First observations of $\overline{B}^0_s \to D^+D^-,$ $D_s^+ D^- \;\rm{and}\; D^0 {\bar D^0}^{\check{}}$ decays

The LHCb collaboration^{[†](#page-0-0)}

Abstract

First observations and measurements of the branching fractions of the $\overline{B}^0_s \to D^+D^-,$ $\bar{B}_s^0 \to D_s^+ D^-$ and $\bar{B}_s^0 \to D^0 \bar{D}^0$ decays are presented using 1.0 fb⁻¹ of data collected by the LHCb experiment. These branching fractions are normalized to those of $\overline{B}^0 \to D^+D^-$, $B^0 \to D_s^+D^-$ and $B^- \to D^0D_s^-$, respectively. An excess of events consistent with the decay $\bar{B}^0 \to D^0 \bar{D}^0$ is also seen, and its branching fraction is measured relative to that of $B^- \to D^0 D_s^-$. Improved measurements of the branching fractions $\mathcal{B}(\overline{B}_s^0 \to D_s^+ D_s^-)$ and $\mathcal{B}(B^- \to D^0 D_s^-)$ are reported, each relative to $\mathcal{B}(B^0 \to D_s^+ D^-)$. The ratios of branching fractions are

$$
\frac{\mathcal{B}(\overline{B}_{s}^{0} \to D^{+}D^{-})}{\mathcal{B}(\overline{B}^{0} \to D^{+}D^{-})} = 1.08 \pm 0.20 \pm 0.10,
$$
\n
$$
\frac{\mathcal{B}(\overline{B}_{s}^{0} \to D_{s}^{+}D^{-})}{\mathcal{B}(B^{0} \to D_{s}^{+}D^{-})} = 0.050 \pm 0.008 \pm 0.004,
$$
\n
$$
\frac{\mathcal{B}(\overline{B}_{s}^{0} \to D^{0}\overline{D}^{0})}{\mathcal{B}(B^{-} \to D^{0}D_{s}^{-})} = 0.019 \pm 0.003 \pm 0.003,
$$
\n
$$
\frac{\mathcal{B}(\overline{B}^{0} \to D^{0}\overline{D}^{0})}{\mathcal{B}(B^{-} \to D^{0}D_{s}^{-})} = 0.0014 \pm 0.0006 \pm 0.0002,
$$
\n
$$
\frac{\mathcal{B}(\overline{B}_{s}^{0} \to D_{s}^{+}D_{s}^{-})}{\mathcal{B}(B^{0} \to D_{s}^{+}D^{-})} = 0.56 \pm 0.03 \pm 0.04,
$$
\n
$$
\frac{\mathcal{B}(B^{-} \to D^{0}D_{s}^{-})}{\mathcal{B}(B^{0} \to D_{s}^{+}D^{-})} = 1.22 \pm 0.02 \pm 0.07,
$$

where the uncertainties are statistical and systematic, respectively.

¹ 1 Introduction

² Double-charm decays of B mesons can be used to probe the Cabibbo-Kobayashi-Maskawa ³ matrix [\[1,](#page-19-0) [2\]](#page-19-1) elements, and provide a laboratory to study final state interactions. The ⁴ time-dependent CP asymmetry in the $B^0 \to D^+D^-$ decay provides a way to measure the $5\quad B^0$ mixing phase [\[3,](#page-19-2) [4\]](#page-19-3), where information from other double-charm final states can be ⁶ used to account for loop (penguin) contributions and other non-factorizable effects [\[5–](#page-19-4)[9\]](#page-19-5). ⁷ Double-charm decays of B mesons can also be used to measure the weak phase γ , assuming ⁸ U-spin symmetry [\[10,](#page-19-6) [11\]](#page-19-7). The purely \mathbb{CP} -even $\overline{B}^0_s \to D_s^+ D_s^-$ decay is also of interest, as it can be used to measure the B_s^0 mixing phase. Moreover, a lifetime measurement 9 ¹⁰ using the $\bar{B}_s^0 \to D_s^+ D_s^-$ decay provides complementary information on $\Delta\Gamma_s$ [\[11](#page-19-7)[–13\]](#page-19-8) to [1](#page-6-0)3 The study of $B \to D\overline{D}'$ decays¹ can also provide a better theoretical understanding ¹⁶ and $\bar{B}^0 \to D^0 \bar{D}^0$ decays are mediated by the W-exchange amplitude, along with penguin-

¹¹ that obtained from direct measurements [\[14\]](#page-20-0), or from lifetime measurements in other CP $_{12}$ eigenstates [\[15,](#page-20-1) [16\]](#page-20-2).

 14 of the processes that contribute to B meson decay. Feynman diagrams contributing to ¹⁵ the decays considered in this paper are shown in Fig. [1.](#page-7-0) The $\overline{B}^0_s \to D^0 \overline{D}^0$, $\overline{B}^0_s \to D^+ D^ 17$ annihilation contributions and rescattering [\[17\]](#page-20-3). The only other observed B meson decays ¹⁸ of this type are $\overline{B}^0 \to D_s^{(*)+} K^{(*)-}$ and $\overline{B}_s^0 \to \pi^+ \pi^-$, with branching fractions of the order ¹⁹ of 10⁻⁵ [\[18\]](#page-20-4) and 10⁻⁶ [\[19\]](#page-20-5), respectively. Predictions of the $\overline{B}^0_s \to D^+D^-$ branching fraction ²⁰ using perturbative approaches yield 3.6×10^{-3} [\[20\]](#page-20-6), while the use of non-perturbative ₂₁ approaches has led to a smaller value of 1×10^{-3} [\[21\]](#page-20-7). More recent phenomenological ²² studies, which assume a dominant contribution from rescattering, predict a significantly a lower branching fraction of $\mathcal{B}(\overline{B}{}^0_s \to D^+D^-) = \mathcal{B}(\overline{B}{}^0_s \to D^0\overline{D}{}^0) = (7.8 \pm 4.7) \times 10^{-5}$ [\[17\]](#page-20-3). ²⁴ This paper reports the first observations of the $\overline{B}^0_s \to D^+D^-$, $\overline{B}^0_s \to D_s^+D^-$ and ²⁵ $\bar{B}_s^0 \to D^0 \bar{D}^0$ decays, and measurements of their branching fractions normalized relative to ²⁶ those of $\overline{B}{}^0 \to D^+D^-$, $B^0 \to D_s^+D^-$ and $B^- \to D^0D_s^-$, respectively. An excess of events consistent with $\bar{B}^0 \to D^0 \bar{D}^0$ is also seen, and its branching fraction is reported. Improved 28 measurements of the ratios of branching fractions $\mathcal{B}(\overline{B}^0_s \to D_s^+ D_s^-)/\mathcal{B}(B^0 \to D_s^+ D_s^-)$ and ²⁹ $\mathcal{B}(B^-\to D^0D^-_s)/\mathcal{B}(B^0\to D_s^+D^-)$ are also presented. All results are based upon an \mathcal{L}^{29} $\mathcal{L}(B \to D D_s)/\mathcal{L}(B \to D_s D')$ are also presented. An results are based upon an integrated luminosity of 1.0 fb⁻¹ of *pp* collision data at $\sqrt{s} = 7$ TeV recorded by the LHCb ³¹ experiment in 2011. Inclusion of charge conjugate final states is implied throughout.

