# First evidence for direct $CP$ violation in beauty to charmonium decays

LHCb collaboration<sup>†</sup>

## Abstract

The  $CP$  asymmetry and branching fraction of the CKM-suppressed decay  $B^+ \rightarrow J/\psi\pi^+$  are precisely measured relative to the favoured decay  $B^+ \rightarrow J/\psi K^+$ , using a sample of proton-proton collision data corresponding to an integrated luminosity of  $5.4 \text{ fb}^{-1}$  recorded at center-of-mass energy of 13 TeV during 2016–2018. The results of the  $CP$  asymmetry difference and branching fraction ratio are

$$\Delta\mathcal{A}^{CP} \equiv \mathcal{A}^{CP}(B^+ \rightarrow J/\psi\pi^+) - \mathcal{A}^{CP}(B^+ \rightarrow J/\psi K^+) = (1.29 \pm 0.49 \pm 0.08) \times 10^{-2},$$

$$\mathcal{R}_{\pi/K} \equiv \frac{\mathcal{B}(B^+ \rightarrow J/\psi\pi^+)}{\mathcal{B}(B^+ \rightarrow J/\psi K^+)} = (3.852 \pm 0.022 \pm 0.018) \times 10^{-2},$$

where the first uncertainties are statistical and the second systematic. A combination with previous LHCb results based on data collected at 7 and 8 TeV in 2011 and 2012 yields  $\Delta\mathcal{A}^{CP} = (1.42 \pm 0.43 \pm 0.08) \times 10^{-2}$  and  $\mathcal{R}_{\pi/K} = (3.846 \pm 0.018 \pm 0.018) \times 10^{-2}$ . The combined  $\Delta\mathcal{A}^{CP}$  value deviates from zero by 3.2 standard deviations, providing the first evidence for direct  $CP$  violation in the amplitudes of beauty decays to charmonium final states.

1 Violation of the charge-parity ( $CP$ ) symmetry is one of the conditions necessary  
 2 to generate the matter-antimatter asymmetry in the Universe [1]. Beauty decays to  
 3 charmonium final states, governed by  $b \rightarrow c\bar{c}q$  quark-level transitions (where  $q = s, d$ ),  
 4 play a pivotal role in the study of  $CP$  violation. In general,  $CP$  violation can arise  
 5 directly from the interference of the leading-order  $W$ -emission (tree) amplitude and the  
 6 loop (penguin) amplitudes of such decays, manifesting as a small decay-rate asymmetry  
 7 between two  $CP$ -conjugated processes, referred to as direct  $CP$  violation. For neutral  
 8  $B$  mesons,  $CP$  violation can also arise from the interference of the direct decay and  
 9 the decay after flavor mixing, manifesting as a time-dependent decay-rate asymmetry.  
 10 Precision measurements of the weak phases  $2\beta = 2\phi_1 \equiv 2 \arg[-(V_{cd}V_{cb}^*)/(V_{td}V_{tb}^*)]$  and  
 11  $2\beta_s \equiv 2 \arg[-(V_{ts}V_{tb}^*)/(V_{cs}V_{cb}^*)]$ , where  $V_{ij}$  are elements of the CKM matrix [2, 3], from  
 12 the time-dependent  $CP$  asymmetries in the the golden channels  $B^0 \rightarrow J/\psi K^0$  [4–6] and  
 13  $B_s^0 \rightarrow J/\psi K^+ K^-$  [7–10], respectively, have provided stringent tests of the Standard Model  
 14 (SM). An open issue in the  $2\beta_{(s)}$  determination is related to the effects of the subleading  
 15 contributions from highly suppressed penguin diagrams in  $b \rightarrow c\bar{c}s$  transitions, which need  
 16 to be fully understood for more precise tests of the SM, but are difficult to calculate  
 17 reliably in theory. Such effects can be eventually controlled with measurements of penguin-  
 18 enhanced  $b \rightarrow c\bar{c}d$  transitions, such as  $B^+ \rightarrow J/\psi\pi^+$  decays,<sup>1</sup> as detailed in Refs. [11–14].  
 19 Specifically, measurements of the direct  $CP$  violation and decay rate of the  $B^+ \rightarrow J/\psi\pi^+$   
 20 process, together with time-dependent  $CP$  asymmetries measured in both  $B^0 \rightarrow J/\psi\pi^0$   
 21 and  $B_s^0 \rightarrow J/\psi\bar{K}^0$  decays, allow the penguin effects in  $B^0 \rightarrow J/\psi K^0$  to be included in the  
 22 determination of the phase  $2\beta$ , using approximate  $SU(3)$  flavor symmetry [11–14].

