# Training Dynamics of Multi-Head Softmax Attention for In-Context Learning: Emergence, Convergence, and Optimality 

Siyu Chen Heejune Sheen Tianhao Wang Zhuoran Yang<br>Department of Statistics and Data Science, Yale University<br>\{siyu.chen.sc3226, heejune.sheen, tianhao.wang, zhuoran.yang\}@yale.edu

#### Abstract

We study the dynamics of gradient flow for training a multi-head softmax attention model for in-context learning of multi-task linear regression. We establish the global convergence of gradient flow under suitable choices of initialization. In addition, we prove that an interesting "task allocation" phenomenon emerges during the gradient flow dynamics, where each attention head focuses on solving a single task of the multi-task model. Specifically, we prove that the gradient flow dynamics can be split into three phases - a warm-up phase where the loss decreases rather slowly and the attention heads gradually build up their inclination towards individual tasks, an emergence phase where each head selects a single task and the loss rapidly decreases, and a convergence phase where the attention parameters converge to a limit. Furthermore, we prove the optimality of gradient flow in the sense that the limiting model learned by gradient flow is on par with the best possible multi-head softmax attention model up to a constant factor. Our analysis also delineates a strict separation in terms of the prediction accuracy of ICL between single-head and multi-head attention models. The key technique for our convergence analysis is to map the gradient flow dynamics in the parameter space to a set of ordinary differential equations in the spectral domain, where the relative magnitudes of the semi-singular values of the attention weights determines task allocation. To our best knowledge, our work provides the first convergence result for the multi-head softmax attention model.

## 1 Introduction

The transformer architecture (Vaswani et al., 2017) is the backbone of many foundational models in artificial intelligence (AI), demonstrating striking empirical success in domains including natural language processing (Devlin et al., 2018), computer vision (Dosovitskiy et al., 2020), and reinforcement learning (Chen et al., 2021). At a high level, a transformer is a sequence-to-sequence model that processes an input sequence of tokens and produces an output sequence of tokens. An autoregressive transformer generates the output in an autoregressive manner, i.e., each new token is generated by taking all previously generated tokens as the input of the transformer model. Autoregressive transformer architecture has emerged as the mainstream paradigm of large language

[^0]models (LLMs), with examples such as GPT (Radford et al., 2019; Brown et al., 2020; Achiam et al., 2023), Claude (Anthropic, 2023), and Gemini (Team et al., 2023).

These LLMs are trained on internet-scale data across a wide range of topics and languages. A distinguishing feature of these models is their ability to learn from a few demonstrations of a new task that does appear in the training data, a phenomenon known as In-Context Learning (ICL) (Brown et al., 2020). That is, without updating the model parameters, by feeding a few inputoutput examples of a task and querying a new input, LLMs are able to give the correct output. The ICL ability serves as the foundation for building more sophisticated prompting methods that uses LLMs for solving complicated problems (Huang and Chang, 2022).

While the ICL capability of transformers has been empirically demonstrated and applied, theoretical understanding of this phenomenon is still in its infancy. In particular, we lack a comprehensive understanding of a key component of the transformer architecture, the attention mechanism (Vaswani et al., 2017), and how it is related to the ICL ability. In the attention mechanism, multiple attention heads attend to tokens in the input sequence by assigning attention weights and aggregates the values according to the weights from all tokens to form the output features. These attention weights are probabilities given by a softmax function and thus the resulting model is referred to as Multi-head Softmax Attention (MS-Attn). Existing works have investigated how single-head attention-based models can be trained for ICL (Zhang et al., 2023a; Huang et al., 2023; Kim and Suzuki, 2024), but the multi-head case is still under-explored, though it has been observed that multi-head attention outperforms single-head attention for ICL (Cui et al., 2024; Xing et al., 2024).

In this work, we aim to make a step towards understanding the role MS-Attn played in the emergence of ICL ability. To this end, we focus on a simple but fundamental setting where transformer is a one-layer multi-head softmax attention model trained for the ICL task of multi-task linear regression. In particular, the MS-Attn model is asked to see $L$ covariate-response examples, $\left\{x_{l}, y_{l}\right\}_{l \in[L]}$, sampled from a randomly sampled noisy multi-task linear regression problem, i.e., $y_{l}=G^{\top} x_{l}+\varepsilon_{l}$, and predict the regression target $G^{\top} q$ of a new covariate $q$, referred to as a query. Here, $G \in \mathbb{R}^{d_{y} \times d}$ is a random matrix sampled randomly from a distribution and $\varepsilon_{l}$ is a random noise. Moreover, we further assume that $G$ admits a multi-task structure in the sense that it can be transformed by two fixed orthogonal matrices $\Phi$ and $\Psi$ into a block diagonal matrix, where each block corresponds to the signal of an individual task. In other words, upon orthogonal transformations, the multi-task linear regression is reduced to a set of independent linear models. We are considering sufficiently large $L$ and $d$ while the dimension-to-sequence length ratio $d / L=\Theta(1)$. To perform ICL, the MS-Attn model is first trained on a variety of randomly sampled instances of multi-task ICL data and then evaluated on a random new instance.

To understand how the attention mechanism enables the ICL ability, we delve into the gradient flow dynamics of training the MS-Attn model at a population level. This corresponds to the setting where the number of instances of multi-task task linear regression goes to infinity. Under such a setting, we aim to address the following questions:
(a) Does gradient flow dynamics of ICL on multi-task linear data converge to a limit?
(b) Does the learned MS-Attn model exhibit ICL ability with high prediction accuracy?
(c) Does the multi-head structure offer any advantage over the single-head version?

We provide affirmative answers to all these three questions. In particular, using a symmetric initialization scheme where the key and query weights are the same, we prove that the gradient flow
with respect to the population loss converges to a limit. In addition, we characterize the prediction error of the limiting MS-Attn model explicitly in terms of the signal-to-noise ratio of the linear model and the the ratio $d / L$ under certain condition, e.g., both $d$ and $L$ are large. Moreover, such an error decays to zero when $d / L$ decreases. We also characterize the minimal error attained by the class of MS-Attn models and prove that the model founded by gradient flow is on par with the best model up to a constant factor. Finally, we demonstrate the superiority of multi-head structure in two aspects. First, the multi-head structure exhibits a "task allocation" phenomenon, where each attention head focuses on solving an individual and non-overlapping task. Second, there exists a strict separation between single-head and multi-head models. In particular, the minimal prediction error achieved by the best single-head model is strictly larger than that of the MS-Attn model learned by gradient flow by a factor of $H$, where $H$ represents the number of heads.

Main Contributions. Our main contributions are summarized as follows:

1. First, we establish the convergence of gradient flow for a one-layer multi-head softmax attention model for ICL (Theorem 3.3). A key technical ingredient is to reduce the gradient flow dynamics in the parameter space to the corresponding spectral dynamics in the eigenspace of the data features, which allows a more tractable analysis (Lemma 3.2). Our analysis captures also fine-grained properties of the dynamics like the phase transition behavior that leads to the sudden emergence of ICL ability.
2. We prove that the convergence point of gradient flow admits the following properties: each attention head focuses on solving an individual task without cross-head interference and acts as the optimal single-head attention model for that task (Lemma 4.1 and Theorem 4.2). In addition, we show that the model found by gradient flow achieves minimal ICL loss up to a constant factor when the number of heads matches the number of tasks (Theorem 4.4).
3. We show that the multi-head model strictly outperforms the single-head model by a factor of $H$ when the number of tasks matches the number of heads. This is demonstrated by comparing the multi-head model found by the gradient flow to the optimal single-head model in terms of the ICL loss.
4. As a byproduct, we identify an interesting "attention allocation" phenomenon for a singlehead softmax attention head to optimally solve multiple tasks (Theorem 4.2). As an extension, we make a comparison between linear and softmax attention in Section 5. Moreover, we show that the model learned by gradient flow generalizes to new data with sequence lengths differing from the training data, while we also characterize its limitation in solving nonlinear tasks.

To our best knowledge, our work is the first to provide a comprehensive analysis of the training dynamics of a single-layer multi-head softmax attention model and the properties of the model trained by gradient flow. Our analysis characterizes, in a unified manner, the rich interplay between different design aspects of the attention mechanism and ICL task-specific properties.

### 1.1 Our Approach: Tracking the Spectral Dynamics

The analysis of the dynamics is challenging due to the symmetries of the loss landscape (see related discussion in $\S 1.2$ ), as well as the nonlinearity introduced by the softmax operation.

Figure 1: Illustration of the training loss and dynamics of the weights of the MS-Attn. The dynamics undergo three phases: warm-up, emergence, and convergence. Here, we set $H=3$ heads, $I=3$ homogeneous tasks with signal strength $\lambda=1$ and no noise, dimension $d=30$ and context sequence length $L=100$. The top two plots show the dynamics of the eigenvalues of two combined weight matrices, $\bar{\omega}^{(h)}$ for $W_{X}^{(h)}$ and $\mu^{(h)}$ for $U_{Y}^{(h)}$ for all $h \in[H]$. The third plot shows the training loss and the last plot shows the value of $\bar{\omega}_{i}^{(h)}$ upon convergence. Here, the optimal head for task $i$ is $h_{i}^{\star}=i$ for $i \in[I]$ by initialization.

1. We address the first challenge by properly aligning the eigenspaces of the weight matrices with those of the context data features under the condition of Decomposable Weights (Definition 3.1). This gives rise to a crucial simplification that allows us to track the spectral dynamics of the attention weights and output weights during the training process.
2. To address the second challenge, we perform careful moment analyses on the attention probability vectors produced by the softmax operation. Based on this, we control the nonlinear effects and prune higher-order terms to extract the key factors driving the learning process. This is essential for both the dynamic analysis and the establishment of optimality bounds.

Combining these two ingredients paves the way for understanding the attention layer's behavior both during the training process and at the convergence point. The following informal theorem summarizes our main result on the dynamics of the multi-head attention model.

Theorem 1.1 (Gradient flow for MS-Attn, informal). Under proper initialization (also satisfying Definition 3.1) of the gradient flow, assume that the number of heads is larger than the number of
tasks, then the following holds:
(i) (Warm-up) There exists a threshold time $T_{0}>0$, before which the loss value decreases slowly, and each attention head gradually adjusts its weights to select one individual task.
(ii) (Emergence) For a brief period around $T_{0}$, the loss undergoes a sudden decrease, each attention head rapidly becomes focused on a single task, and cross-head interference vanishes.
(iii) (Convergence) Finally, gradient flow converges to a point where each task is predominantly handled by a single attention head, in the sense that the output from this head dominates the output of the entire model for this task.

In complement to the dynamics analysis, we further study the optimality property of the convergence point of gradient flow.
(i) We first consider using a single-head softmax attention model to optimally solve multi-task linear regression. We show the lower bound of the optimal ICL loss and construct a group of attention weights to achieve the lower bound. When specialized to a single task, we directly conclude that the optimal attention weights are indeed the same as the convergence point of the gradient flow dynamics. The challenge here is the nonconvexity of the landscape induced by the softmax function, and our main approach is to find the optimal working regime of the softmax attention and derive a good nonlinear approximation to the attention's behavior in this regime. As a byproduct, we also show that the optimal attention weights are decomposable in the sense of Definition 3.1, which justifies our simplification of the gradient flow dynamics to the spectral dynamics.
(ii) For the multi-head case, we consider a subclass of the MS-Attn model bearing a certain symmetric structure called the equiangular weights (Definition 4.3). Under task homogeneity, i.e., all tasks having the same Signal-to-Noise Ratio (SNR) and dimension, we show using a similar technique that the convergence point of the gradient flow is indeed optimal. The analysis demonstrates an additional characterization of the cross-head interference compared with the single-head case.

Organization of the paper. The rest of the paper is organized as follows: We finish the introduction by discussing related works. In Section 2, we introduce the one-layer multi-head softmax attention model and the ICL setting of multi-task linear regression. In Section 3, we present gradient flow dynamics and characterize the emergence and convergence behavior of the attention weights during the training process. In Section 4, we investigate the optimality of the trained model. In Section 5, we discuss extensions of our main results. Detailed proofs and auxiliary results are deferred to the appendix.

### 1.2 Related Work

We briefly review additional related work on ICL and learning properties of transformers in other settings. First, as suggested by empirical evidence, various explicit weight constructions have been proposed to show that transformers can do ICL by emulating specific algorithms such as gradient descent and its variants (Akyürek et al., 2023; Von Oswald et al., 2023; Bai et al., 2023; Fu et al., 2023). It is further theoretically verified via landscape analysis that the global minimizer (or certain
critical points) of the ICL loss corresponds to certain adaptive version of gradient descent (Ahn et al., 2023; Mahankali et al., 2023). Moreover, convergence analyses have also been proposed by Zhang et al. (2023a); Huang et al. (2023); Kim and Suzuki (2024); Nichani et al. (2024) under different model and data assumptions. Nonetheless, these convergence analyses are tailored to single-head attention models and require simplifications of the model such as combining the key and query matrices into a single weight matrix. Though not changing the model's expressiveness, such simplifications make the loss landscape more amenable to analysis by removing the rotational symmetry of the attention weights ${ }^{1}$. Also note that the permutation symmetry between multiple heads further complicates the loss landscape, and so far there is no convergence analysis for multihead attention models for ICL.

The statistical complexity of transformers for ICL of linear functions has been characterized by Wu et al. (2023), and Cheng et al. (2023); Guo et al. (2023); Collins et al. (2024) investigated ICL beyond the simple linear functions. In particular, Collins et al. (2024); Edelman et al. (2024); Makkuva et al. (2024) studied the ICL capability of transformers when data is drawn from Markov chains. There are also works explaining how transformers perform in-context learning from the Bayesian perspective (Xie et al., 2021; Muller et al., 2021; Zhang et al., 2022, 2023b; Ahuja et al., 2023; Jeon et al., 2024). Transformers' capability of in-context decision making has been explored by Lin et al. (2023); Sinii et al. (2023). See also Li et al. (2023a); Dai et al. (2022); Raventós et al. (2023) for other related results on ICL. Existing works have also studied the use of multiple attention heads from different perspectives (An et al., 2020; Mahdavi et al., 2023). Beyond the case of ICL, there have been recent advances in understanding the learning properties of transformers in other settings (Edelman et al., 2022; Li et al., 2023b; Jelassi et al., 2022; Sanford et al., 2023; Giannou et al., 2023; Liu et al., 2022; Tarzanagh et al., 2023a,b; Tian et al., 2023b,a; Song and Zhong, 2023; Deora et al., 2023; Chen and Li, 2024). We do not discuss these works in detail here since they are out of the scope of the current paper.

## 2 Preliminaries

We first introduce the notation conventions used throughout the paper. We use uppercase letters like $A$ and $B$ to denote matrices and lowercase letters like $u$ and $v$ for column vectors. For any positive integer $n$, we denote $[n]:=\{1, \ldots, n\}$. We denote by $\operatorname{span}(M)$ the column space of matrix $M$. For two matrices $A$ and $B$ (not necessarily squared), we write $A \simeq B$ if they share the same singular vector spaces, i.e., $A=U \Sigma V^{\top}$ and $B=U \Lambda V^{\top}$ for some orthogonal matrices $U$ and $V$ and diagonal matrices $\Sigma$ and $\Lambda$. For any vector $v \in \mathbb{R}^{d}$, we define the softmax operation as $\operatorname{softmax}(v):=\left(e^{v_{1}} / \sum_{i=1}^{d} e^{v_{i}}, \ldots, e^{v_{d}} / \sum_{i=1}^{d} e^{v_{i}}\right)^{\top}$. We denote by $\odot$ the element-wise Hadamard product. Let $\mathbb{N}$ be the set of non-negative integers.

Next, we introduce the one-layer multi-head softmax attention model in Section 2.1 and the multi-task linear regression problem for ICL in Section 2.2.

### 2.1 One-Layer Multi-Head Softmax Attention Model

We consider a MS-Attn model with $H$ attention heads and context length $L$, defined as follows: Let $D$ be the input dimension, $d_{y}$ be the output dimension, and $d_{e}$ be the embedding dimension. Throughout the paper, we assume $d_{e} \geq d$, where $d=D-d_{y}$. For each attention head $h \in[H]$, let

[^1]$O^{(h)} \in \mathbb{R}^{d_{y} \times d_{e}}$ and $V^{(h)}, K^{(h)}, Q^{(h)} \in \mathbb{R}^{d_{e} \times D}$ be the output projection, value, key, and query weights, respectively. We let $\Theta=\left\{O^{(h)}, V^{(h)}, K^{(h)}, Q^{(h)}\right\}_{h \in[H]}$ denote the parameters of the MS-Attn model. Then given an input matrix $Z \in \mathbb{R}^{D \times L}$ and a query vector $z_{q} \in \mathbb{R}^{D}$, the output $\widehat{y}_{q}$ of MS-Attn is
\[

$$
\begin{equation*}
\widehat{y}_{q}=\operatorname{MS-Attn}\left(Z, z_{q} ; \Theta\right):=\sum_{h=1}^{H} O^{(h)} V^{(h)} Z \cdot \operatorname{softmax}\left(\frac{Z^{\top} K^{(h)^{\top}} Q^{(h)} z_{q}}{\sqrt{d_{e}}}\right) \in \mathbb{R}^{d_{y}} \tag{2.1}
\end{equation*}
$$

\]

Following from (2.1), given the parameter $\Theta$, for each head $h \in[H]$, we define the attention score vector $s^{(h)} \in \mathbb{R}^{L}$ and the corresponding attention probability vector $p^{(h)} \in \mathbb{R}^{L}$ as

$$
\begin{equation*}
s^{(h)}=\frac{Z^{\top} K^{(h)^{\top}} Q^{(h)} z_{q}}{\sqrt{d_{e}}} \in \mathbb{R}^{L}, \quad p^{(h)}=\operatorname{softmax}\left(s^{(h)}\right) \in \mathbb{R}^{L} \tag{2.2}
\end{equation*}
$$

Intuitively, $s^{(h)}$ measures the similarity between the query vector and each column of $Z$, and $p^{(h)}$ is the probability distribution over $[L]$ that is induced by $s^{(h)}$. Such a distribution is used to weight the value head $V^{(h)} Z \in \mathbb{R}^{d_{e} \times L}$ to get a vector $V^{(h)} Z p^{(h)}$ that lies in the embedded space $\mathbb{R}^{d_{e}}$. The output $\widehat{y}_{q}$ is obtained by mapping such an embedding to the output space $\mathbb{R}^{d_{y}}$ by a linear map $O^{(h)}$. That is, we can equivalently write (2.1) as $\widehat{y}_{q}=\sum_{h=1}^{H} O^{(h)} V^{(h)} Z p^{(h)}$. To further simplify the notation, we define the combined output weight $U^{(h)} \in \mathbb{R}^{d_{y} \times D}$ and attention weight $W^{(h)} \in \mathbb{R}^{D \times D}$ :

$$
\begin{equation*}
U^{(h)}:=O^{(h)} V^{(h)}, \quad W^{(h)}:=\frac{K^{(h) \top} Q^{(h)}}{\sqrt{d_{e}}} \quad \text { for each } h \in[H] \tag{2.3}
\end{equation*}
$$

Throughout the paper, we will consider the query vector $z_{q}$ with the last $d_{y}$ coordinates being zero, i.e., $z_{q}=\left[q^{\top}, 0, \ldots, 0\right]^{\top}$ where $q \in \mathbb{R}^{d}$. The output $\widehat{y}_{q}$ can be viewed as the lower right $d_{y} \times 1$ block of the output of the standard multi-head softmax attention architecture with input matrix $\left[Z, z_{q}\right] \in \mathbb{R}^{D \times(L+1)}$. We remark that the residual connection is omitted in $(2.1)$ since it does not affect the output, and we do not consider any attention mask as there is only one single layer.

### 2.2 In-Context Learning of Multi-Task Linear Regression

We consider a data structure where each input token comprises a covariate with dimension $d$ and a label with dimension $d_{y}$ such that $D=d+d_{y}$. The inputted $Z$ and $z_{q}$ can be decomposed as

$$
Z=\left[\begin{array}{ll}
x_{1} & x_{2} \cdots \cdots x_{L} \\
y_{1} & y_{2} \cdots \cdots
\end{array}\right], \quad y_{L}\left[\begin{array}{c} 
\\
y_{q}
\end{array}\right]\left[\begin{array}{c}
q \\
0
\end{array}\right]
$$

Such input format is standard in recent literature about Transformers and ICL (Garg et al., 2022; Akyürek et al., 2023; Von Oswald et al., 2023; Ahn et al., 2023; Zhang et al., 2023a), but we remark that here we allow $d_{y}>1$, in contrast to the single-task case where $d_{y}=1$ considered in previous works. In the sequel, we denote by $X=\left[x_{1}, \ldots, x_{L}\right] \in \mathbb{R}^{d \times L}$ and $Y=\left[y_{1}, \ldots, y_{L}\right] \in \mathbb{R}^{d_{y} \times L}$. For the ICL, we consider a multi-task linear regression task described by the following data assumption.

Assumption 2.1 (Multi-Task ICL Data). Every in-context sample $\left(Z, z_{q}\right)$ is independently sampled according to the distribution described as follows: First, we assume the covariate vectors and the query vector to be distributed as $x_{1}, \ldots, x_{L} \stackrel{\text { i.i.d. }}{\sim} \mathcal{N}\left(0, I_{d}\right)$ and $q \sim \mathcal{N}\left(0, I_{d}\right)$. Next, for a random coefficient matrix $G \in \mathbb{R}^{d \times d_{y}}$, each response vector is given by $y_{l}=G^{\top} x_{l}+\varepsilon_{l}$ for $l \in[L]$ where
the noise $\varepsilon_{1}, \ldots, \varepsilon_{L} \stackrel{\text { i.i.d. }}{\sim} \mathcal{N}\left(0, \sigma^{2} I_{d_{y}}\right)$. Note that the coefficient matrix $G$ is shared within the context sequence $Z$. Then the goal is to predict the true response vector $y_{q}=G^{\top} q$ given the context $Z$ and the query $z_{q}$. To this end, we assume $G$ to be independent of both the covariate vectors $\left\{x_{l}\right\}_{l=1}^{L}$ and the noise $\left\{\varepsilon_{l}\right\}_{l=1}^{L}$, and moreover, we assume that $G$ admits a multi-task structure:

$$
G=d^{-1 / 2} \cdot \Phi \cdot\left[\begin{array}{cccc}
g_{1} & 0 & \cdots & 0  \tag{2.4}\\
0 & g_{2} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & g_{I}
\end{array}\right] \cdot \Psi^{\top},
$$

where $\Phi \in \mathbb{R}^{d \times d}$ and $\Psi \in \mathbb{R}^{d_{y} \times d_{y}}$ are two fixed orthogonal matrices, and corresponding to each task $i \in[I]$, the random vector $g_{i} \in \mathbb{R}^{d_{i}}$ with dimension $d_{i}$ satisfies $\mathbb{E}\left[g_{i}\right]=0$ and $\operatorname{Cov}\left[g_{i}\right]=\lambda_{i} I_{d_{i}}$ with $\lambda_{i}$ being the signal strength for each task $i \in[I]$. Here, we restrict $I=d_{y}$ for simplicity. In addition, $d^{-1 / 2}$ is the normalization factor which ensures that $\mathbb{E}\left[\left\|y_{q}\right\|_{2}^{2}\right]=1$.

The above decomposition of $G$ breaks down the ICL problem into $I$ components, and inferring the correct response requires simultaneously estimating all $I$ tasks. Note that we allow $G$ to be supported within some subspace. Here we only consider cross-task differences while assuming homogeneous signal strength within each task for ease of analysis. We define the single sample Signal-to-Noise Ratio (SNR) for task $i$ as $\mathrm{SNR}_{i}:=\lambda_{i} d_{i} /\left(d \sigma^{2}\right)$, and also $\phi_{i}:=1+\mathrm{SNR}_{i}^{-1}$. We define $\mathcal{J}_{i}=\left\{d_{1}+\cdots+d_{i-1}+1, \cdots, d_{1}+\cdots+d_{i}\right\}$ as the set of indices for task $i$. Then $\left\{\mathcal{J}_{i}\right\}_{i \in[I]}$ forms a partition of $[d]$. Throughout the paper, we consider sufficiently large context length $L$ and dimension $d$, and we assume that the ratios $d / L=\Theta(1)$ and $d_{i} / d=\Theta(1)$ for all $i \in[I]$.

Assumption 2.2. For a constant $C>0$, it holds that $d / L \in(C, 1 / C)$ and $d_{i} / d>C$ for all $i \in[I]$.
Before we proceed, we first introduce $V_{X}^{(h)}, K_{X}^{(h)}, Q_{X}^{(h)} \in \mathbb{R}^{d_{e} \times d}$ and $V_{Y}^{(h)}, K_{Y}^{(h)}, Q_{Y}^{(h)} \in \mathbb{R}^{d_{e} \times d_{y}}$ as the splits of $V^{(h)}, K^{(h)}, Q^{(h)}$ with respect to the $X$ and $Y$ parts as shown in Figure 2. We split the combined output weights by writing $U_{X}^{(h)}=O^{(h)} V_{X}^{(h)}$ as the left $d_{y} \times d$ block and $U_{Y}^{(h)}=O^{(h)} V_{Y}^{(h)}$ as the right $d_{y} \times d_{y}$ block of $U^{(h)}$, respectively. We also split the combined attention weights by packing $W_{X}^{(h)}=K_{X}^{(h)^{\top}} Q_{X}^{(h)} / \sqrt{d_{e}}$ as the top left $d \times d$ block and $W_{Y}^{(h)}=K_{Y}^{(h)^{\top}} Q_{X}^{(h)} / \sqrt{d_{e}}$ as the bottom left $d_{y} \times d$ block of $W^{(h)}$.

$$
U^{(h)}=\left[\begin{array}{cc}
U_{X}^{(h)} & U_{Y}^{(h)}
\end{array}\right], \quad W^{(h)}=\left[\begin{array}{cc}
W_{X}^{(h)} & \star  \tag{2.5}\\
W_{Y}^{(h)} & \star
\end{array}\right] .
$$

The splitting described above is visualized in Figure 2.
Gradient Flow. We consider a pretraining process with gradient flow on the parameters $\Theta=$ $\left\{O^{(h)}, V^{(h)}, K^{(h)}, Q^{(h)}\right\}_{h \in[H]}$ to minimize the following population mean-squared error:

$$
\begin{equation*}
\mathcal{L}(\Theta)=\mathbb{E}\left[\ell\left(\widehat{y}_{q}, y_{q}\right)\right], \quad \text { where } \quad \ell\left(\widehat{y}_{q}, y_{q}\right)=\left\|\widehat{y}_{q}-y_{q}\right\|_{2}^{2} / 2, \tag{2.6}
\end{equation*}
$$

and the expectation is taken over the distribution over $\left(Z, z_{q}\right)$ in Assumption 2.1. With the parameterization of the MS-Attn in (2.1) and the loss function in (2.6), one can derive the gradient flow dynamics for parameters $\Theta=\left\{O^{(h)}, V^{(h)}, K^{(h)}, Q^{(h)}\right\}_{h \in[H]}$ by moving $\Theta$ along the direction of

Figure 2: Illustration of the MS-Attn with $H$ heads, embedding dimension $d_{e}$, and sequence length $L$. Weights $\left(V^{(h)}, K^{(h)}, Q^{(h)}\right)$ can be split into the $X$ and $Y$ parts. The combined weights $\left(U^{(h)}, W^{(h)}\right)$ are also split into $\left(U_{X}^{(h)}, U_{Y}^{(h)}\right)$ and $\left(W_{X}^{(h)}, W_{Y}^{(h)}\right)$. Under the decomposability assumption $\left(W_{Y}^{(h)}=0, U_{X}^{(h)}=0\right)$, the attention scores only depend on the $X$ part, and the output is an aggregation of the $Y$ part. Although we introduce the concept of combined weights, it is important to note that the gradient flow operates on the individual weights.
the negative gradient of the mean squared loss, i.e., $\partial_{t} \Theta=-\nabla_{\Theta} \mathcal{L}(\Theta)$. By a direct calculation, we have the following dynamics ${ }^{2}$ :

$$
\begin{array}{cc}
\partial_{t} O^{(h)}=-B^{(h)} V^{(h)^{\top}}, & \partial_{t} V^{(h)}=-O^{(h)^{\top}} B^{(h)},  \tag{2.7}\\
\partial_{t} K^{(h)}=-d_{e}^{-1 / 2} Q^{(h)} A^{(h)^{\top}}, & \partial_{t} Q^{(h)}=-d_{e}^{-1 / 2} K^{(h)} A^{(h)},
\end{array}
$$

where $A^{(h)} \in \mathbb{R}^{D \times D}$ and $B^{(h)} \in \mathbb{R}^{d_{y} \times D}$ are defined respectively as

$$
\begin{align*}
A^{(h)} & =\mathbb{E}\left[Z P^{(h)^{\top}} Z^{\top} U^{(h)^{\top}}\left(\sum_{h^{\prime}=1}^{H} U^{\left(h^{\prime}\right)} Z p^{\left(h^{\prime}\right)}-y_{q}\right) z_{q}^{\top}\right],  \tag{2.8}\\
B^{(h)} & =\mathbb{E}\left[\left(\sum_{h^{\prime}=1}^{H} U^{\left(h^{\prime}\right)} Z p^{\left(h^{\prime}\right)}-y_{q}\right) p^{(h)^{\top}} Z^{\top}\right], \tag{2.9}
\end{align*}
$$

where we have an $L \times L$ matrix $\left(P^{(h)}\right)_{l, m}=\partial p_{l}^{(h)} / \partial s_{m}^{(h)}$ and in the case of softmax attention, it takes the form of $P^{(h)}=\operatorname{diag}\left(p^{(h)}\right)-p^{(h)} p^{(h)^{\top}}$.

## 3 Dynamics of Gradient Flow: Emergence and Convergence

In this section, we present our main results on the gradient flow dynamics, stated previously in the informal Theorem 1.1. We first introduce in Section 3.1 the specific set of weights that we will consider. Then we describe the analysis and state the full results in Section 3.2.

[^2]
### 3.1 Decomposable Weights

We introduce the concept of decomposable weights, a key property that will be preserved along gradient flow and will be used for analyzing the induced dynamics in the eigenvalue space.
Definition 3.1. For orthogonal matrices $\Phi \in \mathbb{R}^{d \times d}$ and $\Psi \in \mathbb{R}^{d_{y} \times d_{y}}$, we say the weights of the $M S-A t t n$ are decomposable with respect to $(\Phi, \Psi)$ if for all $h \in[H]$, the following three conditions hold:
(i) (Orthogonality) For the matrices $U^{(h)}$ and $W^{(h)}$ defined in (2.5), we have $U_{X}^{(h)}=W_{Y}^{(h)}=0$. Moreover, the column subspaces (of $\mathbb{R}^{d_{e}}$ ) spanned by $K_{X}^{(h)}$ and $K_{Y}^{(h)}$ are orthogonal, and the column spaces spanned by $V_{X}^{(h)}$ and $V_{Y}^{(h)}$ are orthogonal. That is, $\operatorname{span}\left(K_{X}^{(h)}\right) \perp \operatorname{span}\left(K_{Y}^{(h)}\right)$, and $\operatorname{span}\left(V_{X}^{(h)}\right) \perp \operatorname{span}\left(V_{Y}^{(h)}\right)$.
(ii) (Simultaneous Diagonolizability) We have $K_{X}^{(h)} \simeq Q_{X}^{(h)}$ with the same right eigenvector matrix $\Phi$ and $V_{Y}^{(h)} \simeq O^{(h) \top}$ with the same right eigenvector matrix $\Psi$. That is, there exists an orthogonal matrix $M \in \mathbb{R}^{d_{e} \times d_{e}}$ such that

$$
M^{\top} K_{X}^{(h)} \Phi=\operatorname{diag}\left(\sigma\left(K_{X}^{(h)}\right)\right), \quad M^{\top} Q_{X}^{(h)} \Phi=\operatorname{diag}\left(\sigma\left(Q_{X}^{(h)}\right)\right) .
$$

Here $\sigma\left(K_{X}^{(h)}\right), \sigma\left(Q_{X}^{(h)}\right) \in \mathbb{R}^{d}$ are the d semi-singular values ${ }^{3}$ of $K_{X}^{(h)}$ and $Q_{X}^{(h)}$ respectively, and we let $\operatorname{diag}\left(\sigma\left(K_{X}^{(h)}\right)\right)$ to denote the diagonal matrix in $\mathbb{R}^{d_{e} \times d}$ whose $(j, j)$-th entry is given by $\sigma\left(K_{X}^{(h)}\right)_{j}$, the $j$-th entry of $\sigma\left(K_{X}^{(h)}\right), \forall j \in[d]$. We define $\operatorname{diag}\left(\sigma\left(Q_{X}^{(h)}\right)\right)$ similarly. Besides, there exists an orthogonal matrix $N \in \mathbb{R}^{d_{e} \times d_{e}}$ such that

$$
N^{\top} V_{Y}^{(h)} \Psi=\operatorname{diag}\left(\sigma\left(V_{Y}^{(h)}\right)\right), \quad N^{\top} O^{(h)^{\top}} \Psi=\operatorname{diag}\left(\sigma\left(O^{(h)}\right)\right),
$$

where $\sigma\left(V_{Y}^{(h)}\right), \sigma\left(O^{(h)}\right) \in \mathbb{R}^{d_{y}}$ are the $d_{y}$ semi-singular values of $V_{Y}^{(h)}$ and $O^{(h)}$ respectively. Here $\operatorname{diag}\left(\sigma\left(V_{Y}^{(h)}\right)\right)$ and $\operatorname{diag}\left(\sigma\left(O^{(h)}\right)\right)$ are diagonal matrices in $\mathbb{R}^{d_{e} \times d_{y}}$ defined similarly.
(iii) (Task-wise Homogeneity) Note that $\sigma\left(K_{X}^{(h)}\right)$ and $\sigma\left(Q_{X}^{(h)}\right)$ are vectors in $\mathbb{R}^{d}$ and that $[d]$ is partitioned into I disjoint sets $\mathcal{J}_{1}, \ldots, \mathcal{J}_{I}$. We require that the semi-singular values are the same within each task. That is, if $j, j^{\prime} \in \mathcal{J}_{i}$ for a same task $i$, then we have

$$
\sigma\left(Q_{X}^{(h)}\right)_{j}=\sigma\left(Q_{X}^{(h)}\right)_{j^{\prime}}, \quad \sigma\left(K_{X}^{(h)}\right)_{j}=\sigma\left(K_{X}^{(h)}\right)_{j^{\prime}} .
$$

Definition 3.1(i) asserts that $U_{X}^{(h)}$ and $W_{Y}^{(h)}$ are zero. By (2.1) and (2.2), since the attention scores are computed by $X^{\top} W_{X} q$ and the output is given by $U_{Y} Y q$, this condition implies that the attention probability is only a function of the covariate and the query, and the output is just an aggregation of $Y$. This property further implies that the attention probability is independent of the noise $\epsilon$ and the coefficient $G$, which enables us to simplify gradient flow dynamics. Moreover, Definition 3.1(i) requires that the column spaces spanned by $K_{X}^{(h)}$ and $K_{Y}^{(h)}$ are orthogonal. Similar property holds for $V_{X}^{(h)}$ and $V_{Y}^{(h)}$. As we will see in Appendix C.3, orthogonality of these subspaces ensures that $U_{X}^{(h)}$ and $W_{Y}^{(h)}$ remains zero through the course of gradient flow dynamics.

[^3]In addition, Definition 3.1(ii) suggests that the split weight matrices are simultaneously diagonalizable and that the right eigenvectors are aligned with task-specific directions given by $(\Phi, \Psi)$. In particular, let

$$
\begin{equation*}
\omega^{(h)}=\sigma\left(K_{X}^{(h)}\right) \odot \sigma\left(Q_{X}^{(h)}\right), \quad \mu^{(h)}=\sigma\left(O^{(h)}\right) \odot \sigma\left(V_{Y}^{(h)}\right), \tag{3.1}
\end{equation*}
$$

which are vectors in $\mathbb{R}^{d}$ and $\mathbb{R}^{d_{y}}$ respectively. Then we have $W_{X}^{(h)}=\Phi \operatorname{diag}\left(\omega^{(h)}\right) \Phi^{\top}$ and $U_{Y}^{(h)}=$ $\Psi \operatorname{diag}\left(\mu^{(h)}\right) \Psi^{\top}$. That is, $W_{X}^{(h)}$ and $U_{Y}^{(h)}$ are symmetric matrices and can be diagonalized by $\Phi$ and $\Psi$ respectively, and the eigenvalues are given by $\omega^{(h)}$ and $\mu^{(h)}$ respectively.

Furthermore, Definition 3.1(iii) is a natural assumption given that within task $i$ 's support $\mathcal{J}_{i}$, both $g_{i}$ and $X_{(i)}$ are isotropic random vectors under our data model. That is, the mean is zero and covariance is proportional to the identity matrix. This condition implies that $\omega^{(h)}$ defined in (3.1) should also satisfy the same structure. Here, $X_{(i)}$ is the submatrix of $X$ containing only the rows corresponding to task $i$ 's support $\mathcal{J}_{i}$.

Finally, we remark that the family of decomposable weights seems a bit restrictive. Nevertheless, we will justify this restriction by showing that the minimal ICL loss is approximately attained by decomposable weights in Section 4 (see the discussion below Theorem 4.2). Notably, letting $Q_{X}^{(h)}, K_{X}^{(h)}, V_{Y}^{(h)}, O^{(h)}$ be diagonal matrices (but not necessarily squared) yields a special case of decomposable weights, and any decomposable weights can be transformed to this special case by rotation. Another key feature of decomposable weights is that, when the initial weights are decomposable, such a structure is preserved through the course of gradient flow dynamics. This is shown in the lemma below.

Lemma 3.2 (Preservation of Decomposibility along Gradient Flow). Under Assumption 2.1, suppose the initialization of gradient flow is decomposable with respect to $(\Phi, \Psi)$ in the sense of Definition 3.1. Then the decomposability is preserved along the gradient flow trajectory. Moreover, the semi-singular values of the weight matrices $O^{(h)}, V_{Y}^{(h)}, K_{X}^{(h)}, Q_{X}^{(h)}$ for $h \in[H]$ satisfy

$$
\begin{array}{cc}
\partial_{t} \sigma\left(K_{X}^{(h)}\right)=-d_{e}^{-1 / 2} \sigma\left(Q_{X}^{(h)}\right) \odot \sigma\left(A_{X X}^{(h) \top}\right), & \partial_{t} \sigma\left(Q_{X}^{(h)}\right)=-d_{e}^{-1 / 2} \sigma\left(K_{X}^{(h)}\right) \odot \sigma\left(A_{X X}^{(h)}\right), \\
\partial_{t} \sigma\left(O^{(h)}\right)=-\sigma\left(B_{Y}^{(h)}\right) \odot \sigma\left(V_{Y}^{(h) \top}\right), & \partial_{t} \sigma\left(V_{Y}^{(h)}\right)=-\sigma\left(O^{(h)^{\top}}\right) \odot \sigma\left(B_{Y}^{(h)}\right),
\end{array}
$$

where $A_{X X}^{(h)}$ is the top left $d \times d$ block of $A^{(h)}$ and $B_{Y}^{(h)}$ is the right $d_{y} \times d_{y}$ block of $B^{(h)}$.
When the weights are initialized to be decomposable, the gradient flow dynamics become simpler as described in Lemma 3.2. In particular, this lemma shows that the weight matrices remains decomposable with the same orthogonal matrices $(\Phi, \Psi)$. As a result, we only need to track the evolution os the semi-singular values of the weight matrices, which enables us to focus on the gradient flow dynamics in the spectral domain.

### 3.2 Analysis of Gradient Flow Dynamics

We proceed to give a high level overview of our analysis of the gradient flow dynamics. Here we focus on the dominant part of the gradient flow dynamics to illustrate the main idea, and the complete analysis involving the higher order terms is given in Appendix C. 2 and Appendix D.

When Definition 3.1 is satisfied, we define $\bar{\omega}^{(h)} \in \mathbb{R}^{I}$ to be the vector where each $\bar{\omega}_{i}^{(h)}$ is the average value of the entries of $\omega^{(h)} \in \mathbb{R}^{d}$ corresponding to the $i$-th task in the decomposition of $G$.

That is, $\bar{\omega}_{i}^{(h)}$ is equal to any $\omega_{j}^{(h)}$ with $j \in \mathcal{J}_{i}$. If the weights are decomposable, then the output is only a function of the data, $\bar{\omega}:=\left\{\bar{\omega}^{(h)}\right\}_{h \in[H]}$, and $\mu:=\left\{\mu^{(h)}\right\}_{h \in[H]}$. Recall that $d_{y}=I$ and thus $\mu^{(h)} \in \mathbb{R}^{d_{y}}$ is also a vector in $\mathbb{R}^{I}$. By Definition 3.1(iii) and Lemma 3.2, it suffices to focus on $\bar{\omega}^{(h)}$ and $\mu^{(h)}$ when the weights are initialized to be decomposable.

We assume that at initialization, $\sigma\left(Q_{X}^{(h)}\right)=\sigma\left(K_{X}^{(h)}\right)=\sqrt{\omega_{0}} \mathbf{1}_{d}, \sigma\left(O^{(h)}\right)=\sigma\left(V_{Y}^{(h)}\right)=\left(\mu_{0}^{(h)}\right)^{-1 / 2}$, where $\omega_{0}>0$ is a sufficiently small constant and $\mu_{0}^{(h)}$ is a vector of positive and sufficiently small entries. We thoroughly analyze the signal and interference components of the gradient flow dynamics and observe three phases: warm-up, emergence, and convergence. Specifically, for each task $i$, we analyze the dynamics of the parameters of the optimal head, ( $\bar{\omega}_{i}^{\star}, \mu_{i}^{\star}$ ), as well as those of the non-optimal heads $\left(\bar{\omega}_{i}^{(h)}, \mu_{i}^{(h)}\right)$ for $h \neq h_{i}^{\star}$. Here the optimal head for task $i$ is defined as $h_{i}^{\star}=\operatorname{argmax}_{h \in[H]} \mu_{i}^{(h)}$ and we have the abbreviations $\bar{\omega}_{i}^{\star} \triangleq \bar{\omega}_{i}^{\left(h_{i}^{\star}\right)}$ and $\mu_{i}^{\star} \triangleq \mu^{\left(h_{i}^{\star}\right)}$. Notice that $h_{i}^{\star}$ is actually a function of time $t$. As we will state in Theorem 3.3, in initialization, $h_{i}^{\star}$ is determined by the initial values of $\left\{\mu^{(h)}\right\}_{h \in[H]}$, and the choice of $\mu_{0}^{(h)}$ ensures that $h_{i}^{\star}$ is unique for each task $i$. Then, as we will see below $h_{i}^{\star}$ remains the same throughout the dynamics. That is, the optimal head for each task is fixed during gradient flow and only determined in initialization.

In the following, we characterize the three phases of gradient flow dynamics in the spectral domain. For ease of exposition, we rescale the time by letting $t \leftarrow 2 d t$ in the following discussion.

Phase I: Warm-up. During the warm-up phase, the optimal heads gradually dominate the nonoptimal heads. Recall that $\phi_{i}=1+\operatorname{SNR}_{i}^{-1}=1+\sigma^{2} d /\left(\lambda_{i} d_{i}\right)$ where $\lambda_{i}$ is the signal strength for task $i$. We can prove that the dynamics of $\bar{\omega}_{i}^{(h)}$ and $\mu_{i}^{(h)}$ are approximately given by

$$
\begin{equation*}
\partial_{t} \log \bar{\omega}_{i}^{(h)} \approx \frac{\lambda_{i} \mu_{i}^{(h)}}{\sqrt{d_{e}}}, \quad \partial_{t} \log \mu_{i}^{(h)} \approx d_{i} \lambda_{i} \bar{\omega}_{i}^{(h)}-\underbrace{\sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} d_{i} \lambda_{i} \phi_{i} \mu_{i}^{\left(h^{\prime}\right)}}_{\text {Cross-head interference }}, \tag{3.2}
\end{equation*}
$$

where the second term in the dynamics of $\mu_{i}^{(h)}$ is the cross-head interference term because it contains the contribution of $\mu_{i}^{\left(h^{\prime}\right)}$ for $h^{\prime} \neq h$. When $t$ is small, $\omega^{(h)}$ is not far from the initial value $\omega_{0} \cdot \mathbf{1}_{d}$ for all $h \in[H]$. Thus $\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)$ in (3.2) is roughly of the same order for all $h, h^{\prime}$. As a result, the cross-head interference term is almost the same for all heads as long as $\bar{\omega}^{(h)}$ is small enough at initialization. Then, by comparing heads $h$ with $h_{i}^{\star}$, we eliminate the interference term and get

$$
\begin{equation*}
\partial_{t} \log \left(\frac{\mu_{i}^{\star}}{\mu_{i}^{(h)}}\right) \approx \lambda_{i} d_{i}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right), \quad \partial_{t} \log \left(\frac{\bar{\omega}_{i}^{\star}}{\bar{\omega}_{i}^{(h)}}\right) \approx \frac{\lambda_{i}}{\sqrt{d_{e}}}\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right) . \tag{3.3}
\end{equation*}
$$

Note that $\mu_{i}^{\star}$ is the largest among $\mu_{i}^{(h)}$ for all $h \in[H]$. The second equation in (3.3) ensures that $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$ increases in times. Since they are initialized with the same value $\omega_{0}$, (3.3) implies that $\bar{\omega}_{i}^{\star}$ will grow faster than $\bar{\omega}_{i}^{(h)}$ for all $i \in I$, i.e., $\bar{\omega}_{i}^{\star}=\max _{i \in[I]} \bar{\omega}_{i}^{(h)}$. By examining the two equations in (3.3), we see that the dominance of $\mu_{i}^{\star}$ over each other $\mu^{(h)}$ will induce the dominance of $\bar{\omega}_{i}^{\star}$ over each other $\bar{\omega}_{i}^{(h)}$ through the second equation, which then in-turn reinforces the dominance of $\mu_{i}^{\star}$ via the first equation.

In summary, during the warm up stage, both $\mu_{i}^{\star}$ and $\bar{\omega}_{i}^{\star}$ will increase quickly and keep their dominating role over other heads in terms of solving task $i$. This phase terminates when there
exists an $i \in[I]$ such that $\bar{\omega}_{i}^{\star}$ is sufficiently large such that the interference terms in the dynamics of $\mu_{i}^{(h)}$ cannot be canceled out across different heads.

Phase II: Emergence. After the warm-up phase, the optimal head parameters $\mu_{i}^{\star}$ and $\bar{\omega}_{i}^{\star}$ undergo a rapid and substantial increase for each task $i$. As the optimal head $h_{i}^{\star}$ becomes increasingly dominant, $\left\{\mu_{i}^{(h)}, \bar{\omega}_{i}^{(h)}\right\}_{h \neq h_{i}^{*}}$ for $i \neq h_{i}^{\star}$ will remain small. As a result, we can only focus on the optimal head parameters and neglect the non-optimal head parameters, which yields the following simplified dynamics:

$$
\begin{align*}
& \partial_{t} \mu_{i}^{\star} \approx \lambda_{i} d_{i} \cdot\left(-\exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) \cdot L^{-1} \phi_{i} \mu_{i}^{\star 2}+\left(1-\bar{\omega}_{i}^{\star} \mu_{i}^{\star}\right) \bar{\omega}_{i}^{\star} \mu_{i}^{\star}\right), \\
& \partial_{t} \bar{\omega}_{i}^{\star} \approx\left(1-\left(1+\exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) \cdot L^{-1} \cdot d_{i} \phi_{i}\right) \cdot \mu_{i}^{\star} \bar{\omega}_{i}^{\star}\right) \cdot d_{e}^{-1 / 2} \lambda_{i} \bar{\omega}_{i}^{\star} \mu_{i}^{\star} . \tag{3.4}
\end{align*}
$$

To see that the dynamics in (3.4) captures the gradient flow dynamics, we plot the dynamics of $\mu_{i}^{\star}$ in Figure 3-(a) for $\phi_{i}=\lambda_{i}=1, d_{i}=10, d_{e}=30$, and $L=100$. The curve aligns well with the gradient flow dynamics in the simulation experiments, which is plotted in Figure 1.

To analyze this dynamics, we first note that because the first equation in (3.4) has a factor $d_{i}$ while the second equation is multiplied by $d_{e}^{-1 / 2}$, we can conclude that $\mu_{i}^{\star}$ changes much faster than $\bar{\omega}_{i}^{\star}$. As a result, we leverage a two-timescale analysis by first pushing $\mu_{i}^{\star}$ to its limit and write the limiting value as a function of $\bar{\omega}_{i}^{\star}$. Then we can only focus on the dynamics of $\bar{\omega}_{i}^{\star}$ and analyze its behavior. In particular, setting the right-hand side of the first equation in (3.4) to zero, we have

$$
\begin{equation*}
\mu_{i}^{\star} \approx \frac{\bar{\omega}_{i}^{\star}}{\bar{\omega}_{i}^{\star}}+\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) L^{-1} . \tag{3.5}
\end{equation*}
$$

Then, plugging (3.5) into the dynamics of $\bar{\omega}_{i}^{\star}$, we have

$$
\begin{equation*}
\partial_{t} \bar{\omega}_{i}^{\star} \approx \frac{\left(1-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) \cdot d_{e}^{-1 / 2} \lambda_{i}}{2+\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) /\left(L\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)+L\left(\bar{\omega}_{i}^{\star}\right)^{2} /\left(\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)\right)} . \tag{3.6}
\end{equation*}
$$

Setting the right-hand side of (3.6) to zero yields a critical point $\bar{\omega}_{i}^{\star}=d_{i}^{-1 / 2}$. Thus, when $\bar{\omega}_{i}^{\star}<$ $d_{i}^{-1 / 2}$, the right-hand side of (3.6) is positive, which indicates the growth of $\bar{\omega}_{i}^{\star}$ before its value reaches $d_{i}^{-1 / 2}$. To further understand the dynamics of $\bar{\omega}_{i}^{\star}$, it suffices to consider the behavior of the denominator:

$$
2+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}
$$

For small $\bar{\omega}_{i}^{\star}$, the second term is large and dominates, thus resulting in the slow growth of $\bar{\omega}_{i}^{\star}$ at the beginning. However, as $\bar{\omega}_{i}^{\star}$ grows larger (but still much less than $d_{i}^{-1 / 2}$ ), the value of the denominator quickly decreases, making the growth of $\bar{\omega}_{i}^{\star}$ fast and giving rise to the emergence phase. We also plot the dynamics of $\bar{\omega}_{i}^{\star}$ according to the apprximated dynamics in (3.6) in Figure 3-(b). The curve aligns well Figure 1, which justifies the validity of the approximation.

Phase III: Convergence. As $\bar{\omega}_{i}^{\star}$ approaches $d_{i}^{-1 / 2}$, we see from (3.6) that the growth of $\bar{\omega}_{i}^{\star}$ slows down, and eventually $\bar{\omega}_{i}^{\star}$ converges to $d_{i}^{-1 / 2}$. By also invoking (3.5), we can show that eventually

$$
\bar{\omega}_{i}^{\star} \rightarrow \frac{1}{\sqrt{d_{i}}}, \quad \mu_{i}^{\star} \rightarrow \frac{\sqrt{d_{i}}}{1+e d_{i} \phi_{i} L^{-1}} .
$$

While for each non-optimal head, $\bar{\omega}_{i}^{(h)}$ does not change much from the initialization and $\mu_{i}^{(h)}$ converges to 0 .

Collecting all the above components, we arrive at the main result on gradient flow dynamics presented in Theorem 3.3. For a rigorous analysis, we pick constants $c$ and $\epsilon$ such that

$$
\begin{equation*}
3 \leq c=o(\sqrt{\log L}), \quad \frac{1}{2}>\epsilon \geq \frac{1}{c}+\frac{3}{1+\sqrt{1+c^{2} / 2}} . \tag{3.7}
\end{equation*}
$$

Picking $\epsilon=1 / 4$ suffices, and a smaller value of $\epsilon$ requires larger $L$.

Figure 3: Approximated dynamics of the gradient flow with $d_{i}=10, d_{e}=30, L=100$, $\phi_{i}=1$ and $\lambda_{i}=1$. In (a) we plot the dynamics of $\mu_{i}^{\star}$ in (3.4), starting from $t=4$ and $\left(\bar{\omega}_{i}^{\star}, \mu_{i}^{\star}\right)=(0.01,1)$. In (b) we plot the dynamics of $\bar{\omega}_{i}^{\star}$ in (3.6), starting from $t=4$ and $\bar{\omega}_{i}^{\star}=0.01$. We note that the approximated dynamics given by (3.4) and (3.6) are consistent with the numerical simulations in Figure 1 based on data. In (c) we plot $\partial_{t} \bar{\omega}_{i}^{\star}$ as a function of $\bar{\omega}_{i}^{\star}$ with the same setup. When $\bar{\omega}_{i}^{\star}$ is small (left), the growth of $\partial_{t} \bar{\omega}_{i}^{\star}$ is slow. When $\bar{\omega}_{i}^{\star}$ reaches the middle region, the growth of $\bar{\omega}_{i}^{\star}$ accelerates. When $\bar{\omega}_{i}^{\star}$ grows to the right end, it converges to $d_{i}^{-1 / 2}$.

Theorem 3.3 (Convergence of gradient flow for MS-Attn). Under Assumption 2.1 and Assumption 2.2, let $L$ be sufficiently large such that (3.7) holds. Let $d_{e} \geq d$. Suppose the initialization is decomposable in the sense of Definition 3.1 and moreover,

$$
\sigma\left(Q_{X}^{(h)}\right)=\sigma\left(K_{X}^{(h)}\right)=\sqrt{\omega_{0}} \mathbf{1}_{d}, \quad \sigma\left(O^{(h)}\right)=\sigma\left(V_{Y}^{(h)}\right)=\sqrt{\mu_{0}^{(h)}},
$$

where $\omega_{0}$ and $\mu_{0}^{(h)} \in \mathbb{R}^{d_{y}}$ are positive and sufficiently small in the sense of Assumption D.1. Suppose $H \geq I$ and that at initialization, there exists a unique optimal head $h_{i}^{\star}$ for each task $i$ such that $\left(\mu_{i}^{\star}(0)-\mu_{i}^{(h)}(0)\right) / \mu_{i}^{\star}(0) \geq c_{1}, \forall h \neq h_{i}^{\star}, \forall i \in[I]$, where $c_{1}>0$ is a positive constant. Let $\mu_{i}^{\star}$ and $\bar{\omega}_{i}^{\star}$ be abbreviations of $\mu_{i}^{\left(h_{i}^{\star}\right)}, \bar{\omega}_{i}^{\left(h_{i}^{\star}\right)}$, respectively. We rescale $t \leftarrow 2 d t$. Then the following holds:
(i) (Optimal Head Takes All) For each task $i \in[I]$, the optimal head $h_{i}^{\star}$ determined by initialization will remain optimal during the training process in the sense that $\mu_{i}^{\star}>\mu_{i}^{(h)}$ and $\bar{\omega}_{i}^{\star}>\bar{\omega}_{i}^{(h)}$ for all $h \neq h_{i}^{\star}$. In particular, for any non-optimal head $h \neq h_{i}^{\star}$, we have $\mu_{i}^{(h)} \leq \mu_{i}^{\star} \exp \left(-\Omega\left(\sqrt{d_{e}}\right)\right)$ and $\bar{\omega}_{i}^{(h)} \leq O\left(\omega_{0}\right)$ upon convergence for all $i \in[I]$.
(ii) (Emergence) Fix a small constant $\alpha=\Theta(1)<1$ and let $T_{0, i}=\sqrt{d_{e}} \phi_{i} /\left(\lambda L \omega_{0}\right)$ be the threshold time for task $i$ to emerge. For time $t \leq(1-\alpha) T_{0, i}$, we have $\bar{\omega}_{i}^{\star}(t) \leq \alpha^{-1} \omega_{0}$, which means $\bar{\omega}_{i}^{\star}(t)$
is "fixed" around initialization and the loss for task $i$ is larger than $\Omega\left(\lambda_{i} d_{i} / d\right)$, where $\lambda_{i} d_{i} / d$ is the value of the ICL loss if the attention output is 0 for task $i$. If $t \geq(1+\alpha) T_{0, i}$, then $\bar{\omega}_{i}^{\star}(t) \geq \sqrt{\alpha d_{i}^{-1}}$ and the loss for task $i$ is at most $O\left(e^{\alpha} / \alpha\right)$ times the optimal loss for task $i$ in the single-head case given later by (4.4):

$$
\mathcal{L}_{i}^{\star}:=\frac{\lambda_{i} d_{i}}{d} \cdot \frac{e d_{i} \phi_{i} L^{-1}}{1+e d_{i} \phi_{i} L^{-1}} .
$$

(iii) (Convergence) Consider the optimal head for task i. Let $\delta \in(0,1)$. With training time

$$
\Omega\left(\max _{i \in[I]} \frac{\sqrt{d_{e}} \phi_{i}}{\lambda_{i} L \omega_{0}}+\frac{\sqrt{d_{e}}}{\lambda_{i} \sqrt{d_{i}}} \log \frac{4}{\delta}\right) \leq T \leq \exp \left(O\left(\sqrt{d_{e}}\right)\right),
$$

it holds that

$$
\begin{equation*}
\sup _{i \in[I]}\left|\frac{\bar{\omega}_{i}^{\star}(T)}{d_{i}-1 / 2}-1\right| \leq \delta, \quad \text { and } \quad \sup _{i \in[I]}\left|\frac{\mu_{i}^{\star}(T)}{\sqrt{d_{i}} /\left(1+e d_{i} \phi_{i} L^{-1}\right)}-1\right| \leq O(\delta), \tag{3.8}
\end{equation*}
$$

which is the same as the global optimal solution for a single-head softmax attention trained only for task $i$ (see (4.3)).

The upper bound of the convergence time is due to technical reasons where we need to control the cumulative effect of the approximation error in the gradient flow. We compare our results to the existing literature regarding the training dynamics of attention-based models. Zhang et al. (2023a) proved the convergence of gradient flow for one-layer single-head linear attention, while our results are for multi-head softmax attention and we do not combine the key and query weight matrices into a single matrix. Our results further provide a full characterization of the training dynamics from small initialization to convergence and demonstrate a phase transition in the emergence of the ICL capacity. Huang et al. (2023) was the first to study the training dynamics of softmax attention, but their analysis is limited to the single-head case with context features coming from an orthogonal dictionary. Moreover, the convergence point derived in Huang et al. (2023) is in sharp contrast to ours. As we will show in the following section, we have $\mathbb{E}\left[\|p\|_{2}^{2}\right]=O\left(L^{-1}\right)$ upon convergence, while the convergence point in Huang et al. (2023) has $\mathbb{E}\left[\|p\|_{2}^{2}\right]=\Omega(1)$ as the tokens that are the same as the query will have dominating attention weights. The difference is due to the orthogonality between token features and not taking into account the effect of noise in their analysis. Indeed, we will show in the following section (Theorem 4.2) that having a dominating attention weight is suboptimal in the presence of noise. Finally, Deora et al. (2023) also considered training a multihead softmax attention model, but they focused on the classification setting and their analysis is limited to the regime of neural tangent kernel (Jacot et al., 2018) where the parameters do not evolve much during training.

We conclude this section with a discussion of the convergence point of the gradient flow.

Each Optimal Head Aligns with the Task's Subspace. By Theorem 3.3(iii), for the optimal head $h_{i}^{\star}$ corresponding to task $i$, the attention score is computed as $s=\bar{\omega}_{i}^{\star}(\Phi X)_{(i)}^{\top}(\Phi q)_{(i)}$, where we use subscript " $(i)$ " to denote the slice of a vector (matrix) corresponding to task $i$ 's indices $\mathcal{J}_{i}$. Intuitively, the attention score is obtained by (i) rotating the key and query vectors to align with the task's eigenvectors and (ii) computing the inner product between the aligned key and query vectors after projected onto the task's subspace.

What is the Model learned by Gradient Flow? In addition, it was previously found by Ahn et al. (2023); Mahankali et al. (2023) that the optimal weights of a one-layer linear attention model correspond to one step of preconditioned gradient descent. While in our case, the model in Theorem 4.2 found by gradient flow is analogous to emulating certain kernel regression where the softmax attention aggregates similarity scores between the query and the keys across all tasks. Note that if $(\Phi X)_{(i)}$ and $(\Phi q)_{(i)}$ are of the same 2-norm, then the attention probability is given by $p_{l} \propto \exp \left(-\frac{1}{2} \bar{\omega}_{i}^{\star}\left\|\left(\Phi x_{l}\right)_{(i)}-(\Phi q)_{(i)}\right\|_{2}^{2}\right)$, and the output for task $i, \widehat{y}_{i}=\mu_{i}^{\star} Y p$, is the same as that of the kernel smoothing method based on the radial basis function kernel with bandwidth $\left(\bar{\omega}_{i}^{\star}\right)^{-1 / 2}$.

## 4 Optimality of Convergence Point of Gradient Flow

Next, we discuss the optimality (in terms of the ICL loss value) of the model trained by gradient flow. The main result is summarized in the following lemma. Let us first understand the ICL loss for this solution.

Lemma 4.1 (ICL Loss for MS-Attn). Under the setting of Theorem 3.3, the ICL loss value achieved by the convergence point of gradient flow is upper bounded by

$$
\begin{equation*}
\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot\left(\frac{e d_{i} \phi_{i} L^{-1}}{1+e d_{i} \phi_{i} L^{-1}}+O\left(L^{-(1-\epsilon) / 2}+\delta+\omega_{0}^{2} d\right)\right) \tag{4.1,GF-ICL}
\end{equation*}
$$

where $\epsilon$ is defined in (3.7) and $\delta$ is the error for the convergence point in (3.8).
We defer readers to Lemma E. 9 and its follow-up proof for the detailed derivation. For sequence length $L$, the ICL loss scales with $O(d / L)$ and is simply a summation of individual loss across tasks, which matches our observation that each task $i \in[I]$ is completed by an individual head without cross-head interference. Naturally, one may ask:

1. Given the fact that each task is handled by a unique head, does this dominating head's behavior endure similarity to a single-head softmax attention? Does it achieve the optimal ICL loss on that individual task?
2. Does this model achieve the optimal ICL loss within the class of MS-Attn?

In pursuit of answers to the above question, we continue to study the optimality properties for both single-head softmax attention and MS-Attn. In §4.1, we investigate what are the optimal attention weights and loss value for a single-head softmax attention dealing with multiple tasks. In §4.2, we study lower bound of the optimal ICL loss within the class of equiangular weights under homogeneity assumption on the tasks, and show that the convergence point of the gradient flow matches the lower bound. In $\S 4.3$, we give a proof sketch to these optimality results with more insights into the softmax attention.

### 4.1 The Single-Head Case: Allocation of Attention Budget

We first consider the single-head case where $H=1$, and the goal here is to characterize the minimal value of the ICL loss, as summarized in the following theorem. Here we recall the definition $\phi_{i}=1+\sigma^{2} d /\left(\lambda_{i} d_{i}\right)$.

Theorem 4.2 (Optimal Loss for Single-Head Softmax Attention). Suppose Assumption 2.1 holds with $\Phi$ and $\Psi$ being identity matrices (which is without loss of generality). Under Assumption 2.2, suppose $L$ is sufficiently large such that (3.7) holds with constants $\epsilon$ and $c$. For a single-head softmax attention, assume that $W_{Y}=0$. Consider constant noise level $\sigma^{2}=\Theta(1)$. Suppose for each task $i \in[I]$, the signal strength satisfies either $\lambda_{i}=\Theta(1)$ or $\lambda_{i}=0$ for any $i \in[I]$. The model with the weights

$$
W^{\star}=\left[\right], \quad U^{\star}=\left[\begin{array}{c|cccc}
0 & & 0 & 0 \\
& u_{1}^{\star} & 0 & \cdots & 0 \\
0 & u_{2}^{\star} & \cdots & 0 \\
0 & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & u_{I}^{\star}
\end{array}\right]
$$

approximately achieves the optimal loss in the sense that

$$
\mathcal{L}\left(U^{\star}, W^{\star}\right) \leq \inf _{U, W: W_{Y}=0} \mathcal{L}(U, W)+O\left(L^{-(1-\epsilon) / 2}\right) .
$$

Moreover, $B^{\star}$ and $b^{\star}=\left(b_{i}^{\star}\right)_{i \in[I]}$ are obtained by solving the following optimization problem:

$$
\begin{equation*}
\min _{\substack{c^{-2} 2 \log L \geq B \geq 0, \\ \text { ber } \\+\mathbf{1}^{\top} b=B}} \mathcal{L}_{\operatorname{sim}}(B, b):=\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d}\left(1-\frac{b_{i}}{b_{i}+d_{i} \phi_{i} \cdot \exp (B) \cdot L^{-1}}\right), \tag{4.2,OptS-ICL}
\end{equation*}
$$

and $u_{i}^{\star}=\sqrt{b_{i}^{\star} d_{i}} /\left(b_{i}^{\star}+d_{i} \phi_{i} \exp \left(B^{\star}\right) / L\right)$. In addition, $\left|\mathcal{L}\left(U^{\star}, W^{\star}\right)-\mathcal{L}_{\text {sim }}\left(B^{\star}, b^{\star}\right)\right|=O\left(L^{-(1-\epsilon) / 2}\right)$.
See $\S 4.3$ for a proof sketch and $\S E .1$ for a detailed proof. In a nutshell, Theorem 4.2 shows that the optimal ICL loss and the corresponding weights for a single-head softmax attention are related to the optimal value and solutions to an optimization problem. Our proof is based on first lower bounding the ICL loss for any weights by the optimal value of (4.2, OptS-ICL) and then show the constructed optimal solution achieves the lower bound. Note that the softmax operation induces nonlinearity, and our proof technique is to identify the operating regimes of the softmax attention (Figure 6 in §4.3) and decide the optimal operating regime for the ICL task. After that, we isolate the higher order nonlinear terms and approximate the lower order nonlinear term in the system to make rigorous nonlinear analysis tractable. We also remark that setting $W_{Y}=0$ is a standard practice for analyzing attention-based models for ICL and similar assumptions are also employed in Zhang et al. (2023a); Von Oswald et al. (2023); Ahn et al. (2023); Huang et al. (2023).

Below we provide discussion on the insights and implications of Theorem 4.2.
Optimal Solution is Decomposable. For general orthogonal matrices $\Phi$ and $\Psi$, the corresponding optimal weights can be constructed by applying the rotation to $W_{X}^{\star}$ and $U_{Y}^{\star}$ while keeping the remaining entries zero, i.e., the optimal weights $\widetilde{W}^{\star}$ and $\widetilde{U}^{\star}$ are given by

$$
\widetilde{W}_{X}^{\star}=\Phi^{\top} W_{X}^{\star} \Phi, \quad \widetilde{W}_{Y}^{\star}=0, \quad \widetilde{U}_{Y}^{\star}=\Psi^{\top} U_{Y}^{\star} \Psi, \quad \widetilde{U}_{X}=0 .
$$

To see the equivalence, one can view the rotated data $\widetilde{X}=\Phi^{\top} X, \widetilde{\varepsilon}=\Psi^{\top} \varepsilon$ and $\widetilde{q}=\Phi^{\top} q$ as the new input, and the loss value is preserved due to the rotational invariance of the input distribution (See (E.1)). More importantly, we remark that the optimal weights are decomposable since $W_{X}^{\star}$
and $U_{Y}^{\star}$ are diagonal, and one can always construct the corresponding $Q_{X}^{\star}, K_{X}^{\star}, V_{Y}^{\star}$ and $O^{\star}$ (also subject to rotation for general $\Phi$ and $\Psi)$ that share common eigenvector spaces to get the same model. Moreover, it is clear that the optimal weights also have homogeneous entries within each task. These facts justify the decomposability condition in Definition 3.1.

Allocation of Attention Budget. We interpret the sum of the squared eigenvalues, $\|\omega\|_{2}^{2}=$ $\left\|W_{X}\right\|_{\mathrm{F}}^{2}$, as the total attention budget. Correspondingly, one can intuitively understand the sum of the squared eigenvalues within task $i$ 's support, $\sum_{j \in \mathcal{J}_{i}} \omega_{j}^{2}$, as the allocation of attention budget for task $i$. Then in (4.2, OptS-ICL), B and $b=\left\{b_{i}\right\}_{i \in[I]}$ are the attention budget and the allocation vector of the budget, respectively. Fixing the attention budget $B$, the inner optimization problem over $b$ is simply trying to optimally allocate the budget according to the signal-to-noise ratios $\left\{\mathrm{SNR}_{i}\right\}_{i \in[I]}$ and the task dimensions $\left\{d_{i}\right\}_{i \in[I]}$, which is a convex optimization problem.

Softmax Attention Works in the Exponential Regime. Note that the optimal attention budget scales as $B^{\star}=o(\log L)$ (see the justification of this in Lemma E.6). As we will illustrate later in $\S 4.3$, such an attention budget corresponds to the exponential regime ${ }^{4}$ of softmax attention. This is a consequence of the fact that the $\exp (B)$ in the denominator of (4.2, OptS-ICL) penalizes the attention budget. In contrast, in the saturation regime where the attention budget $B=\Omega(\log L)$, the attention probability vector concentrates on a few tokens, which is suboptimal in the presence of noise (Lemma E. 4 and Lemma E.5).

Given that the attention budget $B=o(\log L)$, the attention probability vector is delocalized ${ }^{5}$ so that the attention is spread out to capture the information from similar tokens in regression tasks and average out the noise. This is in sharp contrast to the solution found by Huang et al. (2023) where the attention probability is concentrated on the tokens that are the same as the query, which is because their context features are from an orthogonal dictionary and the data is noiseless.

MS-Attn Acts as Multiple Optimal Single-Head Softmax Attention. Suppose an attention head focuses on a single task, say task $i$, and treats the other tasks as with zero signal strength, i.e. $\lambda_{j}=0$ for any $j \neq i$. We apply Theorem 4.2 to this head, and the optimal eigenvalues are

$$
\begin{equation*}
\bar{\omega}_{i}=\frac{1}{\sqrt{d_{i}}}, \quad \mu_{i}=\frac{\sqrt{d_{i}}}{1+e d_{i} \phi_{i} L^{-1}}, \quad, \bar{\omega}_{j}=\mu_{j}=0, \quad \forall j \in[I] \backslash\{i\} \tag{4.3}
\end{equation*}
$$

This is obtained by letting $b_{i}=B$ for the inner optimization in (4.2, OptS-ICL) and directly solving the outer optimization problem which gives optimal solution at $B^{\star}=1$. The optimal loss value (up to $O\left(L^{-(1-\epsilon) / 2}\right.$ ) error) for task $i$ is then given by

$$
\begin{equation*}
\mathcal{L}_{i}^{\star}:=\frac{\lambda_{i} d_{i}}{d} \cdot \frac{e d_{i} \phi_{i} L^{-1}}{1+e d_{i} \phi_{i} L^{-1}}=O\left(\frac{d}{L}\right) \tag{4.4}
\end{equation*}
$$

Comparing this to the multi-head model trained by gradient flow in Theorem 3.3, we discover that at the convergence point, the optimal head is acting as an optimal single-head softmax attention for each task. Is this optimal within the class of MS-Attn? We will next investigate this question over a class of equiangular weights, which is a natural class to consider when the tasks are homogeneous in the sense that they share the same dimension and signal strength.

[^4]
### 4.2 The Multi-Head: Equiangular Lower Bound and Bayesian Risk

We start by introducing the following class of weights, which we call equiangular weights.
Definition 4.3 (Equiangular Weights). For weights of a MS-Attn that are decomposable in the sense of Definition 3.1, we say the corresponding task-aggregated eigenvalues $\left\{\bar{\omega}^{(h)}\right\}_{h \in[H]}$ are equiangular if there exist constants $a, b \in \mathbb{R}$ such that $\left\|\bar{\omega}^{(h)}\right\|_{2}^{2}=a$ and $\left\langle\bar{\omega}^{(h)}, \bar{\omega}^{\left(h^{\prime}\right)}\right\rangle=b$ for all distinct $h, h^{\prime} \in[H]$.

The equiangular property ensures the cosine similarity between any two task-aggregated weights to be the same, which reduces the degree of freedom in the system and it suffices to optimize over $a$ and $b$. We remark that the equiangular weights are a reasonable class to consider under the task homogeneity assumption that all tasks have the same dimension and signal strength. The following theorem addresses the optimality among the class of MS-Attn with equiangular weights.

Theorem 4.4 (Lower Bound of MS-Attn within Equiangular Weights). Under Assumption 2.1 and Assumption 2.2, suppose $H \geq 2$ and $I$ tasks are homogeneous such that $d_{i}=d / I=\bar{d}$ and $\lambda_{i}=\lambda$ for all $i \in[I]$. Suppose task coefficient $g_{i} \stackrel{\text { i.i.d. }}{\sim} \mathcal{N}\left(0, \lambda / d \cdot I_{\bar{d}}\right)$ for all $i \in[I]$. Let $c$ and $\epsilon$ satisfy (3.7), and consider the regime where $\left\|\bar{\omega}^{(h)}\right\|_{\infty} \leq \sqrt{2 \log L / 3 d c^{2}},\left\|\mu^{(h)}\right\|_{\infty} \leq L^{3 / 4-\epsilon / 2}$ for all $h \in[H]$. Then for any MS-Attn with equiangular weights in the sense of Definition 4.3, the ICL loss is lower bounded by

$$
\begin{equation*}
\max \{\underbrace{\frac{\lambda}{\phi^{-1} d^{-1} L \cdot(H-1)+1}}_{\text {LB-ICL }}+O\left(L^{-\epsilon / 2}\right), \quad \mathcal{R}_{\text {Bayes }}\} \tag{4.5}
\end{equation*}
$$

where $\mathcal{R}_{\text {Bayes }}$ is the Bayesian risk for this ICL task with prior $g_{i} \stackrel{\text { i.i.d. }}{\sim} \mathcal{N}\left(0, \lambda / d \cdot I_{\bar{d}}\right)$ for all $i \in[I]$. Moreover, by decomposing $\mathcal{R}_{\text {Bayes }}:=$ Variance + Bias, the two terms are given asymptotically by

$$
\begin{aligned}
\text { Variance } & =I \sigma^{2} \cdot \frac{b r+(1+r)-\sqrt{(b r-1+r)^{2}+4 b}}{2 \sqrt{(b r-1+r)^{2}+4 b}} \\
\text { Bias } & =\lambda \cdot\left(\frac{b r(1+r)+(1-r)^{2}-|1-r| \sqrt{(b r-1+r)^{2}+4 b r}}{2 \sqrt{(b r-1+r)^{2}+4 b}}+\left(1-\frac{1}{r}\right) \mathbb{1}(r>1)\right),
\end{aligned}
$$

where $b=\sigma^{2} / \lambda$ and $r=\bar{d} / L$.
See $\S 4.3$ for a proof sketch and $\S E .2$ for a detailed proof. We remark the norm constraints on the weights are without much loss of generality since the optimal weights for the single-head softmax attention satisfy $\bar{\omega}=O\left(d^{-1 / 2}\right)$ and $\mu=O(\sqrt{d})$ as we have shown in Theorem 4.2, which means the attention is working in the exponential regime as we will discuss in §4.3. As a corollary, we give an affirmative answer to the question of the optimality of the model found by gradient flow.

Corollary 4.5. Under the setting of Theorem 4.4, let $H=I$. The ICL loss of the model in Theorem 3.3 achieves the lower bound of the ICL loss given by Theorem 4.4 up to a constant multiplicative factor.

| Case | Lower Bound | Upper Bound | Matched? |
| :---: | :---: | :---: | :---: |
| $H=I$ | LB-ICL $=\frac{\lambda}{(H-1) \phi^{-1} d^{-1} L+1}$ | GF-ICL $=\frac{\lambda}{H e^{-1} \phi^{-1} d^{-1} L+1}$ | $\checkmark$ |
| $H>I$ | MMSE $=\frac{\sigma^{2}}{d^{-1} L+I^{-1}\left(\mathrm{SNR}^{-1}-1\right)}$ | GF-ICL $=\frac{\sigma^{2} \cdot(1+\mathrm{SNR})}{e^{-1} d^{-1} L+I^{-1}\left(1+\mathrm{SNR}^{-1}\right)}$ | $\checkmark($ low SNR $)$ |
| $H<I$ | LB-ICL $=\frac{\lambda}{(H-1) \phi^{-1} d^{-1} L+1}$ | Const-ICL $=\frac{\lambda \cdot e^{-1} \phi^{-1} d^{-1} L+1}{}$ | $\checkmark(I=k H)$ |
| $H=1$ | OptS-ICL $=\frac{\lambda}{e^{-1} \phi^{-1} d^{-1} L+1}$ | same as the lower bound | $\checkmark$ |

Table 1: Summary of lower bounds and upper bounds for different cases. Here, LB-ICL is the lower bound given by (4.5), GF-ICL is the ICL loss of the convergence point of the dynamics in (4.1, GF-ICL) which serves as an upper bound, MMSE is the Bayesian risk, OptS-ICL is given by the optimal value to (4.2, OptS-ICL) that is the optimal ICL loss for a single-head softmax attention. For the $H>I$ case, we rewrite the GF-ICL in terms of the SNR for better comparison. The term "Const-ICL" refers to the ICL loss for the constructed solution under the condition $I=k H$ where each head handles $k$ different tasks optimally and treat other tasks as with zero signal in the sense of Theorem 4.2.

Lower Bound is Achieved by the Convergence Point. Now we compare the upper bound of the ICL loss with the lower bound in (4.5) under different settings. For simplicity, we consider the asymptotic regime $(d, L \rightarrow \infty$ and $d / L=\Theta(1))$ where we neglect the error term that only depends on $L$ and consider a small constant $\bar{d} / L$. The Bayesian risk (or Minimum Mean Square Error (MMSE)) when ignoring higher order terms of $\bar{d} / L$ is given by

$$
\begin{equation*}
\mathrm{MMSE}=\frac{\sigma^{2}}{d^{-1} L+I^{-1}\left(\mathrm{SNR}^{-1}-1\right)} \tag{4.6,MMSE}
\end{equation*}
$$

We consider four cases stratified by the relationship between $H$ and $I$, and compare in each case the lower bound and the upper bound on the ICL loss. The result is summarized in Table 1 and visualized in Figure 5.
(i) If $H=I$, then the ICL loss at the convergence point achieves the lower bound up to a constant factor $e$, where we are exploiting the full power of the MS-Attn to solve the tasks.
(ii) If $H \geq I$, in general the GF-ICL is suboptimal compared with the Bayesian risk. However, in the low SNR regime, i.e., $\mathrm{SNR}=\lambda /\left(I \sigma^{2}\right)=o(1)$, the ICL loss of the trained model also reaches the Bayesian risk up to a constant factor $e$. This is in fact not surprising and is due to the softmax-induced regularization. We will further illustrate this in Section 4.3.
(iii) We do not consider the gradient flow for $H<I$. However, it is not hard to construct a solution when $I=k H$ for some positive integer $k$. In this case, we just let each head handle $k$ different tasks while treating the remaining as with zero signal, and the optimal weights are given by Theorem 4.2 and the ICL loss is given by Const-ICL shown in Table 1. Clearly, the construction achieves the lower bound up to a constant factor $e$.
(iv) When comparing the ICL loss upper bound of the MS-Attn with $H$ heads (Case (i)~(iii)) to the optimal ICL loss for the single-head case (OptS-ICL by Theorem 4.2), we clearly see that

Figure 4: Comparison between the lower bound LB-ICL and the Bayesian risk (MMSE) for different $H$ and $\bar{d} / L$ with $I=10, \lambda=\sigma^{2}=1$. Here, $\bar{d}=d / I$.
the MS-Attn is at least $H \wedge I$ times more efficient than the single-head softmax attention in terms of the ICL loss.

In summary, we have shown by cases the tightness of the lower bound in Theorem 4.4. In particular, the Bayesian risk lower bound is achieved by the convergence point of the MS-Attn for $H \geq I$ in the lower SNR regime.

### 4.3 Softmax-Induced Regularization and Proof Sketch for the Optimality Results

Before presenting our proof sketch for the optimality results, let us first understand the loss decomposition of a single softmax transformer head.

### 4.3.1 Loss Decomposition and Softmax-Induced Regularization

We treat $W$ and $U$ as the combined weights of the single-head attention. For ease of presentation, we only consider one task here while the multi-task case is deferred to the complete proof in §E. Hence, $d_{y}=1$ with $U_{Y}$ being just a scalar, $G=g_{1} \in \mathbb{R}^{d \times 1}$ and we have $\mathbb{E}\left[G G^{\top}\right]=\lambda d^{-1} I_{d}$. Suppose $W_{Y}=0$, then the ICL loss defined in (2.6) can be decomposed into

$$
\mathcal{L}(U, W)=\underbrace{\mathbb{E}\left[\left\|G^{\top} q-U_{Y} G^{\top} X p\right\|_{2}^{2}\right]}_{\text {Signal-induced error }}+\underbrace{\mathbb{E}\left[\left\|U_{X} X p\right\|_{2}^{2}\right]}_{\text {Extra error }}+\underbrace{\mathbb{E}\left[\left\|U_{Y} \varepsilon p\right\|_{2}^{2}\right]}_{\text {Noise-induced variance }} .
$$

Figure 5: Comparison of the ICL loss between (i) ridge regression with regularization parameter penalty $=0.05$ and penalty $=5$; (ii) the Bayesian risk, i.e., MMSE; (iii) the ICL loss for the convergence point of the gradient flow (4.1, GF-ICL) with $H \geq I$; (iv) the ICL loss of the optimal single head attention (4.2, OptS-ICL). Here, $\bar{d}=d / I$. For large $\bar{d} / L$, the GF-ICL loss behaves similarly to ridge regression with large penalty $=5$ and does not have the double descent phenomenon that is observed with insufficient regularization penalty $=0.05$. This is due to the softmax-induced regularization as we will further illustrate in $\S 4.3$. For small $\bar{d} / L$, we see that MS-Attn (GF-ICL) has an $H \wedge I=10$ improvement over the single-head attention (OptS-ICL). We refer readers to $\S E .3$ for more details.

Note that the extra error term vanishes when setting $U_{X}=0$, and the remaining terms are not affected, thus justifying Definition 3.1(i). Expanding the signal-induced error, we have

$$
\mathbb{E}\left[\left\|G^{\top} q-U_{Y} G^{\top} X p\right\|_{2}^{2}\right]=\lambda d^{-1} \cdot \mathbb{E}\left[d-2 U_{Y} \operatorname{Tr}\left(X p q^{\top}\right)+U_{Y}^{2} \operatorname{Tr}\left(X p p^{\top} X^{\top}\right)\right] .
$$

Applying the Stein's lemma for the expectation term (Lemma C.4) yields

$$
\begin{align*}
\mathbb{E}[X p \mid q] & =W_{X} q\left(1-\mathbb{E}\left[\|p\|_{2}^{2} \mid q\right]\right), \\
\mathbb{E}\left[X p p^{\top} X^{\top} \mid q\right] & =W_{X} q q^{\top} W_{X}^{\top} \mathbb{E}\left[1-\|p\|_{2}^{2}-6\|p\|_{3}^{3}+6\|p\|_{2}^{4} \mid q\right]+I_{d} \mathbb{E}\left[\|p\|_{2}^{2} \mid q\right] . \tag{4.7}
\end{align*}
$$

When $W_{X}$ has bounded operator norm (which will be justified later), it holds with high probability that $\left\|W_{X} q\right\|_{2}^{2} \leq O(2 \log L)$, and then we can ignore the higher order terms in the expectation (Lemma B.4). Consequently, we have $\mathbb{E}[X p \mid q] \approx W_{X} q$ and $\mathbb{E}\left[X p p^{\top} X^{\top} \mid q\right] \approx W_{X} q q^{\top} W_{X}^{\top}+$ $I_{d} \mathbb{E}\left[\|p\|_{2}^{2} \mid q\right]$ up to $O\left(L^{-1}\right)$ error. Applying these to simplify the signal-induced error term, we obtain

$$
\begin{equation*}
\mathcal{L}(U, W) \approx \underbrace{\lambda d^{-1} \cdot \mathbb{E}\left[\left\|q-U_{Y} W_{X} q\right\|_{2}^{2}\right]}_{\text {Linearized bias }}+\underbrace{\left(\lambda+\sigma^{2}\right) U_{Y}^{2} \cdot \mathbb{E}\left[\|p\|_{2}^{2}\right]}_{\text {Softmax-induced regularization }} . \tag{4.8}
\end{equation*}
$$

Here, the first term is the linearized bias, where we get rid of the nonlinearity in the attention probability. In particular, this term measures how close $U_{Y} W_{X}$ is to the identity. The second term is a softmax-induced regularization induced by the concentration of the attention probability. With $\|p\|_{2}^{2}$ becoming larger, the attention probability becomes more concentrated on a few input tokens, leading to a larger variance in the output. In particular, when compared to standard linear regression's loss decomposition, a key difference is that the softmax-induced regularization term

Figure 6: The behavior of $\mathbb{E}\left[\|p\|_{2}^{2} \mid r\right]$ as a function of $r$ for $L=10^{4}$. The left figure shows the behavior of $\mathbb{E}\left[\|p\|_{2}^{2} \mid r\right]$ and $\min \left\{\exp \left(r^{2}\right) / L, 1\right\}$ is a good approximation when $r=o(\sqrt{2 \log L})$ (Lemma B.2) in the exponential regime. The right figure shows that $1-\mathbb{E}\left[\|p\|_{2}^{2} \mid r\right]$ for $r \gg$ $\sqrt{2 \log L}$ is upper bounded by $O\left(r^{-1+\epsilon}\right)$ in the saturation regime(Lemma B.5).
also depends on the signal strength $\lambda$ while the standard linear regression's regularization term only depends on the noise level $\sigma^{2}$. Such a fact answers the question of why the MS-Attn's performance matches the MMSE only under the low SNR regime as shown Table 1. The key to our analysis is understanding the softmax-induced regularization term.

