

Multiplicity dependence of charm baryon and baryon meson production in pPb collisions at $\sqrt{s_{\text{NN}}} = 8.16$ TeV

The CMS Collaboration*

Abstract

Measurements of the production yields of charm baryons (Λ_c^+) and charm mesons (D^0) in proton-lead collisions at a nucleon-nucleon center-of-mass energy of 8.16 TeV are presented. The data were collected in 2016 with the CMS experiment and correspond to an integrated luminosity of 186 nb^{-1} . The Λ_c^+ baryon is reconstructed from the decay channel $\Lambda_c^+ \rightarrow K_S^0 p$, while the D^0 meson is reconstructed via $D^0 \rightarrow K^- \pi^+$. The Λ_c^+ baryon and D^0 meson yields are extracted in several charged-particle multiplicity classes. No strong multiplicity dependence of the Λ_c^+ -to- D^0 yield ratio is observed, unlike the observed strange baryon to strange meson yield ratio of $\Lambda/\bar{\Lambda}$ to K_S^0 , which shows a strong multiplicity dependence. This observation indicates different mechanisms for the multiplicity evolution of hadronization processes for charm and strange quarks and provides new constraints to the understanding of heavy flavor production and collectivity in small collision systems.

Submitted to Physics Letters B

1 Introduction

The quark-gluon plasma (QGP), a deconfined phase of quarks and gluons, is formed in ultra-relativistic heavy ion collisions. The collective flow motion (“collectivity”) of this strongly coupled medium in nucleus-nucleus (AA) collisions has been observed at the CERN LHC [1–3] and the BNL RHIC [4–7]. The observed azimuthal anisotropies of the particles emitted [8–13], such as the “elliptic flow,” result from strong interactions between constituents inside the medium that initially has an asymmetric geometrical shape and can be well described by hydrodynamic models [14–16]. Similar observations of a common collective signature for charm mesons [17–19] and bottom mesons [20–22] indicate that heavy quarks may also be strongly coupled to the QGP, even though their interactions with the medium are expected to be much less frequent than for light quarks.

In recent years, unexpected strong collective flow signals were also observed in small systems such as proton-proton (pp) [23–26] and proton-lead (pPb) [27–37] collisions. The elliptic flow for prompt D^0 [18, 38] and J/ψ [39, 40] mesons in pPb collisions was found to be comparable to that of light-flavor hadrons at a given particle transverse momentum (p_T). On the other hand, no evidence for bottom hadron collective flow has been observed yet in small systems, such as pPb collisions [38, 41]. Although effects of final-state partonic rescatterings in a dense medium can successfully explain a large variety of measurements for light quarks (see reviews in Refs. [42, 43]), they alone cannot describe the large flow for charm quarks [44]. Meanwhile, calculations based on initial-state effects, such as gluon saturation models, can successfully describe experimental measurements for several charm and bottom mesons [45].

The study of heavy flavor meson and baryon production yields provides a powerful means to further elucidate the origin of heavy flavor collectivity in small systems, as hadronization processes are also influenced by the presence of final-state rescattering effects. The abundant deconfined quarks in the QGP can coalesce into bound states before fragmenting to low-energy hadrons, resulting in a different modification of the yields for baryons and mesons [46, 47]. This parton coalescence effect is expected to be stronger with increasing system size and can enhance the baryon-to-meson yield ratio at an intermediate hadron p_T range (e.g., 2–6 GeV) [48, 49]. Models in AA collisions incorporating parton coalescence have been able to describe measurements of heavy-flavor hadrons, such as the Λ_c^+ -to- D^0 production yield ratio, at both RHIC and the LHC [50–52]. Because of its dependence on final-state effects, the study of this baryon-to-meson enhancement effect may also contribute to our understanding of the origin of collectivity in small systems.

Measurements of the charged-particle multiplicity dependence of the baryon-to-meson ratio for strange particles show an increasing trend from low to high multiplicity in the intermediate hadron p_T range [53], which is qualitatively consistent with models including final-state effects. Therefore, an enhancement of charm baryon-to-meson yield ratios should be expected for high multiplicity events, if final state effects are the origin of heavy flavor quark collectivity. For inclusive pp and pPb collisions, models assuming the presence of a QGP [54, 55] are in agreement with measurements of Λ_c^+ baryon yields [56–58] when coalescence effects are incorporated. Over the limited range of charged multiplicities in pp collisions, the statistical hadronization model is able to describe the multiplicity dependence of the Λ_c^+ -to- D^0 yield ratio as a function of p_T [59, 60].

In this Letter, the p_T spectra of the Λ_c^+ and D^0 particles and their ratios are measured in the range of 2–10 GeV in pPb collisions at a nucleon-nucleon center-of-mass energy $\sqrt{s_{NN}} = 8.16$ TeV, for the first time in different multiplicity intervals. Tabulated results are provided in the HEPData record for this analysis [61].