23 Unlike the case of  $b \rightarrow c\bar{c}s$  transitions, the penguin contributions in  $B^+ \rightarrow J/\psi\pi^+$  are  
 24 not CKM-suppressed with respect to the leading-order tree diagram. Thus, sizable direct  
 25  $CP$  violation up to the percent level could arise from interference between the tree and  
 26 penguin contributions [15, 16], which is within reach of the LHCb experiment, though  
 27 unobserved to date. In order to subtract the small difference between the production  
 28 cross-sections of  $B^-$  and  $B^+$  mesons, the asymmetry is measured with respect to that of  
 29 the  $B^+ \rightarrow J/\psi K^+$  decay, where direct  $CP$  violation is expected to be negligible due to the  
 30 dominance of the tree diagram, namely

$$\Delta\mathcal{A}^{CP} \equiv \mathcal{A}^{CP}(B^+ \rightarrow J/\psi\pi^+) - \mathcal{A}^{CP}(B^+ \rightarrow J/\psi K^+). \quad (1)$$

31 Here  $\mathcal{A}^{CP}$  is the decay rate asymmetry between  $B^-$  and  $B^+$  mesons. In addition, in-  
 32 formation on the penguin contributions can be obtained from the ratio of branching  
 33 fractions [17],

$$\mathcal{R}_{\pi/K} \equiv \frac{\mathcal{B}(B^+ \rightarrow J/\psi\pi^+)}{\mathcal{B}(B^+ \rightarrow J/\psi K^+)}, \quad (2)$$

34 where the systematic uncertainties related to the trigger, reconstruction and selec-  
 35 tion efficiencies largely cancel out. The LHCb collaboration has previously measured  
 36  $\Delta\mathcal{A}^{CP} = (1.82 \pm 0.86 \text{ (stat)} \pm 0.14 \text{ (syst)}) \times 10^{-2}$ , consistent with  $CP$  conservation, and  
 37  $\mathcal{R}_{\pi/K} = (3.83 \pm 0.03 \text{ (stat)} \pm 0.03 \text{ (syst)}) \times 10^{-2}$  [18], using proton-proton ( $pp$ ) collision  
 38 data collected at center-of-mass energies of 7 and 8 TeV from 2011–2012 (Run 1), corre-  
 39 sponding to an integrated luminosity of  $3 \text{ fb}^{-1}$ .

40 Many efforts have also been made to search for direct  $CP$  violation in other  
 41  $b \rightarrow c\bar{c}d$  processes, such as  $B^0 \rightarrow J/\psi\pi^0$  [19, 20],  $B_s^0 \rightarrow J/\psi\bar{K}^0$  [21],  $B^0 \rightarrow J/\psi\rho^0$  [22, 23],

<sup>1</sup>Unless otherwise stated, the inclusion of charge-conjugate processes is implied throughout.

42  $B_s^0 \rightarrow J/\psi \bar{K}^{*0}$  [24],  $B^+ \rightarrow \psi(2S)\pi^+$  [25, 26],  $B^+ \rightarrow J/\psi \rho^+$  [23, 27],  $B^+ \rightarrow \chi_{c1}(1P)\pi^+$  [28],  
 43 and  $\Lambda_b^0 \rightarrow J/\psi p \pi^-$  [29] decays. However, due to the limited sensitivity, no evidence for  
 44 direct  $CP$  violation has been found in beauty hadron to charmonium decays so far. This  
 45 Letter presents updated measurements of  $\Delta\mathcal{A}^{CP}$  and  $\mathcal{R}_{\pi/K}$  using data recorded by LHCb  
 46 at 13 TeV in 2016–2018 (Run 2), corresponding to an integrated luminosity of  $6 \text{ fb}^{-1}$ .

47 The LHCb detector is a single-arm forward spectrometer covering the pseudorapidity  
 48 range  $2 < \eta < 5$ , described in detail in Refs. [30, 31]. The magnetic-field polarity is  
 49 reversed periodically during data taking to mitigate the differences of reconstruction  
 50 efficiencies of particles with opposite charges. Data sets corresponding to about half of  
 51 the total integrated luminosity are recorded with each magnetic-field configuration.