### 4.3.2 Exponential and Saturation Regime of Softmax Attention

We characterize the behavior of the softmax-induced regularization in two regimes, which we call the exponential regime and the saturation regime, stratified by the scale of the attention budget $\left\|W_{X}\right\|_{\mathrm{F}}^{2}=\mathbb{E}\left[\left\|W_{X} q\right\|_{2}^{2}\right]$. In the sequel, we denote by $\mathbb{E}\left[\|p\|_{2}^{2} \mid r\right]=\mathbb{E}\left[\|p\|_{2}^{2} \mid\left\|W_{X} q\right\|_{2}=r\right]$. Since $r$ is a random variable with $r^{2}$ concentrated around $\left\|W_{X}\right\|_{\mathrm{F}}^{2}$, we also characterize the two regimes by the scale of $r$. Figure 6 illustrates the behavior of the softmax-induced regularization term $\mathbb{E}\left[\|p\|_{2}^{2} \mid r\right]$ as a function of $r$.

Exponential Region ( $r=o(\sqrt{2 \log L})$, Lemma B.2). We name this regime the exponential regime since in this regime, the softmax-induced regularization term in (4.8) is approximately an exponential function of the attention budget. This is also the regime where the optimal ICL rate is achieved (Theorem 4.2). To derive the approximation form, we introduce an index $t \in[0,1]$ and consider function $f(t, q)=\mathbb{E}\left[\left\|\operatorname{softmax}\left(t X^{\top} W_{X} q\right)\right\|_{2}^{2} \mid q\right]$. We then take the derivative $\frac{\partial f}{\partial t}$ to obtain

$$
\frac{\partial f}{\partial t}=\mathbb{E}\left[\|p(t)\|_{2}^{2}-4\|p(t)\|_{3}^{3}+3\|p(t)\|_{2}^{4} \mid q\right] \cdot\left\|W_{X} q\right\|_{2}^{2}
$$

where $p(t)=\operatorname{softmax}\left(t X^{\top} W_{X} q\right)$. This calculation follows from the Stein's lemma. By analyzing the tail of $\max _{l \in[L]} p_{l}(t)$, we can control the higher order moments of $p(t)$ and get

$$
\frac{\partial f}{\partial t} \approx \mathbb{E}\left[\|p(t)\|_{2}^{2} \mid q\right] \cdot\left\|W_{X} q\right\|_{2}^{2}=f(t, q) \cdot\left\|W_{X} q\right\|_{2}^{2}
$$

Integrating this with respect to $t$ from 0 to 1 and by a careful analysis of the error along the integrating path, we conclude that $\mathbb{E}\left[\left\|\operatorname{softmax}\left(t X^{\top} W_{X} q\right)\right\|_{2}^{2} \mid q\right]=f(1, q) \approx \exp \left(\left\|W_{X} q\right\|_{2}^{2}\right) / L$. The analysis can also be extended to the multi-head case and the results are also useful for simplifying the dynamics in §C.2.2.

Saturation Regime ( $r \gg \sqrt{2 \log L \text {, Lemma B.5). The above approximation breaks down for }}$ large $r$. However, in this case we can utilize the fact that the attention probability is concentrated. Note that $\mathbb{E}\left[\|p\|_{2}^{2} \mid r\right]=\mathbb{E}\left[\|\operatorname{softmax}(r z)\|_{2}^{2}\right]$, where $z \sim \mathcal{N}\left(0, I_{d}\right)$. It can be shown that

$$
\begin{equation*}
1-\mathbb{E}\left[\|p\|_{2}^{2} \mid r\right] \leq 2 \mathbb{E}\left[p_{2}+p_{3}+\cdots+p_{L} \mid r\right] \leq 2 \mathbb{E}\left[\sum_{l=2}^{L} \exp \left(-r\left(z_{1}-z_{l}\right)\right)\right] \tag{4.9}
\end{equation*}
$$

where $p_{1}, p_{2}, \ldots, p_{L}$ and $z_{1}, z_{2}, \ldots, z_{L}$ are the (descending) order statistics of $p$ and $z$ respectively. The approach for dealing with (4.9) is to properly choose a threshold $\theta=\log \left(L r^{\alpha}\right) / r$ for some $\alpha>1 / 2$ and then split the sum into two parts based on whether $z_{1}-z_{l}>\theta$ or $z_{1}-z_{l} \leq \theta$. For the first part, we utilize the gap $\theta$ to upper bound the sum by $L \exp (-r \theta)=r^{-\alpha}$. For the second part, we directly upper bound each term by $\exp \left(-r\left(z_{1}-z_{2}\right)\right)$ while controlling the total number of terms $N$. This is essentially equivalent to bounding the tail of a binomial distribution with $L$ trials and success probability roughly $\mathbb{P}_{v \sim \mathcal{N}(0,1)}(\sqrt{2 \log L}-v \leq \theta)$. Finally, combining the moment generating function for $z_{1}-z_{2}$ and also the tail bound for $N$, we can choose $\alpha$ to be some $1-\epsilon$ constant and obtain the desired result.

The Saturation Regime is Suboptimal for ICL with noise. Huang et al. (2023) studied the setting where the context features come from an orthogonal basis and the data is noiseless. Their trained model that assigns $\Omega(1)$ probability to some tokens and falls into the saturation regime. However, in the presence of noise, our analysis clearly shows the suboptimality of the saturation regime for ICL (Lemma E. 4 and Lemma E.5). The proof is a combination of understanding the nonlinear ICL loss for different regions of the attention budget. Notably, the proof of Lemma E. 4 for the very extreme case of the attention budget is given by relating the lower bound of the ICL loss to a group of attention weights operating with normalized query on the sphere.

### 4.3.3 Proof Sketch for the Optimality Results

Now we are ready to sketch the proof for the optimality results.

The Single-Head Case. Recall from (4.8) and we consider the attention to operate in the exponential regime:

$$
\begin{equation*}
\mathcal{L}(U, W) \approx \underbrace{\lambda d^{-1} \cdot \mathbb{E}\left[\left\|I-U_{Y} W_{X}\right\|_{\mathrm{F}}^{2}\right]}_{\text {Linearized bias }}+\underbrace{\left(\lambda+\sigma^{2}\right) \cdot U_{Y}^{2} \cdot \frac{\exp \left(\left\|W_{X}\right\|_{\mathrm{F}}^{2}\right)}{L}}_{\text {Softmax-induced regularization }} . \tag{4.10}
\end{equation*}
$$

The softmax-induced regularization puts a quadratic penalty on the output projection weights $U_{Y}$ and an exponential penalty on the attention budget $\left\|W_{X}\right\|_{\mathrm{F}}^{2}$. In (4.10), it is not hard to see that all attention budget should be concentrated only on the diagonal entries of $W_{X}$ to minimize the loss. For multi-task case, the same argument still holds but needs a more refined analysis, especially for dealing with nonlinearity that is hidden in (4.10) for ease of presentation. By treating $W_{X}=\sqrt{B / d} \cdot I_{d}$ and first optimizing over $U_{Y}$, we arrive at the an optimization problem over $B$ :

$$
\min _{0 \leq B \leq O(\log L)} \frac{\lambda}{d^{-1} L \phi^{-1} \exp (-B) B+1},
$$

where $\phi=1+\operatorname{SNR}^{-1}=1+\sigma^{2} / \lambda$. The optimal is achieved at $B^{\star}=1$ which gives the optimal loss value $\lambda /\left(e^{-1} \phi^{-1} d^{-1} L+1\right)$ and also the optimal solution. The results for the multi-task setting follow from similar ideas.

The Multi-Head Case. Here we need a more refined loss decomposition that isolates task-wise performance as follows:

$$
\begin{gathered}
\mathcal{L}(\mu, \bar{\omega})=\frac{\lambda}{I} \sum_{i=1}^{I} \mathcal{L}_{i}(\mu, \bar{\omega})+O\left(L^{-\epsilon / 2}\right), \quad \text { where } \quad \mathcal{L}_{i}(\mu, \bar{\omega}):=1-2 \mu_{i}^{\top} \bar{\omega}_{i}+\mu_{i}^{\top}\left(\bar{\omega}_{i} \bar{\omega}_{i}^{\top}+B\right) \mu_{i}, \\
\bar{\omega}_{i}=\left(\bar{\omega}_{i}^{(1)}, \ldots, \bar{\omega}_{i}^{(H)}\right)^{\top}, \quad \mu_{i}=\left(\mu_{i}^{(1)}, \ldots, \mu_{i}^{(H)}\right)^{\top}, \quad B \in \mathbb{R}^{H \times H} \operatorname{with}\left(B_{i}\right)_{h h^{\prime}}:=\frac{\phi_{i} \exp \left(\bar{d}\left\langle\bar{\omega}^{(h)}, \bar{\omega}^{\left(h^{\prime}\right)}\right\rangle\right)}{L} .
\end{gathered}
$$

Note that by the equiangular property, we can also decompose $B$ into the diagonal part and the off-diagonal part

$$
B=(\widetilde{a}-\widetilde{b}) I+\widetilde{b} E,
$$

where $E$ is the matrix with all entries being 1 and $\widetilde{a}, \widetilde{b}$ are the diagonal and off-diagonal entries of $B$ respectively. Motivated by the structure of $B$, we can also project $\bar{\omega}_{i}$ into the parallel and orthogonal components with respect to $\mathbf{1}_{H}$. By doing quadratic minimization over $\mu_{i}$, and a nonlinear minimization over $\widetilde{a}, \widetilde{b}$, we arrive at the lower bound for the equiangular weights.

## 5 Extensions

In this section, we discuss some extensions of the main results. Let us first gain more understanding of the relationship between softmax attention and linear attention.

### 5.1 Similarity between Softmax Attention and Linear Attention

Here we consider the optimal single-head attention head and consider the regime $L \gg d$. Consider a query $q$ such that $\left\|W_{X} q\right\|_{2}^{2}=O(1)$ and we ignore the noise term. We invoke (4.7) and also the approximation in the exponential regime (Lemma B.2, which applies regardless of the relative scale of $d$ and $L$ when $\left.\left\|W_{X} q\right\|_{2}^{2}=O(1)\right)$ to get

$$
X p \approx \mathbb{E}[X p \mid q]=W_{X} q\left(1-\mathbb{E}\left[\|p\|_{2}^{2} \mid q\right]\right) \approx W_{X} q \approx \frac{1}{L} X X^{\top} W_{X} q .
$$

Here the first approximation is due to the fact that the second moment is small by (4.7), i.e.,

$$
\operatorname{Tr}\left(\mathbb{E}\left[(X p-\mathbb{E}[X p \mid q])(X p-\mathbb{E}[X p \mid q])^{\top} \mid q\right]\right)=d \cdot \mathbb{E}\left[\|p\|_{2}^{2} \mid q\right]+O\left(L^{-1}\right)=O(d / L) .
$$

Therefore, it follows that

$$
\begin{equation*}
\widehat{y}_{q}=U_{Y} G^{\top} X p \approx \frac{1}{L} U_{Y} Y X^{\top} W_{X} q=\frac{1}{L} U Z Z^{\top} W z_{q}, \tag{5.1}
\end{equation*}
$$

which is equivalent to the linear attention model (Zhang et al., 2022) but with a different scaling of the attention weights. However, such approximation requires a large $L$. For the setting of our main results where $d / L=\Theta(1)$, the approximation is not valid and the analysis has to go beyond the linear case.

### 5.2 Length Generalization

We also consider applying the trained model in Theorem 3.3 with training data of length $L$ to a same ICL tasks with a new sequence of length $\widetilde{L}$, and study the ICL loss for the new tasks. Specifically, the softmax attention model is trained in the same way as in (2.7), but when computing the ICL loss, we use a sequence of length $\widetilde{L}$. That is, in (2.6), $\widehat{y}_{q}$ is computed according to (2.1) but with $Z$ consisting of $\widetilde{L}$ covariate-response pairs from the multi-task linear model introduced in Assumption 2.1. We have the following upper bound on the ICL loss.

Proposition 5.1 (Length Generalization for MS-Attn). For the convergence point of the dynamics described in Theorem 3.3, consider applying the trained model to a new ICL learning task with the same data structure under Assumption 2.1 but a new sequence length $\widetilde{L}$. Then the corresponding loss value is upper bounded by

$$
\begin{equation*}
\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot\left(\frac{e d_{i} \phi_{i} L^{-1}}{1+e d_{i} \phi_{i} L^{-1}}+O\left(L^{-(1-\epsilon) / 2}+\omega_{0}^{2} d+\delta\right)+O\left(\phi_{i} d_{i}\left|L^{-1}-\widetilde{L}^{-1}\right|\right)^{2}\right) \tag{5.2}
\end{equation*}
$$

See $\S$ F. 1 for a proof. Proposition 5.1 shows that the ICL loss scales with $O(d / \widetilde{L})+O((d /(L \wedge$ $\left.\widetilde{L})^{2}\right)$ ). Here in $(5.2)$, the first term is the intrinsic loss and the third term characterizes the error due to the mismatch in sequence length. Notably, since $\bar{\omega}_{i}^{\star}$ is independent of the sequence length, we have the mismatch term coming only from the suboptimality of $\mu_{i}^{\star}$, which is actually a higher order term (for more details, see the quadratic error term in Lemma E.7). Thus, we conclude that the model trained by gradient flow also generalizes well to new sequence length. We also remark that such a nice property is due to the normalization of the softmax function, and the linear attention model does not have such a property as indicated by (5.1) where the weights should directly scale with $1 / L$.

### 5.3 Linear-to-Nonlinear Transfer

We consider first training the model on linear tasks and then applying the trained model to a nonlinear task. We only consider the single-head case for simplicity. Consider replacing $Y=$ $G^{\top} X+\varepsilon$ with $Y=f(X)+\varepsilon$ where $f$ is a nonlinear function in the downstream ICL task (the training data is still linear). Suppose $f$ has degree at most $D$ in the sense that $f$ is a linear combination of $d$ dimensional multivariate Hermite polynomials up to degree $D,\left\{\operatorname{He}_{\alpha}\left|\alpha \in \mathbb{N}^{d},|\alpha|:=\sum_{i=1}^{d} \alpha_{i} \leq D\right\}\right.$.

$$
f(x)=\sum_{|\alpha| \leq D} \widehat{f}_{\alpha} \operatorname{He}_{\alpha}(x), \quad \text { where } \quad \widehat{f}_{\alpha} \in \mathbb{R}
$$

Lemma 5.2 (Generalization of Single-Head Softmax Attention to Nonlinear Tasks). Let $L$ be sufficiently large such that (3.7) holds for constants $\epsilon$ and c. Consider Assumption 2.1 on the data but with a nonlinear task $Y=f(X)+\varepsilon$ where $f$ has degree at most $D=O(1)$. Consider only a single head whose weights are given by the optimal single-head softmax attention trained for this linear task, i.e.,

$$
\begin{equation*}
W_{X}=d^{-1 / 2} \cdot I_{d}, \quad U_{Y}=\mu=\frac{\sqrt{d}}{1+e d \phi L^{-1}} \tag{5.3}
\end{equation*}
$$

Then with probability at least $1-\exp \left(-\left(c^{-2} \log L-1\right)^{2} \wedge d / 2\right)$, the average output of the model for a fixed query q satisfies

$$
\begin{equation*}
\left|\mathbb{E}\left[\hat{y}_{q} \mid q\right]-\mu \cdot \sum_{\alpha:|\alpha| \leq D} \hat{f}_{\alpha} d^{-|\alpha| / 2} \cdot q^{\alpha}\right| \leq O\left(L^{-2(1-\epsilon)}\right) \tag{5.4}
\end{equation*}
$$

where we define $q^{\alpha}=\prod_{i=1}^{d} q_{i}^{\alpha_{i}}$.
See §F. 2 for a proof. Lemma 5.2 indicates that the optimal single-head softmax attention trained for a linear task does not generalize well to a nonlinear task. On one hand, the coefficient is not well preserved due to the additional factor $d^{-|\alpha| / 2}$, especially for high degree terms. On the other hand,

$$
q^{\alpha}=\prod_{i=1}^{d}\left(\sum_{k_{i}=0}^{\left\lfloor\alpha_{i} / 2\right\rfloor} \frac{\operatorname{He}_{\alpha_{i}-2 k_{i}}\left(q_{i}\right)}{k_{i}!2^{k_{i}}\left(\alpha_{i}-2 k_{i}\right)!}\right)=\operatorname{He}_{\alpha}(q)+\sum_{\substack{k \in \mathbb{N}^{d}|l| l \mid \geq 1 \\ k_{i} \leq\left\lfloor\alpha_{i} / 2\right\rfloor, \forall i \in[d]}} \frac{\operatorname{He}_{\alpha-2 k}(q)}{k!2^{k}(\alpha-2 k)!},
$$

where $k!=\prod_{i=1}^{d} k_{i}$ ! and $2^{k}=\prod_{i=1}^{d} 2^{k_{i}}$. Such a fact indicates a "leakage" of the high degree terms to the low degree terms. Notably, when $\alpha=0$, we have output $\mu \widehat{f_{0}}$, where we see that the current attention scales up the constant term up by $\mu=\Omega(\sqrt{d})$. However, this can be remedied by also including a bias term to the output layer, i.e., $\widehat{y}_{q}=U_{Y} Y p+b$ and also before inputting the sequence to the attention layer, i.e., $Y=Y-b^{\prime}$.

At a high level, the failure of capturing higher order nonlinear effect is because the model (5.3) trained on linear tasks only achieves the optimal variance and bias tradeoff for linear tasks, as $W_{X}=d^{-1 / 2} I_{d}$ "downscales" the attention score to have unit variance and $U_{Y} \approx \sqrt{d}$ "upscales" the aggregated output back to its original scale. The "downscaling" seems to be too much for nonlinear tasks with higher degree terms.

## 6 Conclusion and Future Work

In this paper, we study the training dynamics of a single-layer multi-head softmax attention model for the in-context learning problem of multi-task linear regression. By deriving the spectral dynamics of the attention weights induced by gradient flow, we provide a complete characterization of the training dynamics in terms of three phases: warm-up, emergence, and convergence.
(i) The warm-up phase shows that the optimal attention head for each task, which by initialization has small advantage, gradually wins the competition among heads under a strong cross-head interference.
(ii) The emergence phase demonstrates the sudden emergence of the ICL capability with a quick drop in the ICL loss.
(iii) The convergence phase highlights a linear convergence rate to the optimal solution: each task is assigned a unique attention head which operates as the optimal single-head attention for that task.

We also characterize the optimality of the convergence point of gradient flow. Throughout the analysis, we identify two working regions of the softmax attention model and prove that for noisy tasks, the optimal weights lie in the exponential region which demonstrates a unique tradeoff between bias and variance for the softmax attention model.

We also show that the optimal solution for a linear task trained with a fixed context sequence length generalizes well to different sequence length but poorly to nonlinear tasks. For future work, we believe it is important to further incorporate into the analysis other design factors in transformers, such as multi-layers, layer normalization, and positional encodings, etc. It is also an interesting future direction to understand how softmax attention deals with nonlinear tasks, especially for the multi-head attention model.

## A Additional Notations and Organization of the Appendices

Addition Notations for Proofs. For a polynomial $f\left(x_{1}, \ldots, x_{n}\right)=\prod_{i=1}^{n} x_{i}^{a_{i}}$ of $n$ variables where $a_{1}, \ldots, a_{n}$ are positive integers, we say that $f$ is even if all $a_{i}$ 's are even. For any dimension $d$, we denote by $\mathbf{1}_{d}$ the $d$-dimensional all-one vector. We denote by $\operatorname{Diag}(M)$ the column vector created from the diagonal entries of $M$ and $\operatorname{diag}(v)$ the diagonal matrix created from the vector $v$. We denote by $u \otimes v$ the outer product of vectors $u$ and $v$, and denote by $A \otimes_{K} B$ the Kronecker product of matrices $A$ and $B$. Following the convention for tensor inner product, we denote by $A \cdot B$ the inner product of tensors $A$ and $B$ such that $A \cdot B=\sum_{k} A_{:, k} B_{k,:}, A: B$ the double inner
product of tensors $A$ and $B$ such that $A: B=\sum_{k l} A_{:, k, l} B_{l, k,:}$. Here, the ":" in $A_{:, k}$ hides the indices of $A$ except for the last dimension(s).

Roadmap of the Appendices. The remainder of the appendices is organized as follows:

1. Appendix B contains results on the (conditional) moments of the attention probability vector.
2. Section C contains the simplification and approximation of the gradient flow dynamics under the Decomposability Condition. In particular
(a) Appendix C. 1 provides simplifications of the gradient flow dynamics induced by the Decomposability Condition.
(b) Appendix C. 2 contains the approximation of spectral dynamics induced by gradient flow.
(c) Appendix C. 3 provides the proof of Lemma 3.2, the preservation of the Decomposability Condition along gradient flow.
3. Appendix D contains the analyses for the dynamics.
4. Appendix E presents the optimality analysis of the convergence point of gradient flow.
5. Appendix F contains the proofs for the generalization results.
6. Appendix G collects the proofs of auxiliary results used in the analysis.

## B Characterizing Moments of the Attention Probability

In this section, we characterize the correlation of the attention probability $\mathbb{E}\left[\left(p^{h}\right)^{\top} p^{h^{\prime}} \mid q\right]$ by providing an upper and lower bound for this quantity. The idea is to construct a gradient flow dynamics starting from zero for the attention weight $W^{h}$ and $W^{h^{\prime}}$ and bounding the terms in the gradient flow dynamics. In the sequel, we denote by $p$ and $\widetilde{p}$ two attention probability vectors, and by $W$ and $\widetilde{W}$ the corresponding weight matrices, and they are related by

$$
\begin{gathered}
p=\operatorname{softmax}\left(X^{\top} W q\right), \quad \widetilde{p}=\operatorname{softmax}\left(X^{\top} \widetilde{W} q\right), \quad \text { where } \\
X=\left[x_{1}, \ldots, x_{L}\right] \in \mathbb{R}^{d \times L}, \quad x_{l} \stackrel{\text { i.i.d. }}{\sim} \mathcal{N}\left(0, I_{d}\right), \forall l \in[L] .
\end{gathered}
$$

Here, $q \in \mathbb{R}^{d}$ is the query vector and we have $q \sim \mathcal{N}\left(0, I_{d}\right)$. In addition, we define the kernel matrices $P \in \mathbb{R}^{L \times L}$ and $\widetilde{P} \in \mathbb{R}^{L \times L}$ as

$$
P=\operatorname{diag}(p)-p p^{\top}, \quad \widetilde{P}=\operatorname{diag}(\widetilde{p})-\widetilde{p} \tilde{p}^{\top} .
$$

## B. $1 \mathbb{E}\left[\|p\|_{2}^{2} \mid\|W q\|_{2}=r\right]$ Is Monotone in $r$

Let $r=\|W q\|_{2}$. Note that $\mathbb{E}\left[\|p\|_{2}^{2} \mid q\right]$ is just a function of $r$ as we have shown in the previous section.[TODO: explain this] Thus, we also abbreviate $\mathbb{E}\left[\|p\|_{2}^{2} \mid q\right]$ into $\mathbb{E}\left[\|p\|_{2}^{2} \mid\|W q\|_{2}=r\right]$. Note the there is still a gap for $r \in\left(c^{-1} \sqrt{2 \log L}, O\left(\sqrt{2 \log L^{3}}\right)\right.$. To fully understand the behavior of the transformer so as to give the optimality result, we need to show that $\mathbb{E}\left[\|p\|_{2}^{2} \mid\|W q\|_{2}=r\right]$ is a growing function of $r$, which is presented in the following lemma.
Lemma B.1. Suppose $q, x_{1}, \ldots, x_{L} \stackrel{\text { i.i.d. }}{\sim} \mathcal{N}\left(0, I_{d}\right)$, and denote $X=\left[x_{1}, \ldots, x_{L}\right]$. For any fixed $W \in \mathbb{R}^{d \times d}$, let $p=\operatorname{softmax}\left(X^{\top} W q\right)$, then $\mathbb{E}\left[\|p\|_{2}^{2} \mid\|W q\|_{2}=r\right]$ is monotonically increasing in $r$.
Proof of Lemma B.1. Denote $w_{l}:=x_{l}^{\top} W q /\|W q\|_{2}$ for each $l \in[L]$. Differentiating $\|p\|_{2}^{2}$ with respect to $r:=\|W q\|_{2}$ gives

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{~d} r}\|p\|_{2}^{2} & =\frac{\mathrm{d}}{\mathrm{~d} r} \sum_{i=1}^{L}\left(\frac{\exp \left(r w_{i}\right)}{\sum_{j=1}^{L} \exp \left(r w_{j}\right)}\right)^{2} \\
& =\sum_{i=1}^{L} \frac{2 w_{i} \exp \left(2 r w_{i}\right) \sum_{j=1}^{L} \exp \left(r w_{j}\right)-\exp \left(2 r w_{i}\right) 2 \sum_{j=1}^{L} \exp \left(r w_{j}\right) x_{j}}{\left(\sum_{j=1}^{L} \exp \left(r w_{j}\right)\right)^{3}} \\
& =2 \cdot \frac{\sum_{i=1}^{L} w_{i} \exp \left(2 r w_{i}\right) \sum_{j=1}^{L} \exp \left(r w_{j}\right)-\sum_{i=1}^{L} \exp \left(2 r w_{i}\right) \sum_{j=1}^{L} \exp \left(r w_{j}\right) w_{j}}{\left(\sum_{j=1}^{L} \exp \left(r w_{j}\right)\right)^{3}}
\end{aligned}
$$

Further write $v_{i}:=\exp \left(r w_{i}\right)$ for simplicity, then the numerator can be rewritten as

$$
\begin{aligned}
\sum_{i, j=1}^{L} w_{i} v_{i}^{2} v_{j}-\sum_{i, j=1}^{L} w_{j} v_{i}^{2} v_{j} & =\sum_{i, j=1}^{L}\left(w_{i}-w_{j}\right) v_{i}^{2} v_{j}=\frac{1}{2} \sum_{i, j=1}^{L}\left(w_{i}-w_{j}\right) v_{i}^{2} v_{j}+\frac{1}{2} \sum_{i, j=1}^{L}\left(w_{j}-w_{i}\right) v_{j}^{2} v_{i} \\
& =\frac{1}{2} \sum_{i, j=1}^{L}\left(w_{i}-w_{j}\right)\left(v_{i}-v_{j}\right) v_{i} v_{j} \geq 0
\end{aligned}
$$

where the inequality follows from the nonnegativity of $v_{i}$ and the observation that $v_{i}$ is a monotone function of $w_{i}$. Therefore, we conclude that $\|p\|_{2}^{2}$ is a monotonically increasing function of $r$, and hence is $\mathbb{E}\left[\|p\|_{2}^{2} \mid\|W q\|_{2}=r\right]$.

## B. 2 Approximating $\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]$ for small $\|W q\|_{2}$

Construct Pseudo Dynamics. We consider a constant-speed gradient flow on $W(t)$ and $\widetilde{W}(t)$ within time interval $t \in[0,1]$ with initial condition $W(0)=\widetilde{W}(0)=0$ and terminal condition $W(1)=W$ and $\widetilde{W}(1)=\widetilde{W}$. The gradient flow for $\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]$ is given by

$$
\begin{aligned}
\partial_{t} \mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right] & =\sum_{l} \mathbb{E}\left[\partial_{t} p_{l} \widetilde{p}_{l}+p_{l} \partial_{t} \widetilde{p}_{l} \mid q\right] \\
& =\sum_{l m} \mathbb{E}\left[P_{l m} \widetilde{p}_{l} \cdot x_{m}^{\top} \partial_{t} W q+p_{l} \widetilde{P}_{l m} \cdot x_{m}^{\top} \partial_{t} \widetilde{W} q \mid q\right] \\
& =\sum_{l m} \mathbb{E}\left[\nabla_{x_{m}}^{\top}\left(P_{l m} \widetilde{p}_{l}\right) \partial_{t} W q+\nabla_{x_{m}}^{\top}\left(\widetilde{P}_{l m} p_{l}\right) \partial_{t} \widetilde{W} q \mid q\right] . \quad \quad \text { // Stein's Lemma }
\end{aligned}
$$

Here, we use the Stein's Lemma to derive the last equality. Next, we expand the gradient and obtain

$$
\begin{align*}
& \partial_{t} \mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]= \sum_{l m} \mathbb{E}\left[P_{l m}\left(1-2 p_{m}\right) \widetilde{p}_{l} \cdot q^{\top} W^{\top} \partial_{t} W q+P_{l m} \widetilde{P}_{l m} q^{\top} \widetilde{W}^{\top} \partial_{t} W q \mid q\right] \\
&+\sum_{l m} \mathbb{E}\left[\widetilde{P}_{l m} P_{l m} q^{\top} W^{\top} \partial_{t} \widetilde{W} q+\widetilde{P}_{l m}\left(1-2 \widetilde{p}_{m}\right) p_{l} \cdot q^{\top} \widetilde{W}^{\top} \partial_{t} \widetilde{W} q \mid q\right] \\
&= \mathbb{E}\left[-2\left(\widetilde{p}^{\top} p^{\odot 2}-\|p\|_{2}^{2} p^{\top} \widetilde{p}\right) \cdot q^{\top} W^{\top} \partial_{t} W q-2\left(p^{\top} \widetilde{p}^{\odot 2}-\|\widetilde{p}\|_{2}^{2} p^{\top} \widetilde{p}\right) \cdot q^{\top} \widetilde{W}^{\top} \partial_{t} \widetilde{W} q \mid q\right] \\
&+\mathbb{E}\left[\left(p^{\top} \widetilde{p}-p^{\top} \widetilde{p}^{\odot 2}-\widetilde{p}^{\top} p^{\odot 2}+\left(p^{\top} \widetilde{p}\right)^{2}\right) q^{\top}\left(\widetilde{W}^{\top} \partial_{t} W+\partial_{t} \widetilde{W}^{\top} W\right) q \mid q\right] \\
&=\mathbb{E}\left[-\left(\widetilde{p}^{\top} p^{\odot 2}-\|p\|_{2}^{2} p^{\top} \widetilde{p}\right) \cdot q^{\top} \partial_{t}\left(W^{\top} W\right) q-\left(p^{\top} \widetilde{p}^{\odot 2}-\|\widetilde{p}\|_{2}^{2} p^{\top} \widetilde{p}\right) \cdot q^{\top} \partial_{t}\left(\widetilde{W}^{\top} \widetilde{W}\right) q \mid q\right] \\
&+\mathbb{E}\left[\left(p^{\top} \widetilde{p}-p^{\top} \widetilde{p}^{\odot 2}-\widetilde{p}^{\top} p^{\odot 2}+\left(p^{\top} \widetilde{p}\right)^{2}\right) q^{\top} \partial_{t}\left(\widetilde{W}^{\top} W\right) q \mid q\right] \tag{B.1}
\end{align*}
$$

Our next goal is to show that $p^{\top} \widetilde{p}$ is the dominating term. A naive lower bound for $p^{\top} \widetilde{p}$ is given by $p^{\top} \tilde{p} \geq L^{-1}$. So the claim holds if we could show that the remaining terms are of higher order $o\left(L^{-1}\right)$.

Eliminate the Higher Order Terms. In the following, we consider bounding the higher order terms in (B.1). We employ notations $p_{t}, \widetilde{p}_{t}, W_{t}, \widetilde{W}_{t}$ to denote the attention probability vectors and weight matrices at time $t$ We have $p_{0}=\widetilde{p}_{0}=0, W_{0}=\widetilde{W}_{0}=0$ at initialization and $p_{1}=$ $p, \widetilde{p}_{1}=\widetilde{p}, W_{1}=W, \widetilde{W}_{1}=\widetilde{W}$ at terminal time. We work in the region $\tau^{2}:=\max \left\{\|W q\|_{2}^{2},\|\widetilde{W} q\|_{2}^{2}\right\} \leq$ $c^{-2} \cdot 2 \log L$ for some absolute constant $c$. The result for representing the pseudo dynamics with only the dominating term is given by the following lemma.

Lemma B.2. Fix constant $\epsilon \in(0,1)$ and let $c>0$ be the solution to the fixed-point equation

$$
\frac{1}{c}+\frac{3}{1+\sqrt{1+c^{2} / 2}}=\epsilon .
$$

If $\tau^{2}:=\max \left\{\|W q\|_{2}^{2},\|\widetilde{W} q\|_{2}^{2}\right\} \leq c^{-2} \cdot 2 \log L$ holds, we have for $\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]$ that

$$
\xi_{L}:=\left|\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]-\frac{\exp \left(q^{\top} \widetilde{W}^{\top} W q\right)}{L}\right|=O\left(L^{-2(1-\epsilon)}\right) .
$$

Also, for the higher order terms, we also have

$$
\begin{aligned}
\max & \left\{\mathbb{E}\left[p_{t}^{\top} \tilde{p}_{t}^{\odot 2} \mid q\right], \quad \mathbb{E}\left[\widetilde{p}_{t}^{\top} p_{t}^{\odot 2} \mid q\right], \quad \mathbb{E}\left[\left\|p_{t}\right\|_{2}^{2} p_{t}^{\top} \widetilde{p}_{t} \mid q\right], \quad \mathbb{E}\left[\left\|\widetilde{p}_{t}\right\|_{2}^{2} p_{t}^{\top} \widetilde{p}_{t} \mid q\right], \quad \mathbb{E}\left[\left(p_{t}^{\top} \widetilde{p}_{t}\right)^{2} \mid q\right]\right\} \\
& \leq O\left(L^{-2(1-\epsilon)}\right) .
\end{aligned}
$$

Proof of Lemma B.2. The first step is to put an upper bound for the maximum of the softmax probability $p_{l}$. It suffices to look at the attention scores $s_{l}=x_{l}^{\top} W q$, which are i.i.d. distributed as $\mathcal{N}\left(0,\|W q\|_{2}^{2}\right)$, and the variance is bounded by $\|W q\|_{2}^{2} \leq \tau^{2}$. Using the Gaussian tail bound, we have

$$
\mathbb{P}\left(\max _{l \in[L]} s_{l}>\tau \sigma \cdot \sqrt{2 \log L}\right) \leq L^{-\sigma^{2}+1}, \quad \forall \sigma>1
$$

Also, we are able to bound the number of negative attention scores by invoking the Hoeffding's inequality that

$$
\mathbb{P}\left(\sum_{m} \mathbb{1}\left(s_{m} \geq 0\right)<\frac{L}{4}\right) \leq \exp \left(-\frac{2(L / 4)^{2}}{L}\right)=\exp \left(-\frac{L}{8}\right) .
$$

We define the event $\mathcal{E}_{1}(W)$ for the softmax probability $p(t)$ over time $t \in[0,1]$ as

$$
\begin{equation*}
\mathcal{E}_{1}(W)=\left\{\max _{\substack{l \in[1], t \in[0,1]}} p_{l}(t)<\zeta(\tau, \sigma ; L)\right\}, \quad \text { where } \quad \zeta(\tau, \sigma ; L)=\frac{\exp (\tau \sigma \sqrt{2 \log L})}{L / 4} \leq 4 L^{\frac{2 \sigma}{c}-1} \tag{B.2}
\end{equation*}
$$

The event $\mathcal{E}(\widetilde{W})$ is defined similarly. One can bound the probability of $\mathcal{E}_{1}^{c}$ as

$$
\begin{aligned}
\mathbb{P}\left(\mathcal{E}_{1}^{c}\right) & \leq \mathbb{P}\left(\left.\max _{\substack{l \in[L], t \in[0,1]}} p_{l}(t)>\frac{\exp (\tau \sigma \sqrt{2 \log L})}{L / 4} \right\rvert\, \sum_{m} \mathbb{1}\left(s_{m} \geq 0\right) \geq \frac{L}{4}\right)+\mathbb{P}\left(\sum_{m} \mathbb{1}\left(s_{m} \geq 0\right)<\frac{L}{4}\right) \\
& \leq \mathbb{P}\left(\max _{l \in[L]} s_{l}>\tau \sigma \sqrt{2 \log L}\right)+\exp \left(-\frac{L}{8}\right) \\
& \leq L^{-\sigma^{2}+1}+\exp \left(-\frac{L}{8}\right),
\end{aligned}
$$

where the second inequality holds since $\sum_{m} \exp \left(s_{m}\right) \geq \sum_{m} \mathbb{1}\left(s_{m}>0\right) \geq L / 4$ for the normalization of $p$. As a result, we consider two disjoint events $\mathcal{E}_{1}(W) \cap \mathcal{E}_{1}(\widetilde{W}), \mathcal{E}_{1}^{c}(W) \cup \mathcal{E}_{1}^{c}(\widetilde{W})$ and obtain that

$$
\begin{align*}
\max & \left\{\mathbb{E}\left[p_{t}^{\top} \widetilde{p}_{t}^{\odot} \mid q\right], \quad \mathbb{E}\left[\widetilde{p}_{t}^{\top} p_{t}^{\odot 2} \mid q\right], \quad \mathbb{E}\left[\left\|p_{t}\right\|_{2}^{2} p_{t}^{\top} \widetilde{p}_{t} \mid q\right], \quad \mathbb{E}\left[\left\|\widetilde{p}_{t}\right\|_{2}^{2} p_{t}^{\top} \widetilde{p}_{t} \mid q\right], \quad \mathbb{E}\left[\left(p_{t}^{\top} \widetilde{p}_{t}\right)^{2} \mid q\right]\right\} \\
& \leq L \cdot \zeta(\tau, \sigma ; L)^{3}+\mathbb{P}\left(\mathcal{E}_{1}^{c}(W) \cup \mathcal{E}_{1}^{c}(\widetilde{W})\right) \\
& \leq 64 L^{\frac{6 \sigma}{c}-2}+2 L^{-\sigma^{2}+1}+2 \exp (-L / 8) . \tag{B.3}
\end{align*}
$$

Here, the first inequality holds by noting that $p_{l}, \widetilde{p}_{l} \leq \zeta(\tau, \sigma ; L)$ element-wise on $\mathcal{E}_{1}(W) \cap \mathcal{E}_{1}(\widetilde{W})$ and that each term in the maximum is bounded by 1 . Now, we select out the dominating term $p^{\top} \widetilde{p}$ in (B.1) and with a little abuse of notation, denote the remaining terms as err ${ }_{>1}(t ; q)$ given by

$$
\operatorname{err}_{>1}(t ; q)=\partial_{t} \mathbb{E}\left[p_{t}^{\top} \widetilde{p}_{t} \mid q\right]-\mathbb{E}\left[p_{t}^{\top} \widetilde{p}_{t} \mid q\right] q^{\top} \partial_{t}\left(\widetilde{W}_{t}^{\top} W_{t}\right) q .
$$

Then, (B.3) implies that

$$
\begin{aligned}
\left|\operatorname{err}_{>1}(t ; q)\right| \leq & \left(64 L^{\frac{6 \sigma}{c}-2}+2 L^{-\sigma^{2}+1}+2 \exp (-L / 8)\right) \\
& \cdot\left(\left|q^{\top}\left(\partial_{t}\left(W_{t}^{\top} W_{t}\right)+\partial_{t}\left(\widetilde{W}_{t}^{\top} \widetilde{W}_{t}\right)\right) q\right|+2\left|q^{\top} \partial_{t}\left(\widetilde{W}_{t}^{\top} W_{t}\right) q\right|\right) \\
\leq & 4\left(64 L^{\frac{6 \sigma}{c}-2}+2 L^{-\sigma^{2}+1}+2 \exp (-L / 8)\right) \tau^{2}
\end{aligned}
$$

where the last inequality holds since we have constant speed. From the dynamics (B.1), we have

$$
\partial_{t}\left(\exp \left(-q^{\top} \widetilde{W}_{t}^{\top} W_{t} q\right) \cdot \mathbb{E}\left[p_{t}^{\top} \widetilde{p}_{t} \mid q\right]\right)=\exp \left(-q^{\top} \widetilde{W}_{t}^{\top} W_{t} q\right) \cdot \operatorname{err}(t ; q)
$$

By integrating the above equation from $t=0$ to $t=1$, we have

$$
\begin{align*}
& \left|\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]-\frac{\exp \left(q^{\top} \widetilde{W}^{\top} W q\right)}{L}\right| \\
& \quad=\left|\int_{0}^{1} \exp \left(-q^{\top} \widetilde{W}_{t}^{\top} W_{t} q\right) \cdot \operatorname{err}(t ; q) \mathrm{d} t\right| \cdot \exp \left(q^{\top} \widetilde{W}^{\top} W q\right) \\
& \quad \leq 4\left(64 L^{\frac{6 \sigma}{c}-2}+2 L^{-\sigma^{2}+1}+2 \exp (-L / 8)\right) \tau^{2} \cdot \frac{\exp \left(q^{\top} \widetilde{W}^{\top} W q\right)-1}{q^{\top} \widetilde{W}^{\top} W q} \\
& \quad \leq 4\left(64 L^{\frac{6 \sigma}{c}-2}+2 L^{-\sigma^{2}+1}+2 \exp (-L / 8)\right) \cdot \exp \left(\tau^{2}\right) \tag{B.4}
\end{align*}
$$

We invoke the upper bound for $\tau^{2}$ to obtain the final result,

$$
\left|\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]-\frac{\exp \left(q^{\top} \widetilde{W}^{\top} W q\right)}{L}\right| \leq 4\left(64 L^{2 c^{-2}+6 \sigma c^{-1}-2}+2 L^{-\sigma^{2}+1+2 c^{-2}}+2 L^{2 c^{-2}-L(\log L)^{-1} / 8}\right)
$$

Here, we plug in $\sigma=c \cdot\left(1+\sqrt{1+c^{2} / 3}\right)^{-1}$ which make the first and second terms equal in order. We also note that the third term is of higher order. Hence, for each fixed constant $\epsilon \in(0,1)$, we can always find $c>0$ satisfying the fixed-point condition

$$
\frac{1}{c}+\frac{3}{1+\sqrt{1+c^{2} / 2}}=\epsilon
$$

such that for all $\tau^{2}:=\max \left\{\|W q\|_{2}^{2},\|\widetilde{W} q\|_{2}^{2}\right\} \leq c^{-2} \cdot 2 \log L$ :

$$
\left|\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]-\frac{\exp \left(q^{\top} \widetilde{W}^{\top} W q\right)}{L}\right| \leq O\left(L^{2\left(c^{-2}-1\right)+6 \cdot\left(1+\sqrt{1+c^{2} / 2}\right)^{-1}}\right)=O\left(L^{-2(1-\epsilon)}\right)
$$

Notably, the error term in (B.3) is strictly less than the error term in (B.4). Hence for the higher order terms, we also have

$$
\begin{aligned}
\max & \left\{\mathbb{E}\left[p_{t}^{\top} \widetilde{p}_{t}^{\odot 2} \mid q\right], \quad \mathbb{E}\left[\widetilde{p}_{t}^{\top} p_{t}^{\odot 2} \mid q\right], \quad \mathbb{E}\left[\left\|p_{t}\right\|_{2}^{2} p_{t}^{\top} \widetilde{p}_{t} \mid q\right], \quad \mathbb{E}\left[\left\|\widetilde{p}_{t}\right\|_{2}^{2} p_{t}^{\top} \widetilde{p}_{t} \mid q\right], \quad \mathbb{E}\left[\left(p_{t}^{\top} \widetilde{p}_{t}\right)^{2} \mid q\right]\right\} \\
& \leq O\left(L^{-2(1-\epsilon)}\right)
\end{aligned}
$$

Hence, the proof is complete.

Concentration in $q$. Next, we take expectation with respect to $q \sim \mathcal{N}\left(0, I_{D}\right)$. It suffices to consider the expectation $\mathbb{E}\left[\exp \left(q^{\top} \widetilde{W}^{\top} W q\right)\right]$ according to Lemma B.2. The following lemma characterizes the expectation term.
Lemma B.3. Consider that $W \in \mathbb{R}^{D \times D}$ and $\widetilde{W} \in \mathbb{R}^{D \times D}$ share the same left eigenvectors $w_{1}, \ldots, w_{D}$ and also the same right eigenvectors $u_{1}, \ldots, u_{D}$, i.e., $W=\sum_{k=1}^{d} \omega_{k} w_{k} u_{k}^{\top}$ and $\widetilde{W}=\sum_{k=1}^{d} \widetilde{\omega}_{k} w_{k} u_{k}^{\top}$. Here, $d$ is the effective rank for $W$ and $\widetilde{W}$. Suppose

$$
\begin{gathered}
\max \left\{\|\widetilde{\omega}\|_{\infty},\|\omega\|_{\infty}\right\} \leq L^{-1 / 4} \cdot(\log L)^{-1 / 2}, \quad \max \left\{\|\omega\|_{2}^{2},\|\widetilde{\omega}\|_{2}^{2}\right\} \leq \frac{2 \log L}{3 c^{2}}, \\
\max \left\{\|\omega\|_{4}^{4},\|\widetilde{\omega}\|_{4}^{4}\right\} \leq L^{-\left(1-\epsilon_{0}\right)} \cdot(\log L)^{-1}
\end{gathered}
$$

where $c>0$ is a constant depending on a given constant $\epsilon \in(0,1)$ via the fixed-point equation

$$
\frac{1}{c}+\frac{3}{1+\sqrt{1+c^{2} / 2}}=\epsilon,
$$

and $\epsilon_{0} \in(0,1)$ is a constant whose purpose is to make sure $\omega=d^{-1 / 2} \mathbf{1}$ satisfies the forth moment condition and could also be chosen to be the same as $\epsilon$. It then holds that

$$
\mathbb{E}\left[\left(\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]-\frac{\exp \left(\operatorname{Tr}\left[W^{\top} \widetilde{W}\right]\right)}{L}\right)^{2}\right] \leq O\left(L^{-\left(3-\epsilon_{0}\right)}\right)
$$

Proof of Lemma B.3. Under the condition that $\widetilde{W}$ and $W$ have the same left and right eigenvectors, it suffices to study the quantity $\mathbb{E}\left[\exp \left(\sum_{k=1}^{d} \omega_{k} \widetilde{\omega}_{k} v_{k}^{2}\right)\right]$ where $v_{k} \stackrel{\text { i.i.d. }}{\sim} \mathcal{N}(0,1)$. Here, $d$ is the maximal rank of $W$ and $\widetilde{W}$, and $\omega_{k}$ and $\widetilde{\omega}_{k}$ are the eigenvalues of $W$ and $\widetilde{W}$ within the effective dimensions, respectively. We also denote by $\omega$ and $\widetilde{\omega}$ the vector of eigenvalues for $W$ and $\widetilde{W}$ when there is no ambiguity. Note that $v_{k}^{2}$ is a chi-square random variable. We invoke the following tail bound for chi-square distribution, which is given by Lemma 1 in Laurent and Massart (2000).

$$
\begin{gather*}
\mathbb{P}\left(\sum_{k=1}^{d} \omega_{k} \widetilde{\omega}_{k} v_{k}^{2}-\sum_{k=1}^{d} \omega_{k} \widetilde{\omega}_{k} \geq 2\|\omega \odot \widetilde{\omega}\|_{2} \sqrt{x}+2\|\omega \odot \widetilde{\omega}\|_{\infty} x\right) \leq \exp (-x),  \tag{B.5}\\
\mathbb{P}\left(\sum_{k=1}^{d} \omega_{k} \widetilde{\omega}_{k} v_{k}^{2}-\sum_{k=1}^{d} \omega_{k} \widetilde{\omega}_{k} \leq-2\|\omega \odot \widetilde{\omega}\|_{2} \sqrt{x}\right) \leq \exp (-x) .
\end{gather*}
$$

For our purpose, we take $x=4 \log L$, which gives

$$
\begin{equation*}
\mathbb{P}\left(\left|\sum_{k=1}^{d} \omega_{k} \widetilde{\omega}_{k} v_{k}^{2}-\sum_{k=1}^{d} \omega_{k} \widetilde{\omega}_{k}\right| \geq 2\|\omega \odot \widetilde{\omega}\|_{2} \sqrt{4 \log L}+8\|\omega \odot \widetilde{\omega}\|_{\infty} \log L\right) \leq \frac{2}{L^{4}} . \tag{B.6}
\end{equation*}
$$

Define the above event as $\mathcal{E}_{2}^{c}(W, \widetilde{W})$. Before we proceed, one must be aware that to use Lemma B. 2 for approximating $\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]$ with $\exp \left(q^{\top} \widetilde{W}^{\top} W q\right)$, we need to show that event

$$
\mathcal{E}_{3}(W):=\left\{\|W q\|_{2}^{2} \leq c^{-2} \cdot 2 \log L\right\}
$$

also holds with high probability. To show this point, we have by (B.5) where $\widetilde{\omega}$ is replaced by $\omega$ and $x=4 \log L$ that

$$
\begin{equation*}
\mathbb{P}\left(\|W q\|_{2}^{2} \geq\|\omega\|_{2}^{2}+4\|\omega\|_{4}^{2} \sqrt{\log L}+8\|\omega\|_{\infty}^{2} \log L\right) \leq L^{-4} \tag{B.7}
\end{equation*}
$$

Note that under the conditions

$$
\begin{equation*}
\max \left\{\|\omega\|_{4}^{4},\|\widetilde{\omega}\|_{4}^{4}\right\} \leq \frac{\log L}{36 c^{4}}, \quad \max \left\{\|\omega\|_{2}^{2},\|\widetilde{\omega}\|_{2}^{2}\right\} \leq \frac{2 \log L}{3 c^{2}}, \quad \max \left\{\|\omega\|_{\infty},\|\widetilde{\omega}\|_{\infty}\right\} \leq \frac{1}{\sqrt{12} c}, \tag{B.8}
\end{equation*}
$$

it follows that $\mathbb{P}\left(\mathcal{E}_{3}^{c}(W)\right)=\mathbb{P}\left(\|W q\|_{2}^{2} \geq c^{-2} \cdot 2 \log L\right) \leq L^{-4}$, and the same holds for $\mathcal{E}_{3}^{c}(\widetilde{W})$. Hence, we are able to control the difference between $\mathbb{E}\left[p^{\top} \widetilde{p}\right]$ and $\exp \left(\omega^{\top} \widetilde{\omega}\right) / L$ by

$$
\begin{aligned}
\mathbb{E} & {\left[\left(\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]-\frac{\exp \left(\omega^{\top} \widetilde{\omega}\right)}{L}\right)^{2}\right] } \\
\leq & \mathbb{E}\left[\left(\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]-\frac{\exp \left(\omega^{\top} \widetilde{\omega}\right)}{L}\right)^{2} \cdot \mathbb{1}\left[\mathcal{E}_{2}(W, \widetilde{W}) \cap \mathcal{E}_{3}(W) \cap \mathcal{E}_{3}(\widetilde{W})\right]\right] \\
& +\left(\mathbb{P}\left(\mathcal{E}_{2}^{c}(W, \widetilde{W})\right)+\mathbb{P}\left(\mathcal{E}_{3}^{c}(W)\right)+\mathbb{P}\left(\mathcal{E}_{3}^{c}(\widetilde{W})\right)\right) \cdot 2\left(1+\frac{2 \exp \left(\omega^{\top} \widetilde{\omega}\right)}{L^{2}}\right) \\
\leq & 2 \cdot \frac{\exp \left(2 \omega^{\top} \widetilde{\omega}\right)}{L^{2}} \cdot\left(\exp \left(2\|\omega \odot \widetilde{\omega}\|_{2} \sqrt{4 \log L}+8\|\omega \odot \widetilde{\omega}\|_{\infty} \log L\right)-1\right)^{2}+\xi_{L}^{2} \\
& +\frac{6}{L^{4}} \cdot\left(1+\frac{\exp \left(2 \omega^{\top} \widetilde{\omega}\right)}{L^{2}}\right),
\end{aligned}
$$

where the second inequality holds by using the approximation result in Lemma B. 2 with $\xi_{L}=$ $O\left(L^{-2(1-\epsilon)}\right)$, and the last inequality holds by plugging in (B.6). Under the condition

$$
\max \left\{\|\widetilde{\omega}\|_{\infty},\|\omega\|_{\infty}\right\} \leq L^{-1 / 4} \cdot(\log L)^{-1 / 2}, \quad \max \left\{\|\omega\|_{4}^{4},\|\widetilde{\omega}\|_{4}^{4}\right\} \leq L^{-\left(1-\epsilon_{0}\right)} \cdot(\log L)^{-1},
$$

it is easy to show that

$$
\begin{gathered}
\exp \left(2\|\omega \odot \widetilde{\omega}\|_{2} \sqrt{2 \log L}+4\|\omega \odot \widetilde{\omega}\|_{\infty} \log L\right)-1 \leq O\left(L^{-\left(1-\epsilon_{0}\right) / 2}\right), \\
\frac{6}{L^{4}} \cdot\left(1+\frac{\exp \left(2 \omega^{\top} \widetilde{\omega}\right)}{L^{2}}\right)=O\left(L^{-4}\right), \quad \xi_{L}=O\left(L^{-2(1-\epsilon)}\right) .
\end{gathered}
$$

As a result, we conclude that

$$
\mathbb{E}\left[\left(\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right]-\frac{\exp \left(\omega^{\top} \widetilde{\omega}\right)}{L}\right)^{2}\right] \leq O\left(L^{-\left(3-\epsilon_{0}\right)}\right)
$$

which completes the proof.

## B. 3 Controlling the Higher Order Moments.

Lemma B.4. Under Definition C.9, consider a $\mathcal{G}$-induced polynomial $f_{\mathcal{G}}(p, \widetilde{p})=\prod_{v \in \mathcal{V}}\left(p_{v}^{a_{v}} \widetilde{p}_{v}^{b_{v}}\right)$. $\prod_{\left(v, v^{\prime}\right) \in \mathcal{E}} \delta_{v v^{\prime}}$ and let $\operatorname{Ord}(\mathcal{G}) \triangleq \sum_{v \in \mathcal{V}}\left(a_{v}+b_{v}\right)-\left|\mathrm{CC}_{\geq 1}(\mathcal{G})\right|$ be the effective order of $\mathcal{G}$. Here, $p$ and $\widetilde{p}$ are the attention probability vectors for $W$ and $\widetilde{W}$, respectively. Suppose $\operatorname{Ord}(\mathcal{G}) \geq \kappa=2$. Fix any $\epsilon \in(0,1)$ and let $c \geq \frac{2 \operatorname{Deg}(\mathcal{G}) \sqrt{2 \kappa+1}}{\epsilon \kappa}$ where $\operatorname{Deg}(\mathcal{G})=\sum_{v \in \mathcal{V}}\left(a_{v}+b_{v}\right)$. If

$$
\max \left\{\|\omega\|_{4}^{4},\|\widetilde{\omega}\|_{4}^{4}\right\} \leq \frac{\log L}{36 c^{4}}, \max \left\{\|\omega\|_{2}^{2},\|\widetilde{\omega}\|_{2}^{2}\right\} \leq \frac{2 \log L}{3 c^{2}}, \max \left\{\|\omega\|_{\infty},\|\widetilde{\omega}\|_{\infty}\right\} \leq \frac{1}{\sqrt{12} c}
$$

holds, we have

$$
\mathbb{E}\left[f_{\mathcal{G}}(p, \widetilde{p})^{2}\right] \leq O\left(L^{-4(1-\epsilon)}\right) .
$$

Proof of Lemma B.4. Let $n=\left|\mathrm{CC}_{\geq 1}(\mathcal{G})\right|$ and $\operatorname{Deg}(\mathcal{G})=\sum_{v \in \mathcal{V}}^{n}\left(a_{v}+b_{v}\right)$. The argument is a combination of the general ideas in Lemma B. 2 and Lemma B.3. Let us first fix a query $q$. On the success of the event $\mathcal{E}_{1}(W) \cap \mathcal{E}_{1}(\widetilde{W})$ defined in (B.2), one has by definition that

$$
f_{\mathcal{G}}(p, \widetilde{p})^{2} \leq\left(4 L^{\frac{2 \sigma}{c}-1}\right)^{2 m} \cdot L^{2 n}=16^{\operatorname{Deg}(\mathcal{G})} \cdot L^{\frac{4 \sigma}{c} \operatorname{Deg}(\mathcal{G})} \cdot L^{-2 \operatorname{Ord}(\mathcal{G})}
$$

The failure probability for this joint event is at most $2\left(L^{-\sigma^{2}+1}+L^{-\frac{L}{8 \log L}}\right)$ as we have shown in the proof of Lemma B. 2 if $\mathcal{E}_{3}(W) \cap \mathcal{E}_{3}(\widetilde{W})$ holds. Here, $\mathcal{E}_{3}(W)$ is defined by the success of $\|W q\|_{2}^{2} \leq c^{-2} \cdot 2 \log L$. Note that $\left|f_{\mathcal{G}}(p, \widetilde{p})\right| \leq 1$. Therefore, we have on the success of $\mathcal{E}_{3}(W) \cap \mathcal{E}_{3}(\widetilde{W})$ that

$$
\mathbb{E}\left[f(p, \widetilde{p})^{2} \mid q\right] \leq 16^{\operatorname{Deg}(\mathcal{G})} \cdot L^{\frac{4 \sigma}{c} \operatorname{Deg}(\mathcal{G})} \cdot L^{-2 \kappa}+2\left(L^{-\sigma^{2}+1}+L^{-\frac{L}{8 \log L}}\right) .
$$

We take $\sigma=\sqrt{2 \kappa+1}$. By choosing a constant $c=(2 \sigma \operatorname{Deg}(\mathcal{G})) /(\epsilon \cdot \kappa)$ according to $\epsilon$, the total degree $\operatorname{Deg}(\mathcal{G})$, and $\kappa$, we obtain that $\mathbb{E}\left[f(p, \widetilde{p})^{2} \mid q\right] \leq O\left(L^{-2 \kappa \cdot(1-\epsilon)}\right)$ on the success of $\mathcal{E}_{3}(W) \cap \mathcal{E}_{3}(\widetilde{W})$. Following the conditions in (B.8) on the failure probability of $\mathcal{E}_{3}(W) \cap \mathcal{E}_{3}(\widetilde{W})$, we have

$$
\begin{aligned}
\mathbb{E}\left[f(p, \widetilde{p})^{2}\right] & =\mathbb{E}\left[\mathbb{E}\left[f(p, \widetilde{p})^{2} \mid q\right]\right] \\
& \leq \mathbb{E}\left[\mathbb{E}\left[f(p, \widetilde{p})^{2} \mid q\right] \cdot \mathbb{1}\left[\mathcal{E}_{3}(W) \cap \mathcal{E}_{3}(\widetilde{W})\right]\right]+\mathbb{P}\left(\mathcal{E}_{3}^{c}(W)\right)+\mathbb{P}\left(\mathcal{E}_{3}^{c}(\widetilde{W})\right) \\
& \leq O\left(L^{-2 \kappa \cdot(1-\epsilon)}\right)+O\left(L^{-4}\right) \leq O\left(L^{-4(1-\epsilon)}\right),
\end{aligned}
$$

where in the first inequality we use the fact that $\left|f_{\mathcal{G}}(p, \widetilde{p})\right| \leq 1$ and in the last inequality we use the same conditions as (B.8) in order to invoke (B.7). Thus, we complete the proof.

## B. 4 Understanding $\mathbb{E}\left[\|p\|_{2}^{2} \mid q\right]$ for large $\|W q\|_{2}$

Previously, we have a thorough understanding of the behavior of $\mathbb{E}\left[\|p\|_{2}^{2}\right]$ as $\|W q\|_{2}^{2} \leq c^{-2} \cdot 2 \log L$. We are still lacking understanding of what happens if $\|W q\|_{2}^{2} \gg c^{-2} \cdot 2 \log L$. In this section, we give a characterization of the behavior of $\mathbb{E}\left[\|p\|_{2}^{2} \mid q\right]$. Note that $\|p\|_{2}^{2} \leq 1$. When $\|W q\|_{2}$ gets large, we anticipate $\|p\|_{2}^{2}$ to get closer to 1 . Hence, we instead understand the behavior of $h(r)=1-\mathbb{E}\left[\|p\|_{2}^{2} \mid q\right]$, where $r=\|W q\|_{2}$. In the following, we provide an upper bound for $h(r)$.

Lemma B.5. Define $h(r)=1-\mathbb{E}\left[\|p\|_{2}^{2} \mid\|W q\|_{2}=r\right]$. Take a small constant $\epsilon \in(0,1)$. For $r \geq O\left(\sqrt{2 \log L^{3 / \epsilon}}\right)$, it holds that

$$
h(r)=\mathbb{E}\left[1-\|p\|_{2}^{2}\right] \leq O\left(r^{-(1-\epsilon)}\right) .
$$

Proof of Lemma B.5. Let $p_{1}, \ldots, p_{L}$ be the elements of $p$ in the descending order. In the following, we consider $r$ to be fixed and the expectation is taken only with respect to the context $X$ (or equivalently, attention probability $p$ ). We let $s_{1}, \ldots, s_{L}$ be the attention score calculated by $x_{1}^{\top} W q, \ldots, x_{L}^{\top} W q$, also in the same descending order and let $z_{1}, \ldots, z_{L}$ be the projection of $x_{1}, \ldots, x_{L}$ onto the direction of $W q$. We have

$$
h(r) \leq \mathbb{E}\left[1-p_{1}^{2}\right]=\mathbb{E}\left[\left(1-p_{1}\right)\left(1+p_{1}\right)\right] \leq 2 \mathbb{E}\left[1-p_{1}\right]=2 \cdot \mathbb{E}\left[p_{2}+\cdots+p_{L}\right] .
$$

Also we note that

$$
\frac{p_{1}}{p_{l}}=\exp \left(s_{1}-s_{l}\right)=\exp \left(r\left(z_{1}-z_{l}\right)\right) \Rightarrow p_{l} \leq p_{1} \exp \left(-r\left(z_{1}-z_{l}\right)\right) \leq \exp \left(-r\left(z_{1}-z_{l}\right)\right) .
$$

Hence,

$$
h(r) \leq 2 \mathbb{E}\left[\sum_{l=2}^{L} \exp \left(-r\left(z_{1}-z_{l}\right)\right)\right] .
$$

We split the summation into two parts depending on whether $z_{1}-z_{j} \leq \log \left(L r^{\alpha}\right) / r$, where $\alpha>1 / 2$ is a constant to be determined later. Thereby,

$$
\begin{aligned}
h(r) & \leq 2 \mathbb{E}\left[\exp \left(-r\left(z_{1}-z_{2}\right)\right)+\sum_{j \geq 3: z_{1}-z_{j} \leq \log \left(L r^{\alpha}\right) / r} \exp \left(-r\left(z_{1}-z_{j}\right)\right)+L \exp \left(-r \cdot \log \left(L r^{\alpha}\right) / r\right)\right] \\
& \leq 2 \mathbb{E}\left[(N+1) \exp \left(-r\left(z_{1}-z_{2}\right)\right)\right]+\frac{2}{r^{\alpha}},
\end{aligned}
$$

where $N$ is the size of $\left\{j \in\{3, \ldots, L\}: z_{1}-z_{j} \leq \log \left(L r^{\alpha}\right) / r\right\}$ and is also a random variable. Here, we remark that in the second inequality, we just lower bound $z_{1}-z_{j}$ by the minimum $z_{1}-z_{2}$. We pick some small constant $a \in(0,1)$ and note that

$$
\begin{align*}
& 2 \mathbb{E}\left[(N+1) \exp \left(-r\left(z_{1}-z_{2}\right)\right)\right] \\
& =2 \mathbb{E}\left[(N+1) \exp \left(-r\left(z_{1}-z_{2}\right)\right) \mathbb{1}\left(z_{1}>\sqrt{2 a \log L}\right)\right]+2 \mathbb{E}\left[(N+1) \exp \left(-r\left(z_{1}-z_{2}\right)\right) \mathbb{1}\left(z_{1} \leq \sqrt{2 a \log L}\right)\right] \\
& \leq 2 \mathbb{E}\left[(N+1) \exp \left(-r\left(z_{1}-z_{2}\right)\right) \mathbb{1}\left(z_{1}>\sqrt{2 a \log L}\right)\right]+2 L \mathbb{P}\left(z_{1} \leq \sqrt{2 a \log L}\right) \\
& \leq 2 \mathbb{E}\left[\left(N_{1}+1\right) \exp \left(-r\left(z_{1}-z_{2}\right)\right)\right]+2 L \exp \left(-\frac{1}{\sqrt{2 \pi}} \cdot\left(\frac{1}{\sqrt{2 a \log L}}-\frac{1}{\sqrt{2 a \log L^{3}}}\right) L^{1-a}\right), \tag{B.9}
\end{align*}
$$

where we define $N_{1}$ as the size of the class $\left\{j \in\{3, \ldots, L\}: \sqrt{2 a \log L}-z_{j} \leq \log \left(L r^{\alpha}\right) / r\right\}$ and it is obvious that $N \leq N_{1}$ under the condition $z_{1}>\sqrt{2 a \log L}$. Here, in the first inequality, we upper bound $N$ by $L$ and in the second inequality, we invoke the following fact:

Lemma B. 6 (Gaussian First Order Statistics). Let $v$ be the first order statistics of $L$ i.i.d. standard Gaussian random variables. For any $a>0$ :

$$
\mathbb{P}(v \leq \sqrt{2 a \log L}) \leq \exp \left(\frac{1}{\sqrt{2 \pi}} \cdot\left(\frac{1}{\sqrt{2 a \log L}}-\frac{1}{\sqrt{2 a \log L^{3}}}\right) L^{1-a}\right)
$$

We take $a=1-\epsilon$, and to make the second term in (B.9) smaller than $O\left(r^{-\alpha}\right)$, we just need

$$
\epsilon \geq \frac{\log \left(\sqrt{4 \pi \log L} \log \left(L r^{\alpha}\right)\right)}{\log L} \rightarrow \frac{\log (\log L \log r)}{\log L}=o(1),
$$

where the right hand side is $o(1)$ as long as $r=o(\exp (L))$. To this end, we just set the first inequality to be equality for $\epsilon$. Now, for the first term, we have

$$
\begin{aligned}
2 \mathbb{E} & {\left[\left(N_{1}+1\right) \exp \left(-r\left(z_{1}-z_{2}\right)\right)\right] } \\
& =2 \mathbb{E}\left[\sharp\left\{j=2, \ldots, L: z_{j} \geq\left(\sqrt{(1-\epsilon)}-\frac{\log \left(L r^{\alpha}\right)}{r \sqrt{2 \log L}}\right) \cdot \sqrt{2 \log L}\right\} \exp \left(-r\left(z_{1}-z_{2}\right)\right]\right. \\
& \leq 2 \mathbb{E}\left[\sharp\left\{j \in[L]: z_{j} \geq\left(\sqrt{(1-\epsilon)}-\frac{\log \left(L r^{\alpha}\right)}{r \sqrt{2 \log L}}\right) \cdot \sqrt{2 \log L}\right\} \exp \left(-r\left(z_{1}-z_{2}\right)\right]\right. \\
& =2 \mathbb{E}\left[N_{2} \exp \left(-r\left(z_{1}-z_{2}\right)\right],\right.
\end{aligned}
$$

where we define

$$
N_{2}:=\sharp\left\{j \in[L]: z_{j} \geq\left(\sqrt{(1-\epsilon)}-\frac{\log \left(L r^{\alpha}\right)}{r \sqrt{2 \log L}}\right) \cdot \sqrt{2 \log L}\right\}
$$

We note that for a standard Gaussian random variable $z$,

$$
\begin{aligned}
& \mathbb{P}\left(z \geq\left(\sqrt{(1-\epsilon)}-\frac{\log \left(L r^{\alpha}\right)}{r \sqrt{2 \log L}}\right) \cdot \sqrt{2 \log L}\right) \\
& \quad \leq \frac{1}{\sqrt{2 \pi}} \exp \left(-\left(\sqrt{(1-\epsilon)}-\frac{\log \left(L r^{\alpha}\right)}{r \sqrt{2 \log L}}\right)^{2} \cdot \log L\right) \cdot \frac{1}{\sqrt{\log L}} \\
& \quad \leq \frac{1}{\sqrt{2 \pi \log L}} L^{-1+\epsilon+\frac{2 \log \left(L r^{\alpha}\right)}{r \sqrt{2 \log L}}}=L^{-1} \cdot L^{\frac{\log \left(\sqrt{\left.4 \pi \log L \log \left(L r^{\alpha}\right)\right)}\right.}{\log L}+\frac{2 \log \left(L r^{\alpha}\right)}{r \sqrt{2 \log L}-\frac{\log \sqrt{2 \pi \log L}}{\log L}}} .
\end{aligned}
$$

where we invoke the upper bound $\mathbb{P}(z \geq a) \leq f(z) / a$ with $f(\cdot)$ being the density of $z$. For simplicity, we consider function

$$
\varphi(r) \geq \frac{\log \left(\sqrt{4 \pi \log L} \log \left(L r^{\alpha}\right)\right)}{\log L}+\frac{2 \log \left(L r^{\alpha}\right)}{r \sqrt{2 \log L}}-\frac{\log \sqrt{2 \pi \log L}}{\log L},
$$

where we note that $r \ll \exp (L / \alpha)$ (the upper bound is because the first term in $\varphi(r)$ cannot be too large). To this end, we invoke the tail bound for binomial distribution that if $N_{2}$ follows $\operatorname{Binom}(L, q)$, then

$$
\mathbb{P}\left(N_{2} \geq m\right) \leq \exp (-L \mathcal{D}(m / L \| q)),
$$

where $\mathcal{D}\left(q_{1} \| q_{2}\right)$ is the KL divergence between $\operatorname{Bern}\left(q_{1}\right)$ and $\operatorname{Bern}\left(q_{2}\right)$. We plug in the expression for $q=L^{\varphi(r)-1}$ and obtain that

$$
\begin{aligned}
\mathbb{P}\left(N_{2} \geq m\right) & \leq \exp \left(-2 L\left(\frac{m}{L} \log \frac{m}{L^{\varphi(r)}}+\left(1-\frac{m}{L}\right) \log \left(1+\frac{m / L-q}{1-m / L}\right)\right)\right) \\
& \leq \exp \left(-2\left(m \log \frac{m}{L^{\varphi(r)}}+m-L^{\varphi(r)}\right)\right),
\end{aligned}
$$

where in the second inequality we invoke the fact that $\log (1+x) \leq x$. We pick $m=L^{\varphi(r)+\xi(r)}$, where $\xi(r)>0$ is a constant depending on $r$ to be determined later, and obtain

$$
\mathbb{P}\left(N_{2} \geq L^{\varphi(r)+\xi(r)}\right) \leq \exp \left(-2 L^{\varphi(r)+\xi(r)} \cdot(1+\xi(r) \log L)+2 L^{\varphi(r)}\right) \leq L^{-2 L^{\varphi(r)+\xi(r)} \cdot \xi(r)}
$$

Here, the first and the third terms cancel and the second term gives the final upper bound. To this end, we have for $2 \mathbb{E}\left[N_{2} \exp \left(-r\left(z_{1}-z_{2}\right)\right)\right]$ that

$$
\begin{aligned}
& 2 \mathbb{E}\left[N_{2} \exp \left(-r\left(z_{1}-z_{2}\right)\right)\right] \leq 2 \mathbb{E}\left[N_{2} \exp \left(-r\left(z_{1}-z_{2}\right)\right) \mathbb{1}\left(N_{2}<L^{\varphi(r)+\xi(r)}\right)\right] \\
&+2 \mathbb{E}\left[N_{2} \exp \left(-r\left(z_{1}-z_{2}\right)\right) \mathbb{1}\left(N_{2} \geq L^{\varphi(r)+\xi(r)}\right)\right] \\
& \leq 2 L^{\varphi(r)+\xi(r)} \mathbb{E}\left[\exp \left(-r\left(z_{1}-z_{2}\right)\right)\right]+2 L \cdot L^{-2 L^{\varphi(r)+\xi(r)} \xi(r)}
\end{aligned}
$$

Note that to make the second term less than $O\left(r^{-\alpha}\right)$, a sufficient condition we need is

$$
\varphi(r)+\xi(r)-\frac{\log \left(\xi(r)^{-1}\right)}{\log L} \geq \frac{\alpha \log r}{(\log L)^{2}}
$$

Therefore, all we need to do is controlling the Moment Generating Function (MGF) for the difference between the Gaussian's first and second order statistics. Let $u, v$ be the second and the first order statistics of $z_{1}, \ldots, z_{L}$. The joint distribution of $u, v$ is then given by

$$
f(u, g)=\frac{L(L-1)}{2 \pi} \exp \left(-\frac{u^{2}+v^{2}}{2}\right) \Phi(u)^{n-2} \mathbb{1}(u \leq v)
$$

where $\Phi$ is the standard Gaussian Cumulative Distribution Function (CDF). The MGF is then given by

$$
\begin{aligned}
M(r) & =\int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} \frac{L(L-1)}{2 \pi} \exp \left(-\frac{u^{2}+v^{2}}{2}\right) \Phi(u)^{n-2} \mathbb{1}(u \leq v) \exp (-r(v-u)) \mathrm{d} u \mathrm{~d} v \\
& =\int_{-\infty}^{+\infty} \frac{L(L-1)}{\sqrt{2 \pi}} \exp \left(-\frac{u^{2}}{2}\right) \Phi(u)^{n-2} \exp (r u) \cdot \int_{u}^{+\infty} \frac{1}{\sqrt{2 \pi}} \exp \left(-\frac{v^{2}}{2}-r v\right) \mathrm{d} v \cdot \mathrm{~d} u \\
& =\int_{-\infty}^{+\infty} \frac{L(L-1)}{\sqrt{2 \pi}} \exp \left(-\frac{u^{2}}{2}\right) \Phi(u)^{n-2} \exp \left(\frac{r^{2}}{2}+r u\right) \cdot(1-\Phi(u+r)) \cdot \mathrm{d} u
\end{aligned}
$$

We note that the marginal for $u$ is (we just need to plug $r=0$ into the above equation, and after marginalizing $v$ the remaining expression is just $f(u)$ )

$$
f(u)=\frac{L(L-1)}{\sqrt{2 \pi}} \exp \left(-\frac{u^{2}}{2}\right) \Phi(u)^{n-2} \cdot(1-\Phi(u)) .
$$

Notably, in the above calculation we fix $u$ and only marginalize $v$. Thus, a byproduct is the following fact:

$$
\mathbb{E}[\exp (-r(v-u)) \mid u]=\exp \left(\frac{r^{2}}{2}+r u\right) \cdot \frac{\mathbb{P}(z \geq u+r)}{\mathbb{P}(z \geq u)} \leq 1 .
$$

Therefore, the MGF can also be rewritten as

$$
\begin{aligned}
M(r)= & \mathbb{E}_{u}\left[\exp \left(\frac{r^{2}}{2}+r u\right) \cdot \frac{\mathbb{P}(z \geq u+r)}{\mathbb{P}(z \geq u)}\right] \\
=\mathbb{E} & {\left[\exp \left(\frac{r^{2}}{2}+r u\right) \frac{\mathbb{P}(z \geq u+r)}{\mathbb{P}(z \geq u)} \mathbb{1}(u \in(\sqrt{2(1-\widetilde{\epsilon}) \log L}, \sqrt{2(1+b) \log L}))\right] } \\
& +\mathbb{E}\left[\exp \left(\frac{r^{2}}{2}+r u\right) \frac{\mathbb{P}(z \geq u+r)}{\mathbb{P}(z \geq u)} \mathbb{1}(u \notin(\sqrt{2(1-\widetilde{\epsilon}) \log L}, \sqrt{2(1+b) \log L}))\right] \\
=\mathbb{E} & {\left[\exp \left(\frac{r^{2}}{2}+r u\right) \frac{\mathbb{P}(z \geq u+r)}{\mathbb{P}(z \geq u)} \mathbb{1}(u \in(\sqrt{2(1-\widetilde{\epsilon}) \log L}, \sqrt{2(1+b) \log L}))\right] } \\
& +\mathbb{P}(u \notin(\sqrt{2(1-\widetilde{\epsilon}) \log L}, \sqrt{2(1+b) \log L}))
\end{aligned}
$$

where we pick $b \in(0,1)$ and $\tilde{\epsilon} \in\left(O\left((\log L)^{-1}\right), 1\right)$ as small constant to be determined later. For the second order statistics of $L$ i.i.d. Gaussian random variables, we have

Fact B. 7 (Gaussian Second Order Statistics). Let $v, u$ be the first and the second order statistics of $L$ i.i.d. standard Gaussian random variables. Also, let $z$ be another standard Gaussian random variable. Then for any $\epsilon \in\left(O\left((\log L)^{-1}\right), 1\right)$ :

$$
\mathbb{P}(u \geq \sqrt{2(1+\epsilon) \log L}) \leq \mathbb{P}(v \geq \sqrt{2(1+\epsilon) L}) \leq L^{-\epsilon},
$$

and

$$
\begin{aligned}
\mathbb{P}(u \leq \sqrt{2(1-\epsilon) \log L})= & \mathbb{P}\left(z \leq \sqrt{2(1-\epsilon) \log L)^{L-1}} \cdot \mathbb{P}(z \geq \sqrt{2(1-\epsilon) \log L}) \cdot\binom{L}{1}\right. \\
& +\mathbb{P}(z \leq \sqrt{2(1-\epsilon) \log L})^{L} \\
\leq & (L+1) \cdot \mathbb{P}(z \geq \sqrt{2(1-\epsilon) \log L})^{L-1} \\
\leq & (L+1) \cdot \exp \left(-\frac{(L-1)^{\epsilon}}{\sqrt{2 \pi}} \cdot\left(\frac{1}{\sqrt{2(1-\epsilon) \log L}}-\frac{1}{\sqrt{2(1-\epsilon) \log L^{3}}}\right)\right) \\
\leq & (L+1) \cdot \exp \left(-\frac{(L-1)^{\epsilon}}{\sqrt{4 \pi \log L}}\right),
\end{aligned}
$$

where the last inequality holds if $\epsilon \geq O(1 / 2 \log L)$.
Using the above fact, we deduce that

$$
M(r) \leq L^{-b}+(L+1) \cdot \exp \left(-\frac{(L-1)^{\epsilon}}{\sqrt{4 \pi \log L}}\right)+\max _{u \in \mathcal{U}(\underset{\epsilon}{\epsilon}, b)} \exp \left(\frac{r^{2}}{2}+r u\right) \cdot \frac{\mathbb{P}(z \geq u+r)}{\mathbb{P}(z \geq u)},
$$

where for our convenience, we define $\mathcal{U}(\widetilde{\epsilon}, b)=(\sqrt{2(1-\widetilde{\epsilon}) \log L}, \sqrt{2(1+b) \log L})$. Now, we invoke the tail bound for Gaussian distribution and obtain that

$$
\begin{equation*}
\exp \left(\frac{r^{2}}{2}+r u\right) \cdot \frac{\mathbb{P}(z \geq u+r)}{\mathbb{P}(z \geq u)} \leq \exp \left(\frac{r^{2}}{2}+r u\right) \cdot \frac{f(u+r)}{f(u)} \cdot \frac{(u+r)^{-1}}{u^{-1}-u^{-3}}=\frac{u}{u+r} \cdot \frac{1}{1-u^{-2}} \tag{B.10}
\end{equation*}
$$

As the last piece of the jigsaw, we conclude that

$$
\begin{aligned}
2 \mathbb{E} & {\left[N_{2} \exp \left(-r\left(z_{1}-z_{2}\right)\right)\right] } \\
\leq & 2 L^{\varphi(r)+\xi(r)} \mathbb{E}\left[\exp \left(-r\left(z_{1}-z_{2}\right)\right)\right]+2 L \cdot L^{-2 L^{\varphi(r)+\xi(r)} \xi(r)} \\
\leq & 2 L^{\varphi(r)+\xi(r)} \cdot\left(L^{-b}+(L+1) \cdot \exp \left(-\frac{(L-1)^{\epsilon}}{\sqrt{4 \pi \log L}}\right)+\max _{u \in \mathcal{U}(\tilde{\epsilon}, b)} \frac{u}{u+r} \cdot \frac{1}{1-u^{-2}}\right) \\
& +2 L \cdot L^{-2 L^{\varphi(r)+\xi(r)} \xi(r)} .
\end{aligned}
$$

Now, we pick $\beta>0$ and let

$$
L^{-b}=(L+1) \cdot \exp \left(-\frac{(L-1)^{\tilde{\epsilon}}}{\sqrt{4 \pi \log L}}\right)=r^{-\beta}
$$

which implies

$$
b=\frac{\beta \log r}{\log L}, \quad \widetilde{\epsilon}=\frac{\log \left(\log \frac{L+1}{r^{\beta}} \cdot \sqrt{4 \pi \log L}\right)}{\log (L-1)}=o(1),
$$

where the solution also satisfies the contraint $\tilde{\epsilon}>O\left((\log L)^{-1}\right)$ so long as $r \ll(L+1)^{\beta^{-1}}$ and we have

$$
\begin{aligned}
& \max _{u \in \mathcal{U}(\widetilde{\epsilon}, b)} \frac{u}{u+r} \cdot \frac{1}{1-u^{-2}} \\
& \quad \leq \frac{1}{1+r / \sqrt{2(1+b) \log L}} \cdot \frac{1}{1-(2(1-\widetilde{\epsilon}) \log L)^{-2}}=\frac{1+O\left((\log L)^{-2}\right)}{1+r / \sqrt{2(\log L+\beta \log r)}} .
\end{aligned}
$$

Therefore, we have

$$
\begin{align*}
& 2 \mathbb{E}\left[N_{2} \exp \left(-r\left(z_{1}-z_{2}\right)\right)\right] \\
& \quad \leq 2 L^{\varphi(r)+\xi(r)} \cdot\left(\frac{2}{r^{\beta}}+\frac{1+O\left((\log L)^{-2}\right)}{1+r / \sqrt{2(\log L+\beta \log r)}}\right)+2 L^{1-2 L^{\varphi(r)+\xi(r)} \xi(r) .} \tag{B.11}
\end{align*}
$$

To this end, it is clear that the right choice of $\beta$ should be 1 . Here, we recall the definition for $\varphi(r)$ that

$$
\varphi(r) \geq \frac{\log \left(\sqrt{4 \pi \log L} \log \left(L r^{\alpha}\right)\right)}{\log L}+\frac{2 \log \left(L r^{\alpha}\right)}{r \sqrt{2 \log L}}-\frac{\log \sqrt{2 \pi \log L}}{\log L},
$$

and the condition for picking $\xi(r)$ is

$$
\varphi(r)+\xi(r)-\frac{\log \left(\xi(r)^{-1}\right)}{\log L} \geq \frac{\alpha \log r}{(\log L)^{2}}
$$

We redefine $\widetilde{\varphi}(r)=\log L / \log r \cdot \varphi(r)$ and $\widetilde{\xi}(r)=\log L / \log r \cdot \xi(r)$. Then we conclude that

$$
\begin{gathered}
\widetilde{\varphi}(r) \geq \frac{\log \left(\sqrt{4 \pi \log L} \log \left(L r^{\alpha}\right)\right)}{\log r}+\frac{\log \left(L r^{\alpha}\right) \sqrt{2 \log L}}{r \log r}-\frac{\log \sqrt{2 \pi \log L}}{\log r}, \\
\widetilde{\varphi}(r)+\widetilde{\xi}(r)-\frac{\log \left(\tilde{\xi}(r)^{-1} \cdot \log L / \log r\right)}{\log r} \geq \frac{\alpha}{\log L}
\end{gathered}
$$

To make the third term in (B.11) $L^{1-2 L^{\varphi(r)+\xi(r)} \xi(r)}$ also less than $O\left(r^{-\alpha}\right)$, a sufficient condition is that

$$
\frac{\log L}{\log r}-2 r^{\tilde{\varphi}(r)+\tilde{\xi}(r)} \widetilde{\xi}(r) \leq-\alpha
$$

To this end, we can see directly that by choosing $\widetilde{\varphi}(r)$ and $\widetilde{\xi}(r)$ to be small constant, say $\epsilon / 3$, all the inequalities are satisfied for $r \geq O\left((\log L)^{3 / 2}\right.$ ) (in order to make $\frac{\log \left(L r^{\alpha}\right) \sqrt{2 \log L}}{r \log r}$ of the scale $o(1)$ ). In order to make (B.11) of order $O\left(r^{-\alpha}\right)$ with $\alpha=1-\epsilon$, we note that the second term dominates and we just need to ensure that

$$
r^{-1+2 \epsilon / 3} \sqrt{2 \log L} \leq r^{-1+\epsilon} \Rightarrow r \geq \sqrt{2 \log L}{ }^{3 / \epsilon}
$$

and $\alpha=1-\epsilon$. Therefore, we wrap our proof by concluding that for $r \geq O\left(\sqrt{2 \log L^{3 / \epsilon}}\right)$,

$$
h(r)=\mathbb{E}\left[1-\|p\|_{2}^{2}\right] \leq O\left(r^{-(1-\epsilon)}\right) .
$$

## C Simplification and Approximation of the Gradient Flow Dynamics

In this section, we first simplify the gradient flow dynamics of the MS-Attn to the eigenvalue space under the Decomposability Condition introduced in Definition 3.1. Then we approximate the spectral gradient flow dynamics using the results from Appendix B. As a byproduct of the simplification of the gradient flow dynamics, we further prove that the Decomposability Condition is preserved along the gradient flow.