³² Data sample and candidate selection

³³ The LHCb detector [\[22\]](#page-20-8) is a single-arm forward spectrometer covering the pseudorapidity ³⁴ range $2 < \eta < 5$, designed for the study of particles containing b or c quarks. The detector ³⁵ includes a high precision tracking system consisting of a silicon-strip vertex detector ³⁶ surrounding the pp interaction region, a large-area silicon-strip detector located upstream 37 of a dipole magnet with a bending power of about 4 Tm , and three stations of silicon-strip

¹Throughout this paper, the notation D is used to refer to a D^+ , D^0 or D_s^+ meson, and B represents either a B^0 , B^- or B_s^0 meson.

Figure 1: Feynman diagrams contributing to the double-charm final states discussed in this paper. They include (a) tree, (b) W-exchange and (c) penguin diagrams.

³⁸ detectors and straw drift tubes placed downstream. The combined tracking system has a 39 momentum resolution $(\Delta p/p)$ that varies from 0.4% at 5 GeV/c to 0.6% at 100 GeV/c, and ω an impact parameter (IP) resolution of 20 μ m for tracks with high transverse momentum $_{41}$ (p_T). The impact parameter is defined as the distance of closest approach of a given $\frac{42}{42}$ particle to the primary pp interaction vertex (PV). Charged hadrons are identified using ⁴³ two ring-imaging Cherenkov detectors [\[23\]](#page-20-9). Photons, electrons and charged particles are ⁴⁴ identified by a calorimeter system consisting of scintillating-pad and preshower detectors, ⁴⁵ an electromagnetic calorimeter and a hadronic calorimeter. Muons are identified by a ⁴⁶ system composed of alternating layers of iron and multiwire proportional chambers.

⁴⁷ The trigger [\[24\]](#page-20-10) consists of a hardware stage, based on information from the calorimeter ⁴⁸ and muon systems, followed by a software stage that performs a partial event reconstruction 49 (only tracks with $p_T > 0.5$ GeV/c are reconstructed and used). The software trigger 50 requires a two-, three- or four-track secondary vertex with a large track p_T sum and a ⁵¹ significant displacement from any of the reconstructed PVs. At least one track must have ⁵² $p_T > 1.7$ GeV/c and IP χ^2 greater than 16 with respect to all PVs. The IP χ^2 is defined 53 as the difference between the χ^2 of the PV reconstructed with and without the considered ⁵⁴ particle. A multivariate algorithm [\[25\]](#page-20-11) is used to identify secondary vertices that originate ⁵⁵ from the decays of b hadrons.

 For the ratios of branching fractions between modes with identical final states, no requirements are made on the hardware trigger decision. When the final states differ, a trigger selection is applied to facilitate the determination of the relative trigger efficiency. The selection requires that either (i) at least one of the tracks from the reconstructed signal decay is associated with energy depositions in the calorimeters that passed the hardware trigger requirements, or (ii) the event triggered independently of the signal decay

 ϵ_2 particles, e.g., on the decay products of the other b hadron in the event. Events that do 63 not fall into either of these two categories (\sim 5%) are discarded.

 Signal efficiencies and specific backgrounds are studied using simulated events. Proton- proton collisions are generated using Pythia 6.4 [\[26\]](#page-20-12) with a specific LHCb configura- tion [\[27\]](#page-20-13). Decays of hadronic particles are described by EVTGEN [\[28\]](#page-20-14) in which final state radiation is generated using Photos [\[29\]](#page-21-0). The interaction of the generated particles ⁶⁸ with the detector and its response are implemented using the GEANT4 toolkit [\[30\]](#page-21-1) as 69 described in Ref. [\[31\]](#page-21-2). Efficiencies for identifying K^+ and π^+ mesons are determined using τ_0 D^{*+} calibration data, with kinematic quantities reweighted to match those of the signal particles [\[23\]](#page-20-9).

⁷² Signal B candidates are formed by combining pairs of D meson candidates reconstructed in the following decay modes: $D^0 \to K^-\pi^+$ or $K^-\pi^+\pi^-\pi^+$, $D^+ \to K^-\pi^+\pi^+$ and ⁷⁴ $D_s^+ \to K^+K^-\pi^+$. The $D^0 \to K^-\pi^+\pi^-\pi^+$ decay is only used for $\overline{B}_{(s)}^0 \to D^0\overline{D}{}^0$ candidates, ⁷⁵ where a single $D^0 \to K^-\pi^+\pi^-\pi^+$ decay in the final state is allowed, which approximately ⁷⁶ doubles the total signal efficiency. A refit of signal candidates with D mass and vertex 77 constraints is performed to improve the B mass resolution.

The Due to similar kinematics of the $D^+ \to K^-\pi^+\pi^+$, $D_s^+ \to K^+K^-\pi^+$ and $\Lambda_c^+ \to pK^-\pi^+$ $\frac{1}{79}$ decays, there is cross-feed between various b-hadron decays that have two charm particles ^{so} in the final state. Cross-feed between D^+ and D_s^+ occurs when the $K^-\pi^+h^+$ invariant ⁸¹ mass is within 25 MeV/ c^2 (\sim 3 times the experimental resolution) of both the D⁺ and ^{s2} D_s^+ masses under the $h^+ = \pi^+$ and $h^+ = K^+$ hypotheses, respectively. In such cases, an arbitration is performed as follows: if either $|M(K^+K^-) - m_{\phi}| < 10$ MeV/ c^2 or h^+ $\frac{84}{100}$ satisfies a stringent kaon particle identification (PID) requirement, the D candidate is as assigned to be a D_s^+ meson. Conversely, if h^+ passes a stringent pion PID requirement, ⁸⁶ the D candidate is taken to be a D^+ meson. Candidates that do not pass either of these st selections are rejected. A similar veto is applied to D^+ and D_s^+ decays that are consistent ⁸⁸ with the Λ_c^+ $\to pK^-\pi^+$ decay hypothesis if the proton is misidentified as a π^+ or K^+ , \bullet respectively. The efficiencies of these D selections are determined using simulated signal ⁹⁰ decays to model the kinematics of the decay and D^{*+} → $D^0\pi^+$ calibration data for the ⁹¹ PID efficiencies. Their values are given in Table [1.](#page-9-0)

