# Search for a heavy pseudoscalar Higgs boson decaying to a 125 GeV Higgs boson and a Z boson in final states with two tau and two light leptons in proton-proton collisions at $\sqrt{s} = 13$ TeV

The CMS Collaboration\*

## Abstract

A search for a heavy pseudoscalar Higgs boson,  $A$ , decaying to a 125 GeV Higgs boson  $h$  and a  $Z$  boson is presented. The  $h$  boson is identified via its decay to a pair of tau leptons, while the  $Z$  boson is identified via its decay to a pair of electrons or muons. The search targets the production of the  $A$  boson via the gluon-gluon fusion process,  $gg \rightarrow A$ , and in association with bottom quarks,  $b\bar{b}A$ . The analysis uses a data sample corresponding to an integrated luminosity of  $138\text{ fb}^{-1}$  collected with the CMS detector at the CERN LHC in proton-proton collisions at a centre-of-mass energy of  $\sqrt{s} = 13$  TeV. Constraints are set on the product of the cross sections of the  $A$  production mechanisms and the  $A \rightarrow Zh$  decay branching fraction. The observed (expected) upper limit at 95% confidence level ranges from  $0.049$  ( $0.060$ ) pb to  $1.02$  ( $0.79$ ) pb for the  $gg \rightarrow A$  process and from  $0.053$  ( $0.059$ ) pb to  $0.79$  ( $0.61$ ) pb for the  $b\bar{b}A$  process in the probed range of the  $A$  boson mass,  $m_A$ , from 225 GeV to 1 TeV. The results of the search are used to constrain parameters within the  $M_{h,\text{EFT}}^{125}$  benchmark scenario of the minimal supersymmetric extension of the standard model. Values of  $\tan\beta$  below 2.2 are excluded in this scenario at 95% confidence level for all  $m_A$  values in the range from 225 to 350 GeV.

## 1 Introduction

The 2012 observation of a Higgs-like boson with a mass of approximately 125 GeV at the CERN LHC [1–3] completed the set of particles predicted by the standard model (SM). In the years since, LHC collaborations have measured the properties of this Higgs boson across various production modes and decay channels, including refined measurements of its mass, coupling strengths to fermions and gauge bosons, and spin-parity quantum numbers [4, 5]. To date, these refined measurements of the observed boson are compatible with SM expectations. In the SM, the Higgs field is introduced as a complex doublet in the electroweak sector, and the Higgs boson emerges as a massive scalar state with couplings to the massive fermions and gauge bosons from the spontaneous breaking of the electroweak gauge symmetry. These couplings are found to be in good agreement, within the currently attained experimental precision of 5–20% [6–9], with the expectation for a SM Higgs boson with mass  $125.38 \pm 0.14$  GeV [10]. The SM still leaves several fundamental questions open, including the presence of dark matter and the observed baryon asymmetry in our universe. Beyond-the-SM (BSM) scenarios seek to extend our understanding to explain such phenomena, for example by adding structure to its Higgs sector. Two Higgs Doublet Models (2HDMs) are BSM theories introducing a second Higgs doublet, which, following electroweak symmetry breaking, yields five mass eigenstates [11, 12]. Two are charged ( $H^\pm$ ), two are neutral scalars ( $h, H$ ), and one is a massive pseudoscalar boson  $A$ , the subject of this search. Given current experimental constraints, most of the 2HDMs associate the lighter scalar boson  $h$  with the observed 125 GeV Higgs boson and we follow this convention throughout the paper. The 2HDMs are motivated because they contain, or allow, for additional sources of  $CP$  violation that could explain the observed baryon asymmetry in our universe [13]. The presence of two Higgs doublets is also a requirement in the minimal supersymmetric extension of the SM (MSSM) [14, 15], which offers a dark matter candidate, protects the Higgs boson mass from receiving large radiative corrections, and provides conditions for the unification of gauge interactions at the  $10^{16}$  GeV scale [16].

