Search for nuclear modifications of B^+ meson production in pPb collisions at $\sqrt{s_{NN}} = 8.16$ TeV

The CMS Collaboration*

Abstract

Nuclear medium effects on B^+ meson production are studied using the binary-collision scaled cross section ratio between events of different multiplicities from proton-lead collisions. Data, collected by the CMS experiment in 2016 at a nucleon-nucleon center-of-mass energy of $\sqrt{s_{NN}} = 8.16$ TeV, corresponding to an integrated luminosity of 175 nb^{-1} , were used. The scaling factors in the ratio are determined using a novel approach based on the $Z \rightarrow \mu^- \mu^+$ cross sections measured in the same events. The scaled ratio for B^+ is consistent with unity for all event multiplicities, putting stringent constraints on nuclear modification for heavy flavor.

Submitted to Physical Review Letters

In the presence of extreme density and temperature, quantum chromodynamics (QCD) predicts the transition of nuclear matter into a new state, called quark-gluon plasma (QGP) [1, 2]. In this state, quarks and gluons, normally confined within particles such as protons and neutrons, are no longer bound and can move over distances exceeding nucleonic scales.

Evidence for QGP formation came initially from heavy ion collisions, showing particle correlations consistent with the creation of an almost perfect fluid and differences in particle yields compared to expectations based on scaling proton-proton (pp) collision results by the number of binary collisions in the larger system [3–5]. The conditions needed for QGP formation were not expected to exist in collisions of smaller systems. However, long-range correlations, similar to those found in large system collisions, have now also been observed for a number of smaller systems, including proton-lead (pPb) [6–18], and even pp collisions [19–26]. These small system results have led to the suggestion of the creation of quark-gluon droplets, although alternative mechanisms have also been suggested [27–29]. Further studies are needed to establish the mechanism responsible for the small system observations.

Heavy quarks, such as c and b quarks, are invaluable tools for studying QGP [30, 31]. Produced early in the collision, they experience the entire lifetime of the medium, allowing them to probe the media properties throughout its evolution. Their large mass minimizes distortions arising from final-state interactions with other particles. Additionally, well-understood perturbative QCD enables precise calculations of their initial production rates. By studying how the medium affects heavy quarks, for example, in terms of energy loss and fragmentation modification, the properties of the medium can be determined. Evidence for collective effects involving charm and beauty hadrons in small systems has been observed [16, 25, 29, 32]. However, the rapidity dependence of collective effects for beauty hadrons remains poorly constrained [33].

This Letter reports the measurement of the B^+ meson differential cross sections for different multiplicity classes of pPb collision data at a nucleon-nucleon center-of-mass energy of $\sqrt{s_{\text{NN}}} = 8.16$ TeV, recorded by the CMS detector at the CERN LHC in 2016. The event sample corresponds to an integrated luminosity of 175 nb^{-1} . A new observable, R_{HL} , is introduced. It is defined as the ratio of cross sections for events at high multiplicity to those at low multiplicity, scaled by the corresponding number of binary collisions in two multiplicity bins. This observable is used to characterize the nuclear medium effects in the heavy flavor sector. The original feature of this work is the experimental derivation of the scaling factors appearing in the R_{HL} value using the measured Z boson production cross sections from the same events. Conceptually, this new observable is similar to the R_{CP} (“central-to-peripheral”) ratio previously reported in the literature [34–36]. However, it presents the distinct advantage to allow the characterization of nuclear medium effects to rely entirely on data. Throughout this Letter, charge-conjugate modes are implied unless explicitly noted. The measurement is based on the exclusive decay channel $B^+ \rightarrow J/\psi K^+$, where the $J/\psi(1S)$ meson decays to a pair of oppositely-charged muons. The measured inclusive cross section is compared to fixed-order next-to-leading logarithmic (FONLL) calculations [37–39]. Tabulated results are provided in the HEPData record for this analysis [40].