⁹² To suppress contributions from non- $D\overline{D}'$ final states, the reconstructed D decay vertex 93 is required to be downstream of the reconstructed B decay vertex, and the B and D decay vertices are required to have a vertex separation (VS) χ^2 larger than two. Here, the VS χ^2 94 ⁹⁵ is the difference in χ^2 between the nominal vertex fit and a vertex fit where the D is ⁹⁶ assumed to have zero lifetime. The efficiencies of this set of requirements are obtained 97 from simulation and are included in Table [1.](#page-9-0)

98 To further improve the purity of the $B \to D\overline{D}'$ samples, a boosted decision tree 99 (BDT) discriminant is used to distinguish signal D mesons from backgrounds [\[32,](#page-21-3)[33\]](#page-21-4). The 100 BDT uses five variables for the D meson and 23 for each of its children. The variables ¹⁰¹ include kinematic quantities, track quality, and vertex and PID information. The signal ¹⁰² and background distributions used to train the BDT are obtained from $\overline{B}{}^0 \to D^+\pi^-$, ¹⁰³ $B^- \to D^0 \pi^-$ and $\bar{B}^0_s \to D_s^+ \pi^-$ decays from data. The signal distributions are background ¹⁰⁴ subtracted using weights [\[34\]](#page-21-5) obtained from a fit to the B candidate invariant mass

Table 1: Individual contributions to the efficiency for selecting the various $B \to D\overline{D}'$ final states. Shown are the efficiencies to reconstruct and trigger on the final state, and to pass the charm cross-feed veto, the VS χ^2 and BDT selection requirements. The total selection efficiency is the product of these four values. The relative uncertainty on the selection efficiency for each decay mode due to the finite simulation samples sizes is 2%. Entries with a dash indicate that the efficiency factor is not applicable.

	Efficiencies $(\%)$			
		Rec. \times Trig. Cross-feed veto VS χ^2		BDT
$\overline{B}{}^0_s \rightarrow D_s^+ D_s^-$	0.140	88.4	75.4	97.5
$B^0 \to D_s^+ D^-$ (loose selection)	0.130	77.8	82.9	100.0
$\overline{B}^0_{(s)} \rightarrow \overline{D}^0 \overline{D}^0$, $(K^-\pi^+, K^+\pi^-)$ $\overline{B}^0_{(s)} \rightarrow D^0 \overline{D}^0$, $(K^-\pi^+, K^+\pi^-\pi^+\pi^-)$ $B^- \rightarrow D^0 D_s^-$	0.447		73.7	57.8
	0.128		74.6	63.6
	0.238	92.5	75.0	99.2

 $_{105}$ distribution. The background distributions are taken from the high B mass sidebands in ¹⁰⁶ the same data sample.

¹⁰⁷ It is found that making a requirement on the product of the two D meson BDT responses 108 provides better discrimination than applying one to each BDT response individually. The 109 optimal BDT requirement in each decay is chosen by maximizing $N_S/\sqrt{N_S + N_B}$. The $_{110}$ number of signal events, $N_{\rm s}$, is computed using the known (or estimated, if unknown) ¹¹¹ branching fractions, selection efficiencies from simulated events, and the BDT efficiencies F_{112} from the $\overline{B}^0 \to D^+\pi^-$, $B^- \to D^0\pi^-$ and $\overline{B}^0_s \to D_s^+\pi^-$ calibration samples, reweighted to ¹¹³ account for small differences in kinematics between the calibration and signal samples. $_{114}$ The number, $N_{\rm B}$, is the expected background yield for a given BDT requirement. The ¹¹⁵ efficiencies associated with the optimal BDT cut values, determined from an independent $s₁₁₆$ subset of the $B \to D\pi^-$ data, are listed in Table [1.](#page-9-0) Correlations between the BDT values $_{117}$ for the two D mesons are taken into account.

¹¹⁸ For the purpose of measuring $\mathcal{B}(\overline{B}^0_s \to D_s^+ D_s^-)/\mathcal{B}(B^0 \to D_s^+ D^-)$, only loose BDT ¹¹⁹ requirements are imposed since the expected yields are relatively large. On the other hand, ¹²⁰ for $\mathcal{B}(\overline{B}^0_s \to D_s^+ D^-)/\mathcal{B}(B^0 \to D_s^+ D^-)$, the expected signal yield of $\overline{B}^0_s \to D_s^+ D^-$ decays is ¹²¹ small; in this case both the signal and normalization modes are required to pass the same tighter BDT requirement. The different BDT selections applied to the $B^0 \to D_s^+ D^-$ decay ¹²³ are referred to as the "loose selection" and the "tight selection." Since the final state $_{124}$ is identical for the tight selection, the BDT efficiency cancels in the ratio of branching ¹²⁵ fractions, and is not included in Table [1.](#page-9-0)

126 For $\overline{B}^0_{(s)} \to D^0 \overline{D}{}^0$ candidates, a peaking background from $B \to D^{*+} \pi^- \to (D^0 \pi^+) \pi^ _{127}$ decays, where the π^{+} is misidentified as a K^{+} , is observed. This contribution is removed ¹²⁸ by requiring the mass difference, $M(K^-\pi^+\pi^+) - M(K^-\pi^+) > 150 \text{ MeV}/c^2$, where the K⁺ ¹²⁹ in the reconstructed decay is taken to be a π^+ . After the final selection around 2% of

130 events in the $\overline{B}_s^0 \to D_s^+ D_s^-$ decay mode contain multiple candidates; for all other modes ¹³¹ the multiple candidate rate is below 1%. All candidates are kept for the final analysis.

¹³² 3 Signal and background shapes

133 The $B \to D\overline{D}'$ signal shapes are all similar after the D mass and vertex constraints. The ¹³⁴ signal shape is parameterized as the sum of two Crystal Ball (CB) functions [\[35\]](#page-21-6), which ¹³⁵ account for non-Gaussian tails on both sides of the signal peak. The asymmetric shapes ¹³⁶ account for both non-Gaussian mass resolution effects (on both sides) and energy loss ¹³⁷ due to final state radiation. The two CB shapes are constrained to have equal area and ¹³⁸ a common mean. Separate sets of shape parameters are determined for $B^0 \to D_s^+ D^-,$ ¹³⁹ $\bar{B}_s^0 \to D_s^+ D_s^-$ and $B^- \to D^0 D_s^-$ using simulated signal decays. In the fits to data, the ¹⁴⁰ signal shape parameters are fixed to the simulated values, except for a smearing factor ¹⁴¹ that is added in quadrature to the widths from simulation. This number is allowed to ¹⁴² vary independently in each fit, but is consistent with about 4.6 MeV/ c^2 across all modes, ¹⁴³ resulting in a mass resolution of about 9 MeV/ c^2 . For the more rare $\bar{B}^0_{(s)} \to D^0 \bar{D}^0$ and ¹⁴⁴ $\bar{B}_{(s)}^0 \to D^+D^-$ decay modes, the $\bar{B}_s^0 \to D_s^+D_s^-$ signal shape parameters are used. In the signal significances, the signal shape is fixed to that for $\overline{B}_s^0 \to D_s^+ D_s^-$, ¹⁴⁶ including an additional smearing of 4.6 MeV/ c^2 . The impact of using the $B^0 \to D_s^+D^-$ or ¹⁴⁷ $B^- \to D^0 D_s^-$ signal shapes on the signal significances is negligible.

