{zhangyaolun5}@ruc.edu.cn {panyinxu, wangyudong, caijie}@modelbest.cn

#### Abstract

The LLM Agent, equipped with a code interpreter, can automatically solve real-world coding tasks such as data analysis and image editing. However, existing benchmarks primarily focus on either simplistic tasks, such as completing a few lines of code, or on extremely complex and specific tasks at the repository level, neither of which are representative of various daily coding tasks. To address this gap, we introduce PyBench, a benchmark encompassing five main categories of real-world tasks, covering more than 10 types of files. Given a high-level user query and related files, the LLM Agent needs to reason and execute Python code via a code interpreter for a few turns before making a formal response to fulfill the user's requirements. Successfully addressing tasks in PyBench demands a robust understanding of various Python packages, superior reasoning capabilities, and the ability to incorporate feedback from executed code. Our evaluations indicate that current open-source LLMs are struggling with these tasks. Hence, we conduct analysis and experiments on four kinds of datasets, proving that comprehensive abilities are needed for PyBench. Our fine-tuned 8B size model: PyLlama3 achieves an exciting performance on PyBench which surpasses many 33B and 70B size models. Our Benchmark, Training Dataset, and Model are available at: <https://github.com/Mercury7353/PyBench>

#### 1 Introduction

*The best tool is the one that gets the job done.* Enormous real-world tasks like data analysis and image & audio processing can be solved by code. Among many programming languages, Python stands out for its simplicity, ease of use, extensive libraries, and high compatibility, making it a widely used tool for daily tasks. However, individuals often need to invest significant time in learning how to

Figure 1: An Overview of LLMs' performance on *Py-Bench*

use extension packages, even if they are already highly proficient in Python itself. Thanks to LLM's powerful code capabilities, it can act as an automatic agent [\(Wang et al.,](#page-10-0) [2024a;](#page-10-0) [Park et al.,](#page-9-0) [2023;](#page-9-0) [Qin et al.,](#page-10-1) [2023\)](#page-10-1) writing and executing code to solve a wide spectrum of real-world tasks.

However, current LLM code benchmarks have not covered the real-world task area. HumanEval [\(Chen et al.,](#page-8-0) [2021\)](#page-8-0) and MBPP [\(Austin et al.,](#page-8-1) [2021\)](#page-8-1) focus on function complement and simple Python problems, which could not evaluate the usefulness of LLM Agent.

Although benchmarks such as DS-1000 [\(Lai](#page-9-1) [et al.,](#page-9-1) [2023\)](#page-9-1), DevBench [\(Li et al.,](#page-9-2) [2024\)](#page-9-2), and SWE-Bench [\(Jimenez et al.,](#page-9-3) [2023\)](#page-9-3) focus on repositorylevel coding issues, they assess the ability of LLMs to use and manage specific codebases. These tasks are relatively narrow in scope and inherently limited, deviating from practical daily application scenarios and being overly complex for routine use.

To address the lack of benchmarks for real-world coding tasks, we introduce *PyBench*, a comprehensive and versatile benchmark designed to evaluate the practical coding abilities of LLMs. Specifically, we formulated real-world coding tasks into *5* main

<sup>∗</sup>Equal contribution.

<sup>†</sup>Work done during internship at ModelBest Inc.

categories: Chart Analysis, Text Analysis, Image & Audio Editing, Complex Math, and Software & Website Development. Each category consists of comprehensive subclasses of tasks, reflecting real-world situations. Related files are collected for each subclass, and queries are tailored for the content of files. For the quantitative evaluation of *PyBench* tasks, we create a set of unit tests to verify whether the tasks are solved successfully. We also employ GPT-4 as a judge to evaluate the solutions and calculate the Average Turns as a measure of problem-solving efficiency. We evaluate 3 types of models on *PyBench*: Closed-source LLMs, 70B, 33B, and 7B size Open-source LLMs, and Code LLMs specifically tailored for coding tasks. The evaluation results indicate most LLMs struggle to solve *PyBench* tasks.

Consequently, we collect and synthesize four datasets: the homologous training dataset, multiturn code interaction dataset, multi-turn chat dataset, and code-rich corpus for continue pretraining. We then conduct a series of analyses and experiments to figure out what are necessary abilities to solve the *PyBench* tasks and how to improve the LLM performance on real-world coding tasks. The result demonstrates that merely homologous data cannot help the base model adapt to real-world coding tasks. The multi-turn code interaction dataset significantly enhances comprehensive capabilities. Specifically, the multi-turn chat dataset boosts performance in Chart Analysis, while continued pre-training on a code-rich corpus improves Text Analysis. Trained on these datasets, our fine-tuned 8B size model PyLlama3 surpasses Llama3-8B-Instruct on *PyBench*.