52 Samples of simulated events are used to study the properties of the signal mode  
 53  $B^+ \rightarrow J/\psi(\rightarrow \mu^+ \mu^-)\pi^+$  and the control mode  $B^+ \rightarrow J/\psi(\rightarrow \mu^+ \mu^-)K^+$ . These simulated  
 54 events are produced with the software described in Refs. [32–36]. The momentum and  
 55 transverse momentum ( $p_T$ ) spectra of the  $B^+$  mesons as well as the track multiplicity in  
 56 simulation are corrected to match those in data. Additionally, the particle identification  
 57 (PID) performance of the simulation is also calibrated to match that in data evaluated  
 58 with large control samples [37, 38]. The corrections are determined in the initial phase of  
 59 the analysis and are included in all subsequent steps.

60 The online event selection used in this study is performed by a trigger system [38]  
 61 consisting of a hardware stage that selects events containing at least one muon candidate,  
 62 and two software trigger stages in which events with two tracks identified as muons with  
 63  $p_T > 500 \text{ MeV}/c$  are selected. The muon pair is required to have an invariant mass within  
 64  $\pm 150 \text{ MeV}/c^2$  of the known  $J/\psi$  mass [39].

65 In the offline selection, the  $B^+ \rightarrow J/\psi h^+$  candidates (where  $h = \pi, K$ ) are formed  
 66 by combining a  $J/\psi$  with a hadron candidate with  $p_T$  above  $1 \text{ GeV}/c$ . The selection  
 67 criteria for the  $B^+ \rightarrow J/\psi \pi^+$  and  $B^+ \rightarrow J/\psi K^+$  decays are similar except those related to  
 68 the identification of the kaon and pion hadrons in the final states. The accompanying  
 69 hadron is mutually exclusively identified as a pion or kaon using information from the  
 70 ring-imaging Cherenkov detectors [40], and required to be inconsistent with originating  
 71 from any primary  $pp$  collision vertex (PV) and consistent with originating from the  $J/\psi$   
 72 decay vertex. The particle identification criteria achieve a signal efficiency of 96% (92%)  
 73 for the  $B^+ \rightarrow J/\psi \pi^+$  ( $B^+ \rightarrow J/\psi K^+$ ) decay, while rejecting 97% (99%) of the misidentified  
 74 cross-feed background coming from the  $B^+ \rightarrow J/\psi K^+$  ( $B^+ \rightarrow J/\psi \pi^+$ ) decay.

75 Each  $B^+$  candidate must be consistent with originating from a PV. A kinematic  
 76 fit [41] to the signal decay, where the  $J/\psi$  mass is constrained to its known value [39], is  
 77 performed to achieve a better resolution of the reconstructed  $B$  mass. The remaining  $B^+$   
 78 candidates with  $\cos \theta_h < 0$  are rejected to ensure a clear separation of the  $B^+ \rightarrow J/\psi \pi^+$   
 79 and  $B^+ \rightarrow J/\psi K^+$  mass peaks in the  $J/\psi \pi^+$  mass spectrum, where  $\theta_h$  is the angle between  
 80 the momentum of the accompanying hadron in the  $B^+$  rest frame and the  $B^+$  momentum  
 81 in the laboratory frame. Fiducial-volume requirements are also imposed to exclude those  
 82  $B^+$  candidates with accompanying hadrons at the boundaries of the detector acceptance,  
 83 where the detection asymmetry is particularly large. Such requirements retain more than  
 84 95% of the  $B^+ \rightarrow J/\psi h^+$  signals.

85 In order to further suppress the background from random combinations of tracks (com-  
 86 binatorial background), a boosted decision tree (BDT) classifier [42, 43] is trained for each  
 87 of the  $B^+ \rightarrow J/\psi \pi^+$  and  $B^+ \rightarrow J/\psi K^+$  decay modes and each year of data taking. The  
 88 BDT classifier is trained using simulated  $B^+ \rightarrow J/\psi h^+$  decays as a signal proxy and a

Table 1: Signal yields and raw charge asymmetries for  $B^+ \rightarrow J/\psi\pi^+$  and  $B^+ \rightarrow J/\psi K^+$  decays determined from the mass fits, where the uncertainties are statistical only.

