Abstract

We study the arbitrariness of boundary conditions (BCs) on S^1/Z_2 braneworld models with the gauge group U(N). The BCs are chosen independently on the branes and the bulk in this model. There are numerous choices for BCs in general, but some of the BCs are connected through gauge transformations. We show that the equivalent relations are obtained on the UV-brane without relying on specific transformation parameters. There is no other equivalent relation on the UV-brane. On the other hand, we find that a gauge transformation with a kink connects all the BCs on the bulk and IR-brane. It means that the arbitrariness of BCs is completely solved on the bulk and the IR-brane except for the UV-brane.

1 Introduction

In Gauge Higgs Unification (GHU) theories, the Higgs bosons are introduced as extradimensional components of the gauge fields, that is the Higgs bosons are unified with the gauge bosons. Especially, the GHU theories with an orbifold space are phenomenologically attractive. It has been shown that 4D chiral fermions are naturally generated,

^{*}k-takeuchi@hiroshima-u.ac.jp

[†]inagaki@hiroshima-u.ac.jp

and the Higgs mass splitting can be elegantly realized [1–9]. Various models with extradimensions can be constructed by combining a variety of contents such as the structure of space-time, field contents, gauge symmetry, geometric symmetry, and boundary conditions (BCs) imposed on fields.

Realistic combinations of the first four have been actively studied [10–23]. For the last one, however, there remains the arbitrariness problem of BCs. The definition of a model with compactified space requires BCs. There are numerous choices for BCs and the choices lead to physically different models. We are unknown which type of BCs should be selected without relying on phenomenological information. This is the arbitrariness problem of BCs [24–26].

This problem has been partly eliminated. Ref. [26] pointed out that some BCs are connected by gauge transformations. The connected BCs produce a physically equivalent model.¹ We define equivalence classes (ECs), each of which consists of BCs connected by gauge transformations. There are multiple ECs in an orbifold model in general and classifying ECs is the first step to solving the arbitrariness problem of BCs. Many works have been done to study ECs in various orbifold models by using specific gauge transformations [30–35]. Our previous paper [36] has achieved the sufficient classification of ECs without relying on an explicit form of gauge transformations. As a result, the number of ECs in U(N) and SU(N) gauge theories on S^1/Z_2 orbifold is precisely obtained to be $(N + 1)^2$ [30].

In this paper, we consider S^1/Z_2 brane-world model, where the BCs can be chosen independently on the branes and the bulk (see Fig.1). As a result, the BCs cannot be connected by constant parameters, but the equivalent relations are obtained on the UV-brane by coordinate-dependent parameters. It is a sufficient classification because this study does not rely on an explicit form of gauge transformations. On the other hand, we also show that all the BCs on the bulk and the IR-brane can be connected by a gauge transformation with a kink. It means that the arbitrariness of BCs is completely solved on the bulk and IR-brane except for the UV-brane.

In Section 2, the gauge transformations of BCs on S^1/Z_2 are discussed. In Section 3, we consider the case that the transformation parameters are constant. In Section 4, the connections between the BCs are investigated separately on the UV-brane and the others. Section 5 presents the conclusion.

2 Boundary Conditions and Equivalence Classes

In this paper, we focus on U(N) gauge theory on a four-dimensional Minkowski spacetime M^4 and one extra-dimensional space compactified on the S^1/Z_2 orbifold, which is identified as two points on a circle S^1 with radius R by parity. Let x^{μ} ($\mu = 0, 1, 2, 3$) and y be the coordinates of M^4 and S^1/Z_2 , respectively. (Hereafter the subscript μ is omitted). 5D fermion fields $\Psi(x, y)$ and 5D gauge fields $A_M(x, y)$ respectively belong

¹The physical equivalence of the BCs in one EC is guaranteed by the Aharonov-Bohm (AB) phase based on the Hosotani mechanism [27-29].