In summary, our contributions are as follows:

- We construct **PyBench**, the first comprehensive benchmark for evaluating LLM Agents on real-world coding tasks. PyBench includes real-world files and related queries, covering a wide range of daily situations and file types.
- We present PyBench tasks that necessitate the agent's comprehensive capabilities. Using only homologous data is inadequate for adapting base models to real-world coding tasks. The agent's ability for multi-turn interaction is crucial, and continued pre-training on a code-rich corpus is also beneficial.
- We conduct continued pre-training of Llama3- 8B-Base on a code-rich corpus and fine-

tune it on homologous, multi-turn code, and multi-turn chat datasets. Our PyLlama3 model achieves outstanding performance on PyBench.

## 2 Related Works

## 2.1 Benchmark on coding ability

Many existing benchmarks focus on LLM's code ability. HumanEval [\(Chen et al.,](#page-8-0) [2021\)](#page-8-0) and MBPP [\(Austin et al.,](#page-8-1) [2021\)](#page-8-1) are two widely recognized benchmarks primarily evaluating LLM's ability to complete functions or solve simple Python problems. HumanEval-X, HumanEval+, and MBPP+ [\(Zheng et al.,](#page-10-2) [2024a;](#page-10-2) [Liu et al.,](#page-9-4) [2023a\)](#page-9-4) extend the benchmarks by adding multilingual and plenty of extra tests. APPS [\(Hendrycks et al.,](#page-9-5) [2021\)](#page-9-5) focuses on writing code from natural language description. TACO [\(Li et al.,](#page-9-6) [2023\)](#page-9-6) builds a more complex benchmark evaluating LLM on algorithmic code tasks. XCodeEval [\(Khan et al.,](#page-9-7) [2023\)](#page-9-7) and Code-Scope [\(Yan et al.,](#page-10-3) [2024\)](#page-10-3) provide execution-based multilingual code benchmarks but without real interaction with files. MINT [\(Wang et al.,](#page-10-4) [2023a\)](#page-10-4) and  $M<sup>3</sup>$ ToolEval [\(Wang et al.,](#page-10-5) [2024b\)](#page-10-5) aim to evaluate models' multi-turn interaction code ability with tools or human feedback. There are also extremely complex and hard benchmarks evaluating LLMs on software development [\(Qian et al.,](#page-9-8) [2023;](#page-9-8) [Hong et al.,](#page-9-9) [2023\)](#page-9-9), code repository issues [\(Jimenez](#page-9-3) [et al.,](#page-9-3) [2023;](#page-9-3) [Li et al.,](#page-9-2) [2024;](#page-9-2) [Zhang et al.,](#page-10-6) [2023;](#page-10-6) [Du et al.,](#page-9-10) [2023\)](#page-9-10), and data science tasks[\(Lai et al.,](#page-9-1) [2023\)](#page-9-1). However, these benchmarks are all limited to specific scenarios. To the best of our knowledge, no existing benchmark evaluates LLM Agent on real-world coding tasks interacting with files in various situations.

## 2.2 Code LLMs

Previous works enhance LLM's coding ability through various methods. OpenCodeInterpreter [\(Zheng et al.,](#page-10-7) [2024b\)](#page-10-7) introduces the CodeFeedback dataset and a code execution system with feedback. The fine-tuned model achieves a great performance on coding benchmarks. CodeAct [\(Wang et al.,](#page-10-5) [2024b\)](#page-10-5) uses executable Python code to unify LLM agents' action space, enabling sophisticated task execution through multi-turn interactions. NexT [\(Ni et al.,](#page-9-11) [2024\)](#page-9-11) teaches LLM reasoning the execution process of code step by step, effectively improving the code quality. WizardCoder [\(Luo](#page-9-12) [et al.,](#page-9-12) [2023\)](#page-9-12), Magicoder [\(Wei et al.,](#page-10-8) [2024\)](#page-10-8), and

<span id="page-2-0"></span>

Table 1: Type of tasks and related Python packages of *PyBench*. We only select commonly used Python packages for these tasks, though other Python packages may also be used for specific tasks.

