in seconds.

Default: 300.

`--s3-https`

Specifies the HTTPS URL to connect to the S3-compatible object storage.

`-y|--yes`

Approve the operation regardless of whether the file specified in `--s3-config-path` exists.

archive-command

Syntax:

```
shardmanctl [common_options] probackup archive-command [add|rm]  
  -B|--backup-path path  
  [-j|--jobs count]  
  [--compress]  
  [--compress-algorithm algorithm]  
  [--compress-level level]  
  [--batch-size batch_size]  
  [--storage-type mount|remote|S3]  
  [--remote-port port]  
  [--remote-user username]  
  [-s|--shard shard-name]
```

```
[--s3-config-path path]  
[-y|--yes]
```

Adds/removes and enables/disables the archive command for every replication group in the Postgres Pro Shardman cluster to put WAL logs into the initialized backup repository.

add

Adds and enables the `archive` command for every replication group in the Postgres Pro Shardman cluster.

rm

Disables the `archive` command in every replication group in the Postgres Pro Shardman cluster. No additional options are required.

-B *path*

--backup-path *path*

Required when adding `archive_command`. Specifies the path to the backup catalog where the Postgres Pro Shardman cluster backups should be stored.

--batch-size *batch_size*

To speed up the archiving, specify the `--batch-size` option to copy the WAL segments in batches of a specified size. If the `--batch-size` option is used, it is also possible to specify the `-j` option to copy a batch of the WAL segments on multiple threads.

--jobs *count*

-j *count*

The number of parallel threads that `pg_probackup` uses when creating a backup. Default: 1.

--compress

Enables backup compression. If this flag is not specified, compression will be disabled. If the flag is specified, the default `zstd` algorithm is used with the compression level set to 1, while other compression options are ignored even if they are specified.

--compress-algorithm *algorithm*

Defines the compression algorithm: `zlib`, `lz4`, `zstd`, `pglz`, or `none`. Once defined, it checks if the values are valid within the scale of the defined algorithm.

The supported compression algorithms depend on the version of Postgres Pro Shardman that includes the `pg_probackup` used, as explained in [Compression Options](#).

Default: `none`.

--compress-level *level*

Defines the compression level — 0-9 for `zlib`, 1 for `pglz`, 0-22 for `zstd`, and 0-12 for `lz4`.

Default: 1.

--storage-type `mount|remote|S3`

Type of the backup storage. If the value is `remote`, SSH is used to copy data files to the remote backup directory. But this behavior is different if a directory mounted to all nodes or an S3-compatible object storage is used to store backups. To specify these kinds of storage, the value of the `--storage-type` option is set to `mount` or `S3`, respectively.

Default: `remote`.

`--remote-port port`

Specifies the remote ssh port for replication group instances.

Default: 22.

`--remote-user username`

Specifies the remote ssh user for replication group instances.

Default: postgres.

`-s|--shard shard-name`

Specifies the name of the shard where the `archive` command must be added, enabled or disabled. If not specified, the `archive` command is enabled or disabled for every shard.

`--s3-config-path path`

Specifies the path to the S3 configuration file.

Default: <shardman-data-dir>/s3.config.

`-y`

`--yes`

Confirm the restart instead of asking approval from the standard input. Only applies for the `add` command.

backup

Syntax:

```
shardmanctl [common_options] probackup backup -B|--backup-path path
-E|--etcd-path path
-b|--backup-mode MODE
[-j|--jobs count]
[--compress]
[--compress-algorithm algorithm]
[--compress-level level]
[--batch-size batch_size]
[--storage-type mount|remote|S3]
[--remote-port port]
[--remote-user username]
[--ssh-key path]
[-t|--timeout seconds]
[-m|--maxtasks number_of_tasks]
[--log-directory path]
[--s3-config-path path]
[--no-validate]
[--skip-block-validation]
[--log-to-console]
[--retention-redundancy]
[--retention-window]
[--wal-depth]
[--delete-wal]
[--delete-expired]
[--merge-expired]
[-y | --yes]
[--lock-lifetime]
[-e |--external-dirs dir_name]
```

Creates a backup of the Postgres Pro Shardman cluster.

`-B path`

`--backup-path path`

Required. Specifies the path to the backup catalog where Postgres Pro Shardman cluster backups should be stored.

`-E path`

`--etcd-path path`

Required. Specifies the path to the catalog where the etcd dumps should be stored.

`-b MODE`

`--backup-mode MODE`

Required. Defines the backup mode: FULL, PAGE, DELTA, PTRACK.

`--batch-size batch_size`

To speed up the archiving, specify the `--batch-size` option to copy the WAL segments in batches of a specified size. If the `--batch-size` option is used, it is also possible to specify the `-j` option to copy a batch of the WAL segments on multiple threads.

`--jobs count`

`-j count`

The number of parallel threads that `pg_probackup` uses when creating a backup. Default: 1.

`--compress`

Enables backup compression. If this flag is not specified, compression will be disabled. If the flag is specified, the default `zstd` algorithm is used with the compression level set to 1, while other compression options are ignored even if they are specified.

`--compress-algorithm algorithm`

Defines the compression algorithm: `zlib`, `lz4`, `zstd`, `pglz`, or `none`.

The supported compression algorithms depend on the version of Postgres Pro Shardman that includes the `pg_probackup` used, as explained in [Compression Options](#).

Default: `none`.

`--compress-level level`

Defines the compression level — 0-9 for `zlib`, 1 for `pglz`, 0-22 for `zstd`, and 0-12 for `lz4`.

Default: 1.

`--remote-port port`

Specifies the remote ssh port for replication group instances.

Default: 22.

`--remote-user username`

Specifies the remote ssh user for replication group instances.

Default: `postgres`.

`--ssh-key path`

Specifies the ssh private key for execution of remote ssh commands.

Default: `$HOME/.ssh/id_rsa`.

`-t seconds`

`--timeout seconds`

Exit with error after waiting until the cluster is ready for the specified number of seconds.

`-m number_of_tasks`

`--maxtasks number_of_tasks`

Specifies the maximum number of concurrent tasks (`pg_probackup` commands) to run.

Default: number of logical CPUs of the system.

`--no-validate`

Skip automatic validation after the backup is taken. You can use this flag if you validate backups regularly and would like to save time when running backup operations.

Default: `false`.

`--skip-block-validation`

Disables block-level checksum verification to speed up the backup process.

Default: `false`.

`--storage-type mount|remote|S3`

Type of the backup storage. If the value is `remote`, SSH is used to copy data files to the remote backup directory. But this behavior is different if a directory mounted to all nodes or an S3-compatible object storage is used to store backups. To specify these kinds of storage, the value of the `--storage-type` option is set to `mount` or `S3`, respectively.

Default: `remote`.

`--log-to-console`

Enables output of the `pg_probackup` logs to the console.

Default: `false`.

`--log-directory path`

Specifies the directory for `pg_probackup` logs. Required if `--storage-type` is set to `S3` unless the `SDM_LOG_DIRECTORY` environment variable is set.

Default: `<backup-directory>/backup/log`.

`--s3-config-path path`

Specifies the path to the S3 configuration file.

Default: `<shardman-data-dir>/s3.config`.

`--retention-redundancy=redundancy`

Specifies the number of full backup copies to keep in the data directory. Must be a non-negative integer. The zero value disables this setting.

Default: current value of the `pg_probackup.conf` file, 0 if not specified.

`--retention-window=window`

Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

Default: current value of the `pg_probackup.conf` file, 0 if not specified.

`--wal-depth=wal_depth`

Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must be a non-negative integer. The zero value disables this setting.

Default: current value of the `pg_probackup.conf` file, 0 if not specified.

`--delete-wal`

Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

Default: `false`.

`--delete-expired`

Deletes backups that do not conform to the retention policy.

Default: `false`.

`--merge-expired`

Merges the oldest incremental backup that satisfies the requirements of retention policy with its parent backups that have already expired.

Default: `false`.

`-y`

`--yes`

Confirm the restart instead of asking approval from the standard input.

`--lock-lifetime`

Allows setting the maximum time that `probackup` can hold the lock, in seconds.

Default: 1800.

`-e dir_name`

`--external-dirs`

Specifies directories outside `PGDATA` to be included in the backup.

checkdb

Syntax:

```
shardmanctl [common_options] probackup checkdb
[--amcheck [--skip-block-validation] [--heapallindexed]] [--shard shard]
[-m|--maxtasks number_of_tasks]
```

Verifies the Postgres Pro Shardman cluster correctness by detecting physical and logical corruption.

`--amcheck`

Performs logical verification of indexes if no corruption was found while checking data files. You must have the [amcheck](#) extension or the [amcheck_next](#) extension installed in the database to check its indexes. For databases without `amcheck`, index verification will be skipped. The `amcheck` extension is included with the Postgres Pro Shardman package.

`--heapallindexed`

Checks that all heap tuples that should be indexed are actually indexed. You can use this flag only together with the `--amcheck` flag. This option is effective depending on the version of `amcheck/am`

check_next installed. The amcheck extension included in the Postgres Pro Shardman package supports this verification.

`--skip-block-validation`

Skip validation of data files. You can use this flag only together with the `--amcheck` flag, so that only logical verification of indexes is performed.

`--shard shard`

Perform the verification only on the specified shard. By default, the verification is performed on all shards.

`-m number_of_tasks`

`--maxtasks number_of_tasks`

Specifies the maximum number of concurrent tasks (pg_probackup commands) to run.

Default: number of logical CPUs of the system.

delete

Syntax:

```
shardmanctl [common_options] probackup delete -B|--backup-path path
[-i|--backup-id backup_id]
[-j|--jobs count]
[-m|--maxtasks number_of_tasks]
[--storage-type mount|remote|S3]
[--s3-config-path path]
[--delete-wal]
[-y|--yes]
[--retention-redundancy]
[--retention-window]
[--wal-depth]
[--delete-expired]
[--merge-expired]
```

Deletes a backup of the Postgres Pro Shardman cluster with specified `backup_id` or launches the retention purge of backups and archived WAL that do not satisfy the current retention policies.

Note that `backup_id` cannot be used with `merge-expired` or `delete-expired`.

`-B path`

`--backup-path path`

Required. Specifies the path to the backup catalog (or key in the bucket of the S3-compatible storage) where Postgres Pro Shardman cluster backups should be stored.

`-i backup_id`

`--backup-id backup_id`

Specifies the unique identifier of the backup.

`--jobs count`

`-j count`

The number of parallel threads that pg_probackup uses when creating a backup. Default: 1.

`-m number_of_tasks`

`--maxtasks number_of_tasks`

Specifies the maximum number of concurrent tasks (pg_probackup commands) to run.

Default: number of logical CPUs of the system.

`--storage-type mount|remote|S3`

Type of the backup storage. If the value is `remote`, SSH is used to copy data files to the remote backup directory. But this behavior is different if a directory mounted to all nodes or an S3-compatible object storage is used to store backups. To specify these kinds of storage, the value of the `--storage-type` option is set to `mount` or `S3`, respectively.

Default: `remote`.

To delete the backup that was created with a `--storage-type` option with a `S3` value, set a `--storage-type` option to a `S3` value in the `delete` command.

`--s3-config-path path`

Specifies the path to the S3 configuration file.

Default: `<shardman-data-dir>/s3.config`.

`--delete-wal`

Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

Default: `false`.

`-y`

`--yes`

Approve operation.

Default: `false`.

`--retention-redundancy=redundancy`

Specifies the number of full backup copies to keep in the data directory. Must be a non-negative integer. The zero value disables this setting.

Default: current value of the `pg_probackup.conf` file, 0 if not specified.

`--retention-window=window`

Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

Default: current value of the `pg_probackup.conf` file, 0 if not specified.

`--wal-depth=wal_depth`

Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must be a non-negative integer. The zero value disables this setting.

Default: current value of the `pg_probackup.conf` file, 0 if not specified.

`--delete-expired`

Deletes backups that do not conform to the retention policy.

Default: `false`.

`--merge-expired`

Merges the oldest incremental backup that satisfies the requirements of retention policy with its parent backups that have already expired.

Default: `false`.

merge

Syntax:

```
shardmanctl [common_options] probackup merge -B|--backup-path path
-i|--backup-id backup_id
[-j|--jobs count]
[-m|--maxtasks number_of_tasks]
[--no-validate]
[--no-sync]
[-y|--yes]
```

Merges the backups that belong to a common incremental backup chain. The full backup merges the backups with their first incremental backup. The incremental backup merges the backups with their parent full backup, along with all the incremental backups between them. Once the merge is complete, the full backup covers all the merged data, and the incremental backups are removed as redundant.

-B *path*
--backup-path *path*

Required. Specifies the path to the backup catalog where Postgres Pro Shardman cluster backups should be stored.

-i *backup_id*
--backup-id *backup_id*

Required. Specifies the unique identifier of the backup.

--jobs *count*
-j *count*

The number of parallel threads that pg_probackup uses when creating a backup. Default: 1.

-m *number_of_tasks*
--maxtasks *number_of_tasks*

Specifies the maximum number of concurrent tasks (pg_probackup commands) to run.

Default: number of logical CPUs of the system.

--no-sync

Do not sync merged files to disk. You can use this flag to speed up the merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

Default: false.

--no-validate

Skip automatic validation before and after merge.

Default: false.

-y
--yes

Approve the operation.

Default: false.

restore

Syntax:

```
shardmanctl [common_options] probackup restore
-B|--backup-path path
-i|--backup-id id
-j|--jobs count
```

```
[--recovery-target-time timestamp]  
[-I|--recovery-mode incremental_mode]  
[-t|--timeout seconds]  
[-m|--maxtasks number_of_tasks]  
[--metadata-only] [--schema-only] [--shard shard]  
[--no-validate]  
[--skip-block-validation]  
[--s3-config-path path]  
[--storage-type mount|remote|S3]  
[--wal-limit number_of_wal_segments]  
[--log-directory path]  
[--data-validate]  
[-e|--external-dirs dir_name]  
[-T|--tablespace-mapping old_dir=new_dir]  
[-e|--external-mapping old_dir=new_dir]  
[-skip-external-dirs]  
[--reinit-before-restore]
```

Restores a Postgres Pro Shardman cluster from the selected backup.

`-B path`
`--backup-path path`

Required. Specifies the path to the backup catalog where Postgres Pro Shardman cluster backups should be stored.

`-i id`
`--backup-id id`

Required. Specifies backup ID for restore.

`--jobs count`
`-j count`

The number of parallel threads that `pg_probackup` uses when restoring from a backup. Default: 1.

`--recovery-target-time timestamp`

Point-in-Time Recovery (PITR) option. Specifies the timestamp for restore. Example: '2024-01-25 15:30:36' in UTC.

`-I incremental_mode`
`--recovery-mode incremental_mode`

Specifies the incremental restore mode to be used. Possible values are:

- `checksum` — replace only pages with mismatched checksum and LSN.
- `lsn` — replace only pages with LSN greater than point of divergence.
- `none` — regular restore, default.

`-t seconds`
`--timeout seconds`

Exit with error after waiting until the cluster is ready or the recovery is complete for the specified number of seconds.

`--metadata-only`

Perform metadata-only restore. By default, full restore is performed.

`--schema-only`

Perform schema-only restore. By default, full restore is performed.

`--shard shard`

Perform restoring only on the specified shard. By default, restoring is performed on all shards.

`--no-validate`

Skip backup validation. You can use this flag if you validate backups regularly and would like to save time when running restore operations.

Default: `false`.

`--skip-block-validation`

Disable block-level checksum verification to speed up validation. During automatic validation before the restore only file-level checksums will be verified.

Default: `false`.

`--s3-config-path path`

Specifies the path to the S3 configuration file.

Default: `<shardman-data-dir>/s3.config`.

`--storage-type mount|remote|S3`

Type of the backup storage. If the value is `remote`, SSH is used to copy data files to the remote backup directory. But this behavior is different if a directory mounted to all nodes or an S3-compatible object storage is used to store backups. To specify these kinds of storage, the value of the `--storage-type` option is set to `mount` or `S3`, respectively. When creating backup with a `--storage-type` option with a `S3` value, set `--storage-type` option to a `S3` value in the `restore` command.

Default: `remote`.

`--wal-limit number_of_wal_segments`

Specifies the number of WAL segments in which the closest synchronization points will be searched in the case of PITR.

Default: `0` — no limit.

`--log-directory path`

Specifies the directory for `pg_probackup` logs. Required if `--storage-type` is set to `S3` unless the `SDM_LOG_DIRECTORY` environment variable is set.

Default: `<backup-directory>/backup/log`.

`--data-validate`

If enabled, verifies data with `probackup validate` before restoring.

Default: `false`.

`-e dir_name`

`--external-dirs`

Specifies directories outside `PGDATA` to be included in the backup.

`-T`

`--tablespace-mapping old_dir{rgid}=new_dir{rgid}`

Specifies mapping for tablespaces. When being restored, the content of `old_dir` is moved to `new_dir`, if the tablespaces still exist and their location corresponds. Like with [CREATE TABLESPACE](#), you can use `{rgid}` value for a replication group ID.

`-e`
`--external-mapping old_dir=new_dir`
Specifies mapping for external directories from the `--external-dirs` parameter. When being re-stored, the content of *old_dir* is moved to *new_dir*, if the directories still exist.

`--skip-external-dirs`
If specified, no external directories are restored.

`--reinit-before-restore`
Reinitialize the cluster with the same topology before restore.
Default: false.

show**Syntax:**

```
shardmanctl [common_options] probackup show
  -B|--backup-path path
  [-f|--format table|json]
  [--archive ]
  [-i|--backup-id backup-id]
  [--instance instance]
  [--storage-type mount|remote|S3]
  [--s3-config-path path]
```

Shows the list of backups of the Postgres Pro Shardman cluster.

`-B path`
`--backup-path path`
Required. Specifies the path to the backup catalog where Postgres Pro Shardman cluster backups should be stored.

`-f table|json`
`--format table|json`
Specifies the output format.
Default: `table`.

`--archive`
Shows the WAL archive information.

`-i backup-id`
`--backup-id backup-id`
Shows information about the specific backups.

`--instance instance`
Shows information about the specific instance.

`--s3-config-path path`
Specifies the path to the S3 configuration file.
Default: `<shardman-data-dir>/s3.config`.

`--storage-type mount|remote|S3`
Type of the backup storage. If the value is `remote`, SSH is used to copy data files to the remote backup directory. But this behavior is different if a directory mounted to all nodes or an S3-compatible object

storage is used to store backups. To specify these kinds of storage, the value of the `--storage-type` option is set to `mount` or `S3`, respectively. To show a backup that was created with the `S3` value of `--storage-type`, set `--storage-type` to `S3` in the `show` command.

Default: `remote`.

show-config

Syntax:

```
shardmanctl [common_options] probackup show-config
  -B backup_path
  [--format=text|json]
  [--no-scale-units]
  -s|--shard shard_name
  [--s3-config-path path]
  [--storage-type mount|remote|S3]
```

Displays all the current `pg_probackup` configuration settings, including those that are specified in the `pg_probackup.conf` configuration file located in the `backup_dir/backups/shard_name` directory and those that were provided on a command line.

`-B string`
`--backup-path=string`

Required. Specifies the absolute path to the backup catalog.

`--format text|json`

Specifies the output format.

Default: `text`.

`--no-scale-units`

Output the configuration parameter values for the time and the amount of memory in the default units.

Default: `false`.

`-s string`
`--shard=string`

A name of the shard to execute the `show-config` command for.

`--s3-config-path path`

Specifies the path where the S3 configuration file will be created on all Postgres Pro Shardman nodes.

Default: `<shardman-data-dir>/s3.config`.

`--storage-type mount|remote|S3`

Type of the backup storage. If the value is `remote`, SSH is used to copy data files to the remote backup directory. But this behavior is different if a directory mounted to all nodes or an S3-compatible object storage is used to store backups. To specify these kinds of storage, the value of the `--storage-type` option is set to `mount` or `S3`, respectively.

Default: `remote`.

validate

Syntax:

```
shardmanctl [common_options] probackup validate
  -B|--backup-path path
```

```
-i|--backup-id id
[-t|--timeout seconds]
[-m|--maxtasks number_of_tasks]
[--log-to-console]
[--storage-type mount|remote|S3]
[--s3-config-path path]
[--log-directory path]
[--remote-port port]
[--remote-user username]
```

Checks the selected Postgres Pro Shardman cluster backup for integrity.

```
-B path
--backup-path path
```

Required. Specifies the path to the backup catalog where Postgres Pro Shardman cluster backups should be stored.

```
-i id
--backup-id id
```

Required. Specifies backup ID for validation.

```
--log-to-console
```

Enables output of `pg_probackup` logs to the console.

Default: `false`.

```
-t seconds
--timeout seconds
```

Exit with error after waiting until the cluster is ready for the specified number of seconds.

```
-m number_of_tasks
--maxtasks number_of_tasks
```

Specifies the maximum number of concurrent tasks (`pg_probackup` commands) to run.

Default: number of logical CPUs of the system.

```
--s3-config-path path
```

Specifies the path to the S3 configuration file.

Default: `<shardman-data-dir>/s3.config`.

```
--storage-type mount|remote|S3
```

Type of the backup storage. If the value is `remote`, SSH is used to copy data files to the remote backup directory. But this behavior is different if a directory mounted to all nodes or an S3-compatible object storage is used to store backups. To specify these kinds of storage, the value of the `--storage-type` option is set to `mount` or `S3`, respectively. To validate a backup that was created with the `S3` value of `--storage-type`, set `--storage-type` to `S3` in the `validate` command.

Default: `remote`.

```
--log-directory path
```

Specifies the directory for `pg_probackup` logs. Required if `--storage-type` is set to `S3` unless the `SDM_LOG_DIRECTORY` environment variable is set.

Default: `<backup-directory>/backup/log`.

`--remote-port port`

Specifies the remote ssh port for replication group instances.

Default: 22.

`--remote-user username`

Specifies the remote ssh user for replication group instances.

Default: postgres.

`--ssh-key path`

Specifies the ssh private key for execution of remote ssh commands.

Default: `$HOME/.ssh/id_rsa`.

set-config

Syntax:

```
shardmanctl [common_options] probackup set-config
  [--archive-timeout int]
  [-B | --backup-path string]
  [-m | --maxtasks int]
  [--remote-port int]
  [--remote-user string]
  [--retention-redundancy int]
  [--retention-window int]
  [--wal-depth int]
  [--s3-config-path string]
  [-s | --shard string]
  [--storage-type string]
  [-e | --external-dirs dir_name]
```

Adds the specified settings to the `pg_probackup.conf` or modifies those previously added.

`--archive-timeout int`

Sets a timeout for the WAL segment archiving and streaming, in seconds.

Default: `pg_probackup` waits for 300 seconds.

`-B string`

`--backup-path=string`

Specifies the absolute path to the backup catalog.

`-m int`

`--maxtasks=int`

Specifies the maximum number of concurrent tasks (`pg_probackup` commands) to run.

Default: number of logical CPUs of the system.

`--remote-port int`

An SSH remote backup port.

Default: 22.

`--remote-user string`

An SSH remote backup user.

`--retention-redundancy int`

Specifies the number of the full backup copies to store in the data directory. It must be set to a non-negative integer. The zero value disables this setting.

Default: 0.

`--retention-window int`

A number of days of recoverability. It must be set to a non-negative integer. The zero value disables this setting.

Default: 0.

`--wal-depth int`

A number of the latest valid backups on every timeline that must retain the ability to perform PITR. Must be set to a non-negative integer. The zero value disables this setting.

`--s3-config-path string`

A path to the S3 configuration file.

Default: `/var/lib/pgpro/sdm-17/data/s3.config`

`-s string`

`--shard=string`

A name of the shard to make the `set-config` command for. If not specified, the command is run for all the shards.

Default: current value of the `pg_probackup.conf` file.

`--storage-type string`

A backup storage type, the possible values are `remote`, `mount`, `S3`.

Default: `remote`.

`-e dir_name`

`--external-dirs`

Specifies directories outside `PGDATA` to be included in the backup.

Backing up a Postgres Pro Shardman Cluster Using `probackup` Command

On the backup host:

```
groupadd postgres
useradd -m -N -g postgres -r -d /var/lib/postgresql -s /bin/bash
```

Then add SSH keys to provide passwordless SSH connection between the backup host and Postgres Pro Shardman cluster hosts. Then on the backup host:

```
apt-get install pg-probackup shardman-utils
mkdir -p directory
chown postgres:postgres directory -R
shardmanctl [common_options] probackup init --backup-path=directory --etcd-
path=directory/etcd --remote-user=postgres --remote-port=22
shardmanctl [common_options] probackup archive-command --backup-path=directory --
remote-user=postgres --remote-port=22
```

If all the requirements are met, then run the `backup` subcommand for the cluster backup:

```
shardmanctl [common_options] probackup backup --backup-path=directory --etcd-  
path=directory --backup-mode=MODE
```

You must pass the directories through the `--backup-path` and `--etcd-path` options and backup mode through `--backup-mode`. Full and delta backups are available with `FULL`, `DELTA`, `PTRACK` and `PAGE` values. Also it is possible to specify backup compression options through `--compress`, `--compress-algorithm` and `--compress-level` flags, as well as specify `--remote-port` and `--remote-user` flags. You can limit the number of running concurrent tasks when doing backup by passing the limit through the `--maxtasks` flag.

By default, copying data via SSH is used to create a backup. To copy data to a mounted partition instead, use the `--storage-type` option with the `mount` value. This value will be automatically used in the restore process.

You can also copy data to an S3-compatible object storage. To do this, use the `--storage-type` option with the `S3` value. When this value is used, it is required to specify the directory for `pg_probackup` logs. You can do it either by specifying `--log-directory` for each command or set the environment variable `SDM_LOG_DIRECTORY`, for example:

```
export SDM_LOG_DIRECTORY=/backup/logs
```

If you are going to perform backup/restore only for an S3-compatible object storage, you can also set an environment variable instead of specifying `--storage-type` in each `probackup` command:

```
export SDM_STORAGE_TYPE=S3
```

Restoring a Postgres Pro Shardman Cluster using probackup command

`shardmanctl` in `probackup` mode can perform either full restore, metadata-only or schema-only restore of a Postgres Pro Shardman cluster from a backup created by the `probackup backup` command.

To perform full or partial restore, firstly you must select needed backup to restore from. To show list of available backups run the following command:

```
shardmanctl [common_options] probackup show --backup-path=path --format=format [--  
archive ] [-i|--backup-id backup-id] [--instance instance]
```

The output should be a list of backups with their IDs in a table or JSON format. Then pick the needed backup ID and run the `probackup restore` command.

```
shardmanctl [common_options] probackup restore --backup-path=path --backup-id=id
```

Pass the path to the repo through the `--backup-path` option and backup ID through `--backup-id` flag.

If you encounter issues with an `etcd` instance, it makes sense to perform metadata-only restore. To do this, you can run the following command:

```
shardmanctl [common_options] probackup restore --backup-path=path --backup-id=id --  
metadata-only
```

If you need to restore only schema information, like: tables, roles and etc. you should specify `--schema-only` option.

For both kinds of restore, you can specify `--timeout` for the tool to exit with error after waiting until the cluster is ready or the recovery is complete for the specified number of seconds.

You can specify `--shard` parameter for restoring only on the single shard.

Also you can specify `--recovery-target-time` option for Point-in-Time Recovery. In this case Postgres Pro Shardman finds the closest syncpoint to specified timestamp and suggests restoring on the found LSN. You can also specify `--wal-limit` to limit the number of WAL segments to be processed.

Important

Before restoring a Postgres Pro Shardman cluster, make sure that the cluster is up by executing the `shardmanctl status` command. If the output shows errors, performing the restore can result in the cluster becoming unavailable. First, fix the errors by reinitializing the cluster and restoring the etcd metadata. Then you can proceed to restoring the cluster from backup.

Restoring a Postgres Pro Shardman Cluster

`shardmanctl` can perform either full restore, metadata-only or schema-only restore of a Postgres Pro Shardman cluster from a backup created by the `backup` command.

To perform full restore, you can run the following command:

```
shardmanctl [common_options] recover --info file
```

Pass the file to load information about the backup from through the `--info` option. In most cases, set this option to point to the `backup_info` file in the backup directory or to its modified copy.

If you encounter issues with an etcd instance, it makes sense to perform metadata-only restore. To do this, you can run the following command:

```
shardmanctl [common_options] recover --dumpfile file --metadata-only
```

You must pass the file to load the etcd metadata dump from through the `--dumpfile` option.

If you need to restore only schema information, like: tables, roles and etc. you should specify `--schema-only` option.

For all kinds of restore, you can specify `--timeout` for the tool to exit with error after waiting until the cluster is ready or the recovery is complete for the specified number of seconds.

You can specify `--shard` parameter for restoring only on the single shard.

Before running the `recover` command, specify `DataRestoreCommand` and `RestoreCommand` in the `back-up_info` file. `DataRestoreCommand` fetches the base backup and restores it to the shard data directory. `RestoreCommand` fetches the WAL file and saves it to the shard `pg_wal` directory. These commands can use the following substitutions:

`%p`

Destination path on the server.

`%s`

SystemId of the restored database (the same in the backup and in restored cluster).

`%f`

Name of the WAL file to restore.

Shard `keeper` thread runs both commands on each node in the cluster. Therefore:

- Make the backup accessible to these nodes (for example, by storing it in a shared filesystem or by using a remote copy protocol, such as SFTP).
- Commands to fetch the backup are executed as the operating system user under which shards work (usually `postgres`), so set the permissions for the backup files appropriately.

These examples show how to specify `RestoreCommand` and `DataRestoreCommand`:

- If a backup is available through a passwordless SCP, you can use:

```
"DataRestoreCommand": "scp -r user@host:/var/backup/shardman/%s/backup/* %p",  
"RestoreCommand": "scp user@host:/var/backup/shardman/%s/wal/%f %p"
```

- If a backup is stored on NFS and available through `/var/backup/shardman path`, you can use:

```
"DataRestoreCommand": "cp -r /var/backup/shardman/%s/backup/* %p",  
"RestoreCommand": "cp /var/backup/shardman/%s/wal/%f %p"
```

Configuration-related Commands

config get

Syntax:

```
shardmanctl [common_options] config get [-c | --choose-revision] [-r | --revision ] [-f  
| --file]
```

Outputs the current full cluster specification or a configuration of the specified revision.

```
-c  
--choose-revision
```

Enables an interactive mode of choosing a configuration of the specified revision.

```
-r  
--revision
```

ID of a configuration revision.

```
-f file_name  
--file=file_name
```

Name of a file for writing the configuration. If not specified, the value is stdout.

config revisions rm

Syntax:

```
shardmanctl [common_options] config revisions rm [-r | --revision ] [-y | --yes]
```

Deletes a specified configuration revision from history.

```
-r  
--revision
```

ID of a configuration revision. If not specified, enables an interactive mode of choosing a configuration of the specified revision. This is a timestamp of an operation that resulted in Postgres Pro Shardman configuration change.

```
-y  
--yes
```

Perform automatic confirmation.

config update

Syntax:

```
shardmanctl [common_options] config update [[-f|--file shard_spec_file /  
shardman_spec_file]|spec_text [-p|--patch][-w|--wait]] [--force] [-y | --yes]
```

Updates the shard or full Postgres Pro Shardman configuration. Supports the following placeholders for postgres parameters: `{{cluster}}`, `{{shard}}`, `{{dataDir}}`, `{{keeperDir}}`, `{{keeperID}}`, `{{host}}`. See example [here](#).

```
-f shard_spec_file | shardman_spec_file
--specfile=shard_spec_file | shardman_spec_file
```

Specifies the file with the shard or full Postgres Pro Shardman configuration. The configuration file type is determined automatically. The value of `-` means the standard input. By default, the configuration is passed in *spec_text*.

```
-w
--wait
```

Sets `shardmanctl` to wait for configuration changes to take effect. If a new configuration cannot be loaded by all replication groups, `shardmanctl` will wait forever.

```
-p
--patch
```

Merge the new configuration into the existing one. By default, the new configuration replaces the existing one.

```
--force
```

Perform forced update if a cluster operation is in progress.

```
-y
--yes
```

Confirm the restart necessary for the parameters to take effect. If this option is not specified, and the parameters update requires a restart, the manual confirmation will be requested. If not confirmed, the cluster will continue to work, yet the new parameter values will only take effect after the restart.

config rollback

Syntax:

```
shardmanctl [common_options] config rollback [-r | --revision] [-w|--wait time_duration] [--force] [-y|--yes][--repair]
```

Makes a rollback of Postgres Pro Shardman to one of the previous states. When rolling back to the config revision that has `max_connections`, `max_prepared_transactions`, or `max_worker_processes` parameters, the replicas are reinitialized.

When rolling back to one of the previous states, none of the `max_connections`, `max_prepared_transactions`, `max_locks_per_transaction`, `max_wal_senders`, `max_worker_processes` parameters is rolled back if its current value is higher than the one it is rolled back to.

```
-r
--revision
```

ID of a revision the rollback must be made to. It is a timestamp of an operation that resulted in Postgres Pro Shardman configuration change.

If not specified, a user is presented with a list of revisions that he can choose from.

```
-w
--wait
```

Sets `shardmanctl` to wait for configuration changes to take effect. If a new configuration cannot be loaded by all replication groups, `shardmanctl` will wait forever.

Default: 1h.

```
-f
--force
```

Perform forced setting of a parameter if a cluster operation is in progress.

`-y`
`--yes`

Perform automatic confirmation.

`--repair`

Enables the mode of restoring the cluster that failed due to the invalid parameter values.

Default: disabled.

config revisions

Syntax:

```
shardmanctl [common_options] config revisions [-f|--format text|json]
```

Outputs the revision history of the Postgres Pro Shardman cluster configuration. It has the following information for each revision:

- `revision_id` — timestamp of the command that resulted in the Postgres Pro Shardman cluster configuration change
- `host` — name of the host from which this command was executed
- `user` — user who executed this command
- `command` — the command itself

`-f=text|json`
`--format=text|json`

Specifies the output format.

Default: `text`.

config revisions set

Syntax:

```
shardmanctl [common_options] config revisions set [--keep-config-revisions]
```

Allows setting the length of the configuration revision history. This length cannot be lower than 5, in which case it is automatically set to 5. For Postgres Pro Shardman clusters where the configuration revision history was not collected yet, the length is automatically set to 20.

`--keep-config-revisions`

A limit on the number of revisions for one Postgres Pro Shardman configuration. If the limit is lower than the current history length, the older versions out of this limit will be deleted. Also, if the number of operations resulting in configuration changes exceeds the limit, the oldest revision is deleted.

Default: 20.

config update ip

Syntax:

```
shardmanctl [common_options] config update ip [-u|ip_1=ip_2,hostname_1=hostname_2] [-y|--yes] [-repair]
```

Updates the specified node IPs in the cluster.

`-u`
`ip_1=ip_2,hostname_1=hostname_2`

Specifies the node IPs to be updated.

`-y`
`--yes`

Perform automatic confirmation.

`--repair`

Enables the mode of restoring the cluster that failed due to the invalid parameter values.

Default: disabled.

config update credentials

Syntax:

```
shardmanctl [common_options] config update credentials [-u | --user] [-p | --password]
[-k | --ssl-key] [-c | --ssl-cert] [-w|--wait time_duration] [--force] [-y | --yes]
```

Updates password or certificate/key of a user to connect to a Postgres Pro Shardman cluster. It only updates the authentication type that was specified by the user (`scram-sha-256`, `ssl`) and not the type itself.

`-u`
`--user`

User that requires an update of the authentication parameters.

`-p`
`--password`

New password.

`-k`
`--ssl-key`

New SSL key.

`-c`
`--ssl-cert`

New SSL certificate.

`-w`
`--wait`

Sets `shardmanctl` to wait for configuration changes to take effect. If a new configuration cannot be loaded by all replication groups, `shardmanctl` will wait forever.

`--force`

Perform forced update if a cluster operation is in progress.

`-y`
`--yes`

Confirm the operation instead of asking approval from the standard input.

Cluster-related Commands

cluster repfactor set

Syntax:

```
shardmanctl [common_options] cluster repfactor set --value new_repfactor
```

Sets the replication factor for the manual-topology mode.

`--value=new_repfactor`

New replication factor value

cluster start

Syntax:

`shardmanctl [common_options] cluster start`

Starts all PostgreSQL server instances.

cluster stop

Syntax:

`shardmanctl [common_options] cluster stop [-y|--yes] [-m|--message]`

Stops all PostgreSQL server instances.

`-y`

`--yes`

Confirm the operation instead of asking approval from the standard input.

`-m`

`--message`

Explains why the cluster was stopped.

cluster topology

Syntax:

`shardmanctl [common_options] cluster topology -f|--format table|json|text`

Displays the cluster topology.

`-f table|json|text`

`--format=table|json|text`

Output format. For more details, see [the section called “Displaying the Cluster Topology”](#).

init

Syntax:

`shardmanctl [common_options] init [-y|--yes] [-f|--spec-file spec_file_name]|spec_text`

Registers a new Postgres Pro Shardman cluster in the etcd store or reinitializes the existing cluster defining a new cluster configuration and removing all data and nodes.

`-f spec_file_name`

`--specfile=spec_file_name`

Specifies the file with the cluster specification string. The value of `-` means the standard input. By default, the string is passed in `spec_text`. For usage details, see [the section called “Registering a Postgres Pro Shardman Cluster”](#).

`-y`

`--yes`

Confirm the operation instead of asking approval from the standard input.

intcheck

Syntax:

```
shardmanctl [common_options] intcheck [-s|--system] [-u|--user] [-c|--catalog] [-o|--output] [-n|--node node]
```

Runs `pg_integrity_check` on all nodes of a Postgres Pro Shardman cluster or on a selected one node.

`-s`
`--system`
Validate checksums for read-only files. Checksums for read-only files control both file contents and file attributes.

`-u`
`--user`
Validate checksums for additional files. Checksums for additional files control both file contents and file attributes.

`-c`
`--catalog`
Validate checksums for system catalog tables. For the `-c` option to work correctly, the database server must be started and accept connections.

`-o`
`--output`
Recalculate checksums and write them into a file

`-n node_names`
`--node=node_names`
Only execute the `pg_integrity_check` command on the selected node

load

Syntax:

```
shardmanctl [common_options] load [ -b | --batch-size lines_limit] [ --destination-fields fields_list ]  
[ --distributed-keys key_type_list] [ -D | --delimiter character ]  
[ --null-marker string] [ -e | --escape character] [ -f | --file input_file ]  
[ -F | --format text/csv ] [ -j | --jobs task_total] [ -q | --quote character ]  
[ --reject-file filename] [ --schema filename] [ --source file/postgres ]  
[ --source-connstr connect_string] [ --source-fields fields_list] [ --source-table source_table ]  
[ -t | --table destination_table ]
```

Loads data to a Postgres Pro Shardman cluster.

`-b lines_limit`
`--batch-size=lines_limit`
Number of rows per batch to write to the Postgres Pro Shardman cluster.

Default: 1000.

`--destination-fields=fields_list`
Comma-separated list of target table fields. If the value is not set, then all fields of the table are used in the order they are declared.

`--distributed-keys=key_type_list`

Comma-separated list of pairs. Each pair consists of a field number (starting with zero) and a type, which are separated by a colon. The following types are supported: `bool`, `char`, `float4`, `float8`, `int2`, `int4`, `int8`, `name`, `text`, `varchar` and `uuid`.

`-D character`

`--delimiter=character`

Specifies the character that separates columns within each row (line) of the file. This must be a single one-byte character.

Default: `tab` for text format, `comma` for CSV format

`--null-marker=string`

Specifies the string that represents a null value.

Default: `\N` for text format, unquoted empty string for CSV format.

`-e character`

`--escape=character`

Specifies the character that should appear before a data character that matches the `QUOTE` value. The default is the same as the `QUOTE` value (so that the quoting character is doubled if it appears in the data). This must be a single one-byte character. This option is allowed only when using CSV format.

`-f filename`

`--file=filename`

Input data filename (or `-` for stdin)

`-F text/csv`

`--format=text/csv`

Input data format. Possible values are `text` and `csv`.

Default: `text`.

`-j number`

`--jobs=number`

Number of parallel processes to load data.

Default: number of replication groups.

`-q character`

`--quote=character`

Specifies the quoting character to be used when a data value is quoted. The default is double-quote. This must be a single one-byte character. This option is allowed only when using CSV format.

`--reject-file=filename`

All data batches with errors during upload will be written to this file. If the value is not set, then such batches will be skipped.

`--schema=filename`

The schema that defines the rules for transferring data from PostgreSQL to Postgres Pro Shardman. If this option is set, then all other options are not used.

`--source=file/postgres`

Data source type — `file` or `postgres`.

Default: `file`.

`--source-connstr=string`

Data source database connection string

`--source-fields=fields_list`

Comma-separated list of source table fields. If the value is not set, then all fields of the table are used in the order they are declared.

`--source-table=table`

Source table, view or function (`funcname (param1, ..., paramN)`).

`-t table`

`--table=table`

Destination table.

restart

Syntax:

```
shardmanctl [common_options] restart [-y|--yes] [--no-wait] [-m|--message]
```

Restarts a Postgres Pro Shardman cluster.

`-y`

`--yes`

Confirm the operation instead of asking approval from the standard input.

`--no-wait`

Do not wait for the replicas to start.

`-m`

`--message`

Explains why the cluster was restarted.

set

Syntax:

```
shardmanctl [common_options] set param1=value1 [param2=value2 [...]] [-y|--yes] [-w|--wait time_duration] [-f|--force] [--repair]
```

Sets the values of the specified Postgres Pro Shardman cluster database parameters. Supports the following placeholders for postgres parameters: `{{cluster}}`, `{{shard}}`, `{{dataDir}}`, `{{keeperDir}}`, `{{keeperID}}`, `{{host}}`. See example [here](#).