## C. 1 Simplification Induced by the Decomposability Condition

In this section, we aim to show that the gradient flow dynamics in (2.7) admit a simplified form under the Decomposability Condition introduced in Definition 3.1.

Recall that given the parameters $\Theta=\left\{O^{(h)}, V^{(h)}, K^{(h)}, Q^{(h)}\right\}_{h \in[H]}$, the output of the the MS-Attn function, is given by (2.1). The gradient flow for minimizing the mean-squared loss $L(\Theta)$ in (2.6) is introduced in (2.7), which involves matrices $A^{(h)} \in \mathbb{R}^{D \times D}$ and $B^{(h)} \in \mathbb{R}^{d_{y} \times D}$ defined in (2.8) and (2.9), respectively. Here $D=d+d_{y}$ where $d$ and the $d_{y}$ are the dimensions of the covariate and output, respectively. Note that these matrices depends on the attention score $s^{(h)}$ and attention probability $p^{(h)}$ defined in (2.2), and output weight matrix $U^{(h)}$ given in (2.3). Thus, both $A^{(h)}$ and $B^{(h)}$ are (perhaps complicated) functions of the parameter $\Theta$. In the following, we aim to prove that when $\Theta$ satisfies the Decomposability Condition, $A^{(h)}$ and $B^{(h)}$ can be diagonalized using the orthogonal matrices specified by the Decomposability Condition. The main result can be summarized in the following proposition.
Proposition C. 1 (Simplification of $A^{(h)}$ and $B^{(h)}$ ). Let $\Theta=\left\{O^{(h)}, V^{(h)}, K^{(h)}, Q^{(h)}\right\}_{h \in[H]}$ be a set of parameters and let $A^{(h)}$ and $B^{(h)}$ be functions of $\Theta$ defined according to (2.8) and (2.9), respectively. We use subscripts $X$ and $Y$ to indicate the indices that corresponds to the covariate or the response, i.e., $X$ indicate $\{1, \ldots, d\}$ and $Y$ indicates $\{d+1, \ldots, D\}$. Then, when $\Theta$ satisfy the Decomposability Condition in Definition 3.1, $A^{(h)}$ and $B^{(h)}$ can be written as

$$
A^{(h)}=\left[\begin{array}{cc}
A_{X X}^{(h)} & A_{X Y}^{(h)}  \tag{C.1}\\
A_{Y X}^{(h)} & A_{Y X}^{(h)}
\end{array}\right]=\left[\begin{array}{cc}
A_{X X}^{(h)} & \mathbf{0} \\
\mathbf{0} & \mathbf{0}
\end{array}\right], \quad B^{(h)}=\left[\begin{array}{ll}
B_{X}^{(h)} & B_{Y}^{(h)}
\end{array}\right]=\left[\begin{array}{ll}
\mathbf{0} & B_{Y}^{(h)}
\end{array}\right] .
$$

That is, only the top-left block of $A^{(h)}$ and the right block of $B^{(h)}$ are non-zero. Moreover, these two nonzero blocks can be diagonalized by orthogonal matrices $\Phi$ and $\Psi$, respectively, where $\Phi$ and $\Psi$ are introduced by the Decomposability Condition in Definition 3.1. That is, $\Phi^{\top} A_{X X}^{(h)} \Phi$ and $\Psi^{\top} B_{Y}^{(h)} \Psi$ are diagonal matrices.

In the rest of this section, we provide a proof of Proposition C.1. Our proof is split into two parts. First, we use the Decomposability Condition to prove the results in (C.1). Then we use the fact that the covariates are Gaussian distributed to show that the non-zero blocks can be diagonalized by the orthogonal matrices $\Phi$ and $\Psi$.

## C.1.1 Simplification of $A^{(h)}$ and $B^{(h)}$ under the Decomposability Condition

Proof. (Proof of Equation (C.1) in Proposition C.1) We first simplify the expression for $A^{(h)}$ and $B^{(h)}$ in (2.8) and (2.9) under the Decomposability Condition introduced in Definition 3.1, which gives us (C.1).

Simplification of $A^{(h)}$. By the definition of $A^{(h)}$ in (2.8), we have

$$
\begin{equation*}
A^{(h)}=\underbrace{-\mathbb{E}\left[Z P^{(h)^{\top}} Z^{\top} U^{(h)^{\top}} y_{q} z_{q}^{\top}\right]}_{\triangleq A^{(h, 0)}}+\sum_{h^{\prime}=1}^{H} \underbrace{\mathbb{E}\left[Z P^{(h)^{\top}} Z^{\top} U^{(h)^{\top}} U^{\left(h^{\prime}\right)} Z p^{\left(h^{\prime}\right)} z_{q}^{\top}\right]}_{\triangleq A^{\left(h, h^{\prime}\right)}} . \tag{C.2}
\end{equation*}
$$

Recall that $s^{(h)}$ and $p^{(h)}$ in (2.2) are the attention score and probability vectors, and $P^{(h)}=$ $\operatorname{diag}\left(p^{(h)}\right)-p^{(h)} p^{(h)^{\top}}$. Also recall the definition of $U^{(h)}$ and $W^{(h)}$ in (2.3). By Definition 3.1(i), we have $W_{Y}^{(h)}=0$, where $W_{Y}^{(h)}$ is the bottom left block of $W^{(h)}$. As a result, since the last $d_{y}$ indices of $z_{q}$ is zero, we have $s^{(h)}=Z^{\top} W^{(h)} z_{q}=X^{\top} W_{X}^{(h)} q$. This implies that $p^{(h)}$ depends only on the covariates $X$ and the query $q$, and thus $p^{h}, G, \varepsilon$ are independent of each other.

Now we write $Y=G^{\top} X+\varepsilon$ where $\varepsilon \in \mathbb{R}^{d_{y} \times L}$ stands for the noise terms in $Y$. Hence, we can write $Z$ as in the following form:

$$
Z=\left[\begin{array}{l}
X  \tag{C.3}\\
Y
\end{array}\right]=\left[\begin{array}{c}
I_{d} \\
G^{\top}
\end{array}\right] X+\left[\begin{array}{l}
0 \\
\varepsilon
\end{array}\right] .
$$

Substituting $Z$ using (C.3) into (C.2), we can write $A^{(h, 0)}$ as

$$
\begin{aligned}
& A^{(h, 0)}=-\mathbb{E}\left[\left(\left[\begin{array}{c}
I_{d} \\
G^{\top}
\end{array}\right] X+\left[\begin{array}{l}
0 \\
\varepsilon
\end{array}\right]\right) P^{(h)^{\top}}\left(\begin{array}{ll}
X^{\top} & \left.\left[\begin{array}{ll}
I_{d} & G
\end{array}\right]+\left[\begin{array}{ll}
0 & \varepsilon^{\top}
\end{array}\right]\right) U^{(h)^{\top}} G^{\top} q z_{q}^{\top}
\end{array}\right]\right. \\
& =-\left[\begin{array}{cc}
\mathbb{E}\left[X P^{(h)^{\top}} X^{\top} G U_{Y}^{(h)^{\top}} G^{\top} q q^{\top}\right] & \mathbf{0} \\
\mathbb{E}\left[G^{\top} X P^{(h)^{\top}} X^{\top} U_{X}^{(h)}{ }^{\top} G^{\top} q q^{\top}\right] & \mathbf{0}
\end{array}\right]=\left[\begin{array}{cc}
-\mathbb{E}\left[X P^{(h)^{\top}} X^{\top} G U_{Y}^{(h){ }^{\top}} G^{\top} q q^{\top}\right] & \mathbf{0} \\
\mathbf{0} & \mathbf{0}
\end{array}\right] .
\end{aligned}
$$

where in the second equality, we use the fact that $G$ and $\varepsilon$ are independent and mean zero, and thus only the terms with second-order moments of $G$ and $\varepsilon$ are p. Moreover, in the last inequality, we note that submatrix $U_{X}^{(h)}$ is zero by Definition 3.1(i). Thus, we show that $A^{(h, 0)}$ is a block-diagonal matrix with only the top left block being nonzero. The derivation of such simplification is based on (i) the independence between $p^{(h)}, G$ and $\varepsilon$ and (ii) the fact that $U_{X}^{(h)}$ is zero by Definition 3.1(i). Here (i) is implied by the fact that $W_{Y}^{(h)}=0$, given also by Definition 3.1(i). We will use the same argument to simplify $A^{\left(h, h^{\prime}\right)}$ in (C.2) and $B^{(h)}$ in (2.9).

For $A^{\left(h, h^{\prime}\right)}$, by direct calculation, we have

$$
\begin{aligned}
A^{\left(h, h^{\prime}\right)}= & \mathbb{E}\left[\left(\left[\begin{array}{c}
I_{d} \\
G^{\top}
\end{array}\right] X+\left[\begin{array}{l}
0 \\
\varepsilon
\end{array}\right]\right) P^{(h)^{\top}}\left(\left[\begin{array}{c}
I_{d} \\
G^{\top}
\end{array}\right] X+\left[\begin{array}{l}
0 \\
\varepsilon
\end{array}\right]\right)^{\top} U^{(h)^{\top}} U^{\left(h^{\prime}\right)}\left(\left[\begin{array}{c}
I_{d} \\
G^{\top}
\end{array}\right] X+\left[\begin{array}{l}
0 \\
\varepsilon
\end{array}\right]\right) p^{\left(h^{\prime}\right)} z_{q}^{\top}\right] \\
= & {\left[\begin{array}{c}
\mathbb{E}\left[X P^{(h)^{\top}} X^{\top} U_{X}^{(h)^{\top}} U_{X}^{\left(h^{\prime}\right)} X p^{\left(h^{\prime}\right)} z_{q}^{\top}+X P^{(h)^{\top}} X^{\top} G U_{Y}^{(h)^{\top}} U_{Y}^{\left(h^{\prime}\right)} G^{\top} X p^{\left(h^{\prime}\right)} z_{q}^{\top}\right] \\
\left.\mathbb{E}\left[G^{\top} X P^{(h)^{\top}} X^{\top} G U_{Y}^{(h)^{\top}} U_{X}^{\left(h^{\prime}\right)} X p^{\left(h^{\prime}\right)} z_{q}^{\top}+G^{\top} X P^{(h)^{\top}} X^{\top} U_{X}^{(h)^{\top}} U_{Y}^{\left(h^{\prime}\right)} G^{\top} X p^{\left(h^{\prime}\right)} z_{q}^{\top}\right]\right] \\
\\
\end{array}+\left[\begin{array}{r}
\mathbb{E}\left[X P^{(h)^{\top}} \varepsilon^{\top} U_{Y}^{(h)^{\top}} U_{Y}^{\left(h^{\prime}\right)} \varepsilon p^{\left(h^{\prime}\right)} z_{q}^{\top}\right] \\
\left.\mathbb{E}\left[\varepsilon P^{(h)^{\top}} \varepsilon^{\top} U_{Y}^{(h)^{\top}} U_{X}^{\left(h^{\prime}\right)} X p^{\left(h^{\prime}\right)} z_{q}^{\top}+\varepsilon P^{(h)^{\top}} X^{\top} U_{X}^{(h)^{\top}} U_{Y}^{\left(h^{\prime}\right)} \varepsilon p^{\left(h^{\prime}\right)} z_{q}^{\top}\right]\right] .
\end{array} .\right.\right.}
\end{aligned}
$$

Then, using the fact that $p^{(h)}, G$, and $\varepsilon$ are independent, we have

$$
A^{\left(h, h^{\prime}\right)}=\left[\begin{array}{cc}
\mathbb{E}\left[X P^{(h)^{\top}} X^{\top} G U_{Y}^{(h)^{\top}} U_{Y}^{\left(h^{\prime}\right)} G^{\top} X p^{\left(h^{\prime}\right)} q^{\top}+X P^{(h)^{\top}} \varepsilon^{\top} U_{Y}^{(h)^{\top}} U_{Y}^{\left(h^{\prime}\right)} \varepsilon p^{\left(h^{\prime}\right)} q^{\top}\right] & \mathbf{0} \\
\mathbf{0} & \mathbf{0}
\end{array}\right]
$$

Furthermore, we define matrices $A_{\text {Signal }}^{(h)}, A_{\text {Intf }}^{\left(h, h^{\prime}\right)}$, and $A_{\text {Noise }}^{\left(h, h^{\prime}\right)}$ as follows:

$$
\begin{align*}
& A_{\text {Signal }}^{(h)} \triangleq-\mathbb{E}\left[X P^{(h)^{\top}} X^{\top} G U_{Y}^{(h)^{\top}} G^{\top} q q^{\top}\right]  \tag{C.4}\\
& A_{\text {Intf }}^{\left(h, h^{\prime}\right)} \triangleq \mathbb{E}\left[X P^{(h)^{\top}} X^{\top} G U_{Y}^{(h)^{\top}} U_{Y}^{\left(h^{\prime}\right)} G^{\top} X p^{\left(h^{\prime}\right)} q^{\top}\right],  \tag{C.5}\\
& A_{\text {Noise }}^{\left(h, h^{\prime}\right)} \triangleq \mathbb{E}\left[X P^{(h)^{\top}} \varepsilon^{\top} U_{Y}^{(h)^{\top}} U_{Y}^{\left(h^{\prime}\right)} \varepsilon p^{\left(h^{\prime}\right)} q^{\top}\right] . \tag{C.6}
\end{align*}
$$

Here $A_{\text {Signal }}^{(h)}$ is the signal part, which has a negative sign and leads the gradient flow dynamics to a desired solution. Moreover, $A_{\text {Intf }}^{\left(h, h^{\prime}\right)}$ represents the cross-head interference as it involves both $h$-th and $h^{\prime}$-th head, and $A_{\text {Noise }}^{\left(h, h^{\prime}\right)}$ is the noise part as it involves $\varepsilon$.

Therefore, we prove that only the top left block $A_{X X}^{(h)}$ of $A^{(h)}$ is nonzero, and $A_{X X}^{(h)}$ can be written as

$$
\begin{equation*}
A_{X X}^{(h)}=A_{\text {Signal }}^{(h)}+\sum_{h^{\prime}=1}^{H} A_{\mathrm{Intf}}^{\left(h, h^{\prime}\right)}+\sum_{h^{\prime}=1}^{H} A_{\text {Noise }}^{\left(h, h^{\prime}\right)} \tag{C.7}
\end{equation*}
$$

Simplification of $B^{(h)}$. By the definition of $B^{(h)}$ in (2.9), we can write $B^{(h)}$ as

$$
B^{(h)}=\mathbb{E}\left[\sum_{h^{\prime}=1}^{H} U^{\left(h^{\prime}\right)} Z p^{\left(h^{\prime}\right)} p^{(h)^{\top}} Z^{\top}\right]-\mathbb{E}\left[y_{q} p^{(h)^{\top}} Z^{\top}\right]
$$

Note that $y_{q}=G^{\top} q$ and $Y=G^{\top} X+\varepsilon$. Writing in a block matrix form, we have

$$
\begin{aligned}
B^{h}= & \sum_{h^{\prime}=1}^{H}\left[\begin{array}{ll}
U_{X}^{\left(h^{\prime}\right)} & U_{Y}^{\left(h^{\prime}\right)}
\end{array}\right] \cdot\left[\begin{array}{cc}
\mathbb{E}\left[X p^{\left(h^{\prime}\right)} p^{(h)^{\top}} X^{\top}\right] & \mathbb{E}\left[X p^{\left(h^{\prime}\right)} p^{(h)^{\top}}\left(X^{\top} G+\varepsilon^{\top}\right)\right] \\
\mathbb{E}\left[\left(G^{\top} X+\varepsilon\right) p^{\left(h^{\prime}\right)} p^{(h)^{\top}} X^{\top}\right] & \mathbb{E}\left[\left(G^{\top} X+\varepsilon\right) p^{\left.h^{\prime}\right)} p^{(h)^{\top}}\left(X^{\top} G+\varepsilon^{\top}\right)\right]
\end{array}\right] \\
& -\mathbb{E}\left[\begin{array}{ll}
G^{\top} q p^{(h)^{\top}}\left[\begin{array}{ll}
X^{\top} & \left.X^{\top} G+\varepsilon^{\top}\right]
\end{array}\right] .
\end{array}\right.
\end{aligned}
$$

Then using the independence between $\varepsilon, p^{(h)}$, and $G$ implied by Definition 3.1(i) and the fact that $U_{X}^{\left(h^{\prime}\right)}=0$ for all $h^{\prime} \in[H]$, we further have

$$
B^{(h)}=\sum_{h^{\prime}=1}^{H}\left[\begin{array}{ll}
\mathbf{0} & \left.\mathbb{E}\left[U_{Y}^{\left(h^{\prime}\right)} G^{\top} X p^{\left(h^{\prime}\right)} p^{(h)^{\top}} X^{\top} G+U_{Y}^{\left(h^{\prime}\right)} \varepsilon p^{\left(h^{\prime}\right)} p^{(h)^{\top}} \varepsilon^{\top}\right]\right]-\left[\begin{array}{ll}
\mathbf{0} & \left.\mathbb{E}\left[G^{\top} q p^{(h)^{\top}} X^{\top} G\right]\right] . . . ~
\end{array} \text {. }{ }^{\top}\right]
\end{array}\right.
$$

Now we define matrices $B_{\text {Signal }}^{(h)}, B_{\text {Intf }}^{\left(h, h^{\prime}\right)}$, and $B_{\text {Noise }}^{\left(h, h^{\prime}\right)}$ as follows:

$$
\begin{gather*}
B_{\text {Signal }}^{(h)} \triangleq-\mathbb{E}\left[G^{\top} q p^{(h)^{\top}} X^{\top} G\right], \quad B_{\text {Intf }}^{\left(h, h^{\prime}\right)} \triangleq \mathbb{E}\left[U_{Y}^{\left(h^{\prime}\right)} G^{\top} X p^{\left(h^{\prime}\right)} p^{(h)^{\top}} X^{\top} G\right],  \tag{C.8}\\
B_{\text {Noise }}^{\left(h, h^{\prime}\right) \triangleq} \triangleq \mathbb{E}\left[U_{Y}^{\left(h^{\prime}\right)} \varepsilon p^{\left(h^{\prime}\right)} p^{(h)^{\top}} \varepsilon^{\top}\right], \tag{C.9}
\end{gather*}
$$

and $B^{(h)}$ only has the right block ( $Y$ part) being nonzero, which is given by

$$
\begin{equation*}
B_{Y}^{(h)}=B_{\text {Signal }}^{(h)}+\sum_{h^{\prime}=1}^{H} B_{\text {Intf }}^{\left(h, h^{\prime}\right)}+\sum_{h^{\prime}=1}^{H} B_{\text {Noise }}^{\left(h, h^{\prime}\right)} . \tag{C.10}
\end{equation*}
$$

In conclusion, we have proved (C.1) in Proposition C.1, and the nonzero blocks of $A^{(h)}$ and $B^{(h)}$ are given by (C.4)-(C.6), (C.8), and (C.9), respectively.

## C.1.2 Simplification of $A_{X X}^{(h)}$ and $B_{Y}^{(h)}$ with Gaussian Covariate

It remains to prove that the nonzero blocks of $A^{(h)}$ and $B^{(h)}$ can be diagonalized by the orthogonal matrices $\Phi$ and $\Psi$ introduced by the Decomposability Condition in Definition 3.1. We will prove this fact leveraging the fact that the covariate distribution is Gaussian. In the following, for ease of presentation, we introduce some additional notation that will only be used inside this section.

Additional Notation. Consider two heads $h, h^{\prime} \in[H]$, We locally drop the superscript $(h),\left(h^{\prime}\right)$ and write $(\cdot)^{(h)}$ as $(\cdot)$ and $(\cdot)^{\left(h^{\prime}\right)}$ as $\widetilde{(\cdot)}$. For example, under this notation, we write $A^{(h)}$ as $A$ and $A^{\left(h^{\prime}\right)}$ as $\widetilde{A}$. Similarly, the attention scores $s^{(h)}$ and $s^{\left(h^{\prime}\right)}$ are written as $s$ and $\widetilde{s}$, respectively. Since $W_{Y}$ and $\widetilde{W}_{Y}$ are zero matrices, we have $s=X^{\top} W_{X} q$ and $\widetilde{s}=X^{\top} \widetilde{W}_{X} q$. Note that $s, \widetilde{s} \in \mathbb{R}^{L}$ and we let $s_{l}$ and $\widetilde{s}_{l}$ denote the $l$-th entry of $s$ and $\widetilde{s}$, respectively. That is, $s_{l}=x_{l}^{\top} W_{X} q$ and $\widetilde{s}_{l}=x_{l}^{\top} \widetilde{W}_{X} q$. For any $l \in[L]$, we define an operator $\mathcal{T}_{l}$ as follows:

$$
\begin{equation*}
\mathcal{T}_{l} \circ f \triangleq\left(W_{X} q \cdot \frac{\partial}{\partial s_{l}}+\widetilde{W}_{X} q \cdot \frac{\partial}{\partial \widetilde{s}_{l}}\right) \circ f=W_{X} q \cdot \frac{\partial f}{\partial s_{l}}+\widetilde{W}_{X} q \cdot \frac{\partial f}{\partial \widetilde{s}_{l}}, \tag{C.11}
\end{equation*}
$$

where $f$ is any real-valued function of the $l$-th attention scores $s_{l}$ and $\widetilde{s}_{l}$. In particular, $W_{X} \in \mathbb{R}^{d \times d}$, $q \in \mathbb{R}^{d}$, and $\partial f / \partial s_{l} \in \mathbb{R}$. Note that after applying the operator to $f$, the output is a $d$-dimensional vector-valued function of $s_{l}$ and $\widetilde{s}_{l}$. The intuition of the operator $\mathcal{T}_{l}$ is as follows. When $f$ is a function of the attention scores $s$ and $\widetilde{s}$, it is a function of $X$, i.e., $\left\{x_{l}\right\}_{l \in[L]}$. For any fixed $l, x_{l}$ appears in $s$ and $\widetilde{s}$ only through $s_{l}$ and $\widetilde{s}_{l}$. We can prove that $\nabla_{x_{l}} f=\mathcal{T}_{l} \circ f$ by using the chain rule. Furthermore, for regularity, we assume that $f$ is arbitrary-order differentiable and the derivatives have bounded expectations with respect to $x_{l} \stackrel{\text { i.i.d. }}{\sim} \mathcal{N}\left(0, I_{d}\right)$. When it is clear from the context, we write the partial derivatives $\partial / \partial_{s_{l}}$ and $\partial / \partial_{\tilde{s}_{l}}$ as $\partial_{l}$ and $\widetilde{\partial}_{l}$, respectively.

Additionally, we will encounter the composition of operators $\left\{\mathcal{T}_{l}\right\}$. To this end, we extend the definition in (C.11) to vector-valued functions. Specifically, let $F=\left\{F_{i}\right\}_{i \in[m]}: \mathbb{R}^{L} \times \mathbb{R}^{L} \rightarrow \mathbb{R}^{m}$ be a mapping that maps $s$ and $\tilde{s}$ to $\mathbb{R}^{m}$. Then we define $\mathcal{T}_{l} \circ F$ as a matrix in $\mathbb{R}^{d \times m}$ where the $i$-th row is given by $\mathcal{T}_{l} \circ F_{i}$. Then the composition $\left(\mathcal{T}_{l} \circ\left(\mathcal{T}_{m} \circ f\right)\right)$ can be viewed as a matrix-valued function taking values in $\mathbb{R}^{d \times d}$, and ( $\mathcal{T}_{l} \circ\left(\mathcal{T}_{m} \circ\left(\mathcal{T}_{n} \circ f\right)\right)$ ) can be viewed as a function taking values in third-order tensor space $\mathbb{R}^{d \times d \times d}$. To simplify the notation, we denote them by $\left(\mathcal{T}_{l} \otimes \mathcal{T}_{m}\right) \circ f$ and $\left(\mathcal{T}_{l} \otimes \mathcal{T}_{m} \otimes \mathcal{T}_{n}\right) \circ f$, respectively.

Meanwhile, note that when the parameter $\Theta$ satisfies the Decomposability Condition, $W_{X}$ and $\widetilde{W}_{X}$ can be diagonalized by $\Phi$. That is, we have $\widetilde{W}_{X}=\Phi \operatorname{diag}(\widetilde{\omega}) \Phi^{\top}$ and $W_{X}=\Phi \operatorname{diag}(\omega) \Phi^{\top}$. We let $\bar{q}=\Phi^{\top} q$ denote the rotated query vector and define a operator $\overline{\mathcal{T}}_{l}$ by letting

$$
\begin{equation*}
\overline{\mathcal{T}}_{l} \circ f \triangleq\left(\operatorname{diag}(\omega) \cdot \partial_{l}+\operatorname{diag}(\widetilde{\omega}) \cdot \widetilde{\partial}_{l}\right) \circ f=\operatorname{diag}(\omega) \cdot \partial_{l} f+\operatorname{diag}(\widetilde{\omega}) \cdot \widetilde{\partial}_{l} f, \tag{C.12}
\end{equation*}
$$

for any function $f$ of $(s, \widetilde{s})$. It is clear that $\overline{\mathcal{T}}_{l} \circ f$ gives a diagonal matrix as $\operatorname{diag}(\omega)$ is a diagonal matrix and $\partial_{l} f$ is a scalar. Moreover, $\mathcal{T}_{l}$ and $\overline{\mathcal{T}}_{l}$ are connected via the property that

$$
\begin{equation*}
\mathcal{T}_{l} \circ f=\Phi \operatorname{diag}(\omega) \Phi^{\top} q \cdot \partial_{l} f+\Phi \operatorname{diag}(\widetilde{\omega}) \Phi^{\top} q \cdot \widetilde{\partial}_{l} f=\Phi\left(\overline{\mathcal{T}}_{l} \circ f\right) \bar{q} . \tag{C.13}
\end{equation*}
$$

We will also encounter the compositions of operators $\left\{\overline{\mathcal{T}}_{l}\right\}$, which takes a rather simple form. Specifically, we have

$$
\begin{aligned}
& \left(\overline{\mathcal{T}}_{l} \circ\left(\overline{\mathcal{T}}_{m} \circ f\right)\right)=\left(\overline{\mathcal{T}}_{m} \circ\left(\overline{\mathcal{T}}_{l} \circ f\right)\right) \\
& \quad=\operatorname{diag}\left(\omega^{\odot 2}\right) \cdot \partial_{l} \partial_{m} f+\operatorname{diag}\left(\widetilde{\omega}^{\odot 2}\right) \cdot \widetilde{\partial}_{l} \widetilde{\partial}_{m} f+\operatorname{diag}(\omega \odot \widetilde{\omega}) \cdot\left(\partial_{l} \widetilde{\partial}_{m} f+\widetilde{\partial}_{l} \partial_{m} f\right) .
\end{aligned}
$$

Note that $\left(\overline{\mathcal{T}}_{l} \circ\left(\overline{\mathcal{T}}_{m} \circ f\right)\right)$ is a diagonal matrix.
In addition, in the following, to simplify $A^{(h)}$ and $B^{(h)}$ using the Gaussian variate distribution, we will recursively apply the Stein's Lemma, will yields expectations of tensor-valued random variables. For ease of presentation, we introduce the following notation for handling third-order tensors. In particular, suppose $f=\left\{f_{l m n}\right\}_{l, m, n \in[L]}$ is a third-order tensor-value function of $(s, \widetilde{s})$ indexed by $(l, m, n) \in[L] \times[L] \times[L]$, we define

$$
\begin{equation*}
\llbracket f_{l m n} \rrbracket \triangleq \sum_{l^{\prime}, m^{\prime}, n^{\prime} \in[L]} \mathbb{E}\left[f_{l^{\prime} m^{\prime} n^{\prime}} \mid q\right], \tag{C.14}
\end{equation*}
$$

where the expectation is taken with respect to the randomness of covariate $X$. That is, $\llbracket f_{l m n} \rrbracket$ denotes the sum of entries of the expectation of the tensor $\left\{f_{l m n}\right\}$. Here we hide the dependency on $q$ for simplicity. Note that the conditional expectation in (C.14) takes the same value if we instead condition on $\bar{q}$. Besides, we can similarly define $\llbracket f_{l m} \rrbracket$ and $\llbracket f_{l} \rrbracket$ for second-order tensor-value function and vector-value function of $(s, \widetilde{s})$, respectively. Furthermore, for a third-order tensor $M$, we let $M^{\top\left(i_{1} i_{2} i_{3}\right)}$ denote the $\left(i_{1}, i_{2}, i_{3}\right)$ transpose of $M$. For instance, $M^{\top(132)}$ represents the transpose of $M$ by swapping the second and the third dimension.

Gaussian Moments. A nice property of the Gaussian distribution is the Stein's Lemma, which states that $\mathbb{E}[x g(x)]=\mathbb{E}[\nabla g(x)]$ for any function $g$ under some regularity condition. Here the expectation is taken with respect to $x \sim N\left(0, I_{d}\right)$. Note that $A_{X X}^{(h)}$ and $B_{Y}^{(h)}$ are functions $X$. We will leverage the Stein's Lemma to explicitly compute the expectations with respect to $X$ in $A_{X X}^{(h)}$ and $B_{Y}^{(h)}$. In particular, we will resort to the following lemma.

Lemma C.2. Suppose for any $l \in[L]$, the $l$-th covariate $x_{l}$ in the $I C L$ context $Z$ is drawn from a standard normal distribution, i.e., $x_{l} \stackrel{\text { i.i.d. }}{\sim} \mathcal{N}\left(0, I_{d}\right)$. In addition, let $\left\{f_{l m n}\right\}_{l, m, n \in[L]}$ be a third-order tensor-value function of $(s, \widetilde{s})$ indexed by $(l, m, n) \in[L] \times[L] \times[L]$. Similarly, let $\left\{f_{l m}\right\}_{l, m \in[L]}$ be a second-order tensor-value function of $(s, \widetilde{s})$ indexed by $(l, m) \in[L] \times[L]$, and let $\left\{f_{l}\right\}_{l \in[L]}$ be a vector-value function of $(s, \widetilde{s})$ indexed by $l \in[L]$. Then, we have the following results.
(i) $\llbracket f_{l m n} \cdot x_{l} \otimes x_{m} \otimes x_{n} \rrbracket=\llbracket \mathcal{T}_{l} \circ\left(f_{l m m}\right) \otimes I_{d} \rrbracket+\llbracket I_{d} \otimes \mathcal{T}_{l} \circ\left(f_{m m l}\right) \rrbracket$

$$
+\llbracket I_{d} \otimes \mathcal{T}_{l} \circ\left(f_{m l m}\right) \rrbracket^{\top(132)}+\llbracket\left(\mathcal{T}_{l} \otimes \mathcal{T}_{m} \otimes \mathcal{T}_{n}\right) \circ\left(f_{l m n}\right) \rrbracket .
$$

(ii) $\llbracket f_{l m} \cdot x_{l} \otimes x_{m} \rrbracket=\llbracket\left(\mathcal{T}_{l} \otimes \mathcal{T}_{m}\right) \circ f_{l m} \rrbracket+\llbracket f_{l l} \cdot I_{d} \rrbracket$.
(iii) $\llbracket f_{l} x_{l} \rrbracket=\llbracket \mathcal{T}_{l} \circ f_{l} \rrbracket$.

Proof. (Proof of Lemma C.2) See §G.1.1 for a detailed proof.
Now we are ready to simplify $A^{(h)}$ and $B^{(h)}$ by showing that the nonzero blocks of $A^{(h)}$ and $B^{(h)}$ can be diagonalized by the orthogonal matrices $\Phi$ and $\Psi$, respectively.

## Simplification of $A_{X X}^{(h)}$ with Gaussian Covariate

Recall that we show in (C.7) that $A_{X X}^{(h)}$ is equal to a sum of three terms. We first consider $A_{\text {Signal }}^{(h)}$ defined in (C.4). By the second identity of Lemma C.2, we have

$$
\begin{aligned}
A_{\text {Signal }}^{(h)} & =-\mathbb{E}\left[X P^{\top} X^{\top} G U_{Y}^{\top} G^{\top} q q^{\top}\right] \\
& =-\mathbb{E}\left[\left(\left[\left(\mathcal{T}_{l} \otimes \mathcal{T}_{m}\right) \circ P_{m l} \rrbracket+\llbracket P_{l l} \cdot I_{d} \rrbracket\right) G U_{Y}^{\top} G^{\top} q q^{\top}\right]\right.
\end{aligned}
$$

// Lemma C. 2
where the expectation in the second equality is taken with respect to the randomness of $G$ and $q$. Here we omit the superscript ( $h$ ) for simplicity. Besides, we write

$$
\llbracket\left(\mathcal{T}_{l} \otimes \mathcal{T}_{m}\right) \circ P_{m l} \rrbracket=\sum_{l, m} \mathbb{E}\left[\left(\mathcal{T}_{l} \otimes \mathcal{T}_{m}\right) \circ P_{m l} \mid q\right], \quad \llbracket P_{l l} \cdot I_{d} \rrbracket=\sum_{l} \mathbb{E}\left[P_{l l} \cdot I_{d} \mid q\right]
$$

By the definition of $\mathcal{T}_{l}$ in (C.11) and noticing that $P_{m l}$ is a function of $s$ only, we have

$$
\begin{aligned}
\left(\mathcal{T}_{l} \otimes \mathcal{T}_{m}\right) \circ P_{m l} & =W_{X} q q^{\top} W_{X}^{\top} \cdot \partial_{l} \partial_{m} P_{m l}=\Phi \operatorname{diag}(\omega) \Phi^{\top} q q^{\top} \Phi \operatorname{diag}(\omega) \Phi^{\top} \cdot \partial_{l} \partial_{m} P_{m l} \\
& =\Phi \operatorname{diag}(\omega) \bar{q} \bar{q}^{\top} \operatorname{diag}(\omega) \Phi^{\top} \cdot \partial_{l} \partial_{m} P_{m l} \\
& =\Phi\left(\overline{\mathcal{T}}_{l} \circ\left(\bar{q} \bar{q}^{\top} \overline{\mathcal{T}}_{m} \circ P_{m l}\right)\right) \Phi^{\top}:=\Phi\left(\overline{\mathcal{T}}_{l} \bar{q} \bar{q}^{\top} \overline{\mathcal{T}}_{m}\right) \circ P_{m l} \Phi^{\top},
\end{aligned}
$$

where in the first equality we use the fact that $\widetilde{\partial}_{l} P_{m l}=0$ since $P_{m l}$ does not depend on $\widetilde{s}$. In the third equality, we use the fact that $\bar{q}=\Phi^{\top} q$. In the fourth equality we apply the definitions of $\overline{\mathcal{T}_{l}}$ and $\overline{\mathcal{T}}_{m}$. Moreover, we let $\left(\overline{\mathcal{T}}_{l} \bar{q} \bar{q}^{\top} \overline{\mathcal{T}}_{m}\right) \circ f$ denote the operator composition $\overline{\mathcal{T}}_{l} \circ\left(\bar{q} \bar{q}^{\top} \overline{\mathcal{T}}_{m} \circ f\right)$ for any function $f$.

Furthermore, notice that both $\llbracket\left(\mathcal{T}_{l} \otimes \mathcal{T}_{m}\right) \circ P_{m l} \rrbracket$ and $\llbracket P_{l l} \cdot I_{d} \rrbracket$ are functions of $q$ only, and thus are independent of $G$. Thus, we can also take conditional expectation of $G U_{Y}^{\top} G^{\top}$ given $q$ in $A_{\text {Signal }}^{(h)}$. We introduce the following lemma that computes such an expectation.
Lemma C.3. Consider $G=1 / \sqrt{d} \cdot \Phi \bar{G} \Psi^{\top}$ with $\Phi \in \mathbb{O}^{d}, \Psi \in \mathbb{O}^{d_{y}}$, and $\bar{G}$ is a random matrix in $\mathbb{R}^{d \times d_{y}}$. Let $M \in \mathbb{R}^{d_{y} \times d_{y}}$ and $N \in \mathbb{R}^{d \times d}$ be two fixed matrices. Suppose the $d \times d_{y}$ random matrix $\bar{G}$ has independent entries with $\mathbb{E}[\bar{G}]=0$ and $\mathbb{E}\left[\bar{G}^{\odot 2}\right]=\Lambda$. It then holds that

$$
\mathbb{E}\left[G M G^{\top}\right]=1 / d \cdot \Phi \operatorname{diag}\left(\Lambda \operatorname{Diag}\left(\Psi^{\top} M \Psi\right)\right) \Phi^{\top}, \mathbb{E}\left[G^{\top} N G\right]=1 / d \cdot \Psi \operatorname{diag}\left(\Lambda^{\top} \operatorname{Diag}\left(\Phi^{\top} N \Phi\right)\right) \Psi^{\top} .
$$

Here $\operatorname{Diag}(\cdot)$ denotes the vector that consists the digonal entries of a matrix, and $\operatorname{diag}(\cdot)$ denotes the diagonal matrix created from a vector.

This lemma can be computed by direct computation and we omit the proof for brevity. Besides, to simplify the notation, we define

$$
\mathcal{A} \circ M \triangleq 1 / d \cdot \operatorname{diag}\left(\Lambda \operatorname{Diag}\left(\Psi^{\top} M \Psi\right)\right), \quad \mathcal{B} \circ N \triangleq 1 / d \cdot \operatorname{diag}\left(\Lambda^{\top} \operatorname{Diag}\left(\Phi^{\top} N \Phi\right)\right) .
$$

as operators that map a matrix $M \in \mathbb{R}^{d_{y} \times d_{y}}$ or $N \in \mathbb{R}^{d \times d}$ to another diagonal matrix. In particular, if $M=\Psi \bar{M} \Psi$ takes $\Psi$ as its eigenvector matrix and $\bar{M}$ as a diagonal matrix, then $\mathcal{A} \circ M=$ $\operatorname{diag}(\Lambda \operatorname{vec}(\bar{M})) / d$. By this lemma, we have $\mathbb{E}\left[G U_{Y}^{\top} G^{\top} \mid q\right]=\mathcal{A} \circ U_{Y}^{\top}$. Thus, we further have

$$
\begin{align*}
A_{\text {Signal }}^{(h)} & =-\mathbb{E}\left[\left(\Phi \llbracket\left(\overline{\mathcal{T}}_{l} \bar{q} \bar{q}^{\top} \overline{\mathcal{T}}_{m}\right) \circ P_{m l} \rrbracket \Phi^{\top}+\llbracket P_{l l} \cdot I_{d} \rrbracket\right) \Phi\left(\mathcal{A} \circ U_{Y}^{\top}\right) \Phi^{\top} q q^{\top}\right] \\
& =-\Phi \mathbb{E}\left[\left(\llbracket\left(\overline{\mathcal{T}}_{l} \bar{q} \bar{q} \overline{\mathcal{T}}_{m}\right) \circ P_{m l} \rrbracket+\llbracket P_{l l} \cdot I_{d} \rrbracket\right)\left(\mathcal{A} \circ U_{Y}^{\top}\right) \bar{q} \bar{q}^{\top}\right] \Phi^{\top} . \tag{C.15}
\end{align*}
$$

Note that $\left(\overline{\mathcal{T}_{l}} \bar{q} \bar{q} \overline{\mathcal{T}}_{m}\right) \circ P_{m l}, P_{l l} \cdot I_{d}$, and $\mathcal{A} \circ U_{Y}^{\top}$ are all diagonal matrices. Hence, $\Phi^{\top} A_{\text {signal }}^{(h)} \Phi$ is equal to the expectation of the product of a diagonal matrix and a rank-one matrix $\bar{q} \bar{q}^{\top}$, where the diagonal matrix is a function of $\bar{q}$.

We now introduce a key observation, which is a direct result of the inner product structure of the attention scores and the rotation invariance of the distribution of the covariate $x_{l}$.

Lemma C.4. Consider $g(s, \widetilde{s})$ as an arbitrary function of the attention scores $s$ and $\widetilde{s}$. Then, $\mathbb{E}[g(s, \widetilde{s}) \mid q]$, viewed as a function of $\bar{q}$, is a function of only $\left\langle\omega^{\odot 2}, \bar{q}^{\odot 2}\right\rangle,\left\langle\widetilde{\omega}^{\odot 2}, \bar{q}^{\odot 2}\right\rangle$, and $\left\langle\omega \odot \widetilde{\omega}, \bar{q}^{\odot 2}\right\rangle$. Here $\omega$ and $\widetilde{\omega}$ are the eigenvalues of $W_{X}$ and $\widetilde{W}_{X}$, respectively. Here $\omega^{\odot 2}$ denotes the elementwise square of $\omega$, i.e., $\omega^{\odot 2}$ is a vector in $\mathbb{R}^{d}$ with the $i$-th entry being $\omega_{i}^{2}$.

Proof. (Proof of Lemma C.4) See §G.1.2 for a detailed proof.
We remark that Lemma C. 4 shows that when $f$ is a function that simultaneously depends on two attention scores $s$ and $\widetilde{s}$, the conditional expectation $\mathbb{E}[f(s, \widetilde{s}) \mid q]$ is a function of only the second-order moments of $\bar{q}$, i.e., $\left\{\bar{q}_{j}^{2}\right\}_{j \in[d]}$. This fact is a result of the rotational invariance of the covariate distribution. This lemma directly implies that $\Phi^{\top} A_{\text {Signal }}^{(h)} \Phi$ is a diagonal matrix, which is shown in the following lemma.

Lemma C.5. Let $g(\bar{q})=\prod_{i=1}^{d} \bar{q}_{i}^{c_{i}}$ be a polynomial of $\bar{q}$ with $c_{i} \in \mathbb{N}$. Then, if $\sum_{i=1}^{d} c_{i}$ is odd, we have $\mathbb{E}\left[g(\bar{q}) \mid \bar{q}^{\odot 2}\right]=0$. In particular, $\mathbb{E}\left[\bar{q} \bar{q}^{\top} \mid \bar{q}^{\odot 2}\right]$ is a diagonal matrix.

Proof. (Proof of Lemma C.5) Note that when conditioned on $\bar{q}^{\odot 2}$, each entries of $\bar{q}$ are i.i.d. and takes values $-\left|\bar{q}_{i}\right|$ and $\left|\bar{q}_{i}\right|$ with equal probability. Hence, by symmetry, we have $\mathbb{E}\left[g(\bar{q}) \mid \bar{q}^{\odot 2}\right]=0$ if $\sum_{i=1}^{d} c_{i}$ is odd. Therefore, we prove this lemma.

Applying (C.15) and Lemma C. 5 to $A_{\text {Signal }}^{(h)}$, we have

$$
\begin{aligned}
A_{\text {Signal }}^{(h)} & =-\Phi \mathbb{E}\left[\left(\llbracket\left(\overline{\mathcal{T}}_{l} \bar{q} \bar{q}^{\top} \overline{\mathcal{T}}_{m}\right) \circ P_{m l} \rrbracket+\llbracket P_{l l} \cdot I_{d} \rrbracket\right)\left(\mathcal{A} \circ U_{Y}^{\top}\right) \bar{q} \bar{q}^{\top}\right] \Phi^{\top} \\
& =-\Phi \mathbb{E}\left[\mathbb{E}\left[\llbracket\left(\overline{\mathcal{T}}_{l} \bar{q} \bar{q}^{\top} \overline{\mathcal{T}}_{m}\right) \circ P_{m l} \cdot\left(\mathcal{A} \circ U_{Y}^{\top}\right) \bar{q} \bar{q}^{\top} \rrbracket+\llbracket P_{l l} \cdot I_{d} \rrbracket\left(\mathcal{A} \circ U_{Y}^{\top}\right) \bar{q} \bar{q}^{\top} \mid \bar{q}^{\odot 2}\right]\right] \Phi^{\top} .
\end{aligned}
$$

Note that the second term is a diagonal matrix by directly applying Lemma C.5. We note that the first term is also a diagonal matrix since $\bar{q}^{\top} \overline{\mathcal{T}}_{m} \circ P_{m l}\left(\mathcal{A} \circ U_{Y}^{\top}\right) \bar{q}=\left\langle\operatorname{Diag}\left(\overline{\mathcal{T}}_{m}^{\top} \circ P_{m l}\left(\mathcal{A} \circ U_{Y}^{\top}\right)\right), \bar{q}^{\odot 2}\right\rangle$ is a real number and only depends on $\bar{q}^{\odot 2}$. The remaining term $\mathbb{E}\left[\bar{q} \bar{q}^{\top} \mid \bar{q}^{\odot 2}\right]$ clearly gives us a diagonal matrix. Hence, we claim that $A_{\text {Signal }}^{(h)}$ is diagonal. We will leverage the same technique to simplify $A_{\text {Intf }}^{\left(h, h^{\prime}\right)}$ and $A_{\text {Noise }}^{\left(h, h^{\prime}\right)}$, respectively.

For $A_{\text {Intf }}^{\left(h, h^{\prime}\right)}$, by the first identity of Lemma C.2, we have

$$
\begin{aligned}
& A_{\text {Intf }}^{\left(h, h^{\prime}\right)}=\mathbb{E} {\left[X P^{(h)^{\top}} X^{\top} G U_{Y}^{(h)^{\top}} U_{Y}^{\left(h^{\prime}\right)} G^{\top} X p^{\left(h^{\prime}\right)} q^{\top}\right] } \\
&=\mathbb{E}\left[\left(\left(\llbracket \mathcal{T}_{l} \circ\left(P_{m l} \widetilde{p}_{m}\right) \rrbracket \otimes I_{d}+I_{d} \otimes \llbracket \mathcal{T}_{l} \circ\left(P_{m m} \widetilde{p}_{l}\right) \rrbracket+\left(I_{d} \otimes \llbracket \mathcal{T}_{l} \circ\left(P_{l m} \widetilde{p}_{m}\right) \rrbracket\right)^{\top(132)}\right.\right.\right. \\
&\left.\left.\left.\quad+\llbracket\left(\mathcal{T}_{l} \otimes \mathcal{T}_{m} \otimes \mathcal{T}_{n}\right) \circ\left(P_{m l} \widetilde{p}_{n}\right) \rrbracket\right):\left(G \widetilde{U}_{Y}^{\top} U_{Y} G^{\top}\right)\right) \otimes q\right] .
\end{aligned}
$$

Recall that ":" denotes the double inner product of two tensors. In particular, we have the following relationships for the double inner product.

Lemma C.6. Let $N, M \in \mathbb{R}^{d \times d}$ be two matrices and $u, v, w, x \in \mathbb{R}^{d}$ be four vectors. Then we have

$$
\begin{aligned}
v \otimes N: M \otimes u=v u^{\top} \cdot \operatorname{Tr}(N M), & \left(I_{d} \otimes v\right): M=\left(v^{\top} M\right)^{\top}, \\
\left(I_{d} \otimes v\right)^{\top(132)}: M=M v, & u \otimes v \otimes w: M \otimes x=\left(w^{\top} M v\right) u x^{\top} .
\end{aligned}
$$

Combining the first identity in Lemma C. 6 and Lemma C. 3 to the expression of $A_{\text {Intf }}^{\left(h, h^{\prime}\right)}$, we have

$$
\begin{align*}
& \mathbb{E}\left[\llbracket \mathcal{T}_{l} \circ\left(P_{m l} \widetilde{p}_{m}\right) \rrbracket \otimes I_{d}:\left(G \tilde{U}_{Y}^{\top} U_{Y} G^{\top}\right) \otimes q\right] \\
& \quad=\mathbb{E}\left[\llbracket \mathcal{T}_{l} \circ\left(P_{m l} \widetilde{p}_{m}\right) \rrbracket q^{\top} \cdot \operatorname{Tr}\left(\Phi \mathcal{A} \circ\left(\tilde{U}_{Y}^{\top} U_{Y}\right) \Phi^{\top}\right)\right] \\
& \quad=\Phi \mathbb{E}\left[\llbracket \overline{\mathcal{T}}_{l} \circ\left(P_{m l} \widetilde{p}_{m}\right) \rrbracket \bar{q} \bar{q}^{\top} \operatorname{Tr}\left(\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right)\right)\right] \Phi^{\top}, \tag{C.16}
\end{align*}
$$

where $\bar{q}=\Phi^{\top} q$. Besides, using the second identity in Lemma C. 6 and Lemma C.3, we have

$$
\begin{align*}
\mathbb{E}\left[I_{d}\right. & \left.\otimes \llbracket \mathcal{T}_{l} \circ\left(P_{m m} \widetilde{p}_{l}\right) \rrbracket:\left(G \tilde{U}_{Y}^{\top} U_{Y} G^{\top}\right) \otimes q\right] \\
& =\mathbb{E}\left[\Phi \mathcal{A} \circ\left(\tilde{U}_{Y}^{\top} U_{Y}\right) \Phi^{\top} \llbracket \mathcal{T}_{l} \circ\left(P_{m m} \widetilde{p}_{l}\right) \rrbracket q^{\top}\right] \\
& =\Phi \mathbb{E}\left[\mathcal{A} \circ\left(\tilde{U}_{Y}^{\top} U_{Y}\right) \llbracket \overline{\mathcal{T}}_{l} \circ\left(P_{m m} \widetilde{p}_{l}\right) \rrbracket \bar{q} \bar{q}^{\top}\right] \Phi, \tag{C.17}
\end{align*}
$$

where the second equality follows from (C.13). Note that $\llbracket \mathcal{T}_{l} \circ\left(P_{m m} \widetilde{p}_{l}\right) \rrbracket$ is a vector in $\mathbb{R}^{d}$ and $\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right)$ is a diagonal matrix in $\mathbb{R}^{d \times d}$. Moreover, by the third identity in Lemma C. 6 and Lemma C.3, we have

$$
\begin{align*}
\mathbb{E}\left[I_{d}\right. & \left.\otimes \llbracket \mathcal{T}_{l} \circ\left(P_{l m} \widetilde{p}_{m}\right) \rrbracket^{\top(132)}:\left(G \tilde{U}_{Y}^{\top} U_{Y} G^{\top}\right) \otimes q\right] \\
& =\mathbb{E}\left[\Phi \mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right) \Phi^{\top} \llbracket \mathcal{T}_{l} \circ\left(P_{l m} \widetilde{p}_{m}\right) \rrbracket q^{\top}\right] \\
& =\Phi \mathbb{E}\left[\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right) \llbracket \overline{\mathcal{T}}_{l} \circ\left(P_{l m} \widetilde{p}_{m}\right) \rrbracket \bar{q} \bar{q}^{\top}\right] \Phi, \tag{C.18}
\end{align*}
$$

where the second equality follows from (C.13). Finally, note that by the definition of $\mathcal{T}_{l}$ in (C.11), $\mathcal{T}_{l} \otimes \mathcal{T}_{m} \otimes \mathcal{T}_{n} \circ\left(P_{m l} \widetilde{p}_{n}\right)$ is a rank-one third-order tensor. By Lemma C. 3 and the last identity in Lemma C.6, we have

$$
\begin{align*}
& \mathbb{E}\left[\llbracket \mathcal{T}_{l} \otimes \mathcal{T}_{m} \otimes \mathcal{T}_{n} \circ\left(P_{m l} \widetilde{p}_{n}\right) \rrbracket:\left(G \widetilde{U}_{Y}^{\top} U_{Y} G^{\top}\right) \otimes q\right] \\
& \quad=\mathbb{E}\left[\llbracket\left(\left(\mathcal{T}_{l} \mathcal{T}_{n}^{\top}\left(\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right)\right) \mathcal{T}_{m}\right) \circ\left(P_{m l} \widetilde{p}_{n}\right)\right] q^{\top}\right] \\
& \left.\quad=\Phi \mathbb{E}\left[\llbracket\left(\overline{\mathcal{T}}_{l} \bar{q} \bar{q}^{\top} \overline{\mathcal{T}}_{n}\left(\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right)\right) \overline{\mathcal{T}}_{m}\right) \circ\left(P_{m l} \widetilde{p}_{n}\right)\right] \bar{q} \bar{q}^{\top}\right] \Phi, \tag{C.19}
\end{align*}
$$

where the second equality is obtained by applying (C.13) for three times.
Thus, combining (C.16)-(C.19), we have for $A_{\text {Intf }}^{\left(h, h^{\prime}\right)}$ that

$$
\begin{aligned}
A_{\text {Intf }}^{\left(h, h^{\prime}\right)}=\Phi \mathbb{E} & {\left[\llbracket \overline{\mathcal{T}}_{l} \circ\left(P_{m l} \widetilde{p}_{m}\right) \rrbracket \bar{q} \bar{q}^{\top} \operatorname{Tr}\left(\mathcal{A} \circ\left(\tilde{U}_{Y}^{\top} U_{Y}\right)\right)+\mathcal{A} \circ\left(\tilde{U}_{Y}^{\top} U_{Y}\right) \llbracket \overline{\mathcal{T}}_{l} \circ\left(P_{m m} \widetilde{p}_{l}\right) \rrbracket \bar{q} \bar{q}^{\top}\right.} \\
& \left.+\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right) \llbracket \overline{\mathcal{T}}_{l} \circ\left(P_{l m} \widetilde{p}_{m}\right) \rrbracket \bar{q} \bar{q}^{\top}+\llbracket\left(\overline{\mathcal{T}}_{l} \bar{q}^{\top} \overline{\mathcal{T}}_{n}\left(\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right)\right) \overline{\mathcal{T}}_{m}\right) \circ\left(P_{m l} \widetilde{p}_{n}\right) \rrbracket \bar{q} \bar{q}^{\top}\right] \Phi^{\top} .
\end{aligned}
$$

Here, we treat each $\mathcal{T}_{l}$ as a vector and $\overline{\mathcal{T}}_{l}$ as a diagonal matrix. Note that $\mathcal{A} \circ\left(\tilde{U}_{Y}^{\top} U_{Y}\right)$ is a diagonal matrix. Thus, the terms with $\llbracket \rrbracket$ in (C.16), (C.17), and (C.18) are all diagonal matrices. Moreover, they are functions of $s$ and $\widetilde{s}$. Thus, for these three terms, by Lemma C. 4 and Lemma C.5, we can first take a conditional expectation with respect to $\bar{q}^{\odot 2}$ and prove that they are all diagonal
matrices. Moreover, in (C.19), the term $\overline{\mathcal{T}}_{n}\left(\mathcal{A} \circ\left(\tilde{U}_{Y}^{\top} U_{Y}\right)\right) \overline{\mathcal{T}}_{m}$ is a diagonal matrix as it is the product of three diagonal matrices. As a result, $\llbracket\left(\overline{\mathcal{T}}_{l} \bar{q}^{\top} \overline{\mathcal{T}}_{n}\left(\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right)\right) \overline{\mathcal{T}}_{m}\right) \circ\left(P_{m l} \widetilde{p}_{n}\right) \rrbracket \bar{q} \bar{q}^{\top}$ involves fourthorder moments of $\bar{q}$. By applying Lemma C. 4 and Lemma C.5, and taking conditional expectation given $\bar{q}^{\odot 2}$, we can similarly argue that this term is a diagonal matrix. Therefore, we conclude that $A_{\text {Intf }}^{\left(h, h^{\prime}\right)}$ is a diagonal matrix.

Finally, for $A_{\text {Noise }}^{\left(h, h^{\prime}\right)}$, by the last identity of Lemma C. 2 and the first identity of Lemma C.6, we have

$$
\begin{aligned}
A_{\mathrm{Noise}}^{\left(h, h^{\prime}\right)} & =\mathbb{E}\left[X P^{\top} \varepsilon^{\top} U_{Y}^{\top} \widetilde{U}_{Y} \varepsilon \widetilde{p} q^{\top}\right]=\mathbb{E}\left[\left(\llbracket x_{l} \otimes \varepsilon_{m} \otimes \varepsilon_{n} \cdot\left(P_{m l} \widetilde{p}_{n}\right) \rrbracket: \widetilde{U}_{Y} U_{Y}^{\top}\right) q^{\top}\right] \\
& =\sigma^{2} \mathbb{E}\left[\operatorname{Tr}\left(\widetilde{U}_{Y} U_{Y}^{\top}\right) \cdot \llbracket\left(P_{m l} \widetilde{p}_{m}\right) \cdot x_{l} \rrbracket \cdot q^{\top}\right]=\sigma^{2} \mathbb{E}\left[\operatorname{Tr}\left(\widetilde{U}_{Y} U_{Y}^{\top}\right) \cdot \llbracket \mathcal{T}_{l} \circ\left(P_{m l} \widetilde{p}_{m}\right) \rrbracket q^{\top}\right] \\
& =\sigma^{2} \cdot \Phi \mathbb{E}\left[\operatorname{Tr}\left(\widetilde{U}_{Y} U_{Y}^{\top}\right) \cdot \llbracket \widetilde{\mathcal{T}}_{l} \circ\left(P_{m l} \widetilde{p}_{m}\right) \rrbracket \bar{q} \bar{q}^{\top}\right] \Phi^{\top},
\end{aligned}
$$

where the second equality follows from direct computation; in the third equality, we use the fact that $\varepsilon_{l} \stackrel{\text { i.i.d. }}{\sim} \mathcal{N}\left(0, \sigma^{2} I_{d_{y}}\right)$ and the fact that $I: M=\operatorname{Tr}(M)$; in the fourth equality we apply Lemma C.2; the last equality follows from (C.13). Similarly, applying Lemma C. 4 and and Lemma C.5, we prove that $A_{\text {Noise }}^{\left(h, h^{\prime}\right)}$ is a diagonal matrix.

In summary, we have for $A_{X X}^{(h)}$ that

$$
\begin{aligned}
\Phi^{\top} A_{X X}^{(h)} \Phi= & \underbrace{\left.-\mathbb{E}\left[\left(\llbracket\left(\overline{\mathcal{T}}_{l} \bar{q} \bar{q}^{\top} \overline{\mathcal{T}}_{m}^{\top}\right) \circ P_{m l} \rrbracket\right]+\llbracket P_{l l} I_{d} \rrbracket\right)\left(\mathcal{A} \circ U_{Y}^{\top}\right) \bar{q} \bar{q}^{\top}\right]}_{\text {Signal }} \\
& +\underbrace{\sum_{h^{\prime}=1}^{H} \sigma^{2} \mathbb{E}\left[\operatorname{Tr}\left(\widetilde{U}_{Y} U_{Y}^{\top}\right) \llbracket \overline{\mathcal{T}}_{l} \circ\left(P_{m l} \widetilde{p}_{m}\right) \rrbracket \bar{q} \bar{q}^{\top}\right]}_{\text {Noise }}
\end{aligned} \quad \begin{aligned}
&+\sum_{h^{\prime}=1}^{H} \mathbb{E}\left[\llbracket \overline{\mathcal{T}}_{l} \circ\left(P_{m l} \widetilde{p}_{m}\right) \rrbracket \bar{q} \bar{q}^{\top} \operatorname{Tr}\left(\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right)\right)+\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right) \llbracket \overline{\mathcal{T}}_{l} \circ\left(P_{m m} \widetilde{p}_{l}\right) \rrbracket \bar{q} \bar{q}^{\top}\right. \\
&\left.+\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right) \llbracket \overline{\mathcal{T}}_{l} \circ\left(P_{l m} \widetilde{p}_{m}\right) \rrbracket \bar{q} \bar{q}^{\top}+\llbracket\left(\overline{\mathcal{T}}_{l} \bar{q}^{\top} \overline{\mathcal{T}}_{n}^{\top}\left(\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right)\right) \overline{\mathcal{T}}_{m}\right) \circ\left(P_{m l} \widetilde{p}_{n}\right) \rrbracket \bar{q} \bar{q} \overline{I n t e r f e r e n c e}_{\top}\right]
\end{aligned} .
$$

We prove that, when $\Theta$ satisfies Decomposability Condition, only the top left block of $A^{(h)}, A_{X X}^{(h)}$, is non-zero. Moreover, $\Phi^{\top} A_{X X}^{(h)} \Phi$ is a diagonal matrix.

## Simplification of $B_{Y}^{(h)}$ with Gaussian Covariate.

Recall that in (C.10) we show that $B_{Y}^{(h)}$ can be decomposed into three terms: $B_{\text {Signal }}^{(h)}, B_{\text {Intf }}^{\left(h, h^{\prime}\right)}$, and $B_{\text {Noise }}^{\left(h, h^{\prime}\right)}$, which are defined in (C.8) and (C.8). In the following, we prove that each term can be diagonalized by $\Psi$.

For $B_{\text {Signal }}^{(h)}$, by the last identity of Lemma C. 2 and Lemma C.3, we have

$$
\begin{aligned}
B_{\text {Signal }}^{(h)} & =-\mathbb{E}\left[G^{\top} q p^{\top} X^{\top} G\right]=-\Psi \mathbb{E}\left[\mathcal{B} \circ\left(q \llbracket \mathcal{T}_{l} \circ p_{l} \rrbracket^{\top}\right)\right] \Psi^{\top} \\
& =-\Psi \mathbb{E}\left[\mathcal{B} \circ\left(\Phi \bar{q} \bar{q}^{\top} \llbracket \overline{\mathcal{T}}_{l} \circ p_{l} \rrbracket^{\top} \Phi^{\top}\right)\right] \Psi^{\top} .
\end{aligned}
$$

where the last equality holds by (C.13) and the definition $\bar{q}=\Phi^{\top} q$. Note that the operator $\mathcal{B}$ always produces a diagonal matrix, we prove that $\Psi^{\top} B_{\text {Signal }}^{(h)} \Psi$ is a diagonal matrix. For $B_{\text {Intf }}^{\left(h, h^{\prime}\right)}$, by the second identity of Lemma C. 2 and Lemma C.3, we have

$$
\begin{aligned}
B_{\text {Intf }}^{\left(h, h^{\prime}\right)} & =\mathbb{E}\left[\widetilde{U}_{Y} G^{\top} X \widetilde{p}^{\top} X^{\top} G\right] \\
& =\Psi \mathbb{E}\left[\operatorname{diag}(\widetilde{\mu}) \mathcal{B} \circ\left(\llbracket\left(\mathcal{T}_{l} \mathcal{T}_{m}^{\top}\right) \circ\left(\widetilde{p}_{l} p_{m}\right) \rrbracket+\llbracket \widetilde{p}_{l} p_{l} \rrbracket \cdot I_{d}\right)\right] \Psi^{\top} \quad / / \text { Lemma C. } 2 \\
& =\Psi \mathbb{E}\left[\operatorname{diag}(\widetilde{\mu}) \mathcal{B} \circ\left(\Phi\left(\llbracket\left(\overline{\mathcal{T}}_{l} \bar{q} \bar{q}^{\top} \overline{\mathcal{T}}_{m}\right) \circ\left(\widetilde{p}_{l} p_{m}\right) \rrbracket+\llbracket \widetilde{p}_{l} p_{l} \rrbracket \cdot I_{d}\right) \Phi^{\top}\right)\right] \Psi^{\top} .
\end{aligned}
$$

Here, the second equality also holds by Definition 3.1(ii) that $\widetilde{U}_{Y}=\Psi \operatorname{diag}(\widetilde{\mu}) \Psi^{\top}$ and the last equality follows from (C.13). Similarly, thanks to the operator $\mathcal{B}, \Psi^{\top} B_{\text {Intf }}^{\left(h, h^{\prime}\right)} \Psi$ is a diagonal matrix. Finally, for $B_{\text {Noise }}^{\left(h, h^{\prime}\right)}$, we have

$$
B_{\text {Noise }}^{\left(h, h^{\prime}\right)}=\mathbb{E}\left[\widetilde{U}_{Y} \varepsilon \widetilde{p} p^{\top} \varepsilon^{\top}\right]=\sigma^{2} \cdot \mathbb{E}\left[\widetilde{U}_{Y} \llbracket I_{d_{y}} \cdot \widetilde{p}_{l} p_{l} \rrbracket\right]=\sigma^{2} \Psi \mathbb{E}\left[\operatorname{diag}(\widetilde{\mu}) \llbracket \widetilde{p}_{l} p_{l} \rrbracket\right] \Psi^{\top},
$$

where we use the fact that $\varepsilon_{l} \stackrel{\text { i.i.d. }}{\sim} \mathcal{N}\left(0, \sigma^{2} I_{d_{y}}\right)$. This matrix is also digonalizable by $\Psi$ as $\llbracket \widetilde{p}_{l} p_{l} \rrbracket$ is a scalar.

In summary, we have for $B_{Y}^{(h)}$ that

$$
\begin{aligned}
\Psi^{\top} B_{Y}^{(h)} \Psi= & \underbrace{-\mathbb{E}\left[\mathcal{B} \circ\left(\Phi \bar{q} \bar{q}^{\top} \llbracket \overline{\mathcal{T}}_{l} \circ p_{l} \rrbracket^{\top} \Phi^{\top}\right)\right]}_{\text {Signal }}+\underbrace{\sum_{h^{\prime}=1}^{H} \sigma^{2} \mathbb{E}\left[\operatorname{diag}(\widetilde{\mu}) \llbracket \widetilde{p}_{l} p_{l} \rrbracket\right]}_{\text {Noise }} \\
& +\underbrace{\sum_{h^{\prime}=1}^{H} \mathbb{E}\left[\operatorname{diag}(\widetilde{\mu}) \mathcal{B} \circ\left(\Phi\left(\llbracket\left(\overline{\mathcal{T}}_{l} \bar{q} \bar{q}^{\top} \overline{\mathcal{T}}_{m}^{\top}\right) \circ\left(\widetilde{p}_{l} p_{m}\right) \rrbracket+\llbracket \widetilde{p}_{l} p_{l} \rrbracket \cdot I_{d}\right) \Phi^{\top}\right)\right]}_{\text {Interference }} .
\end{aligned}
$$

We prove that, when $\Theta$ satisfies Decomposability Condition, only the right block of $B^{(h)}$, $B_{Y}^{(h)}$, is non-zero. Moreover, $\Psi^{\top} B_{Y}^{(h)} \Psi$ is a diagonal matrix. Therefore, we conclude the proof of Proposition C.1.

## C. 2 Approximation of the Spectral Dynamics

Additional Notations. We follow the same notations as in Section C.1.2. Besides, we denote by $\delta_{i j}$ the Kronecker delta function such that $\delta_{i j}=1$ if $i=j$ and 0 otherwise. Furthermore, we will also encounter graph-theoretic notions. For a graph $\mathcal{G}$, we denote by $\operatorname{CC}(\mathcal{G})$ the set of connected components of $\mathcal{G}$. We denote by $R(v)$ the set of nodes that are reachable from node $v$ in $\mathcal{G}$. Note that $R(v)$ is also the element of $\operatorname{CC}(\mathcal{G})$ that contains $v$.

## C.2.1 Low-Effective Order Approximation to the Derivatives of Softmax Attention Probability

In order to give a rigorous calculation of $A_{X X}^{(h)}$ and $B_{Y}^{(h)}$, we need to compute the derivatives of the attention probability $p_{l}$ and $\widetilde{p}_{l}$ with respect to the attention scores $s$ and $\widetilde{s}$ as implied by the operator $\overline{\mathcal{T}}_{l}$ that

$$
\overline{\mathcal{T}}_{l} \circ f \triangleq\left(\operatorname{diag}(\omega) \partial_{l}+\operatorname{diag}(\widetilde{\omega}) \widetilde{\partial}_{l}\right) \circ f .
$$

For simplicity, we replace $\operatorname{diag}(\omega)$ and $\operatorname{diag}(\widetilde{\omega})$ with $w$ and $\widetilde{w}$ as placeholders, respectively. With such a replacement, we have $\overline{\mathcal{T}}_{l} \circ f=\left(w \partial_{l}+\widetilde{w} \widetilde{\partial}_{l}\right) f$. Also, when considering $\mathcal{T}_{l} \circ f$, we just need to replace $w$ and $\widetilde{w}$ with $W q$ and $\widetilde{W} q$ by multiplying back the rotation matrix $\Phi$ and $\bar{q}=\Phi^{\top} q$ according to (C.13).

Note that $P=\operatorname{diag}(p)-p p^{\top}$ for softmax attention probability $p$, which is a symmetric matrix. For calculation of $A_{X X}^{(h)}$, we need to compute the following derivatives:

$$
\begin{gathered}
\llbracket w^{\otimes 2} \partial_{l} \partial_{m} P_{m l} \rrbracket, \llbracket\left(w \partial_{l}+\widetilde{w} \widetilde{\partial}_{l}\right) P_{m m} \widetilde{p}_{l} \rrbracket, \llbracket\left(w \partial_{l}+\widetilde{w} \widetilde{\partial}_{l}\right) P_{l m} \widetilde{p}_{m} \rrbracket, \\
\llbracket\left(w \partial_{l}+\widetilde{w} \widetilde{\partial}_{l}\right) \otimes\left(w \partial_{m}+\widetilde{w} \widetilde{\partial}_{m}\right) \otimes\left(w \partial_{n}+\widetilde{w} \widetilde{\partial}_{n}\right) P_{m l} \widetilde{p}_{n} \rrbracket .
\end{gathered}
$$

For $B_{Y}^{(h)}$, we need to compute the following derivatives:

$$
\llbracket w \partial_{l} p_{l} \rrbracket, \llbracket\left(w \partial_{l}+\widetilde{w} \widetilde{\partial}_{l}\right) \otimes\left(w \partial_{m}+\widetilde{w} \widetilde{\partial}_{m}\right) \widetilde{p}_{l} p_{m} \rrbracket .
$$

We have the following fact about the derivatives of the attention probabilities.
Lemma C.7. We have the following identities involving partial derivatives of the attention probability $p$ with respect to the attention scores $s$ :
(i) $\partial_{l} p_{m}=P_{m l}=\delta_{l m} p_{l}-p_{l} p_{m}$;
(ii) $\partial_{l m}^{2} p_{n}=\partial_{l} P_{n m}=\delta_{l m n} p_{l}-\delta_{m n} p_{l} p_{m}-\delta_{n l} p_{m} p_{n}-\delta_{l m} p_{n} p_{l}+2 p_{l} p_{m} p_{n}$;
(iii) $\sum_{l} \partial_{l} P_{n l}=\sum_{l} \partial_{n} P_{l l}=\sum_{l} 2 p_{n} p_{l}^{2}-2 p_{n}^{2} \delta_{l n}=2 p_{n}\left(\|p\|_{2}^{2}-p_{n}\right)$;
(iv) $\sum_{l} \partial_{l m} P_{n l}=\partial_{m}\left(\sum_{l} \partial_{l} P_{n l}\right)=2\left(-2 p_{n}^{2} \delta_{l m n}+p_{n} p_{l}^{2} \delta_{m n}+2 p_{n} p_{l}^{2} \delta_{l m}+2 p_{n}^{2} p_{m} \delta_{l n}-3 p_{m} p_{n} p_{l}^{2}\right)$;

Calculations for $B_{Y}^{(h)}$. We give a rigorous calculation of the terms for $B_{Y}^{(h)}$ in the following. By Lemma C.7(i), we have

$$
\llbracket \partial_{l} p_{l} \rrbracket=\llbracket P_{l l} \rrbracket=1-\|p\|_{2}^{2}
$$

Furthermore, by Lemma C.7(ii), we have

$$
\begin{aligned}
& \llbracket\left(w \partial_{l}+\widetilde{w} \widetilde{\partial}_{l}\right) \otimes\left(w \partial_{m}+\widetilde{w} \widetilde{\partial}_{m}\right) \widetilde{p}_{l} p_{m} \rrbracket \\
&= \llbracket w^{\otimes 2} \widetilde{p}_{l}\left(\delta_{l m} p_{m}-p_{l} p_{m}-2 \delta_{l m} p_{m}^{2}+2 p_{l} p_{m}^{2}\right)+\widetilde{w}^{\otimes 2} p_{l}\left(\delta_{l m} \widetilde{p}_{m}-\widetilde{p}_{l} \widetilde{p}_{m}-2 \delta_{l m} \widetilde{p}_{m}^{2}+2 \widetilde{p}_{l} \widetilde{p}_{m}^{2}\right) \\
& \quad+\widetilde{w} \otimes w\left(p_{m}-p_{m}^{2}\right)\left(\widetilde{p}_{l}-\widetilde{p}_{l}^{2}\right)+w \otimes \widetilde{w}\left(\delta_{l m} p_{l}-p_{l} p_{m}\right)\left(\delta_{l m} \widetilde{p}_{l}-\widetilde{p}_{l} \widetilde{p}_{m}\right) \rrbracket \\
&=\mathbb{E} {\left[2 w^{\otimes 2}\left(-\widetilde{p}^{\top} p^{\odot 2}+\widetilde{p}^{\top} p\|p\|_{2}^{2}\right)+2 \widetilde{w}^{\otimes 2}\left(-p^{\top} \widetilde{p}^{\odot 2}+p^{\top} \widetilde{p} \| \widetilde{p}_{2}^{2}\right)\right.} \\
&\left.\quad+\widetilde{w} \otimes w\left(1-\|p\|_{2}^{2}\right)\left(1-\|\widetilde{p}\|_{2}^{2}\right)+w \otimes \widetilde{w}\left(p^{\top} \widetilde{p}-p^{\top} \widetilde{p}^{\odot 2}-\widetilde{p}^{\top} p^{\odot 2}+\left(\widetilde{p}^{\top} p\right)^{2}\right) \mid q\right] .
\end{aligned}
$$

The following fact summarizes the above calculations in the original matrix form (substituting the placeholders $w$ and $\widetilde{w}$ with $W q$ and $\widetilde{W} q$, respectively).

Lemma C.8. Suppose $q$ is the query vector and $W, \widetilde{W}$ are two attention weight matrices such that $p=\operatorname{softmax}\left(X^{\top} W q\right)$ and $\widetilde{p}=\operatorname{softmax}\left(X^{\top} \widetilde{W} q\right)$. Suppose that each column of $X$ is i.i.d. drawn from $\mathcal{N}\left(0, I_{d_{x}}\right)$. Then we have by Lemma C. 2 that

$$
\begin{aligned}
& \mathbb{E}[X p \mid q]=\llbracket \mathcal{T}_{l} \circ p_{l} \rrbracket=W q \cdot \mathbb{E}\left[\left(1-\|p\|_{2}^{2}\right) \mid q\right], \\
& \mathbb{E}\left[X p \widetilde{p} X^{\top} \mid q\right]=\llbracket p_{l} \widetilde{p}_{l} \cdot I_{d_{x}} \rrbracket+\llbracket\left(\mathcal{T}_{l} \otimes \mathcal{T}_{m}\right) \circ\left(p_{l} \widetilde{p}_{m}\right) \rrbracket \\
& =\mathbb{E}\left[p^{\top} \widetilde{p} \mid q\right] \cdot I_{d_{x}}+\mathbb{E}\left[2 W q q^{\top} W^{\top}\left(-\widetilde{p}^{\top} p^{\odot 2}+\widetilde{p}^{\top} p\|p\|_{2}^{2}\right)+2 \widetilde{W} q q^{\top} \widetilde{W}^{\top}\left(-p^{\top} \widetilde{p}^{\odot 2}+p^{\top} \widetilde{p}\|\widetilde{p}\|_{2}^{2}\right)\right. \\
& \left.\quad \quad+\widetilde{W} q q^{\top} W^{\top}\left(1-\|p\|_{2}^{2}\right)\left(1-\|\widetilde{p}\|_{2}^{2}\right)+W q q^{\top} \widetilde{W}^{\top}\left(p^{\top} \widetilde{p}-p^{\top} \widetilde{p}^{\odot 2}-\widetilde{p}^{\top} p^{\odot 2}+\left(\widetilde{p}^{\top} p\right)^{2}\right) \mid q\right] .
\end{aligned}
$$

In particular, if $W=\widetilde{W}$, then we have a simpler form:

$$
\mathbb{E}\left[X p p X^{\top} \mid q\right]=\mathbb{E}\left[W q q^{\top} W^{\top}\left(1-\|p\|_{2}^{2}-6\|p\|_{3}^{3}+6\|p\|_{2}^{4}\right)\right]+I_{d_{x}} \mathbb{E}\left[\|p\|_{2}^{2}\right] .
$$

Calculations for $A_{X X}^{(h)}$. For $A_{X X}^{(h)}$, expanding all these derivatives is tedious and unnecessary. We only need to keep track of those terms that contribute significantly to the final results and view the rest as higher-order noise. This necessitates developing a systematic way to evaluate the importance of each term in the expansion. To this end, in the following, we relate the expansion of partial derivates of a polynomial function of attention probabilities $p$ and $\tilde{p}$ to a graph structure where the nodes are in $\mathcal{V}=[L]$ and the edges are in $\mathcal{E}=[L] \times[L]$. We introduce the notion of graph-induced polynomials and effective order as follows.

Definition C. 9 (Graph-Induced Polynomial and Effective Order). Consider a weighted graph $\mathcal{G}=(\mathcal{V}, \mathcal{E}, a, b)$ where $\mathcal{V}=[L]$ is a set of vertices, $\mathcal{E}=[L] \times[L]$ is a set of undirected edges (we allow self-loop), and $a=\left\{a_{v}\right\}_{v \in \mathcal{V}}, b=\left\{b_{v}\right\}_{v \in \mathcal{V}}$ with $\left(a_{v}, b_{v}\right) \in \mathbb{N}$ are the nonnegative integer weights. For any subgraph $\mathcal{G}^{\prime}$ of $\mathcal{G}$, define the total weights of $\mathcal{G}^{\prime}$ as $W\left(\mathcal{G}^{\prime}\right) \triangleq \sum_{v \in \mathcal{V}^{\prime}}\left(a_{v}+b_{v}\right)$. We have the following definitions:
(i) The polynomial induced by graph $\mathcal{G}$ with variables $p=\left\{p_{v}\right\}_{v \in \mathcal{V}}, \widetilde{p}=\left\{\widetilde{p}_{v}\right\}_{v \in \mathcal{V}}$ is defined as $f_{\mathcal{G}}(p, \widetilde{p})=\prod_{v \in \mathcal{V}}\left(p_{v}^{a_{v}} \stackrel{p}{p}_{v}^{b_{v}}\right) \cdot \prod_{\left(v, v^{\prime}\right) \in \mathcal{E}} \delta_{v v^{\prime}}$.
(ii) Let $\mathrm{CC}_{\geq n}(\mathcal{G}) \triangleq\{c \in \operatorname{CC}(\mathcal{G}) \mid W(c) \geq n\}$ be the set of connected components of $\mathcal{G}$ with total weights no less than $n$.
(iii) We define the effective order of $\mathcal{G}$ as $\operatorname{Ord}(\mathcal{G}) \triangleq \sum_{v \in \mathcal{V}}\left(a_{v}+b_{v}\right)-\left|\mathrm{CC}_{\geq 1}(\mathcal{G})\right|$.
(iv) We say that two graphs $\mathcal{G}$ and $\mathcal{G}^{\prime}$ are equivalent if $\mathcal{V}=\mathcal{V}^{\prime}, a=a^{\prime}, b=b^{\prime}$ and $\mathrm{CC}_{\geq 1}(\mathcal{G})=$ $\mathrm{CC}_{\geq 1}\left(\mathcal{G}^{\prime}\right)$.

Definition C. 9 draws a parallel between the weighted graph structure to polynomials of this form $\prod_{v \in \mathcal{V}}\left(p_{v}^{a_{v}} \tilde{p}_{v}^{b_{v}}\right) \cdot \prod_{\left(v, v^{\prime}\right) \in \mathcal{E}} \delta_{v v^{\prime}}$. We remark that the effective order is critical for our analysis since terms with higher effective order turn out to be higher-ordered smaller in scale. The following fact shows that the polynomial and the underlying graph structure are isomorphic up to the class of equivalent graphs.

Lemma C.10. For any two graphs $\mathcal{G}$ and $\mathcal{G}^{\prime}, f_{\mathcal{G}}(p, \widetilde{p})=f_{\mathcal{G}^{\prime}}(p, \widetilde{p})$ if and only if $\mathcal{G}$ and $\mathcal{G}^{\prime}$ are equivalent. Moreover, any two equivalent graphs have the same effective order.

Proof. (Proof Sketch of Lemma C.10) It is easy to check that $f_{\mathcal{G}}(p, \widetilde{p})=f_{\mathcal{G}^{\prime}}(p, \widetilde{p})$ if and only if $\mathcal{G}$ and $\mathcal{G}^{\prime}$ have the same set of vertices, same weights on the vertices, and the same set of connected components, which is exactly what it means by saying that $\mathcal{G}$ and $\mathcal{G}^{\prime}$ are equivalent. The second claim on the effective order follows directly from the definition that the effective order is only a function of the weights on the vertices and the set of connected components.

To this end, we can also define the effective order of a polynomial as the effective order of any graph that induces this polynomial. We next introduce a partial derivative operator on both the graph and the polynomial.

Definition C. 11 (Derivative Operator). Consider a polynomial $f_{\mathcal{G}}(p, \widetilde{p})=\prod_{v \in \mathcal{V}}\left(p_{v}^{a_{v}} \widetilde{p}_{v}^{b_{v}}\right) \cdot \prod_{\left(v, v^{\prime}\right) \in \mathcal{E}} \delta_{v v^{\prime}}$. Define partial derivative operator $\partial_{u}$ for any $u \in \mathcal{V}$ as

$$
\begin{align*}
& \partial_{u} f_{\mathcal{G}}(p, \widetilde{p}) \triangleq \sum_{s \in \mathcal{V}} a_{s} p_{s}^{a_{s}-1}\left(\delta_{u s} p_{s}-p_{s} p_{u}\right) \widetilde{p}_{s}^{b_{s}} \cdot \prod_{v \in \mathcal{V} \backslash\{s\}}\left(p_{v}^{a_{v}} \bar{p}_{v}^{b_{v}}\right) \cdot \prod_{\left(v, v^{\prime}\right) \in \mathcal{E}} \delta_{v v^{\prime}} \\
& =\underbrace{\sum_{s \in \mathcal{V}} a_{s} \delta_{u s} \cdot \prod_{v \in \mathcal{V}}\left(p_{v}^{a_{v}} 万_{v}^{b_{v}}\right) \cdot \prod_{\left(v, v^{\prime}\right) \in \mathcal{E}} \delta_{v v^{\prime}}}_{\text {Adding an edge }(u, s)}-\underbrace{\left(\sum_{s \in \mathcal{V}} a_{s}\right) \cdot p_{u} \cdot \prod_{v \in \mathcal{V}}\left(p_{v}^{a_{v}} \stackrel{p}{p}_{v}^{b_{v}}\right) \cdot \prod_{\left(v, v^{\prime}\right) \in \mathcal{E}} \delta_{v v^{\prime}}}_{\text {Increasing } a_{u} \text { by } 1} . \tag{C.20}
\end{align*}
$$

Moreover, $\widetilde{\partial}_{u}$ is defined similarly.
Note that the definition of the partial derivative operator is consistent with the definition of the derivative of the attention probability $p$ in Lemma C.7. When combined with the underlying graph structure, we have an intuitive interpretation of the partial derivative operator. The partial derivative operator $\partial_{u}$ produces at most $|\mathcal{V}|+1$ terms in the summation, where each of the first $|\mathcal{V}|$ term adds a new edge $(u, s)$ for some $s \in \mathcal{V}$ to the graph $\mathcal{G}$ and the last term adds 1 to weight $a_{u}$ of vertex $u$ in $\mathcal{G}$. The following fact comes directly from the observation that both adding a new edge or adding 1 to the weight does not decrease the effective order.

Lemma C.12. Consider a $\mathcal{G}$-induced polynomial $f_{\mathcal{G}}(p, \widetilde{p})=\prod_{v \in \mathcal{V}}\left(p_{v}^{a_{v}} \vec{p}_{v}^{b_{v}}\right) \cdot \prod_{\left(v, v^{\prime}\right) \in \mathcal{E}} \delta_{v v^{\prime}}$. Applying $\partial_{v}$ or $\widetilde{\partial}_{v}$ yields in a summation of polynomials where each has an effective order no less than $\operatorname{Ord}(\mathcal{G})$.

Proof. (Proof Sketch of Lemma C.12) The proof follows directly from the definition of the partial derivative operator in Definition C. 11 and that adding a new edge or increasing the weight of a vertex does not decrease the effective order.

Therefore, when applying a sequence of partial derivative operators and want to keep track of only the low-effective-order terms, we can safely ignore higher-order terms after each application of the partial derivative operator. To this end, we use notation $\sum_{i} f_{\mathcal{G}_{i}}(p, \widetilde{p})={ }_{\leqslant k} \sum_{j} f_{\mathcal{G}_{j}^{\prime}}(p, \widetilde{p})$ to denote the low-effective-order equivalence between two expressions if $\sum_{i} f_{\mathcal{G}_{i}}(p, \widetilde{p}) \mathbb{1}\left(\operatorname{Ord}\left(\mathcal{G}_{i}\right) \leq k\right)=$ $\sum_{j} f_{\mathcal{G}_{j}^{\prime}}(p, \widetilde{p}) \mathbb{1}\left(\operatorname{Ord}\left(\mathcal{G}_{j}^{\prime}\right) \leq k\right)$. The following fact helps us simplify the calculation under this low-effective-order equivalence.