AlchemistCoder [\(Song et al.,](#page-10-9) [2024\)](#page-10-9) build effective fine-tuning datasets from massive and multi-source data to train advanced code LLMs. Pre-training on code-rich data is also a good method to help LLM coding. CodeQwen [\(Bai et al.,](#page-8-2) [2023\)](#page-8-2), and DeepSeek-Coder [\(Guo et al.,](#page-9-13) [2024;](#page-9-13) [DeepSeek-AI](#page-8-3) [et al.,](#page-8-3) [2024\)](#page-8-3) develop specialized models for coding by continuing to pre-train on code data and employing supervised fine-tuning strategies.

#### 2.3 LLM Agent for real-world tasks

LLM as Agent is a great [\(Qian et al.,](#page-9-8) [2023;](#page-9-8) [Park](#page-9-0) [et al.,](#page-9-0) [2023;](#page-9-0) [Chen et al.,](#page-8-4) [2024\)](#page-8-4) attempt utilizing LLM in real-world tasks. ReAct [\(Yao et al.,](#page-10-10) [2022\)](#page-10-10) first introduced Agent's Reasoning and Action Format. Previous works design many frameworks that build and organize LLM Agents to complete realworld coding tasks. MetaGPT [\(Hong et al.,](#page-9-9) [2023\)](#page-9-9) ChatDev [\(Qian et al.,](#page-9-8) [2023\)](#page-9-8), DataInterpreter [\(Hong](#page-9-14) [et al.,](#page-9-14) [2024\)](#page-9-14), and MatplotAgent [\(Yang et al.,](#page-10-11) [2024\)](#page-10-11) employ agents to complete software development or data science tasks. AgentCoder [\(Huang et al.,](#page-9-15) [2023\)](#page-9-15) focuses on simple code complement tasks. Furthermore, some general multi-agent systems try to adapt agents to various tasks [\(Chen et al.,](#page-8-5) [2023b](#page-8-5)[,a;](#page-8-6) [Wang et al.,](#page-10-12) [2023b\)](#page-10-12).

## 3 PyBench

Coding is a core skill for LLM Agents. When the agent needs to solve real-world coding tasks, it should not only write executable code but also utilize the results of execution to guide subsequent actions and interact with files. Python is a powerful programming language with almost 4 million packages, capable of covering almost all real-world coding tasks. Therefore, we propose building *PyBench* to evaluate the LLM agent's ability in reasoning, writing executable Python code, and utilizing code results.

#### 3.1 Task Formulation

We first define what kinds of tasks need to be solved as a truly helpful LLM Agent equipped with a Python code interpreter. Given a user query  $q$  described in natural language and the related file  $F_{in}$ , the Agent need to generate a formal answer Ans to user query and output file  $F_{out}$ , which fulfill the user's requirement:

$$
Ans, F_{out} = A(q, F_{in})
$$
 (1)

where  $A$  is the LLM Agent equipped with a code interpreter. To be specific, the query  $q$  from users can be very high level, reflecting common occurrences in daily life where users may not have precise requirements. The related file  $F_{in}$  contains various types of data such as chart, text, audio, image, etc., showcase the LLM Agent should adapt to various real-world coding tasks.

#### 3.2 Task Categories

In the realm of practical coding applications, the LLM Agent is required to autonomously tackle a diverse array of real-world coding challenges. To ensure a comprehensive evaluation of its capabilities, we have meticulously curated five main categories of real-world coding tasks. Each category is designed to test the LLM Agent's proficiency across a broad spectrum of scenarios, ranging from data analysis to software development. Table [1](#page-2-0) demonstrates these categories:

Chart Analysis. In the digital age, the ability to efficiently analyze and interpret data is indispensable. This category focuses on tasks that involve handling *csv* or *xlsx* files for various purposes such as

<span id="page-3-0"></span>

Figure 2: The construction and evaluation workflow of *PyBench*

data preprocessing, transformation, visualization, and the application of machine learning algorithms [\(Hong et al.,](#page-9-14) [2024;](#page-9-14) [Yang et al.,](#page-10-11) [2024\)](#page-10-11). The output from the LLM Agent includes detailed analytical reports, visual representations, or even trained machine learning models in *pkl* or *joblib* formats.

Text Analysis. This category encompasses tasks related to processing *txt* and *pdf* files, including summarization, keyword extraction, word cloud generation, and thematic analysis.

Image & Audio Editing. As visual content becomes increasingly prevalent, the demand for personalized image-processing solutions rises. This category evaluates the LLM Agent's ability to manipulate images in *png* and *jpg* formats through various techniques such as saturation adjustment, merging, cropping, and generating QR codes from scratch. Parallel to image processing, this category also focuses on the manipulation of audio files (*e.g. mp3* and *wav*). Tasks include volume control, audio trimming, and the creation of audio visualizations, reflecting the diverse needs of users in the realm of audio content creation and modification.