`-w`

`--wait`

Sets `shardmanctl` to wait for configuration changes to take effect. Value examples: `2h45m`, `1m30s`, `5m`, `10s`.

Default: `1h`.

`-y`

`--yes`

Confirm the restart necessary for the parameters to take effect. If this option is not specified, and the parameters update requires a restart, the manual confirmation will be requested. If not confirmed, the cluster will continue to work, yet the new parameter values will only take effect after the restart.

`-f`
`--force`

Perform forced setting of a parameter if a cluster operation is in progress.

`--repair`

Enables the mode of restoring the cluster that failed due to the invalid parameter values.

Default: disabled.

unset

Syntax:

```
shardmanctl [common_options] unset pgParam1 [pgParam2 [...]] [-y|--yes] [-w|--wait time_duration] [-f|--force] [--repair]
```

Resets the specified PostgreSQL parameters to their default values.

`-w`
`--wait`

Sets the maximum time that shardmanctl can wait for configuration changes to take effect.

Default: 1h.

`-y`
`--yes`

Confirm the restart necessary for the parameters to take effect. If this option is not specified, and the parameters update requires a restart, the manual confirmation will be requested. If not confirmed, the cluster will continue to work, yet the new parameter values will only take effect after the restart.

`-f`
`--force`

Perform forced setting of a parameter if a cluster operation is in progress.

`--repair`

Enables the mode of restoring the cluster that failed due to the invalid parameter values.

Default: disabled.

Registering a Postgres Pro Shardman Cluster

To register a Postgres Pro Shardman cluster in the etcd store, run the following command:

```
shardmanctl [common_options] init [-y|--yes] [-f|--spec-file spec_file_name] | spec_text
```

You must provide the string with the cluster specification. You can do it as follows:

- On the command line — do not specify the `-f` option and pass the string in `spec_text`.
- On the standard input — specify the `-f` option and pass `-` in `spec_file_name`.
- In a file — specify the `-f` option and pass the filename in `spec_file_name`.

Displaying the Cluster Topology

`cluster topology` displays the current cluster topology. The default is the table mode. All cluster nodes will be grouped by the replication groups they belong to. For each node, its status will be displayed.

```
shardmanctl [common_options] cluster topology -f|--format table|json|text
```

Nodes-related Commands

nodes add

Syntax:

```
shardmanctl [common_options] nodes add -n|--nodes node_names [--no-rebalance]
```

Adds nodes to a Postgres Pro Shardman cluster. Once the command is executed, a dump is created.

```
-n node_names  
--nodes=node_names
```

Required.

Specifies the comma-separated list of nodes to be added.

```
--no-rebalance
```

Skip the step of rebalancing partitions of sharded tables. For more details, see [the section called “Adding Nodes to a Postgres Pro Shardman Cluster”](#).

nodes rm

Syntax:

```
shardmanctl [common_options] nodes rm -n|--nodes node_names
```

Removes nodes from a Postgres Pro Shardman cluster. Once the command is executed, a dump is created.

```
-n node_names  
--nodes=node_names
```

Specifies the comma-separated list of nodes to be removed. For usage details, see [the section called “Removing Nodes from a Postgres Pro Shardman cluster”](#).

nodes start

Syntax:

```
shardmanctl [common_options] nodes start -n|--nodes node_names [--no-wait]
```

Starts the nodes.

```
-n node_names  
--nodes=node_names
```

Node names.

```
--no-wait
```

Sets shardmanctl not to wait for the nodes to start.

nodes restart

Syntax:

```
shardmanctl [common_options] nodes restart -n|--nodes node_names [--no-wait]
```

Restarts the nodes.

```
-n node_names
--nodes=node_names
```

Node names.

```
--no-wait
```

Do not wait for the nodes to restart.

nodes stop

Syntax:

```
shardmanctl [common_options] nodes stop -n|--nodes node_names [--no-wait]
```

Stops the nodes.

```
-n node_names
--nodes=node_names
```

Node names.

```
--no-wait
```

Do not wait for the nodes to stop.

Adding Nodes to a Postgres Pro Shardman Cluster

To add nodes to a Postgres Pro Shardman cluster, run the following command:

```
shardmanctl [common_options] nodes add -n|--nodes node_names
```

You must specify the `-n` (`--nodes`) option to pass the comma-separated list of nodes to be added. Nodes can be referred by their hostname or IP address. Hostnames must be correctly resolved on all nodes.

If `nodes add` command fails during execution, use the `cleanup --after-node-operation` command to fix possible cluster configuration issues.

Removing Nodes from a Postgres Pro Shardman cluster

To remove nodes from a Postgres Pro Shardman cluster, run the following command:

```
shardmanctl [common_options] nodes rm -n|--nodes node_names
```

Specify the `-n` (`--nodes`) option to pass the comma-separated list of nodes to be removed. Recreates all partitions of sharded tables.

Note

Do not use the `cleanup` command to fix possible cluster configuration issues after a failure of `nodes rm`. Redo the `nodes rm` command instead.

To remove all nodes in a cluster and not care about the data, just reinitialize the cluster. If a removed replication group contains local (non-sharded and non-global) tables, the data is silently lost after the replication group removal.

Shard-related Commands

shard add

Syntax:

```
shardmanctl [common_options] shard -s|--shard shard_name add -n|--nodes node_names [--no-wait]
```

Adds a replica to a shard. Once the command is executed, a dump is created.

```
-s shard_name  
--shard=shard_name
```

Shard name.

```
-n node_names  
--nodes=node_names
```

Specifies the comma-separated list of replica nodes to be added.

```
--no-wait
```

Do not wait for the shard to start.

shard master set

Syntax:

```
shardmanctl [common_options] shard -s|--shard shard_name master set -n| node node_names
```

Sets the precedence for a certain primary server for a specified shard.

```
-s shard_name  
--shard=shard_name
```

Shard name.

```
master set
```

Primary server with precedence.

```
-n node_names  
--nodes=node_names
```

Specifies the comma-separated list of replica nodes.

shard master reset

Syntax:

```
shardmanctl [common_options] shard -s|--shard shard_name master reset
```

Resets the parameters of the master with precedence for the shard.

```
-s shard_name  
--shard=shard_name
```

Shard name.

```
master reset
```

Resets the parameters of the master with precedence for the shard.

```
-n node_names  
--nodes=node_names
```

Specifies the comma-separated list of replica nodes.

shard add

Syntax:

```
shardmanctl [common_options] shard -s|--shard shard_name reset [--yes | -y][--new-  
primary | -p]
```

Resets nodes of a replication group if they are in a state of hanging.

`-s shard_name`
`--shard=shard_name`

Shard name.

`-y`
`--yes`

Confirm the operation instead of asking approval from the standard input.

`--new-primary`
`-p`

New primary node host.

shard rm

Syntax:

```
shardmanctl [common_options] shard -s|--shard shard_name rm -n|--nodes node_names  
[-f|--force]
```

Removes a replica from a shard. Once the command is executed, a dump is created.

`-s shard_name`
`--shard=shard_name`

Shard name

`-n node_names`
`--nodes=node_names`

Specifies the comma-separated list of replica nodes to be removed.

`-f`
`--force`

Perform forced removal of the node, even if it is dead.

shard switch

Syntax:

```
shardmanctl [common_options] shard -s|--shard shard_name switch [--new-  
primary node_names]
```

Switches the primary node.

`-s shard_name`
`--shard=shard_name`

Shard name.

`--new-primary=node_names`

New primary node host.

shard start

Syntax:

```
shardmanctl [common_options] shard -s |--shard shard_name start [--no-wait] [-n|--  
node node_name]
```

Starts the shard.

```
-s shard_name  
--shard=shard_name
```

Shard name.

```
--no-wait
```

Do not wait for the shard to start.

```
-n node_name  
--node=node_name
```

Specifies the node to start.

shard stop

Syntax:

```
shardmanctl [common_options] shard -s |--shard shard_name stop [-n|--  
node node_name]
```

Stops the shard.

```
-s shard_name  
--shard=shard_name
```

Shard name.

```
-n node_name  
--node=node_name
```

Specifies the node to stop.

shard replicas reinit

Syntax:

```
shardmanctl [common_options] shard -s|--shard shard_name replicas reinit [-n|--  
node node_names] [-y|--yes] [--no-wait]
```

Resets replicas of a specific shard.

```
-s shard_name  
--shard=shard_name
```

Shard name.

```
-n node_names  
--node=node_names
```

Specifies the node on which to reset replicas. If not specified, checks shard replicas on all nodes.

```
-y  
--yes
```

Confirm the operation instead of asking approval from the standard input.

```
--no-wait
```

Do not wait wait for replicas to become ready.

For more details, see [the section called “Reinitializing Replicas”](#)

Reinitializing Replicas

If replicas are in an incorrect state, you can reset them using the `shardmanctl` command:

```
shardmanctl [common_options] shard --shard=shard_name replicas reinit
```

This command determines the nodes on which replicas of the specified shard are running and sends a request to `shardmand` on these nodes. After receiving this request, `shardmand` clears the postgres data directory and restarts the `keeper` thread that is responsible for managing the replica. After that, the replicas are restarted and begin to receive data from the corresponding primary.

Status-related Commands

status

Syntax:

```
shardmanctl [common_options] status [-f|--format table|json] [--  
filter store|metadata|shardmand|rg|master|dictionary|biha|keeper|restart_required_params]  
[-s|--sort node|rg|status]  
[--  
exclude store|metadata|shardmand|rg|master|dictionary|biha|keeper|restart_required_params]
```

Reports on the health status of Postgres Pro Shardman cluster subsystems. Shows no details or status tables if no issues are found.

```
-f table|json  
--format=table|json
```

Specifies the report format.

Default: `table`.

For more details, see [the section called “Getting the Status of Cluster Subsystems”](#).

```
--filter          store|metadata|shardmand|rg|master|dictionary|biha|keeper|restart_re-  
quired_params
```

Specifies subsystems whose status information should be included in the output.

Default: `all`.

For more details, see [the section called “Getting the Status of Cluster Subsystems”](#).

```
-s node|rg|status  
--sort node|rg|status
```

Sort messages inside one group (table) as specified.

Default: `node`.

For more details, see [the section called “Getting the Status of Cluster Subsystems”](#).

```
--exclude          store|metadata|shardmand|rg|master|dictionary|biha|keeper|restart_re-  
quired_params
```

Specifies subsystems that should not be included in the `status` output.

status transactions

Syntax:

```
shardmanctl [common_options] status transactions [-r|--  
repgroup replication_group_name]
```

Shows distributed transactions that Postgres Pro Shardman built-in monitoring tools failed to resolve.

```
-r replication_group_name
--repgroup=replication_group_name
```

Specifies the replication group for which to output transactions.

Default: all replication groups.

For more details, see [the section called “Outputting the List of Unresolved Distributed Transactions”](#).

Getting the Status of Cluster Subsystems

To get a report on the health status of Postgres Pro Shardman cluster in a table format for `metadata` and `store` subsystems sorted by replication group, run the following command:

```
shardmanctl [common_options] status --filter=metadata,store --sort=rg
```

To get the report in JSON format, use `-f|--format=json` option (omitted above since `table` format is used by default). Each detected issue is reported as an Unknown, Warning, Error or Fatal error status. The tool can also report an Operational error, which means there was an issue during the cluster health check. When the command encounters a Fatal or Operational error, it stops further diagnostics. For example, an inconsistency in the store metadata does not allow correct cluster operations and must be handled first.

Outputting the List of Unresolved Distributed Transactions

To view the list of distributed transactions that Postgres Pro Shardman built-in monitoring tools failed to resolve, run the following command:

```
shardmanctl [common_options] status transactions -r|--
repgroup replication_group_name
```

Each output transaction consists of `tx_id` (transaction ID), `coordinator_id`, `creation_time` and `description` (error or transaction status). To display the list of transactions for a specific replication group, use the `-r|--repgroup` option (for all replication groups by default). In case there are no such transactions, returns `null` value in JSON.

Store-related Commands

store dump

Syntax:

```
shardmanctl [common_options] store dump [-f|--file filename]
```

Dumps current cluster specifications from the store.

```
-f filename
--file=filename
```

Specifies the output file (– for stdout).

Default: –.

For more details, see [the section called “Dumping All Keys from the Store to Debug Error Configuration”](#).

store restore

Syntax:

```
shardmanctl [common_options] store restore [-f|--file filename] [-y|--yes]
```

Allows to safely restore the `etcd` cluster from the dump created with the `shardmanctl store dump`.

```
-f filename  
--file=filename
```

Specifies the name of the `etcd` keys dump.

```
-y  
--yes
```

Perform automatic confirmation.

store lock

Syntax:

```
shardmanctl [common_options] store lock [-f|--format text|json]
```

Shows the current cluster meta lock information.

```
-f=text|json  
--format=text|json
```

Specifies the output format.

Default: `text`.

For more details, see [the section called “Output Current Cluster Meta Lock Information”](#).

store get

Syntax:

```
shardmanctl [common_options] store get [[-a|--alias aliasname]|[-k|--key keyname]]  
[-f|--file filename]
```

Gets the specified key from the store.

```
-a aliasname  
--alias=ladle|cluster |spec|shardspec
```

Specifies the use of alias instead of the full key name. Cannot be used with `--key`.

For more details, see [the section called “Getting the Current Shard Specification”](#).

```
-k keyname  
--key=keyname
```

Specifies the key to retrieve from the store. Cannot be used with `--alias`.

For more details, see [the section called “Getting the Current Shard Specification”](#).

```
-f filename  
--file=filename
```

Specifies the file to print the value to.

Default: `-` (stdout).

For more details, see [the section called “Getting the Current Shard Specification”](#).

store keys

Syntax:

```
shardmanctl [common_options] store keys
```

Gets all keys with the current cluster prefix from the store.

For more details, see [the section called “Getting the Cluster and Ladle Key Names For the Current Cluster”](#).

store set

Syntax:

```
shardmanctl [common_options] store set [[-a|--alias aliasname]|[-k|--key keyname]]  
[-f|--file filename]
```

Creates or rewrites a key in the store.

```
-a ladle|cluster |spec|shardspec  
--alias=ladle|cluster |spec|shardspec
```

Specifies the use of alias instead of the full key name. Cannot be used with `--key`.

```
-k keyname  
--key=keyname
```

Specifies the key name to set in the store. Cannot be used with `--alias`.

```
-f filename  
--file=filename
```

Specifies the file with input data (`-` for stdin).

For more details, see [the section called “Setting a New Spec for the Cluster”](#).

Dumping All Keys from the Store to Debug Error Configuration

After facing an error while using Postgres Pro Shardman cluster, to fill in an exhaustive report, it is convenient to dump all specifications that could produce such an error with the following command:

```
shardmanctl [common_options] store dump -f|--file filename
```

Some harmless errors may be shown, but they will not interrupt dumping. If you do not specify the filename, dump will be sent to stdout and may pollute your terminal.

Getting the Current Shard Specification

To get the current shard specification, which is normally a part of cluster key in the store, use the following command:

```
shardmanctl [common_options] store get -a|--alias shardspec -f|--file filename
```

If the cluster key is corrupted itself, the shard specification will not be shown either. Instead of using the alias, you may also find out the full cluster data key name (by listing all keys with `store keys` command), use `store get` to retrieve it and find the `shard` part there. Mind that while using the last option, `shardman.config_uuid` parameter will not be deleted, which may result in a conflict in later use of this data; for manipulation with shard specification, it is recommended to use `shardmanctl store get -a shardspec` command.

Getting the Cluster and Ladle Key Names For the Current Cluster

To get all key names in the store at once, run the following command:

```
shardmanctl [common_options] store keys
```

It can only be shown in JSON format. It will also print alias names for keys that have them (excluding `shardspec` and `spec`, since they are parts of other keys)

Output Current Cluster Meta Lock Information

You can view information about current cluster meta locks that acquired by any command:

```
shardmanctl [common_options] store lock -f|--format json
```

To get the report in JSON format, use `-f|--format=json` option (omitted above since `text` format is used by default). In case the lock does not exists returns `Lock not found`

Setting a New Spec for the Cluster

To set a new spec part of the cluster specification, run the following command:

```
shardmanctl [common_options] store set --alias=spec --file=spec.json
```

Since `spec` is a part of cluster data key, it cannot be set with `--key`. If the provided file is not a valid JSON, the new spec part will not be set.

Table-related Commands

tables sharded info

Syntax:

```
shardmanctl [common_options] tables sharded info [-t|--table table_name]
```

Gets information about a sharded table.

```
-t table  
--table=table
```

Specifies the name of the table in the format `schema.table`

tables sharded list

Syntax:

```
shardmanctl [common_options] tables sharded list
```

Gets the list of all sharded tables.

tables sharded norebalance

Syntax:

```
shardmanctl [common_options] tables sharded norebalance
```

Gets the list of sharded tables with automatic rebalancing disabled.

tables sharded partmove

Syntax:

```
shardmanctl [common_options] tables sharded partmove [-t|--table table_name] [-s|--shard shard_name] [-p|--partnum number]
```

Moves the specified partition of a sharded table to a new shard.

```
-t table  
--table=table
```

Specifies the name of the table in the format `schema.table`.

```
-p number  
--partnum=number
```

Specifies the number of the partition to move.

```
-s shard_name  
--shard=shard_name
```

Specifies the name of the new shard for the partition.

tables sharded rebalance

Syntax:

```
shardmanctl [common_options] tables sharded rebalance [-t|--table table_name]
```

Enables and runs automatic data rebalancing for the selected sharded table.

```
-t table  
--table=table
```

Specifies the name of the table in the format `schema.table`.

Bench-related Commands

bench init

Syntax:

```
shardmanctl [common_options] bench init [--schema-type single|simple|shardman|custom]  
[--schema-file file_name] [-s|--scale scale_value] [-n|--no-vacuum]  
[-F|--fillfactor fillfactor_value]
```

Initializes the benchmark schema via pgbench. Schema can be custom or predefined. Creates `tpc-b` schema tables and fills them.

```
--schema-type=single|simple|shardman|custom
```

Type of schema used by schema initialization. Possible values:

- `single` — schema for a single PostgreSQL benchmark test
- `simple` — simple sharded schema
- `shardman` — sharded schema optimized for Postgres Pro Shardman
- `custom` — schema initialized by the user from the `--schema-file file`

Default schema: `shardman`.

```
--schema-file=file_name
```

File with DDL query for the custom schema type, to be used to create `tpc-b` tables for pgbench: `pgbench_accounts`, `pgbench_branches`, `pgbench_tellers`, `pgbench_history`.

```
-s scale_value
--scale=scale_value
```

Multiply the number of generated rows by the given scale factor.

```
-n
--no-vacuum
```

Perform no vacuuming during initialization.

```
-F fillfactor_value
--fillfactor=fillfactor_value
```

Fill pgbench tables with the given fillfactor value.

bench run

Syntax:

```
shardmanctl [common_options] bench run [--schema-type single|simple|shardman|custom]
[-f|--file file_name] [-c|--client client_value] [-C|--connect] [--full-output]
[-j|--jobs jobs_value] [-T|--time seconds] [-t|--transactions transactions_value]
[-s|--scale scale_factor] [-P | --progress seconds] [-R | --rate rate] [-M | --
protocol querymode]
```

Runs the initialized benchmark via pgbench. Can use the default pgbench script or a custom script from a file.

```
--schema-type=single|simple|shardman|custom
```

Type of schema used by schema initialization (bench init). Possible values:

- *single* — schema for single PostgreSQL benchmark
- *simple* — simple sharded schema
- *shardman* — sharded schema optimized for Postgres Pro Shardman
- *custom* — schema initialized by the user from the `--schema-file` file.

Default schema: *shardman*.

```
-f file_name
--file=file_name
```

Add a transaction script read from *filename* to the list of scripts to be executed.

Optionally, write an integer weight after @ to adjust the probability of selecting this script versus other ones. The default weight is 1. (To use a script file name that includes an @ character, append a weight so that there is no ambiguity, for example *filen@me@1*).

```
-c client_value
--client=client_value
```

Number of clients simulated, that is, number of concurrent database sessions.

```
-C
--connect
```

Establish a new connection for each transaction rather than doing it just once per client session.

```
--full-output
```

Print all pgbench output.

```
-j jobs_value
--jobs=jobs_value
```

Number of worker threads within pgbench.

`-s scale_factor`
`--scale=scale_factor`

Multiply the number of generated rows by the given scale factor.

`-T seconds`
`--time=seconds`

Run the test with a time limit of the specified number of seconds. The default value is 0, which means that there is no time limit. Note that the `-T` and `-t` flags are mutually exclusive, and the `-T` flag takes precedence. If the `-T` flag is specified, the `-t` flag is ignored.

`-t transactions_value`
`--transactions=transactions_value`

Run the test with a limit of the specified number of transactions on each client. The default value is 10. Note that the `-T` and `-t` flags are mutually exclusive, and the `-T` flag takes precedence. If the `-T` flag is specified, the `-t` flag is ignored.

`-P seconds`
`--progress=seconds`

Show progress report every *sec* seconds. The report includes the time since the beginning of the run, the TPS since the last report, and the transaction latency average, standard deviation, and the number of failed transactions since the last report. Under throttling (`-R`), the latency is computed with respect to the transaction scheduled start time, not the actual transaction beginning time, thus it also includes the average schedule lag time. When `--max-tries` is used to enable transaction retries after serialization/deadlock errors, the report includes the number of retried transactions and the sum of all retries.

`-R rate`
`--rate=rate`

Execute transactions targeting the specified rate instead of running as fast as possible (the default). The rate is given in transactions per second. If the targeted rate is above the maximum possible rate, the rate limit won't impact the results.

`-M querymode`
`--protocol=querymode`

Protocol to use for submitting queries to the server:

- `simple`: use simple query protocol.
- `extended`: use extended query protocol.
- `prepared`: use extended query protocol with prepared statements.

In the `prepared` mode, `pgbench` reuses the parse analysis result starting from the second query iteration, so `pgbench` runs faster than in other modes.

Default: `simple`.

bench cleanup

Syntax:

```
shardmanctl [common_options] bench cleanup
```

Cleans up schema database after benchmarks. Drops `tpc-b` tables.

bench generate

Syntax:

```
shardmanctl [common_options] bench generate [-c|--config file_name] [-o|--output-file file_name]
```

Gets the benchmark configuration from a file and generates a bash script to create a schema optimized for Postgres Pro Shardman and run the benchmark using pgbench. The configuration file must be in yaml format.

`-f file_name`
`--file=file_name`

The configuration file path. The file contains a sequence of script configurations. Each script must have a `schema_type: single|simple|shardman|custom`. For a custom schema it is necessary to specify the `schema_file` with the DDL script. Optional parameters: `init_flags` (default set: `-s 1000`), `run_flags` (default set: `-n -P 10 -c 10 -j 4 -T 60`), `partitions` (default value: 50). It is highly recommended to use `-n` (`--no-vacuum`) parameter inside `run_flags`. Configuration file example:

```
benches:
- schema_type: single
  init_flags: "-s 3"
  run_flags: "-n -P 10 -c 10 -j 4 -T 10"
- schema_type: simple
  init_flags: "-s 4"
  run_flags: "-n -P 10 -c 20 -j 4 -T 10"
  partitions: 100
- schema_type: shardman
  init_flags: "-s 5"
  run_flags: "-n -P 10 -c 20 -j 4 -T 10"
- schema_type: custom
  init_flags: "-s 6"
  schema_file: "schema.psql"
```

`-o file_name`
`--output-file=file_name`

Output file. Default: stdout.

Cleanup-related Commands

cleanup

Syntax:

```
shardmanctl [common_options] cleanup [-p|--processrepgroups] --after-node-operation|--after-rebalance
```

Performs cleanup after the nodes `add` or `rebalance` command.

`-p node_names`
`--processrepgroups=node_names`

Perform an actual cleanup. By default, the tool only shows actions to be done during the actual cleanup. For more details, see [the section called “Performing Cleanup”](#).

`--after-node-operation`

Perform cleanup after a failure of a nodes `add` command.

`--after-rebalance`

Perform cleanup after a failure of a `rebalance` command.

Performing Cleanup

By default, `cleanup` operates in the report-only mode, that is, the following command will only show actions to be done during actual cleanup:

```
shardmanctl [common_options] cleanup --after-node-operation|--after-rebalance
```

To perform the actual cleanup, run the following command:

```
shardmanctl [common_options] cleanup -p|--processrepgroups --after-node-operation|--after-rebalance
```

Schema-related Commands

schema verify

Syntax:

```
shardmanctl [common_options] schema verify [--filter partitions|extension|tables|roles|schemas|sequences]
```

Verifies that a schema has the correct information about partitions, and that they are located on the same primary nodes as the corresponding partitions of a colocated table. It also checks that all the shards have the same global and sharded tables, global roles, and global sequences, and that their names differ from the local versions, as well as checks that the shards have the same schemas and extensions.

```
--filter partitions|extension|tables|roles|schemas|sequences
```

Specifies what is included in the check. If not specified, all the checks are done.

Default: not specified.

schema list

Syntax:

```
shardmanctl [common_options] schema list [-f|--format text|json]
```

Outputs a list of the stored dump IDs of the `shardman` schema.

```
-f=text|json  
--format=text|json
```

Specifies the output format.

Default: text.

schema show

Syntax:

```
shardmanctl [common_options] schema show --shard shard_name --dump-id dump_id
```

Outputs a dump with the specified ID for the specified shard.

```
--shard=shard_name
```

Specifies the name of the shard.

```
--dump-id=dump_id
```

Dump ID.

schema restore

Syntax:

```
shardmanctl [common_options] schema restore --dump-id dump_id [--shards comma_separated_list_of_shards] [--smart]
```

Restores of a `shardman` schema from a dump with a specified ID.

`--dump-id=dump_id`

Dump ID.

`--shards=comma_separated_list_of_shards`

Specifies the list of the shards to restore. If not specified, all the cluster shards are restored. The dump must contain all shards that must be restored.

`--smart`

Restores the `shardman` schema from PostgreSQL system tables if the schema's integrity was violated. It can be used when the `shardmanSchemaDumpMonitorDisabled` configuration parameter is enabled, or if no valid dump for the schema is present. However, in some cases (e.g. if data was lost from all shards) no full functioning restoration is guaranteed, and it is advised to use the partly restored schema as data source to proceed with restoration to a different working Postgres Pro Shardman cluster. It requires the tables that are being restored to be empty, thus making the partial tables restore impossible.

schema dump

Syntax:

```
shardmanctl [common_options] schema dump [--no-verify]
```

Creates a `shardman` schema dump that is saved in the `etcd` with the `shardman/cluster_name/shardman_schema_dumps/dump_id` key. Maximum 10 dumps can be created. Should the limit be reached, the oldest dump is deleted. If a new dump duplicates one of the saved dumps, only the newest one remains.

`--no-verify`

Skip the consistency check of a dump.

Default: false (check is not skipped).

Daemon-related Commands

daemon set

Syntax:

```
shardmanctl [common_options] daemon set [--session-log-level debug | info | warn | error] [--session-log-format json|text] [--session-log-nodes]
```

Allows updating the log parameters “on the fly”.

`--session-log-level debug | info | warn | error`

Updates the log level to debug, info, warn, or error.

`--session-log-format json|text`

Updates the log output format to text or json.

`--session-log-nodes`

Specifies which cluster nodes must be updated. If not specified, the parameters are updated on every node.

Default: all nodes.

daemon check

Syntax:

```
shardmanctl [common_options] daemon check -n|--nodes node_name:port
```

Checks shardmand on nodes.

```
-n node_name:port
--nodes=node_name:port
```

List of nodes to check shardmand on. For more details, see [the section called “Checking shardmand Service on Nodes”](#).

Checking shardmand Service on Nodes

`daemon check` not only checks that shardmand service is running on specified nodes, but also assures those services are configured for the same cluster as shardmanctl:

```
shardmanctl [common_options] daemon check -n|--nodes node_names
```

Other Commands

getconnstr

Syntax:

```
shardmanctl [common_options] getconnstr --all
```

Gets the libpq connection string for connecting to a cluster as administrator.

```
--all
```

Adds replicas to `getconnstr`.

forall

Syntax:

```
shardmanctl [common_options] forall --sql query[ --sql query[ --sql query ...]] [--twophase] [-d --dbname]
```

Executes an SQL statement on all replication groups in a Postgres Pro Shardman cluster.

```
--sql query
```

Specifies the statement to be executed.

```
--twophase
```

Use the two-phase-commit protocol to execute the statement.

```
-d
```

```
--dbname
```

Specifies a database to run the request for. If not specified, the default value is used.

Default: postgres.

rebalance

Syntax:

```
shardmanctl [common_options] rebalance [-f|--force]
```

Rebalances sharded tables. Once the command is executed, a dump is created.

```
-f
--force
```

Perform forced rebalance of sharded tables whose partitions were manually moved.

upgrade

Syntax:

```
shardmanctl [common_options] upgrade
```

Upgrades the shardman database extension and updates `pg_foreign_server` options.

script

Syntax:

```
shardmanctl [common_options] script -s|--shard shard_name [[-f|--file file_name] [--sql query]]
```

Executes non-transactional commands from a file or from the command-line on the specified shards.

```
-s shard_name
--shard=shard_name
```

Shard name.

```
-f file_name
--file=file_name
```

Add a transaction script from the *file_name* file to the list of scripts to be executed.

```
--sql query
```

Specifies the statement to be executed and can only be used separately from `-f`.

psql

Syntax:

```
shardmanctl [common_options] psql -s|--shard shard_name
```

Connects to the first available primary node if no options are specified.

```
-s shard_name
--shard=shard_name
```

Name of the shard. If specified, the connection is installed with this shard current primary.

history

Syntax:

```
shardmanctl [common_options] history [--reverse | -r] [-f|--format json|text] [-l|--limit number_of_commands]
```

Shows history of the commands that updated the cluster. By default, they are sorted from the most recent to the oldest ones.

```
-r
--reverse
```

Switches to the ascending sorting order.

`-f json|text`
`--format=json|text`

Output format.

Default: `text`.

`-l`
`--limit=number_of_commands`

Limit for the number of the most recent commands in the output. The maximum value is 200.

Default: 20.

`--log-format json|text`

Specifies the log output format, `text` or `json`.

Common Options

`shardmanctl` common options are optional parameters that are not specific to the utility. They specify `etcd` connection settings, cluster name and a few more settings. By default `shardmanctl` tries to connect to the `etcd` store `127.0.0.1:2379` and use the `cluster0` cluster name. The default log level is `info`.

`-h, --help`

Show brief usage information.

`--cluster-name cluster_name`

Specifies the name for a cluster to operate on. The default is `cluster0`.

`--log-level level`

Specifies the log verbosity. Possible values of `level` are (from minimum to maximum): `error`, `warn`, `info` and `debug`. The default is `info`.

`--retries number`

Specifies how many times `shardmanctl` retries a failing `etcd` request. If an `etcd` request fails, most likely, due to a connectivity issue, `shardmanctl` retries it the specified number of times before reporting an error. The default is 5.

`--session-timeout seconds`

Specifies the session timeout for `shardmanctl` locks. If there is no connectivity between `shardmanctl` and the `etcd` store for the specified number of seconds, the lock is released. The default is 30.

`--store-endpoints string`

Specifies the `etcd` address in the format: `http[s]://address[:port](,http[s]://address[:port])*`. The default is `http://127.0.0.1:2379`.

`--store-ca-file string`

Verify the certificate of the HTTPS-enabled `etcd` store server using this CA bundle.

`--store-cert-file string`

Specifies the certificate file for client identification by the `etcd` store.

`--store-key string`

Specifies the private key file for client identification by the `etcd` store.

`--store-timeout duration`

Specifies the timeout for a `etcd` request. The default is 5 seconds.

`--monitor-port number`

Specifies the port for the shardmand http server for metrics and probes. The default is 15432.

`--api-port number`

Specifies the port for the shardmand http api server. The default is 15432.

`--version`

Show shardman-utils version information.

Environment

`SDM_BACKUP_MODE`

An alternative to setting the `--backup-mode` option.

`SDM_BACKUP_PATH`

An alternative to setting the `--backup-path` option.

`SDM_CLUSTER_NAME`

An alternative to setting the `--cluster-name` option.

`SDM_ETCD_PATH`

An alternative to setting the `--etcd-path` option.

`SDM_FILE`

An alternative to setting the `--file` option for config update.

`SDM_LOG_LEVEL`

An alternative to setting the `--log-level` option.

`SDM_NODES`

An alternative to setting the `--nodes` option for `nodes add` and `nodes rm`.

`SDM_RETRIES`

An alternative to setting the `--retries` option.

`SDM_SPEC_FILE`

An alternative to setting the `--spec-file` option for `init`.

`SDM_STORE_ENDPOINTS`

An alternative to setting the `--store-endpoints` option.

`SDM_STORE_CA_FILE`

An alternative to setting the `--store-ca-file` option.

`SDM_STORE_CERT_FILE`

An alternative to setting the `--store-cert-file` option.

`SDM_STORE_KEY`

An alternative to setting the `--store-key` option.

`SDM_STORE_TIMEOUT`

An alternative to setting the `--store-timeout` option.

SDM_SESSION_TIMEOUT

An alternative to setting the `--session-timeout` option.

Examples

Initializing the Cluster

To initialize a Postgres Pro Shardman cluster that has the `cluster0` name, uses an etcd cluster consisting of `n1,n2` and `n3` nodes listening on port 2379, ensure proper settings in the spec file `sdmspec.json` and run:

```
$ shardmanctl --store-endpoints http://n1:2379,http://n2:2379,http://n3:2379 init -f sdmspec.json
```

Getting the Cluster Connection String

To get the connection string for a Postgres Pro Shardman cluster that has the `cluster0` name, uses an etcd cluster consisting of `n1,n2` and `n3` nodes listening on port 2379, run:

```
$ shardmanctl --store-endpoints http://n1:2379,http://n2:2379,http://n3:2379 getconnstr
```

```
dbname=postgres host=n1,n4,n2,n1,n1,n2,n4,n3 password=yourpasswordhere
port=5432,5433,5432,5433,5432,5433,5432,5433 user=postgres
```

To add replicas to `getconnstr`, use `--all`.

Getting the Cluster Status

Here is a sample status output from `shardmanctl` with OK and Error statuses:

```
$ shardmanctl status --filter store,shardmand,rg --sort=node
```

== STORE STATUS ==			
STATUS NODE	MESSAGE	REPLICATION GROUP	
OK	etcd store is OK		
== SHARDMAND STATUS ==			
STATUS NODE	MESSAGE	REPLICATION GROUP	
OK 56d819b4e9e4	shardmand on node 56d819b4e9e4 is OK		
OK 6d0aabd50acc	shardmand on node 6d0aabd50acc is OK		
== REPLICATION GROUP STATUS ==			

STATUS NODE	MESSAGE	REPLICATION GROUP	
OK	Replication group clover-1-56d819b4e9e4 is	clover-1-56d819b4e9e4	
	OK		
	Replication connection is down for slave		
Error 6d0aabd50acc:5442	6d0aabd50acc:5442 in replication group clover-1-6d0aabd50acc	clover-1-6d0aabd50acc	
== RESTART REQUIRED PARAMS STATUS ==			
STATUS	MESSAGE	REPLICATION GROUP	NODE
OK	No pending restart parameters	shard-1	shrn1
OK	No pending restart parameters	shard-2	shrn4

Rewriting Shard Specification

First, get the list of available keys in the store using the following command:

```
$ shardmanctl store keys
```

```
$ shardmanctl store keys
```

```
{
  "Key": "shardman/cluster0/biha/cluster/shard-1/clusterdata"
}{
  "Key": "shardman/cluster0/biha/cluster/shard-1/keepers/info/keeper_1"
}{
  "Key": "shardman/cluster0/biha/cluster/shard-2/clusterdata"
}{
  "Key": "shardman/cluster0/biha/cluster/shard-2/keepers/info/keeper_1"
}{
  "Key": "shardman/cluster0/data/cluster",
  "Alias": "cluster"
}{
  "Key": "shardman/cluster0/data/cluster/revisions"
}{
  "Key": "shardman/cluster0/data/cluster/revisions/2024-10-31T09:29:26"
}{
  "Key": "shardman/cluster0/data/ladle",
  "Alias": "ladle"
}{
}
```

```
"Key": "shardman/cluster0/data/repgroups",
"Alias": "repgroups"
}
```

Get the shard configuration from the store and save it in the `shardspec.json` file with the command

```
$ shardmanctl store get -a shardspec -f shardspec.json
```

Apply the necessary changes to the file and upload the new specification using `shardmanctl config update`. **Mind that `shardman.config_uuid` parameter is deleted with `shardmanctl store get -a shardspec` and not with `shardmanctl store get -k full/path/to/clusterspec`; using spec with existing `shardman.config_uuid` will result in a conflict.**

Important

Do not use `store set` command to update cluster configurations because it *does not* apply a new specification on all nodes, it only writes it to the store. For the above example with shard specification, `shardmanctl config update` or `shardmanctl set` is acceptable.

To double-check, you can get the cluster key with new `StolonSpec` by the full key name (which was shown earlier with `store keys` command):

```
$ shardmanctl store get -k shardman/cluster0/data/cluster
```

```
{
  "FormatVersion": 1,
  "Spec": {
    "PgSuAuthMethod": "md5",
    "PgSuPassword": "12345",
    "PgSuUsername": "postgres",
    "PgReplAuthMethod": "md5",
    "PgReplPassword": "12345",
    "PgReplUsername": "repluser",
    "ShardSpec": {
      ...
    }
  }
}
```

Adding Nodes to the Cluster

To add `n1,n2,n3` and `n4` nodes to the cluster, run:

```
$ shardmanctl --store-endpoints http://n1:2379,http://n2:2379,http://n3:2379 nodes add
-n n1,n2,n3,n4
```

The `n1,n2,n3` and `n4` nodes are added as primaries for the replication groups. After that you can get the cluster topology:

```
$ shardmanctl cluster topology
```

```
== REPLICATION GROUP shard-1, RGID - 1 ==
+-----+-----+-----+-----+
| HOST   | PORT | KEEPER | STATUS |
+-----+-----+-----+-----+
| n1     | 2379 | yes    | primary |
+-----+-----+-----+-----+
| n2     | 2379 | yes    | primary |
+-----+-----+-----+-----+
| n3     | 2379 | yes    | primary |
+-----+-----+-----+-----+
| n4     | 2379 | yes    | primary |
+-----+-----+-----+-----+
| PRIORITY |
+-----+-----+-----+-----+
```

shardmanctl

n1	5432	keeper_1	LEADER_RW
NOT SET			
== REPLICATION GROUP shard-2, RGID - 2 ==			
HOST	PORT	KEEPER	STATUS
PRIORITY			
n2	5432	keeper_1	LEADER_RW
NOT SET			
== REPLICATION GROUP shard-3, RGID - 3 ==			
HOST	PORT	KEEPER	STATUS
PRIORITY			
n3	5432	keeper_1	LEADER_RW
NOT SET			
== REPLICATION GROUP shard-4, RGID - 4 ==			
HOST	PORT	KEEPER	STATUS
PRIORITY			
n4	5432	keeper_1	LEADER_RW
NOT SET			

To add a new replica, run:

```
shardmanctl --store-endpoints http://n1:2379,http://n2:2379,http://n3:2379 shard -s  
shard-1 add -n n2
```

This will give a cluster with the following topology:

```
$ shardmanctl cluster topology
```

== REPLICATION GROUP shard-1, RGID - 1 ==			
HOST	PORT	KEEPER	STATUS
PRIORITY			
n1	5432	keeper_1	LEADER_RW
NOT SET			
n2	5433	keeper_2	FOLLOWER
NOT SET			
== REPLICATION GROUP shard-2, RGID - 2 ==			

HOST PRIORITY	PORT	KEEPER	STATUS	
n2 NOT SET	5432	keeper_1	LEADER_RW	
== REPLICATION GROUP shard-3, RGID - 3 ==				
HOST PRIORITY	PORT	KEEPER	STATUS	
n3 NOT SET	5432	keeper_1	LEADER_RW	
== REPLICATION GROUP shard-4, RGID - 4 ==				
HOST PRIORITY	PORT	KEEPER	STATUS	
n4 NOT SET	5432	keeper_1	LEADER_RW	

Removing Nodes from the Cluster

To remove `n1` and `n2` nodes from the `cluster0` cluster, run:

```
$ shardmanctl --store-endpoints http://n1:2379,http://n2:2379,http://n3:2379
nodes rm -n n1,n2
```

If `cross` placement policy is used, then the clovers that contain them will be deleted along with the nodes.

Executing a Query on All Replication Groups

To execute the `select version()` query on all replication groups, run:

```
$ shardmanctl --store-endpoints http://n1:2379,http://n2:2379,http://n3:2379 forall --
sql 'select version()'
```

Node 1 says:

```
[PostgreSQL 13.1 on x86_64-pc-linux-gnu, compiled by gcc (Ubuntu
9.3.0-17ubuntu1~20.04) 9.3.0, 64-bit]
```

Node 4 says:

```
[PostgreSQL 13.1 on x86_64-pc-linux-gnu, compiled by gcc (Ubuntu
9.3.0-17ubuntu1~20.04) 9.3.0, 64-bit]
```

Node 3 says:

```
[PostgreSQL 13.1 on x86_64-pc-linux-gnu, compiled by gcc (Ubuntu
9.3.0-17ubuntu1~20.04) 9.3.0, 64-bit]
```

Node 2 says:

```
[PostgreSQL 13.1 on x86_64-pc-linux-gnu, compiled by gcc (Ubuntu
9.3.0-17ubuntu1~20.04) 9.3.0, 64-bit]
```

Performing Rebalance

To rebalance sharded tables in the `cluster0` cluster, run:

```
$ shardmanctl --store-endpoints http://n1:2379,http://n2:2379,http://n3:2379 rebalance
```

Updating PostgreSQL Configuration Settings

To set the `max_connections` parameter to 200 in the cluster, create the spec file (for instance, `~/shard-spec.json`) with the following contents:

```
{
  "pgParameters": {
    "max_connections": "200"
  }
}
```

Then run:

```
$ shardmanctl --store-endpoints http://n1:2379,http://n2:2379,http://n3:2379 config
update -p -f ~/shardspec.json
```

Since changing `max_connections` requires a restart, DBMS instances are restarted by this command.