Lemma C.13. We denote by $R(v)$ the set of nodes that are reachable from node $v$ in $\mathcal{G}$. Consider a $\mathcal{G}$-induced polynomial $f_{\mathcal{G}}(p, \widetilde{p})=\prod_{v \in \mathcal{V}}\left(p_{v}^{a_{v}} \vec{p}_{v}^{b_{v}}\right) \cdot \prod_{\left(v, v^{\prime}\right) \in \mathcal{E}} \delta_{v v^{\prime}}$. Let $k$ be the effective order of $f_{\mathcal{G}}(p, \widetilde{p})$. Consider two cases: (i) if $W(R(u))=0$, we have

$$
\partial_{u} f_{\mathcal{G}}(p, \widetilde{p})={ }_{\leqslant k} \sum_{s \in \mathcal{V}} a_{s} \delta_{u s} \cdot \prod_{v \in \mathcal{V}}\left(p_{v}^{a_{v}} \widetilde{p}_{v}^{b_{v}}\right) \cdot \prod_{\left(v, v^{\prime}\right) \in \mathcal{E}} \delta_{v v^{\prime}}-\left(\sum_{s \in \mathcal{V}} a_{s}\right) \cdot p_{u} \cdot \prod_{v \in \mathcal{V}}\left(p_{v}^{a_{v}} v_{v}^{b_{v}}\right) \cdot \prod_{\left(v, v^{\prime}\right) \in \mathcal{E}} \delta_{v v^{\prime}},
$$

and (ii) if $W(R(u)) \geq 1$, we only need to keep

$$
\begin{equation*}
\partial_{u} f_{\mathcal{G}}(p, \widetilde{p})=_{\leqslant k}\left(\sum_{s \in R(u)} a_{s}\right) \cdot \prod_{v \in \mathcal{V}}\left(p_{v}^{a_{v}} \widetilde{p}_{v}^{b_{v}}\right) \cdot \prod_{\left(v, v^{\prime}\right) \in \mathcal{E}} \delta_{v v^{\prime}}, \tag{C.21}
\end{equation*}
$$

where $\delta_{u s}$ is not needed since $s \in R(u)$ and deleting the edge $(u, s)$ will not change the connected component structure. Similar result holds for $\widetilde{\partial}_{u} f_{\mathcal{G}}(p, \widetilde{p})$.

Proof. (Proof of Lemma C.13) See Appendix G.2.1 for a detailed proof.
We now characterize each term in the decomposition of $A_{X X}^{(h)}$. By Lemma C.7(iv), we have

$$
\begin{aligned}
\llbracket w^{\otimes 2} \partial_{l} \partial_{m} P_{m l} \rrbracket & =2 w^{\otimes 2} \llbracket-2 p_{m}^{2} \delta_{l m}+2 p_{m} p_{l}^{2} \delta_{l m}+2 p_{m}^{3} \delta_{l m}+p_{m} p_{l}^{2}-3 p_{m}^{2} p_{l}^{2} \rrbracket \\
& =2 w^{\otimes 2} \mathbb{E}\left[-\|p\|_{2}^{2}+4\|p\|_{3}^{3}-3\|p\|_{2}^{4} \mid q\right] .
\end{aligned}
$$

For $\llbracket\left(w \partial_{l}+\widetilde{w} \widetilde{\partial}_{l}\right) P_{m m} \widetilde{p}_{l} \rrbracket$, we have by Lemma C.7(iii) and Lemma C.7(i) that

$$
\begin{aligned}
\llbracket\left(w \partial_{l}+\widetilde{w} \widetilde{\partial}_{l}\right) P_{m m} \widetilde{p}_{l} \rrbracket & =w \llbracket\left(-2 p_{l}^{2} \delta_{l m}+2 p_{l} p_{m}^{2}\right) \widetilde{p}_{l} \rrbracket+\widetilde{w} \llbracket\left(p_{m}-p_{m}^{2}\right)\left(\widetilde{p}_{l}-\widetilde{p}_{l}^{2}\right) \rrbracket \\
& =w \mathbb{E}\left[\widetilde{p}^{\top}\left(-2 p^{\odot 2}+2 p\|p\|_{2}^{2}\right) \mid q\right]+\widetilde{w} \mathbb{E}\left[\left(1-\|p\|_{2}^{2}\right)\left(1-\|\widetilde{p}\|_{2}^{2}\right) \mid q\right],
\end{aligned}
$$

where the last equality holds by noting that $\sum_{l} \delta_{l m} \widetilde{p}_{l}-\widetilde{p}_{l} \widetilde{p}_{m}=0$. For $\llbracket\left(w \partial_{l}+\widetilde{w} \widetilde{\partial}_{l}\right) P_{l m} \widetilde{p}_{m} \rrbracket$, we have also by Lemma C.7(iii) and Lemma C.7(i) that

$$
\begin{aligned}
\llbracket\left(w \partial_{l}+\widetilde{w} \widetilde{\partial}_{l}\right) P_{l m} \widetilde{p}_{m} \rrbracket & =w \llbracket\left(2 p_{m} p_{l}^{2}-2 p_{m}^{2} \delta_{l m}\right) \widetilde{p}_{m} \rrbracket+\widetilde{w} \llbracket\left(\delta_{l m} p_{l}-p_{l} p_{m}\right)\left(\delta_{l m} \widetilde{p}_{l}-\widetilde{p}_{l} \widetilde{p}_{m}\right) \rrbracket \\
& =w \mathbb{E}\left[\widetilde{p}^{\top}\left(-2 p^{\odot 2}+2 p\|p\|_{2}^{2}\right) \mid q\right]+\widetilde{w} \mathbb{E}\left[\widetilde{p}^{\top} p-p^{\top} \widetilde{p}^{\odot 2}-\widetilde{p}^{\top} p^{\odot 2}+\left(\widetilde{p}^{\top} p\right)^{2} \mid q\right] .
\end{aligned}
$$

Lastly, we have

$$
\begin{align*}
& \llbracket\left(w \partial_{l}+\widetilde{w} \widetilde{\partial}_{l}\right) \otimes\left(w \partial_{m}+\widetilde{w} \widetilde{\partial}_{m}\right) \otimes\left(w \partial_{n}+\widetilde{w} \widetilde{\partial}_{n}\right) P_{m l} \widetilde{p}_{n} \rrbracket \\
& \quad=\llbracket\left(w \partial_{m}+\widetilde{w} \widetilde{\partial}_{m}\right) \otimes\left(w \partial_{n}+\widetilde{w} \widetilde{\partial}_{n}\right) \otimes\left(w\left(2 p_{m} p_{l}^{2}-2 p_{m}^{2} \delta_{l m}\right) \widetilde{p}_{n}+\widetilde{w} P_{m l} \widetilde{P}_{n l}\right) \rrbracket^{\top(312)} \\
& \quad=\llbracket\left(w \partial_{m}+\widetilde{w} \widetilde{\partial}_{m}\right) \otimes\left(w \partial_{n}+\widetilde{w} \widetilde{\partial}_{n}\right) \otimes\left(w\left(2 p_{m} p_{l}^{2}-2 p_{m}^{2} \delta_{l m}\right) \widetilde{p}_{n}+\widetilde{w}\left(\delta_{l m} p_{l}-p_{l} p_{m}\right)\left(\delta_{l n} \widetilde{p}_{l}-\widetilde{p}_{l} \widetilde{p}_{n}\right)\right) \rrbracket^{\top(31}
\end{align*}
$$

Note that all the terms in $\left(w\left(2 p_{m} p_{l}^{2}-2 p_{m}^{2} \delta_{l m}\right) \widetilde{p}_{n}+\widetilde{w}\left(\delta_{l m} p_{l}-p_{l} p_{m}\right)\left(\delta_{l n} \widetilde{p}_{l}-\widetilde{p}_{l} \widetilde{p}_{n}\right)\right)$ are of effective order 1 . Now, we apply $\left(w \partial_{m}+\widetilde{w} \widetilde{\partial}_{m}\right)$ to these terms and only keep track of those terms of effective
order 1. Using Lemma C.13, we have

$$
\begin{aligned}
& \llbracket\left(w \partial_{m}+\widetilde{w}_{m}\right)\left(w\left(2 p_{m} p_{l}^{2} \widetilde{p}_{n}-2 p_{m}^{2} \widetilde{p}_{n} \delta_{l m}\right)+\widetilde{w}\left(\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l m} p_{l} \widetilde{p}_{l} \widetilde{p}_{n}-\delta_{l n} p_{l} p_{m} \widetilde{p}_{l}+p_{l} p_{m} \widetilde{p}_{l} \widetilde{p}_{n}\right)\right) \rrbracket^{\top} \\
& ==_{\leqslant 1} \llbracket w^{\otimes 2}\left(2 p_{m} p_{l}^{2} \widetilde{p}_{n}-4 p_{m}^{2} \widetilde{p}_{n} \delta_{l m}\right)+\widetilde{w} \otimes w\left(\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l m} p_{l} \widetilde{p}_{l} \widetilde{p}_{n}-\delta_{l n} p_{l} p_{m} \widetilde{p}_{l}+p_{l} p_{m} \widetilde{p}_{l} \widetilde{p}_{n}\right) \\
& \quad+\widetilde{w}^{\otimes 2}\left(\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l m} p_{l} \widetilde{p}_{l} \widetilde{p}_{n}\right) \rrbracket .
\end{aligned}
$$

In the above calculation, we note that $W(R(m)) \geq 1$ holds for all terms. Hence, we apply (C.21) to these terms for both $\partial_{m}$ and $\widetilde{\partial}_{m}$. For $\left(2 p_{m} p_{l}^{2} \widetilde{p}_{n}-2 p_{m}^{2} \widetilde{p}_{n} \delta_{l m}\right)$, only terms with $\partial_{m}$ survives since $b_{m}=0$ for $\widetilde{p}$. For $\left(\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l m} p_{l} \widetilde{p}_{l} \widetilde{p}_{n}-\delta_{l n} p_{l} p_{m} \widetilde{p}_{l}+p_{l} p_{m} \widetilde{p}_{l} \widetilde{p}_{n}\right)$, when applying $\partial_{m}$, all the terms remain unchanged since the $\sum_{s \in R(m)} a_{s}=1$ and when applying $\widetilde{\partial}_{m}$, we have $\widetilde{\partial}_{m}\left(-\delta_{l n} p_{l} p_{m} \widetilde{p}_{l}+\right.$ $\left.p_{l} p_{m} \widetilde{p}_{l} \widetilde{p}_{n}\right)=0$. Next, we apply $\left(w \partial_{n}+\widetilde{w} \widetilde{\partial}_{n}\right)$ to the above expressions,

$$
\begin{aligned}
& \llbracket\left(w \partial_{n}+\widetilde{w} \widetilde{\partial}_{n}\right)\left(w^{\otimes 2}\left(2 p_{m} p_{l}^{2} \widetilde{p}_{n}-4 p_{m}^{2} \widetilde{p}_{n} \delta_{l m}\right)+\widetilde{w} \otimes w\left(\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l m} p_{l} \widetilde{p}_{l} \widetilde{p}_{n}-\delta_{l n} p_{l} p_{m} \widetilde{p}_{l}+p_{l} p_{m} \widetilde{p}_{l} \widetilde{p}_{n}\right)\right. \\
& \left.\quad+\widetilde{w}^{\otimes 2}\left(\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l m} p_{l} \widetilde{p}_{l} \widetilde{p}_{n}\right)\right) \rrbracket^{\top(231)} \\
& ==_{\leqslant 1} \llbracket w^{\otimes 2} \otimes \widetilde{w}\left(2 p_{m} p_{l}^{2} \widetilde{p}_{n}-4 p_{m}^{2} \widetilde{p}_{n} \delta_{l m}\right)+\widetilde{w} \otimes w \otimes \widetilde{w}\left(\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l m} p_{l} \widetilde{p}_{l} \widetilde{p}_{n}-\delta_{l n} p_{l} p_{m} \widetilde{p}_{l}+p_{l} p_{m} \widetilde{p}_{l} \widetilde{p}_{n}\right) \\
& \quad \quad+\widetilde{w} \otimes w^{\otimes 2}\left(\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l n} p_{l} p_{m} \widetilde{p}_{l}\right)+\widetilde{w}^{\otimes 3}\left(\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l m} p_{l} \widetilde{p}_{l} \widetilde{p}_{n}\right)+\widetilde{w}^{\otimes 2} \otimes w \delta_{l m n} p_{l} \widetilde{p}_{l} \rrbracket \\
& = \\
& =\llbracket w^{\otimes 2} \otimes \widetilde{w}\left(2 p_{m} p_{l}^{2} \widetilde{p}_{n}-4 p_{m}^{2} \widetilde{p}_{n} \delta_{l m}\right)+\widetilde{w}^{\otimes 2} \otimes w \delta_{l m n} p_{l} \widetilde{p}_{l} \rrbracket \\
& =\mathbb{E}\left[-2 w^{\otimes 2} \otimes \widetilde{w}\|p\|_{2}^{2}+\widetilde{w}^{\otimes 2} \otimes w p^{\top} \widetilde{p} \mid q\right] .
\end{aligned}
$$

In the first equality, we again have $W(R(n)) \geq 1$ for all terms and we only use (C.21) for calculation. This time, applying $\partial_{n}$ to $\left(2 p_{m} p_{l}^{2} \widetilde{p}_{n}-4 p_{m}^{2} \widetilde{p}_{n} \delta_{l m}\right)$ gives 0 since $\sum_{s \in R(n)} a_{s}=0$. Applying $\widetilde{\partial}_{n}$ to the second part $\left(\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l m} p_{l} \widetilde{p}_{l} \widetilde{p}_{n}-\delta_{l n} p_{l} p_{m} \widetilde{p}_{l}+p_{l} p_{m} \widetilde{p}_{l} \widetilde{p}_{n}\right)$ does not change the form since $\sum_{s \in R(n)} b_{s}=1$. Applying $\partial_{n}$ to ( $\left.\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l m} p_{l} \widetilde{p}_{l} \widetilde{p}_{n}-\delta_{l n} p_{l} p_{m} \widetilde{p}_{l}+p_{l} p_{m} \widetilde{p}_{l} \widetilde{p}_{n}\right)$ only gives us the first and the third terms. Applying $\widetilde{\partial}_{n}$ to $\left(\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l m} p_{l} \widetilde{p}_{l} \widetilde{p}_{n}\right)$ does not change the form since $\sum_{s \in R(n)} b_{s}=1$ and applying $\partial_{n}$ to $\left(\delta_{l m n} p_{l} \widetilde{p}_{l}-\delta_{l m} p_{l} \widetilde{p}_{l} \widetilde{p}_{n}\right)$ gives us $\delta_{l m n} p_{l} \widetilde{p}_{l}$. Moreover, for the second equality, we have the 2 nd- 4 th terms zero by noting that $\sum_{l} p_{l}=1$ by the normalization of the attention probability.

We summarize the above results into the following table, where the highest degree $\left(\sum_{v \in \mathcal{V}} a_{v}+b_{v}\right)$ is upper bounded by counting the total number of $p, \widetilde{p}$ and $\overline{\mathcal{T}}$ in the expression. Here, $P_{l m}=$ $\delta_{l m} p_{l}-p_{l} p_{m}$ is counted as 2 and each $\overline{\mathcal{T}}$ raises the degree at most 1 by Lemma C.13.

In the sequel, we denote by $\alpha_{\text {Signal }}^{(h)}, \alpha_{\text {Noise }}^{(h)}, \alpha_{\text {Intf }}^{(h)}$ the vector of eigenvalues of $A_{\text {Signal }}^{(h)}, A_{\text {Noise }}^{(h)}, A_{\text {Intf }}^{(h)}$ respectively, and $\beta_{\text {Signal }}^{(h)}, \beta_{\text {Noise }}^{(h)}, \beta_{\text {Intf }}^{(h)}$ the vector of eigenvalues of $B_{\text {Signal }}^{(h)}, B_{\text {Noise }}^{(h)}, B_{\text {Intf }}^{(h)}$ respectively. Combining the above results with the fact that $\Phi^{\top} A_{X X}^{(h)} \Phi$ is diagonal in Proposition C.1, we have for each terms in $\Phi^{\top} A_{X X}^{(h)} \Phi$ that

$$
\begin{aligned}
\alpha_{\text {Signal }}^{(h)}=- & \frac{1}{d_{x}} \mathbb{E}\left[\left(-2\left\|p^{(h)}\right\|_{2}^{2}+\operatorname{err}_{>1}\right) \cdot\left\langle\omega^{(h)} \odot\left(\Lambda \mu^{(h)}\right), \bar{q}^{\odot 2}\right\rangle \cdot \omega^{(h)} \odot \bar{q}^{\odot 2}\right] \\
& -\frac{1}{d_{x}} \mathbb{E}\left[\left(1-\left\|p^{(h)}\right\|_{2}^{2}\right) \cdot\left(\Lambda \mu^{(h)}\right) \odot \bar{q}^{\odot 2}\right],
\end{aligned}
$$

Table 2: Expressions for Terms in the Decomposition of $A_{X X}^{(h)}$ and $B_{Y}^{(h)}$ and Their Highest Degrees.

$$
\begin{aligned}
& \alpha_{\text {Noise }}^{(h)}=\sum_{h^{\prime}=1}^{H} \sigma^{2} \mathbb{E}\left[\left\langle\mu^{(h)}, \mu^{\left(h^{\prime}\right)}\right\rangle \cdot\left(\operatorname{err}_{>1} \cdot \omega^{(h)}+\left(p^{(h)} p^{\top} h^{\left(h^{\prime}\right)}+\operatorname{err}_{>1}\right) \cdot \omega^{\left(h^{\prime}\right)}\right) \odot \bar{q}^{\odot 2}\right], \\
& \alpha_{\text {Intf }}^{(h)}=\sum_{h^{\prime}=1}^{H} \frac{1}{d_{x}} \mathbb{E}\left[\Lambda\left(\mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right) \odot\left(\operatorname{err}_{>1} \omega^{(h)}+\left(1+\operatorname{err}_{>0}\right) \omega^{\left(h^{\prime}\right)}\right) \odot \bar{q}^{\odot 2}\right] \\
& \quad+\sum_{h^{\prime}=1}^{H} \frac{1}{d_{x}} \mathbb{E}\left[( \mathbf { 1 } _ { d _ { x } } ^ { \top } \Lambda ( \mu ^ { ( h ) } \odot \mu ^ { ( h ^ { \prime } ) } ) \mathbf { 1 } _ { d _ { x } } + \Lambda ( \mu ^ { ( h ) } \odot \mu ^ { ( h ^ { \prime } ) } ) ) \odot \left(\operatorname{err}_{>1} \cdot \omega^{(h)}+\left(p^{\left.\left.\left.(h)^{\top} p^{\left(h^{\prime}\right)}+\operatorname{err}_{>1}\right) \cdot \omega^{\left(h^{\prime}\right)}\right) \odot \bar{q}^{\odot 2}\right]}\right.\right.\right. \\
& \quad+\sum_{h^{\prime}=1}^{H} \frac{1}{d_{x}} \mathbb{E}\left[\left(-2\left\|p^{(h)}\right\|_{2}^{2}+\operatorname{err}_{>1}\right) \cdot\left\langle\Lambda\left(\mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right) \odot \omega^{(h)} \odot \omega^{\left(h^{\prime}\right)}, \bar{q}^{\odot 2}\right\rangle \cdot \omega^{(h)} \odot \bar{q}^{\odot 2}\right] \\
& \quad+\sum_{h^{\prime}=1}^{H} \frac{1}{d_{x}} \mathbb{E}\left[\left(p^{(h)^{\top}} p^{\left(h^{\prime}\right)}+\operatorname{err}_{>1}\right) \cdot\left\langle\Lambda\left(\mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right) \odot \omega^{(h)} \odot \omega^{\left(h^{\prime}\right)}, \bar{q}^{\odot 2}\right\rangle \cdot \omega^{\left(h^{\prime}\right)} \odot \bar{q}^{\odot 2}\right] \\
& \quad+\sum_{\left(\omega_{1}, \omega_{2}, \omega_{3}\right) \in \Omega} \sum_{h^{\prime}=1}^{H} \frac{1}{d_{x}} \mathbb{E}\left[\operatorname{err}_{>1} \cdot\left\langle\Lambda\left(\mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right) \odot \omega_{1} \odot \omega_{2}, \bar{q}^{\odot 2}\right\rangle \cdot \omega_{3} \odot \bar{q}^{\odot 2}\right],
\end{aligned}
$$

where we use $\operatorname{err}_{>k}$ to hide terms that are functions of $\left(p^{(h)}, p^{\left(h^{\prime}\right)}\right)$ and are of effective order higher than $k$. In addition, we denote by $\Omega=\left\{\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\}^{3} \backslash\left\{\left(\omega^{(h)}, \omega^{\left(h^{\prime}\right)}, \omega^{(h)}\right),\left(\omega^{(h)}, \omega^{\left(h^{\prime}\right)}, \omega^{\left(h^{\prime}\right)}\right)\right\}$. Here, we also use the fact that $\mathcal{A} \circ\left(\widetilde{U}_{Y}^{\top} U_{Y}\right)=\operatorname{diag}(\Lambda(\widetilde{\mu} \odot \mu))$ and $\mathcal{A} \circ\left(U_{Y}^{\top}\right)=\operatorname{diag}(\Lambda \mu)$ due to the fact that $\widetilde{U}_{Y}$ and $U_{Y}$ are simultaneously diagonalizable by $\Psi$. Similarly, we have for each terms in $\Psi^{\top} B_{Y}^{(h)} \Psi$ that

$$
\begin{aligned}
\beta^{(h)}= & -\frac{1}{d_{x}} \mathbb{E}\left[\left(1-\left\|p^{(h)}\right\|_{2}^{2}\right) \cdot \Lambda^{\top}\left(\omega^{(h)} \odot \bar{q}^{\odot 2}\right)\right]+\sum_{h^{\prime}=1}^{H} \sigma^{2} \mathbb{E}\left[p^{(h)^{\top}} p^{\left(h^{\prime}\right)} \cdot \mu^{\left(h^{\prime}\right)}\right] \\
& +\sum_{h^{\prime}=1}^{H} \frac{1}{d_{x}} \mathbb{E}\left[\mu ^ { ( h ^ { \prime } ) } \odot \Lambda ^ { \top } \left(\left(\omega^{\left(h^{\prime}\right)} \odot \omega^{(h)}\left(1+\operatorname{err}_{>0}\right)+\omega^{\left.\left.\left.(h)^{\odot}{ }^{2} \mathrm{err}_{>1}+\omega^{\left(h^{\prime}\right) \odot 2}{ }^{\operatorname{err}}{ }_{>1}\right) \odot \bar{q}^{\odot 2}\right)\right]}\right.\right.\right. \\
& +\sum_{h^{\prime}=1}^{H} \frac{1}{d_{x}} \mathbb{E}\left[p^{(h)^{\top}} p^{\left(h^{\prime}\right)} \cdot \mu^{\left(h^{\prime}\right)} \odot\left(\Lambda^{\top} \mathbf{1}_{d_{y}}\right)\right] .
\end{aligned}
$$

## C.2.2 Error Analysis for the Approximation of $A_{X X}^{(h)}$ and $B_{Y}^{(h)}$

In order to derive an approximation of $A_{X X}^{(h)}$ and $B_{Y}^{(h)}$, we propose the following conditions on $\mu^{(h)}$ and $\omega^{(h)}$.

Condition C.14. For fixed $\epsilon \in(0,1)$ and $\epsilon_{0} \in(0,1)$, we consider the following regime for $\left\{\omega^{(h)}\right\}_{h \in[H]}$ :

$$
\left\|\omega^{(h)}\right\|_{\infty} \leq L^{-1 / 4} \cdot(\log L)^{-1 / 2}, \quad\left\|\omega^{(h)}\right\|_{2}^{2} \leq \frac{2 \log L}{3 c^{2}}, \quad\left\|\omega^{(h)}\right\|_{4}^{4} \leq L^{-\left(1-\epsilon_{0}\right)} \cdot(\log L)^{-1}
$$

where $c \in \mathbb{R}_{+}$is the minimal constant satisfying

$$
\max \left\{\frac{1}{c}+\frac{3}{1+\sqrt{1+c^{2} / 2}}, \frac{12 \sqrt{5}}{2 c}\right\} \leq \epsilon
$$

We also consider the following regime for $\left\{\mu^{(h)}\right\}_{h \in[H]}$ :

$$
\mu_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{\left(h^{\prime}\right)} \geq 0, \quad \sum_{h^{\prime}=1}^{H} \mu_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{\left(h^{\prime}\right)} \leq O(1), \quad\left|\mu_{i}^{(h)}\right| \leq \sqrt{2 L \phi_{i}^{-1}}, \quad \forall i \in\left[d_{y}\right], h \in[H],
$$

where $\phi_{i}=1+\operatorname{SNR}_{i}^{-1}=1+\left(\sigma^{2} d\right) /\left(d_{i} \lambda_{i}\right)$.
The above conditions on $\omega^{(h)}$ is motivated by Lemma B. 3 and Lemma B. 4 where in Lemma B. 4 we plug in $\operatorname{Deg}(\mathcal{G}) \leq 6$ and $\kappa=2$ in the condition $\frac{2 \operatorname{Deg}(\mathcal{G}) \sqrt{2 \kappa+1}}{\epsilon \kappa} \leq c$. The fact $\operatorname{Deg}(\mathcal{G}) \leq 6$ is according to the highest degree in Table 2. Under Condition C.14, we conclude from Lemma B. 3 that

$$
\begin{equation*}
\mathbb{E}\left[\left(\mathbb{E}\left[p^{(h)^{\top}} p^{\left(h^{\prime}\right)} \mid q\right]-\frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L}\right)^{2}\right] \leq O\left(L^{-\left(3-\epsilon_{0}\right)}\right) . \tag{C.22}
\end{equation*}
$$

And if $\operatorname{Ord}(\mathcal{G}) \geq 2$ and $\operatorname{Deg}(\mathcal{G}) \leq 6$ for some graph $\mathcal{G}$, then the $\mathcal{G}$-induced polynomial $f_{\mathcal{G}}\left(p^{(h)}, p^{\left(h^{\prime}\right)}\right)$ satisfies

$$
\begin{equation*}
\mathbb{E}\left[f_{\mathcal{G}}\left(p^{(h)}, p^{\left(h^{\prime}\right)}\right)^{2}\right] \leq O\left(L^{-4 \cdot(1-\epsilon)}\right) \tag{C.23}
\end{equation*}
$$

by Lemma B.4.
To use the previous results, we need to decouple the randomness in $f_{\mathcal{G}}\left(p^{(h)}, p^{\left(h^{\prime}\right)}\right)$ and some polynomials of $\bar{q}$.

Notations. In the sequel, we use $f_{=1}$ to denote terms with effective order equal to 1 and $f_{>1}$ to denote terms with effective order greater than or equal to 2 where we hide the dependence on $\left(p^{(h)}, p^{\left(h^{\prime}\right)}\right)$ in the notation. For our need, we consider two kinds of polynomials in $\bar{q}:\left(\right.$ i) $g(\bar{q})=\bar{q}^{\odot 2}$ and (ii) $g(\bar{q})=\left\langle v, \bar{q}^{\odot 2}\right\rangle \cdot \bar{q}^{\odot 2}$ where $v \in \mathbb{R}_{+}^{d}$ is a constant vector. We abbreviate $g(\bar{q})$ as $g$ in the sequel. We drop the superscript $(\cdot)^{(h)}$ and replace $(\cdot)^{\left(h^{\prime}\right)}$ by $\widetilde{(\cdot)}$ for simplicity. We denote by $v_{i}$ the $i$-th entry of $v$ and $v_{-i}$ the vector obtained from $v$ with the $i$-th entry removed.

Lemma C.15. Suppose $v \in \mathbb{R}_{+}^{d}$ or $v \in \mathbb{R}_{-}^{d}$. Under Condition C.14, we have

$$
\begin{gathered}
\max \left\{\begin{array}{cc}
\left|\frac{\mathbb{E}\left[\left(p^{\top} \widetilde{p}+f_{>1}\right) \cdot\left\langle v, \bar{q}^{\odot 2}\right\rangle \cdot \bar{q}_{i}^{2}\right]}{\exp (\langle\omega, \widetilde{\omega}\rangle) \cdot L^{-1} \cdot\left(\langle v\rangle+2 v_{i}\right)}-1\right|, & \left.\left|\frac{\mathbb{E}\left[\left(p^{\top} \widetilde{p}+f_{>1}\right) \cdot \bar{q}_{i}^{2}\right]}{\exp (\langle\omega, \widetilde{\omega}\rangle) \cdot L^{-1}}-1\right|\right\} \leq O\left(L^{-\left(1-\epsilon_{0}\right) / 2}\right), \\
\max \left\{\left|\frac{\mathbb{E}\left[f_{>1} \cdot\left\langle v, \bar{q}^{\odot 2}\right\rangle \cdot \bar{q}_{i}^{2}\right]}{\left(\langle v\rangle+2 v_{i}\right)}\right|,\right. & \left.\left|\mathbb{E}\left[f_{>1} \cdot \bar{q}_{i}^{2}\right]\right|\right\} \leq O\left(L^{-2(1-\epsilon)}\right) .
\end{array}\right.
\end{gathered}
$$

Proof. (Proof of Lemma C.15) See Appendix G.2.2 for a detailed proof.
Notations. Recall that

$$
\Lambda=\operatorname{diag}\left(\lambda_{1} \mathbf{1}_{d_{1}}, \ldots, \lambda_{I} \mathbf{1}_{d_{I}}, \mathbf{0}_{d_{I+1}}, \ldots, \mathbf{0}_{d_{d_{y}}}\right)
$$

where $\mathbf{1}_{d_{i}}$ is a $d_{i}$-dimensional all-one vector. For the eigenvalues $\mu^{(h)}$ and $\omega^{(h)}$, we denote by $\mu_{i}^{(h)}$ the $i$-th entry of $\mu^{(h)}$, and $\bar{\omega}_{i}^{(h)}$ the average of the $i$-th block of $\omega^{(h)}$, where the blocks are defined by the row partition of $\Lambda$ for $i \in\left[d_{y}\right]$. Moreover, if $I<d_{y}$, we assign nominal tasks indexed by $j=I+1, \ldots, d_{y}$ with $\lambda_{j}=0$, dimension $d_{j}$ such that $\sum_{j=I+1}^{d_{y}} d_{j}=d-\sum_{i=1}^{I} d_{i}$, and define $\mu_{j}^{(h)}$ and $\bar{\omega}_{j}^{(h)}$ for $j \in\left\{I+1, \ldots, d_{y}\right\}$ accordingly. We let $\boldsymbol{d}=\left(d_{1}, \ldots, d_{d_{y}}\right)$ be the vector containing the dimensions for each corpus. We denote by $\bar{\alpha}_{i}^{(h)}$ the average of $\alpha^{(h)}$ within the $i$ th block and $\bar{\alpha}=\left(\bar{\alpha}_{1}, \ldots, \bar{\alpha}_{d_{y}}\right)$ the vector containing the averages for each corpus. Equipped with Lemma C.15, we have for each terms in $\Phi^{\top} A_{X X}^{(h)} \Phi$ that

$$
\begin{align*}
& d \bar{\alpha}_{\text {Intf }}^{(h)}=\sum_{h^{\prime}=1}^{H} \lambda \odot \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)} \odot \bar{\omega}^{\left(h^{\prime}\right)} \odot\left(1 \pm L^{-1}\right)  \tag{C.24}\\
& +\sum_{h^{\prime}=1}^{H} \lambda \odot \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)} \odot \bar{\omega}^{(h)} \odot\left( \pm L^{-2(1-\epsilon)}\right)  \tag{C.25}\\
& +\sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L}\left\langle\boldsymbol{d} \odot \lambda, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \bar{\omega}^{\left(h^{\prime}\right)} \odot\left(1 \pm\left(d_{\min }^{-1}+L^{-\frac{1-\epsilon_{0}}{2}}\right)\right)  \tag{C.26}\\
& +\sum_{h^{\prime}=1}^{H}\left\langle\boldsymbol{d} \odot \lambda, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \bar{\omega}^{(h)} \odot\left( \pm L^{-2(1-\epsilon)}\right)  \tag{C.27}\\
& -\sum_{h^{\prime}=1}^{H} 2 \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{(h)}\right\rangle\right)}{L}\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \bar{\omega}^{\left(h^{\prime}\right)} \odot \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \bar{\omega}^{(h)} \odot\left(1 \pm\left(d_{\min }^{-1}+L^{-\frac{1-\epsilon_{0}}{2}}\right)\right)  \tag{C.28}\\
& +\sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L}\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \bar{\omega}^{\left(h^{\prime}\right)} \odot \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \bar{\omega}^{\left(h^{\prime}\right)} \odot\left(1 \pm\left(d_{\min }^{-1}+L^{-\frac{1-\epsilon_{0}}{2}}\right)\right)  \tag{C.29}\\
& +\sum_{\left(\bar{\omega}_{1}, \bar{\omega}_{2}, \bar{\omega}_{3}\right) \in \Omega} \sum_{h^{\prime}=1}^{H}\langle\boldsymbol{d} \odot \lambda,| \bar{\omega}_{1} \odot \bar{\omega}_{2} \odot \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}| \rangle \bar{\omega}_{3} \odot\left( \pm L^{-2(1-\epsilon)}\right), \tag{C.30}
\end{align*}
$$

$$
\begin{aligned}
d \bar{\alpha}_{\text {Signal }}^{(h)}= & 2 \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{(h)}\right\rangle\right)}{L}\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle \bar{\omega}^{(h)} \odot\left(1 \pm\left(d_{\min }^{-1}+L^{-\frac{1-\epsilon_{0}}{2}}\right)\right)-\lambda \odot \mu^{(h)} \odot\left(1 \pm L^{-1}\right) \\
d \bar{\alpha}_{\text {Noise }}^{(h)}= & \sum_{h^{\prime}=1}^{H} \sigma^{2} d \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L}\left\langle\mu^{(h)}, \mu^{\left(h^{\prime}\right)}\right\rangle \bar{\omega}^{\left(h^{\prime}\right)} \odot\left(1 \pm L^{-\frac{1-\epsilon_{0}}{2}}\right) \\
& \quad+\sum_{h^{\prime}=1}^{H} \sigma^{2} d\left\langle\mu^{(h)}, \mu^{\left(h^{\prime}\right)}\right\rangle \bar{\omega}^{(h)} \odot\left( \pm L^{-2(1-\epsilon)}\right)
\end{aligned}
$$

where we have

$$
\Omega=\left(\left\{\bar{\omega}^{(h)}, \bar{\omega}^{\left(h^{\prime}\right)}\right\}^{\otimes 2} \backslash\left\{\left(\bar{\omega}^{(h)}, \bar{\omega}^{\left(h^{\prime}\right)}\right)\right\}\right) \otimes\left\{\bar{\omega}^{(h)}, \bar{\omega}^{\left(h^{\prime}\right)}\right\}
$$

as all the possible combinations of $\left(\bar{\omega}^{(h)}, \bar{\omega}^{\left(h^{\prime}\right)}\right)$ except for the combinations that already appear in (C.28) and (C.29). Here, we define $d_{\min }=\min _{i \in[I]} d_{i}$ and the additional error $d_{\min }^{-1}$ comes from the approximation of $\langle v\rangle+2 v_{i}$ in Lemma C. 15 with $\langle v\rangle$ since there are at least $d_{\text {min }}$ terms equal to $v_{i}$ in the summation $\langle v\rangle$ and each coordinate of $v$ is either non-negative or non-positive. Here, $x=a \pm b$ means that the upper bound for $x$ is $a+O(b)$ and the lower bound is $a-O(b)$. In addition, we are able to invoke Lemma C. 15 for (C.28), (C.29) and the first term in $d \bar{\alpha}_{\sigma}^{(h)}$ since $\bar{\omega}^{(h)} \odot \bar{\omega}^{\left(h^{\prime}\right)} \odot \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}$ and $\mu^{(h)} \odot \bar{\omega}^{(h)}$ have non-negative entries according to the condition $\mu_{i}^{(h)} \bar{\omega}_{i}^{(h)} \geq 0$ in Condition C.14. Due to the same reason, we include an absolute value in (C.30) to ensure that the entries of $\bar{\omega}_{1} \odot \bar{\omega}_{2} \odot \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}$ are non-negative in order to invoke Lemma C.15, where we treat (C.30) as an error term. Similarly, for $\Psi^{\top} B_{Y}^{(h)} \Psi$ we have

$$
\begin{align*}
& d \beta^{(h)}=-\boldsymbol{d} \odot \lambda \odot \bar{\omega}^{(h)} \odot\left(1 \pm L^{-1}\right)+\sum_{h^{\prime}=1}^{H} \sigma^{2} d \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} \mu^{\left(h^{\prime}\right)} \odot\left(1 \pm L^{-\frac{1-\epsilon_{0}}{2}}\right)  \tag{C.31}\\
& +\sum_{h^{\prime}=1}^{H} \boldsymbol{d} \odot \lambda \odot \bar{\omega}^{(h)} \odot \bar{\omega}^{\left(h^{\prime}\right)} \odot \mu^{\left(h^{\prime}\right)} \odot\left(1 \pm L^{-1}\right)  \tag{C.32}\\
& +\sum_{h^{\prime}=1}^{H} \boldsymbol{d} \odot \lambda \odot\left(\bar{\omega}^{(h) \odot 2}+\bar{\omega}^{\left(h^{\prime}\right) \odot 2}\right) \odot \mu^{\left(h^{\prime}\right)} \odot\left( \pm L^{-2(1-\epsilon)}\right)  \tag{C.33}\\
& +\sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} \boldsymbol{d} \odot \lambda \odot \mu^{\left(h^{\prime}\right)} \odot\left(1 \pm L^{-\frac{1-\epsilon_{0}}{2}}\right), \tag{C.34}
\end{align*}
$$

## C.2.3 Further Approximation for Symmetric Weights

In this part, we consider the case where both $W_{X}^{(h)}$ and $U_{Y}^{(h)}$ are Positive Semi-definite (PSD) matrices, which means that $\mu_{i}^{(h)} \geq 0$ and $\bar{\omega}_{i}^{(h)} \geq 0$ for all $i \in\left[d_{y}\right]$ and $h \in[H]$. We first simplify $\bar{\alpha}_{\text {Intf }}^{(h)}$. We consider the second order terms which scales as $L^{-2(1-\epsilon)}$. For (C.30), we note that the possible combinations for $\left(\bar{\omega}_{1}, \bar{\omega}_{2}\right)$ are $\left(\bar{\omega}^{(h)}, \bar{\omega}^{(h)}\right)$, $\left(\bar{\omega}^{\left(h^{\prime}\right)}, \bar{\omega}^{\left(h^{\prime}\right)}\right)$, and $\left(\bar{\omega}^{\left(h^{\prime}\right)}, \bar{\omega}^{(h)}\right)$ while $\bar{\omega}_{3}$ can be either $\bar{\omega}^{(h)}$ or $\bar{\omega}^{\left(h^{\prime}\right)}$. If $\left(\bar{\omega}_{1}, \bar{\omega}_{2}\right)=\left(\bar{\omega}^{\left(h^{\prime}\right)}, \bar{\omega}^{(h)}\right)$, we can get rid of the absolute value in (C.30). To this end, we notice that the form of this term is then no different from either (C.28) or (C.29) depending on the choice of $\bar{\omega}_{3}$, while both (C.28) and (C.29) can only be larger than $L^{-1}$. Hence, we can add an additional error term $L^{-(1-2 \epsilon)}$ to both (C.28) and (C.29) and remove the case $\left(\bar{\omega}_{1}, \bar{\omega}_{2}\right)=\left(\bar{\omega}^{\left(h^{\prime}\right)}, \bar{\omega}^{(h)}\right)$ from (C.30).

We further simplify (C.30) if both $\mu$ and $\bar{\omega}$ are non-negative. For the remaining cases, we note that $\bar{\omega}_{1}=\bar{\omega}_{2}$ and $\bar{\omega}_{1}^{\odot 2}$ has each element of order $o(1)$ according to Condition C.14. If $\bar{\omega}_{3}=\bar{\omega}^{(h)}$, we have (C.30) bounded by (C.27) element-wise and if $\bar{\omega}_{3}=\bar{\omega}^{\left(h^{\prime}\right)}$, we have (C.30) bounded by (C.26) times $L^{-(1-2 \epsilon)}$ element-wise. For the second term (C.25), we also have by the non-negativity of $\mu$ that it is bounded by (C.27) element-wise. Hence, we conclude that only (C.27) survives as the second order term in $\bar{\alpha}_{\text {Intf }}^{(h)}$ if both $\mu$ and $\bar{\omega}$ are non-negative.

Next, we consider the first order terms which scales as $L^{-1}$. By noting that $\mu^{\left(h^{\prime}\right)} \odot \bar{\omega}^{\left(h^{\prime}\right)}<O(1)$ element-wise according to Condition C.14, we have that (C.28) is upper bounded by the first term in $d \bar{\alpha}_{\text {Signal }}^{(h)}$ up to some constant. By noting that $\left\|\bar{\omega}^{(h)}\right\|_{\infty}<O\left(L^{-\left(1-\epsilon_{0}\right) / 4}\right)$ according to Condition C.14, we have that (C.29) is upper bounded by (C.26) times $L^{-\left(1-\epsilon_{0}\right) / 2}$. In summary, we have for $\bar{\alpha}^{(h)}$ that

$$
\begin{align*}
& d \bar{\alpha}^{(h)}=-\left(1 \pm L^{-1}\right) \odot \lambda \odot \mu^{(h)}+\sum_{h^{\prime}=1}^{H}\left(1 \pm L^{-1}\right) \odot \lambda \odot \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)} \odot \bar{\omega}^{\left(h^{\prime}\right)}  \tag{C.35}\\
& \quad+\sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L}\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \bar{\omega}^{\left(h^{\prime}\right)} \odot\left(1 \pm\left(d_{\min }^{-1}+L^{-\frac{1-\epsilon_{0}}{2}}+L^{-(1-2 \epsilon)}\right)\right) \\
& \quad+\frac{\exp \left(\left\langle\omega^{(h)}, \omega^{(h)}\right\rangle\right)}{L}\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle \bar{\omega}^{(h)} \odot( \pm 1)+\sum_{h^{\prime}=1}^{H}\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \bar{\omega}^{(h)} \odot\left( \pm L^{-2(1-\epsilon)}\right) .
\end{align*}
$$

For $\beta^{(h)}$, we note that the second term (C.33) is of order $L^{-2(1-\epsilon)}$. Note that $\left\|\bar{\omega}^{(h)}\right\|_{\infty} \leq O\left(L^{-\left(1-\epsilon_{0}\right) / 4}\right)$ according to Condition C.14. Hence, we have (C.34) bounded by (C.34) times $L^{-\left(1-\epsilon_{0}\right) / 2}$. In summary, we have for $\beta^{(h)}$ that

$$
\begin{align*}
d \beta^{(h)}=- & \left(1 \pm L^{-1}\right) \odot \boldsymbol{d} \odot \lambda \odot \bar{\omega}^{(h)}+\sum_{h^{\prime}=1}^{H}\left(1 \pm L^{-1}\right) \odot \boldsymbol{d} \odot \lambda \odot \bar{\omega}^{(h)} \odot \bar{\omega}^{\left(h^{\prime}\right)} \odot \mu^{\left(h^{\prime}\right)} \\
& +\sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} \boldsymbol{d} \odot \lambda \odot \phi \odot \mu^{\left(h^{\prime}\right)} \odot\left(1 \pm L^{-\frac{1-\epsilon_{0}}{2}}\right) . \tag{C.36}
\end{align*}
$$

## C. 3 Preservation of The Decomposability Condition along Gradient Flow

In the previous section, we have shown that the decomposability of the weights implies that both $A^{(h)}$ and $B^{(h)}$ have only one nonzero block, and these submatrices can be diagonalized by $\Phi$ and $\Psi$. In the following, we prove that the Decomposability Condition is preserved during the dynamics, given that the initialization of gradient flow satisfies the Decomposability Condition.

Proof. (Proof of Lemma 3.2) Below we verify the preservation of the conditions in Definition 3.1 one by one.

Preservation of $U_{X}^{(h)}=0$ and $W_{Y}^{(h)}=0$. We first show the easy part in Definition 3.1(i) that $U_{X}^{(h)}=0$ and $W_{Y}^{(h)}=0$ during the dynamics. Recall from Appendix C. 1 that $A^{(h)}$ only has the left-top block $A_{X X}^{(h)} \in \mathbb{R}^{d \times d}$ being non-zero. Therefore, the time-derivative of $W_{Y}^{(h)}=K_{Y}^{(h)^{\top}} Q_{X}^{(h)}$ satisfies

$$
\begin{aligned}
\partial_{t} W_{Y}^{(h)} & =\partial_{t} K_{Y}^{(h)^{\top}} Q_{X}^{(h)}+K_{Y}^{(h)^{\top}} \partial_{t} Q_{X}^{(h)} \\
& =-d_{e}^{-1 / 2}\left(\left[\begin{array}{ll}
A_{Y X}^{(h)} & A_{Y Y}^{(h)}
\end{array}\right] Q^{(h)^{\top}} Q_{X}^{(h)}+K_{Y}^{(h)^{\top}} K^{(h)}\left[\begin{array}{c}
A_{X X}^{(h)} \\
A_{Y X}^{(h)}
\end{array}\right]\right) \\
& =-d_{e}^{-1 / 2} K_{Y}^{(h)^{\top}} K_{X}^{(h)} A_{X X}^{(h)}=0,
\end{aligned}
$$

where the last equality holds by Definition 3.1(i) that $\operatorname{span}\left(K_{X}^{(h)}\right) \perp \operatorname{span}\left(K_{Y}^{(h)}\right)$. Also, we note that $B^{(h)}$ only has the right block $B_{Y}^{(h)} \in \mathbb{R}^{d_{y} \times d_{y}}$ being non-zero. Thus the time-derivative of $U_{X}^{(h)}=O^{(h)} V_{X}^{(h)}$ satisfies

$$
\begin{aligned}
\partial_{t} U_{X}^{(h)} & =\partial_{t} O^{(h)} V_{X}^{(h)}+O^{(h)} \partial_{t} V_{X}^{(h)} \\
& =-\left[\begin{array}{cc}
B_{X}^{(h)} & B_{Y}^{(h)}
\end{array}\right] V^{(h)^{\top}} V_{X}^{(h)}-O^{(h)} O^{(h)^{\top}} B_{X}^{(h)} \\
& =-B_{Y}^{(h)} V_{Y}^{(h)}{ }^{\top} V_{X}^{(h)}=0,
\end{aligned}
$$

where the last equality holds by Definition 3.1(i) that $\operatorname{span}\left(V_{X}^{(h)}\right) \perp \operatorname{span}\left(V_{Y}^{(h)}\right)$. Hence, we conclude that $U_{X}^{(h)} \equiv 0$ and $W_{Y}^{(h)} \equiv 0$ along the gradient flow trajectory if they are initialized to be zero.

Preservation of Subspace Orthogonality. We next show that Definition 3.1(i) is preserved, for which it suffices to show that $\partial_{t}\left(K_{Y}^{(h)^{\top}} K_{X}^{(h)}\right) \equiv 0$ and $\partial_{t}\left(V_{X}^{(h)^{\top}} V_{Y}^{(h)}\right) \equiv 0$. The time derivatives of $K_{X}^{(h)}$ and $K_{Y}^{(h)}$ are given by

$$
\partial_{t} K_{X}^{(h)}=-d_{e}^{-1 / 2} Q^{(h)}\left[\begin{array}{c}
A_{X X}^{(h)^{\top}} \\
A_{X Y}^{(h)}
\end{array}\right]=-d_{e}^{-1 / 2} Q_{X}^{(h)} A_{X X}^{(h)}, \quad \partial_{t} K_{Y}^{(h)}=-d_{e}^{-1 / 2} Q^{(h)}\left[\begin{array}{c}
A_{Y X}^{(h)} \\
A_{Y Y}^{(h)}
\end{array}\right]=0 .
$$

These further imply

$$
\partial_{t}\left(K_{Y}^{(h)^{\top}} K_{X}^{(h)}\right)=K_{Y}^{(h)^{\top}} \partial_{t} K_{X}^{(h)}=-d_{e}^{-1 / 2} K_{Y}^{(h)^{\top}} Q_{X}^{(h)} A_{X X}^{(h)^{\top}}=-d_{e}^{-1 / 2} W_{Y}^{(h)} A_{X X}^{(h)^{\top}}=0 .
$$

Similarly, we have $\partial_{t} V_{X}^{(h)}=-O^{(h)^{\top}} B_{X}^{(h)}=0, \partial_{t} V_{Y}^{(h)}=-O^{(h)^{\top}} B_{Y}^{(h)}$, and thus

$$
\partial_{t}\left(V_{X}^{(h)^{\top}} V_{Y}^{(h)}\right)=V_{X}^{(h)^{\top}} \partial_{t} V_{Y}^{(h)}=-V_{X}^{(h)^{\top}} O^{(h)^{\top}} B_{Y}^{(h)}=-U_{X}^{(h)^{\top}} B_{Y}^{(h)}=0 .
$$

In the above two derivations, we have used Definition 3.1(i) that $U_{X}^{(h)}=0$ and $W_{Y}^{(h)}=0$.
Preservation of Definition 3.1(ii) via diagonality of $\Phi^{\top} A_{X X}^{(h)} \Phi$ and $\Psi^{\top} B_{Y}^{(h)} \Psi$. Under the common singular vector space condition in Definition 3.1(ii), let $\Upsilon^{(h)}=\left[v_{1}^{(h)}, \ldots, v_{d}^{(h)}\right] \in \mathbb{R}^{d_{e} \times d}$ and $\Phi^{(h)} \in \mathbb{R}^{d \times d}$ be the common left- and right-singular vector matrix for both $Q_{X}^{(h)}$ and $K_{X}^{(h)}$, and $\Theta^{(h)}=\left[\theta_{1}^{(h)}, \ldots, \theta_{d_{y}}^{(h)}\right] \in \mathbb{R}^{d_{e} \times d_{y}}$ and $\Psi^{(h)} \in \mathbb{R}^{d_{y} \times d_{y}}$ be the common left- and right-singular vector matrix for both $V_{Y}^{(h)}$ and $O^{(h)^{\top}}$. Simply put, we can decompose $Q_{X}^{(h)}, K_{X}^{h}, V_{Y}^{(h)}$ and $O^{(h)}$ into

$$
\begin{gathered}
Q_{X}^{(h)}=\Upsilon^{(h)} \operatorname{diag}\left(\sigma\left(Q_{X}^{(h)}\right)\right) \Phi^{\top}, \quad K_{X}^{(h)}=\Upsilon^{(h)} \operatorname{diag}\left(\sigma\left(K_{X}^{(h)}\right)\right) \Phi^{\top}, \\
V_{Y}^{(h)}=\Theta^{(h)} \operatorname{diag}\left(\sigma\left(V_{Y}^{(h)}\right)\right) \Psi^{\top}, \quad O^{(h)}=\Psi \operatorname{diag}\left(\sigma\left(O^{(h)}\right)\right) \Theta^{(h)},
\end{gathered}
$$

where $\left(\sigma\left(Q_{X}^{(h)}\right), \sigma\left(K_{X}^{(h)}\right)\right) \in \mathbb{R}^{d}$ and $\left(\sigma\left(V_{Y}^{(h)}\right), \sigma\left(O^{(h)}\right)\right) \in \mathbb{R}^{d_{y}}$ are the semi-singular values ${ }^{6}$. Note that we also have $\sigma\left(Q_{X}^{(h)}\right) \odot \sigma\left(K_{X}^{(h)}\right)=\omega^{(h)}$ and $\sigma\left(V_{Y}^{(h)}\right) \odot \sigma\left(O^{(h)}\right)=\mu^{(h)}$. Our goal is to show that the singular vector spaces remain unchanged for all these four matrices during the dynamics. With the observations that only $A_{X X}^{(h)}$ and $B_{Y}^{(h)}$ are non-zero, we have the following dynamics as we have derived in the previous step:

$$
\begin{aligned}
& \partial_{t} K_{X}^{(h)}=-d_{e}^{-1 / 2} Q_{X}^{(h)} A_{X X}^{(h)}=-d_{e}^{-1 / 2} \Upsilon^{(h)} \operatorname{diag}\left(\sigma\left(Q_{X}^{(h)}\right)\right)\left(\Phi^{\top} A_{X X}^{(h)} \Phi\right)^{\top} \Phi^{\top}, \\
& \partial_{t} Q_{X}^{(h)}=-d_{e}^{-1 / 2} K_{X}^{(h)} A_{X X}^{(h)}=-d_{e}^{-1 / 2} \Upsilon^{(h)} \operatorname{diag}\left(\sigma\left(K_{X}^{(h)}\right)\right)\left(\Phi^{\top} A_{X X}^{(h)} \Phi\right) \Phi^{\top}, \\
& \partial_{t} O^{(h)}=-B_{Y}^{(h)} V_{Y}^{(h)^{\top}=-\Psi\left(\Psi^{\top} B_{Y}^{(h)} \Psi\right) \operatorname{diag}\left(\sigma\left(V_{Y}^{(h)}\right)\right) \Theta^{(h)^{\top}},} \\
& \partial_{t} V_{Y}^{(h)}=-O^{(h)^{\top}} B_{Y}^{(h)}=-\Theta^{(h)} \operatorname{diag}\left(\sigma\left(O^{(h)}\right)\right)\left(\Psi^{\top} B_{Y}^{(h)} \Psi\right) \Psi^{\top} .
\end{aligned}
$$

To this end, it suffices to verify that both $\Phi^{\top} A_{X X}^{(h)} \Phi$ and $\Psi^{\top} B_{Y}^{(h)} \Psi$ are diagonal matrices in order to show that the singular vector spaces remain unchanged. The diagonality of $\Psi^{\top} B_{Y}^{(h)} \Psi$ and $\Phi^{\top} A_{X X}^{(h)} \Phi$ is shown by Proposition C.1. Hence, we conclude that the singular vector spaces remain unchanged during the dynamics.

Preservation of Definition 3.1(iii). Note that the previously, Definition 3.1(i) and Definition 3.1(ii) are self-preserved during the dynamics. We next show that Definition 3.1(iii) is also preserved during the dynamics if the current state satisfies this condition. Let $\mathcal{J}_{i}$ be the index set of the support of the $i$-th task as we have defined in the main text. Given that $\sigma\left(Q_{X}^{(h)}\right)_{m}=\sigma\left(Q_{X}^{(h)}\right)_{n}$ for any $m, n \in \mathcal{J}_{i}$, and the same for $K_{X}^{(h)}$, it suffices to check that the diagonal entries of $\Phi^{\top} A_{X X}^{(h)} \Phi$ are the same for any $m, n \in \mathcal{J}_{i}$. We say a $\mathbb{R}^{d \times \star}$ matrix (or vector) is Within-Task Homogeneous (wth) if the $m$-th and the $n$-th rows (or entries) are always the same. Note that operators $\overline{\mathcal{T}}_{l}$ (by the wth

[^5]of $\omega^{(h)}$ ) and $\mathcal{A}$ (by the wth property of $\Lambda=\mathbb{E}\left[G^{\odot 2}\right]$ ) are both wth. Therefore, it suffices to check that both
$$
\mathbb{E}\left[f(s, \widetilde{s}) \bar{q} \bar{q}^{\top}\right], \quad \mathbb{E}\left[f(s, \widetilde{s}) \sum_{j \in \mathcal{J}_{i}} \bar{q}_{j}^{2} \bar{q} \bar{q}^{\top}\right]
$$
have wth diagonal entries for any function $f$ that only depends on $s$ and $\widetilde{s}$ and any $j \in[d]$. These formulas capture all the terms in the decomposition of $\Phi^{\top} A_{X X}^{(h)} \Phi$. The first term captures the signal term, the noise term, and the first three interference terms in the decomposition of $\Phi^{\top} A_{X X}^{(h)} \Phi$. The last term captures the last interference term in the decomposition of $\Phi^{\top} A_{X X}^{(h)} \Phi$. Notably, by Lemma C.4, $f(s, \widetilde{s})$ is a function of only $\left\langle\omega^{\odot 2}, \bar{q}^{\odot 2}\right\rangle,\left\langle\widetilde{\omega}^{\odot 2}, \bar{q}^{\odot 2}\right\rangle$, and $\left\langle\omega \odot \widetilde{\omega}, \bar{q}^{\odot 2}\right\rangle$. For now, we can rewrite $\left\langle\omega^{\odot 2}, \bar{q}^{\odot 2}\right\rangle=\sum_{i=1}^{I} d_{i}^{-1} \sum_{k \in \mathcal{J}_{i}} \omega_{k}^{2} \cdot \sum_{m \in \mathcal{J}_{i}} \bar{q}_{m}^{2}$ and the same for the remaining terms by the wth property of $\omega$ or $\widetilde{\omega}$. Let $\bar{q}_{(i)}$ be the slice of $\bar{q}$ that contains only the entries in $\mathcal{J}_{i}$. Hence, $f(s, \widetilde{s})$ is just a function of $\left\{\left\|\bar{q}_{(i)}\right\|_{2}\right\}_{i \in[I]}$. Given the 2-norm of $\bar{q}_{(i)}$, the posterior distribution of $\bar{q}_{(i)}$ is shuffling-invariant. Therefore, for the first term, we directly conclude that $\mathbb{E}\left[f(s, \widetilde{s}) \bar{q} \bar{q}^{\top}\right]$ has wth diagonal entries. For the second term, we combine $f(s, \widetilde{s})$ and $\sum_{j \in \mathcal{J}_{i}} \bar{q}_{j}^{2} \bar{q} \bar{q}^{\top}$ to form a new function that only depends on $\left\{\left\|\bar{q}_{(i)}\right\|_{2}\right\}_{i \in[I]}$. Thus, we also conclude that $\mathbb{E}\left[f(s, \widetilde{s}) \sum_{j \in \mathcal{J}_{i}} \bar{q}_{j}^{2} \bar{q} \bar{q}^{\top}\right]$ has wth diagonal entries. Thus, we conclude that Definition 3.1(iii) is also self-preserved during the dynamics.

## D Analysis of the Spectral Gradient Flow

In this section, we analyze the dynamics and convergence of gradient flow. For the analysis we separate the dynamics into two stages: the warm-up stage and the growth stage. The warm-up stage is further divided into five steps, with each step being studied and summarized afterward. The growth stage consists of the emergence and convergence phases. The dynamics paths are summarized in Appendix D.3, while the observations regarding emergence and convergence in the growth stage are summarized in Appendix D.2.4.

Upon success of Lemma 3.2, we have

$$
\begin{array}{cc}
\partial_{t} \sigma\left(K_{X}^{(h)}\right)=-{\sqrt{d_{e}}}^{-1} \sigma\left(Q_{X}^{(h)}\right) \odot \sigma\left(A_{X X}^{(h)}{ }^{\top}\right), & \partial_{t} \sigma\left(Q_{X}^{(h)}\right)=-{\sqrt{d_{e}}}^{-1} \sigma\left(K_{X}^{(h)}\right) \odot \sigma\left(A_{X X}^{(h)}\right), \\
\partial_{t} \sigma\left(O^{(h)}\right)=-\sigma\left(B_{Y}^{(h)}\right) \odot \sigma\left(V_{Y}^{(h)^{\top}}\right), & \partial_{t} \sigma\left(V_{Y}^{(h)}\right)=-\sigma\left(O^{(h)^{\top}}\right) \odot \sigma\left(B_{Y}^{(h)}\right),
\end{array}
$$

Under the Symmetric Weights (Symmetric Weights) initialization, we always have $\sigma\left(Q_{X}^{(h)}\right)=$ $\sigma\left(K_{X}^{(h)}\right)=\sqrt{\omega^{(h)}}$ and $\sigma\left(O^{(h)}\right)=\sigma\left(V_{Y}^{(h)}\right)=\sqrt{\mu^{(h)}}$. Thus, we can further reduce the dynamics to the combined dynamics of $\mu^{(h)}$ and $\omega^{(h)}$ :

$$
\begin{array}{ll}
\partial_{t} \omega^{(h)}=-{\sqrt{d_{e}}}^{-1}\left(\sigma\left(Q_{X}^{(h)}\right)^{\odot 2}+\sigma\left(K_{X}^{(h)}\right)^{\odot 2}\right) \odot \sigma\left(A_{X X}^{(h)}\right) & \\
\partial_{t} \mu^{(h)}=-\left(\sigma\left(O^{(h)}\right)^{\odot 2}+\sigma\left(V_{Y}^{(h)}\right)^{\odot 2}\right) \odot \sigma\left(B_{Y}^{(h)}\right) & \\
=-2 \mu^{(h)} \odot \beta^{(h)} \odot \alpha^{(h)}
\end{array}
$$

In the following, we rescale the time as $t \leftarrow 2 d t$. Note that $\bar{\omega}^{(h)} \in \mathbb{R}^{d_{y}}$ is just a collection of the unique task-wise values in $\omega^{(h)}$. Recall the simplification of $\alpha^{(h)}$ and $\beta^{(h)}$ in (C.35) and (C.36), which gives

$$
\begin{align*}
& \sqrt{d_{e}} \partial_{t} \bar{\omega}^{(h)}=\left(1 \pm L^{-1}\right) \odot \lambda \odot \mu^{(h)} \odot \bar{\omega}^{(h)}-\sum_{h^{\prime}=1}^{H}\left(1 \pm L^{-1}\right) \odot \lambda \odot \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)} \odot \bar{\omega}^{\left(h^{\prime}\right)} \odot \bar{\omega}^{(h)} \\
& \quad-\sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L}\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \bar{\omega}^{\left(h^{\prime}\right)} \odot \bar{\omega}^{(h)} \odot\left(1 \pm\left(d_{\min }^{-1}+L^{-\frac{1-\epsilon_{0}}{2}}+L^{-(1-2 \epsilon)}\right)\right) \\
& \quad-\frac{\exp \left(\left\langle\omega^{(h)}, \omega^{(h)}\right\rangle\right)}{L}\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle\left(\bar{\omega}^{(h)}\right)^{\odot 2} \odot( \pm 1) \\
& \quad-\sum_{h^{\prime}=1}^{H}\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle\left(\bar{\omega}^{(h)}\right)^{\odot 2} \odot\left( \pm L^{-2(1-\epsilon)}\right) . \tag{D.1}
\end{align*}
$$

Here, we denote by $\boldsymbol{d}$ the vector of task dimensions, i.e., $\boldsymbol{d}=\left(d_{1}, \ldots, d_{I}\right)^{\top}$. Also, we have

$$
\begin{align*}
& \partial_{t} \mu^{(h)}=\left(1 \pm L^{-1}\right) \odot \boldsymbol{d} \odot \lambda \odot \bar{\omega}^{(h)} \odot \mu^{(h)}-\sum_{h^{\prime}=1}^{H}\left(1 \pm L^{-1}\right) \odot \boldsymbol{d} \odot \lambda \odot \bar{\omega}^{(h)} \odot \bar{\omega}^{\left(h^{\prime}\right)} \odot \mu^{\left(h^{\prime}\right)} \odot \mu^{(h)} \\
&-\sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} \boldsymbol{d} \odot \lambda \odot \phi \odot \mu^{\left(h^{\prime}\right)} \odot \mu^{(h)} \odot\left(1 \pm L^{-\frac{1-\epsilon_{0}}{2}}\right) \tag{D.2}
\end{align*}
$$

For simplicity, we let

$$
\xi \triangleq L^{-1}, \quad \zeta \triangleq d_{\min }^{-1}+L^{-\frac{1-\epsilon_{0}}{2}}+L^{-(1-2 \epsilon)}, \quad \eta \triangleq L^{-2(1-\epsilon)}
$$

We consider $\mathcal{I}$ to be the set of tasks with $\lambda_{i}=\Theta(1)$ and $\mathcal{I}_{c}$ to be the set of tasks with $\lambda_{i}=0$, which we call the effective and nominal tasks, respectively. This is a generalization of the setting in Theorem 3.3where all tasks are effective. We will study the more general setting in the dynamics' analysis.

In the following, we will study the behavior of the dynamics in (D.1) and (D.2). We assume $\omega^{(h)}$ to have the same initialization for each coordinate and have $\bar{\omega}_{i}^{(h)}(0)=\omega_{0}$ for each $h \in[H]$ and $i \in \mathcal{I}$. For $\mu^{(h)}$, we don't restrict all eigenvalues to be the same. The following is the assumption for the initialization of $\mu^{(h)}$. We also let

$$
\phi_{i}=1+\frac{\sigma^{2} d}{d_{i} \lambda_{i}}=1+\mathrm{SNR}_{i}^{-1}
$$

where $\operatorname{SNR}_{i}=d_{i} \lambda_{i} /\left(\sigma^{2} d\right)$ is the signal-to-noise ratio for the $i$-th task.
Assumption D. 1 (Initialization). We assume $\omega^{(h)}$ to have the same initialization for each coordinate with $\bar{\omega}_{i}^{(h)}=\omega_{0}$ where $\max \left\{\omega_{0}^{2} d, H L \omega_{0}^{2}\right\} \ll 1$ for all $i \in\left[d_{y}\right]$. For each task $i \in \mathcal{I}$, we assume there exist a unique "optimal head" $h_{i}^{\star}$ such that for any $h \neq h_{i}^{\star}, \mu_{i}^{(h)}(0)<\mu_{i}^{\left(h_{i}^{\star}\right)}(0)$, and a minimal marginal difference $\epsilon \in(0,1)$ such that

$$
\frac{\mu_{i}^{\left(h_{i}^{\star}\right)}(0)-\mu_{i}^{(h)}(0)}{\mu_{i}^{\left(h_{i}^{\star}\right)}(0)} \geq \epsilon=\Theta(1), \quad \forall h \neq h_{i}^{\star}, \quad \forall i \in \mathcal{I} .
$$

We consider $h_{i}^{\star} \neq h_{j}^{\star}$ for $i \neq j$, which means that each task has a unique optimal head and no two tasks share the same optimal head. We assume that the initialization $\mu_{i}^{\star}(0)$ satisfies the following condition,

$$
\langle\boldsymbol{d}, \lambda \odot \phi\rangle \lambda_{i}^{-1} \cdot 50 H L \omega_{0}^{3} \epsilon^{-1} \ll \mu_{i}^{\star}(0) \ll L \omega_{0} /\left(2 H \phi_{i}\right), \quad \forall i \in \mathcal{I} .
$$

For the nominal task, we assume $\mu_{j}^{(h)}(0) \ll \min _{i \in \mathcal{I}}\left(L \phi_{i}^{-1} \wedge d_{i}\right) \sqrt{\left|\mathcal{I}_{c}\right|}{ }^{-1} \cdot \omega_{0}, \mu_{j}^{(h)}(0)^{2} \ll \operatorname{SNR}_{i}$. $\left(1 \wedge L /\left(d_{i} \phi_{i}\right)\right) /\left(H\left|\mathcal{I}_{c}\right| \zeta\right)$ for all $h \in[H]$ and $j \in \mathcal{I}_{c}$. Moreover, we assume that $\omega_{0}$ satisfies

$$
\begin{gathered}
\omega_{0} \ll \max _{i \in \mathcal{I}} \frac{\lambda_{i}}{\phi_{i}\langle\boldsymbol{d}, \lambda \odot \phi\rangle \zeta} . \\
\frac{2 C}{\epsilon} \cdot\left(\xi+80 H L \omega_{0}^{2}+\frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 100 H^{2} \omega_{0}^{2} \phi_{i}\right) \ll \frac{\lambda_{i} \phi_{i}^{-1}}{\max _{k \in \mathcal{I}} \lambda_{k} \phi_{k}^{-1}} .
\end{gathered}
$$

When it is clear from the context, we use $\mu_{i}^{\star} \equiv \mu_{i}^{\left(h_{i}^{\star}\right)}$ and $\bar{\omega}_{i}^{\star} \equiv \bar{\omega}_{i}^{\left(h_{i}^{\star}\right)}$. During our analysis, we keep track of the following quantities,

$$
\rho_{i}^{(h)} \triangleq \frac{\mu_{i}^{(h)}}{L \bar{\omega}_{i}^{\star}}, \quad \rho_{i} \triangleq \sum_{h=1}^{H} \rho_{i}^{(h)} .
$$

We denote by $\rho_{i}^{\star} \equiv \rho_{i}^{\left(h_{i}^{\star}\right)}$. The dynamics of $\rho_{i}^{(h)}$ is given by

$$
\begin{equation*}
\partial_{t} \rho_{i}^{(h)}=\frac{\partial_{t} \mu_{i}^{(h)}-\partial_{t} \bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{\star} \cdot \mu_{i}^{(h)}}{L \bar{\omega}_{i}^{\star}}=\frac{\partial_{t} \log \mu_{i}^{(h)}-\partial_{t} \log \bar{\omega}_{i}^{\star}}{L \bar{\omega}_{i}^{\star}} \cdot \mu_{i}^{(h)} . \tag{D.3}
\end{equation*}
$$

## D. 1 Warm-up Stage

We first give a rigorous definition of the warm-up stage.
Definition D. 2 (Warm-up Stage). Let $c>1$ be a constant. Let $T_{\text {warmup }}$ be the first time that at least one of the following conditions is violated:
(A1) $\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right) / \mu_{i}^{\star} \geq \epsilon / c$ holds for all $h \neq h_{i}^{*}$ and $i \in \mathcal{I}$.
(A2) $\bar{\omega}_{k}^{(h)} \leq 4 \omega_{0}$ holds for all $h \in[H]$ and $k \in\left[d_{y}\right]$.
(A3) $\mu_{i}^{(h)} \leq 5 L \omega_{0}$ holds for all $h \in[H]$ and $i \in \mathcal{I}$. $\mu_{j}^{(h)} \leq \mu_{j}^{(h)}(0)$ holds for all $h \in[H]$ and $j \in \mathcal{I}_{c}$.
(A4) $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)} \geq 1$ holds for all $h \neq h_{i}^{*}$ and $i \in \mathcal{I}$.
(A5) $\bar{\omega}_{i}^{\star} / \mu_{i}^{\star} \leq \omega_{0} / \mu_{i}^{\star}(0)$ and $i \in \mathcal{I}$.
(A6) $\mu_{i}^{\star} / \bar{\omega}_{i}^{\star} \leq 2 L \phi_{i}^{-1}$ and $i \in \mathcal{I}$.
By definition, the warm-up stage corresponds to the stage where $\bar{\omega}_{k}^{(h)}$ is within constant factors of $\omega_{0}$ for all $k \in\left[d_{y}\right]$ and $h \in[H]$. Note that Condition (A2) and Condition (A3) already implies all the conditions in Condition C.14. Thus, we can further simplify the dynamics based on (D.1) and (D.2) in the warm-up stage. To further decouple the dynamics for each task, we invoke the following definition.

Definition D. 3 (Task-interference-free Dynamics for the Warm-up Stage). Fix a effective or nominal task $i \in\left[d_{y}\right]$. We say that a dynamics on $\mu_{i}(t)$ and $\bar{\omega}_{i}(t)$ is a Task-Interference-Free dynamics for task $i$ (TIF-i dynamics for short) in the warm-up stage if:
(i) The dynamics for $\mu_{i}(t)$ and $\bar{\omega}_{i}(t)$ are given by (D.2) and (D.1) respectively.
(ii) The initializations of $\mu_{i}(0)$ and $\bar{\omega}_{i}(0)$ satisfy the conditions in Assumption D.1.
(iii) For any other task $k \in\left[d_{y}\right] \backslash\{i\}, \mu_{k}(t)$ and $\bar{\omega}_{k}(t)$ satisfy Condition (A1)-Condition (A6) for task $k$ at any time.

We define $T_{\text {warmup }}^{i}$ be the smallest time that the TIF-i dynamics violate at least one of the Condition (A1)-Condition (A6) for task $i$.

Equipped with the conditions in Definition D. 2 and the definition of the TIF- $i$ dynamics for the warm-up stage, we can first simplify the dynamics of $\bar{\omega}_{i}^{(h)}$ and $\mu_{i}^{(h)}$. When not specified, we use $i$ to denote an effective task and $j$ to denote a nominal task in the sequel.

Simplification of $\partial_{t} \mu_{i}^{(h)}$ and $\partial_{t} \mu_{j}^{(h)}$. Recall by (D.2), we have for the TIF- $i$ dynamics of $\mu_{i}^{(h)}$ that

$$
\begin{gather*}
\partial_{t} \mu_{i}^{(h)}=(1 \pm \xi) d_{i} \lambda_{i} \bar{\omega}_{i}^{(h)} \mu_{i}^{(h)}-\sum_{h^{\prime}=1}^{H}(1 \pm \xi) d_{i} \lambda_{i} \bar{\omega}_{i}^{(h)} \bar{\omega}_{i}^{\left(h^{\prime}\right)} \mu_{i}^{\left(h^{\prime}\right)} \mu_{i}^{(h)} \\
-\sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} d_{i} \lambda_{i} \phi_{i} \mu_{i}^{\left(h^{\prime}\right)} \mu_{i}^{(h)}(1 \pm \zeta) . \tag{D.4}
\end{gather*}
$$

where the ratio between the second and first terms is bounded by

$$
\frac{\sum_{h^{\prime}=1}^{H}(1 \pm \xi) d_{i} \lambda_{i} \bar{\omega}_{i}^{(h)} \bar{\omega}_{i}^{\left(h^{\prime}\right)} \mu_{i}^{\left(h^{\prime}\right)} \mu_{i}^{(h)}}{(1 \pm \xi) d_{i} \lambda_{i} \bar{\omega}_{i}^{(h)} \mu_{i}^{(h)}} \leq 2 \sum_{h^{\prime}=1}^{H} \bar{\omega}_{i}^{\left(h^{\prime}\right)} \mu_{i}^{\left(h^{\prime}\right)} \leq 40 H \omega_{0}^{2} L
$$

where Condition (A2) and Condition (A3) are used for upper bounding $\bar{\omega}_{i}^{\left(h^{\prime}\right)} \mu_{i}^{\left(h^{\prime}\right)}$ in the last inequality. Also for the third term, we have $\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right) \leq \exp \left(16 d \omega_{0}^{2}\right) \leq 1+16 e d \omega_{0}^{2}$ by Condition (A2) and $\exp (x) \leq 1+e x$ for $x \leq 1$. Based on these observations, we define quantities $\widetilde{\xi}$ and $\widetilde{\zeta}$ as

$$
\widetilde{\xi}=\xi+80 H L \omega_{0}^{2} \ll 1, \quad \widetilde{\zeta}=\zeta+32 e \omega_{0}^{2} d \ll 1
$$

and we can simplify the dynamics of $\mu_{i}^{(h)}$ as

$$
\partial_{t} \mu_{i}^{(h)}=\lambda_{i} d_{i} \mu_{i}^{(h)}\left(-(1 \pm \widetilde{\zeta}) \cdot \sum_{h^{\prime}=1}^{H} \frac{\phi_{i}}{L} \mu_{i}^{\left(h^{\prime}\right)}+(1 \pm \widetilde{\xi}) \cdot \bar{\omega}_{i}^{(h)}\right)
$$

As a result, we also have for $\partial_{t}\left(\log \mu_{i}^{\star}-\log \mu_{i}^{(h)}\right)$ that

$$
\begin{aligned}
\partial_{t}\left(\log \mu_{i}^{\star}-\log \mu_{i}^{(h)}\right)= & \lambda_{i} d_{i}\left((1 \pm \widetilde{\xi}) \bar{\omega}_{i}^{\star}-(1 \pm \widetilde{\zeta}) \phi_{i} \sum_{h^{\prime}=1}^{H} \frac{\mu_{i}^{\left(h^{\prime}\right)}}{L}\right) \\
& -\lambda_{i} d_{i}\left((1 \pm \widetilde{\xi}) \bar{\omega}_{i}^{(h)}-(1 \pm \widetilde{\zeta}) \phi_{i} \sum_{h=1}^{H} \frac{\mu_{i}^{\left(h^{\prime}\right)}}{L}\right) \\
= & \lambda_{i} d_{i}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)} \pm \widetilde{\xi}\left(\bar{\omega}_{i}^{\star}+\bar{\omega}_{i}^{(h)}\right) \pm 2 \widetilde{\zeta} \phi_{i} \sum_{h^{\prime}=1}^{H} \frac{\mu_{i}^{\left(h^{\prime}\right)}}{L}\right)
\end{aligned}
$$

For the nominal task $j \in \mathcal{I}_{c}$, we have for $\partial_{t} \mu_{j}^{(h)}$ that

$$
\begin{equation*}
\partial_{t} \mu_{j}^{(h)}=-(1 \pm \widetilde{\zeta}) \cdot \sum_{h^{\prime}=1}^{H} \frac{\sigma^{2} d}{L} \cdot \mu_{j}^{\left(h^{\prime}\right)} \mu_{j}^{(h)} \tag{D.5}
\end{equation*}
$$

Note that this dynamics holds at any time since we are just using $\lambda_{j}=0$ for nominal tasks.
Simplification of $\partial_{t} \bar{\omega}_{i}^{(h)}$ and $\partial_{t} \bar{\omega}_{j}^{(h)}$. Recall by (D.1), we have for the dynamics of $\bar{\omega}_{i}^{(h)}$ that

$$
\begin{aligned}
\sqrt{d}_{e} \cdot \partial_{t} \bar{\omega}_{i}^{(h)}=- & (1 \pm \zeta) \cdot \sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} \cdot\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \cdot \bar{\omega}_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{(h)} \\
& -(1 \pm \xi) \lambda_{i} \cdot \sum_{h^{\prime}=1}^{H} \mu_{i}^{\left(h^{\prime}\right)} \mu_{i}^{(h)} \bar{\omega}_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{(h)}+(1 \pm \xi) \lambda_{i} \cdot \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)} \\
& ( \pm 1) \cdot \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{(h)}\right\rangle\right)}{L} \cdot\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2} \\
& ( \pm \eta) \cdot \sum_{h^{\prime}=1}^{H}\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2}
\end{aligned}
$$

Here, we can upper bound the inner product $\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle$ and $\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle$ using Condition (A2) and Condition (A3) as

$$
\begin{aligned}
\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle & \leq\langle\boldsymbol{d}, \lambda \odot \phi\rangle 25 L^{2} \omega_{0}^{2}, \\
\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle & \leq\langle\boldsymbol{d}, \lambda\rangle 20 L \omega_{0}^{2} .
\end{aligned}
$$

Thus, following the definition of $\widetilde{\zeta}$ and $\widetilde{\xi}$, we have for the dynamics of $\bar{\omega}_{i}^{(h)}$ that

$$
\begin{align*}
\sqrt{d}_{e} \cdot \partial_{t} \bar{\omega}_{i}^{(h)}=- & \left(1 \pm \widetilde{\zeta} \pm H L \eta \pm L^{-1}\right) \cdot\langle\boldsymbol{d}, \lambda \odot \phi\rangle 25 L \omega_{0}^{2} \sum_{h^{\prime}=1}^{H} \bar{\omega}_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{(h)} \\
& +(1 \pm \widetilde{\xi}) \lambda_{i} \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)} \\
= & \pm \frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot\left(1 \pm \widetilde{\zeta} \pm H L \eta \pm L^{-1}\right) \cdot 25 H L \omega_{0}^{2} \cdot \lambda_{i} \bar{\omega}_{i}^{\star} \bar{\omega}_{i}^{(h)} \\
& +(1 \pm \widetilde{\xi}) \lambda_{i} \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)} \\
= & \pm \frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 50 H L \omega_{0}^{2} \cdot \lambda_{i} \bar{\omega}_{i}^{\star} \bar{\omega}_{i}^{(h)}+(1 \pm \widetilde{\xi}) \lambda_{i} \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)} . \tag{D.6}
\end{align*}
$$

where we use Condition (A4) that $\bar{\omega}_{i}^{\left(h^{\prime}\right)} \leq \bar{\omega}_{i}^{\star}$ in the second equality and incorporate the fact that $1+\widetilde{\zeta}+H L \eta+L^{-1} \leq 2$ in the last inequality. Note that it is unclear which term dominates in (D.6) since the ratio $\mu_{i}^{(h)} / \bar{\omega}_{i}^{\star}$ is unknown. However, for $h=h_{i}^{*}$, we have a clear picture that

$$
\begin{aligned}
\sqrt{d_{e}} \cdot \partial_{t} \bar{\omega}_{i}^{\star} & =\left(1 \pm \widetilde{\xi} \pm \frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 50 H L \omega_{0}^{2} \cdot \frac{\bar{\omega}_{i}^{\star}}{\mu_{i}^{\star}}\right) \cdot \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{\star} \\
& =\left(1 \pm \check{\xi}_{i}(t)\right) \cdot \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{\star},
\end{aligned}
$$

where we define $\check{\xi}_{i}(t)$ as

$$
\check{\xi}_{i}(t)=\widetilde{\xi}+\left.\frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 50 H L \omega_{0}^{2} \cdot \frac{\bar{\omega}_{i}^{\star}}{\mu_{i}^{\star}}\right|_{t} \leq \tilde{\xi}+\frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot \frac{50 H L \omega_{0}^{3}}{\mu_{i}^{\star}(0)} \triangleq \check{\xi}_{i}(0) \ll 1
$$

Here, the upper bound is given by Condition (A5) that $\bar{\omega}_{i}^{\star} / \mu_{i}^{\star} \leq \omega_{0} / \mu_{i}^{\star}(0)$. Similarly, we study the dynamics of $\log \bar{\omega}_{i}^{\star}-\log \bar{\omega}_{i}^{(h)}$ for $h \neq h_{i}^{*}$ as

$$
\begin{align*}
\sqrt{d_{e}} \cdot & \partial_{t}\left(\log \bar{\omega}_{i}^{\star}-\log \bar{\omega}_{i}^{(h)}\right) \\
= & \pm \frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 50 H L \omega_{0}^{2} \cdot \lambda_{i} \bar{\omega}_{i}^{\star}+(1 \pm \widetilde{\xi}) \lambda_{i} \mu_{i}^{\star} \\
& \pm \frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 50 H L \omega_{0}^{2} \cdot \lambda_{i} \bar{\omega}_{i}^{\star}-(1 \pm \widetilde{\xi}) \lambda_{i} \mu_{i}^{(h)}  \tag{D.7}\\
= & \left(1 \pm \frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 100 H L \omega_{0}^{2} \cdot \frac{\bar{\omega}_{i}^{\star}}{\mu_{i}^{\star}} \cdot \frac{\mu_{i}^{\star}}{\mu_{i}^{\star}-\mu_{i}^{(h)}} \pm \widetilde{\xi} \cdot \frac{\mu_{i}^{\star}+\mu_{i}^{(h)}}{\mu_{i}^{\star}-\mu_{i}^{(h)}}\right) \\
& \quad \cdot \lambda_{i} \cdot\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right) \\
= & \left(1 \pm \widehat{\xi}_{i}(t)\right) \cdot \lambda_{i}\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right),
\end{align*}
$$

where we define $\widehat{\xi}_{i}(t)$ as

$$
\widehat{\xi}_{i}(t)=\frac{2 \mu_{i}^{\star}}{\mu_{i}^{\star}-\mu_{i}^{(h)}} \check{\xi}_{i}(t) \leq 2 c \epsilon^{-1} \check{\xi}_{i}(t) \leq 2 c \epsilon^{-1} \breve{\xi}_{i}(0) \triangleq \widehat{\xi}_{i}(0) \ll 1 .
$$

Here, we incorporate Condition (A1) to upper bound $\mu_{i}^{\star} /\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right)$ by $c \epsilon^{-1}$. We are also interested in the dynamics of $\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}$ for $h \neq h_{i}^{*}$, which can be lower bounded as

$$
\begin{aligned}
\sqrt{d_{e}} \cdot \partial_{t}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right)= & \pm \frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 50 H L \omega_{0}^{2} \cdot \lambda_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}+(1 \pm \widetilde{\xi}) \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{\star} \\
& \pm \frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 50 H L \omega_{0}^{2} \cdot \lambda_{i} \bar{\omega}_{i}^{\star} \bar{\omega}_{i}^{(h)}-(1 \pm \widetilde{\xi}) \lambda_{i} \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)} \\
\geq- & \frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 50 H L \omega_{0}^{2} \cdot \lambda_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}+(1-\widetilde{\xi}) \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{\star} \\
& -\frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 50 H L \omega_{0}^{2} \cdot \lambda_{i} \bar{\omega}_{i}^{\star} \bar{\omega}_{i}^{\star}-(1+\widetilde{\xi}) \lambda_{i} \mu_{i}^{(h)} \bar{\omega}_{i}^{\star} \\
= & \left(1-\widehat{\xi}_{i}(t)\right) \lambda_{i} \bar{\omega}_{i}^{\star}\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right),
\end{aligned}
$$

where the inequality holds by invoking Condition (A4) that $\bar{\omega}_{i}^{\star} \geq \bar{\omega}_{i}^{(h)}$ and the last equality is given by a simple comparison to the form of (D.7).