Figure 1: S^1/Z_2 brane-world

to U(N) fundamental and adjoint representations. The action is given by

$$S = \int d^4x dy \,\mathcal{L}^{5D} = \int d^4x dy \,\left\{ -\frac{1}{4} F_{MN} F^{MN} + \bar{\Psi} i \Gamma^M D_M \Psi \right\},\tag{2.1}$$

where $x^M = (x^{\mu}, y)$ indicate 5D coordinates, and $\Gamma^M = (\gamma^{\mu}, i\gamma^5)$ are Dirac gamma matrices $(\gamma^5 \equiv i\gamma^0\gamma^1\gamma^2\gamma^3)$. The covariant derivative and the field-strength-tensor are denoted as, $D_M = \partial_M + igA_M(x, y)$ and $F_{MN} = \frac{i}{g}[D_M, D_N]$, respectively. We identify any point on the y-coordinate as, $y \sim y + 2\pi R \sim -y$, and the fundamental region can be written as, $0 \leq y \leq \pi R$.

The 5D Lagrangian on $M^4 \times S^1/Z_2$ is invariant under the following transformations:

$$\hat{\mathcal{T}}: y \to y + 2\pi R, \quad \hat{\mathcal{P}}_0: -y \to +y, \quad \hat{\mathcal{P}}_1: \pi R - y \to \pi R + y.$$
 (2.2)

 $\hat{\mathcal{T}}$ is a translation along the circle. $\hat{\mathcal{P}}_0$ and $\hat{\mathcal{P}}_1$ are respectively parity transformations around the two fixed points, $y = y_0 = 0$ and $y = y_1 = \pi R$, and they satisfy, $\hat{\mathcal{P}}_0^2 = \hat{\mathcal{P}}_1^2 = \hat{\mathcal{I}}$, where $\hat{\mathcal{I}}$ is an identity transformation. We note that only two of them are independent because of $\hat{\mathcal{T}} = \hat{\mathcal{P}}_1 \hat{\mathcal{P}}_0$ is satisfied. We take (P_0, P_1) as the basic boundary conditions (BCs). The BCs of each field are represented as

$$\Psi(x, y_i - y) = P_i \gamma^5 \Psi(x, y_i + y),$$
(2.3)

$$A_{\mu}(x, y_i - y) = P_i A_{\mu}(x, y_i + y) P_i, \qquad (2.4)$$

$$A_y(x, y_i - y) = -P_i A_y(x, y_i + y) P_i,$$
(2.5)

where $N \times N$ representation matrices P_i (i = 0, 1) satisfy parity and unitary conditions, $P_i = P_i^{-1} = P_i^{\dagger}$. These are Hermitian U(N) matrices.

There are numerous choices for the BCs because any (P_0, P_1) is allowed as long as they satisfy parity and unitary conditions. The choice of them lead to physically different models [7]. However, several BCs are connected by gauge transformations [26]. Let us transform each field with a transformation matrices $\Omega(x, y)$. The BCs of the transformed fields are written as

$$\Psi'(x, y_i - y) = P'_i \gamma^5 \Psi'(x, y_i + y), \qquad (2.6)$$

$$A'_{\mu}(x, y_i - y) = P'_i A'_{\mu}(x, y_i + y) P'^{\dagger}_i - P'_i \partial_{\mu} P'^{\dagger}_i, \qquad (2.7)$$

$$A'_{y}(x, y_{i} - y) = -P'_{i}A'_{y}(x, y_{i} + y)P'^{\dagger}_{i} - P'_{i}(-\partial_{y})P'^{\dagger}_{i}, \qquad (2.8)$$