	2016	2017	2018
$N_{J/\psi\pi}$	$15\,500 \pm 140$	$15\,140 \pm 140$	$18\,130 \pm 150$
$N_{J/\psi K}$	$371\,700 \pm 600$	$367\,300 \pm 600$	$454\,100 \pm 700$
$a_{J/\psi\pi}^{\text{raw}} [10^{-2}]$	$0.91 \pm 0.85$	$0.50 \pm 0.85$	$1.42 \pm 0.78$
$a_{J/\psi K}^{\text{raw}} [10^{-2}]$	$-1.35 \pm 0.17$	$-1.12 \pm 0.17$	$-1.07 \pm 0.15$

89 sample of data candidates in the upper mass sideband [5500, 5700] MeV/ $c^2$  above the fit  
90 range as a background proxy. The kinematic and geometrical variables used as inputs  
91 to the BDT classifier include: measures of the likelihood that the  $h^+$ ,  $\mu^\pm$ ,  $J/\psi$  or  $B^+$   
92 candidate comes from the PV; transverse momentum of the  $h^+$ ,  $J/\psi$  and  $B^+$  candidates;  
93 flight distance and vertex fit quality of the  $B^+$  candidate. The  $B^+$  candidates with a BDT  
94 response below a certain threshold are rejected. This threshold for the  $B^+ \rightarrow J/\psi\pi^+$  mode  
95 is chosen to optimize the signal significance. For  $B^+ \rightarrow J/\psi K^+$  decays, the threshold is  
96 chosen to obtain the same BDT selection efficiency as that for the  $B^+ \rightarrow J/\psi\pi^+$  mode.  
97 The optimized BDT selection retains about 95% of both signals, while rejecting more  
98 than 90% of the combinatorial backgrounds.

99 An unbinned extended maximum-likelihood fit is performed simultaneously to the mass  
100 distributions of the selected  $B^+$  and  $B^-$  candidates in the mass range [5050, 5500] MeV/ $c^2$ ,  
101 for each decay mode and each year. For both decay modes, the signal shape is described  
102 by a Hypatia function [44]; the combinatorial background is modeled by an exponential  
103 function; partially reconstructed  $B$ -meson decays, such as  $B \rightarrow J/\psi h\pi$  with the  $\pi$  meson  
104 missing, which contribute in the low-mass region, are described by an ARGUS function [45]  
105 convolved with a Gaussian function. For the CKM-suppressed  $B^+ \rightarrow J/\psi\pi^+$  mode, a  
106 cross-feed background from the favored  $B^+ \rightarrow J/\psi K^+$  decays with the kaon misidentified  
107 as a pion is described by a double-sided Crystal Ball (DSCB) [46] function. The cross-feed  
108 background from  $B^+ \rightarrow J/\psi\pi^+$  decays is conversely negligible for the  $B^+ \rightarrow J/\psi K^+$  mass  
109 fit. All shape and position parameters are shared between the  $B^+$  and  $B^-$  decays in the  
110 baseline fit. The tail parameters of the Hypatia and DSCB functions are fixed to the  
111 values obtained from simulation.

112 Denoting the signal yields for  $B^\pm \rightarrow J/\psi h^\pm$  decays as  $N_{J/\psi h^\pm}$ , their sum  $N_{J/\psi h}$ , and raw  
113 charge asymmetries,  $a_{J/\psi h}^{\text{raw}} \equiv (N_{J/\psi h^-} - N_{J/\psi h^+}) / (N_{J/\psi h^-} + N_{J/\psi h^+})$ , are obtained from the  
114 mass fits and reported in Table 1. Figure 1 shows the mass distributions of the selected  
115  $B^\pm \rightarrow J/\psi\pi^\pm$  and  $B^\pm \rightarrow J/\psi K^\pm$  candidates, together with the fit projections.

116 The ratio of the branching fractions of  $B^+ \rightarrow J/\psi\pi^+$  and  $B^+ \rightarrow J/\psi K^+$  decays is  
117 determined according to

$$\mathcal{R}_{\pi/K} = \frac{N_{J/\psi\pi}}{N_{J/\psi K}} \times \frac{\varepsilon_{J/\psi K}}{\varepsilon_{J/\psi\pi}}, \quad (3)$$

118 where  $\varepsilon_{J/\psi K}$  and  $\varepsilon_{J/\psi\pi}$  stand for the total efficiencies, including those of the detector  
119 acceptance, trigger and offline selection. All efficiencies are estimated from simulation  
120 after corrections are applied, except the PID efficiency. The latter is obtained for the  
121 accompanying hadron using dedicated control samples where pions and kaons are selected  
122 without PID requirements and weighted to match the hadron kinematic spectra and  
123 event multiplicity in the calibrated signal simulation. The ratio of the total efficiencies,

Figure 1: Mass distributions of the (top left)  $B^+ \rightarrow J/\psi\pi^+$ , (top right)  $B^- \rightarrow J/\psi\pi^-$ , (bottom left)  $B^+ \rightarrow J/\psi K^+$  and (bottom right)  $B^- \rightarrow J/\psi K^-$  candidates in the combined data sample collected in 2016–2018, with the fit projections also shown.