The CMS apparatus [41] is a multipurpose, nearly hermetic detector, designed to trigger on [42, 43] and identify electrons, muons, photons, and (charged and neutral) hadrons [44–46]. A global “particle-flow” (PF) algorithm [47] aims to reconstruct all individual particles in an event, combining information provided by the all-silicon inner tracker and by the crystal electromagnetic and brass-scintillator hadron calorimeters, operating inside a 3.8 T superconducting solenoid, with data from the gas-ionization muon detectors embedded in the flux-return yoke outside the solenoid. The reconstructed particles are used to build τ leptons, jets, and

missing transverse momentum [48–50]. The forward hadron (HF) calorimeter uses steel as absorber and quartz fibers as the sensitive material. The two halves of the HF are located 11.2 m from the interaction region, one on each end, and together they provide coverage in the pseudorapidity range $3.0 < |\eta| < 5.2$. They also serve as luminosity monitors. Events are filtered using a two-tiered trigger system [43]. The first level (L1), composed of custom hardware processors, uses information from the calorimeters and muon detectors [42]. The second level, known as the high-level trigger (HLT), consists of a farm of processors running a version of the full event reconstruction software optimized for fast processing, and reduces the event rate to around 1 kHz before data storage [43].

The events are selected with an L1 trigger algorithm requiring the presence of two muon candidates, with no explicit momentum threshold. For the offline analysis, events must pass a set of selection criteria designed to reject background events (from beam-gas collisions), as described in Ref. [51]. Events are required to have at least one reconstructed primary interaction vertex (PV), formed by two or more tracks, with a distance from the center of the nominal interaction region of less than 25 cm along the beam direction and 0.2 cm in the plane transverse to beam direction. In order to select inelastic hadronic collisions, the pPb events are also required to have at least one tower in each of the HF detectors with energy deposits of more than 3 GeV.

The muons used to reconstruct the $J/\psi(1S)$ meson candidates must satisfy the *soft-muon* identification requirements [45] and the following kinematic constraints: the transverse momentum $p_T > 3.4$ GeV for $|\eta| < 0.3$, $p_T > 3.3$ GeV for $0.3 < |\eta| < 1.1$, $p_T > (5.5 - 2|\eta|)$ GeV for $1.1 < |\eta| < 2.1$, and $p_T > 1.3$ GeV in the $2.1 < |\eta| < 2.4$ region. The muon candidates are combined in opposite-charge pairs to form the J/ψ candidates, which are retained in the analysis if they have an invariant mass between 2.9 and 3.3 GeV and an absolute rapidity ($|y|$) less than 2.4. The estimate of the p-value of the fit (sometimes referred to as χ^2 probability) of both muons coming from the same vertex must be greater than 1%.

B^+ mesons are reconstructed by combining a J/ψ candidate (from two muons) with a single *high-purity* track [46] with at least 11 hits (including both strip and pixel hits), p_T relative uncertainty less than 10%, $|\eta| < 2.4$, and $p_T > 1$ GeV. The two muons and the track are fit together, assuming they originate from a common vertex (B^+ meson decay point) and constraining the dimuon invariant mass to the J/ψ meson world-average mass [52]. The K^+ mass [52] is assigned to the single track. The PV is redefined excluding the tracks of the B^+ meson candidates, then the B^+ meson decay length is computed as the distance between the PV and the B^+ decay vertex. The analysis is restricted to B^+ mesons in the phase space window of $3 < p_T < 50$ GeV and $|y| < 1.8$, with a decay length greater than seven times its uncertainty, and a p-value of the vertex fit greater than 7%. If there is more than one B^+ meson candidate in an event, the candidate with the highest p-value of the vertex fit is selected.

The selection criteria described above are optimized using Monte Carlo (MC) simulated samples, which are also used to evaluate the detection efficiency and the shapes of the invariant mass distributions of background components. The simulations include signal events of $B^+ \rightarrow J/\psi K^+$ decays and background events from other b hadron decay chains that involve J/ψ mesons in the final state. Events are generated with PYTHIA 8.212 [53], which handles the production and hadronization steps. The EVTGEN 1.5 package [54] is used to simulate the decay of the b and c hadrons, whereas PHOTOS 215.5 [55] is used for the final-state radiation modeling. The impact of the CMS detector on the generated events, including the trigger and reconstruction steps, is simulated with the GEANT4 package [56], using algorithms identical to those used in the processing of data. Each PYTHIA event is embedded into a simulated pPb collision event generated with EPOS LHC 1.99 [57], which is tuned to reproduce global event properties, such

as the charged-hadron p_T spectrum and particle multiplicity [51].