where

$$P'_{i} = \Omega(x, y_{i} - y)P_{i}\Omega^{\dagger}(x, y_{i} + y).$$

$$(2.9)$$

The transformed set (P'_0, P'_1) generally depend on the coordinates, but if it remains constant and satisfies parity and unitary conditions, then (P'_0, P'_1) can be another choice for (P_0, P_1) . In this case, (P_0, P_1) and (P'_0, P'_1) are generally different but yield a physically equivalent model, denoted as $(P_0, P_1) \sim (P'_0, P'_1)$. Such connected sets of BCs belong to the same equivalence class (EC), each of which consists of physically equivalent BCs. BCs-connecting gauge transformation is defined by the transformation satisfying the following conditions:

$$\partial_M P'_0 = 0, \quad \partial_M P'_1 = 0, \quad P'^{\dagger}_0 = P_0, \quad P'^{\dagger}_1 = P_1.$$
 (2.10)

Both (P_0, P_1) and (P'_0, P'_1) remain constant and satisfy parity and unitary conditions under this transformation.

How is each EC characterized? P_0 and P_1 are not generally diagonal, but Ref. [30] have shown that they can be diagonalized simultaneously by gauge transformations. It means that each EC contains at least one diagonal set, which consists of a diagonal P_0 and a diagonal P_1 . All ECs on S^1/Z_2 are characterized the sets of (P_0, P_1) 's eigenvalues. A diagonal set (P_0, P_1) is rearranged to

$$P_{0} = \operatorname{diag}(\underbrace{+1, \dots, +1, +1, \dots, +1, -1, \dots, -1, -1, \dots, -1}_{p}, \underbrace{-1, \dots, +1}_{q}, \underbrace{+1, \dots, +1}_{r}, \underbrace{-1, \dots, -1}_{s=N-p-q-r}),$$
(2.11)

where p, q, r, s denote non-negative integers and satisfy, $0 \le p, q, r, s \le N$ and p + q + r + s = N. A diagonal set (P_0, P_1) is characterized by a set of non-negative integers:

$$[p, q, r, s].$$
 (2.12)

Each EC contains s diagonal set, but there remains a possibility that it contains more than one, so that we need to investigate whether one diagonal set is transformed into another diagonal set under gauge transformations. It has been investigated by using specific gauge transformations in previous paper [30]. In this paper, we examine it by using the general gauge transformations with arbitrary parameters. The classification of ECs is completed after this sufficient investigation.

3 Analysis of global gauge transformations

In this section, we discuss the case that the transformation matrices Ω are coordinateindependent, called global gauge transformations. It is shown that the global gauge transformations do not achieve the connection between the diagonal sets of BCs. This discussion will be useful for the analysis of the local gauge transformations in Section 4.

A transformation matrix is generally represented as $\Omega(y) = \exp[if^a(\hat{y})T^a]$. Here $\hat{y} \equiv y/2\pi R$ is a dimensionless parameter, $f^a(\hat{y})$ is a continuous real parameter, and T^a is a generator of the U(N) group $(a = 1, \ldots, N^2)$. We drop *x*-dependence since it does not contribute to our discussion. In order to investigate the connection between the diagonal sets of BCs, the generators $\{T^a(a = 1, \ldots, N^2)\}$ are classified into the following four types [34]:

(i) the commutative type:
$$T^{a_{++}} = \begin{pmatrix} \star & 0 & 0 & 0 \\ 0 & \star & 0 & 0 \\ 0 & 0 & \star & 0 \\ 0 & 0 & 0 & \star \end{pmatrix},$$
(3.1)

(ii) the mixed type:
$$T^{a_{+-}} = \begin{pmatrix} 0 & \star & 0 & 0 \\ \star & 0 & 0 & 0 \\ 0 & 0 & 0 & \star \\ 0 & 0 & \star & 0 \end{pmatrix}, \quad T^{a_{-+}} = \begin{pmatrix} 0 & 0 & \star & 0 \\ 0 & 0 & 0 & \star \\ \star & 0 & 0 & 0 \\ 0 & \star & 0 & 0 \end{pmatrix}, \quad (3.2)$$