For the nominal task $j \in \mathcal{I}_{c}$, we have for $\partial_{t} \bar{\omega}_{j}^{(h)}$ that

$$
\begin{aligned}
\sqrt{d_{e}} \partial_{t} \bar{\omega}_{j}^{(h)} \leq & ( \pm 1) \cdot \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{(h)}\right\rangle\right)}{L} \cdot\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle \cdot\left(\bar{\omega}_{j}^{(h)}\right)^{2} \\
& \quad+( \pm \eta) \cdot \sum_{h^{\prime}=1}^{H}\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \cdot\left(\bar{\omega}_{j}^{(h)}\right)^{2} \\
\leq & \left(C L^{-1}\langle\boldsymbol{d}, \lambda\rangle 20 L \omega_{0}^{2}+C\langle\boldsymbol{d}, \lambda \odot \phi\rangle 25 L^{2} \omega_{0}^{2} \eta\right) \cdot\left(\bar{\omega}_{j}^{(h)}\right)^{2} \\
\leq & C(20+25 L \zeta) \cdot\langle\boldsymbol{d}, \lambda \odot \phi\rangle \cdot \omega_{0}^{2} \cdot\left(\bar{\omega}_{j}^{(h)}\right)^{2} \\
\leq & \underbrace{26 C L \zeta \cdot\langle\boldsymbol{d}, \lambda \odot \phi\rangle \cdot \omega_{0}^{2} \cdot\left(\bar{\omega}_{j}^{(h)}\right)^{2},}_{\ll 1}
\end{aligned}
$$

where in the last second inequality, we use the fact that $\zeta \geq L \eta \geq L^{-1}$.
Simplification of $\partial_{t} \rho_{i}^{\star}$ and $\partial_{t} \rho_{i}$. Recall from (D.3) that the dynamics of $\rho_{i}^{\star}$ satisfy

$$
\begin{aligned}
\partial_{t} \rho_{i}^{\star} & =\frac{\partial_{t} \log \mu_{i}^{\star}-\partial_{t} \log \bar{\omega}_{i}^{\star}}{L \bar{\omega}_{i}^{\star}} \cdot \mu_{i}^{\star} \\
& =\frac{\lambda_{i} d_{i}\left(-(1 \pm \widetilde{\zeta}) \cdot \sum_{h^{\prime}=1}^{H} \frac{\phi_{i}}{L} \mu_{i}^{\left(h^{\prime}\right)}+(1 \pm \widetilde{\xi}) \cdot \bar{\omega}_{i}^{\star}\right)-\left(1 \pm \check{\xi}_{i}(t)\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star}}{L \bar{\omega}_{i}^{\star}} \cdot \mu_{i}^{\star} \\
& =\frac{\lambda_{i} d_{i} \mu_{i}^{\star}}{L} \cdot\left(-(1 \pm \widetilde{\zeta}) \cdot \phi_{i} \rho_{i}+(1 \pm \widetilde{\xi})-\frac{\left(1 \pm \widetilde{\xi}_{i}(t)\right)}{\sqrt{d_{e}} d_{i}} \cdot \frac{\mu_{i}^{\star}}{\bar{\omega}_{i}^{\star}}\right) .
\end{aligned}
$$

Here, we invoke the ratio argument in Condition (A6) that $\mu_{i}^{\star} / \bar{\omega}_{i}^{\star} \leq 2 L \phi_{i}^{-1}$ and $\check{\xi}_{i}(t) \leq \check{\xi}_{i}(0) \ll 1$ to upper bound the last term by $\varsigma_{i} \triangleq L /\left(\sqrt{d_{e}} d_{i} \phi_{i}\right) \ll 1$. Hence, we have for the dynamics of $\rho_{i}^{\star}$ that

$$
\partial_{t} \rho_{i}^{\star}=L^{-1} \lambda_{i} d_{i} \mu_{i}^{\star} \cdot\left(-(1 \pm \widetilde{\zeta}) \cdot \phi_{i} \rho_{i}+\left(1 \pm \widetilde{\xi} \pm 4 \varsigma_{i}\right)\right) .
$$

Similarly, we have for the dynamics of $\rho_{i}$ that

$$
\begin{aligned}
\partial_{t} \rho_{i} & =\sum_{h=1}^{H} \frac{\lambda_{i} d_{i}\left(-(1 \pm \widetilde{\zeta}) \cdot \sum_{h^{\prime}=1}^{H} \frac{\phi_{i}}{L} \mu_{i}^{\left(h^{\prime}\right)}+(1 \pm \widetilde{\xi}) \cdot \bar{\omega}_{i}^{(h)}\right)-\left(1 \pm \check{\xi}_{i}(t)\right) \cdot \sqrt{d_{e}-1} \lambda_{i} \mu_{i}^{\star}}{L \bar{\omega}_{i}^{\star}} \cdot \mu_{i}^{(h)} \\
& \leq \lambda_{i} d_{i}\left(-(1 \pm \widetilde{\zeta}) \cdot \phi_{i} \bar{\omega}_{i}^{\star} \rho_{i}^{2}+(1 \pm \widetilde{\xi}) \cdot \frac{\sum_{h=1}^{H} \bar{\omega}_{i}^{(h)} \mu_{i}^{(h)}}{L \bar{\omega}_{i}^{\star}}\right) \\
& \leq \lambda_{i} d_{i} \rho_{i} \bar{\omega}_{i}^{\star}\left(-(1 \pm \widetilde{\zeta}) \cdot \phi_{i} \rho_{i}+(1 \pm \widetilde{\xi})\right) .
\end{aligned}
$$

where in the second inequality, we invoke Condition (A4) that $\bar{\omega}_{i}^{(h)} \leq \bar{\omega}_{i}^{\star}$.
As a summary, we have the following dynamics for the warm-up stage:

| Terms | Simplified Dynamics without Cross-task Interference |
| :--- | :--- |
| $\partial_{t} \mu_{i}^{(h)}$ | $\lambda_{i} d_{i} \mu_{i}^{(h)}\left(-(1 \pm \widetilde{\zeta}) \cdot \phi_{i} L^{-1} \sum_{h^{\prime}=1}^{H} \mu_{i}^{\left(h^{\prime}\right)}+(1 \pm \widetilde{\xi}) \cdot \bar{\omega}_{i}^{(h)}\right)$ |
| $\partial_{t} \bar{\omega}_{i}^{\star}$ | $\left(1 \pm \widetilde{\xi}_{i}(t)\right) \cdot \sqrt{d_{e}-1} \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{\star}$ |
| $\partial_{t}\left(\log \mu_{i}^{\star}-\log \mu_{i}^{(h)}\right)$ | $\lambda_{i} d_{i}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)} \pm \widetilde{\xi}\left(\bar{\omega}_{i}^{\star}+\bar{\omega}_{i}^{(h)}\right) \pm 2 \widetilde{\zeta} \phi_{i} \sum_{h^{\prime}=1}^{H} \frac{\mu_{i}^{\left(h^{\prime}\right)}}{L}\right)$ |
| $\partial_{t}\left(\log \bar{\omega}_{i}^{\star}-\log \bar{\omega}_{i}^{(h)}\right)$ | $\left(1 \pm \widehat{\xi}_{i}(t)\right) \cdot \sqrt{d_{e}-1} \lambda_{i}\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right)$ |
| $\partial_{t}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right)$ | $\geq\left(1-\widehat{\xi}_{i}(t)\right) \cdot \sqrt{d_{e}}-1 \lambda_{i} \bar{\omega}_{i}^{\star}\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right)$ |
| $\partial_{t} \rho_{i}^{\star}$ | $L^{-1} \lambda_{i} d_{i} \mu_{i}^{\star} \cdot\left(-(1 \pm \widetilde{\zeta}) \cdot \phi_{i} \rho_{i}+\left(1 \pm \varsigma_{\varsigma_{i}}\right)\right)$ |
| $\partial_{t} \rho_{i}$ | $\leq \lambda_{i} d_{i} \rho_{i} \bar{\omega}_{i}^{\star}\left(-(1 \pm \widetilde{\zeta}) \cdot \phi_{i} \rho_{i}+(1 \pm \widetilde{\xi})\right)$ |
| $\partial_{t} \mu_{j}^{(h)}, j \in \mathcal{I}_{c}$ | $-\mu_{j}^{(h)}(1 \pm \widetilde{\zeta}) \cdot \sum_{h^{\prime}=1}^{H} \frac{\sigma^{2} d d_{y}}{L} \cdot \mu_{j}^{\left(h^{\prime}\right)}$ |
| $\partial_{t} \bar{\omega}_{j}^{(h)}, j \in \mathcal{I}_{c}$ | $\leq 26 C L \zeta{\sqrt{d_{e}}}^{-1} \cdot\langle\boldsymbol{d}, \lambda \odot \phi\rangle \cdot \omega_{0}^{2}$ |

Table 3: Simplified TIF-i Dynamics for the Warm-up Stage before $T_{\text {warmup }}^{i}$

Under the simplified dynamics in Table 3, one could notice that tasks are decoupled in the sense that the above dynamics are "independent" for each task $i \in \mathcal{I}$ while only cross-head interference exists. Based on this observation, we can further split the dynamics for each task into 4 stages.

Definition D. 4 (Split of the Effective TIF- $i$ Dynamics for the Warm-up Stage). Consider a specific task $i \in \mathcal{I}$ with the corresponding TIF-i dynamics. Define $\vartheta \triangleq \frac{\min _{i \in \mathcal{I}} \phi_{i} \lambda_{i}^{-1}}{\max _{j \in \mathcal{I}} \phi_{j} \lambda_{j}^{-1}} \leq 1$ as the ratio between the smallest and largest $\phi_{i} \lambda_{i}^{-1}$ within the effective task set $\mathcal{I}$. Let $\alpha_{i}, \beta_{i}$, and $\gamma_{i}$ be three small
constants for each $i \in \mathcal{I}$ such that satisfy

$$
\begin{gathered}
\max \left\{\frac{\varsigma_{i}}{\vartheta}\left(\log \left(\frac{2 L \omega_{0}}{\phi_{i} \mu_{i}^{\star}(0)}\right) \vee H\right), \widetilde{\xi}+2 \widetilde{\zeta}+4 \varsigma_{i}, \frac{18 e(\tilde{\xi}+\widetilde{\zeta})}{\left(1-c^{-1}\right) \epsilon} \cdot \log \left(\frac{2 C L \omega_{0}}{\phi_{i} \mu_{i}^{\star}(0)}\right)\right\} \ll \alpha_{i} \ll 1, \\
\max \left\{\frac{c H(\widetilde{\zeta}+\widetilde{\xi})}{\epsilon \vartheta}, \frac{c(\widetilde{\zeta}+\widetilde{\xi})^{2} H}{\left(1-c^{-1}\right) \epsilon^{2} \varsigma_{i}}\right\} \ll \beta_{i} \ll 1, \\
H \cdot \exp \left(-\frac{\epsilon \vartheta^{2}}{64 c H \varsigma_{i}}\right) \ll \gamma_{i} \ll \min \left\{\alpha_{i}, \frac{H \lambda_{i} \phi_{i}^{-1}}{\max _{k \in \mathcal{I}} \lambda_{k} \phi_{k}^{-1}}\right\},
\end{gathered}
$$

We say that the TIF-i dynamics with $i \in \mathcal{I}$ fall into one of the following five steps if both (i) Condition (A1)-Condition (A6) for task $i$ and (ii) additional condition(s) for that corresponding step listed in the following are satisfied:

Step 1. $\rho_{i} \phi_{i} \leq 1-\alpha_{i}$.
Step 2. The following conditions hold:
(a) $\rho_{i}^{\star} \phi_{i} \geq\left(1-\alpha_{i}\right) / H$ and the dynamics have been through Step 1.
(b) There exists at least one $h \in[H] \backslash\left\{h_{i}^{*}\right\}$ such that $\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) / \bar{\omega}_{i}^{\star}<(3 \widetilde{\zeta}+2 \widetilde{\xi}) \beta_{i}^{-1}$.

Step 3. The following conditions hold:
(a) $\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) / \bar{\omega}_{i}^{\star} \geq(3 \widetilde{\zeta}+2 \widetilde{\xi}) \beta_{i}^{-1}$ for any $h \in[H] \backslash\left\{h_{i}^{*}\right\}$.
(b) There exists at least one $h \in[H] \backslash\left\{h_{i}^{*}\right\}$ such that $\mu_{i}^{\star} / \mu_{i}^{(h)}<(H-1) / \gamma_{i}$.

Step 4. the following conditions hold:
(a) $\mu_{i}^{\star} / \mu_{i}^{(h)} \geq(H-1) / \gamma_{i}$ for all $h \in[H] \backslash\left\{h_{i}^{*}\right\}$.
(b) $\rho_{i}^{\star} \phi_{i}<1-\alpha_{i}$.

Step 5. $\rho_{i}^{\star} \phi_{i} \geq 1-\alpha_{i}$.
We observe that there is no overlap between these five steps by definition.
Under the simplified dynamics, one can notice that the conditions in Definition D. 2 are related in the sense that some of these conditions are critical while others are just a byproduct of the dynamics. In the following proposition, we present such relations and show how the "critical" conditions imply the others.

Lemma D. 5 (Critical Conditions). For any $t \in(0, \infty)$, we have the following facts for the TIF-i dynamics where $i \in \mathcal{I}$ :
(i) If Condition (A1)-Condition (A6) hold for $\tau \in[0, t$ ), then Condition (A4)-Condition (A6) always hold with some marginal gap in the inequalities at time $t$.;
(ii) If Condition (A2) holds with some marginal gap at $t$ and Condition (A1) also holds at t, then Condition (A2) and Condition (A3) hold with some marginal gap in the inequalities for any $\tau \in(0, t]$;

In particular, by scrutinizing the simplified dynamics in Table 3, we have $\rho_{i} \phi_{i} \leq 1+\widetilde{\xi}+2 \widetilde{\zeta}$ and that both $\bar{\omega}_{i}^{\star}$ and $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$ are increasing for any $h \in[H] \backslash\left\{h_{i}^{*}\right\}$. For the nominal task $j \in \mathcal{I}_{c}$, we have $\mu_{j}^{(h)}$ nonincreasing for any $h \in[H]$, which holds not only for the warm-up stage but also for the entire training process.
Proof. It is obvious that $\bar{\omega}_{i}^{\star}$ is increasing by just the dynamics in Table 3: $\partial_{t} \bar{\omega}_{i}^{\star}=\left(1 \pm \check{\xi}_{i}(t)\right)$. ${\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{\star}>0$. It is also direct that $\mu_{j}^{(h)}$ is nonincreasing for any $h \in[H]$ by the dynamics in Table 3 for the nominal task $j \in \mathcal{I}_{c}$. For Condition (A4), Condition (A5) and Condition (A6), we aim to show that the dynamics for $0<\tau<t$ already implies some marginal gap in these conditions for time $t$.

For Condition (A4), we have for $0<\tau<t$ that

$$
\begin{aligned}
\left.\partial_{t}\left(\log \bar{\omega}_{i}^{\star}-\log \bar{\omega}_{i}^{(h)}\right)\right|_{\tau} & =\left.\left(1 \pm \widehat{\xi}_{i}(\tau)\right) \cdot \lambda_{i}\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right)\right|_{\tau} \\
& >\left(1 \pm \widehat{\xi}_{i}(0)\right) \cdot \lambda_{i} \epsilon c^{-1} \mu_{i}^{\star}(\tau)>0,
\end{aligned}
$$

// by Condition (A1)
we directly conclude that $\bar{\omega}_{i}^{\star}(t)>\bar{\omega}_{i}^{(h)}(t)$ holds for all $h \neq h_{i}^{*}$ by integrating the above inequality from 0 to $t$ and noting that $\bar{\omega}_{i}^{\star}(0)=\bar{\omega}_{i}^{(h)}(0)=\omega_{0}$. This also verifies the claim that $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$ is increasing for any $h \neq h_{i}^{*}$.

For Condition (A5), recall that we have for $\partial_{t} \rho_{i}^{\star}$ that

$$
\begin{align*}
\partial_{t} \rho_{i}^{\star} & =L^{-1} \lambda_{i} d_{i} \mu_{i}^{\star} \cdot\left(-(1 \pm \widetilde{\zeta}) \cdot \phi_{i} \rho_{i}+\left(1 \pm \widetilde{\xi} \pm 4 \varsigma_{i}\right)\right) \\
& \geq L^{-1} \lambda_{i} d_{i} \mu_{i}^{\star} \cdot\left(-(1 \pm \widetilde{\zeta}) \cdot \phi_{i} H \rho_{i}^{\star}+\left(1 \pm \widetilde{\xi} \pm 4 \varsigma_{i}\right)\right)  \tag{A1}\\
& \geq(1+\widetilde{\zeta})^{-1} L^{-1} \lambda_{i} d_{i} \mu_{i}^{\star} \cdot(-\phi_{i} H \rho_{i}^{\star}+(1-\underbrace{\left(\widetilde{\xi}+4 \alpha_{i}+2 \widetilde{\zeta}\right)}_{\ll})) .
\end{align*}
$$

As long as $\rho_{i}^{\star}<\left(1-\alpha_{i}\right) \phi_{i}^{-1} H^{-1}$, we have $\partial_{t} \rho_{i}^{\star} \geq 0$, which can also be translated as whenever $\mu_{i}^{\star} / \bar{\omega}_{i}^{\star}<\left(1-\alpha_{i}\right) \phi_{i}^{-1} H^{-1} L$, we will have the ratio $\mu_{i}^{\star} / \bar{\omega}_{i}^{\star}$ increasing. Note that at initialization, we have $\mu_{i}^{\star}(0) / \bar{\omega}_{i}^{\star}(0)=\mu_{i}^{\star}(0) \omega_{0}^{-1} \leq L /\left(2 H \phi_{i}\right)<\left(1-\alpha_{i}\right) \phi_{i}^{-1} H^{-1} L$ by Assumption D.1. Hence, the ratio $\mu_{i}^{\star} / \bar{\omega}_{i}^{\star}$ will keep increasing until it reaches $\left(1-\alpha_{i}\right) \phi_{i}^{-1} H^{-1} L$, and then remains above this threshold. Hence, we have for any $t \in\left(0, T_{\text {warmup }}^{i}\right]$ that

$$
\begin{aligned}
\frac{\mu_{i}^{\star}(t)}{\bar{\omega}_{i}^{\star}(t)} & \geq \min \left\{\frac{\mu_{i}^{\star}(t)}{\bar{\omega}_{i}^{\star}(t)},\left(1-\alpha_{i}\right) \phi_{i}^{-1} H^{-1} L\right\} \\
& = \begin{cases}\frac{\mu_{i}^{\star}(t)}{\bar{\omega}_{i}^{\star}(t)} & \text { before } \frac{\mu_{i}^{\star}(t)}{\overline{\omega_{i}^{\star}}(t)} \text { reaches }\left(1-\alpha_{i}\right) \phi_{i}^{-1} H^{-1} L, \\
\left(1-\alpha_{i}\right) \phi_{i}^{-1} H^{-1} L & \text { otherwise. }\end{cases}
\end{aligned}
$$

In both case, we have $\frac{\mu_{i}^{\star}(t)}{\overline{\omega_{i}^{\star}}(t)}>\frac{\mu_{i}^{\star}(0)}{\overline{\omega_{i}^{\star}}(0)}$ holding strictly, which verifies Condition (A5).
Next, for Condition (A6), we upper bound the gradient for $\rho_{i}$ as

$$
\begin{aligned}
\partial_{t} \rho_{i} & \leq L^{-1} \lambda_{i} d_{i} \mu_{i}^{\star} \cdot\left(-(1 \pm \widetilde{\zeta}) \cdot \phi_{i} \rho_{i}+(1 \pm \widetilde{\xi})\right) \\
& \leq(1+\widetilde{\zeta}) L^{-1} \lambda_{i} d_{i} \mu_{i}^{\star} \cdot\left(-\phi_{i} \rho_{i}+(1+\widetilde{\xi}+2 \widetilde{\zeta})\right) .
\end{aligned}
$$

Thus, we conclude that if we initialize with $\rho_{i} \phi_{i}<1, \rho_{i} \phi_{i}$ will not exceed $1+\widetilde{\xi}+2 \widetilde{\zeta}$ during the warm-up stage. As a result, we will always have $\mu_{i}^{\star} \leq \rho_{i} L \bar{\omega}_{i}^{\star} \leq(1+\widetilde{\xi}+2 \widetilde{\zeta}) L \bar{\omega}_{i}^{\star} \phi_{i}^{-1}<2 L \bar{\omega}_{i}^{\star} \phi_{i}^{-1}$ for $t \in\left(0, T_{\text {warmup }}^{i}\right]$, which directly justifies that Condition (A6) holds with some marginal gap.

Lastly, for showing that Condition (A1) and Condition (A2) at time $t$ implies Condition (A3) and Condition (A2) for any $\tau \in(0, t]$, we just invoke the previous bound $\mu_{i}^{\star} / \bar{\omega}_{i}^{\star} \leq(1+\widetilde{\xi}+2 \widetilde{\zeta}) L<1.25 L$. Thus, if $\bar{\omega}_{i}^{\star}(t)<4 \omega_{0}$ strictly holds under Condition (A2), we have that

$$
\mu_{i}^{\star}(\tau)<1.25 L \bar{\omega}_{i}^{\star}(\tau) \leq 1.25 L \bar{\omega}_{i}^{\star}(t) \leq 5 L \omega_{0}, \quad \forall \tau \in(0, t] .
$$

Here the second inequality holds by the monotonicity of $\bar{\omega}_{i}^{\star}$. As a result, we conclude that

$$
\mu_{i}^{(h)}(\tau) \leq \mu_{i}^{\star}(\tau)<5 L \omega_{0}, \quad \bar{\omega}_{i}^{(h)}(\tau) \leq \bar{\omega}_{i}^{\star}(\tau)<\bar{\omega}_{i}^{\star}(t)<4 \omega_{0}, \quad \forall \tau \in(0, t], h \in[H],
$$

where for the non-optimal heads, we just invoke Condition (A1) to have $\mu_{i}^{(h)} \leq \mu_{i}^{\star}$ and the increasing in $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$ that $\bar{\omega}_{i}^{\star} /\left.\bar{\omega}_{i}^{(h)}\right|_{\tau} \geq \bar{\omega}_{i}^{\star} /\left.\bar{\omega}_{i}^{(h)}\right|_{0}=1$.

The message of Lemma D. 5 is that we can just focus on verifying Condition (A1) and Condition (A2) at one time stamp $t$ as the critical conditions for the warm-up stage to hold for any $\tau \in(0, t]$. In other words, if all the conditions in Definition D. 2 are satisfied for time $\tau \in(0, t)$, and the critical conditions Condition (A1) and Condition (A2) are still satisfied with some marginal gap at time $t$, then all the conditions in Definition D. 2 are also satisfied at time $t$ with some marginal gap, which implies that for a sufficiently small time interval $\Delta t$, we are still in the warm-up stage during $[t, t+\Delta t)$. Next, we study each of the 5 steps in Definition D. 4 for an effective task $i \in \mathcal{I}$.

## D.1. 1 Step 1: Growth of $\rho_{i}$

In the first step of the warm-up stage, we show that $\rho_{i} \phi_{i}$ increases to $1-\alpha_{i}$.
Dynamics enter Step 1 at the beginning of the Warm-up Stage. We first show that the warm-up stage starts with Step 1, i.e., at initialization, all the conditions in Definition D. 2 for task $i$ are satisfied. We have by Assumption D. 1 that $\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right) / \mu_{i}^{\star} \geq \epsilon>\epsilon / c$ for all $h \neq h_{i}^{*}$, which implies that Condition (A1) holds. Condition (A3), Condition (A6) and Cond of Step 1 also hold by condition $\mu_{i}^{(h)}(0) \leq \mu_{i}^{\star}(0) \leq L \omega_{0} /\left(2 H \phi_{i}\right)$ in Assumption D.1. The remaining conditions are automatically satisfied by the initialization of $\bar{\omega}_{i}^{(h)}=\omega_{0}$.

Upper Bounding the Duration of Step 1. Let $t_{1}^{i}$ denote the time when the dynamics for task $i$ exits Step 1. Using the dynamics for $\mu_{i}^{\star}$ and $\bar{\omega}_{i}^{\star}$ in Table 3, we have for $t \in\left(0, t_{1}^{i}\right)$ that

$$
\begin{align*}
\frac{\partial_{t} \mu_{i}^{\star}}{\partial_{t} \bar{\omega}_{i}^{\star}}= & \frac{\lambda_{i} d_{i} \mu_{i}^{\star} \cdot\left(\bar{\omega}_{i}^{\star}(1 \pm \widetilde{\xi})-(1 \pm \widetilde{\zeta}) \cdot \sum_{h^{\prime}=1}^{H} \phi_{i} \frac{\mu_{i}^{\left(h^{\prime}\right)}}{L}\right)}{{\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{\star} \cdot\left(1 \pm \check{\xi}_{i}(0)\right)} \\
& =\frac{d_{i} \sqrt{d_{e}} \cdot\left((1 \pm \widetilde{\xi})-(1 \pm \widetilde{\zeta}) \cdot \phi_{i} \rho_{i}\right)}{1 \pm \check{\xi}_{i}(0)} \geq \frac{d_{i} \sqrt{d_{e}} \cdot\left(\alpha_{i}-\widetilde{\xi}-\widetilde{\zeta}\right)}{2}, \tag{D.8}
\end{align*}
$$

where in the last inequality we use the fact that $\rho_{i} \phi_{i} \leq 1-\alpha_{i}$ by Cond of Step 1 and the small error condition $\breve{\xi}_{i}(0) \ll 1$. Thus, we have for $t_{1}^{i}$ that

$$
\left(\bar{\omega}_{i}^{\star}\left(t_{1}^{i}\right)-\omega_{0}\right) \cdot \frac{d_{i} \sqrt{d_{e}} \cdot\left(\alpha_{i}-\widetilde{\xi}-\widetilde{\zeta}\right)}{2} \leq \mu_{i}^{\star}\left(t_{1}^{i}\right)-\mu_{i}^{\star}(0) \leq \sum_{h^{\prime}=1}^{H} \mu_{i}^{\left(h^{\prime}\right)}\left(t_{1}^{i}\right) \leq L \phi_{i}^{-1} \bar{\omega}_{i}^{\star},
$$

where the last inequality holds by using Cond of Step 1. Defining $\widetilde{\alpha}_{i}=\alpha_{i}-\widetilde{\xi}-\widetilde{\zeta}$ and rearranging the above inequality, we have

$$
\begin{equation*}
\bar{\omega}_{i}^{\star}\left(t_{1}^{i}\right) \leq \omega_{0} \cdot\left(1-\frac{2 L}{d_{i} \sqrt{d_{e}} \phi_{i}\left(\alpha_{i}-\widetilde{\xi}-\widetilde{\zeta}\right)}\right)^{-1}=\omega_{0} \cdot\left(1-\frac{2 \varsigma_{i}}{\widetilde{\alpha}_{i}}\right)^{-1}=(1+o(1)) \omega_{0} \tag{D.9}
\end{equation*}
$$

For this upper bound to make sense, we require that $\alpha_{i} \gg \tilde{\xi}+\widetilde{\zeta}+2 \varsigma_{i}$. Consequently, we have for $\mu_{i}^{\star}\left(t_{1}^{i}\right)$ that

$$
\begin{equation*}
\mu_{i}^{\star}\left(t_{1}^{i}\right) \leq \sum_{h^{\prime}=1}^{H} \mu_{i}^{\left(h^{\prime}\right)}\left(t_{1}^{i}\right) \leq L \rho_{i}\left(t_{1}^{i}\right) \bar{\omega}_{i}^{\star}\left(t_{1}^{i}\right) \leq L \phi_{i}^{-1} \omega_{0} \cdot\left(1-\frac{2 \varsigma_{i}}{\widetilde{\alpha}_{i}}\right)^{-1} . \tag{D.10}
\end{equation*}
$$

We can then upper bound the duration of Step 1 by studying the dynamics for $\bar{\omega}_{i}^{\star}$ as

$$
\partial_{t} \log \mu_{i}^{\star}=\lambda_{i} d_{i} \bar{\omega}_{i}^{\star} \cdot\left(-(1 \pm \widetilde{\zeta}) \cdot \phi_{i} \rho_{i}+(1 \pm \widetilde{\xi})\right) \geq \lambda_{i} d_{i} \omega_{0} \widetilde{\alpha}_{i},
$$

where in the last inequality, we use the fact that $\partial_{t} \bar{\omega}_{i}^{\star}>0$ to establish the monotonicity of $\bar{\omega}_{i}^{\star}$ and lower bound $\bar{\omega}_{i}^{\star}$ by its initialization value $\omega_{0}$. Moreover, the $\alpha-\widetilde{\xi}-\widetilde{\zeta}$ term comes from the same argument as in (D.8). As a result, we have for $t \in\left(0, t_{1}^{i}\right]$ that $\mu_{i}^{\star}(t) / \mu_{i}^{\star}(0) \geq \exp \left(\lambda_{i} d_{i} \omega_{0} \widetilde{\alpha}_{i} t\right)$. Combining this lower bound with the upper bound in (D.10), we have for $t \in\left(0, t_{1}^{i}\right]$ that

$$
\exp \left(\lambda_{i} d_{i} \omega_{0} \widetilde{\alpha}_{i} t_{1}^{i}\right) \leq \frac{\mu_{i}^{\star}\left(t_{1}^{i}\right)}{\mu_{i}^{\star}(0)} \leq \frac{L \phi_{i}^{-1} \omega_{0}}{\mu_{i}^{\star}(0)} \cdot\left(1-\frac{2 \varsigma_{i}}{\widetilde{\alpha}_{i}}\right)^{-1}
$$

which implies the upper bound for $t_{1}^{i}$ as

$$
\begin{aligned}
t_{1}^{i} & \leq \frac{1}{\lambda_{i} d_{i} \omega_{0} \widetilde{\alpha}_{i}} \cdot \log \left(\frac{L \phi_{i}^{-1} \omega_{0}}{\mu_{i}^{\star}(0)\left(1-2 \varsigma_{i} \widetilde{\alpha}_{i}^{-1}\right)}\right) \\
& \leq \frac{1}{\lambda_{i} d_{i} \omega_{0} \widetilde{\alpha}_{i}} \cdot \log \left(\frac{2 L \omega_{0}}{\phi_{i} \mu_{i}^{\star}(0)}\right) \triangleq t_{1+}^{i}
\end{aligned}
$$

Only Cond of Step 1 is violated at $t_{1}^{i}$. Here, we aim to show that for a sufficiently small time beyond $t_{1}^{i}$, only Cond of Step 1 is violated. To do so, it suffices to show that the remaining conditions in Definition D. 2 are satisfied for $t \in\left(0, t_{1}^{i}\right]$ and also has some marginal at time $t_{1}^{i}$ such that they will not be violated even if we go beyond $t_{1}^{i}$ for a sufficiently small amount of time. In particular, when appealing to Lemma D.5, we only need to show that Condition (A1) and Condition (A2) are satisfied for $t \in\left(0, t_{1}^{i}\right]$ and also have some marginal gap at $t_{1}^{i}$.

Using the upper bound for $\bar{\omega}_{i}^{\star}$ (D.9) and the fact that $\bar{\omega}_{i}^{\star}$ monotonically increases, we have Condition (A2) satisfied with sufficient marginal gap for $t \in\left(0, t_{1}^{i}\right]$. The last thing to verify is Condition (A1). As we do not have the property that this ratio is monotonically increasing, we need to invoke the upper bound on the duration of Step 1 to show that this ratio must not decrease too much. The following proposition rigorously shows this fact.

Lemma D. 6 (Lower Bounding the Separation for Condition (A1)). Let

$$
T_{\mathrm{U}_{-} \text {thres }} \triangleq \frac{\epsilon}{18 e(\widetilde{\xi}+\widetilde{\zeta}) \lambda_{i} d_{i} \omega_{0}} .
$$

For any $t \in\left[0, T_{\mathrm{U}_{-} \text {thres }} \wedge T_{\text {warmup }}^{i}\right]$, we have for the TIF-i dynamics that

$$
\frac{\mu_{i}^{\star}(t)-\mu_{i}^{(h)}(t)}{\mu_{i}^{\star}(t)} \geq \epsilon \cdot\left(1-\frac{t}{T_{\mathrm{U} \_ \text {thres }}}\right) .
$$

In particular, if $t \ll\left(1-c^{-1}\right) T_{\mathrm{U}}$ _thres, we have Condition (A1) strictly satisfied.
Proof. To provide a lower bound for the separation $\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right) / \mu_{i}^{\star}$, we first derive a lower bound for $\partial_{t} \log \mu_{i}^{\star}-\partial_{t} \log \mu_{i}^{(h)}$ at any $\tau \in(0, t)$ as

$$
\begin{aligned}
\left.\partial_{t}\left(\log \frac{\mu_{i}^{\star}}{\mu_{i}^{(h)}}\right)\right|_{\tau} & =\left.\lambda_{i} d_{i}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)} \pm \widetilde{\xi}\left(\bar{\omega}_{i}^{\star}+\bar{\omega}_{i}^{(h)}\right) \pm 2 \widetilde{\zeta} \phi_{i} \sum_{h^{\prime \prime}=1}^{H} \frac{\mu_{i}^{\left(h^{\prime}\right)}}{L}\right)\right|_{\tau} \\
& \geq-\widetilde{\xi} \lambda_{i} d_{i}\left(\bar{\omega}_{i}^{\star}+\bar{\omega}_{i}^{(h)}\right)-\left.2 \widetilde{\zeta} \lambda_{i} d_{i} \phi_{i} \rho_{i} \bar{\omega}_{i}^{\star}\right|_{\tau} \\
& \geq-\left.2(\widetilde{\xi}+\widetilde{\zeta}) \lambda_{i} d_{i} \cdot \bar{\omega}_{i}^{\star}\left(1+\phi_{i} \rho_{i}\right)\right|_{\tau}
\end{aligned}
$$

where the first and the second inequality hold by Condition (A4) that $\bar{\omega}_{i}^{\star} \geq \bar{\omega}_{i}^{(h)}$. Using the upper bound $\phi_{i} \rho_{i} \leq 1+\widetilde{\xi}+2 \widetilde{\zeta}<1.25$ from Lemma D. 5 together with the upper bound $\widetilde{\omega}_{i}^{\star} \leq 4 \omega_{0}$ by Condition (A2), we conclude that

$$
\left.\partial_{t}\left(\log \frac{\mu_{i}^{\star}}{\mu_{i}^{(h)}}\right)\right|_{\tau} \geq-18(\tilde{\xi}+\widetilde{\zeta}) \lambda_{i} d_{i} \omega_{0},
$$

Thus, for all $t \in\left(0, T_{\mathrm{U}_{-} \text {thres }} \wedge T_{\text {warmup }}^{i}\right.$, we integrate the above inequality from 0 to $t$ to obtain

$$
\log \left(\frac{\mu_{i}^{\star}(t)}{\mu_{i}^{(h)}(t)}\right)-\log \left(\frac{\mu_{i}^{\star}(0)}{\mu_{i}^{(h)}(0)}\right) \geq-18(\widetilde{\xi}+\widetilde{\zeta}) \lambda_{i} d_{i} \omega_{0} \cdot t \geq-1,
$$

where the last inequality holds by definition of $T_{\mathrm{U}_{-} \text {thres }}$. Given the initial condition $\mu_{i}^{(h)}(0) / \mu_{i}^{\star}(0) \leq$ $(1-\epsilon)$, we have for $t \in\left(0, T_{\mathrm{U}_{-} \text {thres }} \wedge T_{\text {warmup }}^{i}\right]$ that

$$
\begin{aligned}
\frac{\mu_{i}^{(h)}(t)}{\mu_{i}^{\star}(t)} & \leq \frac{\mu_{i}^{(h)}(0)}{\mu_{i}^{\star}(0)} \cdot \exp \left(18(\widetilde{\xi}+\widetilde{\zeta}) \lambda_{i} d_{i} \omega_{0} \cdot t\right) \\
& \leq(1-\epsilon) \cdot\left(1+18 e(\widetilde{\xi}+\widetilde{\zeta}) \lambda_{i} d_{i} \omega_{0} \cdot t\right) \\
& \leq 1-\epsilon \cdot\left(1-18 e(\widetilde{\xi}+\widetilde{\zeta}) \lambda_{i} d_{i} \omega_{0} \cdot t \epsilon^{-1}\right),
\end{aligned}
$$

which implies the result

$$
\frac{\mu_{i}^{\star}(t)-\mu_{i}^{(h)}(t)}{\mu_{i}^{\star}(t)} \geq \epsilon \cdot\left(1-18 e(\tilde{\xi}+\widetilde{\zeta}) \lambda_{i} d_{i} \omega_{0} \cdot t \epsilon^{-1}\right)=\epsilon \cdot\left(1-\frac{t}{T_{\mathrm{U}_{-} \text {thres }}}\right) .
$$

as we claimed in Lemma D.6.

Note that $t_{1}^{i} \leq T_{\text {warmup }}^{i}$ and the upper bound $t_{1+}^{i}$ satisfies

$$
t_{1+}^{i}=\frac{1}{\lambda_{i} d_{i} \omega_{0} \widetilde{\alpha}_{i}} \cdot \log \left(\frac{2 L \omega_{0}}{\phi_{i} \mu_{i}^{\star}(0)}\right) \ll \frac{\epsilon\left(1-c^{-1}\right)}{18 e(\widetilde{\xi}+\widetilde{\zeta}) \lambda_{i} d_{i} \omega_{0}}=\left(1-c^{-1}\right) T_{\mathrm{U}_{-} \text {thres }} .
$$

given that $\alpha_{i} \gg \frac{18 e(\widetilde{\xi}+\widetilde{\zeta})}{\left(1-c^{-1}\right) \epsilon} \cdot \log \left(\frac{2 C L \omega_{0}}{\phi_{i} \mu_{i}^{( }(0)}\right)$. Hence, we conclude from Lemma D. 6 that for $t \in\left(0, t_{1}^{i}\right]$, Condition (A1) holds with sufficient margin gap. The following table summarizes the dynamics for $\mu_{i}^{\star}$ and $\bar{\omega}_{i}^{\star}$ in Step 1 of the warm-up stage.

| Properties | Typical Values |
| :--- | :--- |
| Duration | $t_{1}^{i} \leq t_{1+}^{i}=\frac{1}{\lambda_{i} d_{i} \omega_{0} \widetilde{\alpha}_{i}} \cdot \log \left(\frac{2 L \omega_{0}}{\phi_{i} \mu_{i}^{\star}(0)}\right)$ |
| $\mu_{i}^{\star} \nearrow$ | $\mu_{i}^{\star}(0) \leq \mu_{i}^{\star}(t) \leq L \phi_{i}^{-1} \omega_{0} \cdot\left(1-\frac{2 \varsigma_{i}}{\tilde{\alpha}_{i}}\right)^{-1}$ |
| $\bar{\omega}_{i}^{\star} \nearrow$ | $\omega_{0} \leq \bar{\omega}_{i}^{\star}(t) \leq \omega_{0} \cdot\left(1-\frac{2 \varsigma_{i}}{\widetilde{\alpha}_{i}}\right)^{-1}$ |
| $\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right) / \mu_{i}^{\star}$ | lower bounded by $\epsilon \cdot\left(1-\frac{4 e(\tilde{\xi}+\widetilde{\zeta})}{\epsilon \tilde{\alpha}_{i}} \cdot \log \left(\frac{2 C L \omega_{0}}{\phi_{i} \mu_{i}^{\star}(0)}\right)\right)$ |

Table 4: Summary of Step 1 of the Warm-up Stage

Analysis of $\rho_{i}^{\star}$ and $\rho_{i}$ after Step 1. Before we dive into the analysis of Step 2, we first understand two key features of the dynamics: (i) $\rho_{i}^{\star} \phi_{i} \geq\left(1-\alpha_{i}\right) / H$; (ii) $\rho_{i} \phi_{i} \leq 1+\widetilde{\xi}+2 \widetilde{\zeta}$. These properties will preserve in the following steps and will be frequently used for our analysis throughout the warm-up stage. Recall that we have for $\partial_{t} \rho_{i}^{\star}$ that

$$
\begin{equation*}
\partial_{t} \rho_{i}^{\star} \geq(1+\widetilde{\zeta})^{-1} L^{-1} \lambda_{i} d_{i} \mu_{i}^{\star} \cdot(-\phi_{i} H \rho_{i}^{\star}+(1-\underbrace{\left(\tilde{\xi}+4 \varsigma_{i}+2 \widetilde{\zeta}\right)}_{\ll \alpha_{i}})), \tag{D.11}
\end{equation*}
$$

as we have shown in the proof of Lemma D.5. At time $t_{1}^{i}$, we already have $\rho_{\hat{i}}^{\star}\left(t_{1}^{i}\right) \phi_{i} \leq\left(1-\alpha_{i}\right) / H$, and we have $\rho_{i}^{\star}$ still growing for a while after $t_{1}^{i}$ by (D.11) since $\widetilde{\xi}+4 \varsigma_{i}+2 \widetilde{\zeta} \ll \alpha_{i}$. That is, as long as $\rho_{i}^{\star} \phi_{i}$ lies between $\left(1-\alpha_{i}\right) / H$ and $\left(1-\widetilde{\xi}-4 \varsigma_{i}-2 \widetilde{\zeta}\right) / H$, we will have $\partial_{t} \rho_{i}^{\star}>0$. Therefore, the first condition $\rho_{i}^{\star} \phi_{i} \geq\left(1-\alpha_{i}\right) / H$ is preserved in the following steps for $t \in\left[t_{1}^{i}, T_{\text {warmup }}^{i}\right]$. A direct conclusion from this property is that

$$
\begin{align*}
\left.\check{\xi}_{i}(t)\right|_{t \geq t_{1}^{i}} & =\widetilde{\xi}+\left.\frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 50 H L \omega_{0}^{2} \cdot \frac{\bar{\omega}_{i}^{\star}}{\mu_{i}^{\star}}\right|_{t \geq t_{1}^{i}} \\
& =\tilde{\xi}+\frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 50 H L \omega_{0}^{2} \phi_{i} \cdot L^{-1}\left(\left.\rho_{i}^{\star}(t)\right|_{t \geq t_{1}^{i}}\right)^{-1} \phi_{i}^{-1} \\
& \leq \tilde{\xi}+\frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 50 H^{2} \omega_{0}^{2} \phi_{i}\left(1-\alpha_{i}\right)^{-1} \\
& \leq \tilde{\xi}+\frac{\langle\boldsymbol{d}, \lambda \odot \phi\rangle}{\lambda_{i}} \cdot 100 H^{2} \omega_{0}^{2} \phi_{i} \triangleq \check{\xi}_{i}^{\prime} . \tag{D.12}
\end{align*}
$$

And also we have new upper bound

$$
\begin{equation*}
\widehat{\xi}_{i}(t) \leq 2 c \breve{\xi}_{i}(t) \epsilon^{-1} \leq 2 c \epsilon^{-1} \check{\xi}_{i}^{\prime} \triangleq \widehat{\xi}_{i}^{\prime} . \tag{D.13}
\end{equation*}
$$

for $t \in\left[t_{1}^{i}, T_{\text {warmup }}^{i}\right]$. Using these $\breve{\xi}_{i}^{\prime}$ and $\hat{\xi}_{i}^{\prime}$, we have the following upper bound for $\bar{\omega}_{i}^{\star}$.

Lemma D.7. For any $\left(t_{0}, t\right) \in\left[t_{1}^{i}, T_{\text {warmup }}^{i}\right]^{2}$ such that $t_{0}<t$, we have the following upper bounds for $\bar{\omega}_{i}^{\star}$ in the TIF-i dynamics as

$$
\bar{\omega}_{i}^{\star}(t) \leq \frac{1}{\bar{\omega}_{i}^{\star}\left(t_{0}\right)^{-1}-\sigma_{3}^{i}\left(t-t_{0}\right)}, \quad \text { where } \quad \sigma_{3}^{i} \triangleq \frac{\left(1+\check{\xi}_{i}^{\prime}+\widetilde{\xi}+2 \widetilde{\zeta}\right) L \lambda_{i}}{\sqrt{d_{e}} \phi_{i}}
$$

Moreover, we have $\rho_{i}^{\star} \phi_{i} \geq\left(1-\alpha_{i}\right) / H$ for any $t \in\left[t_{1}^{i}, T_{\text {warmup }}^{i}\right]$, which implies a lower bound for $\bar{\omega}_{i}^{\star}$ as

$$
\bar{\omega}_{i}^{\star}(t) \geq \frac{1}{\bar{\omega}_{i}^{\star}\left(t_{0}\right)^{-1}-\sigma_{2}^{i}\left(t-t_{0}\right)}, \quad \text { where } \quad \sigma_{2}^{i} \triangleq \frac{\left(1-\alpha_{i}-\check{\xi}_{i}^{\prime}\right) \cdot L \lambda_{i}}{H \phi_{i} \sqrt{d_{e}}}
$$

Proof. we write down the dynamics for $\bar{\omega}_{i}^{\star}$ as

$$
\begin{align*}
\partial_{t} \bar{\omega}_{i}^{\star} & =\left(1 \pm \check{\xi}_{i}^{\prime}\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{\star}  \tag{D.12}\\
& \leq\left(1+\check{\xi}_{i}^{\prime}\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} L \rho_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2} \\
& \leq \underbrace{\frac{\left(1+\check{\xi}_{i}^{\prime}+\widetilde{\xi}+2 \widetilde{\zeta}\right) L \lambda_{i}}{\sqrt{d_{e}} \phi_{i}}}_{\sigma_{3}^{i}} \cdot\left(\bar{\omega}_{i}^{\star}\right)^{2} .
\end{align*}
$$

$$
\leq\left(1+\check{\xi}_{i}^{\prime}\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} L \rho_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2} \quad / / \mu_{i}^{\star} \leq L \rho_{i} \bar{\omega}_{i}^{\star} \text { by definition }
$$

/ / Lemma D. 5

Since $\bar{\omega}_{i}^{\star}$ is monotonically increasing, we have that

$$
\bar{\omega}_{i}^{\star}\left(t_{0}+\Delta t\right) \leq \frac{1}{\bar{\omega}_{i}^{\star}\left(t_{0}\right)^{-1}-\sigma_{3}^{i} \Delta t}
$$

as we claimed. The second condition $\rho_{i}^{\star} \phi_{i} \geq\left(1-\alpha_{i}\right) / H$ is just a direct conclusion of (D.11) and using the fact that $\rho_{i}^{\star} \phi_{i}$ already reaches $\left(1-\alpha_{i}\right) / H$ at $t_{1}^{i}$. For the lower bound, using the gradient of $\bar{\omega}_{i}^{\star}$, we have

$$
\begin{align*}
\partial_{t} \bar{\omega}_{i}^{\star} & =\left(1 \pm \check{\xi}_{i}^{\prime}\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{\star}  \tag{D.12}\\
& =\left(1 \pm \check{\xi}_{i}^{\prime}\right) \cdot L{\sqrt{d_{e}}}^{-1} \lambda_{i} \rho_{i}^{\star}\left(\bar{\omega}_{i}^{\star}\right)^{2} \\
& \geq \underbrace{\frac{\left(1-\alpha_{i}-\check{\xi}_{i}^{\prime}\right) \cdot L \lambda_{i}}{H \phi_{i} \sqrt{d_{e}}}}_{\triangleq \sigma_{2}^{i}} \cdot\left(\bar{\omega}_{i}^{\star}\right)^{2}
\end{align*}
$$

// lower bound for $\rho_{i}^{\star}$
which implies that

$$
\bar{\omega}_{i}^{\star}\left(t_{0}+\Delta t\right) \geq \frac{1}{\bar{\omega}_{i}^{\star}\left(t_{0}\right)^{-1}-\sigma_{2}^{i} \Delta t}
$$

We complete the proof.

## D.1.2 Step 2: Growth of $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$

In Step 2 of the warm-up stage, we aim to show the Growth of marginal difference $\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) / \bar{\omega}_{i}^{\star}$ for all $h \neq h_{i}^{*}$.

Dynamics Either Enter or Skip Step 2 at $t_{1}^{i}$. Using the inequality

$$
\rho_{i}^{\star}\left(t_{1}^{i}\right) \phi_{i} \leq H^{-1} \cdot \rho_{i}\left(t_{1}^{i}\right) \phi_{i} \leq\left(1-\alpha_{i}\right) / H
$$

where the first inequality holds since Condition (A1) holds at $t=t_{1}^{i}$ and the second inequality holds by Cond of Step 1, we have (a) satisfied. If there exists at least one $h \in[H] \backslash\left\{h_{i}^{*}\right\}$ such that $\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) /\left.\bar{\omega}_{i}^{\star}\right|_{t_{1}^{i}}<(3 \widetilde{\zeta}+2 \widetilde{\xi}) \beta_{i}^{-1}$, the dynamics will enter Step 2 at $t_{1}^{i}$. Otherwise, the dynamics skip Step 2 and we have $t_{2}^{i}=t_{1}^{i}$. Next, we consider the case where the dynamics enter Step 2 at $t_{1}^{i}$.

Upper Bounding the Duration of Step 2. We study the following quantity for $h \neq h_{i}^{*}$ :

$$
\begin{align*}
\frac{\partial_{t}\left(\log \bar{\omega}_{i}^{\star}-\log \bar{\omega}_{i}^{(h)}\right)}{\partial_{t} \log \bar{\omega}_{i}^{\star}} & =\frac{\left(1 \pm \widehat{\xi}_{i}(t)\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i}\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right)}{\left(1 \pm \check{\xi}_{i}(t)\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star}} \\
& =\frac{\left(1 \pm \widehat{\xi}_{i}(t)\right) \cdot\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right)}{\left(1 \pm \check{\xi}_{i}(t)\right) \cdot \mu_{i}^{\star}} \geq\left(1-\widehat{\xi}_{i}^{\prime}-\check{\xi}_{i}^{\prime}\right) c^{-1} \epsilon \tag{D.14}
\end{align*}
$$

where the last inequality holds by Condition (A1) and (D.12) for both $\hat{\xi}_{i}(t)$ and $\breve{\xi}_{i}(t)$. Note that for any $t \in\left[t_{1}^{i}, t_{2}^{i}\right]$, there always exists a $h \in[H] \backslash\left\{h_{i}^{*}\right\}$ such that $\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) /\left.\bar{\omega}_{i}^{\star}\right|_{t}<(3 \widetilde{\zeta}+2 \widetilde{\xi}) \beta_{i}^{-1}$ by (b), which implies that $\bar{\omega}_{i}^{\star} /\left.\bar{\omega}_{i}^{(h)}\right|_{t} \leq\left(1-(3 \widetilde{\zeta}+2 \widetilde{\xi}) \beta_{i}^{-1}\right)^{-1}$. Consequently, we have by the gradient ratio argument in (D.14) that for this pair of $(t, h)$,

$$
\begin{align*}
\log \left(\frac{\bar{\omega}_{i}^{\star}(t)}{\bar{\omega}_{i}^{\star}\left(t_{1}^{i}\right)}\right) & \leq \frac{\log \left(\frac{\bar{\omega}_{i}^{\star}(t)}{\bar{\omega}_{i}^{(h)}(t)}\right)-\log \left(\frac{\bar{\omega}_{i}^{\star}\left(t_{1}^{i}\right)}{\bar{\omega}_{i}^{(h)}\left(t_{1}^{i}\right)}\right)}{\left(1-\widehat{\xi}_{i}^{\prime}-\widetilde{\xi}_{i}^{\prime}\right) c^{-1} \epsilon} \leq \frac{-\log \left(1-(3 \widetilde{\zeta}+2 \widetilde{\xi}) \beta_{i}^{-1}\right)}{\left(1-\widehat{\xi}_{i}^{\prime}-\widetilde{\xi}_{i}^{\prime}\right) c^{-1} \epsilon} \\
& \leq-\log \left(1-\frac{(3 \widetilde{\zeta}+2 \widetilde{\xi}) \beta_{i}^{-1}}{\left(1-\widehat{\xi}_{i}^{\prime}-\widetilde{\xi}_{i}^{\prime}\right) c^{-1} \epsilon}\right) \leq-\log \left(1-\frac{2 c(3 \widetilde{\zeta}+2 \widetilde{\xi})}{\beta_{i} \epsilon}\right) \tag{D.15}
\end{align*}
$$

where the second inequality comes from the fact that $\bar{\omega}_{i}^{\star} \geq \bar{\omega}_{i}^{(h)}$ for all $h \neq h_{i}^{*}$ by Condition (A4), with which we drop the second term in the numerator. Here, the third inequality holds by noting that $k \log (1-x) \geq \log (1-k x)$ for $k>1$ and $0<k x<1$. We can also lower bound the gradient of $\bar{\omega}_{i}^{\star}$ as

$$
\begin{aligned}
\partial_{t} \log \bar{\omega}_{i}^{\star} & =\left(1 \pm \check{\xi}_{i}(t)\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star} \\
& \geq\left(1-\check{\xi}_{i}^{\prime}\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} L \rho_{i}^{\star} \bar{\omega}_{i}^{\star} \\
& \geq\left(1-\check{\xi}_{i}^{\prime}-\alpha_{i}\right) \cdot H^{-1} L{\sqrt{d_{e}}}^{-1} \lambda_{i} \phi_{i}^{-1} \omega_{0}
\end{aligned}
$$

where in the last inequality we use the fact that $\rho_{i}^{\star} \phi_{i} \geq\left(1-\alpha_{i}\right) / H$ by Lemma $D .7$ and that $\bar{\omega}_{i}^{\star} \geq \omega_{0}$ by the monotonicity of $\bar{\omega}_{i}^{\star}$ according to Lemma D.5. It follows that

$$
\begin{equation*}
\log \left(\frac{\bar{\omega}_{i}^{\star}(t)}{\bar{\omega}_{i}^{\star}\left(t_{1}^{i}\right)}\right) \geq\left(1-\check{\xi}_{i}^{\prime}-\alpha_{i}\right) \cdot H^{-1} L{\sqrt{d_{e}}}^{-1} \lambda_{i} \phi_{i}^{-1} \omega_{0} \cdot\left(t-t_{1}^{i}\right) \tag{D.16}
\end{equation*}
$$

Combining the lower (D.16) and upper (D.15) bounds with $t=t_{2}^{i}$, we have

$$
t_{2}^{i}-t_{1}^{i} \leq \frac{-\log \left(1-\frac{2 c(3 \tilde{\zeta}+2 \tilde{\xi})}{\beta_{i} \epsilon}\right) H \sqrt{d_{e}} \phi_{i}}{\left(1-\check{\xi}_{i}^{\prime}-\alpha_{i}\right) \cdot L \lambda_{i} \omega_{0}} \leq \frac{4 c(3 \widetilde{\zeta}+2 \widetilde{\xi}) \cdot H \sqrt{d_{e}} \phi_{i}}{\beta_{i} \epsilon L \lambda_{i} \omega_{0}} \triangleq \Delta t_{2+}^{i}
$$

where in the last inequality we use the scale $\beta_{i} \gg c \epsilon^{-1} \log \left(2 c(3 \widetilde{\zeta}+2 \widetilde{\xi})^{-1}\right)$ and the fact that $\breve{\xi}_{i}^{\prime}+\alpha_{i} \ll$ 1.

Only (b) is violated at $t_{2}^{i}$. Here, we use the same argument as in the analysis of Step 1 to show that only (b) is violated at $t_{2}^{i}$. Note that (a) is already justified by (D.11). To show that the critical condition Condition (A2) holds for $t \in\left(t_{1}^{i}, t_{2}^{i}\right]$ with some marginal gap, we first note that $\bar{\omega}_{i}^{\star}$ is monotonically increasing. We next calculate the upper bound for $\bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right)$. Invoking (D.15), we have

$$
\begin{aligned}
\bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right) & \leq \bar{\omega}_{i}^{\star}\left(t_{1}^{i}\right) \cdot \exp \left(-\log \left(1-\frac{2 c(3 \widetilde{\zeta}+2 \widetilde{\xi})}{\beta_{i} \epsilon}\right)\right) \\
& \leq \omega_{0} \cdot\left(1-\frac{2 \varsigma_{i}}{\widetilde{\alpha}_{i}}\right)^{-1} \cdot\left(1-\frac{2 c(3 \widetilde{\zeta}+2 \widetilde{\xi})}{\beta_{i} \epsilon}\right)^{-1}=(1+o(1)) \omega_{0}
\end{aligned}
$$

where the second inequality holds by the upper bound for $\bar{\omega}_{i}^{\star}\left(t_{1}^{i}\right)$ in (D.9) from step 1 and the fact that $2 c(3 \widetilde{\zeta}+2 \widetilde{\xi}) \epsilon^{-1} \ll \beta_{i}$. Hence, Condition (A2) holds for $t \in\left(t_{1}^{i}, t_{2}^{i}\right]$ with sufficient margin gap.

The next thing is to show that the other one Condition (A1) holds with some marginal gap. In order to invoke Lemma D. 6 again, we check the condition that

$$
\Delta t_{2}^{i} \leq \frac{4 c(3 \widetilde{\zeta}+2 \widetilde{\xi}) \cdot H \sqrt{d_{e}} \phi_{i}}{\beta_{i} \epsilon L \lambda_{i} \omega_{0}} \ll \frac{\epsilon\left(1-c^{-1}\right)}{18 e(\widetilde{\xi}+\widetilde{\zeta}) \lambda_{i} d_{i} \omega_{0}}=\left(1-c^{-1}\right) T_{\mathrm{U}_{-} \text {thres }}
$$

which holds by noting that $\beta_{i} \gg \frac{c(\tilde{\zeta}+\tilde{\xi})^{2} H}{\left(1-c^{-1}\right) \epsilon^{2} \varsigma_{i}}$ in Definition D.4. Together with the previous verified condition $t_{1}^{i} \ll\left(1-c^{-1}\right) T_{U_{-} t h r e s}$, we conclude that Condition (A1) holds with sufficient margin gap for $t=t_{2}^{i}$. To summarize, we have the following table for the dynamics in Step 2.

| Properties | Typical Values |
| :--- | :--- |
| Duration | $\Delta t_{2}^{i} \leq \Delta t_{2}^{i}=\frac{4 c(3 \tilde{\zeta}+2 \tilde{\xi}) \cdot H \sqrt{d_{e}} \phi_{i}}{\beta_{i} \epsilon \epsilon \lambda_{i} \omega_{0}}$ |
| $\mu_{i}^{\star} \nearrow$ | $\mu_{i}^{\star}\left(t_{2}^{i}\right) \leq L \phi_{i}^{-1}(1+\tilde{\xi}+2 \tilde{\zeta}) \bar{\omega}$ |
| $\bar{\omega}_{i}^{\star} \nearrow$ | $\nearrow$ |
| $\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right) / \mu_{i}^{\star}$ | $\bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right) \leq \omega_{0} \cdot\left(1-\frac{2 \varsigma_{i}}{\bar{\alpha}_{i}}\right)^{-1} \cdot\left(1-\frac{2 c(3 \tilde{\zeta}+2 \tilde{\xi})}{\beta_{i} \epsilon}\right)^{-1}$ |

Table 5: Summary of Step 2 of the Warm-up Stage

Growth of $\mu_{i}^{\star} / \mu_{i}^{(h)}$ is guaranteed after Step 2. As long as the dynamics exist Step 2, we will have for any $h \in[H] \backslash\left\{h_{i}^{*}\right\}$ that $\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) / \bar{\omega}_{i}^{(h)} \geq(3 \widetilde{\zeta}+2 \widetilde{\xi}) \beta_{i}^{-1}$. Integrating with the fact that $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$ is monotonically increasing by Lemma D.5, the very same condition will always hold thereafter. We have the following fact for the growth of $\mu_{i}^{\star} / \mu_{i}^{(h)}$.

Lemma D.8. Suppose that $\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) / \bar{\omega}_{i}^{(h)} \geq(3 \widetilde{\zeta}+2 \widetilde{\xi}) \beta_{i}^{-1}$ holds for any $h \in[H] \backslash\left\{h_{i}^{*}\right\}$ at some $\tau$. Then, we have for $t \in\left[\tau, T_{\text {warmup }}^{i}\right]$ that $\mu_{i}^{\star}(\tau) / \mu_{i}^{(h)}(\tau)$ is monotonically increasing for any $h \in$ $[H] \backslash\left\{h_{i}^{*}\right\}$.

Proof. We thus have for the gradient of $\log \mu_{i}^{\star}-\log \mu_{i}^{(h)}$ that

$$
\begin{align*}
& \partial_{t}\left(\log \mu_{i}^{\star}-\log \mu_{i}^{(h)}\right) \\
& \quad=\lambda_{i} d_{i}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)} \pm \widetilde{\xi}\left(\bar{\omega}_{i}^{\star}+\bar{\omega}_{i}^{(h)}\right) \pm 2 \widetilde{\zeta} \phi_{i} \sum_{h^{\prime}=1}^{H} \frac{\mu_{i}^{\left(h^{\prime}\right)}}{L}\right) \\
& \quad=\lambda_{i} d_{i}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right)\left(1 \pm \widetilde{\xi} \cdot \frac{\bar{\omega}_{i}^{\star}+\bar{\omega}_{i}^{(h)}}{\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}} \pm 2 \widetilde{\zeta} \phi_{i} \rho_{i} \cdot \frac{\bar{\omega}_{i}^{\star}}{\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}}\right) \\
& \quad=\left(1 \pm \beta_{i}\right) \lambda_{i} d_{i}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right), \tag{D.17}
\end{align*}
$$

where the last equality holds by using the fact that $\frac{\bar{\omega}_{i}^{\star}+\bar{\omega}_{i}^{(h)}}{\overline{\omega_{i}^{\star}}-\bar{\omega}_{i}^{(h)}} \leq 2 \frac{\bar{\omega}_{i}^{\star}}{\overline{\omega_{i}^{\star}}-\bar{\omega}_{i}^{(h)}} \leq 2 \beta_{i} /(3 \widetilde{\zeta}+2 \widetilde{\xi})$ and that $\phi_{i} \rho_{i} \leq(1+\widetilde{\xi}+2 \widetilde{\zeta}) \leq 1.5$ by Lemma D.5. It is then obvious from (D.17) that $\log \mu_{i}^{\star}-\log \mu_{i}^{(h)}$ is monotonically increasing for $t \in\left[\tau, T_{\text {warmup }}^{i}\right]$ given that $\beta_{i} \ll 1$ and $\bar{\omega}_{i}^{\star} \geq \bar{\omega}_{i}^{(h)}$ for all $h \neq h_{i}^{*}$ under Condition (A4).

## D.1.3 Step 3: Growth of $\mu_{i}^{\star} / \mu_{i}^{(h)}$

In this step, we aim to show the Growth of marginal difference $\mu_{i}^{\star} / \mu_{i}^{(h)}$ to $(H-1) / \gamma_{i}$ for all $h \neq h_{i}^{*}$.
Dynamics Either Enter or Skip Step 3 at $t_{2}^{i}$. After Step 2, we have and (a) satisfied. If there exists at least one $h \in[H] \backslash\left\{h_{i}^{*}\right\}$ such that $\mu_{i}^{\star} /\left.\mu_{i}^{(h)}\right|_{t_{2}^{i}}<(H-1) \gamma_{i}^{-1}$, the dynamics will enter Step 3 at $t_{2}^{i}$. Otherwise the dynamics skip Step 3 and we have $t_{3}^{i}=t_{2}^{i}$. Next, we consider the case where the dynamics enter Step 3 at $t_{2}^{i}$.

Upper Bounding the Duration of Step 3. Suppose the dynamics enter Step 3 at $t_{2}^{i}$. In the previous steps, we establish the upper bounds by controlling the maximal value of $\bar{\omega}_{i}^{\star}$. In this step, we will establish the upper bound in a more direct way-by lower bounding the growth of $\mu_{i}^{\star} / \mu_{i}^{(h)}$.

We first derive a tighter lower bound for $\bar{\omega}_{i}^{\star}$ by incorporating Lemma D. 7 with $t_{0}$ replaced by $t_{2}^{i}$.

$$
\bar{\omega}_{i}^{\star}\left(t_{2}^{i}+\Delta t\right) \geq \frac{1}{\bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right)^{-1}-\sigma_{2}^{i} \Delta t}, \quad \text { where } \quad \sigma_{2}^{i} \triangleq \frac{\left(1-\alpha_{i}-\check{\xi}_{i}^{\prime}\right) \cdot L \lambda_{i}}{H \phi_{i} \sqrt{d_{e}}}
$$

On the other hand, we have for the gradient of $\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}$ that

$$
\begin{align*}
\partial_{t}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) & \geq\left(1-\hat{\xi}_{i}^{\prime}\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} \bar{\omega}_{i}^{\star}\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right)  \tag{D.13}\\
& \geq\left(1-\hat{\xi}_{i}^{\prime}\right) \cdot \sqrt{d_{e}}-\lambda_{i} \bar{\omega}_{i}^{\star} \cdot \frac{\epsilon}{c} \cdot \mu_{i}^{\star} \\
& \geq \underbrace{\frac{\left(1-\hat{\xi}_{i}^{\prime}-\alpha_{i}\right) \cdot L \lambda_{i}}{H \phi_{i} \sqrt{d_{e}}} \cdot \frac{\epsilon}{c}}_{\triangleq \sigma_{1}^{i}} \cdot\left(\bar{\omega}_{i}^{\star}\right)^{2} .
\end{align*}
$$

// Condition (A1)
// Lemma D. 7

We plug in the lower bound for $\bar{\omega}_{i}^{\star}$ and conclude that $\partial_{t}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) \geq \sigma_{1}^{i} \cdot\left(\bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right)^{-1}-\sigma_{2}^{i} \Delta t\right)^{-2}$. Integrating the above inequality, we have

$$
\left.\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right)\right|_{t_{2}^{i}+\Delta t} \geq \frac{\sigma_{1}^{i} \cdot \bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right) \cdot \Delta t}{\bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right)^{-1}-\sigma_{2}^{i} \Delta t}+\left.\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right)\right|_{t_{2}^{i}} \geq \frac{\sigma_{1}^{i} \cdot \bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right) \cdot \Delta t}{\bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right)^{-1}-\sigma_{2}^{i} \Delta t} .
$$

where the last inequality holds by Condition (A4) that $\bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right) \geq \bar{\omega}_{i}^{(h)}\left(t_{2}^{i}\right)$. Moreover, we have for the gradient of $\log \mu_{i}^{\star}-\log \mu_{i}^{(h)}$ following (D.17) that

$$
\partial_{t}\left(\log \mu_{i}^{\star}-\log \mu_{i}^{(h)}\right)=\left(1 \pm \beta_{i}\right) \lambda_{i} d_{i}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right),
$$

Now, we plug in the lower bound for $\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}$ and obtain

$$
\left.\partial_{t}\left(\log \mu_{i}^{\star}-\log \mu_{i}^{(h)}\right)\right|_{t_{2}^{i}+\Delta t} \geq\left(1-\beta_{i}\right) \lambda_{i} d_{i} \cdot \frac{\sigma_{1}^{i} \cdot \bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right) \cdot \Delta t}{\bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right)^{-1}-\sigma_{2}^{i} \Delta t}
$$

Integrating both sides with respect to $\Delta t$, we have

$$
\begin{align*}
\left.\frac{\mu_{i}^{\star}}{\mu_{i}^{(h)}}\right|_{t_{2}^{i}+\Delta t} \geq & \left.\frac{\mu_{i}^{\star}}{\mu_{i}^{(h)}}\right|_{t_{2}^{i}} \cdot \exp \left\{\left(1-\beta_{i}\right) \lambda_{i} d_{i} \bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right)\right. \\
& \left.\cdot\left(-\frac{\sigma_{1}^{i} \Delta t}{\sigma_{2}^{i}}-\frac{\sigma_{1}^{i}}{\left(\sigma_{2}^{i}\right)^{2} \bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right)} \log \left(1-\sigma_{2}^{i} \bar{\omega}_{i}^{\star *}\left(t_{2}^{i}\right) \Delta t\right)\right)\right\} \\
\geq & \left.\frac{\mu_{i}^{\star}}{\mu_{i}^{(h)}}\right|_{t_{2}^{i}} \cdot \exp \left(\left(1-\beta_{i}\right) \lambda_{i} d_{i} \sigma_{1}^{i} \cdot\left(\bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right) \Delta t\right)^{2} / 2\right)  \tag{D.18}\\
\geq & \exp \left(\left(1-\beta_{i}\right) \lambda_{i} d_{i} \sigma_{1}^{i} \cdot\left(\bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right) \Delta t\right)^{2} / 2\right)
\end{align*}
$$

where in the second inequality, we use the fact that $\log (1-x) \geq-x-x^{2} / 2$ for $x \in[0,1 / 2]$ by Taylor expansion and in the last inequality we use the fact that $\mu_{i}^{\star} / \mu_{i}^{(h)} \geq 1$ by Condition (A1). For any $t \in\left[t_{2}^{i}, t_{3}^{i}\right]$, there always exists a $h \in[H] \backslash\left\{h_{i}^{*}\right\}$ such that $\mu_{i}^{\star} /\left.\mu_{i}^{(h)}\right|_{t}<(H-1) \gamma_{i}^{-1}$ by (b). Let $\Delta t=t-t_{2}^{i}$. For this pair of $(\Delta t, h)$, we incorporate the lower and upper bounds and obtain

$$
(H-1) \gamma_{i}^{-1} \geq \exp \left((1-\beta) \lambda_{i} d_{i} \sigma_{1}^{i} \cdot\left(\bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right) \Delta t\right)^{2} / 2\right)
$$

We can solve for the maximal $\Delta t$ and obtain

$$
\Delta t \leq \sqrt{\frac{2 \log \left((H-1) \gamma_{i}^{-1}\right)}{\left(1-\beta_{i}\right) \lambda_{i} d_{i} \sigma_{1}^{i} \bar{\omega}_{i}^{\star}\left(t_{2}^{i}\right)^{2}}} \leq \sqrt{\frac{4 c \log \left((H-1) \gamma_{i}^{-1}\right) \cdot H \phi_{i} \sqrt{d_{e}}}{L \lambda_{i}^{2} d_{i} \omega_{0}^{2} \cdot \epsilon}} \triangleq \Delta t_{3+}^{i},
$$

where the inequality holds by the monotonicity of $\bar{\omega}_{i}^{\star}$.

Only (b) is violated at $t_{3}^{i}$. Note that we no longer need to check Condition (A1) as we have explicitly characterize the growth of $\mu_{i}^{\star} / \mu_{i}^{(h)}$ in (D.18). The growth of $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$ is already established by Lemma D.5, which implies that (a) is satisfied with some marginal gap. Therefore, we only need to verify that Condition (A2) holds for $t=t_{3}^{i}$ with some marginal gap according to Lemma D.5.

To control the upper bound for $\bar{\omega}_{i}^{\star}\left(t_{3}^{i}\right)$, we invoke Lemma D. 7 that for any $t_{1}^{i} \leq t_{0}<t \leq T_{\text {warmup }}^{i}$, it holds that

$$
\bar{\omega}_{i}^{\star}\left(t_{0}+\Delta t\right) \leq \frac{1}{\bar{\omega}_{i}^{\star}\left(t_{0}\right)^{-1}-\sigma_{3}^{i} \Delta t}, \quad \text { where } \quad \sigma_{3}^{i} \triangleq \frac{\left(1+\check{\xi}_{i}^{\prime}+\widetilde{\xi}+2 \widetilde{\zeta}\right) L \lambda_{i}}{\sqrt{d_{e}} \phi_{i}}
$$

Here, we just take $t_{0}=t_{2}^{i}$ and $\Delta t=t_{3}^{i}-t_{2}^{i} \leq \Delta t_{3+}^{i}$ and obtain

$$
\begin{aligned}
\bar{\omega}_{i}^{\star}\left(t_{3}^{i}\right) & \leq \frac{1}{\omega_{0}^{-1} \cdot\left(1-\frac{2 \varsigma_{i}}{\widetilde{\alpha}_{i}}\right) \cdot\left(1-\frac{2 c(3 \tilde{\zeta}+2 \tilde{\xi})}{\beta_{i} \epsilon}\right)-\frac{\left(1+\tilde{\xi}_{i}+\tilde{\xi}+2 \tilde{\zeta}\right) L \lambda_{i}}{\sqrt{d_{e} \phi_{i}}} \sqrt{\frac{4 c \log \left((H-1) \gamma_{i}^{-1}\right) \cdot H \phi_{i} \sqrt{d_{e}}}{L \lambda_{i}^{2} d_{i} \omega_{0}^{2} \cdot \epsilon}}} \\
& \leq \frac{1}{\omega_{0}^{-1} \cdot\left(\left(1-\frac{2 \varsigma_{i}}{{\underset{\alpha}{i}}^{2}}\right) \cdot\left(1-\frac{2 c(3 \tilde{\zeta}+2 \tilde{\xi})}{\beta_{i} \epsilon}\right)-\sqrt{\frac{16 c \log \left((H-1) \gamma_{i}^{-1}\right) \cdot H \varsigma_{i}}{\epsilon}}\right)} \\
& \leq \frac{1}{\omega_{0}^{-1} \cdot\left(1-\frac{2 \varsigma_{i}}{\tilde{\alpha}_{i}}\right) \cdot\left(1-\frac{2 c(3 \tilde{\zeta}+2 \tilde{\xi})}{\beta_{i} \epsilon}\right) \cdot\left(1-\sqrt{\frac{32 c \log \left((H-1) \gamma_{i}^{-1}\right) \cdot H \varsigma_{i}}{\epsilon}}\right)}=(1+o(1)) \omega_{0},
\end{aligned}
$$

where the last inequality holds by the condition that $\gamma_{i} \gg(H-1)^{-1} \exp \left(-\frac{\epsilon}{32 c H_{\varsigma_{i}}}\right)$ in Definition D.4. Hence, we verify Condition (A2) as well. The following table summarizes the dynamics in Step 3.

| Properties | Typical Values |
| :--- | :--- |
| Duration | $\Delta t_{3}^{i} \leq \Delta t_{3+}^{i}=\sqrt{\frac{4 c \log \left((H-1) \gamma_{i}^{-1}\right) \cdot H \phi_{i} \sqrt{d_{e}}}{L \lambda_{i}^{2} d_{i} \omega_{0}^{2} \cdot \epsilon}}$ |
| $\mu_{i}^{\star}$ | $\mu_{i}^{\star}\left(t_{3}^{i}\right) \leq L \phi_{i}^{-1}(1+\widetilde{\xi}+2 \widetilde{\zeta}) \bar{\omega}_{i}^{\star}\left(t_{3}^{i}\right)$ |
| $\bar{\omega}_{i}^{\star} \nearrow$ | $\bar{\omega}_{i}^{\star}\left(t_{3}^{i}\right) \leq \omega_{0} \cdot\left(1-\frac{2 \varsigma_{i}}{\widetilde{\alpha}_{i}}\right)^{-1} \cdot\left(1-\frac{2 c(3 \tilde{\zeta}+2 \widetilde{\xi})}{\beta_{i} \epsilon}\right)^{-1}$. |
|  | $\left(1-\sqrt{\frac{32 c \log \left((H-1) \gamma_{i}^{-1}\right) \cdot H \varsigma_{i}}{\epsilon}}\right)^{-1}$ |
| $\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right) / \mu_{i}^{\star} \nearrow$ | $\left(1-\gamma_{i} /(H-1)\right)$ |

Table 6: Summary of Step 3 of the Warm-up Stage

## D.1.4 Step 4: Growth of $\rho_{i}^{\star}$

The moment the dynamics exist Step 3, we have (a) satisfied. Suppose that at $t_{3}^{i}$, we already have $\rho_{i}^{\star} \geq\left(1-\alpha_{i}\right) / \phi_{i}$. Then, we just set $t_{4}^{i}=t_{3}^{i}$ and skip Step 4 . Next, we consider the case where the dynamics enter Step 4 at $t_{3}^{i}$.