The event-by-event charged-particle multiplicity is defined using tracks originating from the PV, which must be of high purity and satisfy the following criteria: the impact parameter significance ($d/\sigma(d)$) measured with respect to the PV must be less than 3, both along ($d_z/\sigma(d_z)$), and transverse ($d_T/\sigma(d_T)$) to the beam direction, and the relative p_T uncertainty, $\sigma(p_T)/p_T$, must be less than 10%. To ensure high tracking efficiency and to reduce the rate of misreconstructed tracks, the requirements $|\eta| < 2.4$ and $p_T > 0.4$ GeV must be satisfied. The quantity N_{ch} is the corresponding multiplicity corrected for detector and algorithm inefficiencies in the same kinematic region. Events are divided into classes based on N_{ch} . The fraction of the total sample found in each multiplicity interval and the average number of tracks after accounting for the corrections are listed in Table 1. The uncertainty in the average value is 2.4%, coming from tracking efficiency uncertainties [58].

Table 1: Fraction of the full event sample that contains a B^+ meson candidate in each multiplicity class, and corrected multiplicity for charged particles with $|y| < 2.4$ and $p_T > 0.4$ GeV. Systematic uncertainties are given for the corrected multiplicities, while statistical uncertainties are negligible.

Multiplicity class	Fraction (%)	$\langle N_{\text{ch}} \rangle$
$2 \leq N_{\text{ch}} < 250$	100.0	102 ± 2
$2 \leq N_{\text{ch}} < 60$	19.5	43 ± 1
$60 \leq N_{\text{ch}} < 85$	21.1	73 ± 2
$85 \leq N_{\text{ch}} < 110$	20.4	97 ± 2
$110 \leq N_{\text{ch}} < 250$	39.1	149 ± 4

The differential cross section for the B^+ meson production is defined as

$$\frac{d\sigma}{dp_T} = \frac{1}{2} \frac{1}{\Delta p_T} \frac{N(p_T)}{\epsilon \mathcal{B} \mathcal{L}}, \quad (1)$$

where $N(p_T)$ is the measured yield of the B^+ meson in a given p_T bin, obtained from a maximum likelihood fit; Δp_T is the corresponding bin width; and \mathcal{B} is the product of the world-average values for the $B^+ \rightarrow J/\psi K^+$ and $J/\psi(1S) \rightarrow \mu^+ \mu^-$ branching fractions, $(1.026 \pm 0.031) \times 10^{-3}$ and $(5.961 \pm 0.033) \times 10^{-2}$ [52], respectively. The factor of 2 in the denominator reflects the choice used to quote the cross section for a single charge (taken to be the B^+), whereas $N(p_T)$ includes both charge states. Also, ϵ is the total efficiency to reconstruct B^+ meson candidates, calculated for each bin, and \mathcal{L} is the integrated luminosity.

The reconstructed B^+ meson yields are obtained by performing an unbinned maximum likelihood fit to the $J/\psi(1S)K^+$ invariant mass distribution. Results are obtained for six p_T bins (see Table A.1 for the binning definition) of four N_{ch} classes, with ranges from 2–60 to 110–250, defined so as to keep a similar total event fraction in each class as shown in Table 1. In total 24 fits are performed. Figure 1 shows the $J/\psi(1S)K^+$ invariant mass distributions in the inclusive p_T range 3–50 GeV for two N_{ch} classes.

On the basis of studies with simulated samples, the signal peak (red curve) is modeled with the sum of two Gaussian probability density functions with a common mean and independent widths. The common mean is a free parameter in the fit, while the widths and their relative fraction are estimated from simulation and fixed in the fit. The underlying combinatorial background is fit with an exponential distribution (green dashed curve). The $J/\psi(1S)K^+$ sample includes a background contribution from events where the B^+ meson decays to $J/\psi K^+ X$,