(iii) the anti-commutative type:
$$T^{a--} = \begin{pmatrix} 0 & 0 & 0 & \star \\ 0 & 0 & \star & 0 \\ 0 & \star & 0 & 0 \\ \star & 0 & 0 & 0 \end{pmatrix}$$
, (3.3)

where \star stands for non-zero sub-matrices and 0 is a sub-matrix with all components zero (a null sub-matrix).² ³ The numbers of $T^{a_{++}}$, $T^{a_{+-}}$, $T^{a_{-+}}$ and $T^{a_{--}}$ are respectively $p^2 + q^2 + r^2 + s^2$, 2(pq + rs), 2(pr + qs) and 2(ps + qr), and the total number of them is N^2 . These generators commute or anti-commute with P_0 and P_1 :

$$[T^{a_{++}}, P_0] = [T^{a_{++}}, P_1] = 0, (3.4)$$

$$[T^{a_{+-}}, P_0] = \{T^{a_{+-}}, P_1\} = 0, \tag{3.5}$$

$$\{T^{a_{-+}}, P_0\} = [T^{a_{-+}}, P_1] = 0, \tag{3.6}$$

$$\{T^{a_{--}}, P_0\} = \{T^{a_{--}}, P_1\} = 0, \tag{3.7}$$

where $[A, B] \equiv AB - BA$ and $\{A, B\} \equiv AB + BA$.

²The concrete forms of the generators are different in some cases, such as p = 0 and N = 2, 3. The following discussion in this section is also applied to such cases.

³There are gauge transformations with multiple types of the generators, but they cannot construct a unique connection between the BCs in many cases.

We consider global gauge transformations Ω_{\pm} . They have the constant parameters, $f^{a_{\pm}} = c^{a_{\pm}}/2$ ($c^{a_{\pm}} \in \mathbb{R}$), and the generators $T^{a_{\pm}}$, respectively. Let us transform a matrix P by Ω_{\pm} , where $T^{a_{+}}$ commutes with P and $T^{a_{-}}$ anti-commutes with P. The transformation of P (2.9) is calculated as

$$P' = \Omega_+ P \,\Omega_+^\dagger = \Omega_+ \Omega_+^\dagger P = P, \tag{3.8}$$

$$P' = \Omega_- P \,\Omega_-^\dagger = \Omega_- \Omega_- P = e^{iT^-} P, \tag{3.9}$$

where $T^- \equiv c^{a_-}T^{a_-}$ is a Hermitian matrix. Hereafter we employ the notation: $T^{st} \equiv c^{a_{st}}T^{a_{st}}$ (s, t = + or -). (3.8) and (3.9) lead to the following results under the global gauge transformations:

- (i) The commutative type only becomes the identity transformation: $(P'_0, P'_1) = (P_0, P_1).$
- (ii) The mixed type rotates one matrix with the other matrix fixed: $(P'_0, P'_1) = (P_0, e^{iT^{+-}}P_1)$ or $(P'_0, P'_1) = (e^{iT^{-+}}P_0, P_1).$
- (iii) The anti-commutative type rotates both simultaneously: $(P'_0, P'_1) = (e^{iT^{--}}P_0, e^{iT^{--}}P_1).$

Is a diagonal set [p, q, r, s] transformed to a different diagonal set [p', q', r', s'] through such rotations? The answer is NO. The proof will be done step-by-step for the cases that the generators are 2×2 , $N \times N$ with two blocks, and $N \times N$ with four blocks.