Complex Math. Beyond the capabilities of basic calculators or the Chain of Thought methodology [\(Wei et al.,](#page-10-13) [2022\)](#page-10-13), this category presents challenges involving large-scale computations, polynomial equation solving, and advanced calculus. It is designed to test LLM Agents' ability to navigate and solve intricate mathematical problems via a code interpreter.

Website & Software Development. This category

is dedicated to the practical application of coding skills in the development of personal websites and simple software projects, such as a Pac-Man game. It assesses the LLM Agent's ability to translate user requirements into functional and interactive applications, showcasing its versatility and creativity in software development [\(Hong et al.,](#page-9-9) [2023;](#page-9-9) [Qian](#page-9-8) [et al.,](#page-9-8) [2023\)](#page-9-8).

#### 3.3 Data Collection

We collect and filter the files in *PyBench* from two main sources.

Kaggle Data. [Kaggle](https://www.kaggle.com/) is a great platform for machine learning, which contains massive datasets. We obtained *csv* and *xlsx* data on Kaggle through web crawlers. There are two principles of filtering the files. Firstly, the files should not be too large, considering the limited memory in the test environment. Secondly, the data tables must contain multiple columns with clear meaning, simulating commonly used files.

arXiv Data. We collect *pdf* and *txt* from [arXiv.](https://arxiv.org/) The papers on arXiv are high-quality text with a clear theme and structure, which is suitable for text-based QA, Theme Analysis, and drawing word clouds.

Other Sources Data. For other file types, we responsibly collect files, including *png, jpeg, gif, mp3*, and *wav* from the internet, ensuring that all content respects copyright laws, protects user privacy, and is free from harmful elements.

#### 3.4 Task Generation

The queries in *PyBench* must be precisely related to files and diverse to ensure comprehensive coverage. To generate these queries, we designed a multiagent cooperation mechanism. Figure [2](#page-3-0) illustrates the PyBench construction workflow.

First, we prepare lists of keywords for each subclass in a category, forming a keywords dictionary for each category [\(Eldan and Li,](#page-9-16) [2023\)](#page-9-16). The type of file determines which category the task belongs to. Given the initial lines of a file(for chart and text files) and randomly selected keywords from the related category's dictionary, the Query Generator selects appropriate keywords that align with the file content and compose a query. Detailed keyword list examples can be found in Appendix [B.](#page-11-0)

Next, a Keywords Checker and a Content Checker verify if the query aligns with the file content and the selected keywords. Feedback from these checkers is used to refine the query. Once both checkers approve, the query undergoes manual editing to clarify the output format and file path for the convenience of verifying. If the Query Generator fails to produce a proper query within *5* rounds, these files will be skipped.

Queries that pass all checks are paired with their related files to form a query-file pair, which constitutes a task in *PyBench*. Appendix [A.2](#page-11-1) and [A.3](#page-11-2) detailed the prompt of each agent.

#### 3.5 Evaluation

#### <span id="page-4-1"></span>3.5.1 Trajectory Generation

Equip LLM Agent with Code Interpreter. We equipped each LLM with a code interpreter to execute Python code written by the LLM and provide feedback on the execution results. Previous works on LLM tool usage [\(Qin et al.,](#page-10-1) [2023\)](#page-10-1) typically used tools in a function-calling format. Inspired by [\(Wang et al.,](#page-10-5) [2024b\)](#page-10-5), which uses code as an action and outperforms alternatives, we designed two special tokens: *<|execute\_start|>* and *<|execute\_end|>* to help the LLM use the code interpreter more effectively. Appendix [D](#page-11-3) shows the different performance of the two formats.

Reasoning and Action. Given the task description and the uploaded file path, the LLM Agent is prompted to analyze the current situation and plan its actions before writing executable code [\(Yao](#page-10-10) [et al.,](#page-10-10) [2022\)](#page-10-10). The code will be executed in a predefined Python environment (with commonly used packages). The result of the code, whether is an

Figure 3: Function Call vs. Our Code Interpreter Format

output or an error message, well serve as feedback to the LLM. The LLM will follow the loop until it fulfills the task or reaches a maximum step limit (default set to 10). Figure [4](#page-4-0) detailed this process.