148 Several specific backgrounds contribute to the $D\overline{D}'$ mass spectra. In particular, decays 149 such as $B \to D^{(*)}\overline{D}^*$, where the D^* mesons decay through pion or photon emission, produce distinct structures in all decays under consideration. The shapes of these backgrounds are derived from simulation, which are corrected for known resolution differences between data and simulated events, and then fixed in fits to the data. The relative yield of the two ¹⁵³ peaks in the characteristic structure from the decay $D^* \to D^0 \pi$ is allowed to vary freely, to enable better modeling of the background in the low mass region. Since this mass region is significantly below the signal peaks, the impact on the signal yield determinations is negligible.

¹⁵⁷ A source of peaking background that contributes to $B \to DD_s^+$ modes are the ¹⁵⁸ $B \to D\overline{K}^{*0}K^+ \to DK^-\pi^+K^+$ decays, where the $\overline{K}^{*0}K^+$ is not produced in a D_s^+ de-¹⁵⁹ cay. Although the branching fractions for these decays [\[36\]](#page-21-7) are about twice as large as that of the $B \to DD_s^+ \to DK^+ K^- \pi^+$ decay channel, the 25 MeV/ c^2 mass window around ¹⁶¹ the known D_s^+ mass and the VS $\chi^2 > 2$ requirement reduce this contribution to about 1% ¹⁶² of the signal yield. This expectation is corroborated by studying the D_s^+ candidate mass ¹⁶³ sidebands. The shape of this background is obtained from simulation, and is described ¹⁶⁴ by a single Gaussian function which has a width about 2.5 times larger than that of the $_{165}$ signal decay and peaks at the nominal B meson mass.

166 After the charm cross-feed vetoes (see Sect. [2\)](#page-6-1), the cross-feed rate from $B^0 \to D_s^+ D^-$ ¹⁶⁷ decays into the $\bar{B}_s^0 \to D_s^+ D_s^-$ sample is $(0.7 \pm 0.2)\%$. The shape of this misidentification ¹⁶⁸ background is obtained from simulation. A similar cross-feed background contribution ¹⁶⁹ from $\Lambda_b^0 \to \Lambda_c^+ D_s^-$ decays is also expected due to events passing the Λ_c^+ veto. Taking

Figure 2: Invariant mass distributions for (left) $\overline{B}_s^0 \to D_s^+ D_s^-$ and (right) $B^0 \to D_s^+ D^$ candidates in the data with the loose BDT selection applied to the latter. The signal and background components are indicated in the legend. The $\Lambda_b^0 \to \Lambda_c^+ D_s^-$, $\overline{B_s^0} \to D_s^+ K^- K^+ \pi^-$ and $B^0 \to D^-K^+K^-\pi^+$ background components are too small to be seen, and are excluded from the legends.

¹⁷⁰ into account the observed yields of these decays in data, we fix the $B^0 \to D_s^+D^-$ and ¹⁷¹ $\Lambda_b^0 \to \Lambda_c^+ D_s^-$ cross-feed yields to 35 and 15 events, respectively. Investigation of the D m mass sidebands reveals no additional contributions from non- $D\overline{D}$ ['] backgrounds.

¹⁷³ The combinatorial background shape is described by an exponential function whose ¹⁷⁴ slope is determined from wrong-sign candidates. Wrong-sign candidates include the $D_s^+ D_s^+$, ¹⁷⁵ D^0D^0 , or $\overline{D}^0(K^+\pi^-)D_s^-$ final states, in which no signal excesses should be present (neglecting the small contribution from the doubly Cabibbo suppressed $B^- \to D^0(K^+\pi^-)D_s^-$ 176 α_{177} decay). For the $\overline{B}_{(s)}^0 \to D^+D^-$ decay, the exponential shape parameter is allowed to vary ¹⁷⁸ in the fit due to an insufficient number of wrong-sign D^+D^+ candidates.

179 4 Fit results

180 Figure [2](#page-11-0) shows the invariant mass spectra for $\overline{B}^0_s \to D_s^+ D_s^-$ and $B^0 \to D_s^+ D^-$ candidates. ¹⁸¹ The results of unbinned extended maximum likelihood fits to the distributions are overlaid ¹⁸² with the signal and background components indicated in the legends. Signal yields of ¹⁸³ 451 ± 23 $\overline{B_s^0} \rightarrow D_s^+ D_s^-$ and 5157 ± 64 $B^0 \rightarrow D_s^+ D^-$ decays are observed.

Figure [3](#page-12-0) shows the invariant mass spectrum for $B^0 \to D_s^+ D^-$ and $\overline{B_s^0} \to D_s^+ D^-$ ¹⁸⁵ candidates, where the tight BDT selection requirements have been applied as discussed 186 previously. We observe 36 ± 6 $\overline{B}_s^0 \rightarrow D_s^+ D^-$ signal decays, with 2832 ± 53 events in ¹⁸⁷ the $B^0 \to D_s^+ D^-$ normalization mode. The statistical significance of the $\bar{B}_s^0 \to D_s^+ D^-$ ¹⁸⁸ signal corresponds to 10σ by computing $\sqrt{-2\ln(\mathcal{L}_0/\mathcal{L}_{\text{max}})}$, where \mathcal{L}_{max} and \mathcal{L}_0 are the fit ¹⁸⁹ likelihoods with the signal yields allowed to vary and fixed to zero, respectively. Variations ¹⁹⁰ in the signal and background model have only a marginal impact on the signal significance. 191 The $\overline{B}_s^0 \to D^- D_s^+$ decay is thus observed for the first time.

The invariant mass spectrum for $\overline{B}_{(s)}^0 \to D^+D^-$ candidates is shown in Fig. [4](#page-13-0) (left).

Figure 3: Invariant mass distribution for $B^0 \to D_s^+ D^-$ and $\overline{B}_s^0 \to D_s^+ D^-$ candidates in the data, with the tight BDT selection applied. The distribution is plotted on a (left) linear and (right) logarithmic scale to highlight the suppressed $\overline{B}_s^0 \to D_s^+ D^-$ signal. Signal and background components are indicated in the legend.

193 Peaks are seen at both the B^0 and B^0_s meson masses, with yields of 165 ± 13 and 43 ± 7 signal events, respectively. In the lower mass region, two prominent peaks from $\overline{B}^0 \to D^{*+}D^-$ and ¹⁹⁵ $\overline{B}^0 \to D^+D^{*-}$ decays are also evident. The significance of the $\overline{B^0_s} \to D^+D^-$ signal yield is 196 computed as described above, and corresponds to 11σ , establishing the first observation of ¹⁹⁷ this decay mode.