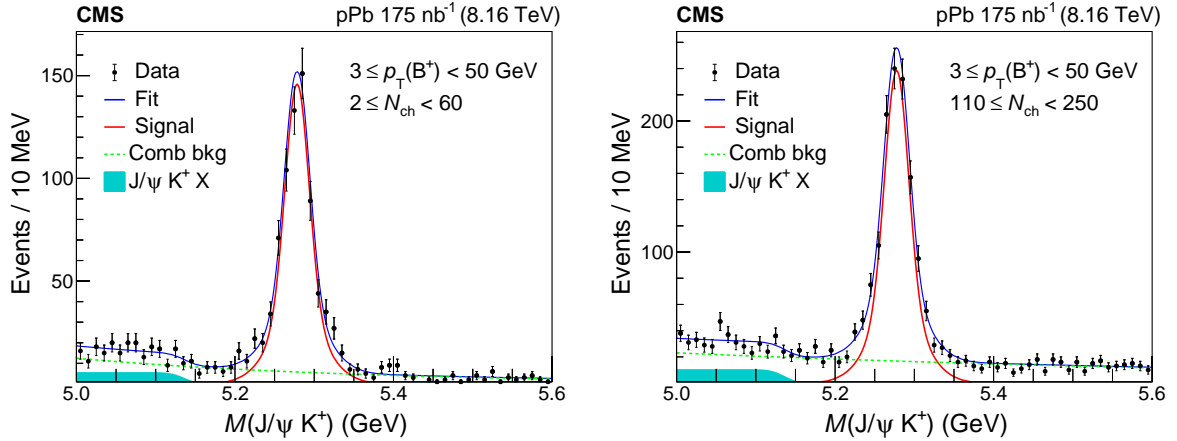

Figure 1: Reconstructed $J/\psi(1S)K^+$ invariant mass distributions for B^+ meson candidates with $3 < p_T < 50$ GeV, in events with $2 < N_{ch} < 60$ (left) or $110 < N_{ch} < 250$ (right). The result of the fit described in the text is also shown.

where X is not reconstructed and represents a π^0 or charged light hadrons. This contribution is described by an error function (cyan area), where the two shape parameters are fixed from simulation.

Detection efficiencies, ϵ , are needed to convert the signal event yields, obtained from the fits illustrated in Fig. 1, to cross sections. They are evaluated using the simulated event samples, reflecting the detector acceptance, as well as the trigger and reconstruction steps. In each bin, the efficiency is calculated as the ratio of events that fire the trigger, are successfully reconstructed by the detector simulation, and satisfy our selection criteria, to the total number of generated B^+ mesons within the specified phase space region $3 < p_T(B^+) < 50$ GeV and $|y(B^+)| < 1.8$. It ranges from 0.1% for $p_T(B^+) \approx 5$ GeV to 45% for $30 < p_T(B^+) < 50$ GeV. In addition to efficiencies derived from simulation, corrections for discrepancies between data and simulated events are applied. The tag-and-probe method [59] is used to derive these corrections.

Systematic uncertainties affect the determination of the signal yields and the evaluation of the efficiency (see Eq. (1)). The uncertainties affecting the signal yields are evaluated by repeating the fits of the mass distributions with alternative models and computing the difference with respect to the nominal results. Three main variations of the fit model are independently considered. First, the signal model uncertainty is assessed by leaving free the mean and widths of the double-Gaussian function in the fit. Additionally, alternative models, like Johnson S_U distribution [60] and t-Student function [61], are considered. The maximum deviation in measured yields from their nominal value is regarded as a systematic uncertainty. Secondly, the combinatorial background is represented by a Chebyshev polynomial instead of an exponential function. Lastly, the uncertainty arising from the description of the partially reconstructed background is quantified by allowing the error function parameters to vary freely in the fit. The fit procedure is verified to provide unbiased results for both the central values and the uncertainties, through a study of one thousand event samples, randomly generated using the nominal likelihood probability distribution functions and fit parameters. The systematic uncertainties in the signal yields, amounting to up to 4% in one of the p_T bins, are dominated by the signal modeling. The systematic uncertainty in the efficiency ranges from 0.6 to 1.6% depending on p_T , reflecting the statistical precision in the simulated event samples. The uncertainty in the efficiency of the muon trigger, reconstruction, and identification is evaluated using a tag-and-probe technique. The data-to-simulation scale factors are employed to determine the