The MSSM Higgs sector is a Type-II 2HDM, which at tree-level is characterized by two parameters, usually taken to be  $\tan\beta = v_2/v_1$ , the ratio of the vacuum expectation values of the two Higgs doublets, and  $m_A$ , the mass of the  $A$  boson. The MSSM Higgs boson masses receive large contributions from radiative loop corrections related to the supersymmetric (SUSY) partners of the SM particles. In many MSSM scenarios, the mass scale of these supersymmetric partners,  $M_{\text{SUSY}}$ , is assumed to be  $\mathcal{O}(1 \text{ TeV})$ . With this assumption, the predicted value for  $m_h$  falls below 125 GeV at  $\tan\beta \lesssim 5 - 7$ . Thus, higher scales for  $M_{\text{SUSY}}$  are required to support the mass of the observed Higgs boson,  $m_h \approx 125$  GeV, in the whole parameter space, including values of  $\tan\beta$  as low as  $\approx 1$ . This paper addresses a specific MSSM benchmark scenario, called  $M_h^{125}$  [17]. This scenario uses an effective field theory (EFT) approach, where the growing logarithmic corrections associated with the large values of  $M_{\text{SUSY}}$  are resummed, and  $M_{\text{SUSY}}$  can reach  $10^{16}$  GeV and is adjusted to values that are compatible with  $m_h \approx 125$  GeV at each point in the  $m_A$ - $\tan\beta$  parameter space individually.

This paper reports a search for a pseudoscalar  $A$  boson decaying to a 125 GeV Higgs boson  $h$  and a  $Z$  boson in proton-proton ( $pp$ ) collisions at  $\sqrt{s} = 13$  TeV. The search uses data collected at the LHC in the period from the year 2016 to 2018, by the CMS experiment, corresponding to an integrated luminosity of  $138 \text{ fb}^{-1}$ . The analysis targets  $A$  boson production via both gluon-gluon fusion,  $gg \rightarrow A$ , and in association with  $b$  quarks,  $bbA$ . The Feynman diagrams for both production processes are shown in Fig. 1. Signal mass hypotheses are tested in the range from 225 GeV, near the kinematic threshold for decays to  $Zh$ , up to 1 TeV. The analysis strategy is optimized for a resolved topology and relies on conventional techniques to identify isolated leptons. This strategy sustains high sensitivity to the signal for  $m_A$  up to 1 TeV. At higher

Figure 1: Feynman diagrams representing the production of the pseudoscalar  $A$  boson via gluon-gluon  $m_A$ - $\tan \beta$  fusion (left) and associated production with a bottom quark-antiquark pair (right). In each case, the  $A$  boson decays to an SM-like  $h$  boson and a  $Z$  boson.

masses, the  $Z$  and  $h$  bosons are produced with high Lorentz boost resulting in overlap of their decay products. As a consequence, the sensitivity of the analysis, targeting resolved topology, rapidly degrades at  $m_A > 1$  TeV. It should be also emphasized that most BSM scenarios predict rapidly decreasing branching fractions of bosonic decays of the  $A$  boson with increasing  $m_A$ .

Previous searches by the ATLAS and CMS Collaborations for  $A \rightarrow Zh$  targeted final states with two light leptons from the  $Z$  boson decay plus two tau leptons from the  $h$  boson decay in pp collision dataset at  $\sqrt{s} = 8$  TeV [18, 19] and  $\sqrt{s} = 13$  TeV [20]. The ATLAS and CMS Collaborations have also used pp collisions at  $\sqrt{s} = 13$  TeV to search for the  $CP$ -odd  $A$  boson decaying to the same intermediate  $Zh$  state, but with the Higgs boson  $h$  decaying to a pair of bottom quarks [21–23]. These analyses set model-independent and model-dependent limits in the context of 2HDMs, including supersymmetric models.

In this analysis, the  $h$  boson is identified by its decay to a pair of tau leptons. Three possible  $\tau\tau$  decay channels are considered:  $e\tau_h$ ,  $\mu\tau_h$  and  $\tau_h\tau_h$ , where  $\tau_h$  denotes hadronic  $\tau$  lepton decays. Throughout the paper, neutrinos are omitted from the notation of the final states. These three decay channels are combined with  $Z$  boson decays into two light leptons,  $Z \rightarrow \ell^+\ell^-$  ( $\ell = e, \mu$ ), resulting in six distinct final states of the  $A$  boson decay. To account for the missing transverse momentum that results from the neutrinos in the final states, we use a modified version of the SVFit algorithm [24], FastMTT, to reconstruct the four-vector of  $h$ , while constraining its mass to 125 GeV. The signal is extracted from the distributions of the reconstructed four-lepton mass obtained in these individual search channels. Furthermore, to increase the sensitivity to different production modes of the  $A$  boson, events are split into two categories depending on the presence of a  $b$  quark in the event.