2 The CMS detector

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorimeter (HCAL), each composed of a barrel and two endcap sections. Hadron forward (HF) calorimeters [62], made of steel and quartz fibers, extend the pseudorapidity ($\eta = -\ln(\tan(\theta/2))$, where the polar angle θ is defined relative to the counterclockwise beam) coverage provided by the barrel and endcap detectors. Muons are measured in gas-ionization detectors embedded in the steel flux-return yoke outside the solenoid. A more detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in Ref. [63].

The silicon tracker measures charged particles within the range $|\eta_{\text{lab}}| < 2.5$ in the laboratory frame. During the LHC running period when the data used in this Letter were recorded, the silicon tracker consisted of 1440 silicon pixel and 15 148 silicon strip detector modules. For particles of $1 < p_{\text{T}} < 10$ GeV and $|\eta_{\text{lab}}| < 1.4$, the track resolutions are typically 1.5% in p_{T} and 25–90 (45–150) μm in the transverse (longitudinal) impact parameter [64].

The event samples are collected by the CMS experiment with a two-level trigger system [65, 66]. At Level-1, events are selected by custom hardware processors, while the high-level trigger (HLT) uses fast versions of the offline software. The pPb data used in this analysis were collected in 2016 at $\sqrt{s_{\text{NN}}} = 8.16$ TeV and correspond to an integrated luminosity of $186.0 \pm 6.5 \text{ nb}^{-1}$ [67]. The beam energies were 6.5 TeV for the protons and 2.56 TeV per nucleon for the lead nuclei. Because of the asymmetric beam conditions, the midrapidity range of $|y_{\text{lab}}| < 1$, which is used for particle selections, corresponds to the rapidity range $-1.46 < y_{\text{cm}} < 0.54$ in the nucleon-nucleon center-of-mass frame, with positive rapidity corresponding to the proton beam direction.

The event reconstruction, event selections, and trigger requirements for minimum bias and high-multiplicity events are identical to those described in Refs. [26, 68, 69]. The minimum bias (MB) 8.16 TeV pPb events are triggered by requiring energy deposits above 1 GeV in at least one of the two HF calorimeters and the presence of at least one track with $p_{\text{T}} > 0.4$ GeV reconstructed using hits from the pixel tracker only. To collect a large sample of high-multiplicity pPb collisions, a dedicated trigger is implemented. At Level-1, the total number of ECAL+HCAL towers having deposited energy above a threshold of 0.5 GeV in transverse energy (E_{T}) is required to be greater than 150. As part of the HLT trigger, the track reconstruction is performed online with the identical reconstruction algorithm used offline [64]. For each event selected at Level-1, the reconstructed vertex with the highest number of associated tracks is selected as the primary vertex (PV) at the HLT. The number of online tracks with $|\eta| < 2.4$, $p_{\text{T}} > 0.4$ GeV, and a distance of closest approach less than 0.12 cm along the beam axis to the PV is determined for each event and is required to exceed 185. The events are required to contain a PV within 15 cm of the nominal interaction point along the beam axis and 0.2 cm in the transverse direction. The integrated luminosity sampled by the minimum bias (high-multiplicity) trigger is $4.22 (97.8) \text{ nb}^{-1}$.

3 Data analysis

Similar to previous measurements [27, 30, 33, 34], hadronic events are selected by requiring the presence of at least one energy deposit greater than 3 GeV in each of the two HF calorimeters. The pPb data are analyzed in several charged-particle multiplicity classes, and defined accord-

ing to the number of selected offline tracks ($N_{\text{trk}}^{\text{offline}}$) with $|\eta_{\text{lab}}| < 2.4$ and $p_T > 0.4$ GeV that originate from the PV [26, 64]. If more than one vertex is found in an event, the vertex associated with the highest number of offline tracks is considered as the PV. The average number of tracks in each $N_{\text{trk}}^{\text{offline}}$ range before and after correcting for inefficiencies and misidentification rates in the tracking system is denoted as $\langle N_{\text{trk}}^{\text{offline}} \rangle$ and $\langle N_{\text{trk}}^{\text{corrected}} \rangle$, respectively. The statistical uncertainty in $\langle N_{\text{trk}}^{\text{corrected}} \rangle$ has been found to be negligible, while the systematic uncertainty is 4% resulting from the uncertainty of tracking efficiency estimated based on simulated events. The $\langle N_{\text{trk}}^{\text{offline}} \rangle$ and $\langle N_{\text{trk}}^{\text{corrected}} \rangle$ values in each $N_{\text{trk}}^{\text{offline}}$ range are summarized in Table 1. To optimize the signal significance and efficiency, a sample of simulated signal events is generated using hard processes in PYTHIA 8.209 [70], using the CUETP8M1 tune [71]. These signal events are embedded into pPb events generated with the EPOS LHC model [72]. The response of the CMS detector for generated events is simulated using the GEANT4 [73] toolkit. The decay kinematics for Λ_c^+ and D^0 particles are simulated using EVTGEN [74].