¹⁹⁸ Figure [4](#page-13-0) (right) shows the $D^0\overline{D}{}^0$ invariant mass distribution and the results of the fit. Both $(K^-\pi^+, K^+\pi^-)$ and $(K^-\pi^+, K^+\pi^-\pi^+\pi^-)$ combinations are included. A $\overline{B}^0_s \to D^0 \overline{D}^0$ 199 200 signal is seen with a significance of 11σ , which establishes the first observation of this ₂₀₁ decay mode. The data also show an excess of events at the $B⁰$ mass. The significance of 202 that excess corresponds to 2.4σ , including both the statistical and systematic uncertainty. 203 The fitted yields in the $\bar{B}^0_s \to D^0 \bar{D}^0$ and $\bar{B}^0 \to D^0 \bar{D}^0$ decay modes are 45 ± 8 and ²⁰⁴ 13 ± 6 events, respectively. If both the $\overline{B}^0_s \to D^0 \overline{D}^0$ and $\overline{B}^0 \to D^0 \overline{D}^0$ decays proceed ²⁰⁵ through W-exchange diagrams, one would expect the signal yield in $\bar{B}^0 \to D^0 \bar{D}^0$ to be 206 ~ $(f_d/f_s) \times |V_{cd}/V_{cs}|^2$ ≈ 0.2 of the yield in $\overline{B}_s^0 \to D^0 \overline{D}^0$, where we have used $|V_{cd}/V_{cs}|^2$ = $_{207}$ 0.054 [\[18\]](#page-20-4) and $f_s/f_d = 0.256 \pm 0.020$ [\[37\]](#page-21-8). The fitted yields are consistent with this ²⁰⁸ expectation. The decay $B^ \rightarrow$ $D^0 D_s^-$ is used as the normalization channel for both $\bar{B}^0_s \to D^0 \bar{D}^0$ and $\bar{B}^0 \to D^0 \bar{D}^0$ branching fraction measurements, where only the $D^0 \to K^-\pi^+$ decay mode is used. The fitted invariant mass distribution for $B^- \to D^0 D_s^-$ 210 211 candidates is shown in Fig. [5.](#page-13-1) The fitted signal yield is 5152 ± 73 events.

212 The measured yields, $N_{B\rightarrow D\bar{D}'}$, relevant for the branching fraction measurements are

Figure 4: Invariant mass distributions for (left) $\overline{B}_{(s)}^0 \to D^+D^-$ and (right) $\overline{B}_{(s)}^0 \to D^0\overline{D}^0$ candidates in the data. Signal and background components are indicated in the legend.

Figure 5: Invariant mass distribution for $B^- \to D^0 D_s^-$ candidates in the data. Signal and background components are indicated in the legend. The $B^- \to D^0 K^- K^+ \pi^-$ background components are too small to be seen, and are excluded from the legend.

²¹³ summarized in Table [2.](#page-14-0) The branching fractions are related to the measured yields by

$$
\frac{\mathcal{B}(\overline{B}_{s}^{0} \to D_{s}^{+} D_{s}^{-})}{\mathcal{B}(B^{0} \to D_{s}^{+} D_{s}^{-})} = \frac{f_{d}}{f_{s}} \cdot \epsilon_{\text{rel}}^{B^{0}/B^{0}_{s}} \cdot \kappa \cdot \frac{\mathcal{B}(D^{+} \to K^{-}\pi^{+}\pi^{+})}{\mathcal{B}(D_{s}^{+} \to K^{+} K^{-}\pi^{+})} \cdot \frac{N_{\overline{B}_{s}^{0} \to D_{s}^{+} D_{s}^{-}}}{N_{B^{0} \to D_{s}^{+} D^{-}}},\tag{1}
$$

$$
\frac{\mathcal{B}(\overline{B}_s^0 \to D_s^+ D^-)}{\mathcal{B}(B^0 \to D_s^+ D^-)} = \frac{f_d}{f_s} \cdot \epsilon_{\text{rel}} \cdot \frac{N_{\overline{B}_s^0 \to D_s^+ D^-}}{N_{B^0 \to D_s^+ D^-}},\tag{2}
$$

$$
\frac{\mathcal{B}(\overline{B}_{s}^{0} \to D^{+} D^{-})}{\mathcal{B}(\overline{B}^{0} \to D^{+} D^{-})} = \frac{f_{d}}{f_{s}} \cdot \epsilon_{\text{rel}} \cdot \kappa \cdot \frac{N_{\overline{B}_{s}^{0} \to D^{+} D^{-}}}{N_{\overline{B}^{0} \to D^{+} D^{-}}},\tag{3}
$$

$$
\frac{\mathcal{B}(\overline{B}^0_s \to D^0 \overline{D}^0)}{\mathcal{B}(B^- \to D^0 D_s^-)} = \frac{f_d}{f_s} \cdot \epsilon'_{\text{rel}} \cdot \kappa \cdot \frac{N_{\overline{B}^0_s \to D^0 \overline{D}^0}}{N_{B^- \to D^0 D_s^-}},\tag{4}
$$

$$
\frac{\mathcal{B}(\overline{B}^0 \to D^0 \overline{D}^0)}{\mathcal{B}(B^- \to D^0 D_s^-)} = \epsilon'_{\text{rel}} \cdot \frac{N_{\overline{B}^0 \to D^0 \overline{D}^0}}{N_{B^- \to D^0 D_s^-}},\tag{5}
$$

Measurement	Signal	Norm.	Rel. eff.
	yield	yield	$\epsilon_{\rm rel}^{(\prime)}$
$\frac{\mathcal{B}(\bar{B}_{s}^{0}\rightarrow D_{s}^{+}D_{s}^{-})}{\mathcal{B}(B^{0}\rightarrow D_{s}^{+}D^{-})}$	451 ± 23	5157 ± 64	0.928 ± 0.027
$\mathcal{B}(\bar{B}^0_s\!\!\rightarrow\!\! D_s^+D^-)$ $\overline{\mathcal{B}(B^0 \rightarrow D_s^+ D^-)}$	36 ± 6	2832 ± 53	1.0

$\mathcal{B}(B^-\rightarrow D^0 D_s^-)$ $\mathcal{B}(B^0 \rightarrow D_s^+ D^-)$	5152 ± 73	5157 ± 64	0.508 ± 0.011

Table 2: Summary of the observed signal and normalization mode yields and their relative efficiencies, as used in the measurements of the ratios of branching fractions. The quoted uncertainties are statistical only.