124  $\varepsilon_{J/\psi\pi}/\varepsilon_{J/\psi K}$ , is found to be  $0.935 \pm 0.004$ ,  $0.936 \pm 0.004$  and  $0.953 \pm 0.005$  for the 2016, 2017  
 125 and 2018 data samples, respectively. Here the uncertainties are due to the limited sizes of  
 126 the simulation and control samples, and are propagated to the statistical uncertainties of  
 127 the  $\mathcal{R}_{\pi/K}$  measurements.

128 The difference in  $CP$  asymmetries between  $B^+ \rightarrow J/\psi\pi^+$  and  $B^+ \rightarrow J/\psi K^+$  decays is  
 129 obtained from the raw-charge asymmetries after correcting for the accompanying-hadron  
 130 detection asymmetries,  $a_{J/\psi h}^{\text{det}}$ , and PID efficiency asymmetries,  $a_{J/\psi h}^{\text{pid}}$ , following

$$\Delta\mathcal{A}^{CP} = (a_{J/\psi\pi}^{\text{raw}} - a_{J/\psi K}^{\text{raw}}) - (a_{J/\psi\pi}^{\text{det}} - a_{J/\psi K}^{\text{det}}) - (a_{J/\psi\pi}^{\text{pid}} - a_{J/\psi K}^{\text{pid}}). \quad (4)$$

131 The effects of different production cross-sections of  $B^-$  and  $B^+$  mesons are largely canceled  
 132 in the  $\Delta\mathcal{A}^{CP}$  measurement, and further reduced by weighting the  $B^+ \rightarrow J/\psi K^+$  sample to  
 133 eliminate a small difference with the  $B^+ \rightarrow J/\psi\pi^+$  sample in the  $B^+$  kinematic distributions.  
 134 The difference of the pion and kaon detection asymmetries as a function of the kaon  
 135 momentum is determined from the raw asymmetries of the decays  $D^+ \rightarrow K^- \pi^+ \pi^+$  and  
 136  $D^+ \rightarrow K_S^0 \pi^+$  measured with Run 2 data, following the method described in Refs. [47, 48].  
 137 Using the kaon momentum spectrum in the selected  $B^+ \rightarrow J/\psi K^+$  sample, the average  
 138 detection asymmetry difference, common to all years of data taking, is computed to be

$$a_{J/\psi\pi}^{\text{det}} - a_{J/\psi K}^{\text{det}} = (0.84 \pm 0.05) \times 10^{-2}, \quad (5)$$

139 where the uncertainty also accounts for the difference between the pion momentum spectra  
 140 in  $B^+ \rightarrow J/\psi\pi^+$  and  $D^+ \rightarrow K^- \pi^+ \pi^+$  decays.

141 The hadron PID asymmetries are obtained by measuring separately the PID efficiencies  
 142 for negative and positive hadrons using Run 2 control samples following the method  
 143 described in Refs. [37,38]. Their values are

$$a_{J/\psi\pi}^{\text{pid}} = \begin{cases} (-0.01 \pm 0.02) \times 10^{-2} & (2016), \\ (+0.00 \pm 0.05) \times 10^{-2} & (2017), \\ (+0.02 \pm 0.06) \times 10^{-2} & (2018), \end{cases} \quad (6)$$

144 and

$$a_{J/\psi K}^{\text{pid}} = \begin{cases} (+0.00 \pm 0.06) \times 10^{-2} & (2016), \\ (+0.03 \pm 0.05) \times 10^{-2} & (2017), \\ (-0.05 \pm 0.06) \times 10^{-2} & (2018), \end{cases} \quad (7)$$

