RADIATION RESISTANCE OF GLASS REINFORCED EPOXY-RESINS

<u>by</u>

G. Pluym and M. van de Voorde

The radiation stability of different, pure and mineral filled epoxy resin compositions has been reported<sup>1)</sup>. From this study we have concluded that the following resins and n se fr  $\mathcal{A}_{\mathcal{L}}$ curing agents give the best results:

EPN 1138 - X33/1020 - Araldite F Resins: Curing Agents: HT 971 - HT 972 - HY 906

In this report results are given using epoxy resins with the following compositions:

On five specimens of each resin system and dose level  $\sim 2.7$ the flexural strength was measured.

The dimensions of the samples were 125 x 12,7 x 3 mm.

1) G. Pluym and M. H. van de Voorde - ISR-MAG/67-3

PS/5845

The data derived from these measurements are presented in figure 1. It can be concluded that:

 $\mathcal{C}$ 

 $\mathfrak{c}$  .

1) The resin composition X33/1020/DDM/Glass is more radiation resistant than F/DDM/Glass. The same conclusion was drawn in report $^{1)}$  with the corresponding unreinforced resin compositions.

In general, we can thus conclude that the basic epoxy structure X33/1020 is always more radiation resistant than the F structure, independent of:

- a) the type of curing agent used (compare curve  $(5)$  with  $(7)$ ;
- b) the glass-fiber addition (compare curve  $(2)$  with  $(4)$ .
- <sup>2</sup>) Glass-reinforced epoxy resins are much more radiation resistant than those without. Compare curves (3) with (5) and  $(4)$  with  $(6)$ . At  $5 \times 10^5$  rad, the mechanical resistance of all unreinforced epoxy resin compositions is very low while, at this level, the glass-reinforced ones are not seriously damaged.
- 3) The curing agent DDM seems to give more radiation resistant compositions than the MNA. Compare the curves (2) with (3) in the figure. Similar results are obtained in  $report<sup>1</sup>$ on unreinforced systems.
- 4) Results reported elsewhere<sup>2)</sup> on the radiation resistance of glass-reinforced X33/1020/MNA differ from ours. This may be due to the difference in radiat.. ion fields used. Curve 1 was obtained using  $\mathscr Y$ -rays from a spent fuel element facility. We irradiated in a reactor (25  $%$ neutrons and  $75$   $\%\mathscr{J}'$ s), which resulted in curve 3.

2) M. J. Price and R. Sheldon - RHEL/R 105

- 2 -

The difference can be qualitatively explained by the presence of boron in the glass, which has a high cross-section for thermal neutrons. The  $\alpha'$  particles from the (n.  $\alpha'$ .) reaction have an energy of 2,5 MeV, which will be locally absorbed and which will, therefore, rupture a high amount of chemical bonds.