Upper Bounding the Duration of Step 4. Using (a), we have for $t>t_{3}^{i}$ that $\rho_{i}^{\star}<\rho_{i} \leq$ $\left(1+\gamma_{i}\right) \rho_{i}^{\star}$. Therefore, we have for the gradient of $\rho_{i}^{\star}$ that

$$
\partial_{t} \rho_{i}^{\star}=L^{-1} \lambda_{i} d_{i} \mu_{i}^{\star} \cdot\left(-\left(1 \pm \widetilde{\zeta} \pm 2 \gamma_{i}\right) \phi_{i} \rho_{i}^{\star}+\left(1 \pm \widetilde{\xi} \pm 4 \varsigma_{i}\right)\right) .
$$

We plug in the upper bound $\rho_{i}^{\star} \leq\left(1-\alpha_{i}\right) \phi_{i}^{-1}$ in (b) and obtain

$$
\begin{aligned}
\partial_{t} \rho_{i}^{\star} & \geq L^{-1} \lambda_{i} d_{i} \mu_{i}^{\star} \cdot\left(-\left(1 \pm \widetilde{\zeta} \pm 2 \gamma_{i}\right)\left(1-\alpha_{i}\right)+\left(1 \pm \widetilde{\xi} \pm 4 \varsigma_{i}\right)\right) \\
& \geq L^{-1} \lambda_{i} d_{i} \mu_{i}^{\star} \cdot\left(\alpha_{i}-\widetilde{\xi}-4 \varsigma_{i}-2 \gamma_{i}-\widetilde{\zeta}\right) .
\end{aligned}
$$

By looking at the ratio between $\partial_{t} \rho_{i}^{\star}$ and $\partial_{t} \log \bar{\omega}_{i}^{\star}$, we have

$$
\begin{aligned}
\frac{\partial_{t} \rho_{i}^{\star}}{\partial_{t} \log \bar{\omega}_{i}^{\star}} & \geq \frac{L^{-1} \lambda_{i} d_{i} \mu_{i}^{\star} \cdot\left(\alpha_{i}-\widetilde{\xi}-4 \varsigma_{i}-2 \gamma_{i}-\widetilde{\zeta}\right)}{\left(1 \pm \breve{\xi}_{i}^{\prime}\right) \cdot \sqrt{d_{e}}{ }^{-1} \lambda_{i} \mu_{i}^{\star}} \\
& \geq \frac{\left(\alpha_{i}-\widetilde{\xi}-4 \varsigma_{i}-2 \gamma_{i}-\widetilde{\zeta}\right)}{\left(1+\breve{\xi}_{i}^{\prime}\right) \varsigma_{i} \phi_{i}} \geq \frac{\alpha_{i}}{2 \varsigma_{i} \phi_{i}},
\end{aligned}
$$

where the last inequality holds by the condition that $\gamma_{i} \ll \alpha_{i}$. The maximal increment of $\rho_{i}^{\star}$ is bounded by the maximal value $\left(1-\alpha_{i}\right) / \phi_{i}$. As a result, the maximal increment of $\log \bar{\omega}_{i}^{\star}$ is bounded by $\frac{\left(1-\alpha_{i}\right) 2 \varsigma_{i}}{\alpha_{i}} \leq \frac{2 \varsigma_{i}}{\alpha_{i}}$. Hence, we have

$$
\begin{equation*}
\frac{\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)}{\bar{\omega}_{i}^{\star}\left(t_{3}^{i}\right)} \leq \exp \left(\frac{2 \varsigma_{i}}{\alpha_{i}}\right) \leq 1+\frac{2 e \varsigma_{i}}{\alpha_{i}}=1+o(1), \tag{D.19}
\end{equation*}
$$

where the last inequality holds by the condition $\alpha \gg \varsigma_{i}$ in Definition D.4. To find a lower bound for $\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)$, we invoke Lemma D. 7 with $t_{0}$ replaced by $t_{3}^{i}$ and obtain

$$
\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right) \geq \frac{1}{\bar{\omega}_{i}^{\star}\left(t_{3}^{i}\right)^{-1}-\sigma_{2}^{i} \Delta t_{4}^{i}}, \quad \text { where } \quad \sigma_{2}^{i} \triangleq \frac{\left(1-\alpha_{i}-\check{\xi}_{i}^{\prime}\right) \cdot L \lambda_{i}}{H \phi_{i} \sqrt{d_{e}}}, \quad \Delta t_{4}^{i} \triangleq t_{4}^{i}-t_{3}^{i}
$$

Comparing the upper and lower bounds, we have

$$
\Delta t_{4}^{i} \leq \frac{2 e H}{\left(1-\alpha_{i}-\check{\xi}_{i}^{\prime}\right) \cdot d_{i} \lambda_{i} \alpha_{i} \cdot \bar{\omega}_{i}^{\star}\left(t_{3}^{i}\right)} \leq \frac{4 e H}{d_{i} \lambda_{i} \alpha_{i} \omega_{0}} \triangleq \Delta t_{4+}^{i}
$$

As discussed previously in Lemma D.8, we have the ratio $\lambda_{U}^{*} / \lambda_{U}^{h}$ monotonically increasing after Step 2. Thus there is no need to check Condition (A1) again. Also, we have from (D.19) that $\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)=(1+o(1)) \bar{\omega}_{i}^{\star}\left(t_{3}^{i}\right)<2 \omega_{0} L$, which implies that Condition (A2) is satisfied with some marginal gap. In the following table, we summarize the dynamics in Step 4.

| Properties | Typical Values |  |
| :--- | :--- | :--- |
| Duration | $\Delta t_{4}^{i} \leq \Delta t_{4+}^{i}=\frac{4 e H}{d_{i} \lambda_{i} \alpha_{i j} \omega_{0}}$ |  |

Table 7: Summary of Step 4 of the Warm-up Stage

## D.1.5 Step 5: Lottery Winner Dominates

After step 4, we summarize all the good properties we have established so far for any $t \in\left[t_{4}^{i}, T_{\text {warmup }}^{i}\right]$ :
(5-1) $\mu_{i}^{\star} / \mu_{i}^{(h)} \geq(H-1) / \gamma_{i}$ for all $h \in[H] \backslash\left\{h_{i}^{*}\right\}$.
(5-2) $\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) / \bar{\omega}_{i}^{\star} \geq(3 \widetilde{\zeta}+2 \widetilde{\xi}) \beta_{i}^{-1}$ for any $h \in[H] \backslash\left\{h_{i}^{*}\right\}$.
(5-3) $1-\alpha_{i} \leq \rho_{i}^{\star} \phi_{i}<\rho_{i} \phi_{i} \leq 1+\widetilde{\xi}+2 \widetilde{\zeta}$.
(5-4) $\bar{\omega}_{i}^{\star}, \bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$ and $\mu_{i}^{\star} / \mu_{i}^{(h)}$ are monotonically increasing for any $h \in[H] \backslash\left\{h_{i}^{*}\right\}$.
In the sequel, we will appeal to these facts and refrain from checking them again.
Lower Bounding the Duration of Step 5. We first understand what's happening in Step 5. We have for $\bar{\omega}_{i}^{\star}$ that

$$
\begin{align*}
\partial_{t} \bar{\omega}_{i}^{\star} & =\left(1 \pm \breve{\xi}_{i}^{\prime}\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{\star}  \tag{D.12}\\
& =\left(1 \pm \check{\xi}_{i}^{\prime}\right) \cdot L{\sqrt{d_{e}}}^{-1} \lambda_{i} \rho_{i}^{\star}\left(\bar{\omega}_{i}^{\star}\right)^{2} \\
& =\left(1 \pm \check{\xi}_{i}^{\prime} \pm 2 \alpha_{i}\right) \cdot L{\sqrt{d_{e}}}^{-1} \lambda_{i} \phi_{i}^{-1}\left(\bar{\omega}_{i}^{\star}\right)^{2}, \tag{5-3}
\end{align*}
$$

where in the last equality we also invoke the fact that $\alpha \gg \widetilde{\zeta}+\widetilde{\xi}$ when comparing the lower bound with the upper bound. As a result, we have for $t=t_{4}^{i}+\Delta t$ that

$$
\begin{equation*}
\bar{\omega}_{i}^{\star \pm}(t)=\frac{1}{\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)^{-1}-\sigma_{4}^{i \pm} \Delta t}, \quad \text { where } \quad \sigma_{4}^{i \pm} \triangleq \frac{\left(1 \pm \check{\xi}_{i}^{\prime} \pm 2 \alpha_{i}\right) \cdot L \lambda_{i}}{\sqrt{d_{e}} \phi_{i}} \tag{D.20}
\end{equation*}
$$

where " + " and " - " correspond to the upper and lower bounds, respectively. Therefore, the duration of Step 5 is given by

$$
\Delta t_{5}^{i}=\frac{\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)^{-1}-\bar{\omega}_{i}^{\star}\left(t_{5}^{i}\right)^{-1}}{\sigma_{4}^{i^{ \pm}}}=\frac{\frac{\omega_{0}}{\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)}-1 / 4}{\omega_{0} \sigma_{4}^{i^{ \pm}}}=\left(\frac{3}{4} \pm o(1)\right) \frac{\sqrt{d_{e}} \phi_{i}}{\omega_{0} L \lambda_{i}},
$$

where in the last inequality we use the fact that $\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)=(1+o(1)) \omega_{0}$.
Growth of $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$ and $\mu_{i}^{\star} / \mu_{i}^{(h)}$. On the other hand, we have for the gradient of $\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}$ that

$$
\begin{align*}
\partial_{t}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) & =\left(1 \pm \hat{\xi}_{i}^{\prime}\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} \bar{\omega}_{i}^{\star}\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right) \\
& \geq\left(1-\hat{\xi}_{i}^{\prime}\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} \bar{\omega}_{i}^{\star} \cdot\left(1-\frac{\gamma_{i}}{H-1}\right) \cdot \mu_{i}^{\star}  \tag{5-1}\\
& \geq \underbrace{\frac{\left(1-\hat{\xi}_{i}^{\prime}-\alpha_{i}-\frac{\gamma_{i}}{H-1}\right) \cdot L \lambda_{i}}{\phi_{i} \sqrt{d_{e}}}}_{\triangleq \sigma_{5}^{i}} \cdot\left(\bar{\omega}_{i}^{\star}\right)^{2} . \tag{5-3}
\end{align*}
$$

$$
/ /(\mathrm{D} .13) \text { for } \widehat{\xi}_{i}(t)
$$

Integrating the above inequality, with the lower bound for $\bar{\omega}_{i}^{\star}$, we conclude that

$$
\begin{aligned}
\left.\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right)\right|_{t} & \geq \sigma_{5}^{i} \int_{0}^{\Delta t} \frac{1}{\left(\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)^{-1}-\sigma_{4}^{i-} \tau\right)^{2}} \mathrm{~d} \tau+\left.\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right)\right|_{t_{4}^{i}} \\
& \geq \frac{\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right) \cdot \sigma_{5}^{i} \Delta t}{\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)^{-1}-\sigma_{4}^{i-} \Delta t},
\end{aligned}
$$

where the last inequality holds by noting that $\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right) \geq \bar{\omega}_{i}^{(h)}\left(t_{4}^{i}\right)$. Now, similar to the analysis in Step 3, with $t_{2}^{i}$ replaced by $t_{5}^{i}, \sigma_{1}^{i}$ replaced by $\sigma_{5}^{i}$, and $\sigma_{2}^{i}$ replaced by $\sigma_{4}^{i-}$, we adapt (D.18) to have that

$$
\begin{aligned}
\left.\frac{\mu_{i}^{\star}}{\mu_{i}^{(h)}}\right|_{t} & \geq\left.\frac{\mu_{i}^{\star}}{\mu_{i}^{(h)}}\right|_{t_{4}^{i}} \cdot \exp \left((1-\beta) \lambda_{i} d_{i} \sigma_{5}^{i} \cdot\left(\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right) \Delta t\right)^{2} / 2\right) \\
& \geq \frac{H-1}{\gamma_{i}} \cdot \exp \left(\frac{1}{2} \cdot(1-\beta) \lambda_{i} d_{i} \sigma_{5}^{i} \cdot\left(\frac{1-\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right) / \bar{\omega}_{i}^{\star}(t)}{\sigma_{4}^{i+}}\right)^{2}\right) \\
& =\frac{H-1}{\gamma_{i}} \cdot \exp \left(\frac{\sigma_{5}^{i}(1-\beta) \lambda_{i} d_{i}\left(1-\kappa_{i}(t)\right)^{2}}{2\left(\sigma_{4}^{i+}\right)^{2}}\right)
\end{aligned}
$$

where the second inequality holds by the upper bound for $\bar{\omega}_{i}^{\star}$ in (D.20), and in the last inequality we define $\kappa_{i}(t) \triangleq \bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right) / \bar{\omega}_{i}^{\star}(t)$. Not that $\kappa_{i}(t)>1 / 4+o(1)$ still makes the dynamics satisfying the condition $\bar{\omega}_{i}^{\star}\left(t_{5}^{i}\right) \leq 4 \omega_{0}$ given that $\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)=(1+o(1)) \omega_{0}$. By Lemma D. 5 and the monotonicity of $\mu_{i}^{\star} / \mu_{i}^{(h)}$, we can guarantee that we are still within the warm-up stage for the TIF- $i$ dynamics. Furthermore, by plugging in the definition of $\sigma_{5}^{i}$ and $\omega_{4}^{+}$, we have

$$
\frac{\sigma_{5}^{i}}{\left(\omega_{4}^{+}\right)^{2}}=\frac{\left(1-\widehat{\xi}_{i}^{\prime}-\alpha_{i}-\frac{\gamma_{i}}{H-1}\right) \cdot \sqrt{d_{e}} \phi_{i}}{\left(1+\check{\xi}_{i}^{\prime}+2 \alpha_{i}\right)^{2} \cdot L \lambda_{i}}=\left(1-\widehat{\xi}_{i}^{\prime}-4 \alpha_{i}-\frac{\gamma_{i}}{H-1}-2 \check{\xi}_{i}^{\prime}\right) \cdot \frac{\sqrt{d_{e}} \phi_{i}}{L \lambda_{i}} \geq \frac{\sqrt{d_{e}} \phi_{i}}{2 L \lambda_{i}} .
$$

In conclusion, we have

$$
\begin{equation*}
\left.\frac{\mu_{i}^{\star}}{\mu_{i}^{(h)}}\right|_{t} \geq \frac{H-1}{\gamma_{i}} \cdot \exp \left(\frac{(1-\beta)\left(1-\kappa_{i}(t)\right)^{2}}{4 \varsigma_{i}}\right) \geq \frac{H-1}{\gamma_{i}} \cdot \exp \left(\frac{\left(1-\kappa_{i}(t)\right)^{2}}{8 \varsigma_{i}}\right) . \tag{D.21}
\end{equation*}
$$

We can roughly estimate the scale of $\varsigma_{i}=L /\left(\sqrt{d_{e}} d_{i} \phi_{i}\right) \approx L / L^{1.5}=1 / \sqrt{L}$ given that both $d_{e}=\mathcal{O}(L)$ and $d_{i}=\mathcal{O}(L)$. As a result, we have the ratio growing exponentially large, which means those nonoptimal head will decay exponentially fast. Similar idea also applies to the ratio $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$ where we do not wish $\bar{\omega}_{i}^{(h)}$ for the nonoptimal head to grow large. For our purpose, we just compare the ratio between $\partial_{t}\left(\log \bar{\omega}_{i}^{\star}-\log \bar{\omega}_{i}^{(h)}\right)$ and $\partial_{t}\left(\log \bar{\omega}_{i}^{\star}\right)$ as

$$
\begin{align*}
\frac{\partial_{t}\left(\log \bar{\omega}_{i}^{\star}-\log \bar{\omega}_{i}^{(h)}\right)}{\partial_{t}\left(\log \bar{\omega}_{i}^{\star}\right)} & =\frac{\left(1 \pm \widehat{\xi}_{i}^{\prime}\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i}\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right)}{\left(1 \pm \check{\xi}_{i}(t)\right) \cdot{\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star}} \\
& =\frac{\left(1 \pm \widehat{\xi}_{i}^{\prime}\right) \cdot\left(1 \pm \gamma_{i} /(H-1)\right)}{\left(1 \pm \check{\xi}_{i}(t)\right)}  \tag{5-1}\\
& =1 \pm \widehat{\xi}_{i}^{\prime} \pm 2 \gamma_{i} /(H-1) \pm 2 \breve{\xi}_{i}^{\prime} .
\end{align*}
$$

The message is that the growth of $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$ is roughly the same as $\bar{\omega}_{i}^{\star}$. As a result, we conclude that for any $t \in\left[t_{4}^{i}, t_{5}^{i}\right]$, it holds that

$$
\begin{equation*}
\log \left(\frac{\bar{\omega}_{i}^{(h)}(t)}{\bar{\omega}_{i}^{(h)}\left(t_{4}^{i}\right)}\right)= \pm\left(\widehat{\xi}_{i}^{\prime}+2 \gamma_{i} /(H-1)+2 \check{\xi}_{i}^{\prime}\right) \cdot \log \left(\frac{\bar{\omega}_{i}^{\star}(t)}{\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)}\right) . \tag{D.22}
\end{equation*}
$$

Therefore, $\bar{\omega}_{i}^{(h)}$ is almost "fixed" at initialization. In the following table, we summarize the dynamics in Step 5.

| Properties | Typical Values |
| :--- | :--- |
| Duration | $\Delta t_{5}^{i} \geq \frac{\sqrt{d_{e} \phi_{i}}}{4 \omega_{0} L_{\lambda} \lambda_{i}}$ |
| $\mu_{i}^{\star}$ | $\mu_{i}^{\star} \leq(1+\widetilde{\xi}+2 \widetilde{\zeta}) L \phi_{i}^{-1} \bar{\omega}_{i}^{\star}$ |
| $\bar{\omega}_{i}^{\star}$ | $\bar{\omega}_{i}^{\star}\left(t_{5}^{i}\right)=4 \omega_{0}$ |
| $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$ | $\log \left(\frac{\bar{\omega}_{i}^{(h)}\left(t_{5}^{i}\right)}{\bar{\omega}_{i}^{h}\left(t_{4}^{i}\right)}\right)= \pm\left(\widehat{\xi}_{i}^{\prime}+2 \gamma_{i} /(H-1)+2 \widetilde{\xi}_{i}^{\prime}\right) \cdot \log \left(\frac{\left(\bar{\omega}_{\star}^{\star}(t)\right.}{\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)}\right)$ |
| $\mu_{i}^{\star} / \mu_{i}^{(h)}$ | $\geq \frac{H-1}{\gamma_{i}} \cdot \exp \left(\frac{\left(1-\kappa_{i}(t)\right)^{2}}{8 \varsigma_{i}}\right)$ |

Table 8: Summary of Step 5 of the Warm-up Stage

The Last Step Takes Much Longer. We first summarize the durations for each of the five steps in the warm-up stage in the following table. We calculate the ratio between the duration of

| Step | Duration |
| :--- | :--- |
| Step 1 | $t_{1}^{i} \leq t_{1+}^{i}=\frac{1}{\lambda_{i} d_{i} \omega_{0} \tilde{\alpha}_{i}} \cdot \log \left(\frac{2 L \omega_{0}}{\phi_{i} \omega_{i}^{*}(0)}\right)$ |
| Step 2 | $\Delta t_{2}^{i} \leq \Delta t_{2+}^{i}=\frac{4 c(3 \tilde{\zeta}+2 \tilde{\xi}) \cdot H \sqrt{d_{e} \phi_{i}}}{\beta_{i} \in L \lambda_{i} \omega_{0}}$ |
| Step 3 | $\Delta t_{3}^{i} \leq \Delta t_{3+}^{i}=\sqrt{\frac{4 c \log \left((H-1) \gamma_{i}^{-1}\right) \cdot H \phi_{i} \sqrt{d_{e}}}{L \lambda_{i}^{2} d_{i} \omega_{0}^{2} \cdot \epsilon}}$ |
| Step 4 | $\Delta t_{4}^{i} \leq \Delta t_{4+}^{i}=\frac{4 e H}{d_{i} \lambda_{i} \alpha_{i} \omega_{0}}$ |
| Step 5 | $\Delta t_{5}^{i} \geq \frac{\sqrt{d_{e} \phi_{i}}}{4 \omega_{0} L \lambda_{i}}$ |

Table 9: Summary of the Durations for Each Step in the Warm-up Stage the first four steps against the last step as

$$
\begin{aligned}
& \frac{t_{1+}^{i}}{\Delta t_{5-}^{i}} \leq \frac{8 \varsigma_{i}}{\alpha_{i}} \cdot \log \left(\frac{2 L \omega_{0}}{\phi_{i} \mu_{i}^{\star}(0)}\right), \quad \frac{\Delta t_{2+}^{i}}{\Delta t_{5-}^{i}} \leq \frac{16 c H(3 \widetilde{\zeta}+2 \widetilde{\xi})}{\beta_{i} \epsilon}, \\
& \frac{\Delta t_{3+}^{i}}{\Delta t_{5-}^{i}} \leq \sqrt{\frac{64 c \log \left((H-1) \gamma_{i}^{-1}\right) \cdot \varsigma_{i} H}{\epsilon}}, \quad \frac{\Delta t_{4+}^{i}}{\Delta t_{5-}^{i}} \leq \frac{16 e \varsigma_{i} H}{\alpha_{i}} .
\end{aligned}
$$

By our conditions for $\alpha_{i}, \beta_{i}, \gamma_{i}$, we can ensure that all these ratios are $o(1)$. To ensure $o(1)$, we need

$$
\alpha_{i} \gg \varsigma_{i} \cdot\left(\log \left(\frac{2 L \omega_{0}}{\phi_{i} \mu_{i}^{\star}(0)}\right) \vee H\right), \quad \beta_{i} \gg \frac{16 c H(3 \widetilde{\zeta}+2 \widetilde{\xi})}{\epsilon}, \quad \gamma_{i} \gg H \cdot \exp \left(-\frac{\epsilon}{64 c \varsigma_{i} H}\right) .
$$

End of the Warm-up Stage. Let us first deal with the nominal task. Our goal is to show that Condition (A2) and Condition (A3) for the nominal task will not be violated even for the upper bound of the duration of the warm-up stage, which is given by $\min _{i \in \mathcal{I}} T_{\text {warmup }}^{i} \leq \min _{i \in \mathcal{I}} \frac{\sqrt{d_{e}} \phi_{i}}{\omega_{0} L \lambda_{i}}$. By the gradient of $\partial_{t} \mu_{j}^{(h)}$ of a nominal task $j \in \mathcal{I}_{c}$, we directly conclude that $\mu_{j}^{(h)}$ cannot increase, which verifies Condition (A3). For the $\bar{\omega}_{j}^{(h)}$, s side, we have by the gradient $\partial_{t} \bar{\omega}_{j}^{(h)} \leq \nu \cdot\left(\bar{\omega}_{j}^{(h)}\right)^{2}$ that

$$
\bar{\omega}_{i}^{(h)} \leq \frac{1}{\omega_{0}^{-1}-26 C L \zeta{\sqrt{d_{e}}}^{-1} \cdot\langle\boldsymbol{d}, \lambda \odot \phi\rangle \cdot \omega_{0}^{2} \cdot \min _{i \in \mathcal{I}} \frac{\sqrt{d_{e} \phi_{i}}}{\omega_{0} L \lambda_{i}}}=\omega_{0}(1+o(1)),
$$

where the last equality holds by our conditions for $\omega_{0}$ that $\omega_{0} \ll \max _{i \in \mathcal{I}} \frac{\lambda_{i}}{\phi_{i}(\boldsymbol{d}, \lambda \odot \phi) \zeta}$. Hence, we also have Condition (A2) satisfied for the nominal task.

Previously, we have shown that the TIF- $i$ dynamics for $i \in \mathcal{I}$ in the warm-up stage can be divided into five steps for individual task $i$. However, the real dynamics does not necessarily roll out in this way, since if one of these tasks finishes the warm-up stage, at least one of the conditions Condition (A1)-Condition (A6) will be violated. In particular, the violated condition will be one of the critical conditions-Condition (A2) for a certain effective task since the other critical condition Condition (A1) will not be violated by the monotonicity of $\mu_{i}^{\star} / \mu_{i}^{(h)}$.

We have $T_{\text {warmup }}=\min _{i \in\left[d_{y}\right]} T_{\text {warmup }}^{i}=\min _{i \in \mathcal{I}} T_{\text {warmup }}^{i}$. Let $i^{*}$ be the task that finishes the warmup stage first. We first argue that at $T_{\text {warmup }}$, the other TIF- $j$ dynamics are all in Step 5 for any $j \in \mathcal{I} \backslash\left\{i^{*}\right\}$.

Lemma D.9. All TIF-j dynamics are in Step 5 at $T_{\text {warmup }}$ for any $j \in \mathcal{I} \backslash\left\{i^{*}\right\}$. In particular, we have

$$
\max _{j \in \mathcal{I}} t_{4+}^{j} / \Delta t_{5-}^{j} \ll \vartheta
$$

Proof. We just need to check that $T_{\text {warmup }}=T_{\text {warmup }}^{i^{*}} \geq t_{4}^{j}$ for any $j \in \mathcal{I} \backslash\left\{i^{*}\right\}$. By the fact that $\Delta t_{l+}^{j} \ll \Delta t_{5-}^{j}$ for any $l \in\{1,2,3,4\}$, it suffices to show that $4 \max _{l \in\{1,2,3,4\}} \Delta t_{l+}^{j} / \Delta t_{5-}^{j} \leq$ $\Delta t_{5-}^{i^{*}} / \Delta t_{5-}^{j}$. The left hand side is bounded by

$$
\begin{gathered}
\max _{l \in\{1,2,3,4\}} \frac{4 \Delta t_{l+}^{j}}{\Delta t_{5-}^{j}} \leq \max _{j \in \mathcal{I}}\left\{\frac{64 e \varsigma_{j}}{\alpha_{j}} \cdot\left(\log \left(\frac{2 L \omega_{0}}{\phi_{j} \mu_{j}^{\star}(0)}\right) \vee H\right), \quad \frac{64 c H(3 \widetilde{\zeta}+2 \tilde{\xi})}{\beta_{j} \epsilon},\right. \\
\\
\left.32 \sqrt{c \log \left((H-1) \gamma_{j}^{-1}\right) \cdot \frac{\varsigma_{j} H}{\epsilon}},\right\}
\end{gathered}
$$

while the right hand side is lower bounded by

$$
\frac{\Delta t_{5-}^{i^{*}}}{\Delta t_{5-}^{j}}=\frac{\phi_{i^{*}} \lambda_{i^{*}}^{-1}}{\phi_{j} \lambda_{j}^{-1}} \geq \frac{\min _{i \in \mathcal{I}} \phi_{i} \lambda_{i}^{-1}}{\max _{j \in \mathcal{I}} \phi_{j} \lambda_{j}^{-1}} \triangleq \vartheta
$$

Hence it suffices to have $\vartheta \gg \max _{l \in\{1,2,3,4\}} \frac{4 \Delta t_{++}^{j}}{\Delta t_{5-}^{j}}$, which is already guaranteed by our conditions for $\alpha_{j}, \beta_{j}, \gamma_{j}$ in Definition D.4.

Since all the TIF- $j$ dynamics are in Step 5, we can easily conclude from (D.22) that for any $i \in \mathcal{I}$ and $h \in[H] \backslash\left\{h_{i}^{*}\right\}$, it holds that

$$
\begin{aligned}
\bar{\omega}_{i}^{(h)}\left(T_{\text {warmup }}\right) & =\bar{\omega}_{i}^{(h)}\left(t_{4}^{i}\right) \cdot \exp \left( \pm\left(\hat{\xi}_{i}^{\prime}+2 \gamma_{i} /(H-1)+2 \breve{\xi}_{i}^{\prime}\right) \cdot \log \left(\frac{\bar{\omega}_{i}^{\star}(t)}{\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)}\right)\right) \\
& \leq \bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right) \cdot\left(1+\left(\hat{\xi}_{i}^{\prime}+\frac{2 \gamma_{i}}{H-1}+2 \check{\xi}_{i}^{\prime}\right) \cdot e \log 4\right)=(1+o(1)) \omega_{0}
\end{aligned}
$$

where the inquality holds by the fact that $\bar{\omega}_{i}^{\star}\left(t_{5}^{i}\right) \leq 4 \omega_{0}$ and $\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)=(1+o(1)) \omega_{0}$. Therefore, $\bar{\omega}_{i}^{(h)}\left(T_{\text {warmup }}\right)$ is "fixed" at initialization as $\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)=(1+o(1)) \omega_{0}$. Meanwhile, we have from (D.20) for $\bar{\omega}_{i}^{\star}\left(T_{\text {warmup }}\right)$ that

$$
\begin{aligned}
\bar{\omega}_{i}^{\star}\left(T_{\text {warmup }}\right) & \geq \frac{1}{\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)^{-1}-\frac{\left(1-\check{\xi}_{i}^{\prime}-2 \alpha_{i}\right) \cdot L \lambda_{i}}{\sqrt{d_{e} \phi_{i}}} \Delta t_{5-}^{i^{\star}}} \\
& \geq\left(\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)^{-1}-\frac{\left(1-\check{\xi}_{i}^{\prime}-2 \alpha_{i}\right)(3 / 4-o(1))}{\omega_{0}} \cdot \frac{\lambda_{i} \phi_{i}^{-1}}{\max _{k \in \mathcal{I}} \lambda_{k} \phi_{k}^{-1}}\right)^{-1} \\
& \geq \bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right) \cdot\left(1-\frac{\lambda_{i} \phi_{i}^{-1}}{1.5 \cdot \max _{k \in \mathcal{I}} \lambda_{k} \phi_{k}^{-1}}\right)^{-1}
\end{aligned}
$$

Thus, we conclude that

$$
\begin{aligned}
& \left.\frac{\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}}{\bar{\omega}_{i}^{\star}}\right|_{T_{\text {narrup }}} \\
& \geq 1-\left(1+\left(\widehat{\xi}_{i}^{\prime}+\frac{2 \gamma_{i}}{H-1}+2 \breve{\xi}_{i}^{\prime}\right) \cdot e \log 4\right) \cdot\left(1-\frac{\lambda_{i} \phi_{i}^{-1}}{1.5 \cdot \max _{k \in \mathcal{I}} \lambda_{k} \phi_{k}^{-1}}\right) \\
& \quad \geq \frac{\lambda_{i} \phi_{i}^{-1}}{1.5 \cdot \max _{k \in \mathcal{I}} \lambda_{k} \phi_{k}^{-1}}-\left(\hat{\xi}_{i}^{\prime}+\frac{2 \gamma_{i}}{H-1}+2 \breve{\xi}_{i}^{\prime}\right) \cdot e \log 4 \geq \frac{\lambda_{i} \phi_{i}^{-1}}{2 \cdot \max _{k \in \mathcal{I}} \lambda_{k} \phi_{k}^{-1}} .
\end{aligned}
$$

Under the condition that $\frac{\lambda_{i} \phi_{i}^{-1}}{\max _{k \in \mathcal{I}} \lambda_{k} \phi_{k}^{-1}} \gg \max \left\{\hat{\xi}_{i}^{\prime}, \gamma_{i} / H, \check{\xi}_{i}^{\prime}\right\}$, At the same time, we have for $\mu_{i}^{(h)}$ with $h \in[H] \backslash\left\{h_{i}^{*}\right\}$ that

$$
\begin{equation*}
\left.\frac{\mu_{i}^{(h)}}{\mu_{i}^{\star}}\right|_{T_{\text {warrup }}} \leq \frac{\gamma_{i}}{H-1} \cdot \exp \left(-\frac{\left(1-\kappa_{i}\left(T_{\text {warmup }}\right)\right)^{2}}{8 \varsigma_{i}}\right) . \tag{D.23}
\end{equation*}
$$

Given that $\kappa_{i}(t)<1$, it suffices to upper bound $\kappa_{i}\left(T_{\text {warmup }}\right)$ for upper bounding the ratio. Recall by definition,

$$
\begin{aligned}
\kappa_{i}\left(T_{\text {warmup }}\right)=\frac{\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)}{\bar{\omega}_{i}^{\star}\left(T_{\text {warmup }}\right)} & \leq \bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right) \cdot\left(\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)^{-1}-\sigma_{4}^{i-}\left(T_{\text {warmup }}-t_{4}^{i}\right)\right) \\
& \leq 1-\omega_{0} \cdot \sigma_{4}^{i-}\left(\Delta t_{5-}^{i^{*}}-t_{4+}^{i}\right),
\end{aligned}
$$

where in the first inequality we invoke (D.20) and in the second inequality we invoke the lower bound for $T_{\text {warmup }}$ since $T_{\text {warmup }}=T_{\text {warmup }}^{i^{*}} \geq \Delta t_{5-}^{i^{*}}$ and lower bound $\bar{\omega}_{i}^{\star}\left(t_{4}^{i}\right)$ by its initial value $\omega_{0}$. To
further lower bound $\Delta t_{5-}^{i^{*}}-t_{4+}^{i}$, we invoke Lemma D. 9 that $\max _{j \in \mathcal{I}} t_{4+}^{j} / \Delta t_{5-}^{j} \ll \vartheta$ and conclude that

$$
\Delta t_{5-}^{i^{*}}-t_{4+}^{i}=\Delta t_{5-}^{i^{*}} \cdot\left(1-\frac{t_{4+}^{i}}{\Delta t_{5-}^{i}} \cdot \frac{\Delta t_{5-}^{i}}{\Delta t_{5-}^{i^{*}}}\right) \geq \Delta t_{5-}^{i^{*}} \cdot\left(1-\frac{t_{4+}^{i}}{\Delta t_{5-}^{i}} \cdot \vartheta^{-1}\right) \geq \frac{\Delta t_{5-}^{i^{*}}}{\sqrt{2}}
$$

Therefore, we have for (D.23) that

$$
\begin{align*}
\left.\frac{\mu_{i}^{(h)}}{\mu_{i}^{\star}}\right|_{T_{\text {varrup }}} & \leq \frac{\gamma_{i}}{H-1} \cdot \exp \left(-\frac{\left(\omega_{0} \cdot \sigma_{4}^{i-} \Delta t_{5-}^{i^{*}}\right)^{2}}{16 \varsigma_{i}}\right) \\
& \leq \frac{\gamma_{i}}{H-1} \cdot \exp \left(-\frac{\left(\omega_{0} \cdot \frac{\left(1-\breve{\xi}_{i}^{\prime}-2 \alpha_{i}\right) \cdot L \lambda_{i}}{\sqrt{d_{e} \phi_{i}}} \cdot \frac{\sqrt{d_{e}} \phi_{i^{*}}}{4 \omega_{0} L \lambda_{i^{*}}}\right)^{2}}{16 \varsigma_{i}}\right) \\
& \leq \frac{\gamma_{i}}{H-1} \cdot \exp \left(-\frac{\left(\lambda_{i^{*}}^{-1} \phi_{i^{*}} /\left(\lambda_{i}^{-1} \phi_{i}\right)\right)^{2}}{256 \varsigma_{i}}\right) \leq \frac{\gamma_{i}}{H-1} \cdot \exp \left(-\frac{\vartheta^{2}}{256 \varsigma_{i}}\right) \triangleq \varrho_{i} \ll 1 . \tag{D.24}
\end{align*}
$$

In conclusion, as long as $\varsigma_{i} \ll \vartheta^{2}$, we have the ratio $\mu_{i}^{(h)} / \mu_{i}^{\star}$ being exponentially small. In the following table, we summarize the dynamics at $T_{\text {warmup }}$.

| Properties | Typical Values |
| :--- | :--- |
| Duration | $T_{\text {warmup }}=\min _{i \in\left[d_{y}\right]} T_{\text {warmup }}^{i}$ |
| $\mu_{i}^{\star}$ | $\left(1-\alpha_{i}\right) \phi_{i}^{-1} L \bar{\omega}_{i}^{\star} \leq \mu_{i}^{\star} \leq(1+\widetilde{\xi}+2 \widetilde{\zeta}) L \phi_{i}^{-1} \bar{\omega}_{i}^{\star}$ |
| $\bar{\omega}_{i}^{\star}$ | $\bar{\omega}_{i}^{\star} \leq 4 \omega_{0}$ with $\bar{\omega}_{i^{\star}}^{\star}=4 \omega_{0}$ |
| $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)}$ | $\log \left(\frac{\bar{\omega}_{i}^{(h)}\left(T_{\text {warnup }}\right)}{\bar{\omega}_{i}^{(h)}\left(t_{4}^{r}\right)}\right)= \pm\left(\widehat{\xi}_{i}^{\prime}+2 \gamma_{i} /(H-1)+2 \breve{\xi}_{i}^{\prime}\right) \cdot \log \left(\frac{\bar{\omega}_{i}^{\star}\left(T_{\text {warnup }}\right)}{\bar{\omega}_{\grave{i}}^{\star}\left(t_{4}^{n}\right)}\right)$ |
| $\mu_{i}^{\star} / \mu_{i}^{(h)}$ | $\left.\frac{\mu_{i}^{(h)}}{\mu_{i}^{\star}}\right\|_{T_{\text {warmup }}} \leq \varrho_{i} \ll 1$ |

Table 10: Summary of the Dynamics at $T_{\text {warmup }}$

## D. 2 Growing Stage

We give the following definition for the growing stage of the dynamics.
Definition D. 10 (Growing Stage). We say that the dynamics is in the growing stage if all the conditions in Condition C. 14 and the following conditions hold:
(i) $\mu_{i}^{\star} \geq L \phi_{i}^{-1} \omega_{0} / \sqrt{2}$ for all $i \in \mathcal{I}$.
(ii) $\bar{\omega}_{i}^{\star}>\bar{\omega}_{i}^{(h)}$, $\bar{\omega}_{i}^{\star} / \bar{\omega}_{i}^{(h)} \geq \bar{\omega}_{i}^{\star} /\left.\bar{\omega}_{i}^{(h)}\right|_{T_{\text {warrup }}}$ and $\mu_{i}^{\star} / \mu_{i}^{(h)} \geq \mu_{i}^{\star} /\left.\mu_{i}^{(h)}\right|_{T_{\text {warmup }}}$ for any $(i, h) \in(\mathcal{I} \otimes$ $[H]) \backslash\left\{\left(i, h_{i}^{*}\right) \mid i \in \mathcal{I}\right\}$.
(iii) $\bar{\omega}_{i}^{(h)} \leq \sqrt{2} \omega_{0}$ for all $(i, h) \in\left(\left[d_{y}\right] \otimes[H]\right) \backslash\left\{\left(i, h_{i}^{*}\right) \mid i \in \mathcal{I}\right\}$.
(iv) $\left(d_{i} \wedge L e^{-1} \phi_{i}^{-1}\right) / 4 \leq \mu_{i}^{\star} / \bar{\omega}_{i}^{\star} \leq \sqrt{2} L \phi_{i}^{-1}$ for all $i \in \mathcal{I}$.
(v) $\mu_{i}^{\star} \bar{\omega}_{i}^{\star} \leq \frac{2}{1+d_{i} \phi_{i} L^{-1}}$ for all $i \in \mathcal{I}$.

Based on these conditions, we can simplify the dynamics based on (D.1) and (D.2) in the growing stage as follows. For completeness, we copy (D.1) here:

$$
\begin{align*}
\sqrt{d_{e}} \cdot \partial_{t} \bar{\omega}_{i}^{(h)}=- & (1 \pm \zeta) \cdot \sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} \cdot\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \cdot \bar{\omega}_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{(h)}  \tag{D.25}\\
& -(1 \pm \xi) \lambda_{i} \cdot \sum_{h^{\prime}=1}^{H} \mu_{i}^{\left(h^{\prime}\right)} \mu_{i}^{(h)} \bar{\omega}_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{(h)}+(1 \pm \xi) \lambda_{i} \cdot \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)}  \tag{D.26}\\
& ( \pm 1) \cdot \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{(h)}\right\rangle\right)}{L} \cdot\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2}  \tag{D.27}\\
& ( \pm \eta) \cdot \sum_{h^{\prime}=1}^{H}\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2} \cdot \tag{D.28}
\end{align*}
$$

We notice that the cross-task interference happens when dealing with $\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle,\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot\right.$ $\left.\mu^{\left(h^{\prime}\right)}\right\rangle$ and $\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle$. For the first term, we have

$$
\begin{align*}
\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle & =\sum_{i=1}^{d_{y}} \bar{\omega}_{i}^{(h)} \bar{\omega}_{i}^{\left(h^{\prime}\right)} d_{i} \\
& \stackrel{(a)}{\leq} \sum_{i=1}^{d_{y}} d_{i} \cdot\left(\bar{\omega}_{i}^{\star} \chi_{i}^{(h)}+\sqrt{2} \omega_{0}\right) \cdot\left(\bar{\omega}_{i}^{\star} \chi_{i}^{\left(h^{\prime}\right)}+\sqrt{2} \omega_{0}\right) \\
& \stackrel{(b)}{=} d_{i_{h}^{*}} \cdot\left(\bar{\omega}_{i_{h}^{*}}^{\star}\right)^{2} \cdot \mathbb{1}\left(h=h^{\prime} \in \mathcal{B}\right)+2 \omega_{0}\left(\sqrt{d_{i^{*}}} \mathbb{1}\left(h^{\prime} \in \mathcal{B}\right)+\sqrt{d_{i^{*}}} \mathbb{1}(h \in \mathcal{B})\right)+2 \omega_{0}^{2} d \\
& \leq d_{i_{h}^{*}} \cdot\left(\bar{\omega}_{i_{h}^{*}}^{\star}\right)^{2} \cdot \mathbb{1}\left(h=h^{\prime} \in \mathcal{B}\right)+\underbrace{\left(4 \omega_{0} \sqrt{d}+2 \omega_{0}^{2} d\right)}_{\ll 1} \leq 1+o(1) \tag{D.29}
\end{align*}
$$

where we define $\chi_{i}^{(h)}$ as an indicator function for which takes value 1 if $h$ is the unique optimal head for task $i \in \mathcal{I}$ and 0 otherwise (also 0 if $i \in \mathcal{I}_{c}$ belongs to the nominal tasks), and $\mathcal{B}=\{h \in$ $[H] \mid \exists i \in \mathcal{I} \quad$ s.t. $\left.\quad h=h_{i}^{*}\right\}$ as the set for the heads that are optimal for some tasks, $\mathbb{1}(\cdot)$ as the indicator function, and $i_{h}^{*}$ as the unique task that takes head $h$ as the optimal head if $h \in \mathcal{B}$.

Here, $(a)$ holds by noting that each task $i$ has a unique optimal head $h_{i}^{*}$ and $\bar{\omega}_{i}^{(h)} \leq \sqrt{2} \omega_{0}$ for all nonoptimal head $h \in[H] \backslash\left\{h_{i}^{*}\right\}$ according to (iii). (b) holds by noting that $\chi_{i}^{(h)} \chi_{i}^{\left(h^{\prime}\right)}=\mathbb{1}(h=$ $\left.h_{i}^{*} \in \mathcal{B}\right)$ by the uniqueness of the optimal head and $\sqrt{d_{i_{h^{\prime}}}}$ and $\sqrt{d_{i_{h}^{*}}}$ comes from the upper bound $\bar{\omega}_{i}^{(h)} \leq \sqrt{2 d_{i}^{-1}}$ according to Condition C.14. The last inequality holds by invoking the upper bound for $\bar{\omega}_{i}^{\star}$ in Condition C.14. A naive lower bound for $\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle$ is

$$
\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle \geq d_{i_{h}^{*}} \cdot\left(\bar{\omega}_{i_{h}^{*}}^{\star}\right)^{2} \cdot \mathbb{1}\left(h=h^{\prime} \in \mathcal{B}\right)
$$

by the nonnegativity of $\bar{\omega}_{i}^{(h)}$ and $\bar{\omega}_{i}^{\left(h^{\prime}\right)}$.

For the second term $\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle$, we have

$$
\begin{aligned}
& \left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle=\sum_{i \in \mathcal{I}} d_{i} \lambda_{i} \phi_{i} \mu_{i}^{(h)} \mu_{i}^{\left(h^{\prime}\right)}+\sum_{j \in \mathcal{I}_{c}} \sigma^{2} d \mu_{j}^{(h)} \mu_{j}^{\left(h^{\prime}\right)} \\
& \stackrel{(a)}{\leq} \sum_{i \in \mathcal{I}} d_{i} \lambda_{i} \phi_{i}\left(\mu_{i}^{\star}\right)^{2} \cdot\left(\chi_{i}^{(h)}+\varrho_{i}\right) \cdot\left(\chi_{i}^{\left(h^{\prime}\right)}+\varrho_{i}\right)+\sum_{j \in \mathcal{I}_{c}} \sigma^{2} d \mu_{j}^{(h)}(0) \mu_{j}^{\left(h^{\prime}\right)}(0) \\
& =E_{i_{h}^{\star}}\left(\mu_{i_{h}^{\star}}^{\star}\right)^{2} \cdot \mathbb{1}\left(h=h^{\prime} \in \mathcal{B}\right)+E_{i_{h}^{*}} \varrho_{i_{h}^{*}}\left(\mu_{i_{h}^{\star}}^{\star}\right)^{2} \cdot \mathbb{1}(h \in \mathcal{B}) \\
& \quad+E_{i_{h^{\prime}}^{*}} \varrho_{i_{i^{\prime}}}\left(\mu_{i_{h^{\prime}}^{\star}}^{\star}\right)^{2} \cdot \mathbb{1}\left(h^{\prime} \in \mathcal{B}\right)+\sum_{i \in \mathcal{I}} E_{i}\left(\mu_{i}^{\star}\right)^{2}\left(\varrho_{i}\right)^{2} \\
& \quad+E_{i_{h}^{*}}\left(\mu_{i_{h^{\prime}}^{\star}}^{\star}\right)^{2} \underbrace{\ll 1}_{\max _{i \in \mathcal{I}, j \in \mathcal{I}_{c}, h \in[H]} \frac{\sigma^{2} d\left|\mathcal{I}_{c}\right|}{E_{i}} \cdot\left(\frac{\mu_{j}^{(h)}(0)}{\frac{1}{4}\left(d_{i} \wedge \frac{L}{e \phi_{i}}\right) \omega_{0}}\right)^{2}}
\end{aligned}
$$

where we define $E_{i}=d_{i} \lambda_{i} \phi_{i}=\left(d_{i} \lambda_{i} /(d)+\sigma^{2}\right) \cdot d$ as the rescaled total energy for task $i$. Here, the first term in (a) holds by noting that $\mu_{i}^{(h)} / \mu_{i}^{\star} \leq \varrho_{i}$ for all nonoptimal head $h \in[H] \backslash\left\{h_{i}^{*}\right\}$ and $i \in \mathcal{I}$ according to (D.24) and (ii) which says that $\mu_{i}^{\star} / \mu_{i}^{(h)} \geq \varrho_{i}$. The second term in (a) holds by noting that $\mu_{j}^{(h)}$ is non-increasing for all $j \in \mathcal{I}_{c}$. Next, we invoke the upper bound $\mu_{i}^{(h)} \leq \sqrt{2 L \phi_{i}^{-1}} \leq \sqrt{2 L}$ in Condition C. 14 to get

$$
\begin{align*}
& \left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \leq E_{i_{h}^{*}}\left(\mu_{i_{h}^{*}}^{\star}\right)^{2} \mathbb{1}\left(h=h^{\prime} \in \mathcal{B}\right)+(4+2|\mathcal{I}| \bar{\varrho}) \bar{E} \bar{\varrho} L+\sigma^{2} d\left|\mathcal{I}_{c}\right| \bar{\mu}^{2}, \\
& \left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \leq E_{i_{h}^{*}} \cdot\left(\mu_{i_{h}^{\star}}^{\star}\right)^{2} \cdot\left(\mathbb{1}\left(h=h^{\prime} \in \mathcal{B}\right)+\nu_{1}\right)+(4+2|\mathcal{I}| \bar{\varrho}) \bar{E} \bar{\varrho} L, \tag{D.30}
\end{align*}
$$

where we define $\bar{E}=\max _{i \in \mathcal{I}} E_{i}, \bar{\varrho}=\max _{i \in \mathcal{I}} \varrho_{i}$, and $\bar{\mu} \triangleq \max _{h \in[H], j \in \mathcal{I}_{c}} \mu_{j}^{(h)}(0)$. A naive lower bound for $\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle$ is

$$
\begin{equation*}
\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \geq E_{i_{h}^{*}} \cdot\left(\mu_{i_{h}^{*}}^{\star}\right)^{2} \cdot \mathbb{1}\left(h=h^{\prime} \in \mathcal{B}\right) . \tag{D.31}
\end{equation*}
$$

Lastly, for $\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle$, we have

$$
\begin{align*}
\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle & =\sum_{i \in \mathcal{I}} d_{i} \lambda_{i} \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)} \\
& \leq \sum_{i \in \mathcal{I}} d_{i} \lambda_{i} \mu_{i}^{\star} \cdot\left(\chi_{i}^{(h)}+\varrho_{i}\left(\chi_{i}^{(h)}\right)^{c}\right) \cdot\left(\tilde{\lambda}_{W}^{*}[i] \chi_{i}^{(h)}+\sqrt{2} \omega_{0}\left(\chi_{i}^{(h)}\right)^{c}\right) \\
& \leq d_{i_{h}^{*}} \lambda_{i_{h}^{*}} \mu_{i_{h}^{*}} \bar{\omega}_{i_{h}^{\star}}^{\star} \mathbb{1}(h \in \mathcal{B})+2 \omega_{0}|\mathcal{I}| \bar{E} \sqrt{L} \bar{\varrho}, \tag{D.32}
\end{align*}
$$

where we additionally define $\left(\chi_{i}^{(h)}\right)^{c}=1-\chi_{i}^{(h)}$ as the complement of $\chi_{i}^{(h)}$. Here, the first inequality holds for the same argument as before, and the second inequality holds by invoking the upper bound for $\mu_{i}^{\star}$ in Condition C.14.

Now, we are ready to simplify the dynamics in the growing stage. Consider $i \in \mathcal{I}$ as a specific
effective task. For (D.25) with $h=h_{i}^{*}$, we have the following ratio bound:

$$
\begin{align*}
& \frac{\sum_{h^{\prime}=1}^{H} \exp \left(\left\langle\omega^{\star}, \omega^{\left(h^{\prime}\right)}\right\rangle\right) L^{-1} \cdot\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \lambda_{U}^{*} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \cdot \bar{\omega}_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{\star}}{\exp \left(\left\langle\omega^{\star}, \omega^{\star}\right\rangle\right) L^{-1} E_{i}\left(\mu_{i}^{\star}\right)^{2} \cdot\left(\bar{\omega}_{i}^{\star}\right)^{2}} \\
& \leq \sum_{h^{\prime}=1}^{H} \exp \left(\left\langle\bar{\omega}^{\star}, \bar{\omega}^{\star}\right\rangle \cdot \mathbb{1}\left(h^{\prime}=h_{i}^{*}\right)+\left(4 \omega_{0} \sqrt{d}+2 \omega_{0}^{2} d\right) \cdot \mathbb{1}\left(h^{\prime} \neq h_{i}^{*}\right)-\left\langle\bar{\omega}^{\star}, \bar{\omega}^{\star}\right\rangle\right) \\
& \quad \cdot \bar{\omega}_{i}^{\left(h^{\prime}\right)} \frac{E_{i} \cdot\left(\mu_{i}^{\star}\right)^{2} \cdot\left(\mathbb{1}\left(h^{\prime}=h_{i}^{*}\right)+\nu_{1}\right)+(4+2|\mathcal{I}| \bar{\varrho}) \bar{E} \bar{\varrho} L}{E_{i}\left(\mu_{i}^{\star}\right)^{2} \bar{\omega}_{i}^{\star}} \quad / /(\text { D.29 })  \tag{D.29}\\
& \leq 1+\underbrace{e H \nu_{1}+\max _{i \in \mathcal{I}} \frac{4 e H(4+2|\mathcal{I}| \bar{\varrho}) \bar{E} \bar{\varrho} L}{E_{i}\left(L \omega_{0} \phi_{i}^{-1}\right)^{2}}}_{\triangleq \nu_{2}}=\triangleq 1+\nu_{2}=1+o(1), \tag{D.33}
\end{align*}
$$

where the second inequality holds by also noting that $\bar{\omega}_{i}^{\left(h^{\prime}\right)} / \bar{\omega}_{i}^{\star} \leq 1$ for all $i \in \mathcal{I}$ and $h^{\prime} \in[H] \backslash\left\{h_{i}^{*}\right\}$ according to (ii), and we also invoke the following lower bound on $\mu_{i}^{\star}$ for all $i \in \mathcal{I}$ by (i):

$$
\begin{equation*}
\mu_{i}^{\star} \geq\left(1-\alpha_{i}\right) \phi_{i}^{-1} L \omega_{0} \geq \frac{L \omega_{0}}{\sqrt{2} \phi_{i}} \tag{D.34}
\end{equation*}
$$

The message from (D.33) is that $\exp \left(\left\langle\omega^{\star}, \omega^{\star}\right\rangle\right) L^{-1} E_{i}\left(\mu_{i}^{\star}\right)^{2} \cdot\left(\bar{\omega}_{i}^{\star}\right)^{2}$ is the dominant term in (D.25) for any $i \in \mathcal{I}$. Again, we need to deal with the error terms (D.27) and (D.28). For (D.27), we observe for any $h \in \mathcal{B}$ that

$$
\begin{align*}
& \frac{( \pm 1) \cdot \exp \left(\left\langle\omega^{(h)}, \omega^{(h)}\right\rangle\right) L^{-1} \cdot\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2}}{\exp \left(\left\langle\omega^{(h)}, \omega^{(h)}\right\rangle\right) L^{-1} \cdot\left\langle\boldsymbol{d} \odot \lambda \odot \phi,\left(\mu^{(h)}\right) \odot 2\right\rangle \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2}} \\
& \quad \stackrel{(a)}{\leq} C \cdot \frac{d_{i_{h}^{*}} \lambda_{i_{h}^{*}} \mu_{i_{h}^{\star}}^{\star} \bar{\omega}_{i_{h}^{*}} \mathbb{1}(h \in \mathcal{B})+\sqrt{2} \omega_{0}|\mathcal{I}| \bar{E} \sqrt{2 L} \bar{\varrho}}{E_{i_{h}^{*}} \cdot\left(\mu_{i_{h}^{*}}^{\star}\right)^{2} \cdot \mathbb{1}(h \in \mathcal{B})} \\
& \quad=C \cdot\left(\frac{\bar{\omega}_{i_{h}^{*}}^{\star}}{\mu_{i_{h}^{*}}^{\star}}+\frac{2 \omega_{0}|\mathcal{I}| \bar{\varrho} \bar{E} \sqrt{L}}{E_{i_{h}^{*}} \cdot\left(\mu_{i_{h}^{*}}^{\star}\right)^{2}}\right) \\
& \quad \stackrel{(b)}{\leq} \max _{i \in \mathcal{I}}\left\{4 C\left(d_{k}^{-1} \vee \frac{e \phi_{k}}{L}\right)+\frac{12 C \omega_{0}|\mathcal{I}| \bar{\varrho} \bar{E} \sqrt{L}}{E_{k} \cdot\left(\phi_{k}^{-1} L \omega_{0}\right)^{2}}\right\} \triangleq \nu_{3} \ll 1, \tag{D.35}
\end{align*}
$$

where in (a) we use the upper bound and lower bound in (D.32) and (D.31) respectively, and in (b) we invoke the lower bound for $\mu_{i}^{\star} / \bar{\omega}_{i}^{\star}$ in (iv) and also the lower bound for $\mu_{i}^{\star}$ in (D.34). The message conveyed here is that (D.27) is negligible compared to (D.25) for any $i \in \mathcal{I}$ and $h \in \mathcal{B}$. On the other hand, when $h \notin \mathcal{B}$, we have following the upper bounds for the above ratio following from (D.29) and (D.32) that

$$
\begin{equation*}
( \pm 1) \cdot \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{(h)}\right\rangle\right)}{L} \cdot\left\langle\boldsymbol{d} \odot \lambda, \bar{\omega}^{(h)} \odot \mu^{(h)}\right\rangle \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2} \leq \frac{2 C e^{1.1} \omega_{0}|\mathcal{I}| \bar{E} \sqrt{L} \bar{\varrho}}{L} \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2} . \tag{D.36}
\end{equation*}
$$

Similarly, we have for the error term (D.28) that when $h \in \mathcal{B}$,

$$
\begin{align*}
& \frac{( \pm \eta) \cdot \sum_{h^{\prime}=1}^{H}\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2}}{\exp \left(\left\langle\omega^{(h)}, \omega^{(h)}\right\rangle\right) L^{-1} \cdot\left\langle\boldsymbol{d} \odot \lambda \odot \phi,\left(\mu^{(h)}\right)^{\odot 2}\right\rangle \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2}} \\
& \quad \leq \frac{\sum_{h^{\prime}=1}^{H}\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle}{\left\langle\boldsymbol{d} \odot \lambda \odot \phi,\left(\mu^{(h)}\right)^{\odot 2}\right\rangle} \cdot C L \eta \\
& \quad \leq \frac{E_{i_{h}^{*}} \cdot\left(\mu_{i_{h}^{\star}}^{\star}\right)^{2} \cdot\left(\mathbb{1}(h \in \mathcal{B})+H \nu_{1}\right)+H(4+2|\mathcal{I}| \bar{\varrho}) \bar{E} \bar{\varrho} L}{E_{i_{h}^{*}} \cdot\left(\mu_{i_{h}^{*}}^{\star}\right)^{2} \cdot \mathbb{1}(h \in \mathcal{B})} \cdot C L \eta  \tag{D.30}\\
& \leq(\left(1+H \nu_{1}\right)+\underbrace{\frac{4 H(4+2|\mathcal{I}| \bar{\varrho}) \bar{E} \bar{\varrho} L}{E_{i_{h}^{*}} \cdot\left(\phi_{i_{h}^{*}}^{-1} L \omega_{0}\right)^{2}}}_{\ll 1}) \cdot C \zeta \leq 2 C \zeta \ll 1, \tag{D.37}
\end{align*}
$$

where the last inequality holds by (D.34) on the lower bound for $\mu_{i_{h}^{\star}}^{\star}$ and by condition $\zeta \geq L \eta$. When $h \notin \mathcal{B}$,

$$
\begin{align*}
& \sum_{h^{\prime}=1}^{H}\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2} \cdot \eta \\
& \quad \leq\left((4+2|\mathcal{I}| \bar{\varrho}) \bar{E} \bar{\varrho} L+\sigma^{2} d H\left|\mathcal{I}_{c}\right| \bar{\mu}^{2}\right) \cdot C \zeta \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2} . \tag{D.38}
\end{align*}
$$

Lastly, for the first term in (D.26), we have for any $i \in \mathcal{I}$ that

$$
\begin{equation*}
\frac{\sum_{h^{\prime}=1}^{H} \mu_{i}^{\left(h^{\prime}\right)} \mu_{i}^{(h)} \bar{\omega}_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{(h)}}{\mu_{i}^{(h)} \bar{\omega}_{i}^{(h)} \mu_{i}^{\star} \bar{\omega}_{i}^{\star}}=1+\sum_{h^{\prime} \neq h_{i}^{*}} \frac{\mu_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{\left(h^{\prime}\right)}}{\mu_{i}^{\star} \bar{\omega}_{i}^{\star}} \leq 1+H \bar{\varrho}, \tag{D.39}
\end{equation*}
$$

where we invoke the upper bound $\mu_{i}^{(h)} / \mu_{i}^{\star} \leq \bar{\varrho}$ by (ii).
Simplifying $\partial_{t} \bar{\omega}_{i}^{(h)}$ in the Growing Stage. We have by (D.1) that when $h \in \mathcal{B}$ and $i \in \mathcal{I}$,

$$
\begin{aligned}
& \sqrt{d_{e}} \cdot \partial_{t} \bar{\omega}_{i}^{(h)}=-(1 \pm \zeta) \cdot \sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} \cdot\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \cdot \bar{\omega}_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{(h)} \\
&-(1 \pm 2 \xi \pm H \bar{\varrho}) \cdot \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{\star} \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)}+(1 \pm \xi) \cdot \lambda_{i} \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)} \quad / /(\mathrm{D} .39) \& i \in \mathcal{I} \\
&\left( \pm\left(\nu_{3}+2 C \zeta\right)\right) \cdot \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{(h)}\right\rangle\right)}{L} \cdot\left\langle\boldsymbol{d} \odot \lambda \odot \phi,\left(\mu^{(h)}\right)^{\odot 2}\right\rangle \cdot\left(\bar{\omega}_{i}^{(h)}\right)^{2} \\
& \quad / /(\mathrm{D} .35) \&(\mathrm{D} .37) \& h \in \mathcal{B} \\
&=-\left(1 \pm\left(2 \zeta+\nu_{3}+2 C \zeta\right)\right) \cdot \sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} \cdot\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \\
& \cdot \bar{\omega}_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{(h)}+\lambda_{i} \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)}\left(-\mu_{i}^{\star} \bar{\omega}_{i}^{\star}+(1 \pm(4 \xi+2 H \bar{\varrho}+\xi))\right),
\end{aligned}
$$

where in the last equality we merge the error terms into the first term and invoke (v) on the upper bound of $\mu_{i}^{\star} \bar{\omega}_{i}^{\star} \leq 2$ to get the error term $4 \xi+2 H \bar{\varrho}+\xi$ out in the last line. Define $\widetilde{\xi}_{1}=4 \xi+2 H \bar{\varrho}+\xi$.

For the case $i \in \mathcal{I}$ with $h \in \mathcal{B} \backslash\left\{h_{i}^{*}\right\}$, we have a naive upper bound for this gradient

$$
\begin{align*}
\partial_{t} \bar{\omega}_{i}^{(h)} & \leq{\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)}\left(-\mu_{i}^{\star} \bar{\omega}_{i}^{\star}+\left(1 \pm \widetilde{\xi}_{1}\right)\right) \\
& \leq \bar{\varrho}{\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{(h)}\left(-\mu_{i}^{\star} \bar{\omega}_{i}^{\star}+\left(1 \pm \widetilde{\xi}_{1}\right)\right) \\
& \leq \bar{\varrho}{\sqrt{d_{e}}}^{-1} \lambda_{i} \sqrt{2 L \phi_{i}^{-1}} \bar{\omega}_{i}^{(h)}\left(-\mu_{i}^{\star} \bar{\omega}_{i}^{\star}+\left(1 \pm \widetilde{\xi}_{1}\right)\right), \tag{D.40}
\end{align*}
$$

where the second inequality holds by invoking the upper bound $\mu_{i}^{(h)} / \mu_{i}^{\star} \leq \bar{\varrho}$ by (ii) and the last inequality holds by invoking Condition C.14. For $\bar{\omega}_{i}^{\star}$ where $i \in \mathcal{I}$, we can further simplify the dynamics as

$$
\begin{align*}
\partial_{t} \bar{\omega}_{i}^{\star}= & -(1 \pm \underbrace{\left(2 \zeta+\nu_{3}+2 C \zeta+2 \nu_{2}\right)}_{\triangleq}) \cdot \sqrt{d_{e}}-\frac{1}{L} \frac{\exp \left(\left\langle\omega^{\star}, \omega^{\star}\right\rangle\right)}{L} E_{i}\left(\mu_{i}^{\star}\right)^{2} \cdot\left(\bar{\omega}_{i}^{\star}\right)^{2}  \tag{D.33}\\
& +{\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star} \bar{\omega}_{i}^{\star}\left(-\mu_{i}^{\star} \bar{\omega}_{i}^{\star}+\left(1 \pm \widetilde{\xi}_{1}\right)\right) \\
= & \left(1-\left(1+\left(1 \pm \widetilde{\zeta}_{1}\right) \cdot \frac{\exp \left(\left\langle\omega^{\star}, \omega^{\star}\right\rangle\right)}{L} d_{i} \phi_{i}\right) \mu_{i}^{\star} \bar{\omega}_{i}^{\star} \pm \widetilde{\xi}_{1}\right){\sqrt{d_{e}}}^{-1} \lambda_{i} \bar{\omega}_{i}^{\star} \mu_{i}^{\star} \\
= & \left(1-\left(1+\frac{\exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L} d_{i} \phi_{i}\right) \mu_{i}^{\star} \bar{\omega}_{i}^{\star} \pm \tau_{1}\right){\sqrt{d_{e}}}^{-1} \lambda_{i} \bar{\omega}_{i}^{\star} \mu_{i}^{\star}, \tag{D.41}
\end{align*}
$$

where we define $\tau_{1} \triangleq \widetilde{\xi}_{1}+2 e \widetilde{\zeta}_{1}+e^{1.1} 2 \omega_{0}^{2} d=4(C+1) e \zeta+4 e \nu_{2}+2 e \nu_{3}+5 \xi+2 H \bar{\varrho}+2 e^{1.1} \omega_{0}^{2} d \ll 1$. The scale of $\tau_{1}$ comes from the upper bound for $\bar{\omega}_{i}^{\star} \mu_{i}^{\star} \leq 2 /\left(1+d_{i} \phi_{i} L^{-1}\right)$ in (v) and also the upper bound $\left\langle\omega^{\left(h_{i}^{*}\right)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2} \leq 2 \omega_{0}^{2} d$ by (iii). For $\omega_{j}^{(h)}$ where $h \in \mathcal{B}$ and $j \in \mathcal{I}_{c}$, we have

$$
\begin{equation*}
\partial_{t} \log \omega_{j}^{(h)}=-\frac{1 \pm \widetilde{\zeta}_{1}}{\sqrt{d_{e}}} \cdot \sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} \cdot\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \cdot \bar{\omega}_{j}^{\left(h^{\prime}\right)}<0 \tag{D.42}
\end{equation*}
$$

since $\lambda_{j}=0$ and we can also combine (D.27) and (D.28) into (D.25) with error $\widetilde{\zeta}_{1}$ since $h \in \mathcal{B}$. Therefore, these $\omega_{j}^{(h)}$ monotonically decrease. For $h \in \mathcal{B}_{c}$ and $k \in\left[d_{y}\right]$, we can upper bound $\bar{\omega}_{k}^{(h)}$ as

$$
\begin{align*}
\partial_{t} \log \bar{\omega}_{k}^{(h)} \leq & 2 \mathbb{1}(k \in \mathcal{I}){\sqrt{d_{e}}}^{-1} \lambda_{k} \sqrt{L \phi_{k}^{-1}} \bar{\varrho}+\frac{2 C e^{1.1} \omega_{0}|\mathcal{I}| \bar{E} \sqrt{L} \bar{\varrho}}{L \sqrt{d_{e}}} \cdot \bar{\omega}_{i}^{(h)} \\
& +\left((4+2|\mathcal{I}| \bar{\varrho}) \bar{E} \bar{\varrho} L+\sigma^{2} d H\left|\mathcal{I}_{c}\right| \bar{\mu}^{2}\right) \cdot{\sqrt{d_{e}}}^{-1} C \zeta \cdot \bar{\omega}_{i}^{(h)} \tag{D.43}
\end{align*}
$$

where we define $\bar{\mu} \triangleq \max _{h \in[H], j \in \mathcal{I}_{c}} \mu_{j}^{(h)}(0)$. Here, the first term comes from upper bounding ${\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)}$ by the upper bound for $\mu_{i}^{(h)}$ in Condition C.14, the second and the third term come from the upper bounds in (D.36) and (D.38) respectively.

Simplification of $\partial_{t} \mu_{i}^{(h)}$. We copy the dynamics for $\mu_{i}^{(h)}$ as

$$
\begin{aligned}
\partial_{t} \mu_{i}^{(h)}= & -\lambda_{i} d_{i} \phi_{i}(1 \pm \zeta) \cdot \sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} \cdot \mu_{i}^{\left(h^{\prime}\right)} \mu_{i}^{(h)} \\
& -\lambda_{i} d_{i}(1 \pm \xi) \cdot \sum_{h^{\prime}=1}^{H} \bar{\omega}_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{(h)} \mu_{i}^{\left(h^{\prime}\right)} \mu_{i}^{(h)}+\lambda_{i} d_{i}(1 \pm \xi) \cdot \bar{\omega}_{i}^{(h)} \mu_{i}^{(h)} .
\end{aligned}
$$

For the first term, we have for $i \in \mathcal{I}$ that

$$
\frac{\lambda_{i} d_{i} \phi_{i} \cdot \sum_{h^{\prime}=1}^{H} \exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right) L^{-1} \cdot \mu_{i}^{\left(h^{\prime}\right)} \mu_{i}^{(h)}}{\lambda_{i} d_{i} \phi_{i} \cdot \exp \left(\left\langle\omega^{(h)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle\right) L^{-1} \cdot \mu_{i}^{\star} \mu_{i}^{(h)}} \leq 1+\frac{e^{1.1} \sum_{h^{\prime} \neq h_{i}^{*}} \mu_{i}^{\left(h^{\prime}\right)}}{\mu_{i}^{\star}} \leq 1+e^{1.1} H \bar{\varrho}=1+o(1) .
$$

As a result, for $\log \mu_{i}^{(h)}$ with $i \in \mathcal{I}$, it holds that

$$
\begin{equation*}
\partial_{t} \log \mu_{i}^{(h)}=\lambda_{i} d_{i}\left(-\left(1 \pm\left(2 \zeta+e^{1.1} H \bar{\varrho}\right)\right) \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle\right)}{L} \phi_{i} \mu_{i}^{\star}+\left(1-\bar{\omega}_{i}^{\star} \mu_{i}^{\star} \pm \widetilde{\xi}_{1}\right) \bar{\omega}_{i}^{(h)}\right) . \tag{D.44}
\end{equation*}
$$

In particular, for $h=h_{i}^{*}$, we have

$$
\begin{aligned}
\partial_{t} \log \mu_{i}^{\star} & =\lambda_{i} d_{i}\left(-\left(1 \pm\left(2 \zeta+e^{1.1} H \bar{\varrho}\right)\right) \frac{\exp \left(\left\langle\omega^{\left(h_{i}^{\star}\right)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle\right)}{L} \phi_{i} \mu_{i}^{\star}+\left(1-\bar{\omega}_{i}^{\star} \mu_{i}^{\star} \pm \widetilde{\xi}_{1}\right) \bar{\omega}_{i}^{\star}\right) \\
& =\lambda_{i} d_{i}\left(-\frac{\exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L} \phi_{i} \mu_{i}^{\star}+\left(1-\bar{\omega}_{i}^{\star} \mu_{i}^{\star} \pm \tau_{2}\right) \bar{\omega}_{i}^{\star}\right),
\end{aligned}
$$

where we define $\tau_{2} \triangleq \widetilde{\xi}_{1}+2 e^{1.1}\left(2 \omega_{0}^{2} d+2 \zeta+e^{1.1} H \varrho \bar{\varrho}\right)=5 \xi+2 H \bar{\varrho}+2 e^{1.1}\left(2 \omega_{0}^{2} d+2 \zeta+e^{1.1} H \bar{\varrho}\right) \ll 1$ and the scale of $\tau_{2}$ comes from the upper bound $\mu_{i}^{\star} / \bar{\omega}_{i}^{\star} \leq 2 L \phi_{i}^{-1}$ in (iv) together with the upper bound $\left\langle\omega^{\left(h_{i}^{*}\right)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2} \leq 2 \omega_{0}^{2} d$ by (iii). For $j \in \mathcal{I}_{c}$, we simply have

$$
\partial_{t} \log \mu_{j}^{(h)}=-\sigma^{2} d(1 \pm \zeta) \cdot \sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} \cdot \mu_{i}^{\left(h^{\prime}\right)} \leq-\sigma^{2} d(1-\zeta) L^{-1} \sum_{h^{\prime}=1}^{H} \mu_{j}^{\left(h^{\prime}\right)} .
$$

Another gradient we keep track of is $\log \mu_{i}^{\star}-\log \mu_{i}^{(h)}$ with $i \in \mathcal{I}$ and $h \neq h_{i}^{*}$, which satisfies

$$
\begin{aligned}
\partial_{t} \log \left(\frac{\mu_{i}^{\star}}{\mu_{i}^{(h)}}\right)= & \lambda_{i} d_{i}\left(\left(1-\bar{\omega}_{i}^{\star} \mu_{i}^{\star}\right) \cdot\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) \pm \widetilde{\xi}_{1}\left(1+\bar{\omega}_{i}^{\star} \mu_{i}^{\star}\right) \cdot\left(\bar{\omega}_{i}^{\star}+\bar{\omega}_{i}^{(h)}\right)\right) \\
& +\lambda_{i} d_{i} L^{-1} \phi_{i} \mu_{i}^{\star}\left(\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle\right)-\exp \left(\left\langle\omega^{\left(h_{i}^{*}\right)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle\right)\right) \\
& \pm\left(2 \zeta+e^{1.1} H \bar{\varrho}\right) \lambda_{i} d_{i} L^{-1} \phi_{i} \mu_{i}^{\star}\left(\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h_{i}^{\star}\right)}\right\rangle\right)+\exp \left(\left\langle\omega^{\left(h_{i}^{*}\right)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle\right)\right)
\end{aligned}
$$

Here, for the second terms, we follow a similar argument as in the warm-up stage and obtain

$$
\begin{aligned}
\lambda_{i} d_{i} \widetilde{\xi}_{1}\left(1+\bar{\omega}_{i}^{\star} \mu_{i}^{\star}\right) \cdot\left(\bar{\omega}_{i}^{\star}+\bar{\omega}_{i}^{(h)}\right) & \leq 2 \lambda_{i} d_{i} \tilde{\xi}_{1} \cdot\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) \cdot \frac{\bar{\omega}_{i}^{\star}}{\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}} \\
& \leq 4 \lambda_{i} d_{i} \tilde{\xi}_{1} \cdot\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) \cdot \frac{\max _{k \in \mathcal{I}} \lambda_{k} \phi_{k}^{-1}}{\lambda_{i} \phi_{i}^{-1}}
\end{aligned}
$$

where in the last inequality we invoke (ii) for the upper bound of $\bar{\omega}_{i}^{(h)} / \bar{\omega}_{i}^{\star}$ by its corresponding value at the end of the warm-up stage. For the third term, we observe that

$$
\begin{aligned}
& \lambda_{i} d_{i} L^{-1} \phi_{i} \mu_{i}^{\star}\left(\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle\right)-\exp \left(\left\langle\omega^{\left(h_{i}^{*}\right)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle\right)\right) \\
& \quad \geq \lambda_{i} d_{i} L^{-1} \phi_{i} \mu_{i}^{\star}\left(1-\exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}+2 \omega_{0}^{2} d\right)\right) \\
& \quad \geq-e^{1.1} \lambda_{i} d_{i} L^{-1} \phi_{i} \mu_{i}^{\star}\left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}+2 \omega_{0}^{2} d\right) .
\end{aligned}
$$

Combining the third and the fourth term, we have

$$
\begin{aligned}
& \lambda_{i} d_{i} L^{-1} \phi_{i} \mu_{i}^{\star}\left(\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle\right)-\exp \left(\left\langle\omega^{\left(h_{i}^{*}\right)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle\right)\right) \\
& \quad \pm\left(2 \zeta+e^{1.1} H \bar{\varrho}\right) \lambda_{i} d_{i} L^{-1} \phi_{i} \mu_{i}^{\star}\left(\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle\right)+\exp \left(\left\langle\omega^{\left(h_{i}^{*}\right)}, \omega^{\left(h_{i}^{*}\right)}\right\rangle\right)\right) \\
& \geq-\lambda_{i} d_{i} L^{-1} \phi_{i} \mu_{i}^{\star}\left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}+2 \omega_{0}^{2} d+4 \zeta+2 e^{1.1} H \bar{\varrho}\right) \\
& \geq-\lambda_{i} d_{i} L^{-1} \phi_{i}\left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}+2 \omega_{0}^{2} d+4 \zeta+2 e^{1.1} H \bar{\varrho}\right) \cdot \frac{\mu_{i}^{\star}}{\bar{\omega}_{i}^{\star}} \cdot \frac{\bar{\omega}_{i}^{\star}}{\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}} \cdot\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) .
\end{aligned}
$$

Using the upper bound $\mu_{i}^{\star} / \bar{\omega}_{i}^{\star} \leq 2 L \phi_{i}^{-1}$ in (v) and the upper bound for $\bar{\omega}_{i}^{(h)} / \bar{\omega}_{i}^{\star}$ by (ii), we have for $\log \mu_{i}^{\star}-\log \mu_{i}^{(h)}$ with $i \in \mathcal{I}$ and $h \neq h_{i}^{*}$ that

$$
\begin{align*}
\partial_{t} \log \left(\frac{\mu_{i}^{\star}}{\mu_{i}^{(h)}}\right) \geq & \lambda_{i} d_{i}\left(-4\left(\widetilde{\xi}_{1}+d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}+2 \omega_{0}^{2} d+4 \zeta+2 e^{1.1} H \bar{\varrho}\right) \frac{\max _{k \in \mathcal{I}} \lambda_{k} \phi_{k}^{-1}}{\lambda_{i} \phi_{i}^{-1}}\right. \\
& \left.+1-\bar{\omega}_{i}^{\star} \mu_{i}^{\star}\right) \cdot\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) \\
\geq & \lambda_{i} d_{i}\left(1-\bar{\omega}_{i}^{\star} \mu_{i}^{\star}-4\left(\tau_{2}+d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) \Phi_{i}^{-1}\right) \cdot\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right) \tag{D.45}
\end{align*}
$$

where we define $\Phi_{i}=\lambda_{i} \phi_{i}^{-1} /\left(\max _{k \in \mathcal{I}} \lambda_{k} \phi_{k}^{-1}\right)$.

## D.2.1 Coupled Growth of $\mu_{i}^{\star}$ and $\bar{\omega}_{i}^{\star}$.

We aim to show that $\mu_{i}^{\star}$ is roughly a function of $\bar{\omega}_{i}^{\star}$ during the growing stage. To this end, we define the following quantity

$$
\begin{equation*}
\pi_{i} \triangleq \mu_{i}^{\star} \cdot\left(\bar{\omega}_{i}^{\star}+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L \bar{\omega}_{i}^{\star}}\right) \tag{D.46}
\end{equation*}
$$

We always have nonnegative $\pi_{i}$. In the following, we only consider $\pi_{i} \in[1 / 2,2]$. We characterize the dynamics for $\log \pi_{i}$ as

$$
\partial_{t} \log \pi_{i}=\partial_{t} \log \mu_{i}^{\star}+\frac{\partial}{\partial \bar{\omega}_{i}^{\star}}\left(\bar{\omega}_{i}^{\star}+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L \bar{\omega}_{i}^{\star}}\right) \cdot \partial_{t} \bar{\omega}_{i}^{\star} .
$$

For the second part in the derivative, we have

$$
\begin{aligned}
& \frac{\partial}{\partial \bar{\omega}_{i}^{\star}}\left(\bar{\omega}_{i}^{\star}+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L \bar{\omega}_{i}^{\star}}\right) \\
& \quad=\frac{\mu_{i}^{\star}}{\pi_{i}} \cdot\left(1+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L}\left(-\frac{1}{\left(\bar{\omega}_{i}^{\star}\right)^{2}}+2 d_{i}\right)\right)
\end{aligned}
$$

Let us look at the scale of the following expression.

$$
\begin{aligned}
& \frac{\left(\mu_{i}^{\star}\right)^{2}}{d_{i}}\left|1+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L}\left(-\frac{1}{\left(\bar{\omega}_{i}^{\star}\right)^{2}}+2 d_{i}\right)\right| \\
& \quad \leq \frac{\left(\mu_{i}^{\star}\right)^{2}}{d_{i}}+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L d_{i}}\left(\frac{\left(\mu_{i}^{\star}\right)^{2}}{\left(\bar{\omega}_{i}^{\star}\right)^{2}}+2 d_{i}\left(\mu_{i}^{\star}\right)^{2}\right) \leq 4 e^{1.1}\left(\frac{L}{\phi_{i} d_{i}}+1\right),
\end{aligned}
$$

where we invoke the upper bound $\mu_{i}^{\star} / \bar{\omega}_{i}^{\star} \leq \sqrt{2} L \phi_{i}^{-1}$ by (iv) and the upper bound $\left(\mu_{i}^{\star}\right)^{2} \leq 2 L \phi_{i}^{-1}$ by Condition C.14. We can also rewrite $\partial_{t} \log \mu_{i}^{\star}$ and $\partial_{t} \bar{\omega}_{i}^{\star}$ in terms of $\pi_{i}$ as

$$
\begin{gather*}
\partial_{t} \log \mu_{i}^{\star}=\lambda_{i} d_{i} \bar{\omega}_{i}^{\star}\left(1-\pi_{i} \pm \tau_{2}\right), \\
\partial_{t} \bar{\omega}_{i}^{\star}={\sqrt{d_{e}}}^{-1} \lambda_{i} \bar{\omega}_{i}^{\star} \mu_{i}^{\star}\left(1-\pi_{i}+\frac{\exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) \phi_{i}}{L} \cdot \frac{\mu_{i}^{\star}}{\bar{\omega}_{i}^{\star}} \cdot\left(1-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) \pm \tau_{1}\right) . \tag{D.47}
\end{gather*}
$$

Here, for $\partial_{t} \bar{\omega}_{i}^{\star}$ we also have the following upper bound

$$
\left|\partial_{t} \bar{\omega}_{i}^{\star}\right| \leq \frac{\lambda_{i} \bar{\omega}_{i}^{\star} \mu_{i}^{\star}}{\sqrt{d_{e}}} \cdot\left(\left|1-\pi_{i}\right|+\sqrt{2} e^{1.1}+\tau_{1}\right),
$$

where we invoke the upper bound $\mu_{i}^{\star} / \bar{\omega}_{i}^{\star} \leq \sqrt{2} L \phi_{i}^{-1}$ by (iv). Therefore, we have for $\partial_{t} \log \pi_{i}$ that

$$
\begin{aligned}
\partial_{t} \log \pi_{i} & =\lambda_{i} d_{i} \bar{\omega}_{i}^{\star}\left(1-\pi_{i} \pm \tau_{2} \pm \frac{1}{\sqrt{d_{e}} \pi_{i}} \cdot\left(\left|1-\pi_{i}\right|+\sqrt{2} e^{1.1}+\tau_{1}\right) \cdot 4 e^{1.1}\left(\frac{L}{\phi_{i} d_{i}}+1\right)\right) \\
& =\lambda_{i} d_{i} \bar{\omega}_{i}^{\star}(1-\pi_{i} \pm \underbrace{\left(\tau_{2}+120 \varsigma_{i}+120{\sqrt{d_{e}}}^{-1}\right)}_{\leq \iota_{i}}) .
\end{aligned}
$$

Define $\iota_{i} \triangleq \max \left\{\tau_{2}+120 \varsigma_{i}+120{\sqrt{d_{e}}}^{-1}, \alpha_{i}+17 d_{i} \omega_{0}^{2}+32 L \omega_{0}^{2} \phi_{i}^{-1}\right\}$, we automatically have from $1-\alpha_{i} \leq \rho_{i}^{*} \phi_{i} \leq 1+\widetilde{\xi}+2 \widetilde{\zeta}$ that at the start of the growing phase, $\pi$ satisfies the following upper bound

$$
\begin{aligned}
\left|\pi_{i}\left(T_{\text {warmup }}\right)-1\right| & \left.=\left|L \rho_{i}^{*} \cdot\left(\left(\bar{\omega}_{i}^{\star}\right)^{2}+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L}\right)-1\right|_{T_{\text {warmup }}} \right\rvert\, \\
& \leq\left(1+\alpha_{i}\right) \cdot\left(1+d_{i} 16 \omega_{0}^{2}\right)-1+32 L \omega_{0}^{2} \phi_{i}^{-1} \\
& \leq \alpha_{i}+17 d_{i} \omega_{0}^{2}+32 L \omega_{0}^{2} \phi_{i}^{-1} .
\end{aligned}
$$

As a result, during the growing stage, we always have $\pi_{i} \in\left[1-\iota_{i}, 1+\iota_{i}\right] \subset[0.5,1.5]$.

## D.2.2 Duration of the Growing Stage.

Under the definition $\pi_{i}=\mu_{i}^{\star} \cdot\left(\bar{\omega}_{i}^{\star}+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L \bar{\omega}_{i}^{\star}}\right)$ and condition $\pi_{i} \in\left[1-\iota_{i}, 1+\iota_{i}\right]$, we have for $\partial_{t} \bar{\omega}_{i}^{\star}$ following (D.47) that

$$
\begin{align*}
\partial_{t} \bar{\omega}_{i}^{\star}= & \left(1-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}+\left(1-\pi_{i}\right)\left(\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}+d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)\right) \pi_{i}{\sqrt{d_{e}}}^{-1} \lambda_{i} \\
& \cdot\left(1+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}\right)^{-1} \cdot\left(1+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}\right)^{-1} \\
= & \left(1-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2} \pm 2 \iota_{i}\left(L d_{i}^{-1} \phi_{i}^{-1}+1\right)\right) \cdot\left(1 \pm \iota_{i}\right){\sqrt{d_{e}}}^{-1} \lambda_{i} \\
& \cdot\left(2+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}\right)^{-1}, \tag{D.48}
\end{align*}
$$

where in the second equality we also invoke the upper bound $\left(\bar{\omega}_{i}^{\star}\right)^{2} \leq 2 d_{i}^{-1}$ by Condition C. 14 to simplify the numerator. Define $\widetilde{\iota}_{i}=2 \iota_{i}\left(L d_{i}^{-1} \phi_{i}^{-1}+1\right) \ll 1$ and consider the regime where $d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2} \leq 1-2 \widetilde{\iota}$. . Equivalently, we have

$$
\begin{equation*}
\frac{\mathrm{d} t}{\mathrm{~d}\left(\bar{\omega}_{i}^{\star}\right)}=\frac{2+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}}{\left(1-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2} \pm \widetilde{\iota}_{i}\right) \cdot\left(1 \pm \iota_{i}\right) \sqrt{d_{e}}{ }^{-1} \lambda_{i}} . \tag{D.49}
\end{equation*}
$$

We first pick $v<1-2 \widetilde{\iota_{i}}$ such that $1-v \geq 3 \widetilde{\iota_{i}}$ and consider the regime where $d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2} \leq v$. In this regime, we can upper bound the above expression by

$$
\frac{\mathrm{d} t}{\mathrm{~d}\left(\bar{\omega}_{i}^{\star}\right)} \leq\left(1+2 \widetilde{\iota_{i}}\right) \cdot \frac{2+\frac{\phi_{i} e^{v}}{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}{\phi_{i}}}{(1-v){\sqrt{d_{e}}}^{-1} \lambda_{i}}=\frac{\left(1+2 \widetilde{\iota_{i}}\right) \cdot \sqrt{d_{e}}}{(1-v) \lambda_{i}} \cdot \frac{\mathrm{~d}}{\mathrm{~d}\left(\bar{\omega}_{i}^{\star}\right)}\left(2\left(\bar{\omega}_{i}^{\star}\right)-\frac{\phi_{i} e^{v}}{L\left(\bar{\omega}_{i}^{\star}\right)}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{3}}{3 \phi_{i}}\right) .
$$

Therefore, the duration of this regime $\Delta t_{6+}^{i}$ where $d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}$ is raised from the value at the end of the warm-up stage to $v$ is upper bounded by

$$
\begin{align*}
\Delta t_{6}^{i} & \leq\left.\frac{\left(1+2 \widetilde{\iota_{i}}\right) \cdot \sqrt{d_{e}}}{(1-v) \lambda_{i}}\left(2\left(\bar{\omega}_{i}^{\star}\right)-\frac{\phi_{i} e^{v}}{L\left(\bar{\omega}_{i}^{\star}\right)}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{3}}{3 \phi_{i}}\right)\right|_{\omega_{0}} ^{\sqrt{v / d_{i}}} \\
& \leq \frac{\left(1+2 \widetilde{\iota}_{i}\right) \cdot \sqrt{d_{e}}}{(1-v) \lambda_{i}}\left(2 \sqrt{v d_{i}}+\frac{\phi_{i} e^{v}}{L \omega_{0}}+\frac{L v^{3 / 2}}{3 \phi_{i} d_{i}^{3 / 2}}\right) . \tag{D.50}
\end{align*}
$$

One should notice that the second term in the above expression dominates as $\omega_{0}$ is small in the sense that $\omega_{0} \ll\left(\phi_{i} L^{-1}{\sqrt{d_{i}}}^{-1}\right) \wedge\left(\phi_{i}^{2} L^{-2} d_{i}^{3 / 2}\right)$. For the other regime where $v \leq d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2} \leq 1-2 \widetilde{\iota_{i}}$, we have

$$
\begin{equation*}
\frac{\mathrm{d} t}{\mathrm{~d}\left(\bar{\omega}_{i}^{\star}\right)} \leq \underbrace{\left(2+\max _{x \in\left\{\sqrt{v / d_{i}}, \sqrt{1 / d_{i}}\right\}}\left\{\frac{\phi_{i} \exp \left(d_{i} x^{2}\right)}{L x^{2}}+\frac{L x^{2}}{\phi_{i} \exp \left(d_{i} x^{2}\right)}\right\}\right)}_{\triangleq \Gamma_{i}} \cdot \frac{\sqrt{d_{e}} \lambda_{i}^{-1}}{\left(1-\widetilde{\iota}_{i}-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)\left(1-\iota_{i}\right)} . \tag{D.51}
\end{equation*}
$$

Here, a typical choice of $v$ is $1 / 2$ for the definition of $\Gamma_{i}$. By integrating the above expression for $\bar{\omega}_{i}^{\star}$ between the above mentioned range, we have

$$
\Delta t_{7}^{i} \leq \frac{\Gamma_{i} \sqrt{d_{e}} \lambda_{i}^{-1}}{\sqrt{d_{i}\left(1-\widetilde{\iota_{i}}\right)^{3}}} \cdot\left(\tanh ^{-1}\left(\sqrt{\frac{1-2 \widetilde{\iota_{i}}}{1-\widetilde{\iota_{i}}}}\right)-\tanh ^{-1}\left(\sqrt{\frac{v}{1-\widetilde{\iota_{i}}}}\right)\right) \leq \frac{\Gamma_{i} \sqrt{d_{e}} \lambda_{i}^{-1}}{\sqrt{d_{i}\left(1-\widetilde{\left.\iota_{i}\right)^{3}}\right.}} \cdot \frac{1}{2} \log \frac{4}{\widetilde{\iota_{i}}}
$$

where the last inequality follows from upper bounding the positive term in the inverse hyperbolic tangent function.

## D.2.3 Verifying the Conditions for the Growing Stage.

Verification for (i). We first verify that $\mu_{i}^{\star} \geq L \phi_{i}^{-1} \omega_{0} / \sqrt{2}$ in (i) for $i \in \mathcal{I}$ during the growing stage. Using the fact that $\pi_{i} \in\left[1-\iota_{i}, 1+\iota_{i}\right]$, we have

$$
\mu_{i}^{\star} \geq\left(\left(\bar{\omega}_{i}^{\star}\right)+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L\left(\bar{\omega}_{i}^{\star}\right)}\right)^{-1} \cdot\left(1-\iota_{i}\right) .
$$

It remains to check that $\left(\bar{\omega}_{i}^{\star}\right) \geq \omega_{0}$. Invoking (D.48), we can easily observe that for $\left(\bar{\omega}_{i}^{\star}\right)<1 / \sqrt{2 d_{i}}$, we have $\partial_{t}\left(\bar{\omega}_{i}^{\star}\right)>0$. Since at the end of the warm-up stage, we already have $\left(\bar{\omega}_{i}^{\star}\right) \geq \omega_{0}$, we can conclude that $\left(\bar{\omega}_{i}^{\star}\right) \geq \omega_{0}$ for all $i \in \mathcal{I}$ during the growing stage.

Verification for (ii). We next check the conditions in (ii). We first show that $\left(\bar{\omega}_{i}^{\star}\right) \geq \bar{\omega}_{i}^{(h)}$ and $\left(\bar{\omega}_{i}^{\star}\right) / \bar{\omega}_{i}^{(h)} \geq\left(\bar{\omega}_{i}^{\star}\right) /\left.\bar{\omega}_{i}^{(h)}\right|_{T_{\text {warrup }}}$ hold for all $i \in \mathcal{I}$ and $h \in \mathcal{B} \backslash\left\{h_{i}^{*}\right\}$. Invoking (D.40) and (D.41), we have for $\partial_{t}\left(\log \left(\bar{\omega}_{i}^{\star}\right)-\log \bar{\omega}_{i}^{(h)}\right)$ that

$$
\begin{aligned}
& \partial_{t}\left(\log \frac{\left(\bar{\omega}_{i}^{\star}\right)}{\bar{\omega}_{i}^{(h)}}\right) \geq\left(1-\left(1+\frac{\exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L} d_{i} \phi_{i}\right) \mu_{i}^{\star}\left(\bar{\omega}_{i}^{\star}\right) \pm \tau_{1}\right){\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star} \\
&-\left(-\mu_{i}^{\star} \bar{\omega}_{i}^{\star}+\left(1 \pm \widetilde{\xi}_{1}\right)\right){\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{(h)} .
\end{aligned}
$$

We split the discussion into two cases based on whether $\left(\bar{\omega}_{i}^{\star}\right) \mu_{i}^{\star}<1 /\left(1+2 e^{1.1} d_{i} \phi_{i} L^{-1}\right)$ or not. If the condition holds, we have following the upper bound $\left(\bar{\omega}_{i}^{\star}\right) \leq(1+o(1)) \sqrt{d_{i}^{-1}}$ by Condition C. 14 that

$$
\partial_{t}\left(\log \frac{\left(\bar{\omega}_{i}^{\star}\right)}{\bar{\omega}_{i}^{(h)}}\right) \geq\left(\frac{e^{1.1} d_{i} \phi_{i} L^{-1}}{1+2 e^{1.1} d_{i} \phi_{i} L^{-1}}-\tau_{1}\right){\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star}-\left(1+\tilde{\xi}_{1}\right){\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{(h)} .
$$

At this point, we invoke the ratio argument $\mu_{i}^{\star} / \mu_{i}^{(h)} \geq \mu_{i}^{\star} /\left.\mu_{i}^{(h)}\right|_{T_{\text {warrup }}} \geq \bar{\varrho}^{-1}$ for any $i \in \mathcal{I}$ in (ii) that

$$
\partial_{t}\left(\log \frac{\left(\bar{\omega}_{i}^{\star}\right)}{\bar{\omega}_{i}^{(h)}}\right) \geq\left(\frac{e^{1.1} d_{i} \phi_{i} L^{-1}}{1+2 e^{1.1} d_{i} \phi_{i} L^{-1}}-\tau_{1}-2 \bar{\varrho}\right){\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star}>0
$$

where we invoke the relationship $\min \left\{e^{1.1} d_{i} \phi_{i} L^{-1}, 1\right\} \gg \tau_{1} \vee \bar{\varrho}$. Therefore, we have $\left(\bar{\omega}_{i}^{\star}\right) / \bar{\omega}_{i}^{(h)}$ growing throughout the first case (Also, note that ( $\bar{\omega}_{i}^{\star}$ ) is also growing under this condition).

Hence, both conditions are satisfied for the first case. For the other case, since we already have $\left(\bar{\omega}_{i}^{\star}\right) \mu_{i}^{\star} \geq 1 /\left(1+2 e^{1.1} d_{i} \phi_{i} L^{-1}\right)$, by incorporating the relationship between ( $\bar{\omega}_{i}^{\star}$ ) and $\mu_{i}^{\star}$ in (D.46) we conclude that $\left(\bar{\omega}_{i}^{\star}\right) \geq \sqrt{1 / 2 d_{i}}$. Therefore, we just need to check that $\bar{\omega}_{i}^{(h)}$ is still somewhere near the initialization. To do so, we incorporate the upper bound for the duration of the growing stage

$$
\Delta t_{6}^{i}+\Delta t_{7}^{i} \leq \max _{k \in \mathcal{I}}\left(2 \frac{\left(1+2 \widetilde{\iota_{k}}\right) \cdot \sqrt{d_{e}}}{(1-v) \lambda_{k}} \cdot \frac{\phi_{k} e^{v}}{L \omega_{0}}+\frac{\Gamma_{k} \sqrt{d_{e}} \lambda_{k}^{-1}}{\sqrt{d_{k}\left(1-\widetilde{\iota}_{k}\right)^{3}}} \cdot \frac{1}{2} \log \frac{4}{\widetilde{\iota}_{k}}\right)
$$

where $v \in(0,1)$ is a absolute constant and $\widetilde{\iota}_{i} \ll 1$ is a chosen small constant. We can now upper bound the maximal value of $\bar{\omega}_{i}^{(h)}$ for $i \in \mathcal{I}$ and $h \neq h_{i}^{*}$ during the growing stage as

$$
\begin{align*}
\log \frac{\bar{\omega}_{i}^{(h)}}{\bar{\omega}_{i}^{(h)}\left(T_{\text {warmup }}\right) \leq} \leq & \bar{\varrho} \lambda_{i} \sqrt{2 L \phi_{i}^{-1}}\left(-\mu_{i}^{\star} \bar{\omega}_{i}^{\star}+\left(1 \pm \widetilde{\xi}_{1}\right)\right) \\
& \cdot \max _{k \in \mathcal{I}}\left(2 \frac{\left(1+2 \widetilde{\iota}_{k}\right)}{(1-v) \lambda_{k}} \cdot \frac{\phi_{k} e^{v}}{L \omega_{0}}+\frac{\Gamma_{k} \lambda_{k}^{-1}}{\sqrt{d_{k}\left(1-\widetilde{\iota}_{k}\right)^{3}}} \cdot \frac{1}{2} \log \frac{4}{\widetilde{\iota_{k}}}\right)=o(1) . \tag{D.52}
\end{align*}
$$

As we have $\omega_{0} \gg \varrho \bar{\rho}$ poly $(L)$ thanks to the exponential decay in $\bar{\varrho}$, the above expression is $o(1)$ for the scale of $\widetilde{\iota}_{i}$ that $\widetilde{\iota_{i}} \geq \varsigma_{i}$. Therefore, for the second case, we still have $\left(\bar{\omega}_{i}^{\star}\right)>\bar{\omega}_{i}^{(h)}$ and $\left(\bar{\omega}_{i}^{\star}\right) / \bar{\omega}_{i}^{(h)} \geq\left(\bar{\omega}_{i}^{\star}\right) /\left.\bar{\omega}_{i}^{(h)}\right|_{T_{\text {warmup }}}$ for all $i \in \mathcal{I}$ and $h \neq h_{i}^{*}$ during the growing stage.