Performing Backup and Recovery

To create a backup of the `cluster0` cluster using `etcd` at `etcdserver` listening on port 2379 and store it in the local directory `/var/backup/shardman`, run:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 backup --datadir=/var/backup/
shardman --use-ssh
```

Assume that you are performing a recovery from a backup to the `cluster0` cluster using `etcd` at `etcdserver` listening on port 2379 and you take the backup description from the `/var/backup/shardman/backup_info` file. Edit the `/var/backup/shardman/backup_info` file, set `DataRestoreCommand`, `RestoreCommand` as necessary and run:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 recover --info /var/backup/
shardman/backup_info
```

For metadata-only restore, run:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 recover --metadata-only --
dumpfile /var/backup/shardman/etcd_dump
```

For schema-only restore, run:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 recover --schema-only --
dumpfile /var/backup/shardman/etcd_dump
```

For single shard restore, run:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 recover --info /var/backup/
shardman/backup_info --shard shard_1
```

Performing Backup and Recovery with probackup Command

To create a backup of the `cluster0` cluster using `etcd` at `etcdserver` listening on port 2379 and store it in the local directory `/var/backup/shardman`, first initialize the backups repository with the `init` subcommand:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 probackup init --backup-path=/
var/backup/shardman --etcd-path=/var/backup/etcd_dump
```

Then add and enable `archive_command` with the `archive-command` subcommand:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 probackup archive-command add --
backup-path=/var/backup/shardman
```

If the repository is successfully initialized and `archive-command` successfully added, create a `FULL` backup with the `backup` subcommand:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 probackup backup --backup-path=/
var/backup/shardman --etcd-path=/var/backup/etcd_dump --backup-mode=FULL --compress --
compress-algorithm=zlib --compress-level=5
```

To create `DELTA`, `PTRACK` or `PAGE` backup, run the `backup` subcommand with `DELTA`, `PTRACK` or `PAGE` value of the `--backup-mode` option:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 probackup backup --backup-path=/
var/backup/shardman --etcd-path=/var/backup/etcd_dump --backup-mode=DELTA --compress --
compress-algorithm=zlib --compress-level=5
```

To show the created backup ID, run `show` subcommand:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 probackup show --backup-path=/
var/backup/shardman --format=table
```

== BACKUP ID 'S88FRO'									
==									
INSTANCE				HOST					
RECOVERY TIME		MODE		WAL MODE		TLI		DATA	
Z-RATIO		START LSN		STOP LSN		STATUS		WAL	
shard-1				n1					
2024-02-02 14:19:05+00		FULL		ARCHIVE		1/0		42.37MiB	
16MiB		1.00		0/C000028		0/D0018B0		OK	
shard-2				n2					
2024-02-02 14:19:05+00		FULL		ARCHIVE		1/0		42.38MiB	
16MiB		1.00		0/C000028		0/D001E00		OK	

In `PTRACK` backup mode, Postgres Pro Shardman tracks page changes on the fly. Continuous archiving is not necessary for it to operate. Each time a relation page is updated, this page is marked in a special `PTRACK` bitmap. Tracking implies some minor overhead on the database server operation, but speeds up incremental backups significantly.

If you are going to use `PTRACK` backups, complete the following additional steps:

- Preload the `ptrack` shared library on each node. This can be done by adding the `ptrack` value to the `shared_preload_libraries` parameter.
- Create the `PTRACK` extension on each cluster node:

```
$ shardmanctl --store-endpoints http://etcdserver:2379
forall --sql "create extension ptrack"
```

- To enable tracking page updates, set the `ptrack.map_size` parameter as follows:

```
$ shardmanctl --store-endpoints http://etcdserver:2379
update '{"pgParameters":{"ptrack.map_size":"64"}}'
```

For optimal performance, it is recommended to set `ptrack.map_size` to $N/1024$, where N is the maximum size of the cluster node, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup. Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but it is not recommended to set this parameter to a value higher than 1024.

To validate the created backup, run `validate` subcommand:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 probackup validate --backup-
path=/var/backup/shardman --backup-id=RFP1FI
```

Assume that you are performing a recovery from a backup to the `cluster0` cluster using `etcd` at `etcd-server` listening on port 2379 and you take the backup ID from the `show` command:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 probackup restore --backup-
path=/var/backup/shardman --backup-id=RFP1FI
```

Finally we need to enable `archive_command` back.

```
$ shardmanctl --store-endpoints http://etcdserver:2379 probackup archive-command add --
backup-path=/var/backup/shardman
```

For metadata-only restore, run:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 probackup restore --metadata-
only --backup-path=/var/backup/shardman --backup-id=RFP1FI
```

For metadata-only restore, run:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 probackup restore --schema-only
--backup-path=/var/backup/shardman --backup-id=RFP1FI
```

For single shard restore, run:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 probackup restore --backup-
path=/var/backup/shardman --backup-id=RFP1FI --shard shard_1
```

For Point-in-Time Recovery, run:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 probackup restore --metadata-
only --backup-path=/var/backup/shardman --backup-id=RFP1FI --recovery-target-
time='2006-01-02 15:04:05' -s
```

Loading Data from a Text File

To load data into a Postgres Pro Shardman cluster, run the following command:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 load --file=/var/load/data.tsv
--table=mytable --source file --format text -j 8
```

In this example, data is loaded from the `/var/load/data.tsv` data file (tab-delimited) into the table `mytable` in 8 parallel threads. You can use `schema.table` as the table name.

Loading data from PostgreSQL table

To load data into a Postgres Pro Shardman cluster from a PostgreSQL table, run the following command:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 load -t desttable --
source postgres --source-connstr "dbname=db host=srchost port=srcport user=login
password=passwd" --source-table sourcetable -j 8
```

In this example, data is loaded from the table `sourcetable` into the `desttable` table in 8 parallel threads. You can use `schema.table` as table names.

Loading Data with a Schema from PostgreSQL

To load data with a schema into Postgres Pro Shardman cluster from PostgreSQL, run the following command:

```
$ shardmanctl --store-endpoints http://etcdserver:2379 load --schema load_schema.yaml
```

The file `load_schema.yaml` has the following format:

```
version: "1.0"
migrate:
  connstr: "dbname=workdb host=workhost port=workport user=workuser
password=workpassword"
  jobs: 8
  batch: 1000
  options:
    - create_schema
    - create_table
    - create_index
    - create_sequence
    - create_foreign_key
    - create_role
    - copy_ownership
    - copy_grants
    - truncate_table
    - skip_no_pkey_tables
    - skip_create_index_error
    - skip_create_extension_error
    - skip_load_errors
    - skip_create_foreign_key_error
    - skip_create_role_error
    - skip_copy_grants_error
    - skip_copy_ownership_error
  schemas:
    - name: public
      all: false
      tables:
        - name: tab1
          type: sharded
          partitions: 6
          distributedby: id
          priority: 3
        - name: tab2
          type: global
        - name: tab3
          type: sharded
          partitions: 6
          distributedby: field_id
          colocatewith: tab1
        - name: table4
          type: global
          source: schema.view
          source_pk: field_id
        - name: table5
          type: global
          source: schema.func(arg)
```

```
        source_pk: field_id
- name: schema2
  all: false
  default_type: sharded
  default_partitions: 6
  tables:
    - name: table1
      distributedby: field_id
      priority: 2
    - name: table2
      type: global
    - name: table3
      source: schema.view
      distributedby: field_id
      priority: 3
    - name: table4
      distributedby: field_id
      source: schema.func(arg)
    - name: table5
      source: schema."complex."table.name"
      distributedby: field_id
- name: schema3
  all: true
  skip_tables: [table1, table2, table3]
roles:
- name: test_user1
  password: test_password
- name: test_user2
```

The `migrate.jobs` value defines the number of parallel data loader processes.

The `migrate.batch` value is the number of rows in one batch (recommended value is 1000).

The `migrate.schemas` section defines an array of source database schemas that you are working with. All other schemas will be skipped.

If the `all` value is set to `true`, then all tables from the current schema will be migrated (with `global` type by default). If a table is listed in the `migrate.schemas.tables` array, then the target table type must be explicitly specified for it. Two types of tables are currently supported: `global` and `sharded`. Global tables are loaded first, then `sharded` tables and at the end `sharded` tables with the `colocatedwith` parameter. The order of loading tables of the same type can be changed using `priority` option.

The `migrate.schemas.skip_tables` section defines an array of table names that will be skipped when the schema is loaded even if the `all` parameter is set to `true`.

For `sharded` tables, the following attributes must be set: `distributedby` (specifies the name of the column to use for the table partitioning) and `partitions` (number of partitions that will be created for this table). Optionally, for `sharded` tables `colocatewith` attribute can be set (name of the table to colocate with). Postgres Pro Shardman will try to place partitions of the created table with the same partition key on the same nodes as the corresponding partitions of the table specified by `colocatewith`.

You can specify the table `default_type` option for a schema: `global` or `sharded` (default: `global`). For the `sharded` type you can also specify the `default_partitions` option (default: 20). If you set `default_type` to `sharded`, you need to specify the `distributedby` option for each table.

The `source` option for a table should include the schema and table source: `schema.source`. The source can be a table, view or function. For example: `public.table`, `public.view`, `public.func(arg)`. If you set the `source` view or function for a `global` table, you should specify `source_pk` to set the primary key

for this table. If `source` is not specified or contains the name of a table, you can also specify `source_pk` to create a primary key or override the existing one.

The `priority` option for table determines the order in which the tables of the same type are loaded. Tables with higher `priority` are loaded earlier. Default `priority` value is 0.

The `migrate.roles` section defines an array of role names and passwords that will be copied from the source database if `create_role` is specified.

The schema supports the following options:

- `create_schema` — create database schemas if they do not exist.
- `create_table` — create tables if they do not exist.
- `create_index` — create indexes after creating tables.
- `create_sequence` — create sequences if they do not exist.
- `create_foreign_key` — create foreign keys after creating tables.
- `truncate_table` — truncate tables before data load.
- `create_role` — create global roles defined in `migrate.roles` and copy role parameters from the source database.
- `copy_grants` — copy access privileges from the source database.
- `copy_ownership` — change of table owners to the owner in the source database.
- `skip_no_pkey_tables` — skip tables without primary keys.
- `skip_create_index_error` — skip index creation errors.
- `skip_create_extension_error` — skip extension creation errors.
- `skip_load_errors` — continue loading if errors occur.
- `skip_create_foreign_key_error` — skip foreign key creation errors.
- `skip_create_role_error` — skip role creation errors.
- `skip_copy_ownership_error` — skip table owner changing errors.
- `skip_copy_grants_error` — skip errors when copying access privileges from the source database.

Initialization and Running Benchmarks

To initialize a benchmark via `shardmanctl` using `pgbench` with the `shardman` schema, `scale=1000`, `partitions=40`, run:

```
$ shardmanctl bench init --schema-type=shardman --scale=1000 --partitions=40
```

To run an initialized benchmark for the same `shardman` schema, number of jobs=4, number of clients=10, duration in seconds=60 and full `pgbench` output, use:

```
$ shardmanctl bench run --schema-type=shardman --jobs=4 --client=10 --time=60 --full-output
```

To initialize a benchmark with the `custom` schema from file `schema.psql` with `scale=1000` run:

```
$ shardmanctl bench init --schema-type=custom --schema-file=schema.psql --scale=1000
```

To run an initialized benchmark with the `custom` schema and custom transaction script from `script.psql` with the number of jobs=4, number of clients=10, duration in seconds=60, use:

```
$ shardmanctl bench run --schema-type=custom --file=script.psql --jobs=4 --client=10 --time=60
```

To clean up a PostgreSQL database of `tpc-b` tables, use:

```
$ shardmanctl bench cleanup
```

Benchmark Generation Scripts

To generate a benchmark sequence via `shardmanctl` from the config file `cfg.yaml` and output the result to file `script.sh`, run:

```
$ shardmanctl bench generate --config=cfg.yaml --output-file=script.sh
```

Configuration file example:

```
benches:
- schema_type: single
  init_flags: "-s 3"
  run_flags: "-n -P 10 -c 10 -j 4 -T 10"
- schema_type: simple
  init_flags: "-s 4"
  run_flags: "-n -P 10 -c 20 -j 4 -T 10"
  partitions: 100
- schema_type: shardman
  init_flags: "-s 5"
  run_flags: "-n -P 10 -c 20 -j 4 -T 10"
- schema_type: custom
  init_flags: "-s 6"
  schema_file: "schema.psql"
```

shardmand

shardmand — Postgres Pro Shardman configuration daemon

Postgres Pro Shardman Start-up with shardmand

shardmand is a Postgres Pro Shardman configuration daemon. It runs on each node in a Shardman cluster, generates a `boot_uuid` at every startup, subscribes for changes of `shardman/cluster0/data/ladle` and `shardman/cluster0/data/cluster` keys in the etcd store (`cluster0` is the default cluster name used by Shardman utils), and manages Postgres Pro Shardman processes on the node where it is running according to the configuration described in these JSON documents.

shardmand manages integrated `keepers` and `sentinels`. On startup and when one of the monitored etcd keys changes, shardmand reconfigures them as follows:

- It calculates the expected node configuration, i. e., the list of `keepers` and `sentinels` expected to run and their configurations, from the `shardman/cluster0/data/ladle` and `shardman/cluster0/data/cluster` values.
- It receives the list of running `keepers` and `sentinels` with their configurations from the internal process manager.
- It stops processes that are not expected to run. This can be a process that belongs to a cluster with the same name, but a different UUID, or a process whose description is no longer present in the expected node configuration. For `keeper` processes, shardmand purges their data directory.
- If a process should be running, but its settings are different from the expected ones, shardmand updates the configuration and restarts the process. If a process should be running, but it is not running, shardmand starts it.

Also, a separate thread of shardmand periodically updates the `shardman/cluster0/data/shardmand/NODENAME` etcd key with the `ClusterUUID` of the last cluster to which the configuration was applied. So, before the [shardmanctl](#) nodes add command tries to initialize new clusters for a clover, the command can ensure that no alive threads from a previous cluster configuration are left on all nodes in the clover.

Additionally, shardmand starts two http servers in separate threads. If servers ports match, a single server running both roles is started. The first server provides following metrics: `shardmand_etcd_unavailable_time_seconds`, `shardmand_healthy_keepers`, `shardmand_sentinels`, `shardmand_uptime`, `shardmand_etcd_errors_total`, `shardmand_reconfigurations_number_total`, `shardmand_demotions_number_total`. Also server provides a `/healthz` endpoint for shardmand health-check. The second server provides the following endpoints:

- `/shardmand/v1/replica` — returns 200 status code if a secondary instance is running on node, 500 status code if a primary instance is running on node, `/shardmand/v1/master` — returns 200 status code if a primary instance is running on node, 500 status code if a secondary instance is running on node, `/shardmand/v1/referee` — returns 200 status code if the only instance running on node is referee, 500 status code if the only instance running on node is primary or secondary, 404 if more than one instance is running. If node both primary and secondary instances are running on node `/shardmand/v1/replica` and `shardmand/v1/master` endpoints return 404 status code.
- `/shardmand/v1/status` — getting information about shardmand status, including `boot_uuid`.

All Postgres Pro Shardman services are managed by `shardmand@cluster0.service`, so when it is started, stopped, or restarted, it also starts, stops, or restarts all other Postgres Pro Shardman processes (including DBMS instances).

shardmand Syntax

```
shardmand [common_options] [ --system-bus ] [ --user user_name ]
```

Here *common_options* are:

```
[ --cluster-name cluster_name ] [ --log-level error | warn | info | debug ] [ --retries retries_number ] [ --session-timeout seconds ] [ --store-endpoints store_endpoints ] [ --store-ca-file store_ca_file ] [ --store-cert-file store_cert_file ] [ --store-key client_private_key ] [ --store-timeout duration ] [ --version ] [ -h | --help ] [ --log-format ]
```

Command-line Reference

This refsection describes `shardmand`-specific command-line options.

`--log-format`

Specifies the log output format, `json` or `text`. The default is `text`.

`--system-bus`

Not used. Left for compatibility. Ignored.

`--user user_name`

Not used. Left for compatibility. Ignored.

Common Options

`shardmand` common options are optional parameters that are not specific to the utility. They specify `etcd` connection settings, cluster name and a few more settings. By default `shardmand` tries to connect to the `etcd` store `127.0.0.1:2379` and use the `cluster0` cluster name. The default log level is `info`.

`-h, --help`

Show brief usage information.

`--cluster-name cluster_name`

Specifies the name for a cluster to operate on. The default is `cluster0`.

`--log-level level`

Specifies the log verbosity. Possible values of *level* are (from minimum to maximum): `error`, `warn`, `info` and `debug`. The default is `info`.

`--retries number`

Specifies how many times `shardmanctl` retries a failing `etcd` request. If an `etcd` request fails, most likely, due to a connectivity issue, `shardmanctl` retries it the specified number of times before reporting an error. The default is 5.

`--session-timeout seconds`

Specifies the session timeout for `shardmanctl` locks. If there is no connectivity between `shardmanctl` and the `etcd` store for the specified number of seconds, the lock is released. The default is 30.

`--store-endpoints string`

Specifies the `etcd` address in the format: `http[s]://address[:port](,http[s]://address[:port])*`. The default is `http://127.0.0.1:2379`.

`--store-ca-file string`

Verify the certificate of the HTTPS-enabled `etcd` store server using this CA bundle.

`--store-cert-file string`

Specifies the certificate file for client identification by the `etcd` store.

`--store-key string`

Specifies the private key file for client identification by the `etcd` store.

`--store-timeout duration`

Specifies the timeout for a etcd request. The default is 5 seconds.

`--monitor-port number`

Specifies the port for the shardmand http server for metrics and probes. The default is 15432.

`--api-port number`

Specifies the port for the shardmand http api server. The default is 15432.

`--version`

Show shardman-utils version information.

shardmand Environment

A shardmand service reads the environment from `/etc/shardman/shardmand-cluster0.env`. The following environment variables affect the behavior of shardmand.

`SDM_CLUSTER_NAME`

An alternative to setting the `--cluster-name` option

`SDM_LOG_LEVEL`

An alternative to setting the `--log-level` option

`SDM_RETRIES`

An alternative to setting the `--retries` option

`SDM_SYSTEM_BUS`

An alternative to setting the `--system-bus` option

`SDM_STORE_ENDPOINTS`

An alternative to setting the `--store-endpoints` option

`SDM_STORE_CA_FILE`

An alternative to setting the `--store-ca-file` option

`SDM_STORE_CERT_FILE`

An alternative to setting the `--store-cert-file` option

`SDM_STORE_KEY`

An alternative to setting the `--store-key` option

`SDM_STORE_TIMEOUT`

An alternative to setting the `--store-timeout` option

`SDM_SESSION_TIMEOUT`

An alternative to setting the `--session-timeout` option

`SDM_USER`

An alternative to setting the `--user` option

Part VII. Internals

This part contains assorted information that might be of use to Postgres Pro developers.

Chapter 53. Overview of Postgres Pro Internals

Author

This chapter originated as part of [sim98](#) Stefan Simkovics' Master's Thesis prepared at Vienna University of Technology under the direction of O.Univ.Prof.Dr. Georg Gottlob and Univ.Ass. Mag. Katrin Seyr.

This chapter gives an overview of the internal structure of the backend of Postgres Pro. After having read the following sections you should have an idea of how a query is processed. This chapter is intended to help the reader understand the general sequence of operations that occur within the backend from the point at which a query is received, to the point at which the results are returned to the client.

53.1. The Path of a Query

Here we give a short overview of the stages a query has to pass to obtain a result.

1. A connection from an application program to the Postgres Pro server has to be established. The application program transmits a query to the server and waits to receive the results sent back by the server.
2. The *parser stage* checks the query transmitted by the application program for correct syntax and creates a *query tree*.
3. The *rewrite system* takes the query tree created by the parser stage and looks for any *rules* (stored in the *system catalogs*) to apply to the query tree. It performs the transformations given in the *rule bodies*.

One application of the rewrite system is in the realization of *views*. Whenever a query against a view (i.e., a *virtual table*) is made, the rewrite system rewrites the user's query to a query that accesses the *base tables* given in the *view definition* instead.

4. The *planner/optimizer* takes the (rewritten) query tree and creates a *query plan* that will be the input to the *executor*.

It does so by first creating all possible *paths* leading to the same result. For example if there is an index on a relation to be scanned, there are two paths for the scan. One possibility is a simple sequential scan and the other possibility is to use the index. Next the cost for the execution of each path is estimated and the cheapest path is chosen. The cheapest path is expanded into a complete plan that the executor can use.

5. The executor recursively steps through the *plan tree* and retrieves rows in the way represented by the plan. The executor makes use of the *storage system* while scanning relations, performs *sorts* and *joins*, evaluates *qualifications* and finally hands back the rows derived.

In the following sections we will cover each of the above listed items in more detail to give a better understanding of Postgres Pro's internal control and data structures.

53.2. Query Processing

Postgres Pro Shardman uses the standard PostgreSQL [Section 53.1](#). Other nodes in the cluster are accessed via the modified `postgres_fdw` extension.

Postgres Pro Shardman query planner takes the query abstract syntax tree (AST) and creates a query plan, which is used by the executor. While evaluating query execution methods, the planner operates with so-called paths, which specify how relations should be accessed. While processing a query join tree, the planner looks at different combinations of how relations can be joined. Each time it examines a join

of two relations, one of which can be a join relation itself. After choosing the order and strategies for joining relations the planner considers the group by, order by and limit operations. When the cheapest path is selected, it is transformed to a query plan. A plan consists of a tree of nodes, each of which has methods to get one next result row (or NULL if there are no more results).

53.2.1. Push-down Technique

53.2.1.1. Joins

The efficiency of query execution in a distributed DBMS is determined by how many operations can be executed on nodes that hold the actual data. For Postgres Pro Shardman, a lot of effort is devoted to pushing down join operations. When the planner finds a relation that is accessible via a foreign data wrapper (FDW), it creates `ForeignPath` to access it. Later, when it examines a join of two relations and both of them are available via `ForeignPath` from the same foreign server, it can consider pushing down this join to the server and generating a so-called `ForeignJoinPath`. The planner can fail to do it if the join type is not supported, if filters attached to the relation should be applied locally, or if the relation scan result contains fields that cannot be evaluated on the remote server. An example of a currently unsupported join type is right anti-join. Local filters attached to the relation should be applied locally when remote execution can lead to a different result or if the `postgres_fdw` module cannot create SQL expressions to apply some of the filters. An example of fields that cannot be evaluated on a remote server are attributes of semi-join inner relation that are not accessible via an outer relation. If the `foreign_join_fast_path` configuration parameter is set to on (which is the default value), the Postgres Pro Shardman planner stops searching for other join strategies of two relations once it finds a foreign join possible for them. When the `postgres_fdw.enforce_foreign_join` configuration parameter is set to on (which is also the default), the cost of a foreign join is estimated so as to be always less than the cost of a local join.

When several sharded tables are joined on a sharding key, a partitionwise join can be possible. This means that instead of joining original tables, we can join their matching partitions. Partitionwise join currently applies only when the join conditions include all the partition keys, which must be of the same data type and have exactly matching sets of child partitions. Partitionwise join is crucial to the efficient query execution as it allows pushing down joins of table partitions. Evidently, to push down a join of several partitions, these partitions should reside on the same node. This is usually the case when sharded tables are created with the same `num_parts` parameter. However, for a rebalance process to move the corresponding partitions to the same nodes, sharded tables should be marked as colocated when created (see [Section 70.1.1](#)). Partitionwise join is enabled with the `enable_partitionwise_join` configuration parameter, which is turned on by default in Postgres Pro Shardman.

When a sharded table is joined to a global table, asymmetric partitionwise join is possible. This means that instead of joining original tables, we can join each partition of the sharded table with the global table. This makes it possible to push down a join of sharded table partitions - with a global table to the foreign server.

53.2.1.2. Aggregations

After planning joins, the planner considers paths for post-join operations, such as aggregations, limiting, sorting and grouping. Not all such operations reach FDW pushdown logic. For example, pushing down the `LIMIT` clause to a remote server is not possible when additional sorting is necessary prior to merging results from different nodes. There are two efficient strategies for executing aggregates on remote nodes. The first one is a partitionwise aggregation — when a `GROUP BY` clause includes a partitioning key, the aggregate can be pushed down together with the `GROUP BY` clause (this behavior is controlled by the `enable_presorted_aggregate`/`enable_partitionwise_aggregate` configuration parameter, which is turned on by default in Postgres Pro Shardman). Alternatively, the planner can decide to execute partial aggregation on each partition of a sharded table and then combine the results. If necessary, the executor can export the representation of the aggregate's internal state on each node, import it locally and execute the final aggregation steps on coordinator. Usually it works for the built-in aggregates. Also the planner refuses pushing down partial aggregates if they contain additional clauses, such as `ORDER BY` or `DISTINCT`, or if the statement has the `HAVING` clause.

53.2.1.3. Subqueries

Generally, subqueries cannot be pushed down to other cluster nodes. However, Postgres Pro Shardman uses subquery unnesting to alleviate this limitation.

In PostgreSQL, non-correlated subqueries can be transformed into semi-joins. In the following example, ANY subquery on non-partitioned tables is transformed to Hash Semi Join:

```
EXPLAIN (COSTS OFF) SELECT * FROM pgbench_branches WHERE bid = ANY (SELECT bid FROM
pgbench_tellers);
```

QUERY PLAN

```
-----
Hash Semi Join
  Hash Cond: (pgbench_branches.bid = pgbench_tellers.bid)
    -> Seq Scan on pgbench_branches
    -> Hash
        -> Seq Scan on pgbench_tellers
```

Planner also can convert some forms of correlated subqueries (i.e., subqueries that reference upper-level relations) into semi-joins. This optimization works for IN and = operators. The transformation has some restrictions. For example, it is not considered if a subquery contains aggregates or references upper-level relations from outside of a WHERE clause. This optimization allows transforming more complex subqueries into semi-joins, like in the following example:

```
EXPLAIN (COSTS OFF) SELECT * FROM pgbench_branches WHERE bid = ANY (SELECT bid FROM
pgbench_tellers WHERE tbalance = bbalance);
```

QUERY PLAN

```
-----
Hash Semi Join
  Hash Cond: ((pgbench_branches.bid = pgbench_tellers.bid) AND
(pgbench_branches.bbalance = pgbench_tellers.tbalance))
    -> Seq Scan on pgbench_branches
    -> Hash
        -> Seq Scan on pgbench_tellers
(5 rows)
```

After applying subquery unnesting, semi-join can be pushed down for execution to a remote node.

53.2.2. Asynchronous Execution

When a sharded table is queried, the Postgres Pro Shardman planner creates `Append` plans to scan all partitions of the table and combine the result. When some of partitions are foreign tables, the planner can decide to use an asynchronous execution. This means that when an `Append` or `MergeAppend` node for the first time after initialization is asked for the tuples, it asks asynchronous child nodes to start fetching the result. For `postgres_fdw` `async ForeignScan` nodes, it means that a remote cursor is declared and a fetch request is sent to the remote server. If Silk transport is used, this means that the query is sent for execution to the remote server as an `MT_SPI` message.

After sending a request to the remote servers, `Append` returns to fetching data from synchronous child nodes — local scan nodes or synchronous `ForeignScan` nodes. Data from such nodes is fetched in a blocking manner. When `Append` ends getting data from synchronous nodes (such as local partitions scans), it looks if `async` nodes have some data. If they do not, it waits for `async` nodes to produce results.

Postgres Pro Shardman can execute several types of plans asynchronously. These are asynchronous `ForeignScans`, projections and trivial subquery scans (`select * from subquery`) over asynchronous plans.

The asynchronous execution is turned on by default on the level of a foreign server. This is controlled by `async_capable postgres_fdw` option. Both `Append` and `MergeAppend` plans support asynchronous execution.

Examples:

```
EXPLAIN (COSTS OFF) SELECT * FROM pgbench_accounts;  
QUERY PLAN
```

Append

```
-> Seq Scan on pgbench_accounts_0 pgbench_accounts_1  
-> Async Foreign Scan on pgbench_accounts_1_fdw pgbench_accounts_2  
-> Async Foreign Scan on pgbench_accounts_2_fdw pgbench_accounts_3  
-> Seq Scan on pgbench_accounts_3 pgbench_accounts_4  
-> Async Foreign Scan on pgbench_accounts_4_fdw pgbench_accounts_5  
-> Async Foreign Scan on pgbench_accounts_5_fdw pgbench_accounts_6  
-> Seq Scan on pgbench_accounts_6 pgbench_accounts_7  
-> Async Foreign Scan on pgbench_accounts_7_fdw pgbench_accounts_8  
-> Async Foreign Scan on pgbench_accounts_8_fdw pgbench_accounts_9  
-> Seq Scan on pgbench_accounts_9 pgbench_accounts_10  
-> Async Foreign Scan on pgbench_accounts_10_fdw pgbench_accounts_11  
-> Async Foreign Scan on pgbench_accounts_11_fdw pgbench_accounts_12  
-> Seq Scan on pgbench_accounts_12 pgbench_accounts_13  
-> Async Foreign Scan on pgbench_accounts_13_fdw pgbench_accounts_14  
-> Async Foreign Scan on pgbench_accounts_14_fdw pgbench_accounts_15  
-> Seq Scan on pgbench_accounts_15 pgbench_accounts_16  
-> Async Foreign Scan on pgbench_accounts_16_fdw pgbench_accounts_17  
-> Async Foreign Scan on pgbench_accounts_17_fdw pgbench_accounts_18  
-> Seq Scan on pgbench_accounts_18 pgbench_accounts_19  
-> Async Foreign Scan on pgbench_accounts_19_fdw pgbench_accounts_20
```

Here we see a typical asynchronous plan. There are asynchronous foreign scans and local sequential scans, which are executed synchronously.

53.2.3. Fetch-all Fallback

There are a lot of cases when operations on data cannot be executed remotely (for example, when some non-immutable function is used in filters, when several sharded tables are joined by an attribute that is not a sharding key, when pushdown of a particular join type is not supported) or when the planner considers local execution to be cheaper. In such cases different operations (selection, joins or aggregations) are not pushed down, but executed locally. This can lead to inefficient query execution due to large inter-cluster traffic and high processing cost on a coordinator. When this happens, you should check if an optimizer has fresh statistics, consider rewriting the query to benefit from different forms of pushdown or at least check that the suggested query plan is reasonable enough.

53.3. How Connections Are Established

Postgres Pro implements a “process per user” client/server model. In this model, every *client process* connects to exactly one *backend process*. As we do not know ahead of time how many connections will be made, we have to use a “supervisor process” that spawns a new backend process every time a connection is requested. This supervisor process is called *postmaster* and listens at a specified TCP/IP port for incoming connections. Whenever it detects a request for a connection, it spawns a new backend process. Those backend processes communicate with each other and with other processes of the *instance* using *semaphores* and *shared memory* to ensure data integrity throughout concurrent data access.

The client process can be any program that understands the Postgres Pro protocol described in [Chapter 56](#). Many clients are based on the C-language library libpq, but several independent implementations of the protocol exist, such as the Java JDBC driver.

Once a connection is established, the client process can send a query to the backend process it's connected to. The query is transmitted using plain text, i.e., there is no parsing done in the client. The backend process parses the query, creates an *execution plan*, executes the plan, and returns the retrieved rows to the client by transmitting them over the established connection.

53.4. The Parser Stage

The *parser stage* consists of two parts:

- The *parser* defined in `gram.y` and `scan.l` is built using the Unix tools `bison` and `flex`.
- The *transformation process* does modifications and augmentations to the data structures returned by the parser.

53.4.1. Parser

The parser has to check the query string (which arrives as plain text) for valid syntax. If the syntax is correct a *parse tree* is built up and handed back; otherwise an error is returned. The parser and lexer are implemented using the well-known Unix tools `bison` and `flex`.

The *lexer* is defined in the file `scan.l` and is responsible for recognizing *identifiers*, the *SQL key words* etc. For every key word or identifier that is found, a *token* is generated and handed to the parser.

The parser is defined in the file `gram.y` and consists of a set of *grammar rules* and *actions* that are executed whenever a rule is fired. The code of the actions (which is actually C code) is used to build up the parse tree.

The file `scan.l` is transformed to the C source file `scan.c` using the program `flex` and `gram.y` is transformed to `gram.c` using `bison`. After these transformations have taken place a normal C compiler can be used to create the parser. Never make any changes to the generated C files as they will be overwritten the next time `flex` or `bison` is called.

Note

The mentioned transformations and compilations are normally done automatically using the *make-files* shipped with the Postgres Pro source distribution.

A detailed description of `bison` or the grammar rules given in `gram.y` would be beyond the scope of this manual. There are many books and documents dealing with `flex` and `bison`. You should be familiar with `bison` before you start to study the grammar given in `gram.y` otherwise you won't understand what happens there.

53.4.2. Transformation Process

The parser stage creates a parse tree using only fixed rules about the syntactic structure of SQL. It does not make any lookups in the system catalogs, so there is no possibility to understand the detailed semantics of the requested operations. After the parser completes, the *transformation process* takes the tree handed back by the parser as input and does the semantic interpretation needed to understand which tables, functions, and operators are referenced by the query. The data structure that is built to represent this information is called the *query tree*.

The reason for separating raw parsing from semantic analysis is that system catalog lookups can only be done within a transaction, and we do not wish to start a transaction immediately upon receiving a query string. The raw parsing stage is sufficient to identify the transaction control commands (`BEGIN`, `ROLLBACK`, etc.), and these can then be correctly executed without any further analysis. Once we know that we are dealing with an actual query (such as `SELECT` or `UPDATE`), it is okay to start a transaction if we're not already in one. Only then can the transformation process be invoked.

The query tree created by the transformation process is structurally similar to the raw parse tree in most places, but it has many differences in detail. For example, a `FuncCall` node in the parse tree represents something that looks syntactically like a function call. This might be transformed to either a `FuncExpr` or `Aggref` node depending on whether the referenced name turns out to be an ordinary function or an

aggregate function. Also, information about the actual data types of columns and expression results is added to the query tree.

53.5. The Postgres Pro Rule System

Postgres Pro supports a powerful *rule system* for the specification of *views* and ambiguous *view updates*. Originally the Postgres Pro rule system consisted of two implementations:

- The first one worked using *row level* processing and was implemented deep in the *executor*. The rule system was called whenever an individual row had been accessed. This implementation was removed in 1995 when the last official release of the Berkeley Postgres project was transformed into Postgres95.
- The second implementation of the rule system is a technique called *query rewriting*. The *rewrite system* is a module that exists between the *parser stage* and the *planner/optimizer*. This technique is still implemented.

The query rewriter is discussed in some detail in [Chapter 42](#), so there is no need to cover it here. We will only point out that both the input and the output of the rewriter are query trees, that is, there is no change in the representation or level of semantic detail in the trees. Rewriting can be thought of as a form of macro expansion.

53.6. Planner/Optimizer

The task of the *planner/optimizer* is to create an optimal execution plan. A given SQL query (and hence, a query tree) can be actually executed in a wide variety of different ways, each of which will produce the same set of results. If it is computationally feasible, the query optimizer will examine each of these possible execution plans, ultimately selecting the execution plan that is expected to run the fastest.

Note

In some situations, examining each possible way in which a query can be executed would take an excessive amount of time and memory. In particular, this occurs when executing queries involving large numbers of join operations. In order to determine a reasonable (not necessarily optimal) query plan in a reasonable amount of time, Postgres Pro uses a *Genetic Query Optimizer* (see [Chapter 61](#)) when the number of joins exceeds a threshold (see [geqo_threshold](#)).

The planner's search procedure actually works with data structures called *paths*, which are simply cut-down representations of plans containing only as much information as the planner needs to make its decisions. After the cheapest path is determined, a full-fledged *plan tree* is built to pass to the executor. This represents the desired execution plan in sufficient detail for the executor to run it. In the rest of this section we'll ignore the distinction between paths and plans.

53.6.1. Generating Possible Plans

The planner/optimizer starts by generating plans for scanning each individual relation (table) used in the query. The possible plans are determined by the available indexes on each relation. There is always the possibility of performing a sequential scan on a relation, so a sequential scan plan is always created. Assume an index is defined on a relation (for example a B-tree index) and a query contains the restriction `relation.attribute OPR constant`. If `relation.attribute` happens to match the key of the B-tree index and `OPR` is one of the operators listed in the index's *operator class*, another plan is created using the B-tree index to scan the relation. If there are further indexes present and the restrictions in the query happen to match a key of an index, further plans will be considered. Index scan plans are also generated for indexes that have a sort ordering that can match the query's `ORDER BY` clause (if any), or a sort ordering that might be useful for merge joining (see below).

If the query requires joining two or more relations, plans for joining relations are considered after all feasible plans have been found for scanning single relations. The three available join strategies are:

- *nested loop join*: The right relation is scanned once for every row found in the left relation. This strategy is easy to implement but can be very time consuming. (However, if the right relation can be scanned with an index scan, this can be a good strategy. It is possible to use values from the current row of the left relation as keys for the index scan of the right.)
- *merge join*: Each relation is sorted on the join attributes before the join starts. Then the two relations are scanned in parallel, and matching rows are combined to form join rows. This kind of join is attractive because each relation has to be scanned only once. The required sorting might be achieved either by an explicit sort step, or by scanning the relation in the proper order using an index on the join key.
- *hash join*: the right relation is first scanned and loaded into a hash table, using its join attributes as hash keys. Next the left relation is scanned and the appropriate values of every row found are used as hash keys to locate the matching rows in the table.

When the query involves more than two relations, the final result must be built up by a tree of join steps, each with two inputs. The planner examines different possible join sequences to find the cheapest one.

If the query uses fewer than `geqo_threshold` relations, a near-exhaustive search is conducted to find the best join sequence. The planner preferentially considers joins between any two relations for which there exists a corresponding join clause in the `WHERE` qualification (i.e., for which a restriction like `where rel1.attr1=rel2.attr2` exists). Join pairs with no join clause are considered only when there is no other choice, that is, a particular relation has no available join clauses to any other relation. All possible plans are generated for every join pair considered by the planner, and the one that is (estimated to be) the cheapest is chosen.

When `geqo_threshold` is exceeded, the join sequences considered are determined by heuristics, as described in [Chapter 61](#). Otherwise the process is the same.

The finished plan tree consists of sequential or index scans of the base relations, plus nested-loop, merge, or hash join nodes as needed, plus any auxiliary steps needed, such as sort nodes or aggregate-function calculation nodes. Most of these plan node types have the additional ability to do *selection* (discarding rows that do not meet a specified Boolean condition) and *projection* (computation of a derived column set based on given column values, that is, evaluation of scalar expressions where needed). One of the responsibilities of the planner is to attach selection conditions from the `WHERE` clause and computation of required output expressions to the most appropriate nodes of the plan tree.

53.7. Executor

The *executor* takes the plan created by the planner/optimizer and recursively processes it to extract the required set of rows. This is essentially a demand-pull pipeline mechanism. Each time a plan node is called, it must deliver one more row, or report that it is done delivering rows.

To provide a concrete example, assume that the top node is a `MergeJoin` node. Before any merge can be done two rows have to be fetched (one from each subplan). So the executor recursively calls itself to process the subplans (it starts with the subplan attached to `lefttree`). The new top node (the top node of the left subplan) is, let's say, a `Sort` node and again recursion is needed to obtain an input row. The child node of the `Sort` might be a `SeqScan` node, representing actual reading of a table. Execution of this node causes the executor to fetch a row from the table and return it up to the calling node. The `Sort` node will repeatedly call its child to obtain all the rows to be sorted. When the input is exhausted (as indicated by the child node returning a `NULL` instead of a row), the `Sort` code performs the sort, and finally is able to return its first output row, namely the first one in sorted order. It keeps the remaining rows stored so that it can deliver them in sorted order in response to later demands.

The `MergeJoin` node similarly demands the first row from its right subplan. Then it compares the two rows to see if they can be joined; if so, it returns a join row to its caller. On the next call, or immediately if it cannot join the current pair of inputs, it advances to the next row of one table or the other (depending on how the comparison came out), and again checks for a match. Eventually, one subplan or the other is exhausted, and the `MergeJoin` node returns `NULL` to indicate that no more join rows can be formed.

Complex queries can involve many levels of plan nodes, but the general approach is the same: each node computes and returns its next output row each time it is called. Each node is also responsible for applying any selection or projection expressions that were assigned to it by the planner.

The executor mechanism is used to evaluate all five basic SQL query types: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and `MERGE`. For `SELECT`, the top-level executor code only needs to send each row returned by the query plan tree off to the client. `INSERT ... SELECT`, `UPDATE`, `DELETE`, and `MERGE` are effectively `SELECT`s under a special top-level plan node called `ModifyTable`.

`INSERT ... SELECT` feeds the rows up to `ModifyTable` for insertion. For `UPDATE`, the planner arranges that each computed row includes all the updated column values, plus the *TID* (tuple ID, or row ID) of the original target row; this data is fed up to the `ModifyTable` node, which uses the information to create a new updated row and mark the old row deleted. For `DELETE`, the only column that is actually returned by the plan is the TID, and the `ModifyTable` node simply uses the TID to visit each target row and mark it deleted. For `MERGE`, the planner joins the source and target relations, and includes all column values required by any of the `WHEN` clauses, plus the TID of the target row; this data is fed up to the `ModifyTable` node, which uses the information to work out which `WHEN` clause to execute, and then inserts, updates or deletes the target row, as required.