<span id="page-4-0"></span>

Figure 4: Generating Trajectory Data by ReAct

#### 3.5.2 Unit Test

To objectively and effectively test whether the LLM Agent has completed a task, we have implemented a unit test for each task in *PyBench*. For tasks with a fixed answer, we verify whether the Agent provides a final response that contains the correct answer. For tasks requiring file output, such as cleaning datasets or editing images and audio, we check whether the output files meet the specified requirements. For tasks without a fixed answer, such as generating a word cloud or a website, we verify the existence of the output files. The design of the unit Test is detailed in Appendix [C](#page-11-4)

#### 3.5.3 LLM as Evaluator

Although unit tests are convenient and objective, they may fail to comprehensively evaluate openended tasks, such as assessing the coherence and fluency of text output by large models. Therefore, we also employ an LLM (GPT-4o) as an evaluator to provide pass-or-fail decisions for each trajectory, serving as an alternative to unit tests. Appendix [A.4](#page-11-5) provides the detailed prompt used for the LLM evaluator.

#### 3.5.4 Evaluation Metrics

There are three evaluation metrics in *PyBench*.

Pass Rate (UT). The percentage of passed tasks evaluated by unit tests.

Pass Rate (LLM). The percentage of passed tasks evaluated by the LLM Evaluator.

Average Turns. The number of steps taken to complete each task. If a task fails, the number of turns is set to the maximum turn limit (10 turns).

# 4 Fine-tuning LLM Agent for Real World Coding Task

In order to figure out what kind of capabilities are required and what training data could help enhance the LLM Agent's performance on *PyBench*, we collect 4 datasets enhancing the Agent's abilities in planning, coding, and multi-turn interaction.

Homologous dataset. Intuitively, homologous datasets can enhance performance on similar tasks. Therefore, we employ GPT-3.5-turbo to synthesize a homologous dataset: *PyInstruct*. We generate tasks using the same method as PyBench, but with different files and without manual modifications. Subsequently, using the method described in Section [3.5.1,](#page-4-1) we synthesized 3,091 trajectories based on these tasks. These trajectories cover every task category in PyBench, resulting in the construction of *PyInstruct* as a homologous dataset to PyBench. Multi-turn of code interaction dataset. Most of the tasks in *PyBench* need multi-turn interaction with the Python code interpreter. It will provide feedback on code execution results or error traceback messages, which should be fully leveraged by the LLM Agent. There are several existing datasets aiming to enhance LLM's ability. *Code-ActInstruct* [\(Wang et al.,](#page-10-5) [2024b\)](#page-10-5) focuses on improving LLM's abilities in various multi-turn tasks such as information seeking, software tool usage, external memory access, and robot planning, all executed in the format of Python code. *CodeFeedback* [\(Zheng et al.,](#page-10-7) [2024b\)](#page-10-7) filters open-source code instruction data and converts them into multi-turn code with execution results. We repurpose the data by "equipping" our special token for the Python code interpreter. These datasets may help enhance LLM's ability to utilize code feedback. Table [2](#page-6-0) shows the statistics information of *CodeFeedback*, *CodeActInstruct*, and *PyInstruct*.

Multi-turn chat dataset. Additionally, in *Py-Bench*, the LLM Agent is expected to comprehend the user's instructions and provide a formal response upon completing the task. High-quality multi-turn chat is also crucial for a Code Agent. *UltraChat* [\(Ding et al.,](#page-9-17) [2023\)](#page-9-17) is a large-scale dataset comprising 1.5 million high-quality multi-turn instructional dialogues specifically designed to improve the performance of open-source conversational models, which is perfectly aligned with our requirements.

Code-Rich corpus. The foundation ability of a code agent is the quality and correctness of its code. We assume that continue pre-train on code-rich corpus could contribute to solving *PyBench* tasks. *The-stack-v2* [\(Lozhkov et al.,](#page-9-18) [2024\)](#page-9-18) introduces a code-rich corpus of Jupyter notebooks, which contains 11 million lines.

After collecting the four types of datasets, we conducted a series of experiments to figure out what are necessary abilities to solve the *PyBench* tasks and how to improve the LLM performance on real-world coding tasks.