145 The systematic uncertainties in the branching fraction ratio  $\mathcal{R}_{\pi/K}$  and  $CP$  asymmetry  
 146 difference  $\Delta\mathcal{A}^{CP}$  for each data-taking year are summarized in Table 2. Sources of systematic  
 147 uncertainties associated with the mass fits, the efficiency evaluation, and the nuisance  
 148 asymmetries are considered. Due to the inevitability of mass mismodeling whenever such  
 149 sizable yields are present, associated systematic uncertainties are evaluated by increasing  
 150 signal and background model sophistication. Mitigating changes include the use of  
 151 alternative functions to describe the signal and background shapes and fit configurations  
 152 that allow the position and width parameters of the  $B^+$  and  $B^-$  signal decays to take  
 153 separate values within the nominal model. The systematic uncertainty associated with  
 154 the trigger efficiency is determined by comparing the trigger efficiency ratio between the  
 155  $B^+ \rightarrow J/\psi\pi^+$  and  $B^+ \rightarrow J/\psi K^+$  modes obtained from simulation to that obtained from  
 156 control samples consisting of events triggered independently of the signal decays using a  
 157 data-driven method [49]. The systematic uncertainty due to imperfect description of the  
 158 detector material, which affects the  $K/\pi$  tracking efficiency from simulation, is estimated  
 159 by varying the amount of material in the relevant detector volumes by about  $\pm 10\%$  [18].  
 160 The systematic uncertainty associated with the corrections to the signal simulation is  
 161 estimated by resampling the relevant simulation and data samples with replacement [50]  
 162 and repeating the kinematic weighting and efficiency estimation procedure multiple times.  
 163 The standard deviation of the efficiency ratio  $\varepsilon_{J/\psi\pi}/\varepsilon_{J/\psi K}$  is propagated to the  $\mathcal{R}_{\pi/K}$   
 164 measurement. A systematic uncertainty in  $\mathcal{R}_{\pi/K}$  related to the PID efficiency calibration  
 165 is also evaluated by changing the hadron  $p_T$  and  $\eta$  bin widths used to divide the control  
 166 samples.

167 The uncertainties of the estimated detection asymmetry difference in Eq. 5 and PID  
 168 asymmetries in Eqs. 6 and 7 are propagated to  $\Delta\mathcal{A}^{CP}$  as systematic uncertainties. For  
 169 the baseline result of  $\Delta\mathcal{A}^{CP}$ , the  $B^+ \rightarrow J/\psi\pi^+$  sample is weighted to match the kinematic  
 170 distribution of the  $B^+ \rightarrow J/\psi K^+$  sample in order to cancel the effect of the  $B^+/B^-$   
 171 production asymmetry on the measurement. The difference of the  $\Delta\mathcal{A}^{CP}$  values obtained  
 172 with and without this weighting step is taken as a systematic uncertainty.

173 Robustness of the fit procedure is tested by splitting the data samples according  
 174 to magnet polarity and by tightening the BDT-output requirements. The results are  
 175 consistent in all checks.

176 Using the estimated signal yields, efficiency ratios, raw-charge and efficiency asymme-  
 177 tries, the ratio of branching fractions and  $CP$  asymmetry difference between  $B^+ \rightarrow J/\psi\pi^+$

Table 2: Relative systematic uncertainties on the branching fraction ratio  $\mathcal{R}_{\pi/K}$  and absolute systematic uncertainties on the  $CP$ -asymmetry difference  $\Delta\mathcal{A}^{CP}$  from each source and their quadratic sum.

	Branching fraction ratio			$CP$ -asymmetry difference		
	2016 [%]	2017 [%]	2018 [%]	2016 [ $10^{-2}$ ]	2017 [ $10^{-2}$ ]	2018 [ $10^{-2}$ ]
Mass fit	0.22	0.16	0.21	0.04	0.06	0.04
Trigger efficiency	0.40	0.39	0.37	–	–	–
Material budget	0.30	0.30	0.30	–	–	–
Simulation correction	0.17	0.15	0.14	–	–	–
PID	0.29	0.22	0.29	0.06	0.07	0.08
Detection asymmetry	–	–	–	0.05	0.05	0.05
Production asymmetry	–	–	–	0.02	0.02	0.02
Total	0.64	0.58	0.61	0.09	0.11	0.11

178 and  $B^+ \rightarrow J/\psi K^+$  decays are determined for each year to be

$$\mathcal{R}_{\pi/K} = \begin{cases} (3.900 \pm 0.040 \pm 0.025) \times 10^{-2} & (2016), \\ (3.858 \pm 0.039 \pm 0.022) \times 10^{-2} & (2017), \\ (3.805 \pm 0.037 \pm 0.023) \times 10^{-2} & (2018), \end{cases}$$

$$\Delta\mathcal{A}^{CP} = \begin{cases} (1.43 \pm 0.87 \pm 0.09) \times 10^{-2} & (2016), \\ (0.81 \pm 0.87 \pm 0.11) \times 10^{-2} & (2017), \\ (1.58 \pm 0.80 \pm 0.11) \times 10^{-2} & (2018), \end{cases}$$