3.1 2×2 matrices

The first step is to consider the following 2×2 generator:

$$T^{-} = \begin{pmatrix} 0 & c \\ c^* & 0 \end{pmatrix}, \qquad (3.10)$$

where c is a complex number. This generator produces the mixed and anti-commutative type transformations in U(2) sub-group in U(N). The *n*-th term in the Taylor expansion of e^{iT^-} is proportional to

$$(T^{-})^{n} = \begin{cases} \begin{pmatrix} |c|^{n} & 0\\ 0 & |c|^{n} \end{pmatrix} & \text{for } n = \text{even}, \\ \begin{pmatrix} 0 & c\\ c^{*} & 0 \end{pmatrix} \begin{pmatrix} |c|^{n-1} & 0\\ 0 & |c|^{n-1} \end{pmatrix} & \text{for } n = \text{odd.} \end{cases}$$
(3.11)

The exponential factor is written as

$$e^{iT^{-}} = \cos|c| \begin{pmatrix} 1 & 0\\ 0 & 1 \end{pmatrix} + \frac{i}{|c|} \sin|c| \begin{pmatrix} 0 & c\\ c^{*} & 0 \end{pmatrix}.$$
 (3.12)

Since (3.12) must be diagonal, the parameter |c| is constrained to be $|c| = m\pi$ (m = 0, 1, 2...). Thus, we get the following diagonal matrix:

$$\operatorname{diag}(e^{iT^{-}}) = \begin{cases} I_2 & \text{for } m = \text{even,} \\ -I_2 & \text{for } m = \text{odd,} \end{cases}$$
(3.13)

where I_2 is an identity matrix. We find that a diagonal set [p, q, r, s] is not transformed to another diagonal set in both cases, even when m = odd.

3.2 $N \times N$ matrices with two blocks

Next we consider the following $N \times N$ generator with two blocks:

$$T^{-} = \begin{pmatrix} 0 & A \\ A^{\dagger} & 0 \end{pmatrix}, \qquad (3.14)$$

where A is an $(a \times b)$ sub-matrix $(a, b \ge 2)$ and 0 is a null sub-matrix. (3.14) is the mixed or anti-commutative type generator in the case that one or more blocks are degenerate, such as [p, q, r, s = 0]. The *n*-th term of e^{iT^-} is proportional to

$$(T^{-})^{n} = \begin{cases} \begin{pmatrix} (AA^{\dagger})^{\frac{n}{2}} & 0\\ 0 & (A^{\dagger}A)^{\frac{n}{2}} \end{pmatrix} & \text{for } n = \text{even}, \\ \begin{pmatrix} 0 & A\\ A^{\dagger} & 0 \end{pmatrix} \begin{pmatrix} (AA^{\dagger})^{\frac{n-1}{2}} & 0\\ 0 & (A^{\dagger}A)^{\frac{n-1}{2}} \end{pmatrix} & \text{for } n = \text{odd.} \end{cases}$$
(3.15)

In order to get a diagonal exponential factor, let us transform T^- by unitary matrix: $U = \text{diag}(U_1, U_2)$, where U_1 and U_2 are $(a \times a)$ and $(b \times b)$ unitary sub-matrices. We note that P_0 and P_1 are invariant under this unitary transformation. The *n*-th term (3.15) is transformed as

$$U(T^{-})^{n}U^{\dagger} = \begin{cases} \begin{pmatrix} (A_{1})^{\frac{n}{2}} & 0\\ 0 & (A_{2})^{\frac{n}{2}} \end{pmatrix} & \text{for } n = \text{even}, \\ \begin{pmatrix} 0 & A'\\ A'^{\dagger} & 0 \end{pmatrix} \begin{pmatrix} (A_{1})^{\frac{n-1}{2}} & 0\\ 0 & (A_{2})^{\frac{n-1}{2}} \end{pmatrix} & \text{for } n = \text{odd}, \end{cases}$$
(3.16)

where we define $A_1 \equiv U_1(AA^{\dagger})U_1^{\dagger}$, $A_2 \equiv U_2(A^{\dagger}A)U_2^{\dagger}$, and $A' \equiv U_1AU_2^{\dagger}$. The two Hermitian matrices (AA^{\dagger}) and $(A^{\dagger}A)$ have the same eigenvalues except for zero. Following the similar calculations in Section 3.1, the following diagonal exponential factor is obtained:

$$Ue^{iT^{-}}U^{\dagger} = \begin{pmatrix} \tilde{I}_{a,X} & 0\\ 0 & \tilde{I}_{b,X} \end{pmatrix}, \qquad (3.17)$$

where $\tilde{I}_{c,X}$ (c = a, b) is a diagonal $(c \times c)$ matrix whose components are ± 1 . The X shows the number of -1 $(0 \le X \le \min(a, b))$. The rotation by (3.17) seemingly moves a diagonal set to another diagonal set, but it cannot be achieved.