#### 5 Experiment

#### 5.1 Main Result on PyBench

Testing Evaluation Setup. Firstly, we prepare a conda environment equipped with 182 commonly used Python packages (Detailed in Appendix [G\)](#page-15-0). The max turn is set to  $k = 10$ . We prompt the LLM to use code interpreter and follow ReAct [\(Yao et al.,](#page-10-10) [2022\)](#page-10-10) format. (Appendix [A.4\)](#page-11-5) The code in LLM's response will be extracted, and the execution result will be returned to LLM. After getting the trajectory and output files, we calculate the pass rate through the unit test set (*UT*) and LLM Evaluator set (LLM). We also adopt other benchmarks to test the model's basic code ability, including HumanEval [\(Chen et al.,](#page-8-0) [2021\)](#page-8-0) and HumanEval+ [\(Liu](#page-9-4) [et al.,](#page-9-4) [2023a\)](#page-9-4) for single-turn code generation, and MBPP [\(Austin et al.,](#page-8-1) [2021\)](#page-8-1) and MBPP+ [\(Liu et al.,](#page-9-4) [2023a\)](#page-9-4) for simple Python programming problems. Results on *PyBench*. Table [3](#page-6-1) shows our main experiment result. GPT-4o scored highly in all five tasks, showing its great ability. However, models including CodeLlama-Instruct-70B, DeepSeekcoder-Instruct-33B, and CodeLlama-Instruct-33B, although trained on code corpus and perform well on HumanEval and MBPP, struggle to solve *Py-Bench* tasks, proving that code ability does not always lead to a good score on *PyBench*. Most of

<span id="page-6-0"></span>

Table 2: Statistics of *CodeFeedback*, *CodaActInstruct*, and *PyInstruct*. Token statistics are computed by using Llama-2 tokenizer.

<span id="page-6-1"></span>

Table 3: The main result table. We test closed-source models, 70B size models, 33B size models, and 7B size models. We bold the best results for each size model's results.

the advanced 7B size models can only solve about 50% of tasks in *PyBench*. Our *PyLlama3*, with continued pre-train and fine-tuning on related datasets, surpasses Llama3-8B-Instruct on Chart Analysis, Text Analysis, and Complex Math.

Coding ability is the foundation. CodeActAgent-Llama-2-7B and CodeActAgent-Mistral-7B [\(Wang](#page-10-5) [et al.,](#page-10-5) [2024b\)](#page-10-5), although trained on CodeActInstruct, who teach LLM Agent use tools in code format, have the weakest performance on *PyBench*. The

<span id="page-7-0"></span>

	PyInst. Code. UltraCh. Jupyter.		Pass Rate(UT)					
							Chart. Text. Image. Math. Software. Over All

$\checkmark$	X	X	40.3	26.1 58.3		83.3	25.0	45.5
$\checkmark$	X	Х	51.6	56.5 60.4		$100.0$ 25.0		56.6
$\checkmark$	✓	Х	62.9	52.2 56.3		83.3	25.0	58.7
$\checkmark$	$\boldsymbol{X}$	$\checkmark$	58.0	52.2 73.0		50.0	50.0	59.4
	$\checkmark$		62.9	65.2 56.3		66.7	50.0	60.8

Table 4: Pass Rate (UT) with different training datasets. *PyInst.* stands for *PyInstruct*. *Code.* refers to *Codefeedback & CodeActInstruct*. *UltraCh.* means *UltraChat*, and *Jupyter.* indicates continuing pre-training on the Jupyter notebook corpus.

failure might be caused by low performance on basic coding ability benchmarks: HumanEval(+) and MBPP(+). The result illustrates basic code ability and the foundation to solve real-world coding tasks in PyBench.

PyBench evaluates comprehensive abilities of LLM Agent. Great performance on basic coding benchmarks does not directly lead to equal performance on PyBench. Although models like DeepSeek-coder-Instruct-33B and CodeLlama-Instruct-34B scored well on HumanEval(+) and  $MBPP(+)$ , they got a weak score on PyBench. This indicates that mere coding ability cannot lead to success in real-world coding tasks. PyBench also evaluates the LLM agent's abilities, including planning, multi-turn interaction, leveraging code feedback, and generating formal responses to the user.

Compare LLM Evaluator and Unit Test. Table [3](#page-6-1) shows that the evaluation results from the LLM and the unit tests are generally consistent, with only minor fluctuations. However, there are significant discrepancies for several models. To investigate this, we randomly selected 60 trajectories from the entire dataset for manual assessment. We found that in over 80% of the cases, the LLM evaluation results were consistent with the unit test results. Nevertheless, in some instances, the LLM evaluator might only determine whether the code executes successfully without verifying its correctness. In other cases, the tested LLM agent might write code or provide answers that coincidentally pass the unit tests. A detailed analysis of these scenarios is provided in Appendix [E.](#page-15-1)

### 5.2 Analysis on the training dataset

In this section, we conduct ablation studies on training datasets to explore the necessary capabilities for solving *PyBench*.