179 where the first uncertainties are statistical and the second systematic. The measurements  
180 for each year are combined using the Best Linear Unbiased Estimator method [51, 52] to  
181 obtain

$$\begin{aligned} \mathcal{R}_{\pi/K} &= (3.852 \pm 0.022 \pm 0.018) \times 10^{-2}, \\ \Delta\mathcal{A}^{CP} &= (1.29 \pm 0.49 \pm 0.08) \times 10^{-2}. \end{aligned}$$

182 The Run 2 results are further combined with the LHCb Run 1 measurements [18] using  
183 the same method, yielding

$$\begin{aligned} \mathcal{R}_{\pi/K} &= (3.846 \pm 0.018 \pm 0.018) \times 10^{-2}, \\ \Delta\mathcal{A}^{CP} &= (1.42 \pm 0.43 \pm 0.08) \times 10^{-2}. \end{aligned}$$

184 In the above combinations, the systematic uncertainties related to the material budget  
185 and hadron detection asymmetries are considered to be fully correlated between different  
186 data-taking periods. The inputs and outcomes of the combination are displayed in Fig. 2.  
187 The significance of the nonzero  $\Delta\mathcal{A}^{CP}$  value is evaluated to be 3.2 standard deviations ( $\sigma$ ),  
188 representing the first evidence for direct  $CP$  violation in beauty to charmonium decays.

189 Using the LHCb measurement of the  $CP$  asymmetry in the  $B^+ \rightarrow J/\psi K^+$  decay [48]  
190 and taking into account its correlation with the  $\Delta\mathcal{A}^{CP}$  measurement from this analysis due

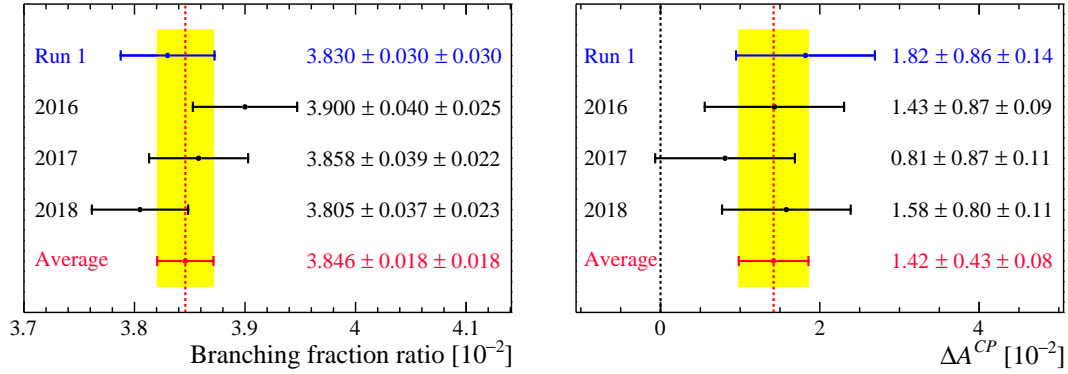

Figure 2: Comparison of the  $\mathcal{R}_{\pi/K}$  and  $\Delta\mathcal{A}^{CP}$  measurements from Run 1, 2016, 2017 and 2018 data, and the average values. The error bars correspond to the sum of the statistical and systematic uncertainties in quadrature.

191 to the overlap in data sets, the  $CP$  asymmetry in the  $B^+ \rightarrow J/\psi\pi^+$  decay is determined  
 192 to be  $\mathcal{A}^{CP}(B^+ \rightarrow J/\psi\pi^+) = (1.51 \pm 0.50 \pm 0.08) \times 10^{-2}$ .

193 In summary, the most precise measurements of the  $CP$ -asymmetry difference between  
 194  $B^+ \rightarrow J/\psi\pi^+$  and  $B^+ \rightarrow J/\psi K^+$  decays and their branching fraction ratio are obtained  
 195 using LHCb data collected at 13 TeV during 2016–2018, corresponding to an integrated  
 196 luminosity of  $5.4 \text{ fb}^{-1}$ . These results are then combined with the previous LHCb Run 1  
 197 measurements. The combined  $CP$  asymmetry difference shows a  $3.2\sigma$  deviation from zero,  
 198 providing the first evidence for direct  $CP$  violation in beauty decays to charmonium final  
 199 states. This effect can be attributed to the enhanced penguin to tree ratio in  $B^+ \rightarrow J/\psi\pi^+$   
 200 decays compared to that in  $b \rightarrow c\bar{c}s$  transitions. The  $\Delta\mathcal{A}^{CP}$  and  $\mathcal{R}_{\pi/K}$  measurements serve  
 201 to control the effects of the penguin contributions in the golden channel  $B^0 \rightarrow J/\psi K^0$   
 202 affecting the determination of the  $CP$ -violating phase  $2\beta$ , using approximate SU(3) flavor  
 203 symmetry. Constraints on the size and strong phase of the penguin contribution relative  
 204 to the tree obtained using the  $\Delta\mathcal{A}^{CP}$  and  $\mathcal{R}_{\pi/K}$  measurements can be found in the  
 205 Supplemental Material [53].