$$
\frac{\mathcal{B}(B^{-} \to D^{0} D_{s}^{-})}{\mathcal{B}(B^{0} \to D_{s}^{+} D^{-})} = \epsilon_{\text{rel}}^{B^{0}/B^{-}} \cdot \frac{\mathcal{B}(D^{+} \to K^{-} \pi^{+} \pi^{+})}{\mathcal{B}(D^{0} \to K^{-} \pi^{+})} \cdot \frac{N_{B^{-} \to D^{0} D_{s}^{-}}}{N_{B^{0} \to D_{s}^{+} D^{-}}} \ . \tag{6}
$$

214 Here, it is assumed that B^- and \overline{B}^0 mesons are produced in equal numbers. The relative efficiencies, ϵ_{rel} , are given in Table [2.](#page-14-0) They account for geometric acceptance, detection and ²¹⁶ trigger efficiencies, and the additional VS χ^2 , BDT, and charm cross-feed veto requirements. ²¹⁷ The first four of these relative efficiencies are obtained from simulation, and the last two ²¹⁸ are data-driven. The indicated uncertainties on the relative efficiencies are due only to the finite sizes of the simulated signal decays. The average selection efficiency for $B^- \to D^0 D_s^-$ 219 ²²⁰ relative to $\overline{B}^0_{(s)} \to D^0 \overline{D}{}^0$ is

$$
\epsilon'_{\text{rel}} = \frac{\epsilon_{B^-\to D^0 D_s^-} \mathcal{B}(D_s^+ \to K^+ K^- \pi^+) \mathcal{B}(D^0 \to K^- \pi^+)}{\epsilon_{K\pi, K\pi} [\mathcal{B}(D^0 \to K^- \pi^+)]^2 + 2\epsilon_{K\pi\pi\pi, K\pi} \mathcal{B}(D^0 \to K^- \pi^+) \mathcal{B}(D^0 \to K^- \pi^+ \pi^- \pi^+)} , \tag{7}
$$

221 where the quantities $\epsilon_{B^-\to D^0 D_s^-} = (0.166 \pm 0.003)\%$, $\epsilon_{K\pi,K\pi} = (0.190 \pm 0.003)\%$ 222 and $\epsilon_{K\pi\pi\pi,K\pi} = (0.061 \pm 0.002)$ % are the selection efficiencies for the B^- → $D^0D_s^-$, 223 $\bar{B}_s^0 \to (D^0 \to K^- \pi^+, \bar{D}^0 \to K^+ \pi^-)$ and $\bar{B}_s^0 \to (D^0 \to K^- \pi^+, \bar{D}^0 \to K^+ \pi^- \pi^+ \pi^-)$ decays, respectively. The D branching fractions, $\mathcal{B}(D^0 \to K^-\pi^+) = (3.88 \pm 0.05)\%$, $B(D^0 \to K^-\pi^+\pi^-\pi^+) = (8.07 \pm 0.20)\%, \quad \mathcal{B}(D_s^+ \to K^+K^-\pi^+) = (5.49 \pm 0.27)\%, \quad \text{and}$ $\mathcal{B}(D_s^+ \to K^+ K^- \pi^+) = (5.49 \pm 0.27)\%,$ 226 $\mathcal{B}(D^+ \to K^-\pi^+\pi^+) = (9.13 \pm 0.19)\%$ are taken from Ref. [\[18\]](#page-20-4).

227 The factor κ is a correction that accounts for the lower selection efficiency associated 228 with the shorter-lifetime CP-even eigenstates of the B_s^0 system compared to flavor-specific ²²⁹ final states [\[14\]](#page-20-0). The impact on the B_s^0 acceptance is estimated by convolving an exponential ²³⁰ distribution that has a 10% smaller lifetime than that in flavor-specific decays with the

simulated lifetime acceptance. The resulting correction is $\kappa = 1.058 \pm 0.029$. In the B^0 231 232 sector, $\Delta \Gamma_d / \Gamma_d$ is below 1% [\[38\]](#page-21-9), and the lifetime acceptance is well described by the ²³³ simulation.

²³⁴ The measured ratios of branching fractions are computed to be

$$
\frac{\mathcal{B}(\overline{B}_{s}^{0} \to D^{+}D^{-})}{\mathcal{B}(\overline{B}^{0} \to D^{+}D^{-})} = 1.08 \pm 0.20 \text{ (stat)} \pm 0.10 \text{ (syst)},

$$

²³⁵ For $\mathcal{B}(\overline{B}^0_s \to D^0 \overline{D}{}^0)/\mathcal{B}(B^- \to D^0 D_s^-),$ the results obtained using the $D^0(K^-\pi^+)\overline{D}{}^0(K^+\pi^-\pi^+\pi^-)$ and $D^0(K^-\pi^+)\overline{D}{}^0(K^+\pi^-)$ final states differ by less ²³⁷ than one standard deviation. For the $\bar{B}^0 \to D^0 \bar{D}^0$ decay, we provide both the central value and the 90% confidence level (CL) upper limit. The upper limit is obtained by convolving the fitted likelihood with a Gaussian function whose width is the total systematic error, and integrating over the physical region.

²⁴¹ 5 Systematic uncertainties

²⁴² A number of systematic uncertainties contribute to the measurements of the ratios of ²⁴³ branching fractions. The sources and their values are summarized in Table [3.](#page-17-0) The dominant ²⁴⁴ source of uncertainty on the branching fraction ratios comes from the b fragmentation ²⁴⁵ fraction ratio, f_d/f_s , which has a total uncertainty of 7.8% [\[37\]](#page-21-8), of which 5.3% is from the ²⁴⁶ ratio of branching fractions $\mathcal{B}(D_s^+ \to K^+ K^- \pi^+)/\mathcal{B}(D^+ \to K^- \pi^+ \pi^+)$. For clarity, we have ²⁴⁷ removed that portion of the uncertainty from f_d/f_s , and included its contribution in the ²⁴⁸ row labeled $\mathcal{B}(D)$ in Table [3.](#page-17-0) For $\mathcal{B}(\overline{B}^0_s \to D_s^+ D_s^-)/\mathcal{B}(B^0 \to D_s^+ D^-)$, the above D_s^+/D^+ 249 branching fraction ratio from f_d/f_s cancels with the corresponding inverted ratio in Eq. [1.](#page-13-2) 250 On the other hand, in the ratio $\mathcal{B}(\overline{B}_{(s)}^0 \to D^0 \overline{D}{}^0)/\mathcal{B}(B^- \to D^0 D_s^-)$, the $D_s^+ \to K^+ K^- \pi^+$ $_{251}$ branching fraction enters as the square, after considering the D branching fractions used ²⁵² in computing f_d/f_s (see Eq. [4\)](#page-13-3). As a result, the uncertainty from $\mathcal{B}(D_s^+\to K^+K^-\pi^+)$ the contributes 9.8% to the total uncertainty on $\mathcal{B}(\overline{B}_{(s)}^0 \to D^0\overline{D}{}^0)/\mathcal{B}(B^- \to D^0D_s^-);$ smaller

²⁵⁴ contributions from the limited knowledge of $\mathcal{B}(D^0 \to K^-\pi^+)$ [1.3%], $\mathcal{B}(D^0 \to K^-\pi^+\pi^-\pi^+)$ ²⁵⁵ [2.5%] and $\mathcal{B}(D^+ \to K^-\pi^+\pi^+)$ [2.1%] are also included in the $\mathcal{B}(D)$ uncertainties.