Figure 2: (left) B^+ differential cross section in p_T bins. Vertical bars (boxes) represent the statistical (systematic) uncertainties. The global systematic uncertainty, not included in the data points, comprises the uncertainties in the integrated luminosity measurement and the B^+ meson branching fraction. Results are compared to FONLL calculations, scaled by the number of binary nucleon-nucleon collisions. The yellow boxes represent the theoretical uncertainties from FONLL calculations [37–39]. (right) B^+ differential cross section shown in p_T bins divided into classes of N_{ch} . For better visibility, data points are scaled by a factor of 2 (blue), 4 (magenta), or 8 (red). Vertical bars represent total uncertainties.

nominal efficiency, while their associated uncertainties are propagated to the systematic uncertainty by varying coherently the scale factors. The difference between the track reconstruction efficiency in data and simulation is estimated based on the method described in Ref. [58]. This method results in a 2.4% uncertainty, which corresponds to the single-track reconstruction uncertainty common to all p_T and N_{ch} classes. Residual differences between N_{ch} and the generator-level charged-particle multiplicity distributions are observed in the simulation, resulting in a systematic uncertainty in the range 1.3–19.2%, depending on the multiplicity class. In addition, a global systematic uncertainty is assigned to account for the uncertainties in the integrated luminosity value (3.5% [62]), and in the B^+ meson branching fraction (3.1% [52]).

The total systematic uncertainties are computed as the sum in quadrature of the individual contributions. They range between 2.8 and 14.5% for the differential cross section measurements, while statistical uncertainties in the range 3.6–11.0%. All systematic uncertainties are assumed to be uncorrelated between multiplicity classes.

The differential cross section measurements for the phase space region $3 < p_T(B^+) < 50$ GeV and $|y(B^+)| < 1.8$ are displayed in Fig. 2 (left). Statistical and systematic uncertainties and the pp FONLL predictions [37–39] are also shown. The reference cross sections are obtained by scaling the FONLL total q_b quark production by the world-average B^+ production fraction of 40.2% [52]. The predictions are scaled by the mass number of the Pb nucleus ($A = 208$) to consider the number of binary nucleon-nucleon collisions. The uncertainties in the FONLL calculations include the effects from the renormalization and factorization scales, the mass of the b quark, and the uncertainties in the proton parton distribution functions (providing the largest contribution) [37–39]. The theoretical predictions are in agreement with the inclusive measurement. Figure 2 (right) shows the differential cross section in p_T bins divided into classes of charged-particle multiplicity.

The effect of the nuclear medium on B^+ meson production is examined through the R_{HL} vari-

able conceptually defined as:

$$R_{\text{HL}} = \frac{\langle N_{\text{coll}} \rangle_{\text{low}} (d\sigma/dp_T)|_{\text{high}}}{\langle N_{\text{coll}} \rangle_{\text{high}} (d\sigma/dp_T)|_{\text{low}}}, \quad (2)$$

where, $\langle N_{\text{coll}} \rangle$ is the average number of incoherent nucleon-nucleon collisions in the events of a certain multiplicity class, and $d\sigma/dp_T$ is the differential cross section as a function of the p_T at high (numerator) or low (denominator) multiplicity. The production of Z bosons is expected to scale with the number of binary collisions and be void of any final-state medium effects; thus, the ratio of Z boson cross section in the same high- and low-multiplicity event classes provides experimental means to determine the scaling factor of Eq. (2). The experimental equivalent of Eq. (2) can be expressed as:

$$R_{\text{HL}} = \frac{(d\sigma^{B^+}/dp_T)|_{\text{high}}}{(d\sigma^{B^+}/dp_T)|_{\text{low}}} \bigg/ \frac{(d\sigma^Z/dp_T)|_{\text{high}}}{(d\sigma^Z/dp_T)|_{\text{low}}}. \quad (3)$$

with $d\sigma/dp_T$ for the Z bosons measured from the same pPb data set. The Z boson reconstruction, selection requirements, and signal extraction are detailed in Ref. [63], while cross sections results are shown in Appendix A. The new measure of B^+ nuclear modification R_{HL} is shown in the left panel of Fig. 3 as a function of p_T , while the right panel presents it as a function of the multiplicity density for the full range of the B^+ meson momentum. The R_{HL} results as a function of p_T and the charged-particle density are consistent with unity at the current level of precision, providing new constraints on possible presence of medium effects in the collisions studied. The approach proposed in this work can be used to study medium effects in other types of collisions, and particularly in systems, where unbiased determination of binary scaling by other means is unreliable.