Table 1: The average multiplicity before (and after) corrections, $\langle N_{\text{trk}}^{\text{offline}} \rangle$ ($\langle N_{\text{trk}}^{\text{corrected}} \rangle$) with track $p_T > 0.4$ GeV and $|\eta_{\text{lab}}| < 2.4$ in each multiplicity interval. The uncertainties reported for $\langle N_{\text{trk}}^{\text{corrected}} \rangle$ are systematic uncertainties, as the statistical uncertainties have been found to be negligible.

Multiplicity interval ($N_{\text{trk}}^{\text{offline}}$)	$\langle N_{\text{trk}}^{\text{offline}} \rangle$	$\langle N_{\text{trk}}^{\text{corrected}} \rangle$
[2, 35)	16.4	20.0 ± 0.8
[35, 60)	46.3	56.4 ± 2.3
[60, 90)	73.0	88.7 ± 3.5
[90, 120)	102	124 ± 5
[120, 185)	140	170 ± 7
[185, 250)	202	245 ± 10

The Λ_c^+ baryons are reconstructed using the decay channel $\Lambda_c^+ \rightarrow K_S^0 p$ with the branching fraction of $(1.59 \pm 0.07)\%$ [75], where K_S^0 mesons are reconstructed via the $K_S^0 \rightarrow \pi^+ \pi^-$ decays with the branching fraction of $(69.20 \pm 0.05)\%$ [75]. Throughout this Letter, charge-conjugate modes are implied unless explicitly noted otherwise. The decay vertex for each K_S^0 meson is reconstructed by fitting a common vertex with two oppositely charged particles inside the CMS tracking detector using a Kalman filter. Selections based on topological information are also applied to optimize the K_S^0 signal yield significance (over the non-signal hypothesis) of these signals, following the same procedures as Ref. [18]. The invariant mass of each K_S^0 candidate ($M_{\pi^+ \pi^-}$) is required to be within $|M_{\pi^+ \pi^-} - M_{K_S^0}| < 0.02$ GeV, where $M_{K_S^0}$ is the K_S^0 meson mass [75]. The secondary decay vertices of the Λ_c^+ baryon are reconstructed by combining a K_S^0 candidate with another charged track in the event. The Λ_c^+ candidates (including signals and backgrounds) with invariant mass falling within $|M_{K_S^0 p} - M_{\Lambda_c^+}| < 0.2$ GeV, are considered in this analysis, where $M_{\Lambda_c^+}$ is the mass of the Λ_c^+ baryon [75]. A multilayer perceptron (MLP) is trained with the Toolkit for Multivariate Data Analysis (TMVA) package [76] using simulated signal events to suppress the combinatorial background. The training variables are: the candidate proton track momentum and η ; the energy loss of the candidate proton track per unit length inside the tracker normalized by the expected mean value for the proton at the corresponding momentum; and the cosine of the pointing angle defined as the angle in three dimensions between the vector connecting the PV with the secondary decay vertex of Λ_c^+ baryons and the momentum of the Λ_c^+ candidate. The energy loss per unit length for each track is calculated with the ‘‘generalized mean’’ of grade-2, as described in Ref. [77].

Events populating the sideband region, defined as $0.06 < |M_{K_S^0 p} - M_{\Lambda_c^+}| < 0.11$ GeV that is at least four standard deviations away from the peak of the signal distribution, are used as background samples in the TMVA training. The optimization of the Λ_c^+ signal significance is performed separately for event classes $2 \leq N_{\text{trk}}^{\text{offline}} < 185$ (from the minimum bias trigger) and $185 \leq N_{\text{trk}}^{\text{offline}} < 250$ (from the high-multiplicity trigger). The maximum statistical significance of these signals after optimization is much larger than 5 standard deviations.

The D^0 candidates are reconstructed using the decay channel $D^0 \rightarrow K^- \pi^+$ with the branching fraction of $(3.947 \pm 0.030)\%$ [75]. The boosted decision tree (BDT) method is used to reject combinatorial backgrounds and to optimize the D^0 signal yield significance. Details about the reconstruction, candidate selection, and correction are reported in Ref. [38].

Figure 1: The fitted mass spectra, along with the goodness-of-fit values, for Λ_c^+ candidates with $3 < p_T < 4$ GeV and $-1.46 < y_{\text{cm}} < 0.54$. The spectrum for the multiplicity class with $2 \leq N_{\text{trk}}^{\text{offline}} < 35$ is shown in the left plot, and the spectrum for $185 \leq N_{\text{trk}}^{\text{offline}} < 250$ is shown in the right plot.

The Λ_c^+ candidate mass spectra are modeled by a double Gaussian function with a common mean and different widths for the signal contribution and a third-order Chebyshev polynomial for the background. The widths of the signal distributions are constrained to those found in simulation to improve the fit stability. Figure 1 shows the mass spectra of the Λ_c^+ candidates for the multiplicity ranges of $2 \leq N_{\text{trk}}^{\text{offline}} < 35$ and $185 \leq N_{\text{trk}}^{\text{offline}} < 250$. The invariant mass of D^0 candidates is modeled by several components: a double Gaussian function with a common mean for the D^0 signal; an additional Gaussian function to describe the invariant mass shape of D^0 candidates with swapped pion and kaon tracks (“swapped component”); two Crystal Ball (CB) functions [78] to describe the processes $D^0 \rightarrow \pi^+ \pi^-$ and $D^0 \rightarrow K^+ K^-$; and a third-order polynomial to model the combinatorial background. Examples of fits to the D^0 invariant mass are shown in Ref. [38].