For the case $h \in \mathcal{B}_{c}$, we have the upper bound for $\partial_{t} \log \bar{\omega}_{i}^{(h)}$ in (D.43). Note that for $\left(\bar{\omega}_{i}^{\star}\right) \mu_{i}^{\star}<$ $1 /\left(1+2 e^{1.1} d_{i} \phi_{i} L^{-1}\right)$, we have

$$
\partial_{t} \log \left(\bar{\omega}_{i}^{\star}\right) \geq\left(\frac{e^{1.1} d_{i} \phi_{i} L^{-1}}{1+2 e^{1.1} d_{i} \phi_{i} L^{-1}}-\tau_{1}\right){\sqrt{d_{e}}}^{-1} \lambda_{i} \mu_{i}^{\star} .
$$

For the terms in (D.43) with $\bar{\varrho}$, the above expression automatically dominates thanks to the exponentially small scale of $\bar{\varrho}$ and the fact that $\bar{\omega}_{i}^{(h)} \leq \sqrt{2} \omega_{0}$ when (iii) holds. The only term we need to consider is $\sigma^{2} d H\left|\mathcal{I}_{c}\right| \bar{\mu}^{2} \cdot{\sqrt{d_{e}}}^{-1} C \zeta \cdot \bar{\omega}_{i}^{(h)} \leq \sigma^{2} d H\left|\mathcal{I}_{c}\right| \bar{\mu}^{2} \cdot \sqrt{d_{e}}{ }^{-1} C \zeta \cdot \sqrt{2} \omega_{0}$. Therefore, we have for the time-derivative of $\log \left(\left(\bar{\omega}_{i}^{\star}\right) / \bar{\omega}_{i}^{(h)}\right)$ that

$$
\begin{aligned}
\partial_{t} \log \frac{\left(\bar{\omega}_{i}^{\star}\right)}{\bar{\omega}_{i}^{(h)}} & \geq\left(\frac{e^{1.1} d_{i} \phi_{i} L^{-1}}{1+2 e^{1.1} d_{i} \phi_{i} L^{-1}}-\tau_{1}-\varrho \bar{\varrho} \operatorname{poly}(L)\right) \frac{\lambda_{i} \mu_{i}^{\star}}{\sqrt{d_{e}}}-\frac{\sigma^{2} d H\left|\mathcal{I}_{c}\right| \bar{\mu}^{2} \cdot C \zeta \cdot \sqrt{2} \omega_{0}}{\sqrt{d_{e}}} \\
& \geq\left(\frac{d_{i} \phi_{i}}{L} \cdot\left(\frac{e^{1.1}}{1+2 e^{1.1} d_{i} \phi_{i} L^{-1}}-\frac{2 C H\left|\mathcal{I}_{c}\right| \bar{\mu}^{2} \zeta}{\operatorname{SNR}[i]}\right)-\tau_{1}-\bar{\varrho} \operatorname{poly}(L)\right) \frac{\lambda_{i} \mu_{i}^{\star}}{\sqrt{d_{e}}}
\end{aligned}
$$

By our initialization condition that $\bar{\mu}^{2} \ll \operatorname{SNR}[i] \cdot\left(1 \wedge L /\left(d_{i} \phi_{i}\right)\right) /\left(H\left|\mathcal{I}_{c}\right| \zeta\right)$, we have the above expression being positive. On the other hand, as $\left(\bar{\omega}_{i}^{\star}\right) \mu_{i}^{\star} \geq 1 /\left(1+2 e^{1.1} d_{i} \phi_{i} L^{-1}\right)$, we have $\left(\bar{\omega}_{i}^{\star}\right) \geq$ $\sqrt{1 / 2 d_{i}}$. Similar to the previous case for $h \in \mathcal{B}$, we can upper bound the total drift of $\log \bar{\omega}_{i}^{(h)}$ for $h \in \mathcal{B}_{c}$ as

$$
\begin{aligned}
\log \frac{\bar{\omega}_{i}^{(h)}}{\bar{\omega}_{i}^{(h)}\left(T_{\text {warmup }}\right) \leq} & \left(\sqrt{2} \sigma^{2} d H\left|\mathcal{I}_{c}\right| \bar{\mu}^{2} \cdot C \zeta+\bar{\varrho} \operatorname{poly}(L) \omega_{0}^{-1}\right) \\
& \cdot \max _{k \in \mathcal{I}}\left(2 \frac{\left(1+2 \widetilde{\iota}_{k}\right)}{(1-v) \lambda_{k}} \cdot \frac{\phi_{k} e^{v}}{L}+\frac{\Gamma_{k} \lambda_{k}^{-1} \omega_{0}}{\sqrt{d_{k}\left(1-\widetilde{\iota}_{k}\right)^{3}}} \cdot \frac{1}{2} \log \frac{4}{\widetilde{\iota}_{k}}\right) .
\end{aligned}
$$

Note that the above terms are $o(1)$ given the scale of $\zeta \bar{\mu}^{2} d \ll 1$ and $\widetilde{\iota_{i}} \geq \varsigma_{i}$.
Next, we have the argument for $\mu_{i}^{\star} / \mu_{i}^{(h)}$ that the ratio is non-decreasing. Recall the lower bound for $\partial_{t} \log \left(\mu_{i}^{\star} / \mu_{i}^{(h)}\right)$ in (D.45). Before ( $\bar{\omega}_{i}^{\star}$ ) reaches $10 \omega_{0}$, we have obviously that the gradient is non-negative for $\log \left(\mu_{i}^{\star} / \mu_{i}^{(h)}\right)$. On the other hand, after $\left(\bar{\omega}_{i}^{\star}\right)$ reaches $10 \omega_{0}$, we have following from (D.44) and the definition of $\pi_{i}$ that

$$
\begin{aligned}
\partial_{t} \log \mu_{i}^{(h)} \leq & \lambda_{i} d_{i}\left(-\left(1-\left(2 \zeta+e^{1.1} H \varrho \bar{\varrho}\right)\right) \phi_{i} L^{-1} \mu_{i}^{\star}+\left(1-\left(\bar{\omega}_{i}^{\star}\right) \mu_{i}^{\star}+\widetilde{\xi}_{1}\right) \bar{\omega}_{i}^{(h)}\right) \\
\leq & \lambda_{i} d_{i}\left(\bar{\omega}_{i}^{\star}\right)\left(\left(1-\left(\bar{\omega}_{i}^{\star}\right) \mu_{i}^{\star}+\widetilde{\xi}_{1}\right) \frac{\bar{\omega}_{i}^{(h)}}{\left(\bar{\omega}_{i}^{\star}\right)}\right. \\
& \left.\quad-\left(1-\left(2 \zeta+e^{1.1} H \bar{\varrho}\right)\right)\left(\pi_{i}-\mu_{i}^{\star}\left(\bar{\omega}_{i}^{\star}\right)\right) \exp \left(-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)\right) \\
\leq & -\lambda_{i} d_{i}\left(\bar{\omega}_{i}^{\star}\right)\left(1-\left(2 \zeta+e^{1.1} H \bar{\varrho}\right)\right) \exp \left(-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) \\
& \cdot\left(1-\mu_{i}^{\star}\left(\bar{\omega}_{i}^{\star}\right)-2 \iota_{i}-2 \widetilde{\xi}_{1}\right) \cdot\left(1-e^{1.1}\left(1+4 \zeta+e^{1.1} H \bar{\varrho}\right) \frac{1+o(1)}{10}\right) .
\end{aligned}
$$

We note that

$$
\begin{aligned}
1-\mu_{i}^{\star}\left(\bar{\omega}_{i}^{\star}\right) & =1-\pi_{i}^{-1}\left(1+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}\right)^{-1} \\
& \geq \frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) /\left(L\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{1+\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) /\left(L\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}-\iota_{i} \\
& \geq \min \left\{\frac{1}{2}, \frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{2 L\left(\bar{\omega}_{i}^{\star}\right)^{2}}\right\}-\iota_{i} \geq \min \left\{\frac{1}{2}, \frac{d_{i} \phi_{i} e}{2 L}\right\}-\iota_{i} .
\end{aligned}
$$

Under the condition that $\min \left\{1, d_{i} \phi_{i} / L\right\} \gg 3 \iota_{i}+2 \tilde{\xi}_{1}$, we have that $\partial_{t} \log \mu_{i}^{(h)} \leq 0$. As $\mu_{i}^{\star}$ is no smaller than the corresponding value when $\left(\bar{\omega}_{i}^{\star}\right)=10 \omega_{0}$, the ratio $\mu_{i}^{\star} / \mu_{i}^{(h)}$ is no smaller than $1 / \bar{\varrho}$.

Verification for (iii). We next check the conditions in (iii). In the previous paragraph, we have already verified that $\bar{\omega}_{i}^{(h)} \leq(1+o(1)) \omega_{0}$ for all $i \in \mathcal{I}$ and $h \neq h_{i}^{*}$ during the growing stage. It remains to characterize the condition for other $j \in \mathcal{I}_{c}$. However, this is trivial as we have $\partial_{t} \log \omega_{j}^{(h)} \leq 0$ for all $j \in \mathcal{I}_{c}$ due to (D.42).

Verification for (iv). We just use the fact that $\pi_{i} \in\left[1-\iota_{i}, 1+\iota_{i}\right]$ to conclude for the ratio $\mu_{i}^{\star} /\left(\bar{\omega}_{i}^{\star}\right)$ that

$$
\frac{\mu_{i}^{\star}}{\left(\bar{\omega}_{i}^{\star}\right)}=\frac{\pi_{i}}{\left(\bar{\omega}_{i}^{\star}\right)^{2}+\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) L^{-1}} .
$$

An upper bound is given by

$$
\frac{\mu_{i}^{\star}}{\left(\bar{\omega}_{i}^{\star}\right)} \leq \frac{1+\iota_{i}}{\phi_{i} L^{-1}} \leq \sqrt{2} L \phi_{i}^{-1},
$$

and an lower bound is given by

$$
\frac{\mu_{i}^{\star}}{\left(\bar{\omega}_{i}^{\star}\right)} \geq \frac{1-\iota_{i}}{2 d_{i}+\phi_{i} e^{1.1} L^{-1}} \geq \frac{d_{i} \wedge L e^{-1} \phi_{i}^{-1}}{4}
$$

where we invoke the upper bound for $\left(\bar{\omega}_{i}^{\star}\right)$ in Condition C. 14 to simplify the denominator.

Verification for ( $\mathbf{v}$ ). Following the definition of $\pi_{i}$ in (D.46), we have

$$
\mu_{i}^{\star}\left(\bar{\omega}_{i}^{\star}\right)=\frac{\pi_{i}}{1+\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) L^{-1} /\left(\bar{\omega}_{i}^{\star}\right)^{2}} \leq \frac{1+\iota_{i}}{1+\phi_{i} L^{-1} d_{i} / 2} \leq \frac{2}{1+d_{i} \phi_{i} L^{-1}}
$$

where the last inequality holds as we have $L \phi_{i}^{-1} d_{i}^{-1} \gg \iota_{i}$.

## D.2.4 Emergence and Convergence of the Growing Stage

Recall that we rescale the time as $t \leftarrow 2 d t$.

Convergence We first check if the dynamics converge or not after the growing stage. By (D.48), after $d_{i} \bar{\omega}_{i}^{\star 2} \geq 1-2 \widetilde{\iota}$, we still have for $d_{i} \bar{\omega}_{i}^{\star 2}$ around 1 that

$$
\begin{gathered}
\partial_{t} \bar{\omega}_{i}^{\star}=\left(1-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2} \pm 2 \iota_{i}\left(L d_{i}^{-1} \phi_{i}^{-1}+1\right)\right) \cdot\left(1 \pm \iota_{i}\right){\sqrt{d_{e}}}^{-1} \lambda_{i} \\
\cdot\left(2+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}\right)^{-1}
\end{gathered}
$$

Notably, if $d_{i} \bar{\omega}_{i}^{\star 2}$ grows larger than $1+2 \widetilde{\iota_{i}}$, the dynamics will "draw" the values back. Thus, we prove that $d_{i} \bar{\omega}_{i}^{\star}$ will be roughly $1 \pm 2 \tilde{\iota_{i}}$, which shows the convergence for $\bar{\omega}_{i}^{\star}$. Since $\pi_{i}$ is "fixed" around $1 \pm \iota_{i}$, we also have $\mu_{i}^{\star}$ "fixed" around

$$
\frac{1 \pm \iota_{i}}{1+\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) L^{-1} /\left(\bar{\omega}_{i}^{\star}\right)^{2}}=\frac{1 \pm \iota_{i}}{1+d_{i} \phi_{i} e L^{-1}\left(1 \pm \widetilde{\iota_{i}}\right)}
$$

For other nonoptimal head, we have following the same argument as (D.52) that

$$
\log \frac{\bar{\omega}_{i}^{(h)}(t)}{\bar{\omega}_{i}^{(h)}\left(T_{\text {warmup }}\right)} \leq \bar{\varrho} \lambda_{i} \sqrt{2 L \phi_{i}^{-1}}\left(-\mu_{i}^{\star} \bar{\omega}_{i}^{\star}+\left(1 \pm \tilde{\xi}_{1}\right)\right) \cdot T=o(1)
$$

thanks to the scale $\bar{\varrho}=\max _{i \in[I]}(H-1)^{-1} \gamma_{i} \exp \left(-\vartheta^{2} /\left(256 \varsigma_{i}\right)\right)$ where $\varsigma_{i}=L /\left(\sqrt{d_{e}} d_{i} \phi_{i}\right) \approx 1 / \sqrt{d_{e}}$ as long as $T \ll \exp \left(O\left(\sqrt{d_{e}}\right)\right)$. This is a fairly long time given that $d_{e} \geq d$. Moreover, as we have discussed, for the nonoptimal head, $\mu_{i}^{(h)}$ dies down as $\partial_{t} \log \mu_{i}^{(h)}<0$. Thus, we have shown the convergence.

Convergence Rate. We integrate (D.51) for $\bar{\omega}_{i}^{\star}$ between $\sqrt{v / d_{i}}$ and $\sqrt{(1-\delta) / d_{i}}$ where $\delta \in$ $\left(2 \tilde{\iota}_{i}, 1-v\right)$ can be arbitrarily picked, we have the following upper bound on the required $t$ to raise $\bar{\omega}_{i}^{\star}$ from $\sqrt{v / d_{i}}$ to $\sqrt{(1-\delta) / d_{i}}$ :

$$
t \leq \frac{\Gamma_{i} \sqrt{d_{e}} \lambda_{i}^{-1}}{\sqrt{d_{i}\left(1-\widetilde{\left.\iota_{i}\right)^{3}}\right.}} \cdot\left(\tanh ^{-1}\left(\sqrt{\frac{1-\delta}{1-\widetilde{\iota_{i}}}}\right)-\tanh ^{-1}\left(\sqrt{\frac{v}{1-\widetilde{\iota_{i}}}}\right)\right) \leq \frac{\Gamma_{i} \sqrt{d_{e}} \lambda_{i}^{-1}}{\sqrt{d_{i}\left(1-\widetilde{\left.\iota_{i}\right)^{3}}\right.}} \cdot \frac{1}{2} \log \frac{4}{\delta}
$$

This clearly shows the convergence rate.

Emergence. The next theorem characterizes the emergence behavior of the dynamics.
Theorem D. 11 (Emergence Behavior). Define

$$
T_{0}=2 d \cdot \frac{\phi_{i} \sqrt{d_{e}}}{\lambda_{i} L \omega_{0}} .
$$

Pick an absolute constant $v \in(0,1 / 4)$. Then, the following holds:

- For the total time less than $(1-v-o(1)) T_{0}$, we must have $\bar{\omega}_{i}^{\star} \leq v^{-1} \omega_{0}$. The loss for task $i$ is a least

$$
\Omega\left(\frac{\lambda_{i} d_{i}}{d}\right) .
$$

- For the total time larger than $(1+e v) T_{0}$, we must have $d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2} \geq v$. The loss for task $i$ is at most

$$
O\left(\frac{\lambda_{i} d_{i}}{d} \cdot\left(1-\frac{1}{1+\left(d_{i} \bar{\omega}_{i}^{\star 2}\right)^{-1} \exp \left(d_{i} \bar{\omega}_{i}^{\star 2}\right) \phi_{i} d_{i} L^{-1}}\right)\right) .
$$

Proof. (Proof of Theorem D.11) In the following discussion, we also rescale the time by $t \leftarrow 2 d t$. At the end of the warm-up phase, we just have by (D.20) in the fifth step of the warm-up phase that

$$
\begin{equation*}
\bar{\omega}_{i}^{\star}\left(T_{\text {warmup }}\right)=\frac{1 \pm o(1)}{\omega_{0}^{-1}-\frac{L \lambda_{i}}{\sqrt{d_{e} \phi_{i}}}\left(T_{\text {warmup }}-t_{4}^{i}\right)} \leq 4 \omega_{0}, \tag{D.53}
\end{equation*}
$$

given that $\bar{\omega}_{i}^{\star}=(1+o(1)) \omega_{0}$ as we have shown for the end of the step 4 of the warm-up stage. Here, $t_{4}^{i}$ is the ending time of step 4 of the warm-up stage for task $i$. Here, the $4 \omega_{0}$ is ensured by the definition of the warm-up stage. Consider a fixed small constant $v \in(0,1 / 4)$. Consider the regime when $\bar{\omega}_{i}^{\star}$ is raised from the value at the end of the warm-up stage to $v^{-1} \omega_{0}$. Recall the derivative of time with respect to $\bar{\omega}_{i}^{\star}$ in (D.49) that

$$
\begin{aligned}
\frac{\mathrm{d} t}{\mathrm{~d}\left(\bar{\omega}_{i}^{\star}\right)} & =\frac{2+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}}{\left(1-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2} \pm \widetilde{\iota_{i}}\right) \cdot\left(1 \pm \iota_{i}\right) \sqrt{d_{e}}{ }^{-1} \lambda_{i}} \geq \frac{2+\frac{\phi_{i}}{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}{\phi_{i} e}}{\sqrt{d_{e}}{ }^{-1} \lambda_{i}} \\
& =\frac{\sqrt{d_{e}}}{\lambda_{i}} \cdot \frac{\mathrm{~d}}{\mathrm{~d} \bar{\omega}_{i}^{\star}}\left(2 \bar{\omega}_{i}^{\star}-\frac{\phi_{i}}{L \bar{\omega}_{i}^{\star}}+\frac{L \bar{\omega}_{i}^{\star 3}}{3 \phi_{i} e}\right) .
\end{aligned}
$$

It is clear that the time used for $\bar{\omega}_{i}^{\star}$ to be raised to $v^{-1} \omega_{0}$, which we define as $\Delta T_{1}$, is lower bounded by

$$
\Delta T_{1} \geq\left.\frac{\sqrt{d_{e}}}{\lambda_{i}}\left(2\left(\bar{\omega}_{i}^{\star}\right)-\frac{\phi_{i}}{L\left(\bar{\omega}_{i}^{\star}\right)}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{3}}{3 \phi_{i} e}\right)\right|_{\bar{\omega}_{i}^{\star}\left(T_{\text {warmup }}\right)} ^{v^{-1} \omega_{0}} \geq \frac{\phi_{i} \sqrt{d_{e}}}{\lambda_{i} L}\left(\bar{\omega}_{i}^{\star}\left(T_{\text {warmup }}\right)^{-1}-v \omega_{0}^{-1}\right) .
$$

Using the result in (D.53), we also have

$$
\begin{equation*}
\bar{\omega}_{i}^{\star}\left(T_{\text {warmup }}\right)^{-1}=\left(\omega_{0}^{-1}-\frac{L \lambda_{i}}{\sqrt{d_{e}} \phi_{i}}\left(T_{\text {warmup }}-t_{4}^{i}\right)\right) \cdot(1 \pm o(1)) . \tag{D.54}
\end{equation*}
$$

Plugging (D.54) into the lower bound for $\Delta T_{1}$, we conclude that

$$
\Delta T_{1} \geq \frac{\phi_{i} \sqrt{d_{e}}}{\lambda_{i} L}\left(\left(\omega_{0}^{-1}-\frac{L \lambda_{i}}{\sqrt{d_{e}} \phi_{i}}\left(T_{\text {warmup }}-t_{4}^{i}\right)\right) \cdot(1-o(1))-v \omega_{0}^{-1}\right),
$$

which shows that

$$
\Delta T_{1}+(1-o(1))\left(T_{\text {warmup }}-t_{4}^{i}\right) \geq \frac{\phi_{i} \sqrt{d_{e}}}{\lambda_{i} L} \cdot(1-o(1)-v) \omega_{0}^{-1} .
$$

Note that $t_{4}^{i}$ is much smaller than $T_{\text {warmup }}$ as we have discussed previously. Define

$$
T_{0}=\frac{\phi_{i} \sqrt{d_{e}}}{\lambda_{i} L \omega_{0}} .
$$

As a result, we conclude that for the total time less than $T_{0} \cdot(1-v-o(1))$, we must have $\bar{\omega}_{i}^{\star} \leq v^{-1} \omega_{0}$. For the other side $T_{0}(1+v)$, we have by (D.50) that the time to raise $d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}$ from the value at the end of the warm-up stage to $v$, which we define as $T_{2}$, is upper bounded by

$$
T_{2} \leq \frac{\left(1+2 \widetilde{\iota_{i}}\right) \cdot \sqrt{d_{e}}}{(1-v) \lambda_{i}}\left(2 \sqrt{v d_{i}}+\frac{\phi_{i} e^{v}}{L \omega_{0}}+\frac{L v^{3 / 2}}{3 \phi_{i} d_{i}^{3 / 2}}\right) .
$$

Note that the second term dominates as we discussed before. Thus, $T_{2}$ is no larger than $(1+$ $o(1)) e^{v} /(1-v) T_{0} \leq(1+e v) T_{0}$.

For the loss before $(1-v-o(1)) T_{0}$, we have by noting that both $\mu_{i}$ and $\bar{\omega}_{i}$ are small that the output for position $i$ is much smaller in scale compared to $\left(y_{q}\right)_{0}$. Hence, the loss is at least $\Omega\left(\frac{\lambda_{i} d_{i}}{d}\right)$. Lastly, for the training loss at $T_{2}$, we notice that $\mu_{i}^{\star}$ is around the optimal value for the corresponding $\bar{\omega}_{i}^{\star}$ as we have

$$
\pi=\mu_{i}^{\star} \bar{\omega}_{i}^{\star} \cdot\left(1+\frac{\phi_{i} d_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L\left(d_{i} \bar{\omega}_{i}^{2}\right)}\right)=1 \pm o(1),
$$

compared to the optimality condition in (E.19) of Lemma E. 7 with $b_{i}$ replaced by $d_{i} \bar{\omega}_{i}^{\star 2}$. Therefore, given that the task is only carried out by its optimal head, the loss for each task is well approximated by

$$
\frac{\lambda_{i} d_{i}}{d} \cdot\left(1-\frac{1}{1+\left(d_{i} \bar{\omega}_{i}^{\star 2}\right)^{-1} \exp \left(d_{i} \bar{\omega}_{i}^{\star 2}\right) \phi_{i} d_{i} L^{-1}}\right) .
$$

Plugging in the value of $\bar{\omega}_{i}^{\star}$, we have the desired result.

## D. 3 Dynamics Path

We give a simplified version of the dynamics path for ease of understanding what's happening during each phase. We remind the readers that the following is not rigorous proof. The Gradient Flow (Gradient Flow) dynamics of $\bar{\omega}^{(h)}$ is approximated by

$$
\begin{aligned}
\sqrt{d}_{e} \cdot \partial_{t} \bar{\omega}_{i}^{(h)}=- & \sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} \cdot\left\langle\boldsymbol{d} \odot \lambda \odot \phi, \mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right\rangle \cdot \bar{\omega}_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{(h)} \\
& -\lambda_{i} \cdot \sum_{h^{\prime}=1}^{H} \mu_{i}^{\left(h^{\prime}\right)} \mu_{i}^{(h)} \bar{\omega}_{i}^{\left(h^{\prime}\right)} \bar{\omega}_{i}^{(h)}+\lambda_{i} \cdot \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)},
\end{aligned}
$$

and the GF dynamics of $\mu^{(h)}$ is approximated by

$$
\partial_{t} \mu_{i}^{(h)}=-\sum_{h^{\prime}=1}^{H} \frac{\exp \left(\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right)}{L} d_{i} \lambda_{i} \phi_{i} \mu_{i}^{\left(h^{\prime}\right)} \mu_{i}^{(h)}-\sum_{h^{\prime}=1}^{H} d_{i} \lambda_{i} \bar{\omega}_{i}^{(h)} \bar{\omega}_{i}^{\left(h^{\prime}\right)} \mu_{i}^{\left(h^{\prime}\right)} \mu_{i}^{(h)}+d_{i} \lambda_{i} \bar{\omega}_{i}^{(h)} \mu_{i}^{(h)} .
$$

Dynamics Path for the Warm-up Phase. Note that during the warmup phase $\bar{\omega}_{i}^{(h)} \approx \omega_{0}$. Hence, any term of 2 or higher order in $\bar{\omega}$ is ignorable. Hence, we have only the signal term for $\partial_{t} \bar{\omega}^{(h)}$ :

$$
\sqrt{d}_{e} \cdot \partial_{t} \bar{\omega}_{i}^{(h)} \approx \lambda_{i} \cdot \mu_{i}^{(h)} \bar{\omega}_{i}^{(h)},
$$

and the last signal term and the first interference term for $\partial_{t} \mu^{(h)}$, where it is more clear to write in the logarithm form:

$$
\begin{equation*}
\partial_{t} \log \mu_{i}^{(h)} \approx d_{i} \lambda_{i} \bar{\omega}_{i}^{(h)}-\sum_{h^{\prime}=1}^{H} L^{-1} d_{i} \lambda_{i} \phi_{i} \mu_{i}^{\left(h^{\prime}\right)} \cdot\left(1+\left\langle\omega^{(h)}, \omega^{\left(h^{\prime}\right)}\right\rangle\right) . \tag{D.55}
\end{equation*}
$$

Mean-Field Interference Makes the Optimal Head Dominate: To understand how the optimal head gradually dominates the other heads, we consider the time-derivative of the ratios:

$$
\partial_{t}\left(\log \frac{\mu_{i}^{\star}}{\mu_{i}^{(h)}}\right) \approx \lambda_{i} d_{i}\left(\bar{\omega}_{i}^{\star}-\bar{\omega}_{i}^{(h)}\right), \quad \partial_{t}\left(\log \frac{\bar{\omega}_{i}^{\star}}{\bar{\omega}_{i}^{(h)}}\right) \approx \lambda_{i}\left(\mu_{i}^{\star}-\mu_{i}^{(h)}\right)
$$

where we actually cancel out the interference term since the interference term is almost the same for all heads as long as $\bar{\omega}^{(h)}$ is small enough! This is the underlying reason why the optimal head can gradually dominates the other heads using the advantage of initialization. In particular, the advantage in $\mu_{i}^{\star}$ will be converted to the advantage in $\bar{\omega}_{i}^{\star}$ through the second equation and then back to the further advantage in $\mu_{i}^{\star}$.

For more insight, note that the dynamics of $\mu^{(h)}$ runs much faster than $\bar{\omega}^{(h)}$ in scale. Therefore, the first step should be $\mu^{(h)}$ trying to reaching the equilibrium given by (D.55):

$$
\begin{equation*}
\sum_{h^{\prime}=1}^{H} \phi_{i} \mu_{i}^{\left(h^{\prime}\right)} \approx L \bar{\omega}_{i}^{(h)} . \tag{D.56}
\end{equation*}
$$

However, the left-hand side of (D.56) is independent of $h$ but the right-hand side is not. Notably, $\sum_{h \in[H]} \phi_{i} \mu_{i}^{(h)}$ should be larger than the smallest $L \bar{\omega}_{i}^{(h)}$ while it should be smaller than the largest $L \bar{\omega}_{i}^{(h)}$, since otherwise we can always find all $\left\{\mu_{i}^{(h)}\right\}_{h \in[H]}$ to simultaneously increase or decrease according to (D.55). As a result, we will have a clear separation between heads: For heads with $L \bar{\omega}_{i}^{(h)}$ larger than the interference level $\sum_{h^{\prime} \in[H]} \phi_{i} \mu_{i}^{\left(h^{\prime}\right)}$, the corresponding $\mu_{i}^{(h)}$ will increase, and vice versa. Only the optimal head will keep going all the time.

Dynamics Path for the Emergence and Convergence Phase (Growing Phase). As the optimal head takes over the other heads, the dynamics of $\bar{\omega}^{(h)}$ and $\mu^{(h)}$ can be simplified to only
the optimal one and neglect the interference terms, which gives us

$$
\begin{aligned}
\partial_{t} \log \mu_{i}^{\star} & \approx \lambda_{i} d_{i}\left(-\frac{\exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L} \phi_{i} \mu_{i}^{\star}+\left(1-\bar{\omega}_{i}^{\star} \mu_{i}^{\star}\right) \bar{\omega}_{i}^{\star}\right), \\
\partial_{t} \bar{\omega}_{i}^{\star} & \approx\left(1-\left(1+\frac{\exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L} d_{i} \phi_{i}\right) \mu_{i}^{\star} \bar{\omega}_{i}^{\star} \pm \tau_{1}\right) \sqrt{d_{e}}{ }^{-1} \lambda_{i} \bar{\omega}_{i}^{\star} \mu_{i}^{\star} .
\end{aligned}
$$

The equilibrium of $\mu^{(h)}$ is given by

$$
\mu_{i}^{\star} \approx \frac{\bar{\omega}_{i}^{\star}}{\bar{\omega}_{i}^{\star 2}+\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) L^{-1}} .
$$

Plugging this into the dynamics of $\bar{\omega}_{i}^{\star}$, we have

$$
\partial_{t} \bar{\omega}_{i}^{\star} \approx\left(1-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) \cdot \sqrt{d_{e}}{ }^{-1} \lambda_{i} \cdot\left(2+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}\right)^{-1}
$$

It is clear that the stationary point is given by $d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}=1$ and before that, $\bar{\omega}_{i}^{\star}$ will keep increasing. To understand the sudden emergence, we just look at the

$$
2+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}
$$

term. For small $\bar{\omega}_{i}^{\star}$, the second term dominates and we have a super large denominator, thus making the growth of $\bar{\omega}_{i}^{\star}$ slow. However, as $\bar{\omega}_{i}^{\star}$ goes somewhere near the valley of the function (not necessarily achieving the minimum) while still remaining away from $\sqrt{1 / d_{i}}$, the value of this term suddenly decreases and makes the growth of $\bar{\omega}_{i}^{\star}$ fast. This is the reason why we have the sudden emergence. After $d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}$ reaches 1, we have the convergence result. To characterize the emergence and convergence behavior, we also consider time $t$ as a function of $\bar{\omega}_{i}^{\star}$ :

$$
\frac{\mathrm{d} t}{\mathrm{~d}\left(\bar{\omega}_{i}^{\star}\right)}=\frac{2+\frac{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}+\frac{L\left(\bar{\omega}_{i}^{\star}\right)^{2}}{\phi_{i} \exp \left(d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right)}}{\left(1-d_{i}\left(\bar{\omega}_{i}^{\star}\right)^{2}\right) \cdot \sqrt{d_{e}}{ }^{-1} \lambda_{i}} .
$$

By integrating this function with respect to $\bar{\omega}_{i}^{\star}$, we obtain some hyperbolic function for the time function upon convergence.

## E Optimality

In this section, we provide optimality results for both the single-head case and the convergence point of the multi-head attention's training dynamics by providing a lower bound.

Notations. We denote by $[A ; B]$ the concatenation of two matrices $A$ and $B$ along the row direction.

## E. 1 Optimality of Single-Head Attention

In this section, we provide a characterization of the global optimality of the single-head case. Under the condition $W_{Y}=0$, we have the training loss given by

$$
\mathcal{L}(U, W) \triangleq \mathbb{E}\left[\left\|G^{\top} q-\left(U_{X} X+U_{Y}\left(G^{\top} X+\varepsilon\right)\right) p\right\|_{2}^{2}\right], \quad \text { where } \quad p=\operatorname{softmax}\left(X^{\top} W_{X} q\right)
$$

Here, $G \in \mathbb{R}^{d \times d_{y}}$ is the random coefficient matrix. Recall that $G=d^{-1 / 2} \Phi \operatorname{diag}\left(g_{1}, \ldots, g_{I}\right) \Psi^{\top}$. Define $G^{\prime}=\operatorname{diag}\left(g_{1}, \ldots, g_{I}\right)$. Since $X, \varepsilon$ and $q$ are rotationally invariant in distribution, one can equivalently consider the rotated input $X^{\prime}=\Phi^{\top} X, \varepsilon^{\prime}=\Psi^{\top} \varepsilon$ and $q^{\prime}=\Phi^{\top} q$, and also rotate the weights by

$$
W_{X}^{\prime}=\Phi^{\top} W_{X} \Phi, \quad U_{Y}^{\prime}=\Psi^{\top} U_{Y} \Psi, \quad U_{X}^{\prime}=\Psi^{\top} U_{X} \Phi
$$

Using the rotated input and weights, we have

$$
\begin{gather*}
p=\operatorname{softmax}\left(X^{\prime \top} W_{X}^{\prime} q^{\prime}\right), \quad y_{q}=G^{\top} q=\Psi G^{\prime \top} q^{\prime}, \\
\widehat{y}_{q}=\left(U_{X} X+U_{Y}\left(G^{\top} X+\varepsilon\right)\right) p=\Psi\left(U_{X}^{\prime} X^{\prime}+U_{Y}^{\prime}\left(G^{\prime \top} X^{\prime}+\varepsilon^{\prime}\right)\right) p,  \tag{E.1}\\
\mathcal{L}\left(U^{\prime}, W^{\prime}\right)=\mathbb{E}\left[\left\|G^{\prime \top} q^{\prime}-\left(U_{X}^{\prime} X^{\prime}+U_{Y}^{\prime}\left(G^{\prime \top} X^{\prime}+\varepsilon^{\prime}\right)\right) p\right\|_{2}^{2}\right]
\end{gather*}
$$

Therefore, it suffices to consider the case where $\Phi$ and $\Psi$ are identity matrices. We aim to prove the following theorem.

Theorem E. 1 (Approximate Optimality of Single-Head Attention). For ssa! (ssa!) with I tasks, assume that $W_{Y}=0$, and the noise level $\sigma>0$ is a constant independent of $d$ and L. Suppose $L=o(\exp (d))$, then for some $b^{\star}=\left(b_{i}^{\star}\right)_{i \in[I]}$ and $u^{\star}=\left(u_{i}^{\star}\right)_{i \in[I]}$, the following solution

$$
W^{\star}=\left[\begin{array}{cccc|c}
\sqrt{b_{1}^{\star} / d_{i}} \cdot I_{d_{1}} & 0 & \cdots & 0 \\
0 & \sqrt{b_{2}^{\star} / d_{i}} \cdot I_{d_{2}} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \sqrt{b_{I}^{\star} / d_{I}} \cdot I_{d_{I}} & \\
0 & 0 & & & \star
\end{array}\right], \quad U^{\star}=\left[\begin{array}{c|ccc}
0 & & & 0 \\
\hline & u_{1}^{\star} & 0 & \cdots \\
0 & u_{2}^{\star} & \cdots & 0 \\
0 & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & u_{I}^{\star}
\end{array}\right]
$$

approximately achieves the minimal loss value in the sense that for any other $(W, U)$ such that $W_{Y}=0$, we have

$$
\mathcal{L}\left(U^{\star}, W^{\star}\right) \leq \mathcal{L}(U, W)+\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot O\left(L^{-(1-\epsilon) / 2}+L^{-1+2\left(c^{-2} \vee \epsilon\right)}\right),
$$

where $\epsilon$ is a small constant. In particular, $b^{\star}$ and $u^{\star}$ can be obtained by first finding the solution $\left(B^{\star}, b^{\star}\right)$ to the following optimization problem for an absolute constant $C \in(0,1)$ :

$$
b^{\star}=\underset{\substack{C \cdot \log L \geq B \geq 0, b \in \mathbb{R}_{+}^{I}, \mathbf{1}^{\top} \\ b=B}}{\operatorname{argmin}} \sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{b_{i}}{b_{i}+d_{i} \phi_{i} \exp (B) / L}\right), \quad \text { and } \quad u_{i}^{\star}=\frac{\sqrt{b_{i}^{\star} d_{i}}}{b_{i}^{\star}+d_{i} \phi_{i} \exp \left(B^{\star}\right) / L}
$$

Before we prove Theorem E.1, we first rewrite the loss function in a more convenient form and discuss some related properties.

## E.1.1 Rewriting and Lower Bounding the Loss Function

Note that $p$ is only a function of $(X, q)$ by $W_{Y}=0$. We use the mutual independence between $(X, q), G$ and $\varepsilon$ to rewrite the loss function as follows:

$$
\begin{align*}
\mathcal{L}(U, W)= & \mathbb{E}\left\|G^{\top} q-U_{Y} G^{\top} X p\right\|_{2}^{2}+\mathbb{E}\left\|U_{X} X p\right\|_{2}^{2}+\mathbb{E}\left\|U_{Y} \varepsilon p\right\|_{2}^{2} \\
= & \mathbb{E}\left[\operatorname{Tr}\left(G G^{\top}\right)-2 \operatorname{Tr}\left(U_{Y} G^{\top} X p q^{\top} G\right)\right. \\
& \left.+\operatorname{Tr}\left(U_{X} X p p^{\top} X^{\top} U_{X}^{\top}+U_{Y} G^{\top} X p p^{\top} X^{\top} G U_{Y}^{\top}+U_{Y} \varepsilon p p^{\top} \varepsilon^{\top} U_{Y}^{\top}\right)\right] \\
\geq & \mathbb{E}\left[\operatorname{Tr}\left(G G^{\top}\right)-2 \operatorname{Tr}\left(U_{Y} G^{\top} X p q^{\top} G\right)+\operatorname{Tr}\left(U_{Y}\left(G^{\top} X p p^{\top} X^{\top} G+\varepsilon p p^{\top} \varepsilon^{\top}\right) U_{Y}^{\top}\right)\right] . \tag{E.2}
\end{align*}
$$

Here, the inequality follows from the fact that the trace of a positive semi-definite matrix is nonnegative and by setting $U_{X}=0$, the inequality becomes an equality. Thus, it is sufficient to consider the case $U_{X}=0$ for optimality. Note that (E.2) is a quadratic function in terms of $U_{Y}$. By optimizing over $U_{Y}$, we obtain $\mathcal{L}(W)$ as a lower bound of the loss value:

$$
\begin{equation*}
\mathcal{L}(W):=\mathbb{E} \operatorname{Tr}\left(G G^{\top}\right)-\operatorname{Tr}\left(\mathbb{E}\left[G^{\top} q p^{\top} X^{\top} G\right] \cdot \mathbb{E}\left[G^{\top} X p p^{\top} X^{\top} G+\varepsilon p p^{\top} \varepsilon^{\top}\right]^{-1} \cdot \mathbb{E}\left[G^{\top} X p q^{\top} G\right]\right) \tag{E.3}
\end{equation*}
$$

Here, the optimal $U_{Y}$ is given by

$$
\begin{equation*}
U_{Y}^{\star}(W)=\mathbb{E}\left[G^{\top} q p^{\top} X^{\top} G\right] \cdot \mathbb{E}\left[G^{\top} X p p^{\top} X^{\top} G+\varepsilon p p^{\top} \varepsilon^{\top}\right]^{-1} \tag{E.4}
\end{equation*}
$$

When plugging in the concrete form of $G$, we notice that $\mathbb{E}\left[G^{\top} M G\right]$ always gives a diagonal matrix for any conformable matrix $M$. In particular,

$$
\mathbb{E}\left[G^{\top} M G\right]=d^{-1} \cdot \operatorname{diag}\left(\lambda_{1} \sum_{i \in \mathcal{J}_{1}} M_{i i}, \ldots, \lambda_{I} \sum_{i \in \mathcal{J}_{I}} M_{i i}\right)
$$

In the sequel, we denote by $\operatorname{Tr}_{i}(M)=\sum_{j \in \mathcal{J}_{i}} M_{j j}$ the sliced trace of the $i$-th block of $M$. Note that $\mathbb{E}\left[\varepsilon p p^{\top} \varepsilon^{\top}\right]=\sigma^{2} I_{d_{y}} \mathbb{E}\left[\|p\|_{2}^{2}\right]$ is also a diagonal matrix. Consequently, (E.3) can be rewritten as

$$
\begin{equation*}
\mathcal{L}(W)=\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d}\left(1-\frac{d_{i}^{-1}\left(\mathbb{E} \operatorname{Tr}_{i}\left(\mathbb{E}[X p \mid q] q^{\top}\right)\right)^{2}}{\mathbb{E} \operatorname{Tr}_{i}\left(\mathbb{E}\left[X p p^{\top} X^{\top} \mid q\right]\right)+\sigma^{2} d \lambda_{i}^{-1} \mathbb{E}\left[\|p\|_{2}^{2}\right]}\right) \tag{E.5}
\end{equation*}
$$

Moreover, $U_{Y}^{\star}(W)$ is also a diagonal matrix:

$$
\begin{equation*}
U_{Y}^{\star}(W)=\operatorname{diag}\left(u_{1}^{\star}(W), \ldots, u_{I}^{\star}(W)\right), \quad u_{i}^{\star}(W):=\frac{\mathbb{E} \operatorname{Tr}_{i}\left(\mathbb{E}[X p \mid q] q^{\top}\right)}{\mathbb{E} \operatorname{Tr}_{i}\left(\mathbb{E}\left[X p p^{\top} X^{\top} \mid q\right]\right)+\sigma^{2} d \lambda_{i}^{-1} \mathbb{E}\left[\|p\|_{2}^{2}\right]} \tag{E.6}
\end{equation*}
$$

To lower bound (E.5), we invoke inequality $\left(\mathbb{E} \operatorname{Tr}_{i}(M N)\right)^{2} \leq \mathbb{E} \operatorname{Tr}_{i}\left(M M^{\top}\right) \cdot \mathbb{E} \operatorname{Tr}_{i}\left(N^{\top} N\right)$ for any two conformable random matrices $M$ and $N$ to obtain

$$
\begin{align*}
\mathcal{L}(W) & \geq \sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d}\left(1-\frac{d_{i}^{-1} \cdot \mathbb{E}\left[\operatorname{Tr}_{i}\left(\mathbb{E}[X p \mid q] \mathbb{E}[X p \mid q]^{\top}\right)\right] \cdot \mathbb{E}\left[\operatorname{Tr}_{i}\left(q q^{\top}\right)\right]}{\mathbb{E} \operatorname{Tr}_{i}\left(\mathbb{E}\left[X p p^{\top} X^{\top} \mid q\right]\right)+\sigma^{2} d \lambda_{i}^{-1} \mathbb{E}\left[\|p\|_{2}^{2}\right]}\right) \\
& =\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d}\left(1-\frac{\mathbb{E}\left[\operatorname{Tr}_{i}\left(\mathbb{E}[X p \mid q] \mathbb{E}[X p \mid q]^{\top}\right)\right]}{\mathbb{E} \operatorname{Tr}_{i}\left(\mathbb{E}\left[X p p^{\top} X^{\top} \mid q\right]\right)+\sigma^{2} d \lambda_{i}^{-1} \mathbb{E}\left[\|p\|_{2}^{2}\right]}\right) . \tag{E.7}
\end{align*}
$$

We apply Stein's lemma to deal with the expectation terms with respect to $X$ and $p$. The result is summarized by Lemma C. 8 to and we defer readers to, we conclude that

$$
\begin{align*}
\mathbb{E}[X p \mid q] & =W_{X} q\left(1-f_{1}\left(\left\|W_{X} q\right\|_{2}^{2}\right)\right), \\
\mathbb{E}\left[X p p^{\top} X^{\top} \mid q\right] & =W_{X} q q^{\top} W_{X}^{\top} f_{2}\left(\left\|W_{X} q\right\|_{2}^{2}\right)+I_{d} f_{1}\left(\left\|W_{X} q\right\|_{2}^{2}\right), \tag{E.8}
\end{align*}
$$

where

$$
f_{1}\left(\left\|W_{X} q\right\|_{2}^{2}\right)=\mathbb{E}\left[\|p\|_{2}^{2} \mid q\right], \quad f_{2}\left(\left\|W_{X} q\right\|_{2}^{2}\right)=\mathbb{E}\left[1-\|p\|_{2}^{2}-6\|p\|_{3}^{3}+6\|p\|_{2}^{4} \mid q\right] .
$$

We remark that both $f_{1}$ and $f_{2}$ are just functions of $\left\|W_{X} q\right\|_{2}^{2}$ as we have proved in Lemma C.4. In the sequel, we drop the dependence of $f_{1}, f_{2}$ on $\left\|W_{X} q\right\|_{2}^{2}$ for simplicity. Plugging (E.8) into (E.5), we obtain

$$
\begin{equation*}
\mathcal{L}(W)=\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d}\left(1-\frac{d_{i}^{-1}\left(\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} q q^{\top}\left(1-f_{1}\right)\right)\right]\right)^{2}}{\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} q q^{\top} W_{X}^{\top} f_{2}\right)+d_{i} \phi_{i} f_{1}\right]}\right) \tag{E.9}
\end{equation*}
$$

where we follow the convention to denote $\phi_{i}=1+\mathrm{SNR}_{i}^{-1}=1+\sigma^{2} d \lambda_{i}^{-1} d_{i}^{-1}$. Also, $U_{Y}^{\star}(W)$ has diagonal entries given by plugging (E.8) into (E.6):

$$
\begin{equation*}
u_{i}^{\star}(W)=\frac{\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} q q^{\top}\left(1-f_{1}\right)\right)\right]}{\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} q q^{\top} W_{X}^{\top} f_{2}\right)+d_{i} \phi_{i} f_{1}\right]} . \tag{E.10}
\end{equation*}
$$

Plugging (E.8) into (E.7), we obtain

$$
\begin{equation*}
\mathcal{L}(W) \geq \sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d}\left(1-\frac{\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} q q^{\top} W_{X}^{\top}\right)\left(1-f_{1}\right)\right]}{\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} q q^{\top} W_{X}^{\top} f_{2}\right)+d_{i} \phi_{i} f_{1}\right]}\right) . \tag{E.11}
\end{equation*}
$$

We remind the readers that we do not make any change to the denominator of (E.11), which is still equal to $\mathbb{E} \operatorname{Tr}_{i}\left(\mathbb{E}\left[X p p^{\top} X^{\top} \mid q\right]\right)+\sigma^{2} d \lambda_{i}^{-1} \mathbb{E}\left[\|p\|_{2}^{2}\right]>0$. Invoking the fact that both $f_{1}$ and $f_{2}$ are just functions of $\left\|W_{X} q\right\|_{2}^{2}=\operatorname{Tr}\left(W_{X} q q^{\top} W_{X}^{\top}\right)$, and that $\mathbb{E}[f(x)] / \mathbb{E}[g(x)] \leq \sup _{x} f(x) / g(x)$ for non-negative function $g$, we have (E.11) further lower bounded by

$$
\begin{equation*}
\mathcal{L}(W) \geq \inf _{\substack{B \geq 0, b \geq 0 \\ 1^{\top} b=B}} \mathcal{L}_{\mathrm{lb}}(B, b), \quad \text { where } \quad \mathcal{L}_{l \mathrm{~b}}(B, b):=\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{b_{i}\left(1-f_{1}(B)\right)^{2}}{b_{i} f_{2}(B)+d_{i} \phi_{i} f_{1}(B)}\right) . \tag{E.12}
\end{equation*}
$$

Comparing (E.12) to (E.11), we are just replacing the sliced trace by $b_{i}$ and the full trace by $B$ and imposing the constraint $\mathbf{1}^{\top} b=B$. We give a physical interpretation of (E.12). If we view $B$ as the "attention budget" and $b_{i}$ as the "attention allocation for task $i$ ", then (E.12) is a bilevel optimization problem where:

- The lower-level problem is to find the optimal allocation of the attention budget to each task for a given attention budget $B$.
- The upper-level problem is then to decide the optimal attention budget $B$.

As a concluding remark for this lower bound, we have the following lemma that shows the achievability of the lower bound.

## E.1.2 Approximations of Nonlinear Functions $f_{1}$ and $f_{2}$

The next thing is to understand the behavior of $f_{1}$ and $f_{2}$. Note that as we have characterized in Appendix $B$, we have under bounded parameter norm condition that
$f_{1}(B)=\mathbb{E}\left[\|p\|_{2}^{2} \mid\left\|W_{X} q\right\|_{2}^{2}=B\right] \approx \frac{\exp (B)}{L}, \quad f_{2}(B)=\mathbb{E}\left[1-\|p\|_{2}^{2}-6\|p\|_{3}^{3}+6\|p\|_{2}^{4} \mid\left\|W_{X} q\right\|_{2}^{2}=B\right] \approx 1$.
Therefore, it suffices to characterize the following dominant part of the loss's lower bound

$$
\mathcal{L}_{\mathrm{sim}}(B, b):=\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{b_{i}}{b_{i}+d_{i} \phi_{i} \cdot \exp (B) \cdot L^{-1}}\right) .
$$

The following lemma gives an approximation of $\mathcal{L}_{\text {lb }}$ with $\mathcal{L}_{\text {sim }}$ when $B$ is bounded from above.
Lemma E. 2 (Simple Approximation of $\mathcal{L}_{1 \mathrm{~b}}$ ). For any $\epsilon>0$, suppose $\sqrt{B} \leq c^{-1} \sqrt{2 \log L}$, where $c$ satisfies

$$
\frac{1}{c}+\frac{3}{1+\sqrt{1+c^{2} / 2}} \leq \epsilon .
$$

Then for any $b$ with non-negative elements such that $\mathbf{1}^{\top} b=B$, it holds that

$$
\left|\mathcal{L}_{1 \mathrm{~b}}(B, b)-\mathcal{L}_{\mathrm{sim}}(B, b)\right| \leq \sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \cdot O\left(L^{-1+2\left(c^{-2} \vee \epsilon\right)}\right)
$$

Proof. (Proof of Lemma E.2) Note that for $\sqrt{B} \leq c^{-1} \sqrt{2 \log L}$, where by our choice $c$ satisfies the conditions in Lemma B.2, we have

$$
\left|f_{1}(B)-\frac{\exp (B)}{L}\right|=\left|\mathbb{E}\left[\|p\|_{2}^{2} \mid\left\|W_{X} q\right\|_{2}^{2}=B\right]-\frac{\exp (B)}{L}\right| \leq O\left(L^{-2(1-\epsilon)}\right) .
$$

In additions, Lemma B. 2 also implies that

$$
\left|f_{2}(B)-1\right|=\left|\mathbb{E}\left[-\|p\|_{2}^{2}-6\|p\|_{3}^{3}+6\|p\|_{2}^{4} \mid\left\|W_{X} q\right\|_{2}^{2}=B\right]\right| \leq \frac{\exp (B)}{L}+O\left(L^{-2(1-\epsilon)}\right) \leq O\left(L^{-1+2 c^{-2}}\right)
$$

Therefore, we have for the target function in (E.12) that

$$
\begin{aligned}
\mathcal{L}_{1 \mathrm{~b}}(B, b) & =\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{b_{i} \cdot\left(1 \pm O\left(L^{-1+2 c^{-2}}\right)\right)^{2}}{b_{i} \cdot\left(1 \pm O\left(L^{-1+2 c^{-2}}\right)\right)+d_{i} \phi_{i} \cdot \exp (B) \cdot L^{-1} \cdot\left(1 \pm O\left(L^{-1+2 \epsilon}\right)\right)}\right) \\
& =\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{b_{i}}{b_{i}+d_{i} \phi_{i} \cdot \exp (B) \cdot L^{-1}} \cdot\left(1 \pm O\left(L^{-1+2\left(c^{-2} \vee \epsilon\right)}\right)\right)\right) \\
& =\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{b_{i}}{b_{i}+d_{i} \phi_{i} \cdot \exp (B) \cdot L^{-1}}\right) \pm \sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \cdot O\left(L^{-1+2\left(c^{-2} \vee \epsilon\right)}\right),
\end{aligned}
$$

where the last equality is due to the fact that $\frac{b_{i}}{b_{i}+d_{i} \phi_{i} \cdot \exp (B) \cdot L^{-1}} \leq 1$.

## E.1.3 The Optimal Attention Budget is Bounded

Following the result of Lemma E.2, we are able to characterize $\mathcal{L}_{\text {sim }}$ in order to understand the behavior of $\mathcal{L}_{l \mathrm{~b}}$ with bounded attention budget $B$. We first give a naive upper bound of $\mathcal{L}_{\mathrm{lb}}$ by plugging in $b_{i}=B d_{i} / d$ for all $i \in[I]$ and $B=1$.
Lemma E. 3 (Upper Bound of $\mathcal{L}_{1 \mathrm{~b}}$ ). For $\mathcal{L}_{\text {lb }}(B, b)$, we have upper bound on the minimal value as

$$
\inf _{\substack{B \geq 0, b \geq 0 \\ 1^{\top} b=B}} \mathcal{L}_{\mathrm{lb}}(B, b) \leq \sum_{i=1}^{I} \frac{\left(d_{i} \lambda_{i}+\sigma^{2} d\right) e \cdot L^{-1}}{1+d \phi_{i} e \cdot L^{-1}}+\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \cdot O\left(L^{-1+2\left(c^{-2} \vee \epsilon\right)}\right)=O(d / L) .
$$

Proof of Lemma E.3. We choose $B=1$ and plug $b_{i}=B d_{i} / d$ into $\mathcal{L}_{\text {sim }}(B, b)$ and have

$$
\begin{aligned}
\left.\mathcal{L}_{\mathrm{sim}}(B, b)\right|_{B=1, b_{i}=B d_{i} / d} & =\left.\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{1}{1+d \phi_{i} \exp (B) B^{-1} \cdot L^{-1}}\right)\right|_{B=1} \\
& =\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \cdot \frac{d \phi_{i} e \cdot L^{-1}}{1+d \phi_{i} e \cdot L^{-1}}=\sum_{i=1}^{I} \frac{\left(d_{i} \lambda_{i}+\sigma^{2} d\right) e \cdot L^{-1}}{1+d \phi_{i} e \cdot L^{-1}}
\end{aligned}
$$

which is clearly of the order $O(d / L)$. In addition, we note that $B=1 \leq c^{-2} \cdot 2 \log L$ for sufficiently large $L$ and any choice of $\epsilon \in(0,1)$ and corresponding $c$. Hence, the condition in Lemma E. 2 is satisfied for this choice of $B, b$. Therefore, we conclude the proof by also including the error of approximating $\mathcal{L}_{\text {lb }}$ with $\mathcal{L}_{\text {sim }}$ in Lemma E.2.

Given the upper bound of the optimal value of $\mathcal{L}_{1 b}$, we next show that it suffices to optimize over $B$ in a small range, i.e., $0 \leq B \leq c^{-2} 2 \log L$ for some small constant $c$. We first consider the large scale regime, i.e., $\sqrt{B} \geq O\left(d^{1-\epsilon}\right)$ with a constant scale of noise $\sigma^{2}=\Omega(1)$. For our convenience, we define a normalized version of the query token as

$$
\widetilde{q}=\left[\begin{array}{c}
\widetilde{q}_{(1)} \\
\vdots \\
\widetilde{q}_{(I)}
\end{array}\right], \quad \text { where } \quad \widetilde{q}_{(i)}=d_{i}\left\|q_{(i)}\right\|_{2}^{-1} \cdot q_{(i)}
$$

Here, we let $q_{(i)}$ be the $i$-th block of $q$ corresponding to task $i$ 's position $\mathcal{J}_{i}$. Notably, each $\widetilde{q}_{(i)}$ is uniformly distributed on the $\sqrt{d_{i}}$-sphere in $\mathbb{R}^{d_{i}}$. Under this model with normalized query token, we have the optimal $U_{Y}$ still given by (E.6) and this time each diagonal element is given by

$$
\begin{equation*}
\widetilde{u}_{i}^{\star}(W):=\frac{\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} \widetilde{q} \widetilde{q}^{\top}\left(1-f_{1}\right)\right)\right]}{\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} \widetilde{q}^{\top} \widetilde{q}^{\top} W_{X}^{\top} f_{2}\right)+d_{i} \phi_{i} f_{1}\right]} . \tag{E.13}
\end{equation*}
$$

In addition, we define the corresponding loss function as

$$
\begin{equation*}
\widetilde{\mathcal{L}}(W):=\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d}\left(1-\frac{d_{i}^{-1}\left(\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} \widetilde{q} \widetilde{q}^{\top}\left(1-f_{1}\right)\right)\right]\right)^{2}}{\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} \widetilde{q} \widetilde{q}^{\top} W_{X}^{\top} f_{2}\right)+d_{i} \phi_{i} f_{1}\right]}\right), \tag{E.14}
\end{equation*}
$$

Lemma E.4. (Large $B$ is suboptimal for constant noise level) Suppose $B=\Omega\left(d^{2-2 \epsilon}\right)$ for some small $\epsilon \in(0,1)$, the noise level $\sigma^{2}=\Omega(1)$, and $L=o(\exp (d))$. Then for any $b$ with non-negative elements such that $\mathbf{1}^{\top} b=B$,

$$
\mathcal{L}_{1 \mathrm{~b}}(B, b) \geq \sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \frac{\sigma^{2} / \lambda_{i}\left(1-O\left(d^{-(1-2 \epsilon)}\right)\right)}{1+\sigma^{2} / \lambda_{i}\left(1-O\left(d^{-(1-2 \epsilon)}\right)\right)}=\Omega(1) .
$$

Proof of Lemma E.4. Note that under the condition $B \geq \Omega\left(d^{2-2 \epsilon}\right)$, it follows from Lemma B. 5 that

$$
\begin{equation*}
f_{1}(B)=\mathbb{E}\left[\|p\|_{2}^{2} \mid\left\|W_{X} q\right\|_{2}^{2}=B\right] \geq 1-O\left(\sqrt{B}^{-(1-\epsilon)}\right) \geq 1-O\left(d^{-(1-2 \epsilon)}\right) \tag{E.15}
\end{equation*}
$$

which means that the attention probability vector is approximately one-hot. Our goal is thus using this "almost deterministic" property to show that as long as we have a constant level of noise, the ICL rate is suboptimal. Our proof is constructive in nature, i.e., relating the loss $\mathcal{L}_{1 b}(B, b)$ to the ICL rate of another model with a constructed attention weights. Consider the following choice of weights:

Recall the definition of $\mathcal{L}_{1 b}(B, b)$ in (E.12) that

$$
\mathcal{L}_{1 \mathrm{~b}}(B, b)=\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{b_{i}\left(1-f_{1}(B)\right)^{2}}{b_{i} f_{2}(B)+d_{i} \phi_{i} f_{1}(B)}\right) .
$$

Note that the denominator $b_{i} f_{2}(B)+d_{i} \phi_{i} f_{1}(B)$ is always positive. In the sequel, we aim to lower bound the value of $\mathcal{L}_{\mathrm{lb}}(B, b)$, thus equivalent to lower bounding the denominator. We have

$$
\begin{aligned}
b_{i} f_{2}(B)+d_{i} \phi_{i} f_{1}(B) & =\operatorname{Tr}_{i}\left(W_{X} \widetilde{q} \widetilde{q}^{\top} W_{X} \cdot f_{2}\left(\left\|W_{X} \widetilde{q}\right\|_{2}^{2}\right)\right)+d_{i} \phi_{i} f_{1}\left(\left\|W_{X} \widetilde{q}\right\|_{2}^{2}\right) \\
& =\operatorname{Tr}_{i}\left(W_{X} \widetilde{q} \widetilde{q}^{\top} W_{X} \cdot f_{2}\left(\left\|W_{X} \widetilde{q}\right\|_{2}^{2}\right)+I_{d} f_{1}\left(\left\|W_{X} \widetilde{q}\right\|_{2}^{2}\right)\right)+\sigma^{2} d \lambda_{i}^{-1} f_{1}(B) \\
& =\operatorname{Tr}_{i}\left(\mathbb{E}\left[X p p^{\top} X^{\top} \mid \widetilde{q}\right]\right)+\sigma^{2} d \lambda_{i}^{-1} f_{1}(B) .
\end{aligned}
$$

Here, $\widetilde{q}$ can be any normalized query token. The first equality holds by noting that $\left\|W_{X} \widetilde{q}\right\|_{2}^{2} \equiv B$ and $\operatorname{Tr}_{i}\left(W_{X} \widetilde{q} \widetilde{q}^{\top} W_{X}^{\top}\right) \equiv b_{i}$ by our construction. The second equality holds by definition $\phi_{i}=$ $1+d \sigma^{2} /\left(\lambda_{i} d_{i}\right)$. The last equality holds by (E.8) where $p=\operatorname{softmax}\left(X^{\top} W_{X} \widetilde{q}\right)$. Meanwhile, we also have for the numerator that

$$
b_{i}\left(1-f_{1}(B)\right)^{2}=\operatorname{Tr}_{i}\left(W_{X} \widetilde{q} \widetilde{q}^{\top} W_{X}^{\top}\left(1-f_{1}(B)\right)^{2}\right)=\operatorname{Tr}_{i}\left(\mathbb{E}[X p \mid \widetilde{q}] \mathbb{E}[X p \mid \widetilde{q}]^{\top}\right)
$$

For $\mathcal{L}_{\mathrm{lb}}(B, b)$, we thus have

$$
\begin{aligned}
\mathcal{L}_{1 \mathrm{~b}}(B, b) & =\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{\operatorname{Tr}_{i}\left(\mathbb{E}[X p \mid \widetilde{q}] \mathbb{E}[X p \mid \widetilde{q}]^{\top}\right)}{\operatorname{Tr}_{i}\left(\mathbb{E}\left[X p p^{\top} X^{\top} \mid \widetilde{q}\right]\right)+\sigma^{2} d \lambda_{i}^{-1} f_{1}(B)}\right) \\
& \geq \sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \cdot \frac{\sigma^{2} d \lambda_{i}^{-1} f_{1}(B)}{\operatorname{Tr}_{i}\left(\mathbb{E}[X p \mid \widetilde{q}] \mathbb{E}[X p \mid \widetilde{q}]^{\top}\right)+\sigma^{2} d \lambda_{i}^{-1} f_{1}(B)} \\
& \geq \sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \cdot \frac{\sigma^{2} \lambda_{i}^{-1} f_{1}(B)}{d^{-1} \cdot\|\mathbb{E}[X p \mid \widetilde{q}]\|_{2}^{2}+\sigma^{2} \lambda_{i}^{-1} f_{1}(B)}
\end{aligned}
$$

Here, the first inequality is Cauchy-Schwarz. Therefore, it suffices to upper bound the term $\|\mathbb{E}[X p \mid \widetilde{q}]\|_{2}^{2}$. Consider $v=W_{X} \widetilde{q} /\left\|W_{X} \widetilde{q}\right\|_{2}$ as the direction of the attention. For each $x_{l}$, we decompose it into the part that is parallel to $v$ and the part that is orthogonal to $v$, i.e., $x_{l}=z_{l} v+x_{l}^{\perp}$
where in distribution $z_{l} \stackrel{\text { i.i.d. }}{\sim} \mathcal{N}(0,1)$ and are independent of $x_{l}^{\perp}$. Define $z=\left(z_{1}, \ldots, z_{L}\right)^{\top}$ and $X^{\perp}=\left(x_{1}^{\perp}, \ldots, x_{L}^{\perp}\right)$. By the definition of the softmax probability, we have

$$
p=\operatorname{softmax}\left(x_{l}^{\top} W_{X} \widetilde{q}\right)=\operatorname{softmax}(\sqrt{B} z)
$$

which is just a function of $z$. Therefore, in expectation, we have

$$
\begin{aligned}
& \mathbb{E}[X p \mid \widetilde{q}]=\mathbb{E}\left[X^{\perp} p+v \cdot z p \mid \widetilde{q}\right]=v \cdot \mathbb{E}[z p \mid \widetilde{q}] \\
& \quad \Rightarrow\|\mathbb{E}[X p \mid \widetilde{q}]\|_{2}^{2}=\mathbb{E}[z p \mid \widetilde{q}]^{2}=\mathbb{E}[z \operatorname{softmax}(\sqrt{B} z)]^{2} \leq\left(\mathbb{E} \max \left\{z_{1}, \ldots, z_{L}\right\}\right)^{2}=O(2 \log L)
\end{aligned}
$$

Here we use the fact that hard max is larger than softmax. Therefore, we have for $\mathcal{L}_{l \mathrm{~b}}(B, b)$ that

$$
\begin{aligned}
\mathcal{L}_{\mathrm{lb}}(B, b) & \geq \sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \cdot \frac{\sigma^{2} \lambda_{i}^{-1} f_{1}(B)}{d^{-1} \cdot\|\mathbb{E}[X p \mid \widetilde{q}]\|_{2}^{2}+\sigma^{2} \lambda_{i}^{-1} f_{1}(B)} \\
& \geq \sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \cdot \frac{\sigma^{2} \lambda_{i}^{-1}\left(1-O\left(d^{-(1-2 \epsilon)}\right)\right)}{O\left(2 d^{-1} \log L\right)+\sigma^{2} \lambda_{i}^{-1}\left(1-O\left(d^{-(1-2 \epsilon)}\right)\right)}
\end{aligned}
$$

Hence, for $L=o(\exp (d))$, we always have $\mathcal{L}_{l \mathrm{~b}}(B, b)=\Omega(1)$ with constant noise level.
Thus, it suffices to focus on the case $0 \leq \sqrt{B} \leq O\left(d^{1-\epsilon}\right)$ for some small $\epsilon \in(0,1)$ when doing the optimization of the target function in (E.12). The next lemma further shows we can further restrict the attention budget to a much smaller range $0 \leq B \leq O(\log L)$.

Lemma E.5. Consider $0 \leq \sqrt{B} \leq O\left(d^{1-\epsilon}\right)$ for some small $\epsilon \in(0,1)$ when doing the optimization of the target function in (E.12). Let $c$ be a constant satisfying

$$
\frac{1}{c}+\frac{3}{1+\sqrt{1+c^{2} / 2}} \leq \epsilon
$$

In addition, we take sufficiently large $L$ such that $c^{-2} \cdot 2 \log L=\Omega(1)$. We have for any $b \geq 0$ such that $\mathbf{1}^{\top} b=B$,

$$
\mathcal{L}_{\mathrm{lb}}(B, b) \geq \min _{\substack{c^{-2} 2 \log L \geq B \geq 0 \\ \mathbf{1}^{\top} b=B, b \geq 0}} \mathcal{L}_{\mathrm{sim}}(B, b)-\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \cdot O\left(L^{-1+2\left(c^{-2} \vee \epsilon\right)}\right)
$$

Proof of Lemma E.5. We discuss the behavior of $\mathcal{L}_{\text {lb }}$ in three cases.

Case 1. For the case $0 \leq \sqrt{B} \leq c^{-1} \sqrt{2 \log L}$, we have following Lemma E. 2 that $\mathcal{L}_{l \mathrm{~b}}(B, b)$ is well approximated by $\mathcal{L}_{\text {sim }}(B, b)$. Combining the discussion in Lemma E. 2 and also the upper bound in Lemma E.3, we have

$$
\min _{\substack{c^{-2} \log L \geq B \geq 0 \\ \mathbf{1}^{\top} b=B, b \geq 0}} \mathcal{L}_{\mathrm{lb}}(B, b)=\min _{\substack{c^{-2} \operatorname{cog} L \geq B \geq 0 \\ \mathbf{1}^{\top} b=B, b \geq 0}} \mathcal{L}_{\mathrm{sim}}(B, b) \pm \sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \cdot O\left(L^{-1+2\left(c^{-2} \vee \epsilon\right)}\right) \leq O(d / L)
$$

The remaining thing is to show for the other case the optimal value of $\mathcal{L}_{l b}$ is much larger than $O(d / L)$.

Case 2. For $O\left(d^{1-\epsilon}\right) \geq \sqrt{B} \geq \Omega\left(\sqrt{2 \log L^{3 / \epsilon}}\right)$, we have $f_{1}(b)=\mathbb{E}\left[\|p\|_{2}^{2} \mid\left\|W_{X} q\right\|_{2}^{2}=B\right] \geq 1-$ $O\left(\sqrt{B}^{-1+\epsilon}\right)$ for some small $\epsilon$ by Lemma B.5. Therefore,

$$
\left.\begin{array}{rl}
\mathcal{L}_{1 \mathrm{~b}}(B, b) & =\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{b_{i}\left(1-f_{1}(B)\right)^{2}}{b_{i} f_{2}(B)+d_{i} \phi_{i} f_{1}(B)}\right) \\
& \left.\geq \sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{b_{i} \cdot O\left(B^{-1+\epsilon}\right)}{-O\left(\sqrt{B}^{-1+\epsilon}\right) \cdot b_{i}+d_{i} \phi_{i} \cdot(1-O(\sqrt{B}}{ }^{-1+\epsilon}\right)\right)
\end{array}\right)
$$

Here, in the first inequality, we have $f_{2}(B)$ lower bounded as

$$
\begin{aligned}
f_{2}(B) & =\mathbb{E}\left[1-\|p\|_{2}^{2}-6\|p\|_{3}^{3}+6\|p\|_{2}^{4} \mid\left\|W_{X} q\right\|_{2}^{2}=B\right] \geq-6 \mathbb{E}\left[\|p\|_{3}^{3}-\|p\|_{2}^{4} \mid\left\|W_{X} q\right\|_{2}^{2}=B\right] \\
& =-\sum_{l=1}^{L} 6 \mathbb{E}\left[p_{l}^{2}\left(p_{l}-\left\|p_{l}\right\|_{2}^{2}\right) \mid\left\|W_{X} q\right\|_{2}^{2}=B\right] \geq-\sum_{l=1}^{L} 6 \mathbb{E}\left[p_{l}^{2}\left(\left\|p_{l}\right\|_{2}-\left\|p_{l}\right\|_{2}^{2}\right) \mid\left\|W_{X} q\right\|_{2}^{2}=B\right] \\
& =-6 \mathbb{E}\left[\|p\|_{2}^{3}\left(1-\|p\|_{2}\right) \mid\left\|W_{X} q\right\|_{2}^{2}=B\right] \geq-3 \mathbb{E}\left[\|p\|_{2}^{2}\left(1+\|p\|_{2}\right)\left(1-\|p\|_{2}\right) \mid\left\|W_{X} q\right\|_{2}^{2}=B\right] \\
& =-3 \mathbb{E}\left[1-\|p\|_{2}^{2} \mid\left\|W_{X} q\right\|_{2}^{2}=B\right] \geq-O\left(\sqrt{B}^{-1+\epsilon}\right) .
\end{aligned}
$$

The second inequality follows by $0 \leq b_{i} \leq B$. And for the last inequality, we notice that

$$
d_{i} \phi_{i}\left(1-O\left(\sqrt{B}^{-1+\epsilon}\right)\right)=O(d), \quad O\left(\sqrt{B}^{1+\epsilon}\right) \leq O\left(d^{1-\epsilon^{2}}\right)=o(d), \quad O\left(\sqrt{B}^{2 \epsilon}\right)=o(d)
$$

Hence, there is no effective ICL learning for this case.
Case 3. For the last case, i.e., $c^{-1} \sqrt{2 \log L} \leq \sqrt{B} \leq O\left(\sqrt{2 \log L^{3 / \epsilon}}\right)$, we apply the monotonicity of $\mathbb{E}\left[\|p\|_{2}^{2} \mid\left\|W_{X} q\right\|_{2}^{2}=B\right]$ with respect to $B$ as is shown in Lemma B.1, which gives us $f_{1}(B) \geq$ $f_{1}\left(c^{-2} 2 \log L\right)=\exp \left(c^{-2} 2 \log L\right) / L-O\left(L^{-2(1-\epsilon)}\right) \geq O\left(L^{2 c^{-2}-1}\right)$. Therefore, it follows that

$$
\mathcal{L}_{\mathrm{lb}}(B, b) \geq \sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{b_{i}}{-6 b_{i}+d_{i} \phi_{i} L^{2 c^{-2}-1}}\right),
$$

where we use the fact that $f_{2}(B) \geq-6$. Note that $d_{i} / L=\Theta(1)$ and $b_{i} \leq B \leq O\left(\sqrt{2 \log L^{3 / \epsilon}}\right) \ll$ $d_{i} L^{2 c^{-2}-1}$. Thus, we conclude that the above term is lower bounded by $\mathcal{L}_{\mathrm{lb}}(B, b) \geq \sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}(1-o(1))$. Combining the above results, we conclude that the optimality could only be achieved in the first case, i.e., $0 \leq \sqrt{B} \leq c^{-1} \sqrt{2 \log L}$.

Let $\left(B^{\star}, b^{\star}\right)$ be the solution to the following optimization problem:

$$
\begin{equation*}
\min _{\substack{c^{-2} \operatorname{cog}_{L} L \geq B \geq 0, b \geq 0, \mathbf{1}^{\top} b=B}} \mathcal{L}_{\mathrm{sim}}(B, b)=\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{b_{i}}{b_{i}+d_{i} \phi_{i} \cdot \exp (B) \cdot L^{-1}}\right) . \tag{E.17}
\end{equation*}
$$

By Lemma E.5, it suffices to consider the range $0 \leq B \leq c^{-2} 2 \log L$ for some constant $c$. However, for our purpose, we need a more refined characterization of the optimal attention budget $B$. The following result shows that the optimal $B$ should be of order $o(\log L)$.

Lemma E.6. Let $\left(B^{\star}, b^{\star}\right)$ be any optimal solution to (E.17). Then it holds that $B^{\star}=o(\log L)$.
Proof of Lemma E.6. Suppose $B^{*}=\beta \log L$ for some constant $\beta$ such that $c^{-2} \geq \beta>0$ and we have $\exp (B) / L=L^{-1+\beta}$. As a result, the value to the optimization target of (E.17) is lower bounded by

$$
\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}\left(1-\frac{\beta \log L}{\beta \log L+d_{i} \phi_{i} \cdot L^{-1+\beta}}\right)=\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d}(1-o(1)),
$$

which, given $d_{i} / L=\Theta(1)$, is clearly suboptimal.

## E.1.4 Perturbation Analysis

In this part, we understand the effect of perturbation of the optimal weights on the ICL rate. Consider the following weights:

$$
W=\left[\begin{array}{cccc|c}
\sqrt{b_{1} / d_{i}} \cdot I_{d_{1}} & 0 & \cdots & 0  \tag{E.18}\\
0 & \sqrt{b_{2} / d_{i}} \cdot I_{d_{2}} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \sqrt{b_{I} / d_{I}} \cdot I_{d_{I}} & \\
0 & 0 & & & \star
\end{array}\right], \quad U=\left[\right] .
$$

We have the following result for the above weights.
Lemma E. 7 (Perturbation of attention weights). We define $\bar{\omega}_{i}=\sqrt{b_{i} / d_{i}}$ and $u_{i}^{\star}(b)$ as

$$
\begin{equation*}
u_{i}^{\star}(b)=\frac{\sqrt{b_{i} d_{i}}}{b_{i}+d_{i} \phi_{i} \exp (B) / L}, \tag{E.19}
\end{equation*}
$$

and consider $u_{i}$ to be the perturbation of $u_{i}^{\star}(b)$. We consider bounded attention budget $0 \leq B=$ $o(\log L)$ and bounded perturbation such that

$$
\begin{equation*}
0<\bar{\omega}_{i} u_{i}=O(1), \quad u_{i}^{2}=O\left(d_{i}\right) . \tag{E.20}
\end{equation*}
$$

Suppose $d / L=\Theta(1)$ and $d_{i} / d=\Theta(1)$. It then holds that
$\mathcal{L}(U, W)=\mathcal{L}_{\mathrm{sim}}(B, b)+\sum_{i=1}^{I} \frac{d_{i}}{d} \cdot\left(\left(\lambda_{i} b_{i}+\frac{\left(d_{i} \lambda_{i}+\sigma^{2} d\right) e^{B}}{L}\right) d_{i}^{-1} \cdot\left(u_{i}-u_{i}^{\star}(b)\right)^{2} \pm \lambda_{i} \cdot O\left(L^{-(1-\epsilon) / 2}\right)\right)$.
If in addition, we have $\left|B-B^{\star}\right|=o\left(B^{\star}\right)$, then we have

$$
\begin{aligned}
\mathcal{L}(U, W)= & \mathcal{L}_{\mathrm{sim}}\left(B^{\star}, b^{\star}\right)+\sum_{i=1}^{I} \frac{\lambda_{i}}{d} \cdot\left(\left(b_{i}^{\star}+\frac{d_{i} \phi_{i} e^{B^{\star}}}{L}\right) \cdot\left(u_{i}-u_{i}^{\star}\right)^{2}\right) \\
& +\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot O\left(u_{i}\left|\bar{\omega}_{i}-\bar{\omega}_{i}^{\star}\right|+\frac{\phi_{i}}{L}\left|B-B^{\star}\right|+\xi\right) .
\end{aligned}
$$

Proof of Lemma E.7. By our previous discussion in Lemma E.6, we restrict our attention budget to the range $0 \leq B=o(\log L)$. Our goal is to understand the ICL loss

$$
\begin{aligned}
\mathcal{L}(U, W) & =\mathbb{E}\left[\left\|G^{\top} q-U_{Y}\left(G^{\top} X+\varepsilon\right) p\right\|_{2}^{2}\right] \\
& =\mathbb{E}\left[\operatorname{Tr}\left(G G^{\top}\right)-2 \operatorname{Tr}\left(U_{Y} G^{\top} X p q^{\top} G\right)+\operatorname{Tr}\left(U_{Y}\left(G^{\top} X p p^{\top} X^{\top} G+\varepsilon p p^{\top} \varepsilon^{\top}\right) U_{Y}^{\top}\right)\right] \\
& =\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot\left(1-2 u_{i} d_{i}^{-1} \mathbb{E} \operatorname{Tr}_{i}\left(X p q^{\top}\right)+u_{i}^{2} d_{i}^{-1}\left(\mathbb{E} \operatorname{Tr}_{i}\left(X p p^{\top} X^{\top}\right)+d \sigma^{2} \lambda_{i}^{-1} \mathbb{E}\left[\|p\|_{2}^{2}\right]\right)\right) .
\end{aligned}
$$

Using (E.8), we have
$\mathcal{L}(U, W)=\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot\left(1-u_{i} d_{i}^{-1} \mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} q q^{\top}\right)\left(1-f_{1}\right)\right]+u_{i}^{2} d_{i}^{-1} \mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} q q^{\top} W_{X}^{\top} f_{2}\right)+d_{i} \phi_{i} f_{1}\right]\right)$.
With $0 \leq B=o(\log L)$, and noting that $b_{i} \leq B$, we have that all the conditions in Lemma B. 3 on the eigenvalues $\omega$ of $W_{X}$ are satisfied given that $d / L=\Theta(1)$ and $d_{i} / d=\Theta(1)$, i.e.,

$$
\|\omega\|_{\infty} \leq L^{-1 / 4} \cdot(\log L)^{-1 / 2}, \quad\|\omega\|_{2}^{2} \leq \frac{2 \log L}{3 c^{2}}, \quad\|\omega\|_{4}^{4} \leq L^{-(1-\epsilon)} \cdot(\log L)^{-1}
$$

We thus conclude that

$$
\mathbb{E}\left[\left(f_{1}\left(\left\|W_{X} q\right\|_{2}^{2}\right)-\frac{\exp (B)}{L}\right)^{2}\right] \leq O\left(L^{-(3-\epsilon)}\right)
$$

This together with the fact that $\|p\|_{3}^{3} \leq\|p\|_{2}^{2}$ and $\|p\|_{2}^{4} \leq\|p\|_{2}^{2}$ implies that

$$
\mathbb{E}\left[\left(f_{2}\left(\left\|W_{X} q\right\|_{2}^{2}\right)-1\right)^{2}\right] \leq O\left(\mathbb{E}\left[f_{1}\left(\left\|W_{X} q\right\|_{2}^{2}\right)^{2}\right]\right) \leq O\left(L^{-2(1-\epsilon)}\right) .
$$

Here, the last inequality holds since $B \leq \epsilon \log L$ for fixed small constant $\epsilon>0$. Therefore, we have each term in the ICL loss to be

$$
\begin{aligned}
\left|\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} q q^{\top}\right)\left(1-f_{1}\right)\right]-\bar{\omega}_{i} d_{i}\right| & =\left|\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} q q^{\top}\right)\left(1-f_{1}\right)\right]-\mathbb{E}\left[\operatorname{Tr}_{i}\left(W_{X} q q^{\top}\right)\right]\right| \\
& \leq\left|\operatorname{Tr}_{i}\left(\sqrt{\mathbb{E}\left[\operatorname{diag}\left(W_{X} q q^{\top}\right) \odot 2\right] \mathbb{E}\left[f_{1}^{2}\right]}\right)\right| \\
& =\bar{\omega}_{i} d_{i} \sqrt{\mathbb{E}\left[\chi^{4}\right] \mathbb{E}\left[f_{1}^{2}\right]}=\bar{\omega}_{i} d_{i} \cdot O\left(L^{-(1-\epsilon)}\right) . \\
\left|\mathbb{E} \operatorname{Tr}_{i}\left(W_{X} q q^{\top} W_{X}^{\top} f_{2}\right)-\bar{\omega}_{i}^{2} d_{i}\right| & =\left|\mathbb{E} \operatorname{Tr}_{i}\left(W_{X} q q^{\top} W_{X}^{\top} f_{2}\right)-\mathbb{E} \operatorname{Tr}_{i}\left(W_{X} q q^{\top} W_{X}^{\top}\right)\right| \\
\leq & \left|\operatorname{Tr}_{i}\left(\sqrt{\mathbb{E}\left[\operatorname{diag}\left(W_{X} q q^{\top} W_{X}^{\top}\right) \odot 2\right] \mathbb{E}\left[\left(f_{2}-1\right)^{2}\right]}\right)\right| \\
& =\bar{\omega}_{i}^{2} d_{i} \sqrt{\mathbb{E}\left[\chi^{4}\right] \mathbb{E}\left[\left(f_{2}-1\right)^{2}\right]}=\bar{\omega}_{i}^{2} d_{i} \cdot O\left(L^{-(1-\epsilon)}\right) .
\end{aligned} \quad \begin{aligned}
& \left|\mathbb{E}\left[f_{1}\right]-\frac{\exp (B)}{L}\right| \leq \sqrt{\mathbb{E}\left[\left(f_{1}-\frac{\exp (B)}{L}\right)^{2}\right]} \leq O\left(L^{-(3-\epsilon) / 2}\right) \leq \frac{\exp (B)}{L} \cdot O\left(L^{-(1-\epsilon) / 2}\right) .
\end{aligned}
$$

Therefore, the ICL loss can be controlled as

$$
\begin{aligned}
\mathcal{L}(U, W) & =\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d}\left(1-2 u_{i} \bar{\omega}_{i}\left(1 \pm \xi^{2}\right)+u_{i}^{2}\left(\bar{\omega}_{i}^{2}\left(1 \pm \xi^{2}\right)+\frac{\phi_{i} e^{B}}{L}(1 \pm \xi)\right)\right) \\
& =\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d}\left(1-2 u_{i} \bar{\omega}_{i}+u_{i}^{2}\left(\bar{\omega}_{i}^{2}+\frac{\phi_{i} e^{B}}{L}\right)\right) \pm \sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot\left(\xi^{2}\left(2 u_{i} \bar{\omega}_{i}+u_{i}^{2} \bar{\omega}_{i}^{2}\right)+\xi u_{i}^{2} \phi_{i} e^{B} / L\right) \\
& =\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot \frac{d_{i} \phi_{i} e^{B} / L}{b_{i}+d_{i} \phi_{i} e^{B} / L}+\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot\left(\left(b_{i}+\frac{d_{i} \phi_{i} e^{B}}{L}\right) \cdot\left(\frac{u_{i}}{\sqrt{d_{i}}}-\frac{\sqrt{b_{i}}}{b_{i}+d_{i} \phi_{i} e^{B} / L}\right)^{2} \pm O(\xi)\right),
\end{aligned}
$$

where $\xi=O\left(L^{-(1-\epsilon) / 2}\right)$. Here, the last upper and lower bound follows from (E.20). Moreover, if we also consider the perturbation of $\bar{\omega}$ from the optimal value, we have with $\left|B-B^{\star}\right|=o\left(B^{\star}\right)$ that

$$
\begin{aligned}
\mathcal{L}(U, W)= & \sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot\left(1-2 u_{i} \bar{\omega}_{i}^{\star}+\left(u_{i}\right)^{2}\left(\left(\bar{\omega}_{i}^{\star}\right)^{2}+\frac{\phi_{i} e^{B^{\star}}}{L}\right) \pm O\left(u_{i}\left|\bar{\omega}_{i}-\bar{\omega}_{i}^{\star}\right|+\frac{\phi_{i}}{L}\left|B^{\star}-B\right|\right)\right) \\
& \pm \sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot O(\xi) \\
= & \sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot \frac{d_{i} \phi_{i} e^{B^{\star}} / L}{b_{i}+d_{i} \phi_{i} e^{B^{\star}} / L}+\sum_{i=1}^{I} \frac{\lambda_{i}}{d} \cdot\left(\left(b_{i}^{\star}+\frac{d_{i} \phi_{i} e^{B^{\star}}}{L}\right) \cdot\left(u_{i}-u_{i}^{\star}\right)^{2}\right) \\
& +\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot O\left(u_{i}\left|\bar{\omega}_{i}-\bar{\omega}_{i}^{\star}\right|+\frac{\phi_{i}}{L}\left|B-B^{\star}\right|+\xi\right) .
\end{aligned}
$$

Hence, we prove the desired result.