3.3 $N \times N$ matrices with four blocks

We consider the most general case as the final step:

$$T^{-} = \begin{pmatrix} 0 & 0 & 0 & A \\ 0 & 0 & B & 0 \\ 0 & B^{\dagger} & 0 & 0 \\ A^{\dagger} & 0 & 0 & 0 \end{pmatrix},$$
(3.18)

where A is a $(p \times s)$ sub-matrix and B is a $(q \times r)$ sub-matrix. The form of (3.18) is the case of the anti-commutative type (3.3), but can also be rearranged into the form of the mixed type (3.2). From the similar calculation in Section 3.2, the diagonal exponential factor is written as,

$$Ue^{iT^{-}}U^{\dagger} = \begin{pmatrix} I_{p,X} & 0 & 0 & 0\\ 0 & \tilde{I}_{q,Y} & 0 & 0\\ 0 & 0 & \tilde{I}_{r,Y} & 0\\ 0 & 0 & 0 & \tilde{I}_{s,X} \end{pmatrix},$$
(3.19)

where X and Y denote the numbers of -1. They satisfy $0 \le X \le \min(p, s)$ and $0 \le Y \le \min(q, r)$. The rotation by (3.19) cannot also achieve the connection between the diagonal sets. Finally, we conclude that the diagonal sets [p, q, r, s] remains invariant and the non-trivial equivalent relations cannot be obtained under global gauge transformations.

4 Analysis of local gauge transformations

Let us consider local gauge transformations, which have y-dependent transformation parameters. In a brane-world model, the BCs can be chosen differently on the branes and the bulk. We discuss the local gauge transformations separately on the UV-brane $(\hat{y} = 0)$ and the others $(0 < \hat{y} \le 1/2)$ (see Fig.1).

4.1 Equivalence classes on the UV-brane

On the UV-brane ($\hat{y} = 0$), we prove that the anti-commutative type gauge transformations produce the following equivalent relations [26, 29]:

$$[p,q,r,s] \sim [p-1,q+1,r+1,s-1] \quad \text{for } p,s \ge 0, \sim [p+1,q-1,r-1,s+1] \quad \text{for } q,r \ge 0.$$

$$(4.1)$$

Also, It is shown that the commutative and mixed type cannot yield any equivalent relation. We derive them without relying on an explicit form of gauge transformations, so that the classification of ECs on the UV-brane is completed in this section. Let us transform P_i (i = 0, 1) into other diagonal matrices P'_i by the generators $T^{a_{\pm}}$ with the parameters $f^{a_{\pm}}(\hat{y})$. Using the commutative generator, P_i is transformed as

$$P'_{i} = \exp\left[if^{a_{+}}(\hat{y}_{i} - \hat{y})T^{a_{+}}\right] \exp\left[-if^{a_{+}}(\hat{y}_{i} + \hat{y})T^{a_{+}}\right]P_{i} \to P_{i} \quad (\hat{y} \to 0),$$
(4.2)

where $\hat{y}_0 = 0$ and $\hat{y}_1 = 1/2$ are the fixed points on S^1/Z_2 . The two exponential factors cancel each other because the parameter functions $f^{a_+}(\hat{y})$ are continuous at $\hat{y} = \hat{y}_0$, \hat{y}_1 . We find that (4.2) is just the identity transformation. By using the anti-commutative generators, P_i is transformed as