A simple `INSERT ... VALUES` command creates a trivial plan tree consisting of a single `Result` node, which computes just one result row, feeding that up to `ModifyTable` to perform the insertion.

Chapter 54. System Catalogs

The system catalogs are the place where a relational database management system stores schema meta-data, such as information about tables and columns, and internal bookkeeping information. Postgres Pro's system catalogs are regular tables. You can drop and recreate the tables, add columns, insert and update values, and severely mess up your system that way. Normally, one should not change the system catalogs by hand, there are normally SQL commands to do that. (For example, `CREATE DATABASE` inserts a row into the `pg_database` catalog — and actually creates the database on disk.) There are some exceptions for particularly esoteric operations, but many of those have been made available as SQL commands over time, and so the need for direct manipulation of the system catalogs is ever decreasing.

54.1. Overview

Table 54.1 lists the system catalogs. More detailed documentation of each catalog follows below.

Most system catalogs are copied from the template database during database creation and are thereafter database-specific. A few catalogs are physically shared across all databases in a cluster; these are noted in the descriptions of the individual catalogs.

Table 54.1. System Catalogs

Catalog Name	Purpose
<code>pg_aggregate</code>	aggregate functions
<code>pg_am</code>	relation access methods
<code>pg_amop</code>	access method operators
<code>pg_amproc</code>	access method support functions
<code>pg_attrdef</code>	column default values
<code>pg_attribute</code>	table columns (“attributes”)
<code>pg_authid</code>	authorization identifiers (roles)
<code>pg_auth_members</code>	authorization identifier membership relationships
<code>pg_cast</code>	casts (data type conversions)
<code>pg_class</code>	tables, indexes, sequences, views (“relations”)
<code>pg_collation</code>	collations (locale information)
<code>pg_constraint</code>	check constraints, unique constraints, primary key constraints, foreign key constraints
<code>pg_conversion</code>	encoding conversion information
<code>pg_database</code>	databases within this database cluster
<code>pg_db_role_setting</code>	per-role and per-database settings
<code>pg_default_acl</code>	default privileges for object types
<code>pg_depend</code>	dependencies between database objects
<code>pg_description</code>	descriptions or comments on database objects
<code>pg_enum</code>	enum label and value definitions
<code>pg_event_trigger</code>	event triggers
<code>pg_extension</code>	installed extensions
<code>pg_foreign_data_wrapper</code>	foreign-data wrapper definitions
<code>pg_foreign_server</code>	foreign server definitions
<code>pg_foreign_table</code>	additional foreign table information
<code>pg_index</code>	additional index information

Catalog Name	Purpose
pg_inherits	table inheritance hierarchy
pg_init_privs	object initial privileges
pg_language	languages for writing functions
pg_largeobject	data pages for large objects
pg_largeobject_metadata	metadata for large objects
pg_namespace	schemas
pg_opclass	access method operator classes
pg_operator	operators
pg_opfamily	access method operator families
pg_parameter_acl	configuration parameters for which privileges have been granted
pg_partitioned_table	information about partition key of tables
pg_policy	row-security policies
pg_proc	functions and procedures
pg_profile	profiles, a set of authentication restrictions
pg_publication	publications for logical replication
pg_publication_namespace	schema to publication mapping
pg_publication_rel	relation to publication mapping
pg_range	information about range types
pg_replication_origin	registered replication origins
pg_rewrite	query rewrite rules
pg_role_password	roles password history
pg_seclabel	security labels on database objects
pg_sequence	information about sequences
pg_shdepend	dependencies on shared objects
pg_shdescription	comments on shared objects
pg_shseclabel	security labels on shared database objects
pg_statistic	planner statistics
pg_statistic_ext	extended planner statistics (definition)
pg_statistic_ext_data	extended planner statistics (built statistics)
pg_subscription	logical replication subscriptions
pg_subscription_rel	relation state for subscriptions
pg_tablespace	tablespaces within this database cluster
pg_transform	transforms (data type to procedural language conversions)
pg_trigger	triggers
pg_ts_config	text search configurations
pg_ts_config_map	text search configurations' token mappings
pg_ts_dict	text search dictionaries
pg_ts_parser	text search parsers

Catalog Name	Purpose
pg_ts_template	text search templates
pg_type	data types
pg_user_mapping	mappings of users to foreign servers

54.2. pg_aggregate

The catalog `pg_aggregate` stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in `pg_aggregate` is an extension of an entry in [pg_proc](#). The `pg_proc` entry carries the aggregate's name, input and output data types, and other information that is similar to ordinary functions.

Table 54.2. `pg_aggregate` Columns

Column Type	Description
<code>aggfnoid regproc</code> (references pg_proc .oid)	<code>pg_proc</code> OID of the aggregate function
<code>aggkind char</code>	Aggregate kind: <code>n</code> for “normal” aggregates, <code>o</code> for “ordered-set” aggregates, or <code>h</code> for “hypothetical-set” aggregates
<code>aggnumdirectargs int2</code>	Number of direct (non-aggregated) arguments of an ordered-set or hypothetical-set aggregate, counting a variadic array as one argument. If equal to <code>pronargs</code> , the aggregate must be variadic and the variadic array describes the aggregated arguments as well as the final direct arguments. Always zero for normal aggregates.
<code>aggtransfn regproc</code> (references pg_proc .oid)	Transition function
<code>aggfinalfn regproc</code> (references pg_proc .oid)	Final function (zero if none)
<code>aggcombinefn regproc</code> (references pg_proc .oid)	Combine function (zero if none)
<code>aggserialfn regproc</code> (references pg_proc .oid)	Serialization function (zero if none)
<code>aggdeserialfn regproc</code> (references pg_proc .oid)	Deserialization function (zero if none)
<code>aggmtransfn regproc</code> (references pg_proc .oid)	Forward transition function for moving-aggregate mode (zero if none)
<code>aggminvtransfn regproc</code> (references pg_proc .oid)	Inverse transition function for moving-aggregate mode (zero if none)
<code>aggmfinalfn regproc</code> (references pg_proc .oid)	Final function for moving-aggregate mode (zero if none)
<code>aggfinalextra bool</code>	True to pass extra dummy arguments to <code>aggfinalfn</code>
<code>aggmfinalextra bool</code>	True to pass extra dummy arguments to <code>aggmfinalfn</code>
<code>aggfinalmodify char</code>	Whether <code>aggfinalfn</code> modifies the transition state value: <code>r</code> if it is read-only, <code>s</code> if the <code>aggtransfn</code> cannot be applied after the <code>aggfinalfn</code> , or <code>w</code> if it writes on the value

Column Type	Description
aggmfinalmodify char	Like aggfinalmodify, but for the aggmfinalfn
aggstortop oid (references pg_operator .oid)	Associated sort operator (zero if none)
aggtranstype oid (references pg_type .oid)	Data type of the aggregate function's internal transition (state) data
aggtransspace int4	Approximate average size (in bytes) of the transition state data, or zero to use a default estimate
aggmtranstype oid (references pg_type .oid)	Data type of the aggregate function's internal transition (state) data for moving-aggregate mode (zero if none)
aggmtransspace int4	Approximate average size (in bytes) of the transition state data for moving-aggregate mode, or zero to use a default estimate
agginitval text	The initial value of the transition state. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.
aggminitval text	The initial value of the transition state for moving-aggregate mode. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.

New aggregate functions are registered with the [CREATE AGGREGATE](#) command. See [Section 39.12](#) for more information about writing aggregate functions and the meaning of the transition functions, etc.

54.3. pg_am

The catalog `pg_am` stores information about relation access methods. There is one row for each access method supported by the system. Currently, only tables and indexes have access methods. The requirements for table and index access methods are discussed in detail in [Chapter 62](#) and [Chapter 63](#) respectively.

Table 54.3. `pg_am` Columns

Column Type	Description
oid oid	Row identifier
amname name	Name of the access method
amhandler regproc (references pg_proc .oid)	OID of a handler function that is responsible for supplying information about the access method
amtype char	t = table (including materialized views), i = index.

Note

Before Postgres Pro 9.6, `pg_am` contained many additional columns representing properties of index access methods. That data is now only directly visible at the C code level. However, `pg_in-`

`dex_column_has_property()` and related functions have been added to allow SQL queries to inspect index access method properties; see [Table 9.74](#).

54.4. `pg_amop`

The catalog `pg_amop` stores information about operators associated with access method operator families. There is one row for each operator that is a member of an operator family. A family member can be either a *search* operator or an *ordering* operator. An operator can appear in more than one family, but cannot appear in more than one search position nor more than one ordering position within a family. (It is allowed, though unlikely, for an operator to be used for both search and ordering purposes.)

Table 54.4. `pg_amop` Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>amopfamily oid (references <code>pg_opfamily</code> .oid)</code>	The operator family this entry is for
<code>amoplefttype oid (references <code>pg_type</code> .oid)</code>	Left-hand input data type of operator
<code>amoprightrighttype oid (references <code>pg_type</code> .oid)</code>	Right-hand input data type of operator
<code>amopstrategy int2</code>	Operator strategy number
<code>amoppurpose char</code>	Operator purpose, either <code>s</code> for search or <code>o</code> for ordering
<code>amopopr oid (references <code>pg_operator</code> .oid)</code>	OID of the operator
<code>amopmethod oid (references <code>pg_am</code> .oid)</code>	Index access method operator family is for
<code>amopsortfamily oid (references <code>pg_opfamily</code> .oid)</code>	The B-tree operator family this entry sorts according to, if an ordering operator; zero if a search operator

A “search” operator entry indicates that an index of this operator family can be searched to find all rows satisfying `WHERE indexed_column operator constant`. Obviously, such an operator must return `boolean`, and its left-hand input type must match the index's column data type.

An “ordering” operator entry indicates that an index of this operator family can be scanned to return rows in the order represented by `ORDER BY indexed_column operator constant`. Such an operator could return any sortable data type, though again its left-hand input type must match the index's column data type. The exact semantics of the `ORDER BY` are specified by the `amopsortfamily` column, which must reference a B-tree operator family for the operator's result type.

Note

At present, it's assumed that the sort order for an ordering operator is the default for the referenced operator family, i.e., `ASC NULLS LAST`. This might someday be relaxed by adding additional columns to specify sort options explicitly.

An entry's `amopmethod` must match the `opfmeth` of its containing operator family (including `amopmethod` here is an intentional denormalization of the catalog structure for performance reasons). Al-

so, `amoplefttype` and `amoprightright` must match the `oprleft` and `oprright` fields of the referenced `pg_operator` entry.

54.5. `pg_amproc`

The catalog `pg_amproc` stores information about support functions associated with access method operator families. There is one row for each support function belonging to an operator family.

Table 54.5. `pg_amproc` Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>amprocfamily oid</code> (references <code>pg_opfamily .oid</code>)	The operator family this entry is for
<code>amproclefttype oid</code> (references <code>pg_type .oid</code>)	Left-hand input data type of associated operator
<code>amprocrighttype oid</code> (references <code>pg_type .oid</code>)	Right-hand input data type of associated operator
<code>amprocnum int2</code>	Support function number
<code>amproc regproc</code> (references <code>pg_proc .oid</code>)	OID of the function

The usual interpretation of the `amproclefttype` and `amprocrighttype` fields is that they identify the left and right input types of the operator(s) that a particular support function supports. For some access methods these match the input data type(s) of the support function itself, for others not. There is a notion of “default” support functions for an index, which are those with `amproclefttype` and `amprocrighttype` both equal to the index operator class's `opcintype`.

54.6. `pg_attrdef`

The catalog `pg_attrdef` stores column default values. The main information about columns is stored in `pg_attribute`. Only columns for which a default value has been explicitly set will have an entry here.

Table 54.6. `pg_attrdef` Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>adrelid oid</code> (references <code>pg_class .oid</code>)	The table this column belongs to
<code>adnum int2</code> (references <code>pg_attribute .attnum</code>)	The number of the column
<code>adbin pg_node_tree</code>	The column default value, in <code>nodeToString()</code> representation. Use <code>pg_get_expr(adbin, adrelid)</code> to convert it to an SQL expression.

54.7. `pg_attribute`

The catalog `pg_attribute` stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and indeed all objects that have `pg_class` entries.)

The term attribute is equivalent to column and is used for historical reasons.

Table 54.7. pg_attribute Columns

Column Type	Description
attrelid oid (references <code>pg_class</code> .oid)	The table this column belongs to
attname name	The column name
atttypid oid (references <code>pg_type</code> .oid)	The data type of this column (zero for a dropped column)
attlen int2	A copy of <code>pg_type.typelen</code> of this column's type
attnum int2	The number of the column. Ordinary columns are numbered from 1 up. System columns, such as <code>ctid</code> , have (arbitrary) negative numbers.
attcacheoff int4	Always -1 in storage, but when loaded into a row descriptor in memory this might be updated to cache the offset of the attribute within the row
atttypmod int4	<code>atttypmod</code> records type-specific data supplied at table creation time (for example, the maximum length of a <code>varchar</code> column). It is passed to type-specific input functions and length coercion functions. The value will generally be -1 for types that do not need <code>atttypmod</code> .
attnndims int2	Number of dimensions, if the column is an array type; otherwise 0. (Presently, the number of dimensions of an array is not enforced, so any nonzero value effectively means "it's an array".)
attbyval bool	A copy of <code>pg_type.typbyval</code> of this column's type
attalign char	A copy of <code>pg_type.typalign</code> of this column's type
attstorage char	Normally a copy of <code>pg_type.typstorage</code> of this column's type. For TOAST-able data types, this can be altered after column creation to control storage policy.
attcompression char	The current compression method of the column. Typically this is <code>'\0'</code> to specify use of the current default setting (see default_toast_compression). Otherwise, <code>'p'</code> selects <code>pglz</code> compression, while <code>'l'</code> selects <code>LZ4</code> compression. However, this field is ignored whenever <code>attstorage</code> does not allow compression.
attnotnull bool	This represents a not-null constraint.
atthasdef bool	This column has a default expression or generation expression, in which case there will be a corresponding entry in the <code>pg_attrdef</code> catalog that actually defines the expression. (Check <code>attgenerated</code> to determine whether this is a default or a generation expression.)
atthasmissing bool	This column has a value which is used where the column is entirely missing from the row, as happens when a column is added with a non-volatile <code>DEFAULT</code> value after the row is created. The actual value used is stored in the <code>attmissingval</code> column.
attidentity char	

Column Type	Description
	If a zero byte (' '), then not an identity column. Otherwise, <code>a</code> = generated always, <code>d</code> = generated by default.
<code>attgenerated char</code>	If a zero byte (' '), then not a generated column. Otherwise, <code>s</code> = stored. (Other values might be added in the future.)
<code>attisdropped bool</code>	This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL.
<code>attislocal bool</code>	This column is defined locally in the relation. Note that a column can be locally defined and inherited simultaneously.
<code>attinhcount int2</code>	The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed.
<code>attcollation oid</code> (references <code>pg_collation .oid</code>)	The defined collation of the column, or zero if the column is not of a collatable data type
<code>attstattarget int2</code>	<code>attstattarget</code> controls the level of detail of statistics accumulated for this column by ANALYZE . A zero value indicates that no statistics should be collected. A null value says to use the system default statistics target. The exact meaning of positive values is data type-dependent. For scalar data types, <code>attstattarget</code> is both the target number of “most common values” to collect, and the target number of histogram bins to create.
<code>attacl aclitem[]</code>	Column-level access privileges, if any have been granted specifically on this column
<code>attoptions text[]</code>	Attribute-level options, as “keyword=value” strings
<code>attfdwoptions text[]</code>	Attribute-level foreign data wrapper options, as “keyword=value” strings
<code>attmissingval anyarray</code>	This column has a one element array containing the value used when the column is entirely missing from the row, as happens when the column is added with a non-volatile <code>DEFAULT</code> value after the row is created. The value is only used when <code>atthasmissing</code> is true. If there is no value the column is null.

In a dropped column's `pg_attribute` entry, `atttypid` is reset to zero, but `attlen` and the other fields copied from `pg_type` are still valid. This arrangement is needed to cope with the situation where the dropped column's data type was later dropped, and so there is no `pg_type` row anymore. `attlen` and the other fields can be used to interpret the contents of a row of the table.

54.8. pg_authid

The catalog `pg_authid` contains information about database authorization identifiers (roles). A role subsumes the concepts of “users” and “groups”. A user is essentially just a role with the `rolcanlogin` flag set. Any role (with or without `rolcanlogin`) can have other roles as members; see [pg_auth_members](#).

Since this catalog contains passwords, it must not be publicly readable. `pg_roles` is a publicly readable view on `pg_authid` that blanks out the password field.

[Chapter 21](#) contains detailed information about user and privilege management.

Because user identities are cluster-wide, `pg_authid` is shared across all databases of a cluster: there is only one copy of `pg_authid` per cluster, not one per database.

Table 54.8. pg_authid Columns

Column	Type	Description
oid	oid	Row identifier
rolname	name	Role name
rolsuper	bool	Role has superuser privileges
rolinherit	bool	Role automatically inherits privileges of roles it is a member of
rolcreatorole	bool	Role can create more roles
rolcreatedb	bool	Role can create databases
rolcanlogin	bool	Role can log in. That is, this role can be given as the initial session authorization identifier.
rolreplication	bool	Role is a replication role. A replication role can initiate replication connections and create and drop replication slots.
rolbypassrsls	bool	Role bypasses every row-level security policy, see Section 5.9 for more information.
rolconnlimit	int4	For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.
rolprofile	regprofile (references pg_profile .oid)	The OID of the role's profile
rolloginattempts	int4	Number of consecutive failed login attempts of a user. It is always 0 if FAILED_LOGIN_ATTEMPTS value of the corresponding role profile is UNLIMITED (see CREATE PROFILE). After a successful login, rolloginattempts is reset to 0.
rollastlogin	timestampz	The timestamp the role logged in last time
rolfirstfailedauth	timestampz	The timestamp of the role's first authentication failure
rolstatus	int2	Status of the role: 0 for the active role, 1 the role is manually locked (see ACCOUNT LOCK in ALTER ROLE), 2 the role is locked because of inactivity (see parameter USER_INACTIVE_TIME in CREATE PROFILE), 4 the role is locked because the number of consecutive authentication failures has reached the limit (see parameter FAILED_LOGIN_ATTEMPTS in CREATE PROFILE)
rolpassword	text	Password (possibly encrypted); null if none. The format depends on the form of encryption used.
rolvaliduntil	timestampz	Password expiry time (only used for password authentication); null if no expiration
rolpasssetat	timestampz	Password set time (only used for password authentication); null if password is not set.

For an MD5 encrypted password, `rolpassword` column will begin with the string `md5` followed by a 32-character hexadecimal MD5 hash. The MD5 hash will be of the user's password concatenated to their user name. For example, if user `joe` has password `xyzyzy`, Postgres Pro will store the md5 hash of `xyzyzyjoe`.

If the password is encrypted with SCRAM-SHA-256, it has the format:

```
SCRAM-SHA-256$<iteration count>:<salt>$<StoredKey>:<ServerKey>
```

where `salt`, `StoredKey` and `ServerKey` are in Base64 encoded format. This format is the same as that specified by [RFC 5803](#).

A password that does not follow either of those formats is assumed to be unencrypted.

54.9. pg_auth_members

The catalog `pg_auth_members` shows the membership relations between roles. Any non-circular set of relationships is allowed.

Because user identities are cluster-wide, `pg_auth_members` is shared across all databases of a cluster: there is only one copy of `pg_auth_members` per cluster, not one per database.

Table 54.9. pg_auth_members Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>roleid oid (references pg_authid .oid)</code>	ID of a role that has a member
<code>member oid (references pg_authid .oid)</code>	ID of a role that is a member of <code>roleid</code>
<code>grantor oid (references pg_authid .oid)</code>	ID of the role that granted this membership
<code>admin_option bool</code>	True if member can grant membership in <code>roleid</code> to others
<code>inherit_option bool</code>	True if the member automatically inherits the privileges of the granted role
<code>set_option bool</code>	True if the member can <code>SET ROLE</code> to the granted role

54.10. pg_cast

The catalog `pg_cast` stores data type conversion paths, both built-in and user-defined.

It should be noted that `pg_cast` does not represent every type conversion that the system knows how to perform; only those that cannot be deduced from some generic rule. For example, casting between a domain and its base type is not explicitly represented in `pg_cast`. Another important exception is that “automatic I/O conversion casts”, those performed using a data type's own I/O functions to convert to or from `text` or other string types, are not explicitly represented in `pg_cast`.

Table 54.10. pg_cast Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>castsource oid (references pg_type .oid)</code>	

Column Type	Description
	OID of the source data type
<code>casttarget oid</code> (references <code>pg_type .oid</code>)	OID of the target data type
<code>castfunc oid</code> (references <code>pg_proc .oid</code>)	The OID of the function to use to perform this cast. Zero is stored if the cast method doesn't require a function.
<code>castcontext char</code>	Indicates what contexts the cast can be invoked in. <code>e</code> means only as an explicit cast (using <code>CAST</code> or <code>::</code> syntax). <code>a</code> means implicitly in assignment to a target column, as well as explicitly. <code>i</code> means implicitly in expressions, as well as the other cases.
<code>castmethod char</code>	Indicates how the cast is performed. <code>f</code> means that the function specified in the <code>castfunc</code> field is used. <code>i</code> means that the input/output functions are used. <code>b</code> means that the types are binary-coercible, thus no conversion is required.

The cast functions listed in `pg_cast` must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or -1 if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise.

It is legitimate to create a `pg_cast` entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent “length coercion functions” that coerce values of the type to be legal for a particular type modifier value.

When a `pg_cast` entry has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

54.11. `pg_class`

The catalog `pg_class` describes tables and other objects that have columns or are otherwise similar to a table. This includes indexes (but see also `pg_index`), sequences (but see also `pg_sequence`), views, materialized views, composite types, and TOAST tables; see `relkind`. Below, when we mean all of these kinds of objects we speak of “relations”. Not all of `pg_class`'s columns are meaningful for all relation kinds.

Table 54.11. `pg_class` Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>relname name</code>	Name of the table, index, view, etc.
<code>relnamespace oid</code> (references <code>pg_namespace .oid</code>)	The OID of the namespace that contains this relation
<code>reltype oid</code> (references <code>pg_type .oid</code>)	The OID of the data type that corresponds to this table's row type, if any; zero for indexes, sequences, and toast tables, which have no <code>pg_type</code> entry
<code>reloftype oid</code> (references <code>pg_type .oid</code>)	For typed tables, the OID of the underlying composite type; zero for all other relations

Column Type	Description
<code>relowner oid</code> (references <code>pg_authid .oid</code>)	Owner of the relation
<code>relam oid</code> (references <code>pg_am .oid</code>)	The access method used to access this table or index. Not meaningful if the relation is a sequence or has no on-disk file, except for partitioned tables, where, if set, it takes precedence over <code>default_table_access_method</code> when determining the access method to use for partitions created when one is not specified in the creation command.
<code>relfilenode oid</code>	Name of the on-disk file of this relation; zero means this is a “mapped” relation whose disk file name is determined by low-level state
<code>reltablespace oid</code> (references <code>pg_tablespace .oid</code>)	The tablespace in which this relation is stored. If zero, the database's default tablespace is implied. Not meaningful if the relation has no on-disk file, except for partitioned tables, where this is the tablespace in which partitions will be created when one is not specified in the creation command.
<code>relpages int4</code>	Size of the on-disk representation of this table in pages (of size <code>BLCKSZ</code>). This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> .
<code>reltuples float4</code>	Number of live rows in the table. This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> . If the table has never yet been vacuumed or analyzed, <code>reltuples</code> contains <code>-1</code> indicating that the row count is unknown.
<code>relallvisible int4</code>	Number of pages that are marked all-visible in the table's visibility map. This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> .
<code>reltoastrelid oid</code> (references <code>pg_class .oid</code>)	OID of the TOAST table associated with this table, zero if none. The TOAST table stores large attributes “out of line” in a secondary table.
<code>relhasindex bool</code>	True if this is a table and it has (or recently had) any indexes
<code>relisshared bool</code>	True if this table is shared across all databases in the cluster. Only certain system catalogs (such as <code>pg_database</code>) are shared.
<code>relpersistence char</code> p = permanent table/sequence, u = unlogged table/sequence, t = temporary table/sequence, c = constant table	
<code>relkind char</code> r = ordinary table, i = index, S = sequence, t = TOAST table, v = view, m = materialized view, c = composite type, f = foreign table, p = partitioned table, I = partitioned index	
<code>relnatts int2</code>	Number of user columns in the relation (system columns not counted). There must be this many corresponding entries in <code>pg_attribute</code> . See also <code>pg_attribute .attnum</code> .
<code>relchecks int2</code>	Number of <code>CHECK</code> constraints on the table; see <code>pg_constraint</code> catalog
<code>relhasrules bool</code>	True if table has (or once had) rules; see <code>pg_rewrite</code> catalog

Column Type	Description
<code>relhastriggers</code> bool	True if table has (or once had) triggers; see <code>pg_trigger</code> catalog
<code>relhassubclass</code> bool	True if table or index has (or once had) any inheritance children or partitions
<code>relrowsecurity</code> bool	True if table has row-level security enabled; see <code>pg_policy</code> catalog
<code>relforcerowsecurity</code> bool	True if row-level security (when enabled) will also apply to table owner; see <code>pg_policy</code> catalog
<code>relispopulated</code> bool	True if relation is populated (this is true for all relations other than some materialized views)
<code>relreplident</code> char	Columns used to form “replica identity” for rows: <code>d</code> = default (primary key, if any), <code>n</code> = nothing, <code>f</code> = all columns, <code>i</code> = index with <code>indisreplident</code> set (same as nothing if the index used has been dropped)
<code>relispartition</code> bool	True if table or index is a partition
<code>relrewrite</code> oid (references <code>pg_class</code> .oid)	For new relations being written during a DDL operation that requires a table rewrite, this contains the OID of the original relation; otherwise zero. That state is only visible internally; this field should never contain anything other than zero for a user-visible relation.
<code>relfrozenxid</code> xid	All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to allow <code>pg_xact</code> to be shrunk. Zero (<code>InvalidTransactionId</code>) if the relation is not a table.
<code>relminmxid</code> xid	All multixact IDs before this one have been replaced by a transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to allow <code>pg_multixact</code> to be shrunk. Zero (<code>InvalidMultiXactId</code>) if the relation is not a table.
<code>relacl</code> aclitem[]	Access privileges; see Section 5.8 for details
<code>reloptions</code> text[]	Access-method-specific options, as “keyword=value” strings
<code>relpartbound</code> <code>pg_node_tree</code>	If table is a partition (see <code>relispartition</code>), internal representation of the partition bound

Several of the Boolean flags in `pg_class` are maintained lazily: they are guaranteed to be true if that's the correct state, but may not be reset to false immediately when the condition is no longer true. For example, `relhasindex` is set by `CREATE INDEX`, but it is never cleared by `DROP INDEX`. Instead, `VACUUM` clears `relhasindex` if it finds the table has no indexes. This arrangement avoids race conditions and improves concurrency.

54.12. `pg_collation`

The catalog `pg_collation` describes the available collations, which are essentially mappings from an SQL name to operating system locale categories. See [Section 23.2](#) for more information.

Table 54.12. `pg_collation` Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>collname name</code>	Collation name (unique per namespace and encoding)
<code>collnamespace oid</code> (references <code>pg_namespace .oid</code>)	The OID of the namespace that contains this collation
<code>collowner oid</code> (references <code>pg_authid .oid</code>)	Owner of the collation
<code>collprovider char</code>	Provider of the collation: <code>d</code> = database default, <code>b</code> = builtin, <code>c</code> = libc, <code>i</code> = icu
<code>collisdeterministic bool</code>	Is the collation deterministic?
<code>collencoding int4</code>	Encoding in which the collation is applicable, or -1 if it works for any encoding
<code>collcollate text</code>	<code>LC_COLLATE</code> for this collation object. If the provider is not <code>libc</code> , <code>collcollate</code> is NULL and <code>colllocale</code> is used instead.
<code>collctype text</code>	<code>LC_CTYPE</code> for this collation object. If the provider is not <code>libc</code> , <code>collctype</code> is NULL and <code>colllocale</code> is used instead.
<code>colllocale text</code>	Collation provider locale name for this collation object. If the provider is <code>libc</code> , <code>colllocale</code> is NULL; <code>collcollate</code> and <code>collctype</code> are used instead.
<code>collicurules text</code>	ICU collation rules for this collation object
<code>collversion text</code>	Provider-specific version of the collation. This is recorded when the collation is created and then checked when it is used, to detect changes in the collation definition that could lead to data corruption.

Note that the unique key on this catalog is (`collname`, `collencoding`, `collnamespace`) not just (`collname`, `collnamespace`). Postgres Pro generally ignores all collations that do not have `collencoding` equal to either the current database's encoding or -1, and creation of new entries with the same name as an entry with `collencoding` = -1 is forbidden. Therefore it is sufficient to use a qualified SQL name (*schema.name*) to identify a collation, even though this is not unique according to the catalog definition. The reason for defining the catalog this way is that `initdb` fills it in at cluster initialization time with entries for all locales available on the system, so it must be able to hold entries for all encodings that might ever be used in the cluster.

In the `template0` database, it could be useful to create collations whose encoding does not match the database encoding, since they could match the encodings of databases later cloned from `template0`. This would currently have to be done manually.

54.13. `pg_constraint`

The catalog `pg_constraint` stores check, primary key, unique, foreign key, and exclusion constraints on tables, as well as not-null constraints on domains. (Column constraints are not treated specially. Every column constraint is equivalent to some table constraint.) Not-null constraints on relations are represented in the `pg_attribute` catalog, not here.

User-defined constraint triggers (created with `CREATE CONSTRAINT TRIGGER`) also give rise to an entry in this table.

Check constraints on domains are stored here, too.

Table 54.13. `pg_constraint` Columns

Column	Type	Description
<code>oid</code>	<code>oid</code>	Row identifier
<code>conname</code>	<code>name</code>	Constraint name (not necessarily unique!)
<code>connamespace</code>	<code>oid</code> (references <code>pg_namespace.oid</code>)	The OID of the namespace that contains this constraint
<code>contype</code>	<code>char</code>	<code>c</code> = check constraint, <code>f</code> = foreign key constraint, <code>n</code> = not-null constraint (domains only), <code>p</code> = primary key constraint, <code>u</code> = unique constraint, <code>t</code> = constraint trigger, <code>x</code> = exclusion constraint
<code>condeferrable</code>	<code>bool</code>	Is the constraint deferrable?
<code>condeferred</code>	<code>bool</code>	Is the constraint deferred by default?
<code>convalidated</code>	<code>bool</code>	Has the constraint been validated? Currently, can be false only for foreign keys and CHECK constraints
<code>conrelid</code>	<code>oid</code> (references <code>pg_class.oid</code>)	The table this constraint is on; zero if not a table constraint
<code>contypid</code>	<code>oid</code> (references <code>pg_type.oid</code>)	The domain this constraint is on; zero if not a domain constraint
<code>conindid</code>	<code>oid</code> (references <code>pg_class.oid</code>)	The index supporting this constraint, if it's a unique, primary key, foreign key, or exclusion constraint; else zero
<code>conparentid</code>	<code>oid</code> (references <code>pg_constraint.oid</code>)	The corresponding constraint of the parent partitioned table, if this is a constraint on a partition; else zero
<code>confrelid</code>	<code>oid</code> (references <code>pg_class.oid</code>)	If a foreign key, the referenced table; else zero
<code>confupdtype</code>	<code>char</code>	Foreign key update action code: <code>a</code> = no action, <code>r</code> = restrict, <code>c</code> = cascade, <code>n</code> = set null, <code>d</code> = set default
<code>confdeltype</code>	<code>char</code>	Foreign key deletion action code: <code>a</code> = no action, <code>r</code> = restrict, <code>c</code> = cascade, <code>n</code> = set null, <code>d</code> = set default
<code>conmatchtype</code>	<code>char</code>	Foreign key match type: <code>f</code> = full, <code>p</code> = partial, <code>s</code> = simple
<code>conislocal</code>	<code>bool</code>	This constraint is defined locally for the relation. Note that a constraint can be locally defined and inherited simultaneously.
<code>coninhcount</code>	<code>int2</code>	The number of direct inheritance ancestors this constraint has. A constraint with a nonzero number of ancestors cannot be dropped nor renamed.

Column Type	Description
<code>connoinherit bool</code>	This constraint is defined locally for the relation. It is a non-inheritable constraint.
<code>conkey int2[] (references pg_attribute .attnum)</code>	If a table constraint (including foreign keys, but not constraint triggers), list of the constrained columns
<code>confkey int2[] (references pg_attribute .attnum)</code>	If a foreign key, list of the referenced columns
<code>conpfeqop oid[] (references pg_operator .oid)</code>	If a foreign key, list of the equality operators for PK = FK comparisons
<code>conppeqop oid[] (references pg_operator .oid)</code>	If a foreign key, list of the equality operators for PK = PK comparisons
<code>conffeqop oid[] (references pg_operator .oid)</code>	If a foreign key, list of the equality operators for FK = FK comparisons
<code>confdelsetcols int2[] (references pg_attribute .attnum)</code>	If a foreign key with a SET NULL or SET DEFAULT delete action, the columns that will be updated. If null, all of the referencing columns will be updated.
<code>conexcllop oid[] (references pg_operator .oid)</code>	If an exclusion constraint, list of the per-column exclusion operators
<code>conbin pg_node_tree</code>	If a check constraint, an internal representation of the expression. (It's recommended to use <code>pg_get_constraintdef()</code> to extract the definition of a check constraint.)

In the case of an exclusion constraint, `conkey` is only useful for constraint elements that are simple column references. For other cases, a zero appears in `conkey` and the associated index must be consulted to discover the expression that is constrained. (`conkey` thus has the same contents as `pg_index.indkey` for the index.)

Note

`pg_class.relchecks` needs to agree with the number of check-constraint entries found in this table for each relation.

54.14. `pg_conversion`

The catalog `pg_conversion` describes encoding conversion functions. See [CREATE CONVERSION](#) for more information.

Table 54.14. `pg_conversion` Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>conname name</code>	Conversion name (unique within a namespace)
<code>connamespace oid (references pg_namespace .oid)</code>	The OID of the namespace that contains this conversion
<code>conowner oid (references pg_authid .oid)</code>	

Column Type	Description
	Owner of the conversion
conforencoding int4	Source encoding ID (<code>pg_encoding_to_char()</code> can translate this number to the encoding name)
contoencoding int4	Destination encoding ID (<code>pg_encoding_to_char()</code> can translate this number to the encoding name)
conproc regproc (references <code>pg_proc</code> .oid)	Conversion function
condefault bool	True if this is the default conversion

54.15. pg_database

The catalog `pg_database` stores information about the available databases. Databases are created with the `CREATE DATABASE` command. Consult [Chapter 22](#) for details about the meaning of some of the parameters.

Unlike most system catalogs, `pg_database` is shared across all databases of a cluster: there is only one copy of `pg_database` per cluster, not one per database.

Table 54.15. pg_database Columns

Column Type	Description
oid oid	Row identifier
datname name	Database name
datdba oid (references <code>pg_authid</code> .oid)	Owner of the database, usually the user who created it
encoding int4	Character encoding for this database (<code>pg_encoding_to_char()</code> can translate this number to the encoding name)
datlocprovider char	Locale provider for this database: <code>b</code> = builtin, <code>c</code> = libc, <code>i</code> = icu
datistemplate bool	If true, then this database can be cloned by any user with <code>CREATEDB</code> privileges; if false, then only superusers or the owner of the database can clone it.
dataallowconn bool	If false then no one can connect to this database. This is used to protect the <code>template0</code> database from being altered.
dathasloginevt bool	Indicates that there are login event triggers defined for this database. This flag is used to avoid extra lookups on the <code>pg_event_trigger</code> table during each backend startup. This flag is used internally by Postgres Pro and should not be manually altered or read for monitoring purposes.
datconlimit int4	Sets maximum number of concurrent connections that can be made to this database. -1 means no limit, -2 indicates the database is invalid.

Column Type	Description
<code>datfrozenxid xid</code>	All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to allow <code>pg_xact</code> to be shrunk. It is the minimum of the per-table <code>pg_class .relfrozenxid</code> values.
<code>datminmxid xid</code>	All multixact IDs before this one have been replaced with a transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to allow <code>pg_multixact</code> to be shrunk. It is the minimum of the per-table <code>pg_class .relminmxid</code> values.
<code>dattablespace oid (references <code>pg_tablespace .oid</code>)</code>	The default tablespace for the database. Within this database, all tables for which <code>pg_class .reltablespace</code> is zero will be stored in this tablespace; in particular, all the non-shared system catalogs will be there.
<code>datcollate text</code>	<code>LC_COLLATE</code> for this database
<code>datctype text</code>	<code>LC_CTYPE</code> for this database
<code>datlocale text</code>	Collation provider locale name for this database. If the provider is <code>libc</code> , <code>datlocale</code> is <code>NULL</code> ; <code>datcollate</code> and <code>datctype</code> are used instead.
<code>datcurules text</code>	ICU collation rules for this database
<code>datcollversion text</code>	Provider-specific version of the collation. This is recorded when the database is created and then checked when it is used, to detect changes in the collation definition that could lead to data corruption.
<code>datacl aclitem[]</code>	Access privileges; see Section 5.8 for details

54.16. `pg_db_role_setting`

The catalog `pg_db_role_setting` records the default values that have been set for run-time configuration variables, for each role and database combination.

Unlike most system catalogs, `pg_db_role_setting` is shared across all databases of a cluster: there is only one copy of `pg_db_role_setting` per cluster, not one per database.

Table 54.16. `pg_db_role_setting` Columns

Column Type	Description
<code>setdatabase oid (references <code>pg_database .oid</code>)</code>	The OID of the database the setting is applicable to, or zero if not database-specific
<code>setrole oid (references <code>pg_authid .oid</code>)</code>	The OID of the role the setting is applicable to, or zero if not role-specific
<code>setconfig text[]</code>	Defaults for run-time configuration variables

54.17. `pg_default_acl`

The catalog `pg_default_acl` stores initial privileges to be assigned to newly created objects.

Table 54.17. pg_default_acl Columns

Column Type	Description
oid oid	Row identifier
defaclrole oid (references pg_authid .oid)	The OID of the role associated with this entry
defaclnamespace oid (references pg_namespace .oid)	The OID of the namespace associated with this entry, or zero if none
defaclobjtype char	Type of object this entry is for: <i>r</i> = relation (table, view), <i>s</i> = sequence, <i>f</i> = function, <i>T</i> = type, <i>n</i> = schema
defaclacl aclitem[]	Access privileges that this type of object should have on creation

A `pg_default_acl` entry shows the initial privileges to be assigned to an object belonging to the indicated user. There are currently two types of entry: “global” entries with `defaclnamespace = zero`, and “per-schema” entries that reference a particular schema. If a global entry is present then it *overrides* the normal hard-wired default privileges for the object type. A per-schema entry, if present, represents privileges to be *added to* the global or hard-wired default privileges.

Note that when an ACL entry in another catalog is null, it is taken to represent the hard-wired default privileges for its object, *not* whatever might be in `pg_default_acl` at the moment. `pg_default_acl` is only consulted during object creation.

54.18. pg_depend

The catalog `pg_depend` records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case.

See also [pg_shdepend](#), which performs a similar function for dependencies involving objects that are shared across a database cluster.

Table 54.18. pg_depend Columns

Column Type	Description
classid oid (references pg_class .oid)	The OID of the system catalog the dependent object is in
objid oid (references any OID column)	The OID of the specific dependent object
objsubid int4	For a table column, this is the column number (the <code>objid</code> and <code>classid</code> refer to the table itself). For all other object types, this column is zero.
refclassid oid (references pg_class .oid)	The OID of the system catalog the referenced object is in
refobjid oid (references any OID column)	The OID of the specific referenced object
refobjsubid int4	For a table column, this is the column number (the <code>refobjid</code> and <code>refclassid</code> refer to the table itself). For all other object types, this column is zero.
deptype char	A code defining the specific semantics of this dependency relationship; see text

In all cases, a `pg_depend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

`DEPENDENCY_NORMAL (n)`

A normal relationship between separately-created objects. The dependent object can be dropped without affecting the referenced object. The referenced object can only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.

`DEPENDENCY_AUTO (a)`

The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made auto-dependent on the table, so that it will go away if the table is dropped.

`DEPENDENCY_INTERNAL (i)`

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A direct `DROP` of the dependent object will be disallowed outright (we'll tell the user to issue a `DROP` against the referenced object, instead). A `DROP` of the referenced object will result in automatically dropping the dependent object whether `CASCADE` is specified or not. If the dependent object has to be dropped due to a dependency on some other object being removed, its drop is converted to a drop of the referenced object, so that `NORMAL` and `AUTO` dependencies of the dependent object behave much like they were dependencies of the referenced object. Example: a view's `ON SELECT` rule is made internally dependent on the view, preventing it from being dropped while the view remains. Dependencies of the rule (such as tables it refers to) act as if they were dependencies of the view.