## E.1.5 Proof of The Main Theorem and Its Consequences

Now we are ready to present the proof of Theorem E.1.
Proof of Theorem E.1. Now, we construct our $W^{\star}$ and $U^{\star}$ matrix for an upper bound:
where $B^{\star}$ and $b^{\star}=\left(b_{1}^{\star}, \ldots, b_{I}^{\star}\right)$ are the optimal solution to (E.17) and each $u_{i}^{\star}$ is given by

$$
u_{i}^{\star}=\frac{\sqrt{b_{i}^{\star} d_{i}}}{b_{i}^{\star}+d_{i} \phi_{i} \exp \left(B^{\star}\right) / L}
$$

according to (E.19). Combining our previous discussions, we already have any group of weights $W, U$ such that $W_{Y}=0$ satisfying the lower bound

$$
\begin{array}{rlr}
\inf _{\substack{U, W \\
W_{Y}=0}} \mathcal{L}(U, W) & \geq \inf _{\substack{1^{\top} \geq 0 \\
1^{\top}=B, b \geq 0}} \mathcal{L}_{\text {lb }}(B, b) & \text { // (E.12) }  \tag{E.12}\\
& \geq \min _{\substack{O\left(d^{2}-2 \epsilon\right) \geq B \geq 0 \\
1^{\top} b=B, b \geq 0}} \mathcal{L}_{l \mathrm{~b}}(B, b) & \text { // Lemma E. } 4 \\
& \geq \min _{\substack{c^{-2} \log L \geq B \geq 0 \\
1^{\top} b=B, b \geq 0}} \mathcal{L}_{\text {sim }}(B, b)-\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \cdot O\left(L^{-1+2\left(c^{-2} \vee \epsilon\right)}\right) . & \text { // Lemma E.5 }
\end{array}
$$

We also note that $B^{\star}=o(\log L)$ by Lemma E.6. In addition, (E.20) is satisfied by our construction. Hence, it holds by Lemma E. 7 that

$$
\mathcal{L}\left(U^{\star}, W^{\star}\right) \leq \min _{\substack{c^{-2} \log L \geq B \geq 0 \\ 1^{\top} b \geq B, b \geq 0}} \mathcal{L}_{\text {sim }}(B, b)+\sum_{i=1}^{I} \frac{d_{i} \lambda_{i}}{d} \cdot O\left(L^{-(1-\epsilon) / 2}\right) .
$$

Hence, we conclude that

$$
\mathcal{L}\left(U^{\star}, W^{\star}\right) \leq \inf _{\substack{U, W \\ W_{Y}=0}} \mathcal{L}(U, W)+\sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot O\left(L^{-(1-\epsilon) / 2}+L^{-1+2\left(c^{-2} \vee \epsilon\right)}\right),
$$

which completes our proof of Theorem E.1.
In the following, we consider a special case where we have only one task $i$ having nonzero signal strength $\lambda_{i}=\Theta(1)$.
Lemma E.8. Suppose that we have only one task $i$ with signal strength $\lambda_{i}=\Theta(1)$ and $\lambda_{j}=0$ for $j \neq i$. Then
(i) The solution to (E.17) is given by $B^{\star}=b_{i}^{\star}=1$ (which implies $\bar{\omega}_{i}^{\star}={\sqrt{d_{i}}}^{-1}$ and $\bar{\omega}_{j}^{\star}=0$ for $j \neq i)$. In addition, we have optimal value $u_{i}^{\star}=\sqrt{d_{i}} /\left(1+d_{i} \phi_{i} e L^{-1}\right)$ and $u_{j}^{\star}=0$ for $j \neq i$. Let $U, W$ be constructed as in (E.21) with $b^{\star}$ and $u^{\star}$ given as above. This gives the optimal ICL loss in the sense that

$$
\mathcal{L}\left(U^{\star}, W^{\star}\right)=\mathcal{L}_{\text {sim }}\left(B^{\star}, b^{\star}\right) \pm \frac{d_{i} \lambda_{i}}{d} \cdot O\left(L^{-(1-\epsilon) / 2}\right) \leq \inf _{\substack{U, W \\ W_{Y}=0}} \mathcal{L}(U, W)+\frac{d_{i} \lambda_{i}}{d} \cdot O\left(L^{-(1-\epsilon) / 2}\right),
$$

where $\mathcal{L}_{\text {sim }}\left(B^{\star}, b^{\star}\right)$ is given by $\mathcal{L}_{\text {sim }}\left(B^{\star}, b^{\star}\right)=\frac{e d_{i} \phi_{i} / L}{1+e d_{i} \phi_{i} / L}$.
(ii) Let $\bar{\omega}^{\star}$ and $u^{\star}$ be defined as in (i). Suppose we have a construction of $\bar{\omega}_{i}$ and $u_{i}$ such that

$$
\begin{equation*}
\left|\frac{\bar{\omega}_{i}}{\bar{\omega}_{i}^{\star}}-1\right| \leq \delta_{\omega}, \quad\left|\frac{u_{i}}{u_{i}^{\star}}-1\right| \leq \delta_{u}, \quad\left|\bar{\omega}_{j}\right| \leq \xi_{\omega}, \quad\left|u_{j}\right| \leq \xi_{u}, \quad \forall j \in[I] \backslash\{i\}, \tag{E.22}
\end{equation*}
$$

where $\delta_{\omega}=o(1), \delta_{u}=o(1), \xi_{\omega}=o\left(d^{-1 / 2}\right)$ and $\xi_{u}=o\left(d^{1 / 2}\right)$. Then the ICL loss for such a construction is upper bounded by

$$
\mathcal{L}(U, W) \leq \mathcal{L}_{\mathrm{sim}}\left(B^{\star}, b^{\star}\right)+\frac{\lambda_{i} d_{i}}{d} \cdot O\left(\delta_{\omega}+\xi_{\omega}^{2} d+\delta_{u}^{2}\right)+\sum_{k=1}^{I} \frac{d_{k} \lambda_{k}}{d} \cdot O\left(L^{-(1-\epsilon) / 2}\right)+\frac{\sigma^{2} I}{L} \cdot O\left(\xi_{u}^{2}\right)
$$

Proof of Lemma E.8. The first argument is straightforward by noting that the inner problem of (E.17) is convex with fixed total attention budget $B$, and we have monotonicity that the more attention budget is allocated to a task, the smaller the loss for that task is. With $\lambda_{j}=0$, the nominal task $j$ has no effect on the ICL loss and thus all attention budget should be allocated to the only task $i$, which gives the simplified loss

$$
\min _{b: \mathbf{1}^{\top} b=B} \mathcal{L}_{\mathrm{sim}}(B, b)=\frac{d_{i} \lambda_{i}}{d} \cdot \frac{1}{B e^{-B} \cdot d_{i}^{-1} \phi_{i}^{-1} L+1} .
$$

Obviously, $B=1$ is the optimal solution to the above problem since $x e^{-x}$ is maximized at $x=1$ for $x \geq 0$. The optimal $u_{i}^{\star}$ is given by (E.19). Invoking Lemma E.7, we have the desired result for the first argument.

For the second argument, we define $b_{i}=\bar{\omega}_{i}^{2} d_{i}$ and $B=\sum_{i=1}^{I} b_{i}$. Under the perturbation of $\bar{\omega}$, we have for task $i$ that
$\left|\frac{d_{i} \phi_{i} e^{B} / L}{b_{i}+d_{i} \phi_{i} e^{B} / L}-\frac{d_{i} \phi_{i} e^{B^{\star}} / L}{b_{i}^{\star}+d_{i} \phi_{i} e^{B^{\star}} / L}\right| \leq \frac{d_{i} \phi_{i} e^{B^{\star}} / L}{b_{i}^{\star}+d_{i} \phi_{i} e^{B^{\star}} / L} \cdot\left|\frac{b_{i}^{\star} e^{B-B^{\star}}}{b_{i}}-1\right| \leq \frac{d_{i} \phi_{i} e^{B^{\star}} / L}{b_{i}^{\star}+d_{i} \phi_{i} e^{B^{\star}} / L} \cdot O\left(\delta_{\omega}+\xi_{\omega}^{2} d\right)$.
and for task $j \neq i$ that

$$
0 \leq \frac{\lambda_{j} d_{j}}{d} \cdot \frac{d_{j} \phi_{j} e^{B} / L}{b_{j}+d_{j} \phi_{j} e^{B} / L} \leq \frac{\lambda_{j} d_{j}}{d}=0 .
$$

In addition, we have

$$
\begin{aligned}
\left|u_{i}^{\star}(b)-u_{i}^{\star}\right| & =\left|\frac{\sqrt{b_{i} d_{i}}}{b_{i}+d_{i} \phi_{i} e^{B} / L}-\frac{\sqrt{b_{i}^{\star} d_{i}}}{b_{i}^{\star}+d_{i} \phi_{i} e^{B^{\star}} / L}\right| \\
& \leq u_{i}^{\star} \cdot\left|\frac{\sqrt{b_{i}}\left(\sqrt{b_{i}^{\star}}-\sqrt{b_{i}}+d_{i} \phi_{i} L^{-1} \cdot\left(e^{B^{\star}} / \sqrt{b_{i}^{\star}}-e^{B} / \sqrt{b_{i}}\right)\right)}{b_{i}+d_{i} \phi_{i} e^{B} / L}\right| \leq u_{i}^{\star} \cdot O\left(\delta_{\omega}+\xi_{\omega}^{2} d\right) .
\end{aligned}
$$

For the perturbation of $u$, we have for task $i$ that

$$
\left|u_{i}-u_{i}^{\star}(b)\right| \leq\left|u_{i}-u_{i}^{\star}\right|+\left|u_{i}^{\star}(b)-u_{i}^{\star}\right| \leq u_{i}^{\star} \cdot O\left(\delta_{\omega}+\delta_{u}+\xi_{\omega}^{2} d\right),
$$

and for task $j \neq i$ that

$$
\left|u_{j}-u_{j}^{\star}(b)\right| \leq \xi_{u} \vee \frac{\sqrt{b_{j} d_{j}}}{b_{j}+d_{j} \phi_{j} e^{B} / L}=\xi_{u} \vee 0=\xi_{u} .
$$

Plugging these error terms into Lemma E.7, we have

$$
\begin{aligned}
\mathcal{L}(U, W) \leq & \mathcal{L}_{\text {sim }}\left(B^{\star}, b^{\star}\right)+\frac{\lambda_{i} d_{i}}{d} \cdot \frac{d_{i} \phi_{i} e^{B^{\star}} / L}{b_{i}^{\star}+d_{i} \phi_{i} e^{B^{\star}} / L} \cdot O\left(\delta_{\omega}+\xi_{\omega}^{2} d\right)+\sum_{k=1}^{I} \frac{d_{k} \lambda_{k}}{d} \cdot O\left(L^{-(1-\epsilon) / 2}\right) \\
& +\left(\lambda_{i} b_{i}+\frac{\left(d_{i} \lambda_{i}+\sigma^{2} d\right) e^{B}}{L}\right) d^{-1}\left(u_{i}^{\star}\right)^{2} \cdot O\left(\delta_{\omega}^{2}+\delta_{u}^{2}+\xi_{\omega}^{4} d^{2}\right)+\sum_{j \neq i} \frac{\sigma^{2} e^{B}}{L} \xi_{u}^{2} \\
\leq & \mathcal{L}_{\text {sim }}\left(B^{\star}, b^{\star}\right)+\frac{\lambda_{i} d_{i}}{d} \cdot O\left(\delta_{\omega}+\xi_{\omega}^{2} d+\delta_{u}^{2}\right)+\sum_{k=1}^{I} \frac{d_{k} \lambda_{k}}{d} \cdot O\left(L^{-(1-\epsilon) / 2}\right)+\frac{\sigma^{2} I}{L} \cdot O\left(\xi_{u}^{2}\right) .
\end{aligned}
$$

This completes the proof.

Lemma E. 9 (Restatement of Lemma 4.1). The ICL loss under the convergence point described for the MS-Attn in Theorem 3.3, which we define as $\mathcal{L}_{\text {Conv }}$, is upper bounded by

$$
\mathcal{L}_{\text {Conv }} \leq \sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot\left(\frac{e d_{i} \phi_{i} L^{-1}}{1+e d_{i} \phi_{i} L^{-1}}+O\left(L^{-(1-\epsilon) / 2}+\omega_{0}^{2} d+\delta\right)\right) .
$$

Proof of Lemma E.9. Same as before, we consider $\Phi$ and $\Psi$ to be identity matrices. Define

$$
G_{i}=\operatorname{diag}(\underbrace{0, \ldots, 0}_{i-1}, g_{i}, \underbrace{0, \ldots, 0}_{I-i})
$$

as the coefficient matrix with only the $i$-th block of $G$. Note that for Decomposable weights we always have $U^{(h)}$ and $W^{(h)}$ satisfying the form in (E.18) with

$$
W^{(h)}=\left[\begin{array}{cccc|c}
\bar{\omega}_{1}^{(h)} \cdot I_{d_{1}} & 0 & \cdots & 0 & \\
0 & \bar{\omega}_{2}^{(h)} \cdot I_{d_{2}} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots & \\
0 & 0 & \cdots & \bar{\omega}_{I}^{(h)} \cdot I_{d_{I}} & \\
0 & 0 & & & \star
\end{array}\right], \quad U^{(h)}=\left[\right] .
$$

With $W_{Y}^{(h)}=0$ and $U_{X}^{(h)}=0$, the ICL loss for MS-Attn is given by

$$
\begin{aligned}
\mathcal{L}\left(\left\{U^{(h)}, W^{(h)}\right\}_{h \in[H]}\right) & =\mathbb{E}\left[\left\|G^{\top} q-\sum_{h=1}^{H} U_{Y}^{(h)}\left(G^{\top} X+\varepsilon^{\top}\right) p^{(h)}\right\|_{2}^{2}\right] \\
& =\sum_{i=1}^{I} \mathbb{E}\left[\left(g_{i}^{\top} q-\mu_{i}^{\star}\left(g_{i}^{\top} X_{(i)}+\varepsilon_{i}^{\top}\right) p_{i}^{\star}+\sum_{h \neq h_{i}^{\star}} \mu_{i}^{(h)}\left(g_{i}^{\top} X_{(i)}+\varepsilon_{i}^{\top}\right) p^{(h)}\right)^{2}\right] \\
& \leq \sum_{i=1}^{I}\left(\mathcal{L}_{i}^{(1)}+2 \sqrt{\mathcal{L}_{i}^{(1)} \cdot I^{2} \mathcal{L}_{i}^{(2)}}+I^{2} \mathcal{L}_{i}^{(2)}\right)
\end{aligned}
$$

Here, we have kinds of errors $\mathcal{L}_{i}^{(1)}$ and $\mathcal{L}_{i}^{(2)}$ in the above loss and the last inequality is due to the Cauchy-Schwarz inequality. The first is the error of the optimal head on each task, which is given by

$$
\mathcal{L}_{i}^{(1)}:=\mathbb{E}\left[\left(g_{i}^{\top} q_{(i)}-\mu_{i}^{\star}\left(g_{i}^{\top} X_{(i)}+\varepsilon_{i}^{\top}\right) p_{i}^{\star}\right)^{2}\right] .
$$

In this case, we can think as having only one head and with only one nonzero task $i$. In addition, we have $u_{j}=0$ for $j \neq i$ for this only head. Invoking the second argument in Lemma E. 8 with $\delta_{\omega}=\delta_{u}=O(\delta)$ (convergence of the optimal heads), $\xi_{u}=0\left(u_{j}=0\right)$, and $\xi_{\omega}=O\left(\omega_{0}\right)$ (nonoptimal head $h \neq h_{i}^{\star}$ has $\bar{\omega}_{i}^{(h)}$ fixed at initialization), we have that the error for each task is upper bounded by

$$
\begin{equation*}
\mathcal{L}_{i}^{(1)} \leq \frac{\lambda_{i} d_{i}}{d} \cdot\left(\frac{e d_{i} \phi_{i} L^{-1}}{1+e d_{i} \phi_{i} L^{-1}}+O\left(\delta+\omega_{0}^{2} d+L^{-(1-\epsilon) / 2}\right)\right) \leq O(1) \tag{E.23}
\end{equation*}
$$

The second kind of error is the error coming from the "leakage" of the nonoptimal heads, which is given by

$$
\mathcal{L}_{i}^{(2)}:=\max _{h \neq h_{i}^{\star}} \mathcal{L}_{i}^{(2, h)}, \quad \text { where } \quad \mathcal{L}_{i}^{(2, h)}:=\mathbb{E}\left[\left(\mu_{i}^{(h)}\left(g_{i}^{\top} X_{(i)}+\varepsilon_{i}^{\top}\right) p^{(h)}\right)^{2}\right] .
$$

We can upper bound this error for each $h \neq h_{i}^{\star}$ by

$$
\begin{aligned}
\mathcal{L}_{i}^{(2, h)} & =\left(\mu_{i}^{(h)}\right)^{2} \cdot\left(\lambda_{i} d^{-1} \operatorname{Tr}\left(\mathbb{E}\left[X_{(i)} p^{(h)} p^{(h)^{\top}} X_{(i)}^{\top}\right]\right)+\sigma^{2} \mathbb{E}\left[\left\|p^{(h)}\right\|_{2}^{2}\right]\right) \\
& \leq\left(\mu_{i}^{(h)}\right)^{2} \cdot \mathbb{E}\left[\lambda_{i} d^{-1}\left\|W_{X}^{(h)} q\right\|_{2}^{2} f_{2}\left(\left\|W_{X}^{(h)} q\right\|_{2}^{2}\right)+\sigma^{2} f_{1}\left(\left\|W_{X}^{(h)} q\right\|_{2}^{2}\right)\right] \\
& \leq\left(\mu_{i}^{(h)}\right)^{2} \cdot\left(\lambda_{i} d^{-1} \cdot O(1)+\sigma^{2} \cdot O\left(L^{-(1-\epsilon)}\right)\right),
\end{aligned}
$$

where in the second inequality we replace the trace on the $i$-th block to the trace on the whole matrix as an upper bound, and in the last inequality, we use the fact that $\operatorname{Tr}\left(W_{X}^{(h)} W_{X}^{(h)^{\top}}\right)=1+o(1)$ at the convergence point. Combining the above results, we conclude that

$$
\begin{aligned}
\mathcal{L}\left(\left\{U^{(h)}, W^{(h)}\right\}_{h \in[H]}\right) \leq & \sum_{i=1}^{I}\left(\mathcal{L}_{i}^{(1)}+2 \sqrt{\mathcal{L}_{i}^{(1)} \cdot I^{2} \mathcal{L}_{i}^{(2)}}+I^{2} \mathcal{L}_{i}^{(2)}\right) \\
\leq & \sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot\left(\frac{e d_{i} \phi_{i} L^{-1}}{1+e d_{i} \phi_{i} L^{-1}}+O\left(\delta+\omega_{0}^{2} d+L^{-(1-\epsilon) / 2}\right)\right) \\
& +O\left(I^{2}\right) \cdot \max _{i, h \neq h_{i}^{\star}} \mu_{i}^{(h)} \cdot \sqrt{\lambda_{i} d^{-1} \cdot O(1)+\sigma^{2} \cdot O\left(L^{-(1-\epsilon)}\right)} .
\end{aligned}
$$

Note that $\mu_{i}^{(h)}=\mu_{i}^{\star} \exp \left(-O\left(\sqrt{d} d_{i} \phi_{i} L^{-1}\right)\right)$, which is sufficiently small in scale. Hence, we just need to consider the first term, which gives the desired result.

## E. 2 Lower Bound for Multi-Head Attention

In this section, we aim to prove the following optimality result for multihead attention within the class of equiangular weights. We consider MS-Attn with $H$ heads and $I$ tasks. Let $\bar{\omega}=\left\{\bar{\omega}_{i}^{(h)}\right\}_{h \in[H]}$ and $\mu=\left\{\mu_{i}^{(h)}\right\}_{h \in[H]}$, and the loss is defined as

$$
\mathcal{L}(\mu, \bar{\omega})=\mathbb{E}\left[\left\|G^{\top} q-\sum_{h=1}^{H} U_{Y}^{(h)}\left(G^{\top} X+\varepsilon\right) p^{(h)}\right\|_{2}^{2}\right], \quad \text { where } \quad p^{(h)}=\operatorname{softmax}\left(X^{\top} W_{X}^{(h)} q\right) .
$$

Theorem E. 10 (Optimality of Multi-Head Attention). Suppose we have $H \geq 2$ heads and I tasks and consider MS-Attn with equiangular weights. Assume that all the tasks are homogeneous, i.e., $d_{i}=\bar{d}:=d / H$ and $\lambda_{i}=\lambda$ for all $i \in[H]$. Consider the regime where

$$
\left\|\bar{\omega}^{(h)}\right\|_{\infty} \leq \sqrt{2 \log L / 3 d c^{2}}, \quad\left\|\mu^{(h)}\right\|_{\infty} \leq L^{3 / 4-\epsilon / 2} \quad \forall h \in[H],
$$

where $c$ is a constant satisfying

$$
\frac{1}{c}+\frac{3}{1+\sqrt{1+c^{2} / 2}} \leq \epsilon .
$$

The ICL loss for MS-Attn is lower bounded by the maximum of

$$
\frac{\lambda}{\phi^{-1} d^{-1} L \cdot(H-1)+1}-O\left(L^{-\epsilon / 2}\right)
$$

and the Bayesian risk
Bayesian Risk $=$ Variance + Bias, where

$$
\begin{aligned}
\text { Variance } & =I \sigma^{2} \cdot \frac{b r+(1+r)-\sqrt{(b r-1+r)^{2}+4 b}}{2 \sqrt{(b r-1+r)^{2}+4 b}} \\
\text { Bias } & =\lambda \cdot\left(\frac{b r(1+r)+(1-r)^{2}-|1-r| \sqrt{(b r-1+r)^{2}+4 b r}}{2 \sqrt{(b r-1+r)^{2}+4 b}}+\left(1-\frac{1}{r}\right) \mathbb{1}(r>1)\right)
\end{aligned}
$$

Proof of Theorem E.10. Under the decomposability assumption, we have the loss function as

$$
\begin{aligned}
\mathcal{L}(\mu, \bar{\omega})=\mathbb{E}[ & q^{\top} G G^{\top} q-2 q^{\top} G \sum_{h \in[H]} U_{Y}^{(h)}\left(G^{\top} X+\varepsilon\right) p^{(h)} \\
& \left.+\sum_{h, h^{\prime} \in[H]} p^{(h)^{\top}}\left(X^{\top} G+\varepsilon^{\top}\right) U_{Y}^{(h)^{\top}} U_{Y}^{\left(h^{\prime}\right)}\left(G^{\top} X+\varepsilon\right) p^{\left(h^{\prime}\right)}\right] \\
= & \lambda- \\
& \frac{2 \lambda}{d} \sum_{h \in[H]} \operatorname{Tr}\left(\left(\operatorname{diag}\left(\mu^{(h)}\right) \otimes_{K} I \bar{d}\right) \mathbb{E}\left[X p^{(h)} q^{\top}\right]\right) \\
& +\frac{\lambda}{d} \sum_{h, h^{\prime} \in[H]} \operatorname{Tr}\left(\left(\operatorname{diag}\left(\mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}\right) \otimes_{K} I_{\bar{d}}\right) \mathbb{E}\left[X p^{(h)} p^{\left(h^{\prime}\right)^{\top}} X^{\top}\right]\right) \\
& +\sum_{h, h^{\prime} \in[H]} \sigma^{2}\left\langle\mu^{(h)}, \mu^{\left(h^{\prime}\right)}\right\rangle \mathbb{E}\left[p^{(h)^{\top}} p^{\left(h^{\prime}\right)}\right] \\
=\lambda- & \frac{2 \lambda}{I} \sum_{h \in[H]} \mathbb{E}\left[\left\langle\mu^{(h)}, \bar{\omega}^{(h)} \odot v^{2}\right\rangle\left(1-f_{3}^{(h, h)}\right)\right] \\
& +\frac{\lambda}{I} \sum_{h, h^{\prime} \in[H]} \mathbb{E}\left[\left\langle\mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}, \bar{\omega}^{(h)} \odot \bar{\omega}^{(h)} \odot v^{2} f_{1}^{\left(h, h^{\prime}\right)}+\bar{\omega}^{\left(h^{\prime}\right)} \odot \bar{\omega}^{\left(h^{\prime}\right)} \odot v^{2} f_{1}^{\left(h^{\prime}, h\right)}\right\rangle\right] \\
& +\frac{\lambda}{I} \sum_{h, h^{\prime} \in[H]} \mathbb{E}\left[\left\langle\mu^{(h)} \odot \mu^{\left(h^{\prime}\right)}, \bar{\omega}^{(h)} \odot \bar{\omega}^{\left(h^{\prime}\right)} \odot v^{2} f_{2}^{\left(h, h^{\prime}\right)}\right\rangle+\left(1+\frac{\sigma^{2} I}{\lambda}\right)\left\langle\mu^{(h)}, \mu^{\left(h^{\prime}\right)}\right\rangle f_{3}^{\left(h, h^{\prime}\right)}\right]
\end{aligned}
$$

where $\otimes_{K}$ denotes the Kronecker product, and $\odot$ denotes the element-wise product. Here, we denote by $v^{2}$ a $d$-dimensional random vector where each entry is drawn i.i.d. from the chi-square distribution with degree 1 . We use the following definition for the last equality,

$$
\begin{aligned}
f_{1}^{\left(h, h^{\prime}\right)} & :=\mathbb{E}\left[\left(p^{\left(h^{\prime}\right)}\right)^{\top}\left(p^{(h)}\right)^{\odot 2}-\left(p^{\left(h^{\prime}\right)}\right)^{\top} p^{(h)}\left\|p^{(h)}\right\|_{2}^{2} \mid q\right] \\
f_{2}^{\left(h, h^{\prime}\right)} & :=\mathbb{E}\left[\left(1-\left\|p^{\left(h^{\prime}\right)}\right\|_{2}^{2}\right)\left(1-\left\|p^{(h)}\right\|_{2}^{2}\right)+\left(p^{(h)}\right)^{\top} p^{\left(h^{\prime}\right)}-\left(p^{\left(h^{\prime}\right)}\right)^{\top}\left(p^{(h)}\right)^{\odot 2}-\left(p^{\left(h^{\prime}\right)}\right)^{\top}\left(p^{(h)}\right)^{\odot 2}+\left(p^{(h)^{\top}} p^{\left(h^{\prime}\right)}\right)^{2} \mid q\right] \\
f_{3}^{\left(h, h^{\prime}\right)} & :=\mathbb{E}\left[\left(p^{(h)}\right)^{\top} p^{\left(h^{\prime}\right)}\right]
\end{aligned}
$$

where the relationship between these terms to $\mathbb{E}[X p]$ and $\mathbb{E}\left[X p^{(h)} p^{\left(h^{\prime}\right)^{\top}} X^{\top}\right]$ is given by Lemma C.8. As a matter of fact, both $f_{1}$ and $f_{2}$ are functions of $q$. Note that $f_{1}^{\left(h, h^{\prime}\right)}$ is actually a higher order term, and according to our regime where $\left\|\bar{\omega}^{(h)}\right\|_{\infty} \leq \sqrt{2 \log L / 3 d c^{2}}$, we have all the conditions in Lemma B. 4 and Lemma B. 3 satisfied and thus

$$
\begin{gathered}
\left|\mathbb{E}\left[v_{i}^{2} \cdot f_{1}^{\left(h, h^{\prime}\right)}\right]\right| \leq \sqrt{\mathbb{E}\left[v_{i}^{4}\right] \cdot \mathbb{E}\left[\left(f_{1}^{\left(h, h^{\prime}\right)}\right)^{2}\right]}=O\left(L^{-2(1-\epsilon)}\right) \\
\left|\mathbb{E}\left[v_{i}^{2} \cdot f_{2}^{\left(h, h^{\prime}\right)}\right]-1\right| \leq \sqrt{\mathbb{E}\left[v_{i}^{4}\right] \cdot \mathbb{E}\left[\left(f_{2}^{\left(h, h^{\prime}\right)}-1\right)^{2}\right]}=O\left(L^{-1}\right) \\
\left|\mathbb{E}\left[f_{3}^{\left(h, h^{\prime}\right)}\right]-\frac{\exp \left(\bar{d}\left\langle\bar{\omega}^{(h)}, \bar{\omega}^{\left(h^{\prime}\right)}\right\rangle\right)}{L}\right| \leq \sqrt{\mathbb{E}\left[\left(f_{3}^{\left(h, h^{\prime}\right)}-\frac{\exp \left(\bar{d}\left\langle\bar{\omega}^{(h)}, \bar{\omega}^{\left(h^{\prime}\right)}\right\rangle\right)}{L}\right)^{2}\right]}=O\left(L^{-(3-\epsilon) / 2}\right)
\end{gathered}
$$

Note that it is hard to optimize for $\mu$ for each individual head. However, we note that by the Decomposability Condition, we can instead optimize for each task separately. In particular, the individual loss of task $i$ is given by

$$
\mathcal{L}_{i}(\mu, \bar{\omega}):=1-2 \mu_{i}^{\top} \bar{\omega}_{i}+\mu_{i}^{\top}\left(\bar{\omega}_{i} \bar{\omega}_{i}^{\top}+B\right) \mu_{i}
$$

The $B \in \mathbb{R}^{H \times H}$ matrix in the above equation is given element-wise by

$$
\left(B_{i}\right)_{h h^{\prime}}:=\phi_{i} L^{-1} \exp \left(\bar{d}\left\langle\bar{\omega}^{(h)}, \bar{\omega}^{\left(h^{\prime}\right)}\right\rangle\right)
$$

Here, we denote by $\mu_{i}=\left(\mu_{i}^{(h)}\right)_{h \in[H]}$ and $\bar{\omega}_{i}=\left(\bar{\omega}_{i}^{(h)}\right)_{h \in[H]}$ the eigenvalues of the attention weights for task $i$. Here, we drop the energy term $\lambda / I$ in the definition. Note that we also ignore the higher order terms by suffering from an error of $O\left(L^{-\epsilon / 2}\right)$ given the scale of $\mu$ and $\bar{\omega}$. As a result, the relationship between $\mathcal{L}$ and $\mathcal{L}_{i}$ is given by

$$
\mathcal{L}(\mu, \bar{\omega})=\frac{\lambda}{I} \sum_{i=1}^{I} \mathcal{L}_{i}(\mu, \bar{\omega})+O\left(L^{-\epsilon / 2}\right)
$$

Lower Bound for the ICL Loss. We define an operator $\mathcal{R}$ that applies the following elementwise transformation to a matrix $A$ :

$$
(\mathcal{R} \circ A)_{m n}=\phi_{i} L^{-1} \exp \left(\bar{d} A_{m n}\right)
$$

Let $M=\left(\bar{\omega}^{(1)}, \ldots, \bar{\omega}^{(H)}\right) \in \mathbb{R}^{I \times H}$. To this end, we can rewrite $B$ as

$$
B=\mathcal{R} \circ\left(M^{\top} M\right)
$$

Solving for this quadratic problem, we obtain

$$
\begin{equation*}
\mu_{i}^{\star}=\left(\bar{\omega}_{i} \bar{\omega}_{i}^{\top}+B\right)^{-1} \bar{\omega}_{i} \tag{E.24}
\end{equation*}
$$

and the corresponding loss

$$
\mathcal{L}_{i}(\bar{\omega}):=1-\bar{\omega}_{i}^{\top}\left(\bar{\omega}_{i} \bar{\omega}_{i}^{\top}+B\right)^{-1} \bar{\omega}_{i}
$$

Note that although we restrict $\left\|\mu^{(h)}\right\|_{\infty} \leq L^{3 / 4-\epsilon / 2}$, the optimal $\mu_{i}^{\star}$ in (E.24) can be much larger than $L^{3 / 4-\epsilon / 2}$, which may lead to a looser lower bound. However, as we will show later, this only leads to an additional constant multiplicative factor in the lower bound. By property of the equiangular weights, $M^{\top} M$ has the same value for the diagonal elements, which we denote by $a$, and also the same value for off-diagonal elements, which we denote by $b$. The same also holds for $B$, and we denote the value for the diagonal elements by $\widetilde{a}$ and the value for the off-diagonal elements by $\widetilde{b}$. The quadratic term can be simplified as

$$
A_{i}:=\bar{\omega}_{i} \bar{\omega}_{i}^{\top}+(\widetilde{a}-\widetilde{b}) I+\widetilde{b} E .
$$

We note that

$$
\Upsilon_{i}=\left(\frac{\mathbf{1}_{H}}{\sqrt{H}}, \bar{\omega}_{i}-\frac{\mathbf{1}_{H}^{\top} \bar{\omega}_{i}}{H} \cdot \mathbf{1}_{H}, \ldots\right)
$$

forms an orthogonal basis. Let $q_{i}=\mathbf{1}_{H}^{\top} \bar{\omega}_{i} / \sqrt{H}$ be the inner product of $\mathbf{1}_{H} / \sqrt{H}$ and $\bar{\omega}_{i}$ and $\widetilde{\omega}_{i}=\bar{\omega}_{i}-q_{i} \cdot \mathbf{1}_{H} / \sqrt{H}$ be the orthogonal projection of $\bar{\omega}_{i}$ onto the orthogonal complement of $\mathbf{1}_{H} / \sqrt{H}$. We thus have

$$
\Upsilon_{i}^{\top} A_{i} \Upsilon_{i}=\left[\begin{array}{ccc}
q_{i}^{2}+\widetilde{a}+(H-1) \widetilde{b} & q_{i}\left\|\widetilde{\omega}_{i}\right\|_{2} & 0 \\
q_{i}\left\|\widetilde{\omega}_{i}\right\|_{2} & \left\|\widetilde{\omega}_{i}\right\|_{2}^{2}+\widetilde{a}-\widetilde{b} & 0 \\
0 & 0 & (\widetilde{a}-\widetilde{b}) I_{H-2}
\end{array}\right] .
$$

The inverse of the above matrix is given by

$$
\left(\Upsilon_{i}^{\top} A_{i} \Upsilon_{i}\right)^{-1}=\left[\begin{array}{ccc}
\frac{\left\|\widetilde{\omega}_{i}\right\|_{2}^{2}+\tilde{a}-\tilde{b}}{} & -\frac{q_{i}\left\|\widetilde{\omega}_{i}\right\|_{2}}{q_{i}} & 0 \\
-\frac{q_{i}\left\|\widetilde{\omega}_{i}\right\|_{2}}{\Delta} & \frac{q_{i}^{2}+\widetilde{a}+(H-1) \tilde{b}}{\Delta} & 0 \\
0 & 0 & \frac{I_{H-1}}{\widetilde{a}-\tilde{b}}
\end{array}\right] .
$$

where

$$
\begin{aligned}
\Delta & =\left(q_{i}^{2}+\widetilde{a}+(H-1) \widetilde{b}\right)\left(\left\|\widetilde{\omega}_{i}\right\|_{2}^{2}+\widetilde{a}-\widetilde{b}\right)-q_{i}^{2}\left\|\widetilde{\omega}_{i}\right\|_{2}^{2} \\
& =(\widetilde{a}+(H-1) \widetilde{b})\left\|\widetilde{\omega}_{i}\right\|_{2}^{2}+q_{i}^{2}(\widetilde{a}-\widetilde{b})+(\widetilde{a}+(H-1) \widetilde{b})(\widetilde{a}-\widetilde{b})
\end{aligned}
$$

is the determinant of top left $2 \times 2$ submatrix of $\Upsilon_{i}^{\top} A_{i} \Upsilon_{i}$. Therefore,

$$
\begin{aligned}
\bar{\omega}_{i}^{\top} A_{i}^{-1} \bar{\omega}_{i} & =\left(\Upsilon_{i}^{\top} \bar{\omega}_{i}\right)^{\top}\left(\Upsilon_{i}^{\top} A_{i} \Upsilon_{i}\right)^{-1}\left(\Upsilon_{i}^{\top} \bar{\omega}_{i}\right) \\
& =\left[\begin{array}{lll}
q_{i} & \left\|\widetilde{\omega}_{i}\right\|_{2} & 0
\end{array}\right] \cdot\left[\begin{array}{ccc}
\frac{\left\|\widetilde{\omega}_{i}\right\|_{2}^{2}+\widetilde{a}-\tilde{b}}{\Delta} & -\frac{q_{i}\left\|\widetilde{\omega}_{i}\right\|_{2}}{\Delta} & 0 \\
-\frac{q_{i}\left\|\widetilde{\omega}_{i}\right\|_{2}}{\Delta} & \frac{q_{i}^{2}+\widetilde{a}+(H-1) \tilde{b}}{\Delta} & 0 \\
0 & 0 & \frac{I_{H-1}}{\widetilde{a}-\tilde{b}}
\end{array}\right] \cdot\left[\begin{array}{c}
q_{i} \\
\left\|\widetilde{\omega}_{i}\right\|_{2} \\
0
\end{array}\right] \\
& =\frac{q_{i}^{2}\left(\left\|\widetilde{\omega}_{i}\right\|_{2}^{2}+\widetilde{a}-\widetilde{b}\right)+\left\|\widetilde{\omega}_{i}\right\|_{2}^{2}\left(q_{i}^{2}+\widetilde{a}+(H-1) \widetilde{b}\right)-2 q_{i}^{2}\left\|\widetilde{\omega}_{i}\right\|_{2}^{2}}{\Delta} \\
& =1-\frac{(\widetilde{a}-\widetilde{b})(\widetilde{a}+(H-1) \widetilde{b})}{\Delta} .
\end{aligned}
$$

As a result, we have

$$
\begin{align*}
& \frac{1}{I} \sum_{i=1}^{I} \mathcal{L}_{i}(\bar{\omega}) \\
& \quad=\frac{1}{I} \sum_{i=1}^{I} \frac{(\widetilde{a}-\widetilde{b})(\widetilde{a}+(H-1) \widetilde{b})}{(\widetilde{a}+(H-1) \widetilde{b})\left\|\widetilde{\omega}_{i}\right\|_{2}^{2}+q_{i}^{2}(\widetilde{a}-\widetilde{b})+(\widetilde{a}+(H-1) \widetilde{b})(\widetilde{a}-\widetilde{b})} \\
& \quad \geq \frac{(\widetilde{a}-\widetilde{b})(\widetilde{a}+(H-1) \widetilde{b})}{(\widetilde{a}+(H-1) \widetilde{b}) \cdot \frac{1}{I} \sum_{i=1}^{I}\left\|\widetilde{\omega}_{i}\right\|_{2}^{2}+\frac{1}{I} \sum_{i=1}^{I} q_{i}^{2}(\widetilde{a}-\widetilde{b})+(\widetilde{a}+(H-1) \widetilde{b})(\widetilde{a}-\widetilde{b})}  \tag{E.25}\\
& \\
& =\frac{(\widetilde{a}-\widetilde{b})(\widetilde{a}+(H-1) \widetilde{b})}{(\widetilde{a}+(H-1) \widetilde{b}) \cdot I^{-1}(H-1)(a-b)+I^{-1}(a+(H-1) b)(\widetilde{a}-\widetilde{b})+(\widetilde{a}+(H-1) \widetilde{b})(\widetilde{a}-\widetilde{b})},
\end{align*}
$$

where in the inequality we use the Jensen's inequality for the convex function $x \mapsto 1 /(1+x)$. In the last equality, we note that

$$
\sum_{i=1}^{I}\left\|\bar{\omega}_{i}\right\|_{2}^{2}=\operatorname{Tr}\left(M^{\top} M\right)=H a, \quad \sum_{i=1}^{I} q_{i}^{2}=\sum_{i=1}^{I}\left\|\mathbf{1}_{H}^{\top} \bar{\omega}_{i} / \sqrt{H}\right\|_{2}^{2}=H^{-1} \operatorname{Tr}\left(E M^{\top} M\right)=a+(H-1) b
$$

As a result, $I^{-1} \sum_{i=1}^{I}\left\|\widetilde{\omega}_{i}\right\|_{2}^{2}=I^{-1} \sum_{i=1}^{I}\left\|\bar{\omega}_{i}\right\|_{2}^{2}-I^{-1} \sum_{i=1}^{I} q_{i}^{2}=I^{-1}(H-1)(a-b)$ and $I^{-1} \sum_{i=1}^{I} q_{i}^{2}=$ $I^{-1}(a+(H-1) b)$. By a direction calculation, we also have

$$
\begin{aligned}
\frac{1}{I} \sum_{i=1}^{I} \mathcal{L}_{i}(\bar{\omega}) & \geq \frac{1}{\frac{(H-1)(a-b)}{I(\widetilde{a}-\tilde{b})}+\frac{a+(H-1) b}{I(\widetilde{a}+(H-1) \tilde{b})}+1} \\
& =\frac{1}{\widetilde{b}^{-1} \cdot \frac{(H-1)(a-b)}{I(\widetilde{a} / \tilde{b}-1)}+\widetilde{b}^{-1} \cdot \frac{a+(H-1) b}{I(\widetilde{a} / \tilde{b}+(H-1))}+1} .
\end{aligned}
$$

Now, we plug in the definition $\widetilde{a}=\phi L^{-1} \exp (\bar{d} a)$ and $\widetilde{b}=\phi L^{-1} \exp (\bar{d} b)$, and we have

$$
\frac{1}{I} \sum_{i=1}^{I} \mathcal{L}_{i}(\bar{\omega}) \geq \frac{1}{I^{-1} \phi^{-1} L \exp (-\bar{d} b) \cdot\left(\frac{(H-1)(a-b)}{\exp (\bar{d}(a-b))-1}+\frac{a+(H-1) b}{\exp (\bar{d}(a-b))+H-1}\right)+1} .
$$

To this end, we define $x=\bar{d}(a-b)$ and $y=\bar{d} b$. Our target is thus to optimize:

$$
\max _{x, y} g(x, y):=\exp (-y) \cdot\left(\frac{(H-1) x}{\exp (x)-1}+\frac{x+H y}{\exp (x)+H-1}\right) .
$$

However, there are constraints we need to consider, given the nonnegativity of the energy:

$$
\begin{array}{rlr}
\sum_{i=1}^{I}\left\|\widetilde{\omega}_{i}\right\|_{2}^{2}=(H-1)(a-b) \geq 0 & \Rightarrow & x \geq 0 \\
\sum_{i=1}^{I} q_{i}^{2}=a+(H-1) b \geq 0 & \Rightarrow & x+H y \geq 0
\end{array}
$$

We first optimize $y$ given $x$. The partial derivative of $g(x, y)$ with respect to $y$ is given by

$$
\frac{\partial g(x, y)}{\partial y}=C(x, y) \cdot\left(1+(H-2) x-y e^{x}(x+y-1)\right)
$$

where $C: \mathbb{R} \times \mathbb{R} \mapsto \mathbb{R}_{+}$is a positive function. Let

$$
y_{0}=-\frac{e^{x}(x-1)+1+(H-2) x}{e^{x}-1} .
$$

Note that the above function increases when $y \leq y_{0}$ and decreases when $y \geq y_{0}$. Our constraint also requires that $y \geq-x / H$. We just need to decide which one is larger between $-x / H$ and $y_{0}$. Suppose $y_{0}>-x / H$. With a little bit of algebra, we have this condition equivalent to

$$
\frac{H}{H-1}>\left(1+\frac{H}{e^{x}-1}\right) x
$$

given the nonnegativity of $x$. Note that the left hand side decreases to 1 as $H$ increases, and the right hand side increases. Thus, we just need to check the case when $H=2$, and we consider another function

$$
g_{1}(x)=x+\frac{2 x}{e^{x}-1}-2 .
$$

Notably, this function is increasing as $x \geq 0$, and the minimal value is achieved at $x=0$ which gives $g_{1}(0)=0$. Thus, we have $y_{0}>-x / H$ impossible for $H \geq 2$. As a result, we conclude that the optimal $y$ should always be $y^{\star}(x):=-\frac{x}{H}$. The remaining is just a simple plug in, which gives

$$
g\left(x, y^{\star}\right)=\exp \left(\frac{x}{H}\right) \cdot \frac{(H-1) x}{\exp (x)-1},
$$

where the optimal $x$ is given by finding the maximum of the above function when $x \geq 0$. Let the optimal $x$ be $x^{\star}$. Clearly $0<x^{\star} \leq 1$ as for $x=0, \exp (x / H) x$ has a faster growing rate than $\exp (x)$ in a sufficiently small region. For the other side, it is not hard to see that function decreases for $x \geq 1$. We have the loss lower bounded by

$$
\begin{align*}
\mathcal{L}(\mu, \bar{\omega}) & \geq \frac{\lambda}{I} \sum_{i=1}^{I} \mathcal{L}_{i}(\mu, \bar{\omega})-O\left(L^{-\epsilon / 2}\right) \\
& \geq \frac{\lambda}{I^{-1} \phi^{-1} \bar{d}^{-1} L \cdot \max _{x \geq 0} \frac{\exp (x / H)(H-1) x}{\exp (x)-1}+1}-O\left(L^{-\epsilon / 2}\right) \\
& =\frac{\lambda}{\phi^{-1} d^{-1} L \cdot \max _{x \geq 0} \frac{\exp (x / H)(H-1) x}{\exp (x)-1}+1}-O\left(L^{-\epsilon / 2}\right) . \tag{E.26}
\end{align*}
$$

Note that the loss in (E.26) cannot be better than the loss achieved by the Bayesian posterior mean estimator. Let $b=\sigma^{2} / \lambda$. The Bayesian risk in our case is just the MMSE. Asymptotically, i.e., $d \rightarrow \infty$ and $L \rightarrow \infty$ with $\bar{d} / L \rightarrow r$, the MMSE is given by
Bayesian Risk $=$ Variance + Bias, where

$$
\begin{aligned}
\text { Variance } & =I \sigma^{2} \cdot \frac{b r+(1+r)-\sqrt{(b r-1+r)^{2}+4 b r}}{2 \sqrt{(b r-1+r)^{2}+4 b r}} \\
\text { Bias } & =\lambda \cdot\left(\frac{b r(1+r)+(1-r)^{2}-|1-r| \sqrt{(b r-1+r)^{2}+4 b r}}{2 \sqrt{(b r-1+r)^{2}+4 b r}}+\left(1-\frac{1}{r}\right) \mathbb{1}(r>1)\right) .
\end{aligned}
$$

(E.27, MMSE \& Ridge)
where $r=\bar{d} / L=d /(I L)$. Here, characterizing the asymptotical behavior of the MMSE is just a matter of calculating the following variance and bias term in the limit $\bar{d} / L \rightarrow r$ :

$$
\begin{aligned}
\text { Variance } & :=\sum_{i=1}^{I} \sigma^{2} \mathbb{E}\left[\operatorname{Tr}\left(\left(X_{(i)} X_{(i)}^{\top}+b d I_{\bar{d}}\right)^{-1} X_{(i)} X_{(i)}^{\top}\left(X_{(i)} X_{(i)}^{\top}+b d I_{\bar{d}}\right)^{-1}\right)\right], \\
\text { Bias } & :=\sum_{i=1}^{I} \frac{\lambda}{d} \cdot \mathbb{E}\left[\operatorname{Tr}\left(\left(\left(X_{(i)} X_{(i)}^{\top}+b d I_{\bar{d}}\right)^{-1} X_{(i)}-I_{\bar{d}}\right)\left(\left(X_{(i)} X_{(i)}^{\top}+b d I_{\bar{d}}\right)^{-1} X_{(i)}-I_{\bar{d}}\right)^{\top}\right)\right] .
\end{aligned}
$$

Let $\nu$ be the Marchenko-Pastur distribution (Marchenko and Pastur, 1967) for the eigenvalues of $X_{(i)} X_{(i)}^{\top} / L$, which is the same for different $i$ since we assume the homogeneity of the tasks. Therefore, we have

$$
\text { Variance }=\sigma^{2} d \cdot \mathbb{E}_{s \sim \nu}\left[\frac{L s}{(L s+b d)^{2}}\right], \text { Bias }=\lambda \cdot \mathbb{E}_{s \sim \nu}\left[\frac{(b d)^{2}}{(L s+b d)^{2}}\right],
$$

which gives the result in (E.27, MMSE \& Ridge). In particular, if $r \rightarrow 0$, i.e., large sequence length, the MMSE is approximately given by This completes the proof.

Discussion of the ICL Loss Lower Bound. Note that throughout the proof of the lower bound, the first inequality we are using is (E.25), where equality holds if

$$
\left\|\widetilde{\omega}_{i}\right\|_{2}^{2}=\left\|\widetilde{\omega}_{j}\right\|_{2}^{2} \quad \text { for all } i, j \in[I] \quad \text { and } \quad q_{i}^{2}=q_{j}^{2} \quad \text { for all } i, j \in[I],
$$

and the second optimality condition is $y^{\star}=-x^{\star} / H$ with $x^{\star}$ solved by $\operatorname{argmax}_{x \geq 0} \frac{\exp (x / H)(H-1) x}{\exp (x)-1}$. Note that $x+H y=0 \Rightarrow a+(H-1) b=0 \Rightarrow \sum_{i=1}^{I} q_{i}^{2}=0$, which means that the projection of $\bar{\omega}_{i}$ onto $\mathbf{1}_{H} / \sqrt{H}$ is zero for all $i \in[I]$. Therefore, we just need to ensure $\left\|\bar{\omega}_{i}\right\|_{2}^{2}=\left\|\bar{\omega}_{j}\right\|_{2}^{2}$ for all $i, j \in[I]$. Consider matrix $M=\left(\bar{\omega}^{(1)}, \ldots, \bar{\omega}^{(H)}\right) \in \mathbb{R}^{I \times H}$. Our condition is just saying that
(i) the row sum of $M$ is 0 .
(ii) the row norm of $M$ is the same for all rows.
(iii) the columns of $M$ form an equiangular system.
(iv) $\operatorname{Tr}\left(M^{\top} M\right)=(H-1) x^{\star}$.

However, observant readers might have noticed that the optimal $x^{\star}$ is always 0 for $H \geq 2$. This is not realistic as $\operatorname{Tr}\left(M^{\top} M\right)=0$ just means $W=0$, which is not learning anything. We remark that this issue is due to our approximation of the loss function's landscape and allowing violation of the $\left\|\mu^{(h)}\right\|_{\infty} \leq L^{3 / 4-\epsilon / 2}$ condition in (E.24). However, we remark that (E.26) still gives us a correct lower bound on the ICL rate, where the difference between letting $x \rightarrow 0$ and $x=\Theta(1)$ is just a loss of a constant multiplicative factor as we can clearly see from (E.26). Although condition (iv) is not realistic, the remaining conditions are indeed realistic and achievable by the gradient flow of the MS-Attn as we will show in the experiment.

## E. 3 Comparison

In the following discussion, we neglect some error terms for simplicity and only consider the regime where $L / d$ beats the SNR, i.e., $r=\bar{d} / L=o\left(\lambda / \sigma^{2}\right)$. Note that when we are having a single head to solve the multitask problem, the optimal rate given by Theorem E. 1 is

$$
\begin{equation*}
\frac{\lambda}{e^{-1} \phi^{-1} d^{-1} L+1} \approx e\left(\lambda+\sigma^{2} I\right) \cdot \frac{d}{L}, \tag{E.28,OptS-ICL}
\end{equation*}
$$

while the lower bound in (E.26) is given by

$$
\begin{equation*}
\frac{\lambda}{\phi^{-1} d^{-1} L \cdot(H-1)+1} \approx(H-1)^{-1} \cdot\left(\lambda+\sigma^{2} I\right) \cdot \frac{d}{L} . \tag{E.29,LB-ICL}
\end{equation*}
$$

The ICL loss achieved by the convergence point of the gradient flow of the MS-Attn with $H \geq I$ characterized by Lemma 4.1,

$$
\begin{equation*}
\frac{\lambda}{I e^{-1} \phi^{-1} d^{-1} L+1} \approx e I^{-1} \cdot\left(\lambda+\sigma^{2} I\right) \cdot \frac{d}{L} . \tag{E.30,GF-ICL}
\end{equation*}
$$

Moreover, the Bayesian risk is given by (E.27, MMSE \& Ridge), which for $r=\bar{d} / L \leq 1$ is approximately given by the variance term

$$
\begin{equation*}
\frac{I \sigma^{2} r}{1+(b-1) r}=\frac{I \sigma^{2}}{I \cdot d^{-1} L+\sigma^{2} / \lambda-1} \approx \sigma^{2} \cdot \frac{d}{L} . \tag{MMSE}
\end{equation*}
$$

In addition, when using a ridge regression with regularization parameter $b d$ for each task, i.e.,

$$
\widehat{g}_{i}=\underset{g \in \mathbb{R}^{\bar{d}}}{\operatorname{argmin}}\left\|Y_{i}-g^{\top} X_{(i)}\right\|_{2}^{2}+b d \cdot\|g\|_{2}^{2},
$$

and use the minimizer as the estimator for the query, we still have the rate given by (E.27, MMSE \& Ridge) ( $b$ functions as the regularization parameter). Notably, as the number of tasks $I$ increases, the ICL loss achieved by the gradient flow of the MS-Attn is getting closer to the MMSE but only with a constant multiplicative factor gap. There is clear gap between the single head and the multihead ICL loss.

Figure 7: Comparison of loss functions

## F Generalization

In this section, we provide generalization results both to a new sequence length and nonlinear tasks. Before we proceed, we first introduce the basic definition of multivariate Hermite polynomials and some additional notations.

## F. 1 Length Generalization

We first consider generalization of the optimal single-head softmax attention to a new sequence length $\widetilde{L}$.

Proof of Proposition 5.1. The proof is a combination of Lemma E. 8 and the proof of Lemma E.9. Note that for a new sequence length $\widetilde{L}$, the optimal $W_{X}$ remains unchanged. Also, we can equivalently view $U_{Y}$ as a perturbation of the optimal $U_{Y}$ under $\widetilde{L}$. Let $\bar{\omega}_{i}^{\star}$ and $\mu_{i}^{\star}$ be the optimal (nonzero) eigenvalues for $W_{X}^{\left(h_{i}^{\star}\right)}$ and $U_{Y}^{\left(h_{i}^{\star}\right)}$ at task $i$ 's position under the new sequence length $\widetilde{L}$. Let $\bar{\omega}_{i}^{(h)}$ and $\bar{\omega}_{i}^{(h)}$ be the eigenvalues at the convergence point of the gradient flow trained under the original sequence length $L$. In particular,

$$
\begin{gathered}
\bar{\omega}_{i}^{\star}=d_{i}^{-1 / 2}, \quad \mu_{i}^{\star}=\frac{\sqrt{d_{i}}}{1+e \phi_{i} d_{i} / \widetilde{L}}, \quad\left|\frac{\bar{\omega}_{i}^{\left(h_{i}^{\star}\right)}}{d_{i}^{-1 / 2}}-1\right| \leq O(\delta), \quad\left|\frac{\mu_{i}^{\left(h_{i}^{\star}\right)}}{\sqrt{d_{i}} /\left(1+e \phi_{i} d_{i} L^{-1}\right)}-1\right| \leq O(\delta) . \\
\bar{\omega}_{i}^{(h)}=O\left(\omega_{0}\right), \quad \mu_{i}^{(h)}=\frac{\sqrt{d_{i}}}{1+e \phi_{i} d_{i} L^{-1}} \cdot \exp \left(-O\left(\sqrt{d} d_{i} \phi_{i} L^{-1}\right)\right), \quad \forall h \in[H] \backslash\left\{h_{i}^{\star}\right\} .
\end{gathered}
$$

Therefore, we have for the convergence point of the gradient flow,

$$
\left|\frac{\bar{\omega}_{i}^{\left(h_{i}^{\star}\right)}}{\bar{\omega}_{i}^{\star}}-1\right| \leq O(\delta), \quad\left|\frac{\mu_{i}^{\left(h_{i}^{\star}\right)}}{\mu_{i}^{\star}}-1\right| \leq O(\delta) \cdot \frac{1+e \phi_{i} d_{i} L^{-1}}{1+e \phi_{i} d_{i} \widetilde{L}^{-1}}+e \phi_{i} d_{i}\left|L^{-1}-\widetilde{L}^{-1}\right| .
$$

We observe that the only difference from the previous proof is the last error in $\mu_{i}^{\left(h_{i}^{\star}\right)}$. Therefore, the only difference is in the first kind of error concerning the optimal head previously described by (E.23). In this case, we have following Lemma E. 8 to get (E.23) replaced by

$$
\mathcal{L}_{i}^{(1)} \leq \frac{\lambda_{i} d_{i}}{d} \cdot\left(\frac{e d_{i} \phi_{i} \widetilde{L}^{-1}}{1+e d_{i} \phi_{i} \widetilde{L}^{-1}}+O\left(\delta+\omega_{0}^{2} d+L^{-(1-\epsilon) / 2}\right)+O\left(e \phi_{i} d_{i}\left|L^{-1}-\widetilde{L}^{-1}\right|\right)^{2}\right) \leq O(1) .
$$

Therefore, we have the result in Lemma E. 9 replaced by

$$
\mathcal{L}_{\text {Conv }} \leq \sum_{i=1}^{I} \frac{\lambda_{i} d_{i}}{d} \cdot\left(\frac{e d_{i} \phi_{i} L^{-1}}{1+e d_{i} \phi_{i} L^{-1}}+O\left(L^{-(1-\epsilon) / 2}+\omega_{0}^{2} d+\delta\right)+O\left(\phi_{i} d_{i}\left|L^{-1}-\widetilde{L}^{-1}\right|\right)^{2}\right)
$$

Hence, we have the result in Proposition 5.1.

## F. 2 Generalization to Nonlinear Task

In this section, we provide proof for the nonlinear generalization of the optimal single-head softmax attention for a single task.

Proof of Lemma 5.2. Since at the convergence point of the gradient flow, each optimal head is handling a unique task as the optimal single-head softmax attention, the generalization for the multi-head case is consequently implied by the single-head case. To this end, we consider a nonlinear task $y=f(x)$, where $f$ is a nonlinear function. Suppose $f$ has degree at most $D$ in the sense that $f$ is a linear combination of $d$-dimensional multivariate Hermite polynomials $\left\{\operatorname{He}_{\alpha}\left|\alpha \in \mathbb{N}^{d},|\alpha|=\right.\right.$ $\left.\sum_{i=1}^{d} \alpha_{i} \leq D\right\}$ as

$$
f(x)=\sum_{|\alpha| \leq D} \widehat{f}_{\alpha} \operatorname{He}_{\alpha}(x), \quad \text { where } \quad \hat{f}_{\alpha} \in \mathbb{R}
$$

We consider only the bias for the softmax attention and it suffices to only consider

$$
\mathbb{E}\left[\sum_{l=1}^{L} f\left(x_{l}\right) p_{l} \mid q\right], \quad \text { where } \quad p=\operatorname{softmax}(s), \quad s_{l}=x_{l}^{\top} W_{X} q
$$

We consider each term in the decomposition of $f(x)$ separately. For degree $\alpha$, we have

$$
\begin{aligned}
\mathbb{E}\left[\sum_{l=1}^{L} \mathrm{He}_{\alpha}\left(x_{l}\right) p_{l}(s) \mid q\right] & =\sum_{l=1}^{L} \mathbb{E}\left[(-1)^{|\alpha|} e^{\left\|x_{l}\right\|_{2}^{2} / 2} \frac{\partial^{|\alpha|}}{\partial x^{\alpha}} e^{-\left\|x_{l}\right\|_{2}^{2} / 2} \cdot p_{l}(s)\right] \\
& =\sum_{l=1}^{L} \int_{x_{l}}(-1)^{|\alpha|} \frac{\partial^{|\alpha|}}{\partial x_{l}^{\alpha}} \frac{e^{-\left\|x_{l}\right\|_{2}^{2} / 2}}{\sqrt{2 \pi}^{d}} \cdot p_{l}(s) \mathrm{d} x_{l} \\
& =\sum_{l=1}^{L} \mathbb{E}\left[\left.\frac{\partial^{|\alpha|}}{\partial x_{l}^{\alpha}} p_{l}(s) \right\rvert\, q\right]=\prod_{i=1}^{d}\left(\bar{\omega} q_{i}\right)^{\alpha_{i}} \cdot \sum_{l=1}^{L} \mathbb{E}\left[\left.\frac{\partial^{|\alpha|} p_{l}(s)}{\partial s_{l}^{|\alpha|}} \right\rvert\, q\right]
\end{aligned}
$$

where the last equality is by integrate by parts. The derivative of the softmax probability with respect to the attention score will yield a polynomial of $p$ as well since $\partial p_{l} / \partial s_{l}=p_{l}\left(1-p_{l}\right)$. Note that since the optimal attention works in the linear operating region and we have low degree $|\alpha| \leq D$, we can safely apply the low-effective-order (Definition C.9) approximation since the coefficient before each term is constant and we have at most $D$ terms $\partial^{|\alpha|} p_{l} / \partial s_{l}^{|\alpha|}$. Note that $p_{l}$ has effective order $0, p_{l}-p_{l}^{2}$ also has lowest effective order 0 and low effective order approximation $p_{l}-p_{l}^{2}={ }_{\leqslant 0} p_{l}$. As a matter of fact, by Lemma C. 12 and (C.21) in Lemma C.13, we can always ensures that

$$
\frac{\partial^{|\alpha|}}{\partial s_{l}^{|\alpha|}} p_{l}={ }_{\leqslant 0} p_{l}
$$

We have by the tail bound of chi-square distribution (by (B.5)) that for any $\delta \in(0,1)$,

$$
\begin{equation*}
\mathbb{P}\left(\left\|W_{X} q\right\|_{2}^{2} \geq\left\|W_{X}\right\|_{\mathrm{F}}^{2}+2\left\|W_{X}\right\|_{\mathrm{F}}^{2} \sqrt{\log \delta^{-1}}+2\left\|W_{X}\right\|_{\mathrm{op}}^{2} \log \delta^{-1}\right) \leq \delta \tag{F.1}
\end{equation*}
$$

Since $W_{X}=d^{-1 / 2} I_{d}$, to ensure $\left\|W_{X} q\right\|_{2}^{2} \leq c^{-2} \cdot 2 \log L$ for some constant $c$ such that

$$
\frac{1}{c}+\frac{3}{1+\sqrt{1+c^{2} / 2}}=\epsilon
$$

holds for some small constant $\epsilon$, we just need to set

$$
\delta=\exp \left(-\left(c^{-2} \log L-1\right)^{2}\right) \vee \exp (-d / 2)
$$

Notably, we have all terms with higher effective order upper bounded by the only term with effective order 1, i.e., $\|p\|_{2}^{2}$, since $p_{l} \leq 1$ for all $l \in[L]$. Thus, by Lemma B.2, we have with probability at least $1-\delta$ that the terms effective order higher than 0 in $p$ (e.g., $\mathbb{E}\left[\|p\|_{2}^{2} \mid q\right], \mathbb{E}\left[\|p\|_{3}^{3} \mid q\right]$ ) is upper bounded by $O\left(L^{-2(1-\epsilon)}\right)$ given that $D$ is constant. Thus, conditioned on the success of the event in (F.1), we have

$$
\sum_{l=1}^{L} \mathbb{E}\left[\left.\frac{\partial^{|\alpha|} p_{l}(s)}{\partial s_{l}^{|\alpha|}} \right\rvert\, q\right]=\mathbb{E}\left[\|p\|_{1} \mid q\right] \pm O\left(L^{-2(1-\epsilon)}\right)=1 \pm O\left(L^{-2(1-\epsilon)}\right)
$$

Thus, we conclude that

$$
\begin{aligned}
& \mathbb{P}\left(\forall|\alpha| \leq D, \quad\left|\mathbb{E}\left[\sum_{l=1}^{L} \operatorname{He}_{\alpha}\left(x_{l}\right) p_{l}(s) \mid q\right]-\prod_{i=1}^{d}\left(\bar{\omega} q_{i}\right)^{\alpha_{i}}\right| \geq O\left(L^{-2(1-\epsilon)}\right)\right) \\
& \quad \leq \exp \left(-\left(c^{-2} \log L-1\right)^{2}\right) \vee \exp (-d / 2) .
\end{aligned}
$$

Therefore,

$$
\mathbb{P}\left(\left|\mathbb{E}[\mu Y p \mid q]-\mu \cdot \sum_{\alpha:|\alpha| \leq D} \widehat{f}_{\alpha} \bar{\omega}^{|\alpha|} \cdot q^{\alpha}\right| \geq O\left(L^{-2(1-\epsilon)}\right)\right) \leq \exp \left(-\left(\frac{\log L}{c^{2}}-1\right)^{2} \wedge \frac{d}{2}\right),
$$

where we define $q^{\alpha}=\prod_{i=1}^{d} q_{i}^{\alpha_{i}}$. Thus, we conclude the result in Lemma 5.2.

## G Auxiliary Results

We collect the proofs of the auxiliary results used before.

## G. 1 Proof of Auxiliary Results in §C. 1

## G.1. 1 Proof of Lemma C. 2

Proof. We give a proof for the first equality in Lemma C. 2 and the remaining two can be calculated using a similar argument. The proof is based on the Stein's Lemma, which states that for a Gaussian random variable $x \sim N\left(0, I_{d}\right)$ and a differentiable function $g: \mathbb{R}^{d} \rightarrow \mathbb{R}$ with $\mathbb{E}\left[\|\nabla g(x)\|_{2}\right]$ finite, we have

$$
\mathbb{E}[x \cdot g(x)]=\mathbb{E}[\nabla g(X)]
$$

We apply the Stein's Lemma to the function $f_{l m n}$ recursively for three times. Note that $f_{l m n}$ is a function of the attention scores $s_{l}$ and $\widetilde{s}_{l}$, and thus is a function of the covariate sequence $\left\{x_{l}\right\}_{l \in[L]}$ in the ICL. By chain rule, we have

$$
\begin{aligned}
\mathbb{E}\left[f_{l m n} \cdot x_{l} \otimes x_{m} \otimes x_{n}\right] & =\mathbb{E}\left[\nabla_{x_{l}} \otimes\left(f_{l m n} \cdot x_{m} \otimes x_{n}\right)\right] \\
& =\mathbb{E}\left[\nabla_{x_{l}} f_{l m n} \otimes x_{m} \otimes x_{n}+\delta_{l m} f_{l m n} \cdot I_{d} \otimes x_{n}+\delta_{l n} f_{l m n} \cdot\left(I_{d} \otimes x_{m}\right)^{\top(132)}\right] .
\end{aligned}
$$

Here the first equality is due to the Stein's lemma, and the second equality is due to the chain rule, where we use the fact that $\nabla_{x_{l}}\left(x_{m}\right)=\delta_{l m} I_{d}$. Moreover, applying the Stein's Lemma again, we have

$$
\begin{aligned}
\mathbb{E}\left[\nabla_{x_{l}} f_{l m n} \otimes x_{m} \otimes x_{n}\right] & =\mathbb{E}\left[\left(\nabla_{x_{l}} \otimes \nabla_{x_{m}}\right) f_{l m n} \otimes x_{n}+\delta_{m n} \nabla_{x_{l}} f_{l m n} \otimes I_{d}\right] \\
& =\mathbb{E}\left[\left(\nabla_{x_{l}} \otimes \nabla_{x_{m}} \otimes \nabla_{x_{n}}\right) f_{l m n}+\delta_{m n} \nabla_{x_{l}} f_{l m n} \otimes I_{d}\right], \\
\mathbb{E}\left[\delta_{l m} f_{l m n} \cdot I_{d} \otimes x_{n}\right] & =\mathbb{E}\left[\delta_{l m} \cdot I_{d} \otimes \nabla_{x_{n}} f_{l m n}\right], \\
\mathbb{E}\left[\delta_{l n} f_{l m n} \cdot\left(I_{d} \otimes x_{m}\right)^{\top(132)}\right] & =\mathbb{E}\left[\delta_{l n} f_{l m n} \cdot\left(I_{d} \otimes \nabla_{x_{m}} f_{l m n}\right)^{\top(132)}\right],
\end{aligned}
$$

where we apply the Stein's Lemma twice in the first equation. Therefore, we have

$$
\begin{aligned}
\mathbb{E}\left[f_{l m n} \cdot x_{l} \otimes x_{m} \otimes x_{n}\right]=\mathbb{E} & {\left[\left(\nabla_{x_{l}} \otimes \nabla_{x_{m}} \otimes \nabla_{x_{n}}\right) f_{l m n}+\delta_{m n} \nabla_{x_{l}} f_{l m n} \otimes I_{d}\right] } \\
& +\mathbb{E}\left[\delta_{l m} \cdot I_{d} \otimes \nabla_{x_{n}} f_{l m n}+\delta_{l n} f_{l m n} \cdot\left(I_{d} \otimes \nabla_{x_{m}} f_{l m n}\right)^{\top(132)}\right] .
\end{aligned}
$$

Notice that $x_{l}$ only appears in the attention scores $s_{l}$ and $\widetilde{s}_{l}$. This is because $s_{l}=x_{l}^{\top} W_{X} q$ and $\widetilde{s}_{l}=x_{l}^{\top} \widetilde{W}_{X} q$. As a result, we can write $\nabla_{x_{l}}=\left(W_{X} q \partial_{l}+\widetilde{W}_{X} q \widetilde{\partial}_{l}\right)$. Plugging in the definition of $\mathcal{T}_{l}$ in (C.11), we obtain that $\nabla_{x_{l}} f_{l m n}=\mathcal{T}_{l} \circ f_{l m n}$, i.e., we can replace $\nabla_{x_{l}}$ by the operator $\mathcal{T}_{l}$ in the above equation. Finally, taking the summation over $l, m, n \in[H]$, we obtain the desired result.

For the second equality, consider the second-order tensor $\left\{f_{l m}\right\}_{l, m \in[L]}$. By applying the Stein's Lemma twice, we have

$$
\mathbb{E}\left[f_{l m} \cdot x_{l} \otimes x_{m}\right]=\mathbb{E}\left[\nabla_{x_{l}} f_{l m} \otimes x_{m}+\delta_{l m} f_{l m} \cdot I_{d}\right]=\mathbb{E}\left[\left(\nabla_{x_{l}} \otimes \nabla_{x_{m}}\right) f_{l m}+\delta_{l m} f_{l m} \cdot I_{d}\right]
$$

Then replacing $\nabla_{x_{l}}$ by $\mathcal{T}_{l}$ and taking the summation over $l, m \in[H]$, we obtain the desired result.
Finally, the last equality can be proved by directly applying the Stein's Lemma to the function $f_{l}$, i.e.,

$$
\mathbb{E}\left[f_{l} \cdot x_{l}\right]=\mathbb{E}\left[\nabla_{x_{l}} f_{l}\right]
$$

Therefore, we conclude the proof.

## G.1. 2 Proof of Lemma C. 4

Proof. We define $\nu=\operatorname{diag}(\omega) \bar{q}$ and $\widetilde{\nu}=\operatorname{diag}(\widetilde{\omega}) \bar{q}$. Note that the joint distribution of $(s, \widetilde{s}) \mid q$ can be factorized as a tensor product of the distribution of each individual $\left(s_{1}, \widetilde{s}_{1}\right) \mid q$ since $\left\{x_{l}\right\}_{l \in[L]}$ are independently sampled. It suffices to show that the distribution of $\left(s_{1}, \widetilde{s}_{1}\right) \mid q$ is fully determined by $\|\nu\|_{2},\|\widetilde{\nu}\|_{2}$ and $\langle\nu, \widetilde{\nu}\rangle$. For fixed $\|\nu\|_{2},\|\widetilde{\nu}\|_{2}$ and $\langle\nu, \widetilde{\nu}\rangle$, there exist constants $c_{1}$ and $c_{2}$ that depend on $\|\nu\|_{2},\|\widetilde{\nu}\|_{2}$ and $\langle\nu, \widetilde{\nu}\rangle$ such that we can rewrite $\widetilde{\nu}$ as $\widetilde{\nu}=c_{1} \nu_{/ /}+c_{2} \nu_{\perp}$, where $\nu_{/ /}=\nu /\|\nu\|_{2}$ and $\nu_{\perp}$ is orthogonal to $\nu_{/ /}$. By definition, we have

$$
\begin{aligned}
& s_{1}=\bar{x}_{1}^{\top} \operatorname{diag}(\omega) \bar{q}=\left\langle\bar{x}_{1}, \nu\right\rangle=\|\nu\|_{2} \cdot\left\langle\bar{x}_{1}, \nu_{\|}\right\rangle, \\
& \widetilde{s}_{1}=\bar{x}_{1}^{\top} \operatorname{diag}(\widetilde{\omega}) \bar{q}=\left\langle\bar{x}_{1}, \widetilde{\nu}\right\rangle=c_{1} \cdot\left\langle\bar{x}_{1}, \nu_{\|}\right\rangle+c_{2} \cdot\left\langle\bar{x}_{1}, \nu_{\perp}\right\rangle,
\end{aligned}
$$

where $\bar{x}_{1}=\Phi^{\top} x_{1}$ is the rotated covariate of the first context token, whose distribution is also rotationally invariant. Therefore, the joint distribution of $\left\langle\bar{x}_{1}, \nu_{/ /}\right\rangle$and $\left\langle\bar{x}_{1}, \nu_{\perp}\right\rangle$ does not depend on the specific choice of $\nu_{/ /}$and $\nu_{\perp}$. Thus, the joint distribution of $\left(s_{1}, \widetilde{s}_{1}\right) \mid q$ is fully determined by $\left(\|\nu\|_{2}, c_{1}, c_{2}\right)$, and thus by $\left(\|\nu\|_{2},\|\widetilde{\nu}\|_{2},\langle\nu, \widetilde{\nu}\rangle\right)$. Thus, we conclude the proof.

## G. 2 Proof of Auxiliary Results in §C. 2

## G.2.1 Proof of Lemma C. 13

Proof. For the last term in (C.20), if $W(R(u)) \geq 1$, then adding 1 to $a_{u}$ will not change $\mathrm{CC}_{\geq 1}(\mathcal{G})$ and only increase the effective order by 1 . If $W(R(u))=0$, then adding 1 to $a_{u}$ will also include $R(u)$ in $\mathrm{CC}_{\geq 1}(\mathcal{G})$ and increase the cardinality of $\mathrm{CC}_{\geq 1}(\mathcal{G})$ by 1 , which offsets the effect of the increase in $a_{u}$. Therefore, the conditions for keeping effective order $k$ is $W(R(u))=0$ for the last term.

We next consider the first $|\mathcal{V}|$ terms in the summation, where each term only adds a new edge $(u, s)$ for some $s \in \mathcal{V}$ to the graph $\mathcal{G}$. The requirement $a_{s} \geq 1$ is obvious, which also suggests that $R(s) \in \mathrm{CC}_{\geq 1}(\mathcal{G})$. To this end, it suffices to see under what conditions will adding an edge $(u, s)$ to the graph $\mathcal{G}$ not affect $\left|\mathrm{CC}_{\geq 1}(\mathcal{G})\right|$. If $s \in R(u)$, then adding an edge $(u, s)$ within the same connected component will not change anything. If $s \notin R(u)$, consider two cases: (i) $W(R(u))=0$ and (ii) $W(R(u)) \geq 1$. If $W(R(u))=0$, then $R(u) \notin \mathrm{CC}_{\geq 1}(\mathcal{G})$ and adding an edge (u,s) only replaces $R(s)$ with $R(s) \cup R(u)$ in $\mathrm{CC}_{\geq 1}(\mathcal{G})$, which does not change the cardinality of $\mathrm{CC}_{\geq 1}(\mathcal{G})$. If $W(R(u)) \geq 1$, then $R(u) \in \mathrm{CC}_{\geq 1}(\mathcal{G})$ and adding an edge ( $\left.u, s\right)$ will merge $R(u)$ and $R(s)$ into a single connected component, which decreases the cardinality of $\mathrm{CC}_{>1}(\mathcal{G})$ by 1 . Therefore, the conditions for keeping effective order $k$ is $s \in R(u) \vee W(R(u))=0$.

## G.2.2 Proof of Lemma C. 15

Proof. We denote by $f_{=1}$ the terms $p^{\top} \widetilde{p}$ and $f_{>1}$ the terms of higher effective order. Let $f=$ $f_{=1}+f_{>1}$. We denote by $f^{*}=L^{-1} \cdot \exp (\langle\omega, \widetilde{\omega}\rangle)$ as the approximation of $f$. Invoking (C.22) and (C.23), we have

$$
\frac{\sqrt{\mathbb{E}\left[\left(f-f^{*}\right)^{2}\right]}}{f^{*}} \leq \frac{\sqrt{2 \mathbb{E}\left[\left(f_{>1}\right)^{2}\right]+2 \mathbb{E}\left[\left(f_{=1}-f^{*}\right)^{2}\right]}}{L^{-1} \cdot \exp (\langle\omega, \widetilde{\omega}\rangle)} \leq O\left(L^{-\left(1-\epsilon_{0}\right) / 2}\right) .
$$

For the first case, we denote by $g=\left\langle v, \bar{q}^{\odot 2}\right\rangle \cdot \bar{q}_{i}^{2}$ and $g^{*}=\mathbb{E}[g]=\langle v\rangle+2 v_{i}$. For the second case, we denote by $g=\bar{q}_{i}^{2}$ and $g^{*}=\mathbb{E}[g]=1$. We use the following error decomposition

$$
\begin{aligned}
\left|\frac{\mathbb{E}[f g]}{f^{*} g^{*}}-1\right| & \leq \frac{\left|\mathbb{E}\left[\left(f-f^{*}\right)\left(g-g^{*}\right)\right]\right|+\left|\mathbb{E}\left[\left(f-f^{*}\right) g^{*}\right]\right|+\left|f^{*} \mathbb{E}\left[\left(g-g^{*}\right)\right]\right|}{\left|f^{*} g^{*}\right|} \\
& \leq \frac{\sqrt{\mathbb{E}\left[\left(f-f^{*}\right)^{2}\right] \cdot \mathbb{E}\left[\left(g-g^{*}\right)^{2}\right]}}{\left|f^{*} g^{*}\right|}+\frac{\sqrt{\mathbb{E}\left[\left(f-f^{*}\right)^{2}\right]}}{\left|f^{*}\right|} \\
& \leq\left(2+\frac{\sqrt{\mathbb{E}\left[\left(g-g^{*}\right)^{2}\right]}}{\left|g^{*}\right|}\right) \cdot O\left(L^{-\left(1-\epsilon_{0}\right) / 2}\right) .
\end{aligned}
$$

where in the second inequality, we use the Cauchy-Schwarz inequality and the fact that $\mathbb{E}\left[\left(g-g^{*}\right)\right]=$ 0 . It suffices to verify that $\sqrt{\mathbb{E}}\left[\left(g-g^{*}\right)^{2}\right] /\left|g^{*}\right|=O(1)$ for both cases. For the first case, we have the following calculation:

$$
\begin{aligned}
\mathbb{E}\left[\left(g-g^{*}\right)^{2}\right] & =\operatorname{Var}[g]=\operatorname{Var}\left[\left\langle v_{-i}, \bar{q}_{-i}^{\odot 2}\right\rangle \bar{q}_{i}^{2}+v_{i} \bar{q}_{i}^{4}\right] \leq 2 \operatorname{Var}\left[\left\langle v_{-i}, \bar{q}_{-i}^{\odot 2}\right\rangle \bar{q}_{i}^{2}\right]+2 \operatorname{Var}\left[v_{i} \bar{q}_{i}^{4}\right] \\
& =2\left(\mathbb{E}\left[\left\langle v_{-i}, \bar{q}_{-i}^{\odot 2}\right\rangle^{2}\right] \cdot \mathbb{E}\left[\bar{q}_{i}^{4}\right]-\mathbb{E}\left[\left\langle v_{-i}, \bar{q}_{-i}^{\odot 2}\right\rangle\right]^{2} \cdot \mathbb{E}\left[\bar{q}_{i}^{2}\right]^{2}\right)+2 \operatorname{Var}\left[v_{i} \bar{q}_{i}^{4}\right] \\
& =2\left(3 v_{-i}^{\top}\left(\mathbf{1 1}{ }^{\top}+2 I_{d-1}\right) v_{-i}-\left\langle v_{-i}\right\rangle^{2}\right)+192 v_{i}^{2}=4\left\langle v_{-i}\right\rangle^{2}+12\left\langle v_{-i}^{\odot 2}\right\rangle+192 v_{i}^{2} .
\end{aligned}
$$

Therefore,

$$
\frac{\sqrt{\mathbb{E}\left[\left(g-g^{*}\right)^{2}\right]}}{\left|g^{*}\right|} \leq \frac{\sqrt{4\left\langle v_{-i}\right\rangle^{2}+12\left\langle v_{-i}^{\odot 2}\right\rangle+192 v_{i}^{2}}}{\left|\langle v\rangle+2 v_{i}\right|} \leq \frac{4\left\langle v_{-i}\right\rangle+\sqrt{192} v_{i}}{\langle v\rangle+2 v_{i}} \leq O(1)
$$

where we use the fact that $\left\langle v_{-i}^{\odot_{2}^{2}}\right\rangle \leq\left\langle v_{-i}\right\rangle^{2}$ and $\left|\left\langle v_{-i}\right\rangle\right| \leq|\langle v\rangle|$ if $v \in \mathbb{R}_{+}^{d}$ or $v \in \mathbb{R}_{-}^{d}$. For the second case, we have $\mathbb{E}\left[\left(g-g^{*}\right)^{2}\right]=\operatorname{Var}[g]=\operatorname{Var}\left[\bar{q}_{i}^{2}\right]=2$ and hence $\sqrt{\mathbb{E}\left[\left(g-g^{*}\right)^{2}\right]} / g^{*}=\sqrt{2}=O(1)$. Next, we consider only having terms with higher effective order. Using the same definition for $g$ and $g^{*}$, it holds that

$$
\begin{aligned}
\left|\frac{\mathbb{E}\left[f_{>1} g\right]}{g^{*}}\right| & \leq\left|\frac{\mathbb{E}\left[f_{>1}\left(g-g^{*}\right)\right]+\mathbb{E}\left[f_{>1} g^{*}\right]}{g^{*}}\right| \leq \frac{\sqrt{\mathbb{E}\left[\left(f_{>1}\right)^{2}\right] \cdot \mathbb{E}\left[\left(g-g^{*}\right)^{2}\right]}+g^{*} \mathbb{E}\left[f_{>1}\right]}{\left|g^{*}\right|} \\
& \leq\left(1+\frac{\sqrt{\mathbb{E}\left[\left(g-g^{*}\right)^{2}\right]}}{\left|g^{*}\right|}\right) \cdot \sqrt{\mathbb{E}\left[\left(f_{>1}\right)^{2}\right]}=O\left(L^{-2(1-\epsilon)}\right),
\end{aligned}
$$

where in the last inequality, we have already proved that $\sqrt{\mathbb{E}\left[\left(g-g^{*}\right)^{2}\right]} / g^{*}=O(1)$ for both cases. We also invoke (C.23) to conclude that $\sqrt{\mathbb{E}\left[\left(f_{>1}\right)^{2}\right]}=O\left(L^{-2(1-\epsilon)}\right)$.

[^0]:    Accepted for presentation at the Conference on Learning Theory (COLT) 2024

[^1]:    ${ }^{1}$ Here we are refering to the fact that $K^{\top} Q=(O K)^{\top}(O Q)$ for any orthogonal matrix $O$.

[^2]:    ${ }^{2}$ Here we omit the time dependence of the weights for simplicity.

[^3]:    ${ }^{3}$ The difference between semi-singular values and standard singular values is that we allow semi-singular values to be negative.

[^4]:    ${ }^{4}$ See Figure 6 for a graphic illustration of the "exponential" behavior of the softmax attention in this regime
    ${ }^{5}$ This is a direct result of Lemma B. 3 applied to a single head which says $\mathbb{E}\left[\|p\|_{2}^{2}\right] \approx \exp \left(\|\omega\|_{2}^{2}\right) / L=o(1)$

[^5]:    ${ }^{6}$ We use the phrase "semi-singular" since $\sigma\left(Q_{X}^{(h)}\right), \sigma\left(K_{X}^{(h)}\right), \sigma\left(V_{Y}^{(h)}\right)$ and $\sigma\left(O^{(h)}\right)$ are not necessarily non-negative.