Figure 3: The R_{HL} for B^+ in p_T bins for the highest and lowest multiplicity classes (left), and in the full p_T range and as a function of the multiplicity density (right). The error bars correspond to the statistical uncertainty, and the boxes represent the sum in quadrature of systematic uncertainties.

In summary, the B^+ meson differential production cross sections have been measured as a function of the meson transverse momentum in proton-lead (pPb) collisions at a nucleon-nucleon center-of-mass energy of 8.16 TeV. The exclusive $B^+ \rightarrow J/\psi K^+$ decay channel was used to reconstruct the B^+ mesons. The fixed-order next-to-leading logarithmic predictions are in agreement with the inclusive measurement. The B^+ cross section has been measured for the first time in

different classes of charged-particle multiplicity in pPb collisions, revealing an expected rising trend in the B^+ production with increasing charged-particle multiplicity.

The scaled ratio of B^+ meson cross sections in high- to low-multiplicity events were used to study nuclear medium effects on heavy flavor production. The scaling factors, characterizing the relative number of binary collisions between event classes of different multiplicities, were obtained, for the first time, in a data-driven way from ratios of the measured Z boson cross sections in the same events. The observed ratios are consistent with unity within uncertainties for all event selections studied, setting constraints on possible presence of medium effects in the B^+ meson production. The novel approach relying on the Z boson measurements to extract the scaling factors provides future opportunities for medium effect searches, particularly in small collision systems.

Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid and other centers for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC, the CMS detector, and the supporting computing infrastructure provided by the following funding agencies: SC (Armenia), BMBWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP (Brazil); MES and BNSF (Bulgaria); CERN; CAS, MoST, and NSFC (China); MINCIENCIAS (Colombia); MSES and CSF (Croatia); RIF (Cyprus); SENESCYT (Ecuador); ERC PRG, RVTT3 and MoER TK202 (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); SRNSF (Georgia); BMBF, DFG, and HGF (Germany); GSRI (Greece); NKFIH (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); MES (Latvia); LMTLT (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MOS (Montenegro); MBIE (New Zealand); PAEC (Pakistan); MES and NSC (Poland); FCT (Portugal); MESTD (Serbia); MCIN/AEI and PCTI (Spain); MOSTR (Sri Lanka); Swiss Funding Agencies (Switzerland); MST (Taipei); MHESI and NSTDA (Thailand); TUBITAK and TENMAK (Turkey); NASU (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

A Supplemental material

A.1 Numerical differential cross section results for the B^+ meson in bins of p_T

Table A.1 provides the numerical differential cross sections results in bins of p_T as shown in Fig. 2 (left).

Table A.1: Summary of differential cross sections ($\mu\text{b GeV}^{-1}$) as a function of p_T (B^+) in pPb collisions at $\sqrt{s_{\text{NN}}} = 8.16$ TeV. The uncertainties in the integrated luminosity measurement and the B^+ meson branching fraction are not included in the systematic uncertainties.

p_T (GeV)	$d\sigma/dp_T$	Stat. Unc.	Syst. Unc.
3–7	1423	157	73
7–10	647	39	22
10–15	202	7	10
15–20	51.4	2.0	2.6
20–30	11.3	0.5	1.0
30–50	1.35	0.09	0.20

A.2 $Z \rightarrow \mu^- \mu^+$ differential cross section measurement

The differential cross section of $Z \rightarrow \mu^- \mu^+$ decays is measured in pPb collisions at a center-of-mass energy of 8.16 TeV per nucleon. The Z boson reconstruction, selection requirements, the signal extraction, and the definition of the $Z \rightarrow \mu^- \mu^+$ cross section are described in Ref. [63]. The detection efficiencies are evaluated using the same procedure used for the B^+ meson. The identical p_T binning, the definition of multiplicity and its classes, as well as the tracking efficiency utilized in the cross section measurement of the B^+ meson are also applied to the corresponding measurement with the Z boson. The same systematic sources as in the B^+ meson measurement are considered. The differential cross section measurement of $Z \rightarrow \mu^- \mu^+$ decays in p_T bins, and for different multiplicity classes is shown in Fig. A.1.