`DEPENDENCY_PARTITION_PRI (P)`

`DEPENDENCY_PARTITION_SEC (S)`

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation; however, unlike `INTERNAL`, there is more than one such referenced object. The dependent object must not be dropped unless at least one of these referenced objects is dropped; if any one is, the dependent object should be dropped whether or not `CASCADE` is specified. Also unlike `INTERNAL`, a drop of some other object that the dependent object depends on does not result in automatic deletion of any partition-referenced object. Hence, if the drop does not cascade to at least one of these objects via some other path, it will be refused. (In most cases, the dependent object shares all its non-partition dependencies with at least one partition-referenced object, so that this restriction does not result in blocking any cascaded delete.) Primary and secondary partition dependencies behave identically except that the primary dependency is preferred for use in error messages; hence, a partition-dependent object should have one primary partition dependency and one or more secondary partition dependencies. Note that partition dependencies are made in addition to, not instead of, any dependencies the object would normally have. This simplifies `ATTACH/DETACH PARTITION` operations: the partition dependencies need only be added or removed. Example: a child partitioned index is made partition-dependent on both the partition table it is on and the parent partitioned index, so that it goes away if either of those is dropped, but not otherwise. The dependency on the parent index is primary, so that if the user tries to drop the child partitioned index, the error message will suggest dropping the parent index instead (not the table).

`DEPENDENCY_EXTENSION (e)`

The dependent object is a member of the *extension* that is the referenced object (see `pg_extension`). The dependent object can be dropped only via `DROP EXTENSION` on the referenced object. Functionally this dependency type acts the same as an `INTERNAL` dependency, but it's kept separate for clarity and to simplify `pg_dump`.

`DEPENDENCY_AUTO_EXTENSION (x)`

The dependent object is not a member of the extension that is the referenced object (and so it should not be ignored by `pg_dump`), but it cannot function without the extension and should be auto-dropped

if the extension is. The dependent object may be dropped on its own as well. Functionally this dependency type acts the same as an `AUTO` dependency, but it's kept separate for clarity and to simplify `pg_dump`.

Other dependency flavors might be needed in future.

Note that it's quite possible for two objects to be linked by more than one `pg_depend` entry. For example, a child partitioned index would have both a partition-type dependency on its associated partition table, and an auto dependency on each column of that table that it indexes. This sort of situation expresses the union of multiple dependency semantics. A dependent object can be dropped without `CASCADE` if any of its dependencies satisfies its condition for automatic dropping. Conversely, all the dependencies' restrictions about which objects must be dropped together must be satisfied.

Most objects created during `initdb` are considered “pinned”, which means that the system itself depends on them. Therefore, they are never allowed to be dropped. Also, knowing that pinned objects will not be dropped, the dependency mechanism doesn't bother to make `pg_depend` entries showing dependencies on them. Thus, for example, a table column of type `numeric` notionally has a `NORMAL` dependency on the `numeric` data type, but no such entry actually appears in `pg_depend`.

54.19. `pg_description`

The catalog `pg_description` stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` commands. Descriptions of many built-in system objects are provided in the initial contents of `pg_description`.

See also `pg_shdescription`, which performs a similar function for descriptions involving objects that are shared across a database cluster.

Table 54.19. `pg_description` Columns

Column Type	Description
<code>objoid oid</code> (references any OID column)	The OID of the object this description pertains to
<code>classoid oid</code> (references <code>pg_class</code> .oid)	The OID of the system catalog this object appears in
<code>objsubid int4</code>	For a comment on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
<code>description text</code>	Arbitrary text that serves as the description of this object

54.20. `pg_enum`

The `pg_enum` catalog contains entries showing the values and labels for each enum type. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`.

Table 54.20. `pg_enum` Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>enumtypid oid</code> (references <code>pg_type</code> .oid)	The OID of the <code>pg_type</code> entry owning this enum value
<code>enumsortorder float4</code>	

Column Type	Description
	The sort position of this enum value within its enum type
enumlabel name	The textual label for this enum value

The OIDs for `pg_enum` rows follow a special rule: even-numbered OIDs are guaranteed to be ordered in the same way as the sort ordering of their enum type. That is, if two even OIDs belong to the same enum type, the smaller OID must have the smaller `enumsortorder` value. Odd-numbered OID values need bear no relationship to the sort order. This rule allows the enum comparison routines to avoid catalog lookups in many common cases. The routines that create and alter enum types attempt to assign even OIDs to enum values whenever possible.

When an enum type is created, its members are assigned sort-order positions 1..*n*. But members added later might be given negative or fractional values of `enumsortorder`. The only requirement on these values is that they be correctly ordered and unique within each enum type.

54.21. pg_event_trigger

The catalog `pg_event_trigger` stores event triggers. See [Chapter 41](#) for more information.

Table 54.21. pg_event_trigger Columns

Column Type	Description
oid oid	Row identifier
evtname name	Trigger name (must be unique)
evtevent name	Identifies the event for which this trigger fires
evtowner oid (references pg_authid .oid)	Owner of the event trigger
evtfoid oid (references pg_proc .oid)	The function to be called
evtenabled char	Controls in which session_replication_role modes the event trigger fires. <code>O</code> = trigger fires in “origin” and “local” modes, <code>D</code> = trigger is disabled, <code>R</code> = trigger fires in “replica” mode, <code>A</code> = trigger fires always.
evttags text[]	Command tags for which this trigger will fire. If NULL, the firing of this trigger is not restricted on the basis of the command tag.

54.22. pg_extension

The catalog `pg_extension` stores information about the installed extensions. See [Section 39.17](#) for details about extensions.

Table 54.22. pg_extension Columns

Column Type	Description
oid oid	Row identifier
extname name	

Column Type	Description
	Name of the extension
extowner oid (references pg_authid .oid)	Owner of the extension
extnamespace oid (references pg_namespace .oid)	Schema containing the extension's exported objects
extrelocatable bool	True if extension can be relocated to another schema
extversion text	Version name for the extension
extconfig oid[] (references pg_class .oid)	Array of regclass OIDs for the extension's configuration table(s), or NULL if none
extcondition text[]	Array of WHERE-clause filter conditions for the extension's configuration table(s), or NULL if none

Note that unlike most catalogs with a “namespace” column, `extnamespace` is not meant to imply that the extension belongs to that schema. Extension names are never schema-qualified. Rather, `extnamespace` indicates the schema that contains most or all of the extension's objects. If `extrelocatable` is true, then this schema must in fact contain all schema-qualifiable objects belonging to the extension.

54.23. `pg_foreign_data_wrapper`

The catalog `pg_foreign_data_wrapper` stores foreign-data wrapper definitions. A foreign-data wrapper is the mechanism by which external data, residing on foreign servers, is accessed.

Table 54.23. `pg_foreign_data_wrapper` Columns

Column Type	Description
oid oid	Row identifier
fdwname name	Name of the foreign-data wrapper
fdwowner oid (references pg_authid .oid)	Owner of the foreign-data wrapper
fdwhandler oid (references pg_proc .oid)	References a handler function that is responsible for supplying execution routines for the foreign-data wrapper. Zero if no handler is provided
fdwvalidator oid (references pg_proc .oid)	References a validator function that is responsible for checking the validity of the options given to the foreign-data wrapper, as well as options for foreign servers and user mappings using the foreign-data wrapper. Zero if no validator is provided
fdwacl aclitem[]	Access privileges; see Section 5.8 for details
fdwoptions text[]	Foreign-data wrapper specific options, as “keyword=value” strings

54.24. `pg_foreign_server`

The catalog `pg_foreign_server` stores foreign server definitions. A foreign server describes a source of external data, such as a remote server. Foreign servers are accessed via foreign-data wrappers.

Table 54.24. pg_foreign_server Columns

Column Type	Description
oid oid	Row identifier
srvname name	Name of the foreign server
srvowner oid (references pg_authid .oid)	Owner of the foreign server
srvfdw oid (references pg_foreign_data_wrapper .oid)	OID of the foreign-data wrapper of this foreign server
srvtype text	Type of the server (optional)
srvversion text	Version of the server (optional)
srvacl aclitem[]	Access privileges; see Section 5.8 for details
srvoptions text[]	Foreign server specific options, as “keyword=value” strings

54.25. pg_foreign_table

The catalog `pg_foreign_table` contains auxiliary information about foreign tables. A foreign table is primarily represented by a [pg_class](#) entry, just like a regular table. Its `pg_foreign_table` entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

Table 54.25. pg_foreign_table Columns

Column Type	Description
ftrelid oid (references pg_class .oid)	The OID of the pg_class entry for this foreign table
ftserver oid (references pg_foreign_server .oid)	OID of the foreign server for this foreign table
ftoptions text[]	Foreign table options, as “keyword=value” strings

54.26. pg_index

The catalog `pg_index` contains part of the information about indexes. The rest is mostly in [pg_class](#).

Table 54.26. pg_index Columns

Column Type	Description
indexrelid oid (references pg_class .oid)	The OID of the pg_class entry for this index
indrelid oid (references pg_class .oid)	The OID of the pg_class entry for the table this index is for
indnatts int2	The total number of columns in the index (duplicates <code>pg_class.relnatts</code>); this number includes both key and included attributes
indnkeyatts int2	

Column Type	Description
	The number of <i>key columns</i> in the index, not counting any <i>included columns</i> , which are merely stored and do not participate in the index semantics
<code>indisunique</code> bool	If true, this is a unique index
<code>indnullsnotdistinct</code> bool	This value is only used for unique indexes. If false, this unique index will consider null values distinct (so the index can contain multiple null values in a column, the default Postgres Pro behavior). If it is true, it will consider null values to be equal (so the index can only contain one null value in a column).
<code>indisprimary</code> bool	If true, this index represents the primary key of the table (<code>indisunique</code> should always be true when this is true)
<code>indisexclusion</code> bool	If true, this index supports an exclusion constraint
<code>indimmediate</code> bool	If true, the uniqueness check is enforced immediately on insertion (irrelevant if <code>indisunique</code> is not true)
<code>indisclustered</code> bool	If true, the table was last clustered on this index
<code>indisvalid</code> bool	If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by <code>INSERT/UPDATE</code> operations, but it cannot safely be used for queries. If it is unique, the uniqueness property is not guaranteed true either.
<code>indcheckxmin</code> bool	If true, queries must not use the index until the <code>xmin</code> of this <code>pg_index</code> row is below their <code>TransactionXmin</code> event horizon, because the table may contain broken HOT chains with incompatible rows that they can see
<code>indisready</code> bool	If true, the index is currently ready for inserts. False means the index must be ignored by <code>INSERT/UPDATE</code> operations.
<code>indislive</code> bool	If false, the index is in process of being dropped, and should be ignored for all purposes (including HOT-safety decisions)
<code>indisreplident</code> bool	If true this index has been chosen as “replica identity” using <code>ALTER TABLE ... REPLICA IDENTITY USING INDEX ...</code>
<code>indkey</code> int2vector (references <code>pg_attribute.attnum</code>)	This is an array of <code>indnatts</code> values that indicate which table columns this index indexes. For example, a value of 1 3 would mean that the first and the third table columns make up the index entries. Key columns come before non-key (included) columns. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference.
<code>indcollation</code> oidvector (references <code>pg_collation.oid</code>)	For each column in the index key (<code>indnkeyatts</code> values), this contains the OID of the collation to use for the index, or zero if the column is not of a collatable data type.
<code>indclass</code> oidvector (references <code>pg_opclass.oid</code>)	For each column in the index key (<code>indnkeyatts</code> values), this contains the OID of the operator class to use. See <code>pg_opclass</code> for details.
<code>indoption</code> int2vector	

Column Type	Description
	This is an array of <code>indnkeyatts</code> values that store per-column flag bits. The meaning of the bits is defined by the index's access method.
<code>indexprs pg_node_tree</code>	Expression trees (in <code>nodeToString()</code> representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in <code>indkey</code> . Null if all index attributes are simple references.
<code>indpred pg_node_tree</code>	Expression tree (in <code>nodeToString()</code> representation) for partial index predicate. Null if not a partial index.

54.27. `pg_inherits`

The catalog `pg_inherits` records information about table and index inheritance hierarchies. There is one entry for each direct parent-child table or index relationship in the database. (Indirect inheritance can be determined by following chains of entries.)

Table 54.27. `pg_inherits` Columns

Column Type	Description
<code>inhrelid oid</code> (references <code>pg_class .oid</code>)	The OID of the child table or index
<code>inhparent oid</code> (references <code>pg_class .oid</code>)	The OID of the parent table or index
<code>inhseqno int4</code>	If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1. Indexes cannot have multiple inheritance, since they can only inherit when using declarative partitioning.
<code>inhdetachpending bool</code>	<code>true</code> for a partition that is in the process of being detached; <code>false</code> otherwise.

54.28. `pg_init_privs`

The catalog `pg_init_privs` records information about the initial privileges of objects in the system. There is one entry for each object in the database which has a non-default (non-NULL) initial set of privileges.

Objects can have initial privileges either by having those privileges set when the system is initialized (by `initdb`) or when the object is created during a `CREATE EXTENSION` and the extension script sets initial privileges using the `GRANT` system. Note that the system will automatically handle recording of the privileges during the extension script and that extension authors need only use the `GRANT` and `REVOKE` statements in their script to have the privileges recorded. The `privtype` column indicates if the initial privilege was set by `initdb` or during a `CREATE EXTENSION` command.

Objects which have initial privileges set by `initdb` will have entries where `privtype` is 'i', while objects which have initial privileges set by `CREATE EXTENSION` will have entries where `privtype` is 'e'.

Table 54.28. `pg_init_privs` Columns

Column Type	Description
<code>objoid oid</code> (references any OID column)	

Column Type	Description
	The OID of the specific object
<code>classoid oid</code> (references <code>pg_class</code> .oid)	The OID of the system catalog the object is in
<code>objsubid int4</code>	For a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
<code>privtype char</code>	A code defining the type of initial privilege of this object; see text
<code>initprivs aclitem[]</code>	The initial access privileges; see Section 5.8 for details

54.29. pg_language

The catalog `pg_language` registers languages in which you can write functions or stored procedures. See [CREATE LANGUAGE](#) and [Chapter 43](#) for more information about language handlers.

Table 54.29. pg_language Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>lanname name</code>	Name of the language
<code>lanowner oid</code> (references <code>pg_authid</code> .oid)	Owner of the language
<code>lanispl bool</code>	This is false for internal languages (such as SQL) and true for user-defined languages. Currently, <code>pg_dump</code> still uses this to determine which languages need to be dumped, but this might be replaced by a different mechanism in the future.
<code>lanpltrusted bool</code>	True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers can create functions in untrusted languages.
<code>lanplcallfoid oid</code> (references <code>pg_proc</code> .oid)	For noninternal languages this references the language handler, which is a special function that is responsible for executing all functions that are written in the particular language. Zero for internal languages.
<code>laninline oid</code> (references <code>pg_proc</code> .oid)	This references a function that is responsible for executing “inline” anonymous code blocks (DO blocks). Zero if inline blocks are not supported.
<code>lanvalidator oid</code> (references <code>pg_proc</code> .oid)	This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.
<code>lanacl aclitem[]</code>	Access privileges; see Section 5.8 for details

54.30. pg_largeobject

The catalog `pg_largeobject` holds the data making up “large objects”. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or “pages” small enough

to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZE` (which is currently `BLCKSZ/4`, or typically 2 kB).

Prior to PostgreSQL 9.0, there was no permission structure associated with large objects. As a result, `pg_largeobject` was publicly readable and could be used to obtain the OIDs (and contents) of all large objects in the system. This is no longer the case; use `pg_largeobject_metadata` to obtain a list of large object OIDs.

Table 54.30. `pg_largeobject` Columns

Column Type	Description
<code>loid oid</code> (references <code>pg_largeobject_metadata .oid</code>)	Identifier of the large object that includes this page
<code>pageno int4</code>	Page number of this page within its large object (counting from zero)
<code>data bytea</code>	Actual data stored in the large object. This will never be more than <code>LOBLKSIZE</code> bytes and might be less.

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset (`pageno * LOBLKSIZE`) within the object. The implementation allows sparse storage: pages might be missing, and might be shorter than `LOBLKSIZE` bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

54.31. `pg_largeobject_metadata`

The catalog `pg_largeobject_metadata` holds metadata associated with large objects. The actual large object data is stored in `pg_largeobject`.

Table 54.31. `pg_largeobject_metadata` Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>lomowner oid</code> (references <code>pg_authid .oid</code>)	Owner of the large object
<code>lomacl aclitem[]</code>	Access privileges; see Section 5.8 for details

54.32. `pg_namespace`

The catalog `pg_namespace` stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

Table 54.32. `pg_namespace` Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>nspname name</code>	Name of the namespace
<code>nspowner oid</code> (references <code>pg_authid .oid</code>)	Owner of the namespace
<code>nspsecofficer oid</code>	

Column Type	Description
	Security officer of the namespace
nspacl aclitem[]	Access privileges; see Section 5.8 for details

54.33. pg_opclass

The catalog `pg_opclass` defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are whichever ones accept the column's data type as their left-hand input.

Operator classes are described at length in [Section 39.16](#).

Table 54.33. pg_opclass Columns

Column Type	Description
oid oid	Row identifier
opcmethod oid (references pg_am .oid)	Index access method operator class is for
opcname name	Name of this operator class
opcnamespace oid (references pg_namespace .oid)	Namespace of this operator class
opcowner oid (references pg_authid .oid)	Owner of the operator class
opcfamily oid (references pg_opfamily .oid)	Operator family containing the operator class
opcintype oid (references pg_type .oid)	Data type that the operator class indexes
opcdefault bool	True if this operator class is the default for opcintype
opckeytype oid (references pg_type .oid)	Type of data stored in index, or zero if same as opcintype

An operator class's `opcmethod` must match the `opfmeth` of its containing operator family. Also, there must be no more than one `pg_opclass` row having `opcdefault` true for any given combination of `opcmethod` and `opcintype`.

54.34. pg_operator

The catalog `pg_operator` stores information about operators. See [CREATE OPERATOR](#) and [Section 39.14](#) for more information.

Table 54.34. pg_operator Columns

Column Type	Description
oid oid	Row identifier
oprname name	

Column Type	Description
	Name of the operator
oprnamespace oid (references pg_namespace .oid)	The OID of the namespace that contains this operator
oprowner oid (references pg_authid .oid)	Owner of the operator
oprkind char	b = infix operator (“both”), or l = prefix operator (“left”)
oprcanmerge bool	This operator supports merge joins
oprcanhash bool	This operator supports hash joins
oprleft oid (references pg_type .oid)	Type of the left operand (zero for a prefix operator)
oprright oid (references pg_type .oid)	Type of the right operand
oprresult oid (references pg_type .oid)	Type of the result (zero for a not-yet-defined “shell” operator)
oprcom oid (references pg_operator .oid)	Commutator of this operator (zero if none)
oprnegate oid (references pg_operator .oid)	Negator of this operator (zero if none)
oprcode regproc (references pg_proc .oid)	Function that implements this operator (zero for a not-yet-defined “shell” operator)
oprrrest regproc (references pg_proc .oid)	Restriction selectivity estimation function for this operator (zero if none)
oprjoin regproc (references pg_proc .oid)	Join selectivity estimation function for this operator (zero if none)

54.35. pg_opfamily

The catalog `pg_opfamily` defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all “compatible”, in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

Operator families are described at length in [Section 39.16](#).

Table 54.35. `pg_opfamily` Columns

Column Type	Description
oid oid	Row identifier
opfmethod oid (references pg_am .oid)	Index access method operator family is for
opfname name	Name of this operator family
opfnamespace oid (references pg_namespace .oid)	

Column Type	Description
	Namespace of this operator family
opfowner oid (references pg_authid .oid)	Owner of the operator family

The majority of the information defining an operator family is not in its `pg_opfamily` row, but in the associated rows in `pg_amop`, `pg_amproc`, and `pg_opclass`.

54.36. `pg_parameter_acl`

The catalog `pg_parameter_acl` records configuration parameters for which privileges have been granted to one or more roles. No entry is made for parameters that have default privileges.

Unlike most system catalogs, `pg_parameter_acl` is shared across all databases of a cluster: there is only one copy of `pg_parameter_acl` per cluster, not one per database.

Table 54.36. `pg_parameter_acl` Columns

Column Type	Description
oid oid	Row identifier
parname text	The name of a configuration parameter for which privileges are granted
paracl aclitem[]	Access privileges; see Section 5.8 for details

54.37. `pg_partitioned_table`

The catalog `pg_partitioned_table` stores information about how tables are partitioned.

Table 54.37. `pg_partitioned_table` Columns

Column Type	Description
partrelid oid (references pg_class .oid)	The OID of the pg_class entry for this partitioned table
partstrat char	Partitioning strategy; h = hash partitioned table, l = list partitioned table, r = range partitioned table
partnatts int2	The number of columns in the partition key
partdefid oid (references pg_class .oid)	The OID of the pg_class entry for the default partition of this partitioned table, or zero if this partitioned table does not have a default partition
partattrs int2vector (references pg_attribute .attnum)	This is an array of <code>partnatts</code> values that indicate which table columns are part of the partition key. For example, a value of 1 3 would mean that the first and the third table columns make up the partition key. A zero in this array indicates that the corresponding partition key column is an expression, rather than a simple column reference.
partclass oidvector (references pg_opclass .oid)	For each column in the partition key, this contains the OID of the operator class to use. See pg_opclass for details.
partcollation oidvector (references pg_collation .oid)	

Column Type	Description
	For each column in the partition key, this contains the OID of the collation to use for partitioning, or zero if the column is not of a collatable data type.
partexprs pg_node_tree	Expression trees (in <code>nodeToString()</code> representation) for partition key columns that are not simple column references. This is a list with one element for each zero entry in <code>partattrs</code> . Null if all partition key columns are simple references.

54.38. pg_policy

The catalog `pg_policy` stores row-level security policies for tables. A policy includes the kind of command that it applies to (possibly all commands), the roles that it applies to, the expression to be added as a security-barrier qualification to queries that include the table, and the expression to be added as a `WITH CHECK` option for queries that attempt to add new records to the table.

Table 54.38. pg_policy Columns

Column Type	Description
oid oid	Row identifier
polname name	The name of the policy
polrelid oid (references <code>pg_class</code> .oid)	The table to which the policy applies
polcmd char	The command type to which the policy is applied: <code>r</code> for <code>SELECT</code> , <code>a</code> for <code>INSERT</code> , <code>w</code> for <code>UPDATE</code> , <code>d</code> for <code>DELETE</code> , or <code>*</code> for all
polpermissive bool	Is the policy permissive or restrictive?
polroles oid[] (references <code>pg_authid</code> .oid)	The roles to which the policy is applied; zero means <code>PUBLIC</code> (and normally appears alone in the array)
polqual pg_node_tree	The expression tree to be added to the security barrier qualifications for queries that use the table
polwithcheck pg_node_tree	The expression tree to be added to the <code>WITH CHECK</code> qualifications for queries that attempt to add rows to the table

Note

Policies stored in `pg_policy` are applied only when `pg_class.relrowsecurity` is set for their table.

54.39. pg_proc

The catalog `pg_proc` stores information about functions, procedures, aggregate functions, and window functions (collectively also known as routines). See [CREATE FUNCTION](#), [CREATE PROCEDURE](#), and [Section 39.3](#) for more information.

If `prokind` indicates that the entry is for an aggregate function, there should be a matching row in `pg_aggregate`.

Table 54.39. pg_proc Columns

Column	Type	Description
oid	oid	Row identifier
proname	name	Name of the function
pronamespace	oid (references pg_namespace .oid)	The OID of the namespace that contains this function
proowner	oid (references pg_authid .oid)	Owner of the function
prolang	oid (references pg_language .oid)	Implementation language or call interface of this function
procost	float4	Estimated execution cost (in units of cpu_operator_cost); if <code>proretset</code> , this is cost per row returned
prorows	float4	Estimated number of result rows (zero if not <code>proretset</code>)
provariadic	oid (references pg_type .oid)	Data type of the variadic array parameter's elements, or zero if the function does not have a variadic parameter
prosupport	regproc (references pg_proc .oid)	Planner support function for this function (see Section 39.11), or zero if none
prokind	char	<code>f</code> for a normal function, <code>p</code> for a procedure, <code>a</code> for an aggregate function, or <code>w</code> for a window function
prosecdef	bool	Function is a security definer (i.e., a “setuid” function)
proleakproof	bool	The function has no side effects. No information about the arguments is conveyed except via the return value. Any function that might throw an error depending on the values of its arguments is not leak-proof.
proisstrict	bool	Function returns null if any call argument is null. In that case the function won't actually be called at all. Functions that are not “strict” must be prepared to handle null inputs.
proretset	bool	Function returns a set (i.e., multiple values of the specified data type)
provolatile	char	<code>provolatile</code> tells whether the function's result depends only on its input arguments, or is affected by outside factors. It is <code>i</code> for “immutable” functions, which always deliver the same result for the same inputs. It is <code>s</code> for “stable” functions, whose results (for fixed inputs) do not change within a scan. It is <code>v</code> for “volatile” functions, whose results might change at any time. (Use <code>v</code> also for functions with side-effects, so that calls to them cannot get optimized away.)
proparallel	char	<code>proparallel</code> tells whether the function can be safely run in parallel mode. It is <code>s</code> for functions which are safe to run in parallel mode without restriction. It is <code>r</code> for functions which can be run in parallel mode, but their execution is restricted to the parallel group leader; parallel worker processes cannot invoke these functions. It is <code>u</code> for functions which are unsafe in parallel mode; the presence of such a function forces a serial execution plan.
pronargs	int2	

Column Type	Description
	Number of input arguments
<code>pronargdefaults int2</code>	Number of arguments that have defaults
<code>prorettytype oid</code> (references pg_type .oid)	Data type of the return value
<code>proargtypes oidvector</code> (references pg_type .oid)	An array of the data types of the function arguments. This includes only input arguments (including <code>INOUT</code> and <code>VARIADIC</code> arguments), and thus represents the call signature of the function.
<code>proallargtypes oid[]</code> (references pg_type .oid)	An array of the data types of the function arguments. This includes all arguments (including <code>OUT</code> and <code>INOUT</code> arguments); however, if all the arguments are <code>IN</code> arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons <code>proargtypes</code> is subscripted from 0.
<code>proargmodes char[]</code>	An array of the modes of the function arguments, encoded as <code>i</code> for <code>IN</code> arguments, <code>o</code> for <code>OUT</code> arguments, <code>b</code> for <code>INOUT</code> arguments, <code>v</code> for <code>VARIADIC</code> arguments, <code>t</code> for <code>TABLE</code> arguments. If all the arguments are <code>IN</code> arguments, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code> .
<code>proargnames text[]</code>	An array of the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code> .
<code>proargdefaults pg_node_tree</code>	Expression trees (in <code>nodeToString()</code> representation) for default values. This is a list with <code>pronargdefaults</code> elements, corresponding to the last <i>N</i> input arguments (i.e., the last <i>N</i> <code>proargtypes</code> positions). If none of the arguments have defaults, this field will be null.
<code>protrftypes oid[]</code> (references pg_type .oid)	An array of the argument/result data type(s) for which to apply transforms (from the function's <code>TRANSFORM</code> clause). Null if none.
<code>prosrc text</code>	This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.
<code>probin text</code>	Additional information about how to invoke the function. Again, the interpretation is language-specific.
<code>prosqlbody pg_node_tree</code>	Pre-parsed SQL function body. This is used for SQL-language functions when the body is given in SQL-standard notation rather than as a string literal. It's null in other cases.
<code>proconfig text[]</code>	Function's local settings for run-time configuration variables
<code>proacl aclitem[]</code>	Access privileges; see Section 5.8 for details

For compiled functions, both built-in and dynamically loaded, `prosrc` contains the function's C-language name (link symbol). For SQL-language functions, `prosrc` contains the function's source text if that is specified as a string literal; but if the function body is specified in SQL-standard style, `prosrc` is unused (typically it's an empty string) and `prosqlbody` contains the pre-parsed definition. For all other current-

ly-known language types, `prosrc` contains the function's source text. `probin` is null except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

54.40. `pg_profile`

The catalog `pg_profile` lists all profiles available for your cluster. For details on profiles, see [CREATE PROFILE](#).

Profiles are cluster-wide, so `pg_profile` is shared across all databases of a cluster. This catalog is not publicly readable.

Table 54.40. `pg_profile` Columns

Column Type	Description
oid oid	Row identifier
pflname name	Profile name
pflfailedloginattempts int4 FAILED_LOGIN_ATTEMPTS	parameter value
pflfailedauthkeepstime int4 FAILED_AUTH_KEEP_TIME	parameter value (in seconds)
pfluserinactivetime int4 USER_INACTIVE_TIME	parameter value (in seconds)
pflpasswordreusetime int4 PASSWORD_REUSE_TIME	parameter value (in seconds)
pflpasswordreusemax int4 PASSWORD_REUSE_MAX	parameter value
pflpasswordlifetime int4 PASSWORD_LIFE_TIME	parameter value (in seconds)
pflpasswordgracetime int4 PASSWORD_GRACE_TIME	parameter value (in seconds)
pflpasswordminuniqchars int4 PASSWORD_MIN_UNIQUE_CHARS	parameter value
pflpasswordminlen int4 PASSWORD_MIN_LEN	parameter value
pflpasswordrequirecomplex int4 PASSWORD_REQUIRE_COMPLEX	parameter value

The `UNLIMITED` and `DEFAULT` parameter values are stored in `pg_profile` as `-1` and `-2`, respectively.

54.41. `pg_publication`

The catalog `pg_publication` contains all publications created in the database. For more on publications see [Section 29.1](#).

Table 54.41. `pg_publication` Columns

Column Type	Description
oid oid	Row identifier
pubname name	

Column Type	Description
	Name of the publication
pubowner oid (references pg_authid .oid)	Owner of the publication
puballtables bool	If true, this publication automatically includes all tables in the database, including any that will be created in the future.
pubinsert bool	If true, INSERT operations are replicated for tables in the publication.
pubupdate bool	If true, UPDATE operations are replicated for tables in the publication.
pubdelete bool	If true, DELETE operations are replicated for tables in the publication.
pubtruncate bool	If true, TRUNCATE operations are replicated for tables in the publication.
pubviaroot bool	If true, operations on a leaf partition are replicated using the identity and schema of its top-most partitioned ancestor mentioned in the publication instead of its own.

54.42. pg_publication_namespace

The catalog `pg_publication_namespace` contains the mapping between schemas and publications in the database. This is a many-to-many mapping.

Table 54.42. pg_publication_namespace Columns

Column Type	Description
oid oid	Row identifier
pnpubid oid (references pg_publication .oid)	Reference to publication
pnnspid oid (references pg_namespace .oid)	Reference to schema

54.43. pg_publication_rel

The catalog `pg_publication_rel` contains the mapping between relations and publications in the database. This is a many-to-many mapping. See also [Section 55.18](#) for a more user-friendly view of this information.

Table 54.43. pg_publication_rel Columns

Column Type	Description
oid oid	Row identifier
prpubid oid (references pg_publication .oid)	Reference to publication
prrelid oid (references pg_class .oid)	Reference to relation
prqual pg_node_tree	

Column Type	Description
	Expression tree (in <code>nodeToString()</code> representation) for the relation's publication qualifying condition. Null if there is no publication qualifying condition.
<code>prattrs int2vector</code> (references <code>pg_attribute.attnum</code>)	This is an array of values that indicates which table columns are part of the publication. For example, a value of <code>1 3</code> would mean that the first and the third table columns are published. A null value indicates that all columns are published.

54.44. `pg_range`

The catalog `pg_range` stores information about range types. This is in addition to the types' entries in `pg_type`.

Table 54.44. `pg_range` Columns

Column Type	Description
<code>rngtypeid oid</code> (references <code>pg_type.oid</code>)	OID of the range type
<code>rngsubtype oid</code> (references <code>pg_type.oid</code>)	OID of the element type (subtype) of this range type
<code>rngmultitypid oid</code> (references <code>pg_type.oid</code>)	OID of the multirange type for this range type
<code>rngcollation oid</code> (references <code>pg_collation.oid</code>)	OID of the collation used for range comparisons, or zero if none
<code>rngsubopc oid</code> (references <code>pg_opclass.oid</code>)	OID of the subtype's operator class used for range comparisons
<code>rngcanonical regproc</code> (references <code>pg_proc.oid</code>)	OID of the function to convert a range value into canonical form, or zero if none
<code>rngsubdiff regproc</code> (references <code>pg_proc.oid</code>)	OID of the function to return the difference between two element values as double precision, or zero if none

`rngsubopc` (plus `rngcollation`, if the element type is collatable) determines the sort ordering used by the range type. `rngcanonical` is used when the element type is discrete. `rngsubdiff` is optional but should be supplied to improve performance of GiST indexes on the range type.

54.45. `pg_replication_origin`

The `pg_replication_origin` catalog contains all replication origins created. For more on replication origins see [Chapter 51](#).

Unlike most system catalogs, `pg_replication_origin` is shared across all databases of a cluster: there is only one copy of `pg_replication_origin` per cluster, not one per database.

Table 54.45. `pg_replication_origin` Columns

Column Type	Description
<code>roident oid</code>	A unique, cluster-wide identifier for the replication origin. Should never leave the system.
<code>roname text</code>	The external, user defined, name of a replication origin.

54.46. pg_rewrite

The catalog `pg_rewrite` stores rewrite rules for tables and views.

Table 54.46. pg_rewrite Columns

Column	Type	Description
<code>oid</code>	<code>oid</code>	Row identifier
<code>rulename</code>	<code>name</code>	Rule name
<code>ev_class</code>	<code>oid</code> (references <code>pg_class.oid</code>)	The table this rule is for
<code>ev_type</code>	<code>char</code>	Event type that the rule is for: 1 = <code>SELECT</code> , 2 = <code>UPDATE</code> , 3 = <code>INSERT</code> , 4 = <code>DELETE</code>
<code>ev_enabled</code>	<code>char</code>	Controls in which <code>session_replication_role</code> modes the rule fires. <code>O</code> = rule fires in “origin” and “local” modes, <code>D</code> = rule is disabled, <code>R</code> = rule fires in “replica” mode, <code>A</code> = rule fires always.
<code>is_instead</code>	<code>bool</code>	True if the rule is an <code>INSTEAD</code> rule
<code>ev_qual</code>	<code>pg_node_tree</code>	Expression tree (in the form of a <code>nodeToString()</code> representation) for the rule's qualifying condition
<code>ev_action</code>	<code>pg_node_tree</code>	Query tree (in the form of a <code>nodeToString()</code> representation) for the rule's action

Note

`pg_class.relhasrules` must be true if a table has any rules in this catalog.

54.47. pg_role_password

The catalog `pg_role_password` records role's passwords history used to enforce authentication restrictions.

Unlike most system catalogs, `pg_role_password` is shared across all databases of a cluster: there is only one copy of `pg_role_password` per cluster, not one per database.

Table 54.47. pg_role_password Columns

Column	Type	Description
<code>passsetat</code>	<code>timestamp_tz</code>	Password set time
<code>passrole</code>	<code>regprofile</code> (references <code>pg_authid.oid</code>)	The OID of the role
<code>passpassword</code>	<code>text</code>	Password of the role (possibly encrypted)

54.48. pg_seclabel

The catalog `pg_seclabel` stores security labels on database objects. Security labels can be manipulated with the `SECURITY LABEL` command. For an easier way to view security labels, see [Section 55.23](#).

See also `pg_shseclabel`, which performs a similar function for security labels of database objects that are shared across a database cluster.

Table 54.48. `pg_seclabel` Columns

Column Type	Description
<code>objoid oid</code> (references any OID column)	The OID of the object this security label pertains to
<code>classoid oid</code> (references <code>pg_class</code> .oid)	The OID of the system catalog this object appears in
<code>objsubid int4</code>	For a security label on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
<code>provider text</code>	The label provider associated with this label.
<code>label text</code>	The security label applied to this object.

54.49. `pg_sequence`

The catalog `pg_sequence` contains information about sequences. Some of the information about sequences, such as the name and the schema, is in `pg_class`

Table 54.49. `pg_sequence` Columns

Column Type	Description
<code>seqrelid oid</code> (references <code>pg_class</code> .oid)	The OID of the <code>pg_class</code> entry for this sequence
<code>seqtypeid oid</code> (references <code>pg_type</code> .oid)	Data type of the sequence
<code>seqstart int8</code>	Start value of the sequence
<code>seqincrement int8</code>	Increment value of the sequence
<code>seqmax int8</code>	Maximum value of the sequence
<code>seqmin int8</code>	Minimum value of the sequence
<code>seqcache int8</code>	Cache size of the sequence
<code>seqcycle bool</code>	Whether the sequence cycles

54.50. `pg_shdepend`

The catalog `pg_shdepend` records the dependency relationships between database objects and shared objects, such as roles. This information allows Postgres Pro to ensure that those objects are unreferenced before attempting to delete them.

See also [pg_depend](#), which performs a similar function for dependencies involving objects within a single database.

Unlike most system catalogs, `pg_shdepend` is shared across all databases of a cluster: there is only one copy of `pg_shdepend` per cluster, not one per database.

Table 54.50. `pg_shdepend` Columns

Column Type	Description
<code>dbid oid</code> (references pg_database .oid)	The OID of the database the dependent object is in, or zero for a shared object
<code>classid oid</code> (references pg_class .oid)	The OID of the system catalog the dependent object is in
<code>objid oid</code> (references any OID column)	The OID of the specific dependent object
<code>objsubid int4</code>	For a table column, this is the column number (the <code>objid</code> and <code>classid</code> refer to the table itself). For all other object types, this column is zero.
<code>refclassid oid</code> (references pg_class .oid)	The OID of the system catalog the referenced object is in (must be a shared catalog)
<code>refobjid oid</code> (references any OID column)	The OID of the specific referenced object
<code>deptype char</code>	A code defining the specific semantics of this dependency relationship; see text

In all cases, a `pg_shdepend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

`SHARED_DEPENDENCY_OWNER` (o)

The referenced object (which must be a role) is the owner of the dependent object.

`SHARED_DEPENDENCY_SECURITY_OFFICER` (s)

The referenced object (which must be a role) is the security officer of the dependent object.

`SHARED_DEPENDENCY_ACL` (a)

The referenced object (which must be a role) is mentioned in the ACL (access control list, i.e., privileges list) of the dependent object. (A `SHARED_DEPENDENCY_ACL` entry is not made for the owner of the object, since the owner will have a `SHARED_DEPENDENCY_OWNER` entry anyway.)

`SHARED_DEPENDENCY_INITACL` (i)

The referenced object (which must be a role) is mentioned in a [pg_init_privs](#) entry for the dependent object.

`SHARED_DEPENDENCY_POLICY` (r)

The referenced object (which must be a role) is mentioned as the target of a dependent policy object.

`SHARED_DEPENDENCY_TABLESPACE` (t)

The referenced object (which must be a tablespace) is mentioned as the tablespace for a relation that doesn't have storage.

Other dependency flavors might be needed in future. Note in particular that the current definition only supports roles and tablespaces as referenced objects.

As in the `pg_depend` catalog, most objects created during `initdb` are considered “pinned”. No entries are made in `pg_shdepend` that would have a pinned object as either referenced or dependent object.

54.51. `pg_shdescription`

The catalog `pg_shdescription` stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` commands.

See also `pg_description`, which performs a similar function for descriptions involving objects within a single database.

Unlike most system catalogs, `pg_shdescription` is shared across all databases of a cluster: there is only one copy of `pg_shdescription` per cluster, not one per database.

Table 54.51. `pg_shdescription` Columns

Column Type	Description
<code>objoid oid</code> (references any OID column)	The OID of the object this description pertains to
<code>classoid oid</code> (references <code>pg_class .oid</code>)	The OID of the system catalog this object appears in
<code>description text</code>	Arbitrary text that serves as the description of this object

54.52. `pg_shseclabel`

The catalog `pg_shseclabel` stores security labels on shared database objects. Security labels can be manipulated with the `SECURITY LABEL` command. For an easier way to view security labels, see [Section 55.23](#).

See also `pg_seclabel`, which performs a similar function for security labels involving objects within a single database.

Unlike most system catalogs, `pg_shseclabel` is shared across all databases of a cluster: there is only one copy of `pg_shseclabel` per cluster, not one per database.

Table 54.52. `pg_shseclabel` Columns

Column Type	Description
<code>objoid oid</code> (references any OID column)	The OID of the object this security label pertains to
<code>classoid oid</code> (references <code>pg_class .oid</code>)	The OID of the system catalog this object appears in
<code>provider text</code>	The label provider associated with this label.
<code>label text</code>	The security label applied to this object.

54.53. `pg_statistic`

The catalog `pg_statistic` stores statistical data about the contents of the database. Entries are created by `ANALYZE` and subsequently used by the query planner. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

Normally there is one entry, with `stainherit = false`, for each table column that has been analyzed. If the table has inheritance children or partitions, a second entry with `stainherit = true` is also created. This row represents the column's statistics over the inheritance tree, i.e., statistics for the data you'd see with `SELECT column FROM table*`, whereas the `stainherit = false` row represents the results of `SELECT column FROM ONLY table`.

`pg_statistic` also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, `starelid` references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have `stainherit = false`.

Since different kinds of statistics might be appropriate for different kinds of data, `pg_statistic` is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in `pg_statistic`. Everything else is stored in “slots”, which are groups of associated columns whose content is identified by a code number in one of the slot's columns.

`pg_statistic` should not be readable by the public, since even statistical information about a table's contents might be considered sensitive. (Example: minimum and maximum values of a salary column might be quite interesting.) `pg_stats` is a publicly readable view on `pg_statistic` that only exposes information about those tables that are readable by the current user.