Relative to the CMS search performed using the 2016 data [20], this analysis benefits from the increased integrated luminosity and novel machine learning based identification of hadronic decays of  $\tau$  leptons [25] and of jets originating from bottom quarks [26]. It also includes the production of an  $A$  boson in association with  $b$  quarks, a process not considered previously, and extends the range of probed masses of the pseudoscalar boson up to 1 TeV. This analysis provides complementary results to the recent ATLAS search in the  $(Z \rightarrow \nu\bar{\nu}/\ell\ell)(h \rightarrow b\bar{b})$  channels performed on  $139 \text{ fb}^{-1}$  of data collected at the same centre-of-mass energy [23].

A complete set of tabulated results of the current analysis for all tested mass hypotheses is

---

available in the HEPData record [27].

## 2 The CMS detector

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorimeter, each composed of a barrel and two endcap sections. Forward calorimeters extend the pseudorapidity ( $\eta$ ) coverage provided by the barrel and endcap detectors. Muons are reconstructed using gas-ionization detectors embedded in the steel flux-return yoke outside the solenoid. Events of interest are selected using a two-tiered trigger system. The first level (L1), composed of custom hardware processors, uses information from the calorimeters and muon detectors to select events at a rate of around 100 kHz within a fixed latency of about  $4\ \mu\text{s}$  [28]. The second level, known as the high-level trigger, consists of a farm of processors running a version of the full event reconstruction software optimized for fast processing and reduces the event rate to around 1 kHz before data storage [29]. A more detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in Ref. [30].

## 3 Event reconstruction

The reconstruction of the pp collision products is based on the particle-flow (PF) algorithm [31], which combines information from all CMS subdetectors to reconstruct a set of particle candidates (PF candidates), identified as charged and neutral hadrons, electrons, photons, and muons. The primary vertex (PV) is taken to be the vertex corresponding to the hardest scattering in the event, evaluated using tracking information alone, as described in Ref. [32]. Secondary vertices, which are displaced from the PV, might be associated with decays of long-lived particles emerging from the PV. Any other collision vertices in the event are associated with additional, mostly soft, inelastic pp collisions, referred to as pileup (PU). In the 2016 (2017–2018) datasets, the average number of PU pp collisions was 23 (32).

Electrons are reconstructed using tracks from hits in the tracking system and calorimeter deposits in the ECAL [33]. To increase their purity, reconstructed electrons are required to pass a multivariate electron identification discriminant, which combines information on track quality, shower shape, and kinematic quantities. For this analysis, a working point with an identification efficiency of 90% is used, for a rate of jets misidentified as electrons of  $\approx 1\%$ . Muons in the event are reconstructed by combining the information from the tracker and the muon detectors [34]. The mere presence of hits in the muon detectors leads to a strong suppression of particles misidentified as muons. Additional identification requirements on the track fit quality and the compatibility of individual track segments with the fitted track can reduce the misidentification rate further. For this analysis, muon identification requirements with an efficiency of  $\approx 99\%$  are chosen, with a misidentification rate below 0.2% for hadrons.

The contributions from backgrounds to the electron and muon selections are further reduced by requiring the corresponding lepton to be isolated from any hadronic activity in the detector. This property is quantified by an isolation variable

$$I_{\text{rel}}^{\text{e}(\mu)} = \frac{1}{p_{\text{T}}^{\text{e}(\mu)}} \left( \sum p_{\text{T}}^{\text{charged}} + \max \left( 0, \sum E_{\text{T}}^{\text{neutral}} + \sum E_{\text{T}}^{\gamma} - p_{\text{T}}^{\text{PU}} \right) \right), \quad (1)$$

where  $p_T^{e(\mu)}$  corresponds to the electron (muon)  $p_T$  and  $\sum p_T^{\text{charged}}$ ,  $\sum E_T^{\text{neutral}}$ , and  $\sum E_T^\gamma$  to the  $p_T$  (or transverse energy  $E_T$ ) sum of all charged particles, neutral hadrons, and photons, in a predefined cone of radius  $\Delta R = \sqrt{(\Delta\eta)^2 + (\Delta\varphi)^2}$  around the lepton direction at the PV, where  $\Delta\eta$  and  $\Delta\varphi$  (measured in radians) correspond to the angular distances of the particle to the lepton in the  $\eta$  and azimuthal angle  $\varphi$  directions. The chosen cone size is  $\Delta R = 0.3$  (0.4) for electrons (muons). The lepton itself is excluded from the calculation. To mitigate any distortions from PU, only those charged particles whose tracks are associated with the PV are included. Since an unambiguous association with the PV is not possible for neutral hadrons and photons, an estimate of the contribution from PU ( $p_T^{\text{PU}}$ ) is subtracted from the sum of  $\sum E_T^{\text{neutral}}$  and  $\sum E_T^\gamma$ . This estimate is obtained from the mean energy flow in the case of  $I_{\text{rel}}^e$  and from tracks not associated with the PV in the case of  $I_{\text{rel}}^\mu$ . For negative values, the neutral part of  $I_{\text{rel}}$  is set to zero.