Figure A.1: Z boson differential cross section in p_T bins for the different multiplicity classes. The vertical bars represent the total uncertainties.

V. Chekhovsky, V. Makarenko 

†: Deceased

¹Also at Yerevan State University, Yerevan, Armenia

²Also at TU Wien, Vienna, Austria

³Also at Institute of Basic and Applied Sciences, Faculty of Engineering, Arab Academy for

Science, Technology and Maritime Transport, Alexandria, Egypt

⁴Also at Ghent University, Ghent, Belgium

⁵Also at Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

⁶Also at Universidade Estadual de Campinas, Campinas, Brazil

⁷Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil

⁸Also at UFMS, Nova Andradina, Brazil

⁹Also at Nanjing Normal University, Nanjing, China

¹⁰Now at The University of Iowa, Iowa City, Iowa, USA

¹¹Also at University of Chinese Academy of Sciences, Beijing, China

¹²Also at China Center of Advanced Science and Technology, Beijing, China

¹³Also at University of Chinese Academy of Sciences, Beijing, China

¹⁴Also at China Spallation Neutron Source, Guangdong, China

¹⁵Now at Henan Normal University, Xinxiang, China

¹⁶Also at Université Libre de Bruxelles, Bruxelles, Belgium

¹⁷Also at an institute or an international laboratory covered by a cooperation agreement with CERN

¹⁸Also at Suez University, Suez, Egypt

¹⁹Now at British University in Egypt, Cairo, Egypt

²⁰Also at Purdue University, West Lafayette, Indiana, USA

²¹Also at Université de Haute Alsace, Mulhouse, France

²²Also at Istinye University, Istanbul, Turkey

²³Also at Ilia State University, Tbilisi, Georgia

²⁴Also at The University of the State of Amazonas, Manaus, Brazil

²⁵Also at University of Hamburg, Hamburg, Germany

²⁶Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany

²⁷Also at Bergische University Wuppertal (BUW), Wuppertal, Germany

²⁸Also at Brandenburg University of Technology, Cottbus, Germany

²⁹Also at Forschungszentrum Jülich, Juelich, Germany

³⁰Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland

³¹Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary

³²Now at Universitatea Babeş-Bolyai - Facultatea de Fizică, Cluj-Napoca, Romania

³³Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary

³⁴Also at HUN-REN Wigner Research Centre for Physics, Budapest, Hungary

³⁵Also at Physics Department, Faculty of Science, Assiut University, Assiut, Egypt

³⁶Also at Punjab Agricultural University, Ludhiana, India

³⁷Also at University of Visva-Bharati, Santiniketan, India

³⁸Also at Indian Institute of Science (IISc), Bangalore, India

³⁹Also at IIT Bhubaneswar, Bhubaneswar, India

⁴⁰Also at Institute of Physics, Bhubaneswar, India

⁴¹Also at University of Hyderabad, Hyderabad, India

⁴²Also at Deutsches Elektronen-Synchrotron, Hamburg, Germany

⁴³Also at Isfahan University of Technology, Isfahan, Iran

⁴⁴Also at Sharif University of Technology, Tehran, Iran

⁴⁵Also at Department of Physics, University of Science and Technology of Mazandaran, Behshahr, Iran