The differential yields for Λ_c^+ and D^0 particles are computed using

$$\frac{dN}{dp_T} = \frac{f^{\text{prompt}} N^{\text{sig}}}{2\alpha\epsilon\Delta p_T} \frac{1}{\mathcal{B}'} \quad (1)$$

where N^{sig} is the raw yield from the fit to the invariant mass in each p_T and multiplicity bin, α is the acceptance, ϵ is the reconstruction efficiency, Δp_T is the width of p_T interval, \mathcal{B}' is the

branching fraction, and f^{prompt} is the corresponding prompt component fraction for Λ_c^+ and D^0 hadrons, respectively. Prompt mesons are those directly produced in pPb collisions or from strong decays of excited charm hadrons, rather than from decays of bottom hadrons. The factor of two in the denominator takes into account the inclusion of both charge-conjugate particles in the raw yield. The acceptance and reconstruction efficiencies are obtained from simulated events in bins of p_T , where the resolution is much narrower than the bin width.

The fraction f^{prompt} for Λ_c^+ events is estimated following a procedure similar to the one described in Ref. [56]. The estimation of nonprompt Λ_c^+ contributions from bottom hadron decays considers inputs including the Λ_b^0 and B production cross sections and the inclusive decay branching fractions of Λ_b^0 and B (B^+ , B^0) mesons to Λ_c^+ , i.e., $\Lambda_b^0 \rightarrow \Lambda_c^+ + X$ and $B \rightarrow \Lambda_c^+ + X$. The Λ_b^0 production cross section is derived from that for B meson production, computed using the “fixed order next-to-leading logarithmic” (FONLL) perturbative quantum chromodynamics calculation [79] and rescaled according to the fragmentation fractions measured by the LHCb Collaboration [80]. It is then multiplied by $A = 208$, the atomic number of the lead nucleus, to map it to pPb collisions. Modifications due to nuclear effects are allowed at the level of 25% in the systematic uncertainties, as discussed in Section 4. The $\mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ X)$ value is set to 83%, as in the EVTGEN package, and it includes the contributions from unobserved decay channels [81]. The corresponding branching fractions for the B mesons are set to 5% by summing over all channels reported in Ref. [75]. The correlations between the kinematic distributions of b hadrons and Λ_c^+ particles are simulated using EVTGEN. The cross section of nonprompt Λ_c^+ baryon production is further corrected for the acceptance and reconstruction efficiency. The fraction of feed-down contribution is assumed to be multiplicity independent in the range $2 \leq N_{\text{trk}}^{\text{offline}} < 185$, as the same candidate selection is applied in all the multiplicity ranges. A summary of the nonprompt Λ_c^+ baryon fraction ($1-f^{\text{prompt}}$), which has little dependence on p_T and $N_{\text{trk}}^{\text{offline}}$ within uncertainties, is given in Table 2.

Table 2: Summary table for the fraction of nonprompt Λ_c^+ baryons ($1-f^{\text{prompt}}$) relative to inclusive Λ_c^+ baryons. The fraction is evaluated in different multiplicity ranges. Details regarding the systematic uncertainties are described in Section 4.

p_T (GeV)	$2 \leq N_{\text{trk}}^{\text{offline}} < 185$ (%)	$185 \leq N_{\text{trk}}^{\text{offline}} < 250$ (%)
2–3	$6.8^{+11}_{-6.8}$	—
3–4	$4.1^{+5.8}_{-4.1}$	$4.3^{+6.0}_{-4.3}$
4–5	$3.3^{+5.5}_{-3.3}$	$3.4^{+5.7}_{-3.4}$
5–6	$3.6^{+2.9}_{-2.9}$	$3.6^{+3.0}_{-3.0}$
6–8	$3.5^{+3.8}_{-3.5}$	$3.1^{+3.4}_{-3.1}$
8–10	$3.9^{+5.5}_{-3.9}$	$4.3^{+6.2}_{-4.3}$

The f^{prompt} fraction for D^0 mesons is obtained using a template fit method. The prompt and nonprompt D^0 mesons can be distinguished based on the distributions of their distance of closest approach (DCA) with respect to the PV of the event. A two-component fit with DCA templates from simulated prompt and nonprompt D^0 samples is performed to the DCA distribution in data. Examples of the template fit to DCA distributions for D^0 mesons can be found in Ref. [38].