For each event, hadronic jets are clustered from the PF candidates using the infrared and collinear safe anti- $k_T$  algorithm [35, 36] with a distance parameter of 0.4. Jet momentum is determined as the vector sum of all particle momenta in the jet, and is found from simulation to be, on average, within 5 to 10% of the true momentum over the whole  $p_T$  spectrum and detector acceptance. Pileup can contribute extraneous tracks and calorimetric energy depositions to the jet momentum measurement. To mitigate this effect, charged particles identified to be originating from pileup vertices are discarded and an offset correction is applied to account for the remaining contributions. Jet energy corrections are derived from simulation to bring the measured response of jets to that of particle level jets on average. In situ measurements of the momentum balance in dijet, photon + jet, Z + jet, and multijet events are used to account for any residual differences in the jet energy scale between data and simulation [37]. The jet energy resolution amounts typically to 15–20% at 30 GeV, 10% at 100 GeV, and 5% at 1 TeV [37]. Additional selection criteria are applied to each jet to remove jets potentially dominated by anomalous contributions from various subdetector components or reconstruction failures.

To identify jets resulting from the hadronization of b quarks (b jets) the DeepJet algorithm is used, as described in Refs. [26, 38]. In this analysis, a working point of this algorithm is chosen that corresponds to a b jet identification efficiency of  $\approx 80\%$  for a misidentification rate for jets originating from light-flavour quarks or gluons of  $\mathcal{O}(1\%)$  [39]. Jets with  $p_T > 30$  GeV and  $|\eta| < 4.7$ , and b jets with  $p_T > 20$  GeV and  $|\eta| < 2.4$  are used in the analysis of the 2016 data. From 2017 onwards, after the upgrade of the silicon pixel detector, the b jet  $\eta$  range is extended to  $|\eta| < 2.5$ .

Jets are also used as seeds for the reconstruction of  $\tau_h$  candidates. This is done by utilizing the features of the PF candidates within the distance parameter of jets using the “hadrons-plus-strips” algorithm, as described in Refs. [25, 40]. Decays to one or three charged hadrons with up to two neutral pions with  $p_T > 2.5$  GeV are used (referred to as  $\tau_h$  decay mode thereafter). Neutral pions are reconstructed as strips with dynamic size in  $\eta$ - $\varphi$  from reconstructed photons and electrons contained in the seeding jet, where the electrons originate from photon conversions. The strip size varies as a function of the  $p_T$  of the electron or photon candidates. The  $\tau_h$  decay mode is then obtained by combining the charged hadrons with the strips. To distinguish  $\tau_h$  candidates from jets originating from the hadronization of quarks or gluons, and from electrons or muons, the DeepTau [25] (DT) algorithm is used. This algorithm uses information from the event, such as tracking, impact parameter, calorimeter cluster composition, and the kinematic and object identification properties of the PF candidates in the vicinity of the  $\tau_h$  candidate, as well as quantities that estimate the PU density of the event. This process results in a multiclassification output  $y_\alpha^{\text{DT}}$  ( $\alpha = \tau, e, \mu, \text{jet}$ ) that quantifies compatibility of  $\tau_h$  candidate

with the hypothesis of a genuine  $\tau$  lepton, an electron, a muon, or the hadronization of a quark or gluon. From this output, three discriminants are built according to

$$D_\alpha = \frac{y_\tau^{\text{DT}}}{y_\tau^{\text{DT}} + y_\alpha^{\text{DT}}}, \quad \alpha = e, \mu, \text{jet}. \quad (2)$$

For the analysis presented here, predefined working points of  $D_e$ ,  $D_\mu$ , and  $D_{\text{jet}}$  [25] are chosen depending on the  $h \rightarrow \tau\tau$  final state, for which the  $\tau_h$  selection efficiencies and misidentification rates are given in Table 1. The  $Z \rightarrow \tau\tau$  decay is used to measure the  $\tau_h$  identification efficiency. Samples of  $Z \rightarrow ee$  and  $Z \rightarrow \mu\mu$  decays are employed to measure the  $e \rightarrow \tau_h$  and  $\mu \rightarrow \tau_h$  misidentification rates, respectively. Samples of  $W(\rightarrow \ell\nu) + \text{jets}$  events and top quark-antiquark pairs are used to measure the jet  $\rightarrow \tau_h$  misidentification rate.