#### 5.2.1 Train Setup

We conduct full-parameter supervised fine-tuning on Llama3-8B with a sequence length of 32768 tokens [\(Liu et al.,](#page-9-19) [2023b;](#page-9-19) [Roziere et al.,](#page-10-14) [2023;](#page-10-14) [Tou](#page-10-15)[vron et al.,](#page-10-15) [2023\)](#page-10-15), ensuring it could handle the content of chart and text files. For each version of the supervised fine-tuning model, we use 32 A100 GPU and train 4000 steps. The learning rate is set as 1e-5 with a 0.05 warm-up ratio and a cosine scheduler. As for the continue pre-trained model, we added an extra 3000 steps to train the corpus.

#### 5.2.2 Ablation study

LLMs' performance on specific tasks can often be enhanced through supervised fine-tuning on homologous datasets, where the model learns exactly what to do in particular situations. Initially, we hypothesized that training the Llama3-8B-base model on *PyInstruct*, 3k homologous trajectories data, would teach the model to handle real-world coding tasks. However, as shown in Table [4,](#page-7-0) this model struggles with *PyBench* tasks. From the generated trajectories, we observed that the model fails to follow human instructions and even struggles to locate the correct file paths.

To address the drawbacks, we add two multiturn code interaction datasets: *CodeActInstruct* [\(Wang et al.,](#page-10-5) [2024b\)](#page-10-5) and *CodeFeedback* [\(Zheng](#page-10-7) [et al.,](#page-10-7) [2024b\)](#page-10-7). We train the model on these datasets and PyInstruct. The result indicated a significant improvement. But when we remove *PyInstruct* and train the model only on *CodeActInstruct* and *CodeFeedback*, the model's performance suffers a sharp decline in Chart Analysis and Text Analysis, demonstrating *PyInstruct* can enhance the model's capability.

Additionally, to further enhance the model's capabilities, we added *UltraChat* [\(Ding et al.,](#page-9-17) [2023\)](#page-9-17) in the training datasets and trained the model with the same training settings. However, the result shows adding *UltraChat* only brings improvement to Chart Analysis tasks.

We found that the model still struggles with using some packages and specific techniques for realworld coding tasks. Consequently, we conducted continue pre-train on a Jupyter Notebook corpus [\(Lozhkov et al.,](#page-9-18) [2024\)](#page-9-18) before fine-tuning on *PyInstruct, CodeFeedback, CodeActInstruct*, and *UltraChat*. As shown in Table [4,](#page-7-0) continue pre-train can also bring great improvement to Text Analysis tasks. The continued pretraining model achieves the best performance after fine-tuning on *PyInstruct, CodeFeedback, CodeActInstruct*, and *UltraChat*, which we named to PyLlama3. And the version without continue pre-train is named PyLlama3(w/o cpt).

In conclusion, we figured out that PyBench requires the model's basic coding abilities, which instruct them to write Python properly, as well as multi-turn interaction and reasoning abilities to solve real-world tasks.

## 6 Conclusion

In this paper, we propose PyBench, a comprehensive benchmark encompassing five main categories that reflect real-world coding situations. Through collecting files and generating related queries, Py-Bench could evaluate LLM's usability and efficiency in real-world tasks. After evaluating plenty of LLMs, we find many of them are struggling with real-world coding tasks. We collected and synthesized four datasets and trained PyLlama3 whose performance surpass many 7B, 33B, and 70B size models. Our ablation studies prove the effectiveness of the datasets, figuring out a way to train a model that could adapt to real-world coding tasks. Solving PyBench tasks means the LLM could interact with the file system with Python code, which symbolizes a great milestone in developing a really usable LLM Agent who can serve as a helpful life

assistant for humankind.

#### 7 limitations

Our work introduces a comprehensive benchmark: PyBench to evaluate LLM Agent on real-world coding tasks. Although five main categories are included in PyBench, there are many cases in the real world that have not been covered. The coding problem that uses other coding languages instead of Python is not covered either.

# A Prompts

# A.1 Equip LLM with a code interpreter

Fig [5](#page-11-6) shows how we prompt the LLM to use code interpreter.

<span id="page-11-6"></span>You are equipped with a code interpreter. Submit the Python code and get the result. You can use it in the following format:  $\le$  execute start  $\ge$ "python" <your code>

 $\le$  execute\_end  $\ge$ 

Figure 5: Prompt equipping LLM Agent with a code interpreter

# <span id="page-11-1"></span>A.2 Query Generation Prompt

Fig [6](#page-12-0) is the prompt to generate a related and diverse  $3$ query from given file content.

# <span id="page-11-2"></span>A.3 Checker Prompt

Fig [7](#page-13-0) and Fig [8](#page-13-1) are the prompts for the content checker and keywords checker.