²⁵⁶ Another significant uncertainty results from the precision on b-hadron lifetimes and ²⁵⁷ decays of B^0 and B^0_s to CP eigenstates. Using the measured value of the width difference, ²⁵⁸ $\Delta\Gamma_s = 0.116 \pm 0.018 \pm 0.006$ ps⁻¹ [\[39\]](#page-21-10) we conservatively assume the CP-even lifetime to ²⁵⁹ be in the range from 0.85 to 0.95 times the flavor-specific decay lifetime. With this allowed ²⁶⁰ range a 2.9% uncertainty on the efficiencies for \overline{B}_s^0 decays to CP eigenstates is found. The ²⁶¹ average B_s^0 lifetime is known only to a precision of 3%, which leads to a 1.5% uncertainty ²⁶² on the selection efficiencies for B_s^0 decays to flavor-specific final states. The B^0 and B^- ²⁶³ lifetimes are known with sufficient precision that the associated uncertainty is negligible. ²⁶⁴ Several of the efficiency factors are estimated from simulation. Most, but not all, of ²⁶⁵ the associated systematic uncertainties cancel due to the similar or identical final states ²⁶⁶ for the signal and normalization modes. For modes with an unequal number of tracks $_{267}$ in the final state, a 1\% uncertainty due to small differences in the IP resolution between 268 data and simulation is assigned. The efficiency of the VS χ^2 requirement is checked ²⁶⁹ using the large $B^0 \to D_s^+ D^-$ signal in data, and the agreement to within 1% with the 270 efficiency from simulation is the assigned uncertainty. For $\mathcal{B}(B^- \to D^0 D_s^-)/\mathcal{B}(B^0 \to D^0 D_s^-)$ ²⁷¹ $D_s^+D^-$), a 1% uncertainty is attributed to the efficiency of track reconstruction. For ²⁷² $\mathcal{B}(\overline{B}^0_s \to D^0 \overline{D}^0)/\mathcal{B}(B^- \to D^0 D_s^-)$, the one fewer track in the $D^0(K\pi)\overline{D}^0(K\pi)$ final state is ²⁷³ offset by the one extra track in $D^0(K\pi)\overline{D}^0(K\pi\pi\pi)$, relative to $D^0(K\pi)D_s^-(KK\pi)$, leading ²⁷⁴ to a negligible tracking uncertainty. The mass resolution in data is slightly larger than 275 in simulation, resulting in slightly different efficiencies for the reconstructed D^0 , D^+ and ²⁷⁶ D_s^+ invariant masses to lie within 25 MeV/ c^2 of their known masses. This introduces ²⁷⁷ a maximum of 1% uncertainty on the relative branching fractions. To estimate the ²⁷⁸ uncertainty on the trigger efficiencies determined from simulation, the hadron trigger ²⁷⁹ efficiency ratios were also determined using data. These efficiencies were measured using ²⁸⁰ trigger-unbiased samples of kaons and pions identified in $D^{*+} \to D^0 \pi^+$ decays. Using ²⁸¹ this alternative procedure, we find that the simulated trigger efficiency ratios have an ²⁸² uncertainty of 2%. The combined systematic uncertainties in the efficiencies obtained from ²⁸³ simulation are given in Table [3.](#page-17-0)

The limited sizes of the $B \to D\pi^-$ calibration samples lead to uncertainties in the ²⁸⁵ BDT efficiencies. The uncertainties on the ratios vary from 1.0% to 2.0%. The uncertainty ²⁸⁶ on the efficiency of the $D_{(s)}$ and Λ_c^+ vetoes is dominated by the PID efficiencies, but they 287 only apply to the subset of D candidates that fall within the mass window of two charm hadrons, e.g., both the D^+ and D_s^+ mesons, which occurs about 20% of the time for D_s^+ 288 ²⁸⁹ decays. Taking this fraction and the uncertainty in the PID efficiency into account, the veto efficiencies are estimated to have uncertainties of 1.0% for the D^+ veto, 0.5% for the ²⁹¹ D_s^+ veto, and 0.3% for the Λ_c^+ veto.

²⁹² The fit model is validated using simulated experiments, and is found to be unbiased. ²⁹³ To assess the uncertainty due to the imperfect knowledge of the various parameters ²⁹⁴ used in the fit model, a number of variations are investigated. The only non-negligible 295 uncertainties are due to the $B \to DK^-K^+\pi^-$ background contribution, which is varied 296 from 0% to 2%, and the cross-feed from $\overline{B_s^0} \to D_s^+D^-$ decays into the $\overline{B_s^0} \to D_s^+D_s^-$ sample.

Source		$\frac{\bar{B}^0_s\!\to\! D^+_sD^-_s}{B^0\!\to\! D^+_sD^-}\quad \ \frac{\bar{B}^0_s\!\to\! D^+_sD^-}{B^0\!\to\! D^+_sD^-}\quad \ \frac{\bar{B}^0_s\!\to\! D^+D^-}{\bar{B}^0\!\to\! Table 3: Sources of systematic uncertainty and their values (in %) for the ratios of branching fractions of the indicated decays. For $\mathcal{B}(\overline{B}_{(s)}^0 \to D^0 \overline{D}^0)/\mathcal{B}(B^- \to D^0 D_s^-)$, the error on f_d/f_s only applies to the $\overline{B}_s^0 \to D^0 \overline{D}{}^0$ decay, as indicated by the values in parentheses.