⁴⁶Also at Department of Physics, Isfahan University of Technology, Isfahan, Iran

⁴⁷Also at Department of Physics, Faculty of Science, Arak University, ARAK, Iran

⁴⁸Also at Helwan University, Cairo, Egypt

- ⁴⁹Also at Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Bologna, Italy
- ⁵⁰Also at Centro Siciliano di Fisica Nucleare e di Struttura Della Materia, Catania, Italy
- ⁵¹Also at Università degli Studi Guglielmo Marconi, Roma, Italy
- ⁵²Also at Scuola Superiore Meridionale, Università di Napoli 'Federico II', Napoli, Italy
- ⁵³Also at Fermi National Accelerator Laboratory, Batavia, Illinois, USA
- ⁵⁴Also at Consiglio Nazionale delle Ricerche - Istituto Officina dei Materiali, Perugia, Italy
- ⁵⁵Also at Department of Applied Physics, Faculty of Science and Technology, Universiti Kebangsaan Malaysia, Bangi, Malaysia
- ⁵⁶Also at Consejo Nacional de Ciencia y Tecnología, Mexico City, Mexico
- ⁵⁷Also at Trincomalee Campus, Eastern University, Sri Lanka, Nilaveli, Sri Lanka
- ⁵⁸Also at Saegis Campus, Nugegoda, Sri Lanka
- ⁵⁹Also at National and Kapodistrian University of Athens, Athens, Greece
- ⁶⁰Also at Ecole Polytechnique Fédérale Lausanne, Lausanne, Switzerland
- ⁶¹Also at Universität Zürich, Zurich, Switzerland
- ⁶²Also at Stefan Meyer Institute for Subatomic Physics, Vienna, Austria
- ⁶³Also at Laboratoire d'Annecy-le-Vieux de Physique des Particules, IN2P3-CNRS, Annecy-le-Vieux, France
- ⁶⁴Also at Near East University, Research Center of Experimental Health Science, Mersin, Turkey
- ⁶⁵Also at Konya Technical University, Konya, Turkey
- ⁶⁶Also at Izmir Bakircay University, Izmir, Turkey
- ⁶⁷Also at Adiyaman University, Adiyaman, Turkey
- ⁶⁸Also at Bozok Universitetesi Rektörlüğü, Yozgat, Turkey
- ⁶⁹Also at Marmara University, Istanbul, Turkey
- ⁷⁰Also at Milli Savunma University, Istanbul, Turkey
- ⁷¹Also at Kafkas University, Kars, Turkey
- ⁷²Now at Istanbul Okan University, Istanbul, Turkey
- ⁷³Also at Hacettepe University, Ankara, Turkey
- ⁷⁴Also at Erzincan Binali Yildirim University, Erzincan, Turkey
- ⁷⁵Also at Istanbul University - Cerrahpasa, Faculty of Engineering, Istanbul, Turkey
- ⁷⁶Also at Yildiz Technical University, Istanbul, Turkey
- ⁷⁷Also at Vrije Universiteit Brussel, Brussel, Belgium
- ⁷⁸Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
- ⁷⁹Also at IPPP Durham University, Durham, United Kingdom
- ⁸⁰Also at Monash University, Faculty of Science, Clayton, Australia
- ⁸¹Also at Università di Torino, Torino, Italy
- ⁸²Also at Bethel University, St. Paul, Minnesota, USA
- ⁸³Also at Karamanoğlu Mehmetbey University, Karaman, Turkey
- ⁸⁴Also at California Institute of Technology, Pasadena, California, USA
- ⁸⁵Also at United States Naval Academy, Annapolis, Maryland, USA
- ⁸⁶Also at Ain Shams University, Cairo, Egypt
- ⁸⁷Also at Bingol University, Bingol, Turkey
- ⁸⁸Also at Georgian Technical University, Tbilisi, Georgia
- ⁸⁹Also at Sinop University, Sinop, Turkey
- ⁹⁰Also at Erciyes University, Kayseri, Turkey
- ⁹¹Also at Horia Hulubei National Institute of Physics and Nuclear Engineering (IFIN-HH), Bucharest, Romania

⁹²Now at another institute or international laboratory covered by a cooperation agreement with CERN

⁹³Also at Texas A&M University at Qatar, Doha, Qatar

⁹⁴Also at Kyungpook National University, Daegu, Korea

⁹⁵Also at another institute or international laboratory covered by a cooperation agreement with CERN

⁹⁶Also at Institute of Nuclear Physics of the Uzbekistan Academy of Sciences, Tashkent, Uzbekistan

⁹⁷Also at Northeastern University, Boston, Massachusetts, USA

⁹⁸Also at Imperial College, London, United Kingdom

⁹⁹Now at Yerevan Physics Institute, Yerevan, Armenia

¹⁰⁰Also at Universiteit Antwerpen, Antwerpen, Belgium