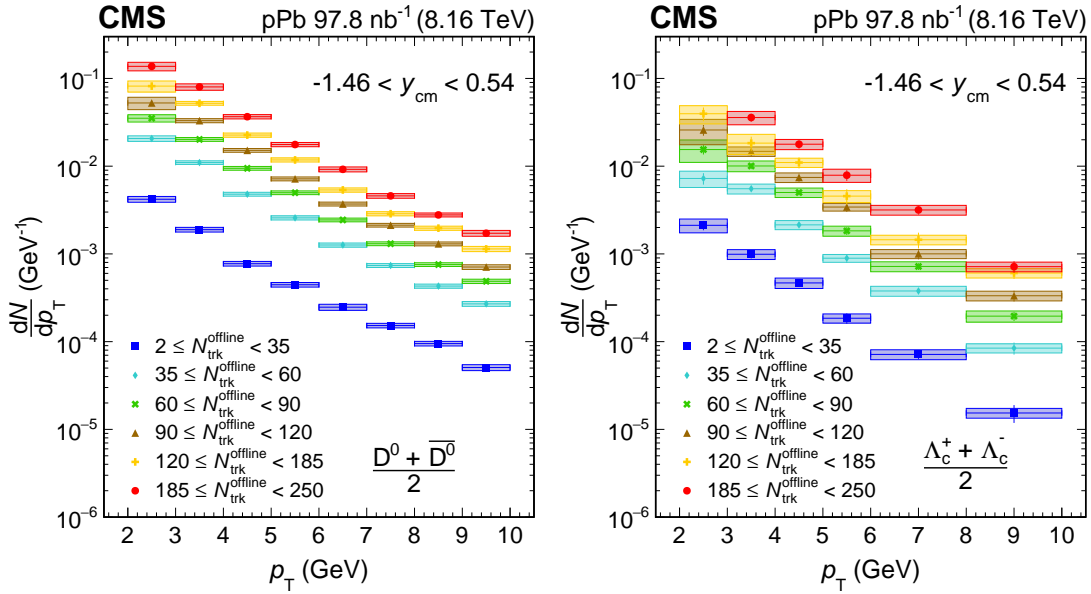

Figure 2: Transverse momentum spectra for Λ_c^+ baryons (left) and D^0 mesons (right) with $-1.46 < y_{\text{cm}} < 0.54$ in different multiplicity classes. The vertical bars show the statistical uncertainties while the shaded areas represent the systematic uncertainties.

4 Systematic uncertainties

The candidate selection uncertainty is estimated by varying the MLP or BDT classifier cut over a wide range, which yields a relative uncertainty of 2–6% for Λ_c^+ baryons and 1–5% for D^0 mesons, respectively, depending on the $N_{\text{trk}}^{\text{offline}}$ and charm hadron p_T . The uncertainty of the fit procedure is estimated by changing the signal shape from a double Gaussian to a Gaussian+CB function for the Λ_c^+ baryon, and via changing the background function to a second- and fourth-order polynomial for both Λ_c^+ and D^0 particles. These variations yield a relative uncertainty of 6–28% for Λ_c^+ baryons and less than 2% for D^0 mesons.

The uncertainty in feed-down from b hadrons for Λ_c^+ is estimated from the following components. The associated systematic uncertainty from FONLL calculations is evaluated by varying its central values by its uncertainties [79]. Another variation is performed by comparing the FONLL calculations with PYTHIA. The value of the Pb-normalized FONLL calculations is also varied by 25% to account for potential nuclear effects. No significant nuclear modifications to the b-hadrons production cross sections in pPb collisions are observed within $\pm 25\%$ [82]. The uncertainty from the LHCb fragmentation fraction measurements is also considered [80]. The assumption that the feed-down is uniform across multiplicities is studied using D^0 mesons and assumed to have similar behavior for Λ_c^+ baryons, because both nonprompt Λ_c^+ and D^0 production originates from b hadrons. The maximum of the difference of f^{prompt} for D^0 mesons between different multiplicity classes is taken as an estimate for the systematic uncertainty in the Λ_c^+ measurements. The sum in quadrature of these sources yields a total relative uncertainty of 4–12% for the feed-down estimation. The uncertainty related to template fits in DCA for D^0 mesons is estimated by varying the DCA resolution of simulated samples to explore the discrepancy between simulated samples and data. This source yields an uncertainty of less than 15%.

The systematic uncertainty from the tracking efficiency is 2.3% per track [83], which is propagated to 7% for Λ_c^+ baryon yields and 5% for D^0 meson yields since the former are reconstructed from three tracks and the latter are from two. The uncertainty related to trigger effi-

ciency is found to be negligible, as the main inefficiency affects mostly very low multiplicity events while those containing a heavy flavor hadron production are strongly biased toward higher average multiplicity within each class. Occasionally, there are multiple collisions per bunch crossing, and these additional collisions are referred to as pileup interactions. The pileup effects are studied by requiring different minimum distances between multiple reconstructed PVs according to the final-state track multiplicity. The systematic uncertainty due to pileup effects turns out to be 3–6% (from low to high $N_{\text{trk}}^{\text{offline}}$) for Λ_c^+ baryons and $< 1\%$ for D^0 mesons. The total systematic uncertainty of the production yields is calculated by assuming all sources are independent and adding them in quadrature.