$$P'_{i} = \exp\left[-if^{a_{-}}(\hat{y}_{i} - \hat{y})T^{a_{-}}\right] \exp\left[-if^{a_{-}}(\hat{y}_{i} + \hat{y})T^{a_{-}}\right]P_{i} \to e^{-ic_{i}^{a_{-}}T^{a_{-}}}P_{i} \quad (\hat{y} \to 0),$$

$$(4.3)$$

where $f^{a_-}(\hat{y}_0) = c_0^{a_-}/2$ and $f^{a_-}(\hat{y}_1) = c_1^{a_-}/2$ $(c_0^{a_-}, c_1^{a_-} \in \mathbb{R})$. From (4.2) and (4.3), we conclude that a diagonal set [p, q, r, s] do not move to a different diagonal set by the commutative and mixed generators, as shown in the global cases. On the other hand, under the anti-commutative gauge transformations, P_0 and P_1 are rotated not simultaneously but independently with $(c_0^{a_-}, c_1^{a_-})$. We find that it is different from the global case.

As an example, we independently rotate the set [p, q = 0, r = 0, s]. P_0 and P_1 are respectively rotated by

$$D_0 \equiv \operatorname{diag}(e^{iT_0^{--}}) = \begin{pmatrix} \tilde{I}_{p,X} & 0\\ 0 & \tilde{I}_{s,X} \end{pmatrix}, \qquad (4.4)$$

$$D_1 \equiv \operatorname{diag}(e^{iT_1^{--}}) = \begin{pmatrix} \tilde{I}_{p,Y} & 0\\ 0 & \tilde{I}_{s,Y} \end{pmatrix}, \qquad (4.5)$$

where X and Y satisfy $0 \le X, Y \le \min(p, s)$ and generally have different values. We count the number of the same and different eigenvalues between D_0 and D_1 . Let t, u, and v be respectively the number of the same +1, the same -1, and the different eigenvalues (t + u + v = p + s, 2u + v = 2X + 2Y). Such transformations produce

$$[p,q,r,s] \sim [p-v,q+v,r+v,s-v].$$
(4.6)

This is just the equivalence relations (4.1).

4.2 Equivalence classes on the Bulk and IR-brane

Next, we discuss the BCs on the bulk and the IR-brane $(0 < \hat{y} \le 1/2)$. We show that the commutative gauge transformations produce a new equivalent relation and it connects between all diagonal sets.

We suppose that all of the parameters $\{f^{a_{++}}(\hat{y})\}\$ are proportional to a function $f(\hat{y})$, i.e., $f^{a_{++}}(\hat{y}) = c^{a_{++}}f(\hat{y})$. in this case, P_i (i = 0, 1) are calculated as

$$P'_{i} = \exp\left[-i\left\{f(\hat{y}_{i} + \hat{y}) - f(\hat{y}_{i} - \hat{y})\right\}T^{++}\right]P_{i},\tag{4.7}$$

where $T^{++} \equiv c^{a_{++}}T^{a_{++}}$ is a Hermitian matrix and its form is the commutative type (3.1). In order to achieve a non-trivial relation, the value of $\{f(\hat{y}_i + \hat{y}) - f(\hat{y}_i - \hat{y})\}$ must be a non-zero constant. Such a function does not exist on the UV-brane because of the continuity of the parameters, but exists on the bulk and IR-brane. In order to show that, we consider the following y-dependent parameters with a kink at the fixed points $\hat{y} = \hat{y}_0 = 0$ and $\hat{y} = \hat{y}_1 = 1/2$ (see Fig.2):

$$f_0(\hat{y}) = \frac{1}{2} \tanh[\lambda \left(\hat{y} - \hat{y}_0\right)], \tag{4.8}$$

$$f_1(\hat{y}) = \frac{1}{2} \tanh[\lambda(\hat{y} - \hat{y}_1)].$$
(4.9)