# <span id="page-11-5"></span>A.4 Evaluation Prompt

Figure [9](#page-14-0) shows the LLM Evaluator's prompt.

# <span id="page-11-0"></span>B Key words example for each category

Fig [10](#page-15-2) is a keywords list example for Chart Analysis tasks

# <span id="page-11-4"></span>C Example Unit Test

We show three types of Unit Tests in this appendix.

# C.1 Directly Verify the Answer

For the task with a fixed answer, we check whether the final response contains the answer

```
1 def test_task_19 (trajectory):
2 final_answer = trajectory [ -1][ 'content
          ']
      answer\_list = [' -346", " 2504"]4 for ans in answer_list:
          assert ans in final_answer
```
# C.2 Verify the output file

For task clarify the output file, we check whether the output file fulfills the requirements.

```
def test_task_88(trajectory):
2 image_path = "'.\sqrt{ output /88. png"
      ref\_path = "./data/88.jpgimage = Image.open(image\_path)gray\_image = image.count('L')6 \mid gray_array = np.array (gray_image)
7 black_threshold = 508 black_pixels = np.sum(gray_array <=
          black_threshold )
9 total_pixels = gray_array . size
10 black_ratio = black_pixels /
          total_pixels
      assert black_ratio > 0.25, "The
          black pixel percentage does not
          exceed 30%.
```
# C.3 Verify the output file path

For Open-end tasks like website development, we simply detect whether the output file exists.

```
1 def test_task_141 (trajectory):
2 output_folder = "./output/141"
      html_files_exist = any(file.endswith
          ('. html ') for file in os . listdir
          ( output_folder ) )
4 assert html_files_exist
```
# <span id="page-11-3"></span>D Code as Action VS Function Calling

We conducted an ablation study on the format of calling code interpreter. For function calling, we defined an *execute\_python* function where the LLM passes a code string as the parameter and uses a special token <*|tool\_call*} before the function.

We repurposed all code snippets in PyInstruct, CodeFeedback, and CodeActInstruct to follow the function calling format. We trained the model without continue pre-train on code-rich corpus for it exactly aligns with our format. Compare it to PyL $lama3(w/o$  cpt), Table [5](#page-11-7) shows that the function calling format struggles with real-world code tasks. The model often fails to follow the format and frequently neglects to call the *execute\_python* tool, leading to failures.

<span id="page-11-7"></span>

Table 5: Function Call vs Our format

<span id="page-12-0"></span>Select a proper task from the task list and generate a query (Describe by Natural Language). Your answer should follow this format: File Description: <description> Selected tasks: <list of tasks> will be combined into a high-level query. [Query]  $\le$ query> [\Query] The task list (The task in the task list is just a guideline; you need to generate a complicated task according to the data description by yourself): {task list} Example 1: Description: This data set is about house price in Boston, with columns of house price, house location, floor space Selected tasks: [Draw a line plot, Train a regression model] [Query] Analyze how the floor space influences the house price by visualizing the data and training a linear model. [\Query] Example 2: Description: This dataset has only one column, which is the titles of BBC news Selected tasks: [Clean null values, LDA analysis] [Query] Execute LDA analysis on this news title dataset after preprocessing. [\Query] Some Query examples: 1. Run data analysis on the sklearn Iris dataset, including a plot

2. Run data analysis on the sklearn Wine recognition dataset, draw a plot, and train a model to predict wine class with 20% as a test set and show prediction accuracy.

Figure 6: Prompt guide the LLM to generate queries

<span id="page-13-0"></span>

<span id="page-13-1"></span>

<span id="page-14-0"></span>You are a code reviewer who is responsible for select a better solution from two agent's trajectories on solving a code problem.

The file and user query provided for each agent are the same.

After that, You should evaluate both solutions in the following dimensions: Pass: Whether the code is executed correctly (without any error)? Give a label Pass or Failed.

Reasoning Quality: Does the reasoning process correctly analyze the user input or code feedback?

Code Quality: Evaluate The code's correctness and whether it fulfills the user query.

Your final decision must follow this JSON format use "" "" strictly:

```
"Pass": {
"Agent1": "Pass/Failed",
"Agent2": "Pass/Failed"
\}\left\{ \right.
```
Here is an example: Reasoning: Agent1's reasoning quality is xx, and Agent1's code quality is xx, So the solution is Pass/Failed

Agent2's reasoning quality is xx, and Agent2's code quality is xx, So the solution is Pass/Failed  $\overline{\cdots}$ 

```
\{"Pass": {
"Agent1": "Pass",
"Agent2": "Failed"
ł
\left\{ \right.
```