Table 54.53. `pg_statistic` Columns

Column Type	Description
<code>starelid oid</code> (references <code>pg_class .oid</code>)	The table or index that the described column belongs to
<code>staattnum int2</code> (references <code>pg_attribute .attnum</code>)	The number of the described column
<code>stainherit bool</code>	If true, the stats include values from child tables, not just the values in the specified relation
<code>stanullfrac float4</code>	The fraction of the column's entries that are null
<code>stawidth int4</code>	The average stored width, in bytes, of nonnull entries
<code>stadistinct float4</code>	The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a multiplier for the number of rows in the table; for example, a column in which about 80% of the values are nonnull and each nonnull value appears about twice on average could be represented by <code>stadistinct = -0.4</code> . A zero value means the number of distinct values is unknown.
<code>stakindN int2</code>	A code number indicating the kind of statistics stored in the <i>N</i> th “slot” of the <code>pg_statistic</code> row.
<code>staopN oid</code> (references <code>pg_operator .oid</code>)	An operator used to derive the statistics stored in the <i>N</i> th “slot”. For example, a histogram slot would show the <code><</code> operator that defines the sort order of the data. Zero if the statistics kind does not require an operator.
<code>stacollN oid</code> (references <code>pg_collation .oid</code>)	The collation used to derive the statistics stored in the <i>N</i> th “slot”. For example, a histogram slot for a collatable column would show the collation that defines the sort order of the data. Zero for noncollatable data.
<code>stanumbersN float4[]</code>	

Column Type	Description
	Numerical statistics of the appropriate kind for the <i>n</i> th “slot”, or null if the slot kind does not involve numerical values
<code>stavalues</code> <i>N</i> <code>anyarray</code>	Column data values of the appropriate kind for the <i>n</i> th “slot”, or null if the slot kind does not store any data values. Each array's element values are actually of the specific column's data type, or a related type such as an array's element type, so there is no way to define these columns' type more specifically than <code>anyarray</code> .

54.54. `pg_statistic_ext`

The catalog `pg_statistic_ext` holds definitions of extended planner statistics. Each row in this catalog corresponds to a *statistics object* created with `CREATE STATISTICS`.

Table 54.54. `pg_statistic_ext` Columns

Column Type	Description
<code>oid</code> <code>oid</code>	Row identifier
<code>stxrelid</code> <code>oid</code> (references <code>pg_class</code> .oid)	Table containing the columns described by this object
<code>stxname</code> <code>name</code>	Name of the statistics object
<code>stxnamespace</code> <code>oid</code> (references <code>pg_namespace</code> .oid)	The OID of the namespace that contains this statistics object
<code>stxowner</code> <code>oid</code> (references <code>pg_authid</code> .oid)	Owner of the statistics object
<code>stxkeys</code> <code>int2</code> <code>vector</code> (references <code>pg_attribute</code> .attnum)	An array of attribute numbers, indicating which table columns are covered by this statistics object; for example a value of <code>1 3</code> would mean that the first and the third table columns are covered
<code>stxstattarget</code> <code>int2</code>	<code>stxstattarget</code> controls the level of detail of statistics accumulated for this statistics object by <code>ANALYZE</code> . A zero value indicates that no statistics should be collected. A null value says to use the maximum of the statistics targets of the referenced columns, if set, or the system default statistics target. Positive values of <code>stxstattarget</code> determine the target number of “most common values” to collect.
<code>stxkind</code> <code>char</code> []	An array containing codes for the enabled statistics kinds; valid values are: <code>d</code> for n-distinct statistics, <code>f</code> for functional dependency statistics, <code>m</code> for most common values (MCV) list statistics, and <code>e</code> for expression statistics
<code>stxexprs</code> <code>pg_node_tree</code>	Expression trees (in <code>nodeToString()</code> representation) for statistics object attributes that are not simple column references. This is a list with one element per expression. Null if all statistics object attributes are simple references.

The `pg_statistic_ext` entry is filled in completely during `CREATE STATISTICS`, but the actual statistical values are not computed then. Subsequent `ANALYZE` commands compute the desired values and populate an entry in the `pg_statistic_ext_data` catalog.

54.55. `pg_statistic_ext_data`

The catalog `pg_statistic_ext_data` holds data for extended planner statistics defined in `pg_statistic_ext`. Each row in this catalog corresponds to a *statistics object* created with `CREATE STATISTICS`.

Normally there is one entry, with `stxdinherit = false`, for each statistics object that has been analyzed. If the table has inheritance children or partitions, a second entry with `stxdinherit = true` is also created. This row represents the statistics object over the inheritance tree, i.e., statistics for the data you'd see with `SELECT * FROM table*`, whereas the `stxdinherit = false` row represents the results of `SELECT * FROM ONLY table`.

Like `pg_statistic`, `pg_statistic_ext_data` should not be readable by the public, since the contents might be considered sensitive. (Example: most common combinations of values in columns might be quite interesting.) `pg_stats_ext` is a publicly readable view on `pg_statistic_ext_data` (after joining with `pg_statistic_ext`) that only exposes information about tables the current user owns.

Table 54.55. `pg_statistic_ext_data` Columns

Column Type	Description
<code>stxoid oid</code> (references <code>pg_statistic_ext .oid</code>)	Extended statistics object containing the definition for this data
<code>stxdinherit bool</code>	If true, the stats include values from child tables, not just the values in the specified relation
<code>stxdndistinct pg_ndistinct</code>	N-distinct counts, serialized as <code>pg_ndistinct type</code>
<code>stxddependencies pg_dependencies</code>	Functional dependency statistics, serialized as <code>pg_dependencies type</code>
<code>stxdmcv pg_mcv_list</code>	MCV (most-common values) list statistics, serialized as <code>pg_mcv_list type</code>
<code>stxdexpr pg_statistic[]</code>	Per-expression statistics, serialized as an array of <code>pg_statistic type</code>

54.56. `pg_subscription`

The catalog `pg_subscription` contains all existing logical replication subscriptions. For more information about logical replication see [Chapter 29](#).

Unlike most system catalogs, `pg_subscription` is shared across all databases of a cluster: there is only one copy of `pg_subscription` per cluster, not one per database.

Access to the column `subconninfo` is revoked from normal users, because it could contain plain-text passwords.

Table 54.56. `pg_subscription` Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>subdbid oid</code> (references <code>pg_database .oid</code>)	OID of the database that the subscription resides in
<code>subskiplsn pg_lsn</code>	Finish LSN of the transaction whose changes are to be skipped, if a valid LSN; otherwise 0/0.
<code>subname name</code>	Name of the subscription
<code>subowner oid</code> (references <code>pg_authid .oid</code>)	

Column Type	Description
	Owner of the subscription
subenabled bool	If true, the subscription is enabled and should be replicating
subbinary bool	If true, the subscription will request that the publisher send data in binary format
substream char	Controls how to handle the streaming of in-progress transactions: <code>f</code> = disallow streaming of in-progress transactions, <code>t</code> = spill the changes of in-progress transactions to disk and apply at once after the transaction is committed on the publisher and received by the subscriber, <code>p</code> = apply changes directly using a parallel apply worker if available (same as <code>t</code> if no worker is available)
subtwophasestate char	State codes for two-phase mode: <code>d</code> = disabled, <code>p</code> = pending enablement, <code>e</code> = enabled
subdisableonerr bool	If true, the subscription will be disabled if one of its workers detects an error
subpasswordrequired bool	If true, the subscription will be required to specify a password for authentication
subrunasowner bool	If true, the subscription will be run with the permissions of the subscription owner
subfailover bool	If true, the associated replication slots (i.e. the main slot and the table sync slots) in the upstream database are enabled to be synchronized to the standbys
subconninfo text	Connection string to the upstream database
subslotname name	Name of the replication slot in the upstream database (also used for the local replication origin name); null represents <code>NONE</code>
subsynchronouscommit text	The <code>synchronous_commit</code> setting for the subscription's workers to use
subpublications text[]	Array of subscribed publication names. These reference publications defined in the upstream database. For more on publications see Section 29.1 .
suborigin text	The origin value must be either <code>none</code> or <code>any</code> . The default is <code>any</code> . If <code>none</code> , the subscription will request the publisher to only send changes that don't have an origin. If <code>any</code> , the publisher sends changes regardless of their origin.

54.57. pg_subscription_rel

The catalog `pg_subscription_rel` contains the state for each replicated relation in each subscription. This is a many-to-many mapping.

This catalog only contains tables known to the subscription after running either `CREATE SUBSCRIPTION` or `ALTER SUBSCRIPTION ... REFRESH PUBLICATION`.

Table 54.57. pg_subscription_rel Columns

Column Type	Description
srsubid oid	(references <code>pg_subscription.oid</code>)

Column Type	Description
	Reference to subscription
srrelid oid (references pg_class .oid)	Reference to relation
srsubstate char	State code: <i>i</i> = initialize, <i>d</i> = data is being copied, <i>f</i> = finished table copy, <i>s</i> = synchronized, <i>r</i> = ready (normal replication)
srsublsn pg_lsn	Remote LSN of the state change used for synchronization coordination when in <i>s</i> or <i>r</i> states, otherwise null

54.58. pg_tablespace

The catalog `pg_tablespace` stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout.

Unlike most system catalogs, `pg_tablespace` is shared across all databases of a cluster: there is only one copy of `pg_tablespace` per cluster, not one per database.

Table 54.58. pg_tablespace Columns

Column Type	Description
oid oid	Row identifier
spcname name	Tablespace name
spcowner oid (references pg_authid .oid)	Owner of the tablespace, usually the user who created it
spcacl aclitem[]	Access privileges; see Section 5.8 for details
spcoptions text[]	Tablespace-level options, as “keyword=value” strings

54.59. pg_transform

The catalog `pg_transform` stores information about transforms, which are a mechanism to adapt data types to procedural languages. See [CREATE TRANSFORM](#) for more information.

Table 54.59. pg_transform Columns

Column Type	Description
oid oid	Row identifier
trftype oid (references pg_type .oid)	OID of the data type this transform is for
trflang oid (references pg_language .oid)	OID of the language this transform is for
trffromsql regproc (references pg_proc .oid)	The OID of the function to use when converting the data type for input to the procedural language (e.g., function parameters). Zero is stored if the default behavior should be used.

Column Type	Description
<code>trftosql regproc</code> (references <code>pg_proc .oid</code>)	The OID of the function to use when converting output from the procedural language (e.g., return values) to the data type. Zero is stored if the default behavior should be used.

54.60. `pg_trigger`

The catalog `pg_trigger` stores triggers on tables and views. See [CREATE TRIGGER](#) for more information.

Table 54.60. `pg_trigger` Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>tgrelid oid</code> (references <code>pg_class .oid</code>)	The table this trigger is on
<code>tgparentid oid</code> (references <code>pg_trigger .oid</code>)	Parent trigger that this trigger is cloned from (this happens when partitions are created or attached to a partitioned table); zero if not a clone
<code>tgname name</code>	Trigger name (must be unique among triggers of same table)
<code>tgfoid oid</code> (references <code>pg_proc .oid</code>)	The function to be called
<code>tgtype int2</code>	Bit mask identifying trigger firing conditions
<code>tgenabled char</code>	Controls in which session_replication_role modes the trigger fires. <code>O</code> = trigger fires in “origin” and “local” modes, <code>D</code> = trigger is disabled, <code>R</code> = trigger fires in “replica” mode, <code>A</code> = trigger fires always.
<code>tgisinternal bool</code>	True if trigger is internally generated (usually, to enforce the constraint identified by <code>tgconstraint</code>)
<code>tgconstrrelid oid</code> (references <code>pg_class .oid</code>)	The table referenced by a referential integrity constraint (zero if trigger is not for a referential integrity constraint)
<code>tgconstrindid oid</code> (references <code>pg_class .oid</code>)	The index supporting a unique, primary key, referential integrity, or exclusion constraint (zero if trigger is not for one of these types of constraint)
<code>tgconstraint oid</code> (references <code>pg_constraint .oid</code>)	The <code>pg_constraint</code> entry associated with the trigger (zero if trigger is not for a constraint)
<code>tgdeferrable bool</code>	True if constraint trigger is deferrable
<code>tginitdeferred bool</code>	True if constraint trigger is initially deferred
<code>tgargs int2</code>	Number of argument strings passed to trigger function
<code>tgattr int2vector</code> (references <code>pg_attribute .attnum</code>)	Column numbers, if trigger is column-specific; otherwise an empty array

Column Type	Description
tgargs bytea	Argument strings to pass to trigger, each NULL-terminated
tgqual pg_node_tree	Expression tree (in <code>nodeToString()</code> representation) for the trigger's <code>WHEN</code> condition, or null if none
tgoldtable name	REFERENCING clause name for <code>OLD TABLE</code> , or null if none
tgnewtable name	REFERENCING clause name for <code>NEW TABLE</code> , or null if none

Currently, column-specific triggering is supported only for `UPDATE` events, and so `tgattr` is relevant only for that event type. `tgtype` might contain bits for other event types as well, but those are presumed to be table-wide regardless of what is in `tgattr`.

Note

When `tgconstraint` is nonzero, `tgconstrrelid`, `tgconstrindid`, `tgdeferrable`, and `tginitdeferred` are largely redundant with the referenced `pg_constraint` entry. However, it is possible for a non-deferrable trigger to be associated with a deferrable constraint: foreign key constraints can have some deferrable and some non-deferrable triggers.

Note

`pg_class.relhastriggers` must be true if a relation has any triggers in this catalog.

54.61. pg_ts_config

The `pg_ts_config` catalog contains entries representing text search configurations. A configuration specifies a particular text search parser and a list of dictionaries to use for each of the parser's output token types. The parser is shown in the `pg_ts_config` entry, but the token-to-dictionary mapping is defined by subsidiary entries in `pg_ts_config_map`.

Postgres Pro's text search features are described at length in [Chapter 12](#).

Table 54.61. `pg_ts_config` Columns

Column Type	Description
oid oid	Row identifier
cfgname name	Text search configuration name
cfgnamespace oid (references <code>pg_namespace</code> .oid)	The OID of the namespace that contains this configuration
cfgowner oid (references <code>pg_authid</code> .oid)	Owner of the configuration
cfgparser oid (references <code>pg_ts_parser</code> .oid)	

Column Type
Description
The OID of the text search parser for this configuration

54.62. pg_ts_config_map

The `pg_ts_config_map` catalog contains entries showing which text search dictionaries should be consulted, and in what order, for each output token type of each text search configuration's parser.

Postgres Pro's text search features are described at length in [Chapter 12](#).

Table 54.62. pg_ts_config_map Columns

Column Type
Description
mapcfg oid (references <code>pg_ts_config</code> .oid) The OID of the <code>pg_ts_config</code> entry owning this map entry
maptokentype int4 A token type emitted by the configuration's parser
mapseqno int4 Order in which to consult this entry (lower <code>mapseqnos</code> first)
mapdict oid (references <code>pg_ts_dict</code> .oid) The OID of the text search dictionary to consult

54.63. pg_ts_dict

The `pg_ts_dict` catalog contains entries defining text search dictionaries. A dictionary depends on a text search template, which specifies all the implementation functions needed; the dictionary itself provides values for the user-settable parameters supported by the template. This division of labor allows dictionaries to be created by unprivileged users. The parameters are specified by a text string `dictinitoption`, whose format and meaning vary depending on the template.

Postgres Pro's text search features are described at length in [Chapter 12](#).

Table 54.63. pg_ts_dict Columns

Column Type
Description
oid oid Row identifier
dictname name Text search dictionary name
dictnamespace oid (references <code>pg_namespace</code> .oid) The OID of the namespace that contains this dictionary
dictowner oid (references <code>pg_authid</code> .oid) Owner of the dictionary
dicttemplate oid (references <code>pg_ts_template</code> .oid) The OID of the text search template for this dictionary
dictinitoption text Initialization option string for the template

54.64. pg_ts_parser

The `pg_ts_parser` catalog contains entries defining text search parsers. A parser is responsible for splitting input text into lexemes and assigning a token type to each lexeme. Since a parser must be implemented by C-language-level functions, creation of new parsers is restricted to database superusers.

Postgres Pro's text search features are described at length in [Chapter 12](#).

Table 54.64. `pg_ts_parser` Columns

Column Type	Description
oid oid	Row identifier
prsname name	Text search parser name
prsnamespace oid (references pg_namespace .oid)	The OID of the namespace that contains this parser
prsstart regproc (references pg_proc .oid)	OID of the parser's startup function
prstoken regproc (references pg_proc .oid)	OID of the parser's next-token function
prsend regproc (references pg_proc .oid)	OID of the parser's shutdown function
prsheadline regproc (references pg_proc .oid)	OID of the parser's headline function (zero if none)
prsllextype regproc (references pg_proc .oid)	OID of the parser's lextype function

54.65. `pg_ts_template`

The `pg_ts_template` catalog contains entries defining text search templates. A template is the implementation skeleton for a class of text search dictionaries. Since a template must be implemented by C-language-level functions, creation of new templates is restricted to database superusers.

Postgres Pro's text search features are described at length in [Chapter 12](#).

Table 54.65. `pg_ts_template` Columns

Column Type	Description
oid oid	Row identifier
tmplname name	Text search template name
tmplnamespace oid (references pg_namespace .oid)	The OID of the namespace that contains this template
tmplinit regproc (references pg_proc .oid)	OID of the template's initialization function (zero if none)
tmpllexize regproc (references pg_proc .oid)	OID of the template's lexize function

54.66. `pg_type`

The catalog `pg_type` stores information about data types. Base types and enum types (scalar types) are created with [CREATE TYPE](#), and domains with [CREATE DOMAIN](#). A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

Table 54.66. pg_type Columns

Column Type	Description
oid oid	Row identifier
typname name	Data type name
typnamespace oid (references pg_namespace .oid)	The OID of the namespace that contains this type
typowner oid (references pg_authid .oid)	Owner of the type
typlen int2	For a fixed-size type, <code>typlen</code> is the number of bytes in the internal representation of the type. But for a variable-length type, <code>typlen</code> is negative. -1 indicates a “varlena” type (one that has a length word), -2 indicates a null-terminated C string.
typbyval bool	<code>typbyval</code> determines whether internal routines pass a value of this type by value or by reference. <code>typbyval</code> had better be false if <code>typlen</code> is not 1, 2, or 4 (or 8 on machines where Datum is 8 bytes). Variable-length types are always passed by reference. Note that <code>typbyval</code> can be false even if the length would allow pass-by-value.
typtype char	<code>typtype</code> is <code>b</code> for a base type, <code>c</code> for a composite type (e.g., a table's row type), <code>d</code> for a domain, <code>e</code> for an enum type, <code>p</code> for a pseudo-type, <code>r</code> for a range type, or <code>m</code> for a multirange type. See also <code>typrelid</code> and <code>typbasetype</code> .
typcategory char	<code>typcategory</code> is an arbitrary classification of data types that is used by the parser to determine which implicit casts should be “preferred”. See Table 54.67 .
typispreferred bool	True if the type is a preferred cast target within its <code>typcategory</code>
typisdefined bool	True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When <code>typisdefined</code> is false, nothing except the type name, namespace, and OID can be relied on.
typdelim char	Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type.
typrelid oid (references pg_class .oid)	If this is a composite type (see <code>typtype</code>), then this column points to the pg_class entry that defines the corresponding table. (For a free-standing composite type, the pg_class entry doesn't really represent a table, but it is needed anyway for the type's pg_attribute entries to link to.) Zero for non-composite types.
typsubscript regproc (references pg_proc .oid)	Subscripting handler function's OID, or zero if this type doesn't support subscripting. Types that are “true” array types have <code>typsubscript</code> = <code>array_subscript_handler</code> , but other types may have other handler functions to implement specialized subscripting behavior.
typelem oid (references pg_type .oid)	If <code>typelem</code> is not zero then it identifies another row in <code>pg_type</code> , defining the type yielded by subscripting. This should be zero if <code>typsubscript</code> is zero. However, it can be zero when <code>typsubscript</code> isn't zero, if the handler doesn't need <code>typelem</code> to determine the subscripting result type. Note that a <code>typelem</code> dependency is considered to imply physical containment of the element type in this type; so DDL changes on the element type might be restricted by the presence of this type.

Column Type	Description
<code>typarray oid</code> (references <code>pg_type .oid</code>)	If <code>typarray</code> is not zero then it identifies another row in <code>pg_type</code> , which is the “true” array type having this type as element
<code>typinput regproc</code> (references <code>pg_proc .oid</code>)	Input conversion function (text format)
<code>typoutput regproc</code> (references <code>pg_proc .oid</code>)	Output conversion function (text format)
<code>typreceive regproc</code> (references <code>pg_proc .oid</code>)	Input conversion function (binary format), or zero if none
<code>typsend regproc</code> (references <code>pg_proc .oid</code>)	Output conversion function (binary format), or zero if none
<code>typmodin regproc</code> (references <code>pg_proc .oid</code>)	Type modifier input function, or zero if type does not support modifiers
<code>typmodout regproc</code> (references <code>pg_proc .oid</code>)	Type modifier output function, or zero to use the standard format
<code>typanalyze regproc</code> (references <code>pg_proc .oid</code>)	Custom <code>ANALYZE</code> function, or zero to use the standard function
<code>typalign char</code>	<p><code>typalign</code> is the alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside Postgres Pro. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are:</p> <ul style="list-style-type: none"> • <code>c</code> = char alignment, i.e., no alignment needed. • <code>s</code> = short alignment (2 bytes on most machines). • <code>i</code> = int alignment (4 bytes on most machines). • <code>d</code> = double alignment (8 bytes on many machines, but by no means all). • <code>x</code> = xid alignment (8 bytes on all machines).
<code>typstorage char</code>	<p><code>typstorage</code> tells for varlena types (those with <code>typplen = -1</code>) if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are:</p> <ul style="list-style-type: none"> • <code>p</code> (plain): Values must always be stored plain (non-varlena types always use this value). • <code>e</code> (external): Values can be stored in a secondary “TOAST” relation (if relation has one, see <code>pg_class.reltoastrelid</code>). • <code>m</code> (main): Values can be compressed and stored inline. • <code>x</code> (extended): Values can be compressed and/or moved to a secondary relation. <p><code>x</code> is the usual choice for toast-able types. Note that <code>m</code> values can also be moved out to secondary storage, but only as a last resort (<code>e</code> and <code>x</code> values are moved first).</p>
<code>typnotnull bool</code>	<code>typnotnull</code> represents a not-null constraint on a type. Used for domains only.
<code>typbasetype oid</code> (references <code>pg_type .oid</code>)	If this is a domain (see <code>typtype</code>), then <code>typbasetype</code> identifies the type that this one is based on. Zero if this type is not a domain.
<code>tyttypmod int4</code>	

Column Type	Description
	Domains use <code>typmod</code> to record the <code>typmod</code> to be applied to their base type (-1 if base type does not use a <code>typmod</code>). -1 if this type is not a domain.
<code>typndims int4</code>	<code>typndims</code> is the number of array dimensions for a domain over an array (that is, <code>typbasetype</code> is an array type). Zero for types other than domains over array types.
<code>typcollation oid</code> (references <code>pg_collation .oid</code>)	<code>typcollation</code> specifies the collation of the type. If the type does not support collations, this will be zero. A base type that supports collations will have a nonzero value here, typically <code>DEFAULT_COLLATION_OID</code> . A domain over a collatable type can have a collation OID different from its base type's, if one was specified for the domain.
<code>typdefaultbin pg_node_tree</code>	If <code>typdefaultbin</code> is not null, it is the <code>nodeToString()</code> representation of a default expression for the type. This is only used for domains.
<code>typdefault text</code>	<code>typdefault</code> is null if the type has no associated default value. If <code>typdefaultbin</code> is not null, <code>typdefault</code> must contain a human-readable version of the default expression represented by <code>typdefaultbin</code> . If <code>typdefaultbin</code> is null and <code>typdefault</code> is not, then <code>typdefault</code> is the external representation of the type's default value, which can be fed to the type's input converter to produce a constant.
<code>typacl aclitem[]</code>	Access privileges; see Section 5.8 for details

Note

For fixed-width types used in system tables, it is critical that the size and alignment defined in `pg_type` agree with the way that the compiler will lay out the column in a structure representing a table row.

[Table 54.67](#) lists the system-defined values of `typcategory`. Any future additions to this list will also be upper-case ASCII letters. All other ASCII characters are reserved for user-defined categories.

Table 54.67. `typcategory` Codes

Code	Category
A	Array types
B	Boolean types
C	Composite types
D	Date/time types
E	Enum types
G	Geometric types
I	Network address types
N	Numeric types
P	Pseudo-types
R	Range types
S	String types
T	Timespan types
U	User-defined types

Code	Category
V	Bit-string types
X	unknown type
Z	Internal-use types

54.67. pg_user_mapping

The catalog `pg_user_mapping` stores the mappings from local user to remote. Access to this catalog is restricted from normal users, use the view `pg_user_mappings` instead.

Table 54.68. pg_user_mapping Columns

Column Type	Description
<code>oid oid</code>	Row identifier
<code>umuser oid (references <code>pg_authid</code> .oid)</code>	OID of the local role being mapped, or zero if the user mapping is public
<code>umserver oid (references <code>pg_foreign_server</code> .oid)</code>	The OID of the foreign server that contains this mapping
<code>umoptions text[]</code>	User mapping specific options, as “keyword=value” strings

Chapter 55. System Views

In addition to the system catalogs, Postgres Pro provides a number of built-in views. Some system views provide convenient access to some commonly used queries on the system catalogs. Other views provide access to internal server state.

The information schema ([Chapter 38](#)) provides an alternative set of views which overlap the functionality of the system views. Since the information schema is SQL-standard whereas the views described here are Postgres Pro-specific, it's usually better to use the information schema if it provides all the information you need.

[Table 55.1](#) lists the system views described here. More detailed documentation of each view follows below. There are some additional views that provide access to accumulated statistics; they are described in [Table 27.2](#).

55.1. Overview

[Table 55.1](#) lists the system views. More detailed documentation of each catalog follows below. Except where noted, all the views described here are read-only.

Table 55.1. System Views

View Name	Purpose
<code>pg_available_extensions</code>	available extensions
<code>pg_available_extension_versions</code>	available versions of extensions
<code>pg_backend_memory_contexts</code>	backend memory contexts
<code>pg_config</code>	compile-time configuration parameters
<code>pg_cursors</code>	open cursors
<code>pg_file_settings</code>	summary of configuration file contents
<code>pg_group</code>	groups of database users
<code>pg_hba_file_rules</code>	summary of client authentication configuration file contents
<code>pg_ident_file_mappings</code>	summary of client user name mapping configuration file contents
<code>pg_indexes</code>	indexes
<code>pg_locks</code>	locks currently held or awaited
<code>pg_matviews</code>	materialized views
<code>pg_policies</code>	policies
<code>pg_prepared_statements</code>	prepared statements
<code>pg_autoprepared_statements</code>	autoprepared statements
<code>pg_prepared_xacts</code>	prepared transactions
<code>pg_publication_tables</code>	publications and information of their associated tables
<code>pg_replication_origin_status</code>	information about replication origins, including replication progress
<code>pg_replication_slots</code>	replication slot information
<code>pg_roles</code>	database roles
<code>pg_rules</code>	rules
<code>pg_seclabels</code>	security labels
<code>pg_sequences</code>	sequences

View Name	Purpose
pg_settings	parameter settings
pg_shadow	database users
pg_shmem_allocations	shared memory allocations
pg_stats	planner statistics
pg_stats_ext	extended planner statistics
pg_stats_ext_exprs	extended planner statistics for expressions
pg_stats_vacuum_database	statistics about database vacuuming
pg_stats_vacuum_indexes	statistics about index vacuuming
pg_stats_vacuum_tables	statistics about table vacuuming
pg_tables	tables
pg_timezone_abbrevs	time zone abbreviations
pg_timezone_names	time zone names
pg_user	database users
pg_user_mappings	user mappings
pg_views	views
pg_wait_events	wait events

55.2. pg_available_extensions

The `pg_available_extensions` view lists the extensions that are available for installation. See also the [pg_extension](#) catalog, which shows the extensions currently installed.

Table 55.2. `pg_available_extensions` Columns

Column Type	Description
<code>name name</code>	Extension name
<code>default_version text</code>	Name of default version, or <code>NULL</code> if none is specified
<code>installed_version text</code>	Currently installed version of the extension, or <code>NULL</code> if not installed
<code>comment text</code>	Comment string from the extension's control file

The `pg_available_extensions` view is read-only.

55.3. pg_available_extension_versions

The `pg_available_extension_versions` view lists the specific extension versions that are available for installation. See also the [pg_extension](#) catalog, which shows the extensions currently installed.

Table 55.3. `pg_available_extension_versions` Columns

Column Type	Description
<code>name name</code>	Extension name
<code>version text</code>	

Column Type	Description
Version name	
installed bool	True if this version of this extension is currently installed
superuser bool	True if only superusers are allowed to install this extension (but see <code>trusted</code>)
trusted bool	True if the extension can be installed by non-superusers with appropriate privileges
relocatable bool	True if extension can be relocated to another schema
schema name	Name of the schema that the extension must be installed into, or <code>NULL</code> if partially or fully relocatable
requires name[]	Names of prerequisite extensions, or <code>NULL</code> if none
comment text	Comment string from the extension's control file

The `pg_available_extension_versions` view is read-only.

55.4. `pg_backend_memory_contexts`

The view `pg_backend_memory_contexts` displays all the memory contexts of the server process attached to the current session.

`pg_backend_memory_contexts` contains one row for each memory context.

Table 55.4. `pg_backend_memory_contexts` Columns

Column Type	Description
name text	Name of the memory context
ident text	Identification information of the memory context. This field is truncated at 1024 bytes
parent text	Name of the parent of this memory context
level int4	Distance from <code>TopMemoryContext</code> in context tree
total_bytes int8	Total bytes allocated for this memory context
total_nblocks int8	Total number of blocks allocated for this memory context
free_bytes int8	Free space in bytes
free_chunks int8	Total number of free chunks
used_bytes int8	Used space in bytes

By default, the `pg_backend_memory_contexts` view can be read only by superusers or roles with the privileges of the `pg_read_all_stats` role.

55.5. pg_config

The view `pg_config` describes the compile-time configuration parameters of the currently installed version of Postgres Pro. It is intended, for example, to be used by software packages that want to interface to Postgres Pro to facilitate finding the required header files and libraries. It provides the same basic information as the `pg_config` Postgres Pro client application.

By default, the `pg_config` view can be read only by superusers.

Table 55.5. pg_config Columns

Column Type	Description
name text	The parameter name
setting text	The parameter value

55.6. pg_cursors

The `pg_cursors` view lists the cursors that are currently available. Cursors can be defined in several ways:

- via the `DECLARE` statement in SQL
- via the Bind message in the frontend/backend protocol, as described in [Section 56.2.3](#)
- via the Server Programming Interface (SPI), as described in [Section 48.1](#)

The `pg_cursors` view displays cursors created by any of these means. Cursors only exist for the duration of the transaction that defines them, unless they have been declared `WITH HOLD`. Therefore non-holdable cursors are only present in the view until the end of their creating transaction.

Note

Cursors are used internally to implement some of the components of Postgres Pro, such as procedural languages. Therefore, the `pg_cursors` view might include cursors that have not been explicitly created by the user.

Table 55.6. pg_cursors Columns

Column Type	Description
name text	The name of the cursor
statement text	The verbatim query string submitted to declare this cursor
is_holdable bool	true if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); false otherwise
is_binary bool	true if the cursor was declared <code>BINARY</code> ; false otherwise
is_scrollable bool	true if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); false otherwise
creation_time timestamptz	The time at which the cursor was declared

The `pg_cursors` view is read-only.

55.7. pg_file_settings

The view `pg_file_settings` provides a summary of the contents of the server's configuration file(s). A row appears in this view for each “name = value” entry appearing in the files, with annotations indicating whether the value could be applied successfully. Additional row(s) may appear for problems not linked to a “name = value” entry, such as syntax errors in the files.

This view is helpful for checking whether planned changes in the configuration files will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the files, not on what was last applied by the server. (The `pg_settings` view is usually sufficient to determine that.)

By default, the `pg_file_settings` view can be read only by superusers.

Table 55.7. pg_file_settings Columns

Column Type	Description
sourcefile text	Full path name of the configuration file
sourceline int4	Line number within the configuration file where the entry appears
seqno int4	Order in which the entries are processed (1.. <i>n</i>)
name text	Configuration parameter name
setting text	Value to be assigned to the parameter
applied bool	True if the value can be applied successfully
error text	If not null, an error message indicating why this entry could not be applied

If the configuration file contains syntax errors or invalid parameter names, the server will not attempt to apply any settings from it, and therefore all the `applied` fields will read as false. In such a case there will be one or more rows with non-null `error` fields indicating the problem(s). Otherwise, individual settings will be applied if possible. If an individual setting cannot be applied (e.g., invalid value, or the setting cannot be changed after server start) it will have an appropriate message in the `error` field. Another way that an entry might have `applied = false` is that it is overridden by a later entry for the same parameter name; this case is not considered an error so nothing appears in the `error` field.

See [Section 19.1](#) for more information about the various ways to change run-time parameters.

55.8. pg_group

The view `pg_group` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows the names and members of all roles that are marked as not `rolcanlogin`, which is an approximation to the set of roles that are being used as groups.

Table 55.8. pg_group Columns

Column Type	Description
groname name (references <code>pg_authid</code> .rolname)	Name of the group
grosysid oid (references <code>pg_authid</code> .oid)	

Column Type	Description
	ID of this group
grolist oid[]	(references pg_authid .oid) An array containing the IDs of the roles in this group

55.9. pg_hba_file_rules

The view `pg_hba_file_rules` provides a summary of the contents of the client authentication configuration file, `pg_hba.conf`. A row appears in this view for each non-empty, non-comment line in the file, with annotations indicating whether the rule could be applied successfully.

This view can be helpful for checking whether planned changes in the authentication configuration file will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the file, not on what was last loaded by the server.

By default, the `pg_hba_file_rules` view can be read only by superusers.

Table 55.9. pg_hba_file_rules Columns

Column Type	Description
rule_number int4	Number of this rule, if valid, otherwise NULL. This indicates the order in which each rule is considered until a match is found during authentication.
file_name text	Name of the file containing this rule
line_number int4	Line number of this rule in <code>file_name</code>
type text	Type of connection
database text[]	List of database name(s) to which this rule applies
user_name text[]	List of user and group name(s) to which this rule applies
address text	Host name or IP address, or one of <code>all</code> , <code>samehost</code> , or <code>samenet</code> , or null for local connections
netmask text	IP address mask, or null if not applicable
auth_method text	Authentication method
options text[]	Options specified for authentication method, if any
error text	If not null, an error message indicating why this line could not be processed

Usually, a row reflecting an incorrect entry will have values for only the `line_number` and `error` fields.

See [Chapter 20](#) for more information about client authentication configuration.

55.10. pg_ident_file_mappings

The view `pg_ident_file_mappings` provides a summary of the contents of the client user name mapping configuration file, `pg_ident.conf`. A row appears in this view for each non-empty, non-comment line in the file, with annotations indicating whether the map could be applied successfully.

This view can be helpful for checking whether planned changes in the authentication configuration file will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the file, not on what was last loaded by the server.

By default, the `pg_ident_file_mappings` view can be read only by superusers.

Table 55.10. `pg_ident_file_mappings` Columns

Column Type	Description
<code>map_number int4</code>	Number of this map, in priority order, if valid, otherwise <code>NULL</code>
<code>file_name text</code>	Name of the file containing this map
<code>line_number int4</code>	Line number of this map in <code>file_name</code>
<code>map_name text</code>	Name of the map
<code>sys_name text</code>	Detected user name of the client
<code>pg_username text</code>	Requested Postgres Pro user name
<code>error text</code>	If not <code>NULL</code> , an error message indicating why this line could not be processed

Usually, a row reflecting an incorrect entry will have values for only the `line_number` and `error` fields.

See [Chapter 20](#) for more information about client authentication configuration.

55.11. `pg_indexes`

The view `pg_indexes` provides access to useful information about each index in the database.

Table 55.11. `pg_indexes` Columns

Column Type	Description
<code>schemaname name (references pg_namespace .nspname)</code>	Name of schema containing table and index
<code>tablename name (references pg_class .relname)</code>	Name of table the index is for
<code>indexname name (references pg_class .relname)</code>	Name of index
<code>tablespace name (references pg_tablespace .spcname)</code>	Name of tablespace containing index (null if default for database)
<code>indexdef text</code>	Index definition (a reconstructed CREATE INDEX command)

55.12. `pg_locks`

The view `pg_locks` provides access to information about the locks held by active processes within the database server. See [Chapter 13](#) for more discussion of locking.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant process. Thus, the same lockable object might appear many times, if multiple processes are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (e.g., tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects (identified by class OID and object OID, in the same way as in [pg_description](#) or [pg_depend](#)). Also, the right to extend a relation is represented as a separate lockable object, as is the right to update `pg_database.datfrozenxid`. Also, “advisory” locks can be taken on numbers that have user-defined meanings.

Table 55.12. `pg_locks` Columns

Column Type	Description
<code>locktype</code> text	Type of the lockable object: <code>relation</code> , <code>extend</code> , <code>frozenid</code> , <code>page</code> , <code>tuple</code> , <code>transactionid</code> , <code>virtualxid</code> , <code>spectoken</code> , <code>object</code> , <code>userlock</code> , <code>advisory</code> , <code>applytransaction</code> , or <code>shardman</code> . (See also Table 27.11 .)
<code>database oid</code> (references <code>pg_database .oid</code>)	OID of the database in which the lock target exists, or zero if the target is a shared object, or null if the target is a transaction ID
<code>relation oid</code> (references <code>pg_class .oid</code>)	OID of the relation targeted by the lock, or null if the target is not a relation or part of a relation
<code>page</code> int4	Page number targeted by the lock within the relation, or null if the target is not a relation page or tuple
<code>tuple</code> int2	Tuple number targeted by the lock within the page, or null if the target is not a tuple
<code>virtualxid</code> text	Virtual ID of the transaction targeted by the lock, or null if the target is not a virtual transaction ID; see Chapter 67
<code>transactionid</code> xid	ID of the transaction targeted by the lock, or null if the target is not a transaction ID; Chapter 67
<code>classid oid</code> (references <code>pg_class .oid</code>)	OID of the system catalog containing the lock target, or null if the target is not a general database object
<code>objid oid</code> (references any OID column)	OID of the lock target within its system catalog, or null if the target is not a general database object
<code>objsubid</code> int2	Column number targeted by the lock (the <code>classid</code> and <code>objid</code> refer to the table itself), or zero if the target is some other general database object, or null if the target is not a general database object
<code>virtualtransaction</code> text	Virtual ID of the transaction that is holding or awaiting this lock
<code>pid</code> int4	Process ID of the server process holding or awaiting this lock, or null if the lock is held by a prepared transaction
<code>mode</code> text	Name of the lock mode held or desired by this process (see Section 13.3.1 and Section 13.2.3)
<code>granted</code> bool	True if lock is held, false if lock is awaited
<code>fastpath</code> bool	

Column Type	Description
	True if lock was taken via fast path, false if taken via main lock table
<code>waitstart timestampz</code>	Time when the server process started waiting for this lock, or null if the lock is held. Note that this can be null for a very short period of time after the wait started even though <code>granted</code> is false.

`granted` is true in a row representing a lock held by the indicated process. False indicates that this process is currently waiting to acquire this lock, which implies that at least one other process is holding or waiting for a conflicting lock mode on the same lockable object. The waiting process will sleep until the other lock is released (or a deadlock situation is detected). A single process can be waiting to acquire at most one lock at a time.

Throughout running a transaction, a server process holds an exclusive lock on the transaction's virtual transaction ID. If a permanent ID is assigned to the transaction (which normally happens only if the transaction changes the state of the database), it also holds an exclusive lock on the transaction's permanent transaction ID until it ends. When a process finds it necessary to wait specifically for another transaction to end, it does so by attempting to acquire share lock on the other transaction's ID (either virtual or permanent ID depending on the situation). That will succeed only when the other transaction terminates and releases its locks.

Although tuples are a lockable type of object, information about row-level locks is stored on disk, not in memory, and therefore row-level locks normally do not appear in this view. If a process is waiting for a row-level lock, it will usually appear in the view as waiting for the permanent transaction ID of the current holder of that row lock.

A speculative insertion lock consists of a transaction ID and a speculative insertion token. The speculative insertion token is displayed in the `objid` column.

Advisory locks can be acquired on keys consisting of either a single `bigint` value or two integer values. A `bigint` key is displayed with its high-order half in the `classid` column, its low-order half in the `objid` column, and `objsubid` equal to 1. The original `bigint` value can be reassembled with the expression `(classid::bigint << 32) | objid::bigint`. Integer keys are displayed with the first key in the `classid` column, the second key in the `objid` column, and `objsubid` equal to 2. The actual meaning of the keys is up to the user. Advisory locks are local to each database, so the `database` column is meaningful for an advisory lock.

Apply transaction locks are used in parallel mode to apply the transaction in logical replication. The remote transaction ID is displayed in the `transactionid` column. The `objsubid` displays the lock subtype which is 0 for the lock used to synchronize the set of changes, and 1 for the lock used to wait for the transaction to finish to ensure commit order.

`pg_locks` provides a global view of all locks in the database cluster, not only those relevant to the current database. Although its `relation` column can be joined against `pg_class.oid` to identify locked relations, this will only work correctly for relations in the current database (those for which the `database` column is either the current database's OID or zero).

The `pid` column can be joined to the `pid` column of the `pg_stat_activity` view to get more information on the session holding or awaiting each lock, for example

```
SELECT * FROM pg_locks pl LEFT JOIN pg_stat_activity psa
    ON pl.pid = psa.pid;
```

Also, if you are using prepared transactions, the `virtualtransaction` column can be joined to the `transaction` column of the `pg_prepared_xacts` view to get more information on prepared transactions that hold locks. (A prepared transaction can never be waiting for a lock, but it continues to hold the locks it acquired while running.) For example:

```
SELECT * FROM pg_locks pl LEFT JOIN pg_prepared_xacts ppx
ON pl.virtualtransaction = '-1/' || ppx.transaction;
```

While it is possible to obtain information about which processes block which other processes by joining `pg_locks` against itself, this is very difficult to get right in detail. Such a query would have to encode knowledge about which lock modes conflict with which others. Worse, the `pg_locks` view does not expose information about which processes are ahead of which others in lock wait queues, nor information about which processes are parallel workers running on behalf of which other client sessions. It is better to use the `pg_blocking_pids()` function (see [Table 9.69](#)) to identify which process(es) a waiting process is blocked behind.