²⁹⁷ The uncertainty varies from 1.7% to 2.1%. For $\mathcal{B}(\overline{B}^0_s \to D^+D^-)/\mathcal{B}(\overline{B}^0 \to D^+D^-)$ and ²⁹⁸ $\mathcal{B}(\overline{B}^0_s \to D_s^+ D^-)/\mathcal{B}(B^0 \to D_s^+ D^-)$, we assign an uncertainty of 0.5%, which accounts for potentially small differences in the signal shape for \overline{B}^0 and \overline{B}^0_s decays (due to the B^0 - B^0_s 299 ³⁰⁰ mass difference). Lastly, the finite size of the samples of simulated decays contributes ³⁰¹ 3% uncertainty to all the measurements. In total, the systematic uncertainties on the ³⁰² branching fraction ratios range from 5.5% to 13.0%, as indicated in Table [3.](#page-17-0)

303 6 Discussion and summary

³⁰⁴ First observations and measurements of the relative branching fractions for the decays ³⁰⁵ $\bar{B}_s^0 \to D^+D^-$, $\bar{B}_s^0 \to D_s^+D^-$ and $\bar{B}_s^0 \to D^0\bar{D}^0$ have been presented, along with measure-306 ments of $\mathcal{B}(\overline{B}_s^0 \to D_s^+ D_s^-)$ and $\mathcal{B}(B^- \to D^0 D_s^-)$. Taking the world average values for ³⁰⁷ $\mathcal{B}(B^0 \to D_s^+ D^-) = (7.2 \pm 0.8) \times 10^{-3}$ [\[18\]](#page-20-4), the absolute branching fractions are

$$
\mathcal{B}(B^- \to D^0 D_s^-) = (8.6 \pm 0.2 \text{ (stat)} \pm 0.4 \text{ (syst)} \pm 1.0 \text{ (norm)}) \times 10^{-3},
$$

$$
\mathcal{B}(\overline{B}_s^0 \to D_s^+ D_s^-) = (4.0 \pm 0.2 \text{ (stat)} \pm 0.3 \text{ (syst)} \pm 0.4 \text{ (norm)}) \times 10^{-3}.
$$

 The third uncertainty reflects the precision of the branching fraction for the normaliza- tion mode. These measurements are consistent with, and more precise than, both the current world average measurements [\[18\]](#page-20-4) as well as the more recent measurement of $\mathcal{B}(\overline{B}{}^0_s\to D_s^+D_s^-)$ [\[40\]](#page-21-11).

312 The measured value of $\mathcal{B}(\overline{B}_s^0 \to D_s^+ D_s^-)/\mathcal{B}(B^0 \to D_s^+ D^-) = 0.55 \pm 0.06$ is signif-³¹³ icantly lower than the naive expectation of unity for the case that both decays are $_{314}$ dominated by tree amplitudes (see Fig. [1\(](#page-7-0)a)), assuming small non-factorizable effects and

comparable magnitudes of the $B_{(s)} \to D_{(s)}^+$ ³¹⁵ comparable magnitudes of the $B_{(s)} \to D_{(s)}^+$ form factors [\[41\]](#page-21-12). Unlike $B^0 \to D_s^+ D^-$, the 316 $\bar{B}_s^0 \to D_s^+ D_s^-$ decay receives a contribution from the W-exchange process (see Fig. [1\(](#page-7-0)b)), ³¹⁷ suggesting that this amplitude may not be negligible. Interestingly, when comparing the ³¹⁸ $\overline{B}_s^0 \to D_s^+ D_s^-$ and $\overline{B}^0 \to D^+ D^-$ decays, which have the same set of amplitudes, one finds s зія $|V_{cd}/V_{cs}|^2\cdot {\cal B}(\overline B^0_s\to D_s^+D_s^-)/{\cal B}(\overline B^0\to D^+D^-)\sim 1.$ 320 Using $\mathcal{B}(\overline{B}^0 \to D^+D^-) = (2.11 \pm 0.31) \times 10^{-4}$ and $\mathcal{B}(B^- \to D^0D_s^-) = (10.0 \pm 1.7) \times$

 10^{-3} [\[18\]](#page-20-4), the following values for the branching fractions are obtained

$$
\mathcal{B}(\overline{B}_s^0 \to D^+D^-) = (2.2 \pm 0.4 \text{ (stat)} \pm 0.2 \text{ (syst)} \pm 0.3 \text{ (norm)}) \times 10^{-4},
$$

$$
\mathcal{B}(\overline{B}_s^0 \to D^0 \overline{D}^0) = (1.9 \pm 0.3 \text{ (stat)} \pm 0.3 \text{ (syst)} \pm 0.3 \text{ (norm)}) \times 10^{-4},
$$

$$
\mathcal{B}(\overline{B}^0 \to D^0 \overline{D}^0) = (1.4 \pm 0.6 \text{ (stat)} \pm 0.2 \text{ (syst)} \pm 0.2 \text{ (norm)}) \times 10^{-5}.
$$

322 The first of these results disfavors the predicted values for $\mathcal{B}(\overline{B}^0_s \to D^+D^-)$ in Refs. [\[20,](#page-20-6)[21\]](#page-20-7), which are about 5–15 times larger than our measured value. The measured branching fractions are about a factor of 2–3 larger than the predictions obtained by assuming that these decay amplitudes are dominated by rescattering [\[17\]](#page-20-3). As discussed above for the $\mathcal{B}(\overline{B}_s^0 \to D_s^+ D_s^-)$ measurement, this may also suggest that the W-exchange amplitude ³²⁷ contribution is not negligible in $B \to D\overline{D}'$ decays. For precise quantitative comparisons of these B_s^0 branching fraction measurements to theoretical predictions, one should account for the different total widths of the CP-even and CP-odd final states [\[12\]](#page-19-9).

330 The Cabibbo suppressed $\bar{B}_s^0 \to D_s^+ D^-$ decay is also observed for the first time. Its ³³¹ absolute branching fraction is

$$
\mathcal{B}(\overline{B}_s^0 \to D_s^+ D^-) = (3.6 \pm 0.6 \text{ (stat)} \pm 0.3 \text{ (syst)} \pm 0.4 \text{ (norm)}) \times 10^{-4}.
$$

332 This value is consistent with the expected suppression of $|V_{cd}/V_{cs}|^2$.

333 The results reported here are based on an integrated luminosity of 1.0 $\rm fb^{-1}$. A data sample with approximately 2.5 times larger yields in these modes has already been collected in 2012, and larger samples are anticipated in the next few years. These samples give good prospects for CP-violation measurements, lifetime studies, and obtaining a deeper understanding of the decay mechanisms that contribute to b-hadron decays.

³³⁸ Acknowledgements

 We express our gratitude to our colleagues in the CERN accelerator departments for the excellent performance of the LHC. We thank the technical and administrative staff at the LHCb institutes. We acknowledge support from CERN and from the national agencies: CAPES, CNPq, FAPERJ and FINEP (Brazil); NSFC (China); CNRS/IN2P3 and Region Auvergne (France); BMBF, DFG, HGF and MPG (Germany); SFI (Ireland); INFN (Italy); FOM and NWO (The Netherlands); SCSR (Poland); ANCS/IFA (Romania); MinES, Rosatom, RFBR and NRC "Kurchatov Institute" (Russia); MinECo, XuntaGal and GENCAT (Spain); SNSF and SER (Switzerland); NAS Ukraine (Ukraine); STFC (United Kingdom); NSF (USA). We also acknowledge the support received from the ERC

 under FP7. The Tier1 computing centres are supported by IN2P3 (France), KIT and BMBF (Germany), INFN (Italy), NWO and SURF (The Netherlands), PIC (Spain), GridPP (United Kingdom). We are thankful for the computing resources put at our disposal by Yandex LLC (Russia), as well as to the communities behind the multiple open source software packages that we depend on.