## 206 Acknowledgements

207 We express our gratitude to our colleagues in the CERN accelerator departments for the  
 208 excellent performance of the LHC. We thank the technical and administrative staff at the  
 209 LHCb institutes. We acknowledge support from CERN and from the national agencies:

## 227 Supplemental material

228 The  $B^+ \rightarrow J/\psi\pi^+$  and  $B^+ \rightarrow J/\psi K^+$  decay amplitudes can be expressed in the following  
 229 forms,

$$A(B^+ \rightarrow J/\psi\pi^+) = -\lambda\mathcal{A}(1 + ae^{i\theta}e^{i\gamma}), \quad (1)$$

230 and

$$A(B^+ \rightarrow J/\psi K^+) = (1 - \lambda^2/2)\mathcal{A}'(1 + \epsilon a'e^{i\theta'}e^{i\gamma}), \quad (2)$$

231 where  $\lambda = V_{us}$ ,  $\epsilon = \lambda^2/(1 - \lambda^2)$ ,  $\mathcal{A}^{(\prime)}$  is the hadronic matrix element for the tree topology,  
 232 and  $a^{(\prime)}$  and  $\theta^{(\prime)}$  are the relative size and strong-phase difference between the penguin and  
 233 tree contributions, respectively. The weak phase difference is given by the CKM angle  
 234  $\gamma = \phi_3 \equiv \arg[-(V_{ud}V_{ub}^*)/(V_{cd}V_{cb}^*)]$ . Assuming SU(3) flavor symmetry, it follows that

$$a = a', \quad \theta = \theta'. \quad (3)$$

235 Using the value for the ratio of hadronic matrix elements  $\mathcal{A}'/\mathcal{A} = 1.32 \pm 0.07$  from  
 236 Ref. [14] and the recent LHCb combination result of the angle  $\gamma = (64.6 \pm 2.8)^\circ$  [54], the  
 237 two-dimensional 68% confidence-level contours determined from  $\chi^2$  tests using the  $\Delta\mathcal{A}^{CP}$   
 238 and  $\mathcal{R}_{\pi/K}$  measurements are shown in Fig. S1. It can be seen that the  $\Delta\mathcal{A}^{CP}$  measurement  
 239 provides a strong constraint on the imaginary part of  $ae^{i\theta}$ . A complete study that takes  
 240 into account the effects of SU(3) flavor-symmetry breaking is needed when using this  
 241 constraint in the determination of the phase  $2\beta$  in  $B^0 \rightarrow J/\psi K^0$  decays.

Figure S1: The 68% confidence-level contours in the complex plane of  $ae^{i\theta}$ , derived from the  $\Delta\mathcal{A}^{CP}$  measurement, the  $\mathcal{R}_{\pi/K}$  measurement and their combination. The solid lines correspond to the central values of the measurements. The right figure shows a zoomed-in view of the intersecting region in the left one.

## 365 **PRL Justification**

366 Decays of beauty mesons to charmonium final states play a central role in the study  
367 of  $CP$  violation. While  $CP$  violation in the interference between mixing and decay has  
368 been long established in such processes, direct  $CP$  violation remains to be observed.  
369 This paper presents high-precision measurements of the  $CP$  asymmetry difference and  
370 branching fraction ratio between  $B^+ \rightarrow J/\psi\pi^+$  and  $B^+ \rightarrow J/\psi K^+$  decays obtained using  
371 LHCb Run 2 data, and reports the first evidence for direct  $CP$  violation in beauty to  
372 charmonium decays. These results provide important information to reduce theoretical  
373 uncertainty in the determination of the  $CP$ -violating parameter  $\sin 2\beta$  from the golden  
374 channel  $B^0 \rightarrow J/\psi K^0$ , allowing for more stringent tests of the Standard Model.