The `pg_locks` view displays data from both the regular lock manager and the predicate lock manager, which are separate systems; in addition, the regular lock manager subdivides its locks into regular and *fast-path* locks. This data is not guaranteed to be entirely consistent. When the view is queried, data on fast-path locks (with `fastpath = true`) is gathered from each backend one at a time, without freezing the state of the entire lock manager, so it is possible for locks to be taken or released while information is gathered. Note, however, that these locks are known not to conflict with any other lock currently in place. After all backends have been queried for fast-path locks, the remainder of the regular lock manager is locked as a unit, and a consistent snapshot of all remaining locks is collected as an atomic action. After unlocking the regular lock manager, the predicate lock manager is similarly locked and all predicate locks are collected as an atomic action. Thus, with the exception of fast-path locks, each lock manager will deliver a consistent set of results, but as we do not lock both lock managers simultaneously, it is possible for locks to be taken or released after we interrogate the regular lock manager and before we interrogate the predicate lock manager.

Locking the regular and/or predicate lock manager could have some impact on database performance if this view is very frequently accessed. The locks are held only for the minimum amount of time necessary to obtain data from the lock managers, but this does not completely eliminate the possibility of a performance impact.

55.13. pg_matviews

The view `pg_matviews` provides access to useful information about each materialized view in the database.

Table 55.13. `pg_matviews` Columns

Column Type	Description
<code>schemaname name</code> (references <code>pg_namespace .nspname</code>)	Name of schema containing materialized view
<code>matviewname name</code> (references <code>pg_class .relname</code>)	Name of materialized view
<code>matviewowner name</code> (references <code>pg_authid .rolname</code>)	Name of materialized view's owner
<code>tablespace name</code> (references <code>pg_tablespace .spcname</code>)	Name of tablespace containing materialized view (null if default for database)
<code>hasindexes bool</code>	True if materialized view has (or recently had) any indexes
<code>ispopulated bool</code>	True if materialized view is currently populated
<code>definition text</code>	Materialized view definition (a reconstructed <code>SELECT</code> query)

55.14. pg_policies

The view `pg_policies` provides access to useful information about each row-level security policy in the database.

Table 55.14. `pg_policies` Columns

Column Type	Description
<code>schemaname name</code> (references <code>pg_namespace .nspname</code>)	Name of schema containing table policy is on
<code>tablename name</code> (references <code>pg_class .relname</code>)	Name of table policy is on
<code>polICYname name</code> (references <code>pg_policy .polname</code>)	Name of policy
<code>permissive text</code>	Is the policy permissive or restrictive?
<code>roles name[]</code>	The roles to which this policy applies
<code>cmd text</code>	The command type to which the policy is applied
<code>qual text</code>	The expression added to the security barrier qualifications for queries that this policy applies to
<code>with_check text</code>	The expression added to the WITH CHECK qualifications for queries that attempt to add rows to this table

55.15. `pg_prepared_statements`

The `pg_prepared_statements` view displays all the prepared statements that are available in the current session. See [PREPARE](#) for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, via the [DEALLOCATE](#) command).

Table 55.15. `pg_prepared_statements` Columns

Column Type	Description
<code>name text</code>	The identifier of the prepared statement
<code>statement text</code>	The query string submitted by the client to create this prepared statement. For prepared statements created via SQL, this is the <code>PREPARE</code> statement submitted by the client. For prepared statements created via the frontend/backend protocol, this is the text of the prepared statement itself.
<code>prepare_time timestamptz</code>	The time at which the prepared statement was created
<code>parameter_types regtype[]</code>	The expected parameter types for the prepared statement in the form of an array of <code>regtype</code> . The OID corresponding to an element of this array can be obtained by casting the <code>regtype</code> value to <code>oid</code> .
<code>result_types regtype[]</code>	

Column Type	Description
	The types of the columns returned by the prepared statement in the form of an array of <code>reg-type</code> . The OID corresponding to an element of this array can be obtained by casting the <code>reg-type</code> value to <code>oid</code> . If the prepared statement does not provide a result (e.g., a DML statement), then this field will be null.
<code>from_sql</code> <code>bool</code>	<code>true</code> if the prepared statement was created via the <code>PREPARE SQL</code> command; <code>false</code> if the statement was prepared via the frontend/backend protocol
<code>generic_plans</code> <code>int8</code>	Number of times generic plan was chosen
<code>custom_plans</code> <code>int8</code>	Number of times custom plan was chosen

The `pg_prepared_statements` view is read-only.

55.16. pg_autoprepared_statements

The `pg_autoprepared_statements` view displays all the autoprepared statements that are available in the current session. See [Section 14.5](#) for more information about autoprepared statements.

Table 55.16. pg_autoprepared_statements Columns

Name	Type	Description
<code>statement</code>	<code>text</code>	The query string submitted by the client from which this prepared statement was created. Note that literals in this string are not replaced with prepared statement placeholders.
<code>parameter_types</code>	<code>regtype[]</code>	The expected parameter types for the autoprepared statement in the form of an array of <code>reg-type</code> . The OID corresponding to an element of this array can be obtained by casting the <code>regtype</code> value to <code>oid</code> .
<code>exec_count</code>	<code>int8</code>	Number of times this statement was executed.

The `pg_autoprepared_statements` view is read only.

55.17. pg_prepared_xacts

The view `pg_prepared_xacts` displays information about transactions that are currently prepared for two-phase commit (see [PREPARE TRANSACTION](#) for details).

`pg_prepared_xacts` contains one row per prepared transaction. An entry is removed when the transaction is committed or rolled back.

Table 55.17. pg_prepared_xacts Columns

Column Type	Description
<code>transaction_xid</code>	Numeric transaction identifier of the prepared transaction
<code>gid</code> <code>text</code>	

Column Type	Description
	Global transaction identifier that was assigned to the transaction
prepared timestamp tz	Time at which the transaction was prepared for commit
owner name (references pg_authid .rolname)	Name of the user that executed the transaction
database name (references pg_database .datname)	Name of the database in which the transaction was executed
state3pc text	State of the three-phase commit

When the `pg_prepared_xacts` view is accessed, the internal transaction manager data structures are momentarily locked, and a copy is made for the view to display. This ensures that the view produces a consistent set of results, while not blocking normal operations longer than necessary. Nonetheless there could be some impact on database performance if this view is frequently accessed.

55.18. `pg_publication_tables`

The view `pg_publication_tables` provides information about the mapping between publications and information of tables they contain. Unlike the underlying catalog `pg_publication_rel`, this view expands publications defined as `FOR ALL TABLES` and `FOR TABLES IN SCHEMA`, so for such publications there will be a row for each eligible table.

Table 55.18. `pg_publication_tables` Columns

Column Type	Description
pubname name (references pg_publication .pubname)	Name of publication
schemaname name (references pg_namespace .nspname)	Name of schema containing table
tablename name (references pg_class .relname)	Name of table
attnames name[] (references pg_attribute .attname)	Names of table columns included in the publication. This contains all the columns of the table when the user didn't specify the column list for the table.
rowfilter text	Expression for the table's publication qualifying condition

55.19. `pg_replication_origin_status`

The `pg_replication_origin_status` view contains information about how far replay for a certain origin has progressed. For more on replication origins see [Chapter 51](#).

Table 55.19. `pg_replication_origin_status` Columns

Column Type	Description
local_id oid (references pg_replication_origin .roident)	internal node identifier
external_id text (references pg_replication_origin .roname)	external node identifier
remote_lsn pg_lsn	

Column Type	Description
	The origin node's LSN up to which data has been replicated.
local_lsn pg_lsn	This node's LSN at which <code>remote_lsn</code> has been replicated. Used to flush commit records before persisting data to disk when using asynchronous commits.

55.20. pg_replication_slots

The `pg_replication_slots` view provides a listing of all replication slots that currently exist on the database cluster, along with their current state.

For more on replication slots, see [Section 26.2.6](#) and [Chapter 50](#).

Table 55.20. pg_replication_slots Columns

Column Type	Description
slot_name name	A unique, cluster-wide identifier for the replication slot
plugin name	The base name of the shared object containing the output plugin this logical slot is using, or null for physical slots.
slot_type text	The slot type: <code>physical</code> or <code>logical</code>
datoid oid (references pg_database .oid)	The OID of the database this slot is associated with, or null. Only logical slots have an associated database.
database name (references pg_database .datname)	The name of the database this slot is associated with, or null. Only logical slots have an associated database.
temporary bool	True if this is a temporary replication slot. Temporary slots are not saved to disk and are automatically dropped on error or when the session has finished.
active bool	True if this slot is currently being streamed
active_pid int4	The process ID of the session streaming data for this slot. <code>NULL</code> if inactive.
xmin xid	The oldest transaction that this slot needs the database to retain. <code>VACUUM</code> cannot remove tuples deleted by any later transaction.
catalog_xmin xid	The oldest transaction affecting the system catalogs that this slot needs the database to retain. <code>VACUUM</code> cannot remove catalog tuples deleted by any later transaction.
restart_lsn pg_lsn	The address (LSN) of oldest WAL which still might be required by the consumer of this slot and thus won't be automatically removed during checkpoints unless this LSN gets behind more than max_slot_wal_keep_size from the current LSN. <code>NULL</code> if the LSN of this slot has never been reserved.
confirmed_flush_lsn pg_lsn	The address (LSN) up to which the logical slot's consumer has confirmed receiving data. Data corresponding to the transactions committed before this LSN is not available anymore. <code>NULL</code> for physical slots.

Column	Type	Description
<code>wal_status</code>	<code>text</code>	<p>Availability of WAL files claimed by this slot. Possible values are:</p> <ul style="list-style-type: none"> <code>reserved</code> means that the claimed files are within <code>max_wal_size</code> . <code>extended</code> means that <code>max_wal_size</code> is exceeded but the files are still retained, either by the replication slot or by <code>wal_keep_size</code> . <code>unreserved</code> means that the slot no longer retains the required WAL files and some of them are to be removed at the next checkpoint. This state can return to <code>reserved</code> or <code>extended</code>. <code>lost</code> means that some required WAL files have been removed and this slot is no longer usable. <p>The last two states are seen only when <code>max_slot_wal_keep_size</code> is non-negative. If <code>restart_lsn</code> is NULL, this field is null.</p>
<code>safe_wal_size</code>	<code>int8</code>	<p>The number of bytes that can be written to WAL such that this slot is not in danger of getting in state "lost". It is NULL for lost slots, as well as if <code>max_slot_wal_keep_size</code> is -1.</p>
<code>two_phase</code>	<code>bool</code>	<p>True if the slot is enabled for decoding prepared transactions. Always false for physical slots.</p>
<code>inactive_since</code>	<code>timestampz</code>	<p>The time when the slot became inactive. NULL if the slot is currently being streamed. Note that for slots on the standby that are being synced from a primary server (whose <code>synced</code> field is <code>true</code>), the <code>inactive_since</code> indicates the time when slot synchronization (see Section 50.2.3) was most recently stopped. NULL if the slot has always been synchronized. On standby, this is useful for slots that are being synced from a primary server (whose <code>synced</code> field is <code>true</code>) so they know when the slot stopped being synchronized.</p>
<code>conflicting</code>	<code>bool</code>	<p>True if this logical slot conflicted with recovery (and so is now invalidated). When this column is true, check <code>invalidation_reason</code> column for the conflict reason. Always NULL for physical slots.</p>
<code>invalidation_reason</code>	<code>text</code>	<p>The reason for the slot's invalidation. It is set for both logical and physical slots. NULL if the slot is not invalidated. Possible values are:</p> <ul style="list-style-type: none"> <code>wal_removed</code> means that the required WAL has been removed. <code>rows_removed</code> means that the required rows have been removed. It is set only for logical slots. <code>wal_level_insufficient</code> means that the primary doesn't have a <code>wal_level</code> sufficient to perform logical decoding. It is set only for logical slots.
<code>failover</code>	<code>bool</code>	<p>True if this is a logical slot enabled to be synced to the standbys so that logical replication can be resumed from the new primary after failover. Always false for physical slots.</p>
<code>synced</code>	<code>bool</code>	<p>True if this is a logical slot that was synced from a primary server. On a hot standby, the slots with the <code>synced</code> column marked as true can neither be used for logical decoding nor dropped manually. The value of this column has no meaning on the primary server; the column value on the primary is default false for all slots but may (if leftover from a promoted standby) also be true.</p>

55.21. pg_roles

The view `pg_roles` provides access to information about database roles. This is simply a publicly readable view of `pg_authid` that blanks out the password field.

Table 55.21. pg_roles Columns

Column	Type	Description
rolname	name	Role name
rolsuper	bool	Role has superuser privileges
rolinherit	bool	Role automatically inherits privileges of roles it is a member of
rolcreaterole	bool	Role can create more roles
rolcreatedb	bool	Role can create databases
rolcanlogin	bool	Role can log in. That is, this role can be given as the initial session authorization identifier
rolreplication	bool	Role is a replication role. A replication role can initiate replication connections and create and drop replication slots.
rolconnlimit	int4	For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.
rolprofile	regprofile (references pg_profile .oid)	The OID of the role's profile
rolloginattempts	int4	Number of consecutive failed login attempts of a user. It is always 0 if <code>FAILED_LOGIN_ATTEMPTS</code> value of the corresponding role profile is <code>UNLIMITED</code> . After a successful login, <code>rolloginattempts</code> is reset to 0.
rollastlogin	timestampz	The timestamp the role logged in last time
rolfirstfailedauth	timestampz	The timestamp of the role's first authentication failure
rolstatus	int2	Status of the role: 0 for the active role, 1 the role is manually locked (see <code>ACCOUNT LOCK</code> in ALTER ROLE), 2 the role is locked because of inactivity (see parameter <code>USER_INACTIVE_TIME</code> in CREATE PROFILE), 4 the role is locked because the number of consecutive authentication failures has reached the limit (see parameter <code>FAILED_LOGIN_ATTEMPTS</code> in CREATE PROFILE)
rolpassword	text	Not the password (always reads as <code>*****</code>)
rolvaliduntil	timestampz	Password expiry time (only used for password authentication); null if no expiration
rolpasssetat	timestampz	Password set time (only used for password authentication); null if password is not set.
rolbypassrsls	bool	Role bypasses every row-level security policy, see Section 5.9 for more information.
rolconfig	text[]	Role-specific defaults for run-time configuration variables
oid	oid (references pg_authid .oid)	ID of role

55.22. pg_rules

The view `pg_rules` provides access to useful information about query rewrite rules.

Table 55.22. pg_rules Columns

Column Type	Description
<code>schemaname name</code> (references <code>pg_namespace .nspname</code>)	Name of schema containing table
<code>tablename name</code> (references <code>pg_class .relname</code>)	Name of table the rule is for
<code>rulename name</code> (references <code>pg_rewrite .rulename</code>)	Name of rule
<code>definition text</code>	Rule definition (a reconstructed creation command)

The `pg_rules` view excludes the `ON SELECT` rules of views and materialized views; those can be seen in `pg_views` and `pg_matviews`.

55.23. pg_seclabels

The view `pg_seclabels` provides information about security labels. It is an easier-to-query version of the `pg_seclabel` catalog.

Table 55.23. pg_seclabels Columns

Column Type	Description
<code>objoid oid</code> (references any OID column)	The OID of the object this security label pertains to
<code>classoid oid</code> (references <code>pg_class .oid</code>)	The OID of the system catalog this object appears in
<code>objsubid int4</code>	For a security label on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
<code>objtype text</code>	The type of object to which this label applies, as text.
<code>objnamespace oid</code> (references <code>pg_namespace .oid</code>)	The OID of the namespace for this object, if applicable; otherwise NULL.
<code>objname text</code>	The name of the object to which this label applies, as text.
<code>provider text</code> (references <code>pg_seclabel .provider</code>)	The label provider associated with this label.
<code>label text</code> (references <code>pg_seclabel .label</code>)	The security label applied to this object.

55.24. pg_sequences

The view `pg_sequences` provides access to useful information about each sequence in the database.

Table 55.24. pg_sequences Columns

Column Type	Description
schemaname name (references pg_namespace .nspname)	Name of schema containing sequence
sequencename name (references pg_class .relname)	Name of sequence
sequenceowner name (references pg_authid .rolname)	Name of sequence's owner
data_type regtype (references pg_type .oid)	Data type of the sequence
start_value int8	Start value of the sequence
min_value int8	Minimum value of the sequence
max_value int8	Maximum value of the sequence
increment_by int8	Increment value of the sequence
cycle bool	Whether the sequence cycles
cache_size int8	Cache size of the sequence
last_value int8	The last sequence value written to disk. If caching is used, this value can be greater than the last value handed out from the sequence.

The `last_value` column will read as null if any of the following are true:

- The sequence has not been read from yet.
- The current user does not have `USAGE` or `SELECT` privilege on the sequence.
- The sequence is unlogged and the server is a standby.

55.25. pg_settings

The view `pg_settings` provides access to run-time parameters of the server. It is essentially an alternative interface to the [SHOW](#) and [SET](#) commands. It also provides access to some facts about each parameter that are not directly available from [SHOW](#), such as minimum and maximum values.

Table 55.25. pg_settings Columns

Column Type	Description
name text	Run-time configuration parameter name
setting text	Current value of the parameter
unit text	Implicit unit of the parameter
category text	Logical group of the parameter
short_desc text	

Column	Type	Description
		A brief description of the parameter
extra_desc	text	Additional, more detailed, description of the parameter
context	text	Context required to set the parameter's value (see below)
vartype	text	Parameter type (bool, enum, integer, real, or string)
source	text	Source of the current parameter value
min_val	text	Minimum allowed value of the parameter (null for non-numeric values)
max_val	text	Maximum allowed value of the parameter (null for non-numeric values)
enumvals	text[]	Allowed values of an enum parameter (null for non-enum values)
boot_val	text	Parameter value assumed at server startup if the parameter is not otherwise set
reset_val	text	Value that RESET would reset the parameter to in the current session
sourcefile	text	Configuration file the current value was set in (null for values set from sources other than configuration files, or when examined by a user who neither is a superuser nor has privileges of <code>pg_read_all_settings</code>); helpful when using <code>include</code> directives in configuration files
sourceline	int4	Line number within the configuration file the current value was set at (null for values set from sources other than configuration files, or when examined by a user who neither is a superuser nor has privileges of <code>pg_read_all_settings</code>).
pending_restart	bool	<code>true</code> if the value has been changed in the configuration file but needs a restart; or <code>false</code> otherwise.

There are several possible values of `context`. In order of decreasing difficulty of changing the setting, they are:

internal

These settings cannot be changed directly; they reflect internally determined values. Some of them may be adjustable by rebuilding the server with different configuration options, or by changing options supplied to `initdb`.

postmaster

These settings can only be applied when the server starts, so any change requires restarting the server. Values for these settings are typically stored in the `postgresql.conf` file, or passed on the command line when starting the server. Of course, settings with any of the lower `context` types can also be set at server start time.

sighup

Changes to these settings can be made in `postgresql.conf` without restarting the server. Send a **SIGHUP** signal to the postmaster to cause it to re-read `postgresql.conf` and apply the changes. The postmaster will also forward the **SIGHUP** signal to its child processes so that they all pick up the new value.

superuser-backend

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq's `PGOPTIONS` environment variable), but only if the connecting user is a superuser or has been granted the appropriate `SET` privilege. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

backend

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq's `PGOPTIONS` environment variable); any user can make such a change for their session. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

superuser

These settings can be set from `postgresql.conf`, or within a session via the `SET` command; but only superusers and users with the appropriate `SET` privilege can change them via `SET`. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

user

These settings can be set from `postgresql.conf`, or within a session via the `SET` command. Any user is allowed to change their session-local value. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

See [Section 19.1](#) for more information about the various ways to change these parameters.

This view cannot be inserted into or deleted from, but it can be updated. An `UPDATE` applied to a row of `pg_settings` is equivalent to executing the `SET` command on that named parameter. The change only affects the value used by the current session. If an `UPDATE` is issued within a transaction that is later aborted, the effects of the `UPDATE` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `UPDATE` or `SET`.

This view does not display [customized options](#) unless the extension module that defines them has been loaded by the backend process executing the query (e.g., via a mention in [shared_preload_libraries](#), a call to a C function in the extension, or the `LOAD` command). For example, since [archive modules](#) are normally loaded only by the archiver process not regular sessions, this view will not display any customized options defined by such modules unless special action is taken to load them into the backend process executing the query.

55.26. pg_shadow

The view `pg_shadow` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows properties of all roles that are marked as `rolcanlogin` in `pg_authid`.

The name stems from the fact that this table should not be readable by the public since it contains passwords. `pg_user` is a publicly readable view on `pg_shadow` that blanks out the password field.

Table 55.26. pg_shadow Columns

Column Type	Description
username name	(references <code>pg_authid</code> .rolname)

Column Type	Description
User name	
usesysid oid (references <code>pg_authid .oid</code>)	ID of this user
usecreatedb bool	User can create databases
usesuper bool	User is a superuser
userepl bool	User can initiate streaming replication and put the system in and out of backup mode.
usebypassrls bool	User bypasses every row-level security policy, see Section 5.9 for more information.
passwd text	Password (possibly encrypted); null if none. See <code>pg_authid</code> for details of how encrypted passwords are stored.
valuntil timestamptz	Password expiry time (only used for password authentication)
useconfig text[]	Session defaults for run-time configuration variables

55.27. pg_shmem_allocations

The `pg_shmem_allocations` view shows allocations made from the server's main shared memory segment. This includes both memory allocated by Postgres Pro itself and memory allocated by extensions using the mechanisms detailed in [Section 39.10.10](#).

Note that this view does not include memory allocated using the dynamic shared memory infrastructure.

Table 55.27. `pg_shmem_allocations` Columns

Column Type	Description
name text	The name of the shared memory allocation. NULL for unused memory and <code><anonymous></code> for anonymous allocations.
off int8	The offset at which the allocation starts. NULL for anonymous allocations, since details related to them are not known.
size int8	Size of the allocation in bytes
allocated_size int8	Size of the allocation in bytes including padding. For anonymous allocations, no information about padding is available, so the <code>size</code> and <code>allocated_size</code> columns will always be equal. Padding is not meaningful for free memory, so the columns will be equal in that case also.

Anonymous allocations are allocations that have been made with `ShmemAlloc()` directly, rather than via `ShmemInitStruct()` or `ShmemInitHash()`.

By default, the `pg_shmem_allocations` view can be read only by superusers or roles with privileges of the `pg_read_all_stats` role.

55.28. pg_stats

The view `pg_stats` provides access to the information stored in the `pg_statistic` catalog. This view allows access only to rows of `pg_statistic` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats` is also designed to present the information in a more readable format than the underlying catalog — at the cost that its schema must be extended whenever new slot types are defined for `pg_statistic`.

Table 55.28. `pg_stats` Columns

Column Type	Description
<code>schemaname name</code> (references <code>pg_namespace .nspname</code>)	Name of schema containing table
<code>tablename name</code> (references <code>pg_class .relname</code>)	Name of table
<code>attname name</code> (references <code>pg_attribute .attname</code>)	Name of column described by this row
<code>inherited bool</code>	If true, this row includes values from child tables, not just the values in the specified table
<code>null_frac float4</code>	Fraction of column entries that are null
<code>avg_width int4</code>	Average width in bytes of column's entries
<code>n_distinct float4</code>	If greater than zero, the estimated number of distinct values in the column. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when <code>ANALYZE</code> believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.
<code>most_common_vals anyarray</code>	A list of the most common values in the column. (Null if no values seem to be more common than any others.)
<code>most_common_freqs float4[]</code>	A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when <code>most_common_vals</code> is.)
<code>histogram_bounds anyarray</code>	A list of values that divide the column's values into groups of approximately equal population. The values in <code>most_common_vals</code> , if present, are omitted from this histogram calculation. (This column is null if the column data type does not have a < operator or if the <code>most_common_vals</code> list accounts for the entire population.)
<code>correlation float4</code>	Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is null if the column data type does not have a < operator.)
<code>most_common_elems anyarray</code>	A list of non-null element values most often appearing within values of the column. (Null for scalar types.)
<code>most_common_elem_freqs float4[]</code>	A list of the frequencies of the most common element values, i.e., the fraction of rows containing at least one instance of the given value. Two or three additional values follow the per-el-

Column Type	Description
	ement frequencies; these are the minimum and maximum of the preceding per-element frequencies, and optionally the frequency of null elements. (Null when <code>most_common_elems</code> is.)
<code>elem_count_histogram float4[]</code>	A histogram of the counts of distinct non-null element values within the values of the column, followed by the average number of distinct non-null elements. (Null for scalar types.)
<code>range_length_histogram anyarray</code>	A histogram of the lengths of non-empty and non-null range values of a range type column. (Null for non-range types.) This histogram is calculated using the <code>subtype_diff</code> range function regardless of whether range bounds are inclusive.
<code>range_empty_frac float4</code>	Fraction of column entries whose values are empty ranges. (Null for non-range types.)
<code>range_bounds_histogram anyarray</code>	A histogram of lower and upper bounds of non-empty and non-null range values. (Null for non-range types.) These two histograms are represented as a single array of ranges, whose lower bounds represent the histogram of lower bounds, and upper bounds represent the histogram of upper bounds.

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` run-time parameter.

55.29. pg_stats_ext

The view `pg_stats_ext` provides access to information about each extended statistics object in the database, combining information stored in the `pg_statistic_ext` and `pg_statistic_ext_data` catalogs. This view allows access only to rows of `pg_statistic_ext` and `pg_statistic_ext_data` that correspond to tables the user owns, and therefore it is safe to allow public read access to this view.

`pg_stats_ext` is also designed to present the information in a more readable format than the underlying catalogs — at the cost that its schema must be extended whenever new types of extended statistics are added to `pg_statistic_ext`.

Table 55.29. pg_stats_ext Columns

Column Type	Description
<code>schemaname name (references pg_namespace .nspname)</code>	Name of schema containing table
<code>tablename name (references pg_class .relname)</code>	Name of table
<code>statistics_schemaname name (references pg_namespace .nspname)</code>	Name of schema containing extended statistics object
<code>statistics_name name (references pg_statistic_ext .stxname)</code>	Name of extended statistics object
<code>statistics_owner name (references pg_authid .rolname)</code>	Owner of the extended statistics object
<code>attnames name[] (references pg_attribute .attname)</code>	Names of the columns included in the extended statistics object
<code>exprs text []</code>	

Column Type	Description
	Expressions included in the extended statistics object
kinds char[]	Types of extended statistics object enabled for this record
inherited bool (references <code>pg_statistic_ext_data</code> . <code>stxdinherit</code>)	If true, the stats include values from child tables, not just the values in the specified relation
n_distinct pg_ndistinct	N-distinct counts for combinations of column values. If greater than zero, the estimated number of distinct values in the combination. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when <code>ANALYZE</code> believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique combination of columns in which the number of distinct combinations is the same as the number of rows.
dependencies pg_dependencies	Functional dependency statistics
most_common_vals text[]	A list of the most common combinations of values in the columns. (Null if no combinations seem to be more common than any others.)
most_common_val_nulls bool[]	A list of NULL flags for the most common combinations of values. (Null when <code>most_common_vals</code> is.)
most_common_freqs float8[]	A list of the frequencies of the most common combinations, i.e., number of occurrences of each divided by total number of rows. (Null when <code>most_common_vals</code> is.)
most_common_base_freqs float8[]	A list of the base frequencies of the most common combinations, i.e., product of per-value frequencies. (Null when <code>most_common_vals</code> is.)

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` run-time parameter.

55.30. pg_stats_ext_exprs

The view `pg_stats_ext_exprs` provides access to information about all expressions included in extended statistics objects, combining information stored in the `pg_statistic_ext` and `pg_statistic_ext_data` catalogs. This view allows access only to rows of `pg_statistic_ext` and `pg_statistic_ext_data` that correspond to tables the user owns, and therefore it is safe to allow public read access to this view.

`pg_stats_ext_exprs` is also designed to present the information in a more readable format than the underlying catalogs — at the cost that its schema must be extended whenever the structure of statistics in `pg_statistic_ext` changes.

Table 55.30. pg_stats_ext_exprs Columns

Column Type	Description
schemaname name (references <code>pg_namespace</code> . <code>nspname</code>)	Name of schema containing table
tablename name (references <code>pg_class</code> . <code>relname</code>)	Name of table the statistics object is defined on
statistics_schemaname name (references <code>pg_namespace</code> . <code>nspname</code>)	

Column Type	Description
	Name of schema containing extended statistics object
statistics_name name (references pg_statistic_ext .stxname)	Name of extended statistics object
statistics_owner name (references pg_authid .rolname)	Owner of the extended statistics object
expr text	Expression included in the extended statistics object
inherited bool (references pg_statistic_ext_data .stxdinherit)	If true, the stats include values from child tables, not just the values in the specified relation
null_frac float4	Fraction of expression entries that are null
avg_width int4	Average width in bytes of expression's entries
n_distinct float4	If greater than zero, the estimated number of distinct values in the expression. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when <code>ANALYZE</code> believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the expression seems to have a fixed number of possible values.) For example, -1 indicates a unique expression in which the number of distinct values is the same as the number of rows.
most_common_vals anyarray	A list of the most common values in the expression. (Null if no values seem to be more common than any others.)
most_common_freqs float4[]	A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when <code>most_common_vals</code> is.)
histogram_bounds anyarray	A list of values that divide the expression's values into groups of approximately equal population. The values in <code>most_common_vals</code> , if present, are omitted from this histogram calculation. (This expression is null if the expression data type does not have a <code><</code> operator or if the <code>most_common_vals</code> list accounts for the entire population.)
correlation float4	Statistical correlation between physical row ordering and logical ordering of the expression values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the expression will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This expression is null if the expression's data type does not have a <code><</code> operator.)
most_common_elems anyarray	A list of non-null element values most often appearing within values of the expression. (Null for scalar types.)
most_common_elem_freqs float4[]	A list of the frequencies of the most common element values, i.e., the fraction of rows containing at least one instance of the given value. Two or three additional values follow the per-element frequencies; these are the minimum and maximum of the preceding per-element frequencies, and optionally the frequency of null elements. (Null when <code>most_common_elems</code> is.)
elem_count_histogram float4[]	A histogram of the counts of distinct non-null element values within the values of the expression, followed by the average number of distinct non-null elements. (Null for scalar types.)

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` run-time parameter.

55.31. pg_stats_vacuum_database

The view `pg_stats_vacuum_database` will contain one row for each database in the current cluster, showing statistics about vacuuming that database.

Table 55.31. pg_stats_vacuum_database Columns

Column	Type	Description
<code>dboid</code>	<code>oid</code>	OID of a database
<code>db_blks_read</code>	<code>int8</code>	Number of database blocks read by vacuum operations performed on this database
<code>db_blks_hit</code>	<code>int8</code>	Number of times database blocks were found in the buffer cache by vacuum operations performed on this database
<code>total_blks_dirtied</code>	<code>int8</code>	Number of database blocks dirtied by vacuum operations performed on this database
<code>total_blks_written</code>	<code>int8</code>	Number of database blocks written by vacuum operations performed on this database
<code>wal_records</code>	<code>int8</code>	Total number of WAL records generated by vacuum operations performed on this database
<code>wal_fpi</code>	<code>int8</code>	Total number of WAL full page images generated by vacuum operations performed on this database
<code>wal_bytes</code>	<code>numeric</code>	Total amount of WAL bytes generated by vacuum operations performed on this database
<code>blk_read_time</code>	<code>float8</code>	Time spent reading database blocks by vacuum operations performed on this database, in milliseconds (if <code>track_io_timing</code> is enabled, otherwise zero)
<code>blk_write_time</code>	<code>float8</code>	Time spent writing database blocks by vacuum operations performed on this database, in milliseconds (if <code>track_io_timing</code> is enabled, otherwise zero)
<code>delay_time</code>	<code>float8</code>	Time spent sleeping in a vacuum delay point by vacuum operations performed on this database, in milliseconds (see Section 19.4.4 for details)
<code>system_time</code>	<code>float8</code>	System CPU time of vacuuming this database, in milliseconds
<code>user_time</code>	<code>float8</code>	User CPU time of vacuuming this database, in milliseconds
<code>total_time</code>	<code>float8</code>	Total time of vacuuming this database, in milliseconds
<code>interrupts</code>	<code>int4</code>	Number of times vacuum operations performed on this database were interrupted on any errors

Note

On upgrading your server just by replacing the executables, update the `pg_stats_vacuum_database` view as superuser who ran `initdb`:

- For each database, including `template1`, but not including `template0`, run:

```
CREATE OR REPLACE VIEW pg_stats_vacuum_database AS
SELECT
    db.oid as dboid,  stats.db_blks_read,
    stats.db_blks_hit,
    stats.total_blks_dirtied,
    stats.total_blks_written,  stats.wal_records,
    stats.wal_fpi,
    stats.wal_bytes,  stats.blk_read_time,
    stats.blk_write_time,  stats.delay_time,
    stats.system_time,
    stats.user_time,
    stats.total_time,  stats.interrupts
FROM
    pg_database db LEFT JOIN pg_stats_vacuum_database(db.oid) stats
ON
    db.oid = stats.dboid;
```

- For the `template0` database, run:

```
\c template1
ALTER DATABASE template0 ALLOW_CONNECTIONS on;
\c template0
CREATE OR REPLACE VIEW pg_stats_vacuum_database AS
SELECT
    db.oid as dboid,  stats.db_blks_read,
    stats.db_blks_hit,
    stats.total_blks_dirtied,
    stats.total_blks_written,  stats.wal_records,
    stats.wal_fpi,
    stats.wal_bytes,  stats.blk_read_time,
    stats.blk_write_time,  stats.delay_time,
    stats.system_time,
    stats.user_time,
    stats.total_time,  stats.interrupts
FROM
    pg_database db LEFT JOIN pg_stats_vacuum_database(db.oid) stats
ON
    db.oid = stats.dboid;
\c template1
ALTER DATABASE template0 ALLOW_CONNECTIONS off;
```

55.32. `pg_stats_vacuum_indexes`

The view `pg_stats_vacuum_indexes` will contain one row for each index in the current database (including TOAST table indexes), showing statistics about vacuuming that specific index.

Table 55.32. `pg_stats_vacuum_indexes` Columns

Column Type	Description
<code>relid oid</code>	OID of an index

Column	Type	Description
schema_name	name	Name of the schema this index is in
relname	name	Name of this index
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this index
total_blks_hit	int8	Number of times database blocks were found in the buffer cache by vacuum operations performed on this index
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this index
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this index
rel_blks_read	int8	Number of blocks vacuum operations read from this index
rel_blks_hit	int8	Number of times blocks of this index were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)
pages_deleted	int8	Number of pages deleted by vacuum operations performed on this index
tuples_deleted	int8	Number of dead tuples vacuum operations deleted from this index
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this index
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this index
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this index
blk_read_time	int8	Time spent reading database blocks by vacuum operations performed on this index, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	int8	Time spent writing database blocks by vacuum operations performed on this index, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this index, in milliseconds (see Section 19.4.4 for details)
system_time	float8	System CPU time of vacuuming this index, in milliseconds
user_time	float8	User CPU time of vacuuming this index, in milliseconds
total_time	float8	Total time of vacuuming this index, in milliseconds
interrupts	integer	Number of times vacuum operations performed on this index were interrupted on any errors

55.33. pg_stats_vacuum_tables

The view `pg_stats_vacuum_tables` will contain one row for each table in the current database (including TOAST tables), showing statistics about vacuuming that specific table.

Table 55.33. pg_stats_vacuum_tables Columns

Column	Type	Description
<code>relid</code>	<code>oid</code>	OID of a table
<code>schema</code>	<code>name</code>	Name of the schema this table is in
<code>relname</code>	<code>name</code>	Name of this table
<code>total_blks_read</code>	<code>int8</code>	Number of database blocks read by vacuum operations performed on this table
<code>total_blks_hit</code>	<code>int8</code>	Number of times database blocks were found in the buffer cache by vacuum operations performed on this table
<code>total_blks_dirtied</code>	<code>int8</code>	Number of database blocks dirtied by vacuum operations performed on this table
<code>total_blks_written</code>	<code>int8</code>	Number of database blocks written by vacuum operations performed on this table
<code>rel_blks_read</code>	<code>int8</code>	Number of blocks vacuum operations read from this table
<code>rel_blks_hit</code>	<code>int8</code>	Number of times blocks of this table were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)
<code>pages_scanned</code>	<code>int8</code>	Number of pages examined by vacuum operations performed on this table
<code>pages_removed</code>	<code>int8</code>	Number of pages removed from the physical storage by vacuum operations performed on this table
<code>pages_frozen</code>	<code>int8</code>	Number of times vacuum operations marked pages of this table as all-frozen in the visibility map
<code>pages_all_visible</code>	<code>int8</code>	Number of times vacuum operations marked pages of this table as all-visible in the visibility map
<code>tuples_deleted</code>	<code>int8</code>	Number of dead tuples vacuum operations deleted from this table
<code>tuples_frozen</code>	<code>int8</code>	Number of tuples of this table that vacuum operations marked as frozen
<code>dead_tuples</code>	<code>int8</code>	Number of dead tuples vacuum operations left in this table due to their visibility in transactions
<code>index_vacuum_count</code>	<code>int8</code>	Number of times indexes on this table were vacuumed
<code>rev_all_frozen_pages</code>	<code>int8</code>	

Column Type	Description
	Number of times the all-frozen mark in the visibility map was removed for pages of this table
rev_all_visible_pages int8	Number of times the all-visible mark in the visibility map was removed for pages of this table
wal_records int8	Total number of WAL records generated by vacuum operations performed on this table
wal_fpi int8	Total number of WAL full page images generated by vacuum operations performed on this table
wal_bytes numeric	Total amount of WAL bytes generated by vacuum operations performed on this table
blk_read_time int8	Time spent reading database blocks by vacuum operations performed on this table, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time int8	Time spent writing database blocks by vacuum operations performed on this table, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this table, in milliseconds (see Section 19.4.4 for details)
system_time float8	System CPU time of vacuuming this table, in milliseconds
user_time float8	User CPU time of vacuuming this table, in milliseconds
total_time float8	Total time of vacuuming this table, in milliseconds
interrupts integer	Number of times vacuum operations performed on this table were interrupted on any errors

Columns `total_*`, `wal_*` and `blk_*` include data on vacuuming indexes on this table, while columns `system_time` and `user_time` only include data on vacuuming the heap.

55.34. pg_tables

The view `pg_tables` provides access to useful information about each table in the database.

Table 55.34. pg_tables Columns

Column Type	Description
schemaname name (references pg_namespace .nspname)	Name of schema containing table
tablename name (references pg_class .relname)	Name of table
tableowner name (references pg_authid .rolname)	Name of table's owner
tablespace name (references pg_tablespace .spcname)	Name of tablespace containing table (null if default for database)
hasindexes bool (references pg_class .relhasindex)	True if table has (or recently had) any indexes
hasrules bool (references pg_class .relhasrules)	

Column Type	Description
	True if table has (or once had) rules
hastriggers bool (references pg_class .relhastriggers)	True if table has (or once had) triggers
rowsecurity bool (references pg_class .relrowsecurity)	True if row security is enabled on the table

55.35. pg_timezone_abbrevs

The view `pg_timezone_abbrevs` provides a list of time zone abbreviations that are currently recognized by the datetime input routines. The contents of this view change when the [timezone_abbreviations](#) run-time parameter is modified.

Table 55.35. pg_timezone_abbrevs Columns

Column Type	Description
abbrev text	Time zone abbreviation
utc_offset interval	Offset from UTC (positive means east of Greenwich)
is_dst bool	True if this is a daylight-savings abbreviation

While most timezone abbreviations represent fixed offsets from UTC, there are some that have historically varied in value (see [Section B.4](#) for more information). In such cases this view presents their current meaning.

55.36. pg_timezone_names

The view `pg_timezone_names` provides a list of time zone names that are recognized by `SET TIMEZONE`, along with their associated abbreviations, UTC offsets, and daylight-savings status. (Technically, Postgres Pro does not use UTC because leap seconds are not handled.) Unlike the abbreviations shown in [pg_timezone_abbrevs](#), many of these names imply a set of daylight-savings transition date rules. Therefore, the associated information changes across local DST boundaries. The displayed information is computed based on the current value of `CURRENT_TIMESTAMP`.

Table 55.36. pg_timezone_names Columns

Column Type	Description
name text	Time zone name
abbrev text	Time zone abbreviation
utc_offset interval	Offset from UTC (positive means east of Greenwich)
is_dst bool	True if currently observing daylight savings

55.37. pg_user

The view `pg_user` provides access to information about database users. This is simply a publicly readable view of [pg_shadow](#) that blanks out the password field.

Table 55.37. pg_user Columns

Column Type	Description
username name	User name
usesysid oid	ID of this user
usecreatedb bool	User can create databases
usesuper bool	User is a superuser
userepl bool	User can initiate streaming replication and put the system in and out of backup mode.
usebypassrls bool	User bypasses every row-level security policy, see Section 5.9 for more information.
passwd text	Not the password (always reads as <code>*****</code>)
valuntil timestampz	Password expiry time (only used for password authentication)
useconfig text[]	Session defaults for run-time configuration variables

55.38. pg_user_mappings

The view `pg_user_mappings` provides access to information about user mappings. This is essentially a publicly readable view of `pg_user_mapping` that leaves out the `options` field if the user has no rights to use it.