The relative systematic uncertainty for the yield ratio of Λ_c^+ -to- D^0 is computed by adding in quadrature the relative Λ_c^+ and D^0 yield uncertainties including the effects of candidate selections, fit procedures, b hadron feed-down, and branching fractions. The uncertainties from tracking efficiency and pileup effects are taken to be fully correlated between the D^0 and Λ_c^+ samples, resulting in uncertainties of 2.3% and 2–4% for the Λ_c^+ -to- D^0 ratio, respectively.

A summary of systematic uncertainties in measurements of the Λ_c^+ and D^0 differential yields can be found in Table 3.

Table 3: Summary of relative uncertainties in the differential yields.

Source	Λ_c^+ (%)	D^0 (%)
Selections	2–6	1–5
Fit	6–28	< 2
b feed-down	3–11	< 15
Tracking efficiency	7	5
Pileup effects	3–6	< 1
Branching fraction	5	1
Total	10–32	5–16

5 Results

The p_T spectra for Λ_c^+ and D^0 hadrons in each multiplicity class are shown in Fig. 2. The production of charm hadron yield per event increases with multiplicity. The p_T spectra follow approximately an exponential falling trend for all multiplicity classes.

The corresponding Λ_c^+ -to- D^0 ratios are presented in Fig 3. The Λ_c^+ -to- D^0 ratio tends to decrease with p_T , both for low- and high-multiplicity events. The ratios in Fig. 3 are also consistent with those obtained in inclusive pPb collisions at $\sqrt{s_{\text{NN}}} = 5.02$ TeV reported in Refs. [56, 58]. No strong multiplicity dependence is observed within one standard deviation, in contrast to the enhanced baryon-to-meson ratio for strange hadrons as the multiplicity increases [53].

To further investigate the system size dependence, the charm baryon-to-meson ratio is also plotted as a function of $N_{\text{trk}}^{\text{offline}}$ in Fig. 4. In contrast to what is observed in the strange-quark sector, the charm baryon-to-meson ratio is approximately constant over a large range of multiplicity. This may indicate a possible mass dependence for the particle hadronization mechanism. If a coalescence process is present, it may happen earlier for charm quarks than for light quarks during the system evolution.

The observed independence of the Λ_c^+ -to- D^0 ratio on the multiplicity might indicate a difference between heavy and light quarks, even though these particles show similar elliptic flow signals as a function of multiplicity [18, 40]. In models of QGP formation, charm quarks are

Figure 3: Ratio of Λ_c^+ baryons to D^0 mesons production in pPb collisions at $\sqrt{s_{NN}} = 8.16$ TeV with $2 \leq N_{\text{trk}}^{\text{offline}} < 35$ and $185 \leq N_{\text{trk}}^{\text{offline}} < 250$. The vertical bars show the statistical uncertainties while the shaded areas represent the systematic uncertainties. The grey markers are for Λ baryon to (two times) K_S^0 meson production at $\sqrt{s_{NN}} = 5.02$ TeV from Ref. [53].

expected to experience kinetic propagation inside the liquid QGP [49, 84], while light quarks are in general thermalized in the hot QGP. The larger mean free path of heavy quarks compared with light quarks in pPb collisions may lead to less pronounced effects from the dense medium. On the other hand, a model incorporating an initial-state gluon saturation scenario without QGP production shows agreement with the elliptic flow of D^0 mesons in pPb collisions [45, 85].

The charm baryon-to-meson ratio as a function of p_T in pPb collisions at 8.16 TeV is also compared with that in pp and PbPb collisions at 5.02 TeV [52, 86] in Fig. 5. The results in the range $2 < p_T < 10$ GeV are consistent with inclusive events in pp collisions and mid-central (e.g., 30–50% centrality) PbPb collisions. The decreasing trend with p_T for the charm baryon-to-meson ratio is also observed in these systems. Further studies of the multiplicity dependence of this ratio in pPb collisions for the very high- p_T regime are crucial to find out whether this convergence is universal across different colliding systems and event activities.

6 Summary

The first measurements of Λ_c^+ baryon and D^0 meson yields, as well as their yield ratios, as a function of the charged-particle multiplicity in proton-lead (pPb) collisions are presented. At a nucleon-nucleon center-of-mass energy of 8.16 TeV, the Λ_c^+ baryon is reconstructed using the decay channel $\Lambda_c^+ \rightarrow K_S^0 p$, while the D^0 meson is reconstructed from $D^0 \rightarrow K^- \pi^+$. The Λ_c^+ and D^0 production yields, and the Λ_c^+ -to- D^0 yield ratio are studied as a function of transverse momentum and charged-particle multiplicity. No strong multiplicity dependence is observed

Figure 4: Ratio of Λ_c^+ baryon to D^0 meson production with $-1.46 < y_{\text{cm}} < 0.54$ in pPb collisions at $\sqrt{s_{\text{NN}}} = 8.16$ TeV as a function of $N_{\text{trk}}^{\text{offline}}$. The vertical bars show the statistical uncertainties while the shaded areas represent the systematic uncertainties. The ratio of Λ baryon to (two times) K_S^0 meson production at $\sqrt{s_{\text{NN}}} = 5.02$ TeV obtained from data in Ref. [53] is also shown for comparisons, denoted by grey markers.

within the experimental uncertainties. The absence of any significant multiplicity dependence of the yield ratio differs strikingly from that for strange hadrons, which is observed to increase with multiplicity. The difference between these results for charm quarks and those for strange quarks might indicate that the conjectured coalescence processes of heavy quarks happen earlier than those of strange quarks.

Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid and other centers for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC, the CMS detector, and the supporting computing infrastructure provided by the following funding agencies: SC (Armenia), BMBWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP (Brazil); MES and BNSF (Bulgaria); CERN; CAS, MoST, and NSFC (China); MINCIENCIAS (Colombia); MSES and CSF (Croatia); RIF (Cyprus); SENESCYT (Ecuador); ERC PRG, RVTT3 and MoER TK202 (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); SRNSF (Georgia); BMBF, DFG, and HGF (Germany); GSRI (Greece); NKFIH (Hungary); DAE and DST (In-

Figure 5: Comparison between the Λ_c^+ -to- D^0 ratio as a function of p_T in pp, pPb, and PbPb (different centrality ranges) collisions at the nucleon-nucleon center-of-mass energies of 5.02, 8.16, and 5.02 TeV, respectively [52, 86]. The uncertainties are denoted by vertical bars. The ratio is measured with the rapidity ranges $-1.46 < y_{\text{cm}} < 0.54$ in pPb collisions and $|y_{\text{cm}}| < 1$ in pp and PbPb collisions by the CMS Collaboration [86] and $|y_{\text{cm}}| < 0.5$ by the ALICE Collaboration [52].

†: Deceased

¹Also at Yerevan State University, Yerevan, Armenia²Also at TU Wien, Vienna, Austria³Also at Institute of Basic and Applied Sciences, Faculty of Engineering, Arab Academy for Science, Technology and Maritime Transport, Alexandria, Egypt⁴Also at Ghent University, Ghent, Belgium⁵Also at Universidade Estadual de Campinas, Campinas, Brazil⁶Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil⁷Also at UFMS, Nova Andradina, Brazil⁸Also at Nanjing Normal University, Nanjing, China⁹Now at The University of Iowa, Iowa City, Iowa, USA¹⁰Also at University of Chinese Academy of Sciences, Beijing, China¹¹Also at China Center of Advanced Science and Technology, Beijing, China¹²Also at University of Chinese Academy of Sciences, Beijing, China¹³Also at China Spallation Neutron Source, Guangdong, China¹⁴Now at Henan Normal University, Xinxiang, China¹⁵Also at Université Libre de Bruxelles, Bruxelles, Belgium¹⁶Also at University of Latvia (LU), Riga, Latvia¹⁷Also at an institute or an international laboratory covered by a cooperation agreement with CERN¹⁸Now at British University in Egypt, Cairo, Egypt¹⁹Now at Cairo University, Cairo, Egypt²⁰Also at Birla Institute of Technology, Mesra, Mesra, India²¹Also at Purdue University, West Lafayette, Indiana, USA²²Also at Université de Haute Alsace, Mulhouse, France²³Also at Istinye University, Istanbul, Turkey²⁴Also at Tbilisi State University, Tbilisi, Georgia²⁵Also at The University of the State of Amazonas, Manaus, Brazil²⁶Also at Erzincan Binali Yildirim University, Erzincan, Turkey²⁷Also at University of Hamburg, Hamburg, Germany²⁸Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany²⁹Also at Isfahan University of Technology, Isfahan, Iran³⁰Also at Bergische University Wuppertal (BUW), Wuppertal, Germany³¹Also at Brandenburg University of Technology, Cottbus, Germany³²Also at Forschungszentrum Jülich, Juelich, Germany³³Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland³⁴Also at Institute of Physics, University of Debrecen, Debrecen, Hungary³⁵Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary³⁶Now at Universitatea Babeş-Bolyai - Facultatea de Fizica, Cluj-Napoca, Romania³⁷Also at Physics Department, Faculty of Science, Assiut University, Assiut, Egypt³⁸Also at HUN-REN Wigner Research Centre for Physics, Budapest, Hungary³⁹Also at Faculty of Informatics, University of Debrecen, Debrecen, Hungary⁴⁰Also at Punjab Agricultural University, Ludhiana, India⁴¹Also at University of Hyderabad, Hyderabad, India⁴²Also at University of Visva-Bharati, Santiniketan, India⁴³Also at Indian Institute of Science (IISc), Bangalore, India⁴⁴Also at IIT Bhubaneswar, Bhubaneswar, India