Here we adjust the parameter λ to a large value and redefine the area of the bulk and the IR-brane as $1/\lambda \ll \hat{y} \leq 1/2$. In this case, (4.8) and (4.9) satisfy

$$f_0(\hat{y}_0 + \hat{y}) - f_0(\hat{y}_0 - \hat{y}) = 1, \quad f_0(\hat{y}_1 + \hat{y}) - f_0(\hat{y}_1 - \hat{y}) = 0, \tag{4.10}$$

$$f_1(\hat{y}_0 + \hat{y}) - f_1(\hat{y}_0 - \hat{y}) = 0, \quad f_1(\hat{y}_1 + \hat{y}) - f_1(\hat{y}_1 - \hat{y}) = 1.$$
(4.11)

Therefore, we find that (4.8) rotates P_0 with P_1 fixed: $(P'_0, P'_1) = (e^{-iT_0^{++}}P_0, P_1)$. (4.9) rotates P_0 with P_1 fixed: $(P'_0, P'_1) = (P_0, e^{-iT_1^{++}}P_1)$ under the commutative type gauge transformations. Here T_0^{++} and T_1^{++} are the generators with $f_0(\hat{y})$ and $f_1(\hat{y})$.

Figure 2: The transformation parameters $f_0(\hat{y})$ and $f_1(\hat{y})$

Now let us take all sub-matrices in T^{++} diagonal, i.e. $T^{++} = \text{diag}(a_1, a_2, \dots, a_N)$. The exponential factor is written as

$$e^{iT^{++}} = \begin{pmatrix} e^{ia_1} & 0 \\ & \ddots & \\ 0 & e^{ia_N} \end{pmatrix}.$$
 (4.12)

Since the transformed matrix P' must be Hermite, the parameters are constrained to $a_i = n_i \pi$ $(i = 1, 2, ..., N; n_i \in \mathbb{Z})$. Thus, the transformation of P is written as

$$P' = \tilde{I}P, \tag{4.13}$$

where \tilde{I} is a diagonal matrix with components +1 or -1. It means that the sign of the components of P_0 (P_1) can be freely flipped while P_1 (P_0) remains fixed. As a result, all of the diagonal sets [p, q, r, s] are connected by the commutative gauge transformations with kink parameters.

5 Conclusions

We have classified equivalence classes (ECs) of the boundary conditions (BCs) in U(N)gauge theories on S^1/Z_2 brane-world models, where the BCs can be independently chosen on the branes and the bulk. The diagonal BCs cannot be connected by the global gauge transformations with constant parameters, but the equivalent relations (4.1) have been produced on the UV-brane by the anti-commutative type gauge transformations with coordinate-dependent parameters. We have proven that there is no connection except for (4.1) on the UV-brane by using not specific but general transformation parameters. Also, it has been shown that all the diagonal BCs can be connected on the bulk and the IR-brane by the commutative type gauge transformations with a kink at the fixed points. Therefore, we conclude that the arbitrariness of BCs is solved on the bulk and the IR-brane in this model. We expect that this work will be useful for completely solving the arbitrariness problem of BCs in extra-dimensional models on compact space. The different ECs on the UV-brane could be related by using the fact that all the BCs are connected on the bulk and the IR-brane.

A new problem emerges through this study: How should we define the physical observable on the bulk and IR-brane? The fact that all BCs are connected means that the physical mass spectra of the fields are independent of the BCs. The physical equivalence between the BCs in one EC has been verified by the combination of BCs and dynamical Wilson line phases based on Hosotani mechanism [27–29]. However, this statement is not valid for the commutative type gauge transformations with a kink. We hope that the study of how the Hosotani mechanism works in this model might lead to a solution to the arbitrariness problem. We will continue our work and hope to report on this problem.

Acknowledgment

The authors would like to thank Kouki Nakamura and Reishi Maeta for useful discussions. We are indebted to members of our laboratory for encouragements.