Table 55.38. pg_user_mappings Columns

Column Type	Description
umid oid (references <code>pg_user_mapping</code> .oid)	OID of the user mapping
srvid oid (references <code>pg_foreign_server</code> .oid)	The OID of the foreign server that contains this mapping
srvname name (references <code>pg_foreign_server</code> .srvname)	Name of the foreign server
umuser oid (references <code>pg_authid</code> .oid)	OID of the local role being mapped, or zero if the user mapping is public
username name	Name of the local user to be mapped
umoptions text[]	User mapping specific options, as “keyword=value” strings

To protect password information stored as a user mapping option, the `umoptions` column will read as null unless one of the following applies:

- current user is the user being mapped, and owns the server or holds `USAGE` privilege on it
- current user is the server owner and mapping is for `PUBLIC`
- current user is a superuser

55.39. pg_views

The view `pg_views` provides access to useful information about each view in the database.

Table 55.39. pg_views Columns

Column Type	Description
<code>schemaname name</code> (references <code>pg_namespace .nspname</code>)	Name of schema containing view
<code>viewname name</code> (references <code>pg_class .relname</code>)	Name of view
<code>viewowner name</code> (references <code>pg_authid .rolname</code>)	Name of view's owner
<code>definition text</code>	View definition (a reconstructed <code>SELECT</code> query)

55.40. pg_wait_events

The view `pg_wait_events` provides description about the wait events.

Table 55.40. pg_wait_events Columns

Column Type	Description
<code>type text</code>	Wait event type
<code>name text</code>	Wait event name
<code>description text</code>	Wait event description

55.41. Global Views for Distributed System

Postgres Pro Shardman has a list of global views based on the corresponding local views. The definition of global view columns is the same as in its corresponding local view. Fetching from a global view returns a union of rows from the corresponding local views. The rows are fetched from each of their cluster nodes. Another difference is that the global views have an added column `rgid`. The `rgid` value shows the replication group ID of the cluster node from which a row is fetched.

55.41.1. Global Views for Statistics

Below is the list of the statistics-related global views with links to their corresponding local views:

Table 55.41. Statistics-related global and local views

Global view	Local view	Description
<code>shardman.gv_stats</code>	pg_stats	One row per planner statistics.
<code>shardman.gv_stats_ext</code>	pg_stats_ext	Provides access to information about each extended statistics object in the database.
<code>shardman.gv_stats_ext_exprs</code>	pg_stats_ext_exprs	Provides access to information about all expressions included in extended statistics objects.
<code>shardman.gv_stat_activity</code>	pg_stat_activity	One row per server process, showing information related

Global view	Local view	Description
		to the current activity of that process.
shardman.gv_stats_vacuum_database	pg_stats_vacuum_database	One row for each index in the current database (including TOAST table indexes), showing statistics about vacuuming that specific index.
shardman.gv_stats_vacuum_indexes	pg_stats_vacuum_indexes	One row for each database in the current cluster, showing statistics about vacuuming that database.
shardman.gv_stats_vacuum_tables	pg_stats_vacuum_tables	One row for each table in the current database (including TOAST tables), showing statistics about vacuuming that specific table.
shardman.gv_stat_replication	pg_stat_replication	One row per WAL sender process, showing statistics about replication to that sender's connected standby server.
shardman.gv_stat_replication_slots	pg_stat_replication_slots	One row per replication slot, showing statistics about the replication slot's usage.
shardman.gv_pgpro_stat_wal_activity	pgpro_stat_wal_activity	One row per server process, showing information related to the current activity of that process.
shardman.gv_stat_subscription	pg_stat_subscription	One row per subscription for main worker (with null PID if the worker is not running), and additional rows for workers handling the initial data copy of the subscribed tables.
shardman.gv_stat_subscription_stats	pg_stat_subscription_stats	One row per subscription.
shardman.gv_stat_ssl	pg_stat_ssl	One row per backend or WAL sender process, showing statistics about SSL usage on this connection.
shardman.gv_stat_gssapi	pg_stat_gssapi	One row per backend, showing information about GSSAPI usage on this connection.
shardman.gv_stat_archiver	pg_stat_archiver	One row only, showing statistics about the WAL archiver process's activity.
shardman.gv_stat_io	pg_stat_io	One row only for each combination of backend type, target I/O object, and I/O context, showing cluster-wide I/O statistics.

Global view	Local view	Description
shardman.gv_stat_bgwriter	pg_stat_bgwriter	One row only, showing statistics about the background writer process's activity.
shardman.gv_stat_progress_analyze	pg_stat_progress_analyze	One row for each backend (including autovacuum worker processes) running ANALYZE, showing current progress.
shardman.gv_stat_progress_basebackup	pg_stat_progress_basebackup	One row for each WAL sender process streaming a base backup, showing current progress.
shardman.gv_stat_progress_cluster	pg_stat_progress_cluster	One row for each backend running CLUSTER or VACUUM FULL, showing current progress.
shardman.gv_stat_checkpoint	pg_stat_checkpoint	One row only, containing data about the checkpoint process of the cluster.
shardman.gv_statistic_ext	pg_statistic_ext	Extended planner statistics (definition).
shardman.gv_stat_progress_create_index	pg_stat_progress_create_index	One row for each backend running CREATE INDEX or REINDEX, showing current progress.
shardman.gv_stat_progress_vacuum	pg_stat_progress_vacuum	One row for each backend (including autovacuum worker processes) that is currently vacuuming.
shardman.gv_stat_progress_copy	pg_stat_progress_copy	One row for each backend running COPY, showing current progress.
shardman.gv_stat_wal	pg_stat_wal	One row only, showing statistics about WAL activity.
shardman.gv_stat_database	pg_stat_database	One row per database, showing database-wide statistics about query cancels due to conflict with recovery on standby servers.
shardman.gv_stat_database_conflicts	pg_stat_database_conflicts	One row per database, showing database-wide statistics about query cancels occurring due to conflicts with recovery on standby servers. This view will only contain information on standby servers, since conflicts do not occur on primary servers.
shardman.gv_stat_all_tables	pg_stat_all_tables	One row for each table in the current database, showing statistics about accesses to that specific table.
shardman.gv_stat_sys_tables	pg_stat_sys_tables	Same as pg_stat_sys_tables , only as a global view.

Global view	Local view	Description
shardman.gv_stat_user_tables	pg_stat_user_tables	Same as pg_stat_user_tables , only as a global view.
shardman.gv_stat_all_indexes	pg_stat_all_indexes	One row for each index in the current database, showing statistics about accesses to that specific index.
shardman.gv_stat_sys_indexes	pg_stat_sys_indexes	Same as pg_stat_sys_indexes , only as a global view.
shardman.gv_stat_user_indexes	pg_stat_user_indexes	Same as pg_stat_user_indexes , only as a global view.
shardman.gv_statio_all_tables	pg_statio_all_tables	One row for each table in the current database, showing statistics about I/O on that specific table.
shardman.gv_statio_sys_tables	pg_statio_sys_tables	Same as pg_statio_sys_tables , only as a global view.
shardman.gv_statio_user_tables	pg_statio_user_tables	Same as pg_statio_user_tables , only as a global view.
shardman.gv_statio_all_indexes	pg_statio_all_indexes	One row for each index in the current database, showing statistics about I/O on that specific index.
shardman.gv_statio_sys_indexes	pg_statio_sys_indexes	Same as pg_statio_sys_indexes , only as a global view.
shardman.gv_statio_user_indexes	pg_statio_user_indexes	Same as pg_statio_user_indexes , only as a global view.
shardman.gv_statio_all_sequences	pg_statio_all_sequences	One row for each sequence in the current database, showing statistics about I/O on that specific sequence.
shardman.gv_statio_sys_sequences	pg_statio_sys_sequences	Same as pg_statio_sys_sequences , only as a global view.
shardman.gv_statio_user_sequences	pg_statio_user_sequences	Same as pg_statio_user_sequences , only as a global view.
shardman.gv_stat_user_functions	pg_stat_user_functions	One row for each tracked function, showing statistics about executions of that function.
shardman.gv_stat_slru	pg_stat_slru	One row per SLRU, showing statistics of operations.
shardman.gv_stat_csn	shardman.pg_stat_csn	One row showing statistics on delays that take place during import of CSN snapshots.
shardman.gv_stat_monitor	shardman.pg_stat_monitor	One row showing metrics of the Postgres Pro Shardman monitor.
shardman.gv_stat_netusage	shardman.pg_stat_net_usage	One row showing the cumulative network traffic between Postgres Pro Shardman cluster nodes.

Global view	Local view	Description
<code>shardman.gv_stat_xact_time</code>	<code>shardman.pg_stat_xact_time</code>	One row showing statistics for the time spent on a transaction.
<code>shardman.gv_lock_graph</code>	<code>shardman.lock_graph</code>	One row showing a graph of locks between processes on Postgres Pro Shardman cluster nodes including external locks. This view is based on the <code>pg_locks</code> and <code>pg_prepared_xacts</code> system views and on the <code>pg_stat_activity</code> view of the cumulative statistics system .
<code>shardman.gv_stat_foreign_bytes</code>	<code>shardman.pg_stat_foreign_stat_bytes</code>	One row showing the amount of statistics for foreign relations transferred over the network between Postgres Pro Shardman cluster nodes.
<code>shardman.gv_stat_recovery_prefetch</code>	<code>pg_stat_recovery_prefetch</code>	One row, the columns <code>wal_distance</code> , <code>block_distance</code> and <code>io_depth</code> show current values, and the other columns show cumulative counters that can be reset with the <code>pg_stat_reset_shared</code> function.
<code>shardman.gv_stat_wal_receiver</code>	<code>pg_stat_wal_receiver</code>	One row, showing statistics about the WAL receiver from that receiver's connected server.
<code>shardman.gv_stat_xact_all_tables</code>	<code>pg_stat_xact_all_tables</code>	Similar to <code>pg_stat_all_tables</code> , but counts actions taken so far within the current transaction (which are <i>not</i> yet included in <code>pg_stat_all_tables</code> and related views). The columns for numbers of live and dead rows and vacuum and analyze actions are not present in this view.
<code>shardman.gv_stat_xact_sys_tables</code>	<code>pg_stat_xact_sys_tables</code>	Same as <code>pg_stat_xact_sys_tables</code> , only as a global view.
<code>shardman.gv_stat_xact_user_tables</code>	<code>pg_stat_xact_user_tables</code>	Same as <code>pg_stat_xact_user_tables</code> , only as a global view
<code>shardman.gv_stat_xact_user_functions</code>	<code>pg_stat_xact_user_functions</code>	Similar to <code>pg_stat_user_functions</code> , but counts only calls during the current transaction (which are <i>not</i> yet included in <code>pg_stat_user_functions</code>).
<code>shardman.gv_sharded_tables</code>		Displays information on all the sharded tables in the cluster.
<code>shardman.gv_global_tables</code>		Displays information on all the global tables in the cluster.

55.41.2. Global Views for System Catalog and System Views

Below is the list of the global views that relate to the system catalog and system views, and links to their corresponding local views:

Table 55.42. Global and local views for system catalog and system views

Global view	Local view	Description
shardman.gv_aggregate	pg_aggregate	Stores information about aggregate functions
shardman.gv_am	pg_am	Relation access methods
shardman.gv_amop	pg_amop	Access method operators
shardman.gv_amproc	pg_amproc	Access method support functions
shardman.gv_attrdef	pg_attrdef	Column default values
shardman.gv_attribute	pg_attribute	Table columns (“attributes”)
shardman.gv_auth_members	pg_auth_members	Authorization identifier membership relationships
shardman.gv_available_extension_versions	pg_available_extension_versions	Specific extension versions that are available for installation
shardman.gv_available_extensions	pg_available_extensions	Extensions that are available for installation
shardman.gv_cast	pg_cast	Casts (data type conversions)
shardman.gv_class	pg_class	Tables, indexes, sequences, views (“relations”)
shardman.gv_collation	pg_collation	Collations (locale information)
shardman.gv_config	pg_config	Compile-time configuration parameters of the currently installed version of Postgres Pro
shardman.gv_constraint	pg_constraint	Check constraints, unique constraints, primary key constraints, foreign key constraints
shardman.gv_conversion	pg_conversion	Encoding conversion information
shardman.gv_database	pg_database	Databases within this database cluster
shardman.gv_db_role_setting	pg_db_role_setting	Per-role and per-database settings
shardman.gv_default_acl	pg_default_acl	Default privileges for object types
shardman.gv_depend	pg_depend	Dependencies between database objects
shardman.gv_description	pg_description	Descriptions or comments on database objects
shardman.gv_enum	pg_enum	Enum label and value definitions
shardman.gv_event_trigger	pg_event_trigger	Event triggers
shardman.gv_extension	pg_extension	Installed extensions
shardman.gv_file_settings	pg_file_settings	Installed extensions
shardman.gv_foreign_data_wrapper	pg_foreign_data_wrapper	Foreign-data wrapper definitions

Global view	Local view	Description
shardman.gv_foreign_server	pg_foreign_server	Foreign server definitions
shardman.gv_foreign_table	pg_foreign_table	Additional foreign table information
shardman.gv_group	pg_group	Exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1
shardman.gv_hba_file_rules	pg_hba_file_rules	Summary of the contents of the client authentication configuration file <code>pg_hba.conf</code>
shardman.gv_ident_file_mappings	pg_ident_file_mappings	Summary of the contents of the client user name mapping configuration file <code>pg_hba.conf</code>
shardman.gv_index	pg_index	Additional index information
shardman.gv_indexes	pg_indexes	Provides access to useful information about each index in the database
shardman.gv_inherits	pg_inherits	Table inheritance hierarchy
shardman.gv_init_privs	pg_init_privs	Object initial privileges
shardman.gv_language	pg_language	Languages for writing functions
shardman.gv_largeobject	pg_largeobject	Data pages for large objects
shardman.gv_largeobject_metadata	pg_largeobject_metadata	Metadata associated with large objects
shardman.gv_matviews	pg_matviews	Provides access to useful information about each materialized view in the database
shardman.gv_namespace	pg_namespace	Schemas
shardman.gv_opclass	pg_opclass	Access method operator classes
shardman.gv_operator	pg_operator	Operators
shardman.gv_opfamily	pg_opfamily	Access method operator families
shardman.gv_parameter_acl	pg_parameter_acl	Configuration parameters for which privileges have been granted
shardman.gv_partitioned_table	pg_partitioned_table	Information about partition key of tables
shardman.gv_proc	pg_proc	Functions and procedures
shardman.gv_profile	pg_profile	Profiles, a set of authentication restrictions
shardman.gv_publication	pg_publication	Publications for logical replication
shardman.gv_publication_namespace	pg_publication_namespace	Schema to publication mapping
shardman.gv_publication_rel	pg_publication_rel	Relation to publication mapping

Global view	Local view	Description
shardman.gv_publication_tables	pg_publication_tables	Information about the mapping between publications and information of tables they contain
shardman.gv_range	pg_range	Information about range types
shardman.gv_replication_origin	pg_replication_origin	Registered replication origins
shardman.gv_replication_origin_status	pg_replication_origin_status	Information about how far replay for a certain origin has progressed
shardman.gv_replication_slots	pg_replication_slots	Provides a listing of all replication slots that currently exist on the database cluster, along with their current state
shardman.gv_rewrite	pg_rewrite	Query rewrite rules
shardman.gv_rules	pg_rules	Provides access to useful information about query rewrite rules
shardman.gv_seclabel	pg_seclabel	Security labels on database objects
shardman.gv_seclabels	pg_seclabels	Provides information about security labels
shardman.gv_sequence	pg_sequence	Information about sequences
shardman.gv_sequences	pg_sequences	Provides access to useful information about each sequence in the database
shardman.gv_settings	pg_settings	Provides access to run-time parameters of the server
shardman.gv_shdepend	pg_shdepend	Dependencies on shared objects
shardman.gv_shdescription	pg_shdescription	Comments on shared objects
shardman.gv_shseclabel	pg_shseclabel	Security labels on shared database objects
shardman.gv_subscription	pg_subscription	Logical replication subscriptions
shardman.gv_subscription_rel	pg_subscription_rel	Relation state for subscriptions
shardman.gv_tablespace	pg_tablespace	Tablespaces within this database cluster
shardman.gv_tables	pg_tables	Provides access to useful information about each table in the database
shardman.gv_prepared_xacts	pg_prepared_xacts	Provides information about transactions that are currently prepared for two-phase commit
shardman.gv_timezone_names	pg_timezone_names	List of time zone names that are recognized by <code>SET TIMEZONE</code> , along with their associated abbreviations, UTC offsets, and daylight-savings status

Global view	Local view	Description
shardman.gv_timezone_abbrevs	pg_timezone_abbrevs	List of time zone abbreviations that are currently recognized by the datetime input routines
shardman.gv_transform	pg_transform	Transforms (data type to procedural language conversions)
shardman.gv_trigger	pg_trigger	Triggers
shardman.gv_ts_config	pg_ts_config	Text search configurations
shardman.gv_ts_config_map	pg_ts_config_map	Text search configurations' token mappings
shardman.gv_ts_dict	pg_ts_dict	Text search dictionaries
shardman.gv_ts_parser	pg_ts_parser	Text search parsers
shardman.gv_ts_template	pg_ts_template	Text search templates
shardman.gv_type	pg_type	Data types
shardman.gv_user_mapping	pg_user_mapping	Mappings of users to foreign servers
shardman.gv_user_mappings	pg_user_mappings	Provides access to information about user mappings
shardman.gv_views	pg_views	Provides access to useful information about each view in the database
shardman.gv_wait_events	pg_wait_events	Provides description about the wait events
shardman.gv_locks	pg_locks	Provides access to information about the locks held by active processes within the database server.
shardman.gv_shmem_allocations	pg_shmem_allocations	Shows allocations made from the server's main shared memory segment.

Chapter 56. Frontend/Backend Protocol

Postgres Pro uses a message-based protocol for communication between frontends and backends (clients and servers). The protocol is supported over TCP/IP and also over Unix-domain sockets. Port number 5432 has been registered with IANA as the customary TCP port number for servers supporting this protocol, but in practice any non-privileged port number can be used.

This document describes version 3.0 of the protocol, implemented in PostgreSQL 7.4 and later. For descriptions of the earlier protocol versions, see previous releases of the PostgreSQL documentation. A single server can support multiple protocol versions. The initial startup-request message tells the server which protocol version the client is attempting to use. If the major version requested by the client is not supported by the server, the connection will be rejected (for example, this would occur if the client requested protocol version 4.0, which does not exist as of this writing). If the minor version requested by the client is not supported by the server (e.g., the client requests version 3.1, but the server supports only 3.0), the server may either reject the connection or may respond with a `NegotiateProtocolVersion` message containing the highest minor protocol version which it supports. The client may then choose either to continue with the connection using the specified protocol version or to abort the connection.

In order to serve multiple clients efficiently, the server launches a new “backend” process for each client. In the current implementation, a new child process is created immediately after an incoming connection is detected. This is transparent to the protocol, however. For purposes of the protocol, the terms “backend” and “server” are interchangeable; likewise “frontend” and “client” are interchangeable.

56.1. Overview

The protocol has separate phases for startup and normal operation. In the startup phase, the frontend opens a connection to the server and authenticates itself to the satisfaction of the server. (This might involve a single message, or multiple messages depending on the authentication method being used.) If all goes well, the server then sends status information to the frontend, and finally enters normal operation. Except for the initial startup-request message, this part of the protocol is driven by the server.

During normal operation, the frontend sends queries and other commands to the backend, and the backend sends back query results and other responses. There are a few cases (such as `NOTIFY`) wherein the backend will send unsolicited messages, but for the most part this portion of a session is driven by frontend requests.

Termination of the session is normally by frontend choice, but can be forced by the backend in certain cases. In any case, when the backend closes the connection, it will roll back any open (incomplete) transaction before exiting.

Within normal operation, SQL commands can be executed through either of two sub-protocols. In the “simple query” protocol, the frontend just sends a textual query string, which is parsed and immediately executed by the backend. In the “extended query” protocol, processing of queries is separated into multiple steps: parsing, binding of parameter values, and execution. This offers flexibility and performance benefits, at the cost of extra complexity.

Normal operation has additional sub-protocols for special operations such as `COPY`.

56.1.1. Messaging Overview

All communication is through a stream of messages. The first byte of a message identifies the message type, and the next four bytes specify the length of the rest of the message (this length count includes itself, but not the message-type byte). The remaining contents of the message are determined by the message type. For historical reasons, the very first message sent by the client (the startup message) has no initial message-type byte.

To avoid losing synchronization with the message stream, both servers and clients typically read an entire message into a buffer (using the byte count) before attempting to process its contents. This allows easy recovery if an error is detected while processing the contents. In extreme situations (such as not

having enough memory to buffer the message), the receiver can use the byte count to determine how much input to skip before it resumes reading messages.

Conversely, both servers and clients must take care never to send an incomplete message. This is commonly done by marshaling the entire message in a buffer before beginning to send it. If a communications failure occurs partway through sending or receiving a message, the only sensible response is to abandon the connection, since there is little hope of recovering message-boundary synchronization.

56.1.2. Extended Query Overview

In the extended-query protocol, execution of SQL commands is divided into multiple steps. The state retained between steps is represented by two types of objects: *prepared statements* and *portals*. A prepared statement represents the result of parsing and semantic analysis of a textual query string. A prepared statement is not in itself ready to execute, because it might lack specific values for *parameters*. A portal represents a ready-to-execute or already-partially-executed statement, with any missing parameter values filled in. (For `SELECT` statements, a portal is equivalent to an open cursor, but we choose to use a different term since cursors don't handle non-`SELECT` statements.)

The overall execution cycle consists of a *parse* step, which creates a prepared statement from a textual query string; a *bind* step, which creates a portal given a prepared statement and values for any needed parameters; and an *execute* step that runs a portal's query. In the case of a query that returns rows (`SELECT`, `SHOW`, etc.), the execute step can be told to fetch only a limited number of rows, so that multiple execute steps might be needed to complete the operation.

The backend can keep track of multiple prepared statements and portals (but note that these exist only within a session, and are never shared across sessions). Existing prepared statements and portals are referenced by names assigned when they were created. In addition, an “unnamed” prepared statement and portal exist. Although these behave largely the same as named objects, operations on them are optimized for the case of executing a query only once and then discarding it, whereas operations on named objects are optimized on the expectation of multiple uses.

56.1.3. Formats and Format Codes

Data of a particular data type might be transmitted in any of several different *formats*. As of PostgreSQL 7.4 the only supported formats are “text” and “binary”, but the protocol makes provision for future extensions. The desired format for any value is specified by a *format code*. Clients can specify a format code for each transmitted parameter value and for each column of a query result. Text has format code zero, binary has format code one, and all other format codes are reserved for future definition.

The text representation of values is whatever strings are produced and accepted by the input/output conversion functions for the particular data type. In the transmitted representation, there is no trailing null character; the frontend must add one to received values if it wants to process them as C strings. (The text format does not allow embedded nulls, by the way.)

Binary representations for integers use network byte order (most significant byte first). For other data types consult the documentation to learn about the binary representation. Keep in mind that binary representations for complex data types might change across server versions; the text format is usually the more portable choice.

56.2. Message Flow

This section describes the message flow and the semantics of each message type. (Details of the exact representation of each message appear in [Section 56.7.](#)) There are several different sub-protocols depending on the state of the connection: start-up, query, function call, `COPY`, and termination. There are also special provisions for asynchronous operations (including notification responses and command cancellation), which can occur at any time after the start-up phase.

56.2.1. Start-up

To begin a session, a frontend opens a connection to the server and sends a startup message. This message includes the names of the user and of the database the user wants to connect to; it also identifies the

particular protocol version to be used. (Optionally, the startup message can include additional settings for run-time parameters.) The server then uses this information and the contents of its configuration files (such as `pg_hba.conf`) to determine whether the connection is provisionally acceptable, and what additional authentication is required (if any).

The server then sends an appropriate authentication request message, to which the frontend must reply with an appropriate authentication response message (such as a password). For all authentication methods except GSSAPI, SSPI and SASL, there is at most one request and one response. In some methods, no response at all is needed from the frontend, and so no authentication request occurs. For GSSAPI, SSPI and SASL, multiple exchanges of packets may be needed to complete the authentication.

The authentication cycle ends with the server either rejecting the connection attempt (`ErrorResponse`), or sending `AuthenticationOk`.

The possible messages from the server in this phase are:

`ErrorResponse`

The connection attempt has been rejected. The server then immediately closes the connection.

`AuthenticationOk`

The authentication exchange is successfully completed.

`AuthenticationKerberosV5`

The frontend must now take part in a Kerberos V5 authentication dialog (not described here, part of the Kerberos specification) with the server. If this is successful, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`. This is no longer supported.

`AuthenticationCleartextPassword`

The frontend must now send a `PasswordMessage` containing the password in clear-text form. If this is the correct password, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`.

`AuthenticationMD5Password`

The frontend must now send a `PasswordMessage` containing the password (with user name) encrypted via MD5, then encrypted again using the 4-byte random salt specified in the `AuthenticationMD5Password` message. If this is the correct password, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`. The actual `PasswordMessage` can be computed in SQL as `concat('md5', md5(concat(md5(concat(password, username)), random-salt)))`. (Keep in mind the `md5()` function returns its result as a hex string.)

`AuthenticationGSS`

The frontend must now initiate a GSSAPI negotiation. The frontend will send a `GSSResponse` message with the first part of the GSSAPI data stream in response to this. If further messages are needed, the server will respond with `AuthenticationGSSContinue`.

`AuthenticationSSPI`

The frontend must now initiate an SSPI negotiation. The frontend will send a `GSSResponse` with the first part of the SSPI data stream in response to this. If further messages are needed, the server will respond with `AuthenticationGSSContinue`.

`AuthenticationGSSContinue`

This message contains the response data from the previous step of GSSAPI or SSPI negotiation (`AuthenticationGSS`, `AuthenticationSSPI` or a previous `AuthenticationGSSContinue`). If the GSSAPI or SSPI data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another `GSSResponse` message. If GSSAPI or SSPI authentication is completed by this message, the server will next send `AuthenticationOk` to indicate successful authentication or `ErrorResponse` to indicate failure.

AuthenticationSASL

The frontend must now initiate a SASL negotiation, using one of the SASL mechanisms listed in the message. The frontend will send a `SASLInitialResponse` with the name of the selected mechanism, and the first part of the SASL data stream in response to this. If further messages are needed, the server will respond with `AuthenticationSASLContinue`. See [Section 56.3](#) for details.

AuthenticationSASLContinue

This message contains challenge data from the previous step of SASL negotiation (`AuthenticationSASL`, or a previous `AuthenticationSASLContinue`). The frontend must respond with a `SASLResponse` message.

AuthenticationSASLFinal

SASL authentication has completed with additional mechanism-specific data for the client. The server will next send `AuthenticationOk` to indicate successful authentication, or an `ErrorResponse` to indicate failure. This message is sent only if the SASL mechanism specifies additional data to be sent from server to client at completion.

NegotiateProtocolVersion

The server does not support the minor protocol version requested by the client, but does support an earlier version of the protocol; this message indicates the highest supported minor version. This message will also be sent if the client requested unsupported protocol options (i.e., beginning with `_pq_`) in the startup packet. This message will be followed by an `ErrorResponse` or a message indicating the success or failure of authentication.

If the frontend does not support the authentication method requested by the server, then it should immediately close the connection.

After having received `AuthenticationOk`, the frontend must wait for further messages from the server. In this phase a backend process is being started, and the frontend is just an interested bystander. It is still possible for the startup attempt to fail (`ErrorResponse`) or the server to decline support for the requested minor protocol version (`NegotiateProtocolVersion`), but in the normal case the backend will send some `ParameterStatus` messages, `BackendKeyData`, and finally `ReadyForQuery`.

During this phase the backend will attempt to apply any additional run-time parameter settings that were given in the startup message. If successful, these values become session defaults. An error causes `ErrorResponse` and exit.

The possible messages from the backend in this phase are:

BackendKeyData

This message provides secret-key data that the frontend must save if it wants to be able to issue cancel requests later. The frontend should not respond to this message, but should continue listening for a `ReadyForQuery` message.

ParameterStatus

This message informs the frontend about the current (initial) setting of backend parameters, such as [client encoding](#) or [DateStyle](#). The frontend can ignore this message, or record the settings for its future use; see [Section 56.2.7](#) for more details. The frontend should not respond to this message, but should continue listening for a `ReadyForQuery` message.

ReadyForQuery

Start-up is completed. The frontend can now issue commands.

ErrorResponse

Start-up failed. The connection is closed after sending this message.

NoticeResponse

A warning message has been issued. The frontend should display the message but continue listening for ReadyForQuery or ErrorResponse.

The ReadyForQuery message is the same one that the backend will issue after each command cycle. Depending on the coding needs of the frontend, it is reasonable to consider ReadyForQuery as starting a command cycle, or to consider ReadyForQuery as ending the start-up phase and each subsequent command cycle.

56.2.2. Simple Query

A simple query cycle is initiated by the frontend sending a Query message to the backend. The message includes an SQL command (or commands) expressed as a text string. The backend then sends one or more response messages depending on the contents of the query command string, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new command. (It is not actually necessary for the frontend to wait for ReadyForQuery before issuing another command, but the frontend must then take responsibility for figuring out what happens if the earlier command fails and already-issued later commands succeed.)

The possible response messages from the backend are:

CommandComplete

An SQL command completed normally.

CopyInResponse

The backend is ready to copy data from the frontend to a table; see [Section 56.2.6](#).

CopyOutResponse

The backend is ready to copy data from a table to the frontend; see [Section 56.2.6](#).

RowDescription

Indicates that rows are about to be returned in response to a `SELECT`, `FETCH`, etc. query. The contents of this message describe the column layout of the rows. This will be followed by a DataRow message for each row being returned to the frontend.

DataRow

One of the set of rows returned by a `SELECT`, `FETCH`, etc. query.

EmptyQueryResponse

An empty query string was recognized.

ErrorResponse

An error has occurred.

ReadyForQuery

Processing of the query string is complete. A separate message is sent to indicate this because the query string might contain multiple SQL commands. (CommandComplete marks the end of processing one SQL command, not the whole string.) ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

NoticeResponse

A warning message has been issued in relation to the query. Notices are in addition to other responses, i.e., the backend will continue processing the command.

The response to a `SELECT` query (or other queries that return row sets, such as `EXPLAIN` or `SHOW`) normally consists of RowDescription, zero or more DataRow messages, and then CommandComplete. `COPY` to or

from the frontend invokes special protocol as described in [Section 56.2.6](#). All other query types normally produce only a `CommandComplete` message.

Since a query string could contain several queries (separated by semicolons), there might be several such response sequences before the backend finishes processing the query string. `ReadyForQuery` is issued when the entire string has been processed and the backend is ready to accept a new query string.

If a completely empty (no contents other than whitespace) query string is received, the response is `EmptyQueryResponse` followed by `ReadyForQuery`.

In the event of an error, `ErrorResponse` is issued followed by `ReadyForQuery`. All further processing of the query string is aborted by `ErrorResponse` (even if more queries remained in it). Note that this might occur partway through the sequence of messages generated by an individual query.

In simple Query mode, the format of retrieved values is always text, except when the given command is a `FETCH` from a cursor declared with the `BINARY` option. In that case, the retrieved values are in binary format. The format codes given in the `RowDescription` message tell which format is being used.

A frontend must be prepared to accept `ErrorResponse` and `NoticeResponse` messages whenever it is expecting any other type of message. See also [Section 56.2.7](#) concerning messages that the backend might generate due to outside events.

Recommended practice is to code frontends in a state-machine style that will accept any message type at any time that it could make sense, rather than wiring in assumptions about the exact sequence of messages.

56.2.2.1. Multiple Statements in a Simple Query

When a simple Query message contains more than one SQL statement (separated by semicolons), those statements are executed as a single transaction, unless explicit transaction control commands are included to force a different behavior. For example, if the message contains

```
INSERT INTO mytable VALUES(1);
SELECT 1/0;
INSERT INTO mytable VALUES(2);
```

then the divide-by-zero failure in the `SELECT` will force rollback of the first `INSERT`. Furthermore, because execution of the message is abandoned at the first error, the second `INSERT` is never attempted at all.

If instead the message contains

```
BEGIN;
INSERT INTO mytable VALUES(1);
COMMIT;
INSERT INTO mytable VALUES(2);
SELECT 1/0;
```

then the first `INSERT` is committed by the explicit `COMMIT` command. The second `INSERT` and the `SELECT` are still treated as a single transaction, so that the divide-by-zero failure will roll back the second `INSERT`, but not the first one.

This behavior is implemented by running the statements in a multi-statement Query message in an *implicit transaction block* unless there is some explicit transaction block for them to run in. The main difference between an implicit transaction block and a regular one is that an implicit block is closed automatically at the end of the Query message, either by an implicit commit if there was no error, or an implicit rollback if there was an error. This is similar to the implicit commit or rollback that happens for a statement executed by itself (when not in a transaction block).

If the session is already in a transaction block, as a result of a `BEGIN` in some previous message, then the Query message simply continues that transaction block, whether the message contains one statement or several. However, if the Query message contains a `COMMIT` or `ROLLBACK` closing the existing transaction

block, then any following statements are executed in an implicit transaction block. Conversely, if a `BEGIN` appears in a multi-statement Query message, then it starts a regular transaction block that will only be terminated by an explicit `COMMIT` or `ROLLBACK`, whether that appears in this Query message or a later one. If the `BEGIN` follows some statements that were executed as an implicit transaction block, those statements are not immediately committed; in effect, they are retroactively included into the new regular transaction block.

A `COMMIT` or `ROLLBACK` appearing in an implicit transaction block is executed as normal, closing the implicit block; however, a warning will be issued since a `COMMIT` or `ROLLBACK` without a previous `BEGIN` might represent a mistake. If more statements follow, a new implicit transaction block will be started for them.

Savepoints are not allowed in an implicit transaction block, since they would conflict with the behavior of automatically closing the block upon any error.

Remember that, regardless of any transaction control commands that may be present, execution of the Query message stops at the first error. Thus for example given

```
BEGIN;  
SELECT 1/0;  
ROLLBACK;
```

in a single Query message, the session will be left inside a failed regular transaction block, since the `ROLLBACK` is not reached after the divide-by-zero error. Another `ROLLBACK` will be needed to restore the session to a usable state.

Another behavior of note is that initial lexical and syntactic analysis is done on the entire query string before any of it is executed. Thus simple errors (such as a misspelled keyword) in later statements can prevent execution of any of the statements. This is normally invisible to users since the statements would all roll back anyway when done as an implicit transaction block. However, it can be visible when attempting to do multiple transactions within a multi-statement Query. For instance, if a typo turned our previous example into

```
BEGIN;  
INSERT INTO mytable VALUES(1);  
COMMIT;  
INSERT INTO mytable VALUES(2);  
SELC 1/0;
```

then none of the statements would get run, resulting in the visible difference that the first `INSERT` is not committed. Errors detected at semantic analysis or later, such as a misspelled table or column name, do not have this effect.

56.2.3. Extended Query

The extended query protocol breaks down the above-described simple query protocol into multiple steps. The results of preparatory steps can be re-used multiple times for improved efficiency. Furthermore, additional features are available, such as the possibility of supplying data values as separate parameters instead of having to insert them directly into a query string.

In the extended protocol, the frontend first sends a Parse message, which contains a textual query string, optionally some information about data types of parameter placeholders, and the name of a destination prepared-statement object (an empty string selects the unnamed prepared statement). The response is either ParseComplete or ErrorResponse. Parameter data types can be specified by OID; if not given, the parser attempts to infer the data types in the same way as it would do for untyped literal string constants.

Note

A parameter data type can be left unspecified by setting it to zero, or by making the array of parameter type OIDs shorter than the number of parameter symbols ($\$n$) used in the query string.

Another special case is that a parameter's type can be specified as `void` (that is, the OID of the `void` pseudo-type). This is meant to allow parameter symbols to be used for function parameters that are actually OUT parameters. Ordinarily there is no context in which a `void` parameter could be used, but if such a parameter symbol appears in a function's parameter list, it is effectively ignored. For example, a function call such as `foo($1,$2,$3,$4)` could match a function with two IN and two OUT arguments, if `$3` and `$4` are specified as having type `void`.

Note

The query string contained in a Parse message cannot include more than one SQL statement; else a syntax error is reported. This restriction does not exist in the simple-query protocol, but it does exist in the extended protocol, because allowing prepared statements or portals to contain multiple commands would complicate the protocol unduly.

If successfully created, a named prepared-statement object lasts till the end of the current session, unless explicitly destroyed. An unnamed prepared statement lasts only until the next Parse statement specifying the unnamed statement as destination is issued. (Note that a simple Query message also destroys the unnamed statement.) Named prepared statements must be explicitly closed before they can be redefined by another Parse message, but this is not required for the unnamed statement. Named prepared statements can also be created and accessed at the SQL command level, using `PREPARE` and `EXECUTE`.

Once a prepared statement exists, it can be readied for execution using a Bind message. The Bind message gives the name of the source prepared statement (empty string denotes the unnamed prepared statement), the name of the destination portal (empty string denotes the unnamed portal), and the values to use for any parameter placeholders present in the prepared statement. The supplied parameter set must match those needed by the prepared statement. (If you declared any `void` parameters in the Parse message, pass NULL values for them in the Bind message.) Bind also specifies the format to use for any data returned by the query; the format can be specified overall, or per-column. The response is either `BindComplete` or `ErrorResponse`.

Note

The choice between text and binary output is determined by the format codes given in Bind, regardless of the SQL command involved. The `BINARY` attribute in cursor declarations is irrelevant when using extended query protocol.

Query planning typically occurs when the Bind message is processed. If the prepared statement has no parameters, or is executed repeatedly, the server might save the created plan and re-use it during subsequent Bind messages for the same prepared statement. However, it will do so only if it finds that a generic plan can be created that is not much less efficient than a plan that depends on the specific parameter values supplied. This happens transparently so far as the protocol is concerned.

If successfully created, a named portal object lasts till the end of the current transaction, unless explicitly destroyed. An unnamed portal is destroyed at the end of the transaction, or as soon as the next Bind statement specifying the unnamed portal as destination is issued. (Note that a simple Query message also destroys the unnamed portal.) Named portals must be explicitly closed before they can be redefined by another Bind message, but this is not required for the unnamed portal. Named portals can also be created and accessed at the SQL command level, using `DECLARE CURSOR` and `FETCH`.

Once a portal exists, it can be executed using an Execute message. The Execute message specifies the portal name (empty string denotes the unnamed portal) and a maximum result-row count (zero meaning "fetch all rows"). The result-row count is only meaningful for portals containing commands that return row sets; in other cases the command is always executed to completion, and the row count is ignored.

The possible responses to `Execute` are the same as those described above for queries issued via simple query protocol, except that `Execute` doesn't cause `ReadyForQuery` or `RowDescription` to be issued.

If `Execute` terminates before completing the execution of a portal (due to reaching a nonzero result-row count), it will send a `PortalSuspended` message; the appearance of this message tells the frontend that another `Execute` should be issued against the same portal to complete the operation. The `CommandComplete` message indicating completion of the source SQL command is not sent until the portal's execution is completed. Therefore, an `Execute` phase is always terminated by the appearance of exactly one of these messages: `CommandComplete`, `EmptyQueryResponse` (if the portal was created from an empty query string), `ErrorResponse`, or `PortalSuspended`.

At completion of each series of extended-query messages, the frontend should issue a `Sync` message. This parameterless message causes the backend to close the current transaction if it's not inside a `BEGIN/COMMIT` transaction block ("close" meaning to commit if no error, or roll back if error). Then a `ReadyForQuery` response is issued. The purpose of `Sync` is to provide a resynchronization point for error recovery. When an error is detected while processing any extended-query message, the backend issues `ErrorResponse`, then reads and discards messages until a `Sync` is reached, then issues `ReadyForQuery` and returns to normal message processing. (But note that no skipping occurs if an error is detected *while* processing `Sync` — this ensures that there is one and only one `ReadyForQuery` sent for each `Sync`.)

Note

`Sync` does not cause a transaction block opened with `BEGIN` to be closed. It is possible to detect this situation since the `ReadyForQuery` message includes transaction status information.

In addition to these fundamental, required operations, there are several optional operations that can be used with extended-query protocol.

The `Describe` message (portal variant) specifies the name of an existing portal (or an empty string for the unnamed portal). The response is a `RowDescription` message describing the rows that will be returned by executing the portal; or a `NoData` message if the portal does not contain a query that will return rows; or `ErrorResponse` if there is no such portal.

The `Describe` message (statement variant) specifies the name of an existing prepared statement (or an empty string for the unnamed prepared statement). The response is a `ParameterDescription` message describing the parameters needed by the statement, followed by a `RowDescription` message describing the rows that will be returned when the statement is eventually executed (or a `NoData` message if the statement will not return rows). `ErrorResponse` is issued if there is no such prepared statement. Note that since `Bind` has not yet been issued, the formats to be used for returned columns are not yet known to the backend; the format code fields in the `RowDescription` message will be zeroes in this case.

Tip

In most scenarios the frontend should issue one or the other variant of `Describe` before issuing `Execute`, to ensure that it knows how to interpret the results it will get back.

The `Close` message closes an existing prepared statement or portal and releases resources. It is not an error to issue `Close` against a nonexistent statement or portal name. The response is normally `CloseComplete`, but could be `ErrorResponse` if some difficulty is encountered while releasing resources. Note that closing a prepared statement implicitly closes any open portals that were constructed from that statement.

The `Flush` message does not cause any specific output to be generated, but forces the backend to deliver any data pending in its output buffers. A `Flush` must be sent after any extended-query command except `Sync`, if the frontend wishes to examine the results of that command before issuing more commands.

Without Flush, messages returned by the backend will be combined into the minimum possible number of packets to minimize network overhead.

Note