- ⁴⁵Also at Institute of Physics, Bhubaneswar, India
- ⁴⁶Also at Deutsches Elektronen-Synchrotron, Hamburg, Germany
- ⁴⁷Also at Department of Physics, Isfahan University of Technology, Isfahan, Iran
- ⁴⁸Also at Sharif University of Technology, Tehran, Iran
- ⁴⁹Also at Department of Physics, University of Science and Technology of Mazandaran, Behshahr, Iran
- ⁵⁰Also at Helwan University, Cairo, Egypt
- ⁵¹Also at Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Bologna, Italy
- ⁵²Also at Centro Siciliano di Fisica Nucleare e di Struttura Della Materia, Catania, Italy
- ⁵³Also at Università degli Studi Guglielmo Marconi, Roma, Italy
- ⁵⁴Also at Scuola Superiore Meridionale, Università di Napoli 'Federico II', Napoli, Italy
- ⁵⁵Also at Fermi National Accelerator Laboratory, Batavia, Illinois, USA
- ⁵⁶Also at Ain Shams University, Cairo, Egypt
- ⁵⁷Also at Consiglio Nazionale delle Ricerche - Istituto Officina dei Materiali, Perugia, Italy
- ⁵⁸Also at Riga Technical University, Riga, Latvia
- ⁵⁹Also at Department of Applied Physics, Faculty of Science and Technology, Universiti Kebangsaan Malaysia, Bangi, Malaysia
- ⁶⁰Also at Consejo Nacional de Ciencia y Tecnología, Mexico City, Mexico
- ⁶¹Also at Trincomalee Campus, Eastern University, Sri Lanka, Nilaveli, Sri Lanka
- ⁶²Also at INFN Sezione di Pavia, Università di Pavia, Pavia, Italy
- ⁶³Also at National and Kapodistrian University of Athens, Athens, Greece
- ⁶⁴Also at Ecole Polytechnique Fédérale Lausanne, Lausanne, Switzerland
- ⁶⁵Also at University of Vienna, Vienna, Austria
- ⁶⁶Also at Universität Zürich, Zurich, Switzerland
- ⁶⁷Also at Stefan Meyer Institute for Subatomic Physics, Vienna, Austria
- ⁶⁸Also at Laboratoire d'Annecy-le-Vieux de Physique des Particules, IN2P3-CNRS, Annecy-le-Vieux, France
- ⁶⁹Also at Near East University, Research Center of Experimental Health Science, Mersin, Turkey
- ⁷⁰Also at Konya Technical University, Konya, Turkey
- ⁷¹Also at Izmir Bakircay University, Izmir, Turkey
- ⁷²Also at Adiyaman University, Adiyaman, Turkey
- ⁷³Also at Bozok Universitetesi Rektörlüğü, Yozgat, Turkey
- ⁷⁴Also at Marmara University, Istanbul, Turkey
- ⁷⁵Also at Milli Savunma University, Istanbul, Turkey
- ⁷⁶Also at Kafkas University, Kars, Turkey
- ⁷⁷Now at Istanbul Okan University, Istanbul, Turkey
- ⁷⁸Also at Hacettepe University, Ankara, Turkey
- ⁷⁹Also at Istanbul University - Cerrahpasa, Faculty of Engineering, Istanbul, Turkey
- ⁸⁰Also at Yildiz Technical University, Istanbul, Turkey
- ⁸¹Also at Vrije Universiteit Brussel, Brussel, Belgium
- ⁸²Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
- ⁸³Also at University of Bristol, Bristol, United Kingdom
- ⁸⁴Also at IPPP Durham University, Durham, United Kingdom
- ⁸⁵Also at Monash University, Faculty of Science, Clayton, Australia
- ⁸⁶Now at another institute or international laboratory covered by a cooperation agreement with CERN

⁸⁷Also at Università di Torino, Torino, Italy

⁸⁸Also at Bethel University, St. Paul, Minnesota, USA

⁸⁹Also at Karamanoğlu Mehmetbey University, Karaman, Turkey

⁹⁰Also at California Institute of Technology, Pasadena, California, USA

⁹¹Also at United States Naval Academy, Annapolis, Maryland, USA

⁹²Also at Bingöl University, Bingöl, Turkey

⁹³Also at Georgian Technical University, Tbilisi, Georgia

⁹⁴Also at Sinop University, Sinop, Turkey

⁹⁵Also at Erciyes University, Kayseri, Turkey

⁹⁶Also at Horia Hulubei National Institute of Physics and Nuclear Engineering (IFIN-HH), Bucharest, Romania

⁹⁷Also at Texas A&M University at Qatar, Doha, Qatar

⁹⁸Also at Kyungpook National University, Daegu, Korea

⁹⁹Also at another institute or international laboratory covered by a cooperation agreement with CERN

¹⁰⁰Also at Institute of Nuclear Physics of the Uzbekistan Academy of Sciences, Tashkent, Uzbekistan

¹⁰¹Also at Northeastern University, Boston, Massachusetts, USA

¹⁰²Also at Imperial College, London, United Kingdom

¹⁰³Now at Yerevan Physics Institute, Yerevan, Armenia

¹⁰⁴Also at Universiteit Antwerpen, Antwerpen, Belgium