While neutrinos cannot be detected directly, they contribute to the missing transverse momentum. The missing transverse momentum vector  $\vec{p}_T^{\text{miss}}$  is computed as the negative vector sum of the transverse momenta of all the PF candidates in an event [41]. The  $\vec{p}_T^{\text{miss}}$  is modified to account for corrections to the energy scale of the reconstructed jets in the event. With  $p_T^{\text{miss}}$  we refer to the magnitude of this quantity.

Table 1: Efficiencies for the identification of  $\tau_h$  decays and corresponding misidentification rates (given in parentheses) for the working points of  $D_e$ ,  $D_\mu$ , and  $D_{\text{jet}}$ , chosen for the  $h \rightarrow \tau\tau$  selection, depending on the  $\tau\tau$  final state. The numbers are given as percentages. Efficiencies and misidentification rates are determined from dedicated studies [25].

$\tau\tau$ channel	$D_e$ (%)	$D_\mu$ (%)	$D_{\text{jet}}$ (%)
$e\tau_h$	>80 (<0.5)	>99 (<0.5)	>65 (1–3)
$\mu\tau_h$	>95 (1–2)	>97 (<0.1)	>65 (1–3)
$\tau_h\tau_h$	>95 (1–2)	>99 (<0.5)	>65 (1–3)

The mass of the  $A$  boson candidate is reconstructed using the FastMTT algorithm, which uses a simplified mass likelihood function to reduce the computation time. This algorithm makes use of  $\vec{p}_T^{\text{miss}}$  and its uncertainty, and the four-vectors of the reconstructed visible  $\tau$  lepton decay products to calculate an estimate of the mass of the parent boson and the full four-momenta of the  $h$  decay products. Compared to the SVFit algorithm, the FastMTT algorithm removes the contributions of the leptonic and hadronic  $\tau$  lepton decay matrix elements to the likelihood function, and assumes that visible  $\tau$  lepton decay products move collinearly with the original  $\tau$  lepton momentum. This gives a mass resolution that is similar to that of the SVFit algorithm, but the computation time is reduced by two orders of magnitude. Further improvement in the four-lepton mass resolution for  $h \rightarrow \tau\tau$  decays is achieved by imposing the mass constraint  $m_{\tau\tau} = m_h = 125 \text{ GeV}$ .

In summary, three mass reconstruction techniques have been studied in the course of this analysis: in the first, the four-lepton mass is computed using the leptons from the  $Z$  boson decay and only visible decay products of the  $\tau$  leptons, denoted  $m_{\ell\ell\tau\tau}^{\text{vis}}$ . This method yields a mass resolution of 20–30%. In the second, the four-lepton mass is computed using the  $Z$  boson decay leptons and the FastMTT-corrected  $\tau$  lepton four-vectors with no mass constraint, denoted  $m_{\ell\ell\tau\tau}^{\text{corr}}$ . This method yields a mass resolution of 10–15%. In the third, the four-lepton mass is computed with the  $Z$  decay leptons and the FastMTT-corrected  $\tau$  four vectors with a mass constraint of  $m_{\tau\tau} = 125 \text{ GeV}$  imposed, denoted  $m_{\ell\ell\tau\tau}^{\text{cons}}$ . This method yields the best mass resolution of about 5–7% and removes bias in the mean value of the reconstructed mass, which is present in the other two methods.

These strategies are compared in Fig. 2, where all final states of the A boson decay are combined and the distributions are obtained after applying a selection of  $Z \rightarrow \ell\ell$  and  $h \rightarrow \tau\tau$  candidates, as described in Section 5. The analysis employs the second method to obtain the best estimate for the mass of the h candidate from the FastMTT-corrected four vectors of  $\tau$  candidates,  $m_{\tau\tau}^{\text{corr}}$ . This variable is used in the event selection, as described in Section 5. The third method is used to reconstruct the mass of A candidate,  $m_{\ell\ell\tau\tau}^{\text{cons}}$ . This observable serves as a final discriminant in the statistical inference.

Figure 2: The distribution of the reconstructed mass of the  $h \rightarrow \tau\tau$  candidate (left plot) and of the  $A \rightarrow Zh \rightarrow (\ell\ell)(\tau\tau)$  candidate (right plot) in a 2018 simulated sample of  $gg \rightarrow A$  events with  $m_A = 300$  GeV. Several methods of mass reconstruction are compared: 1) using only the visible decay products of  $\tau$  lepton ( $m_{\tau\tau}^{\text{vis}}$  in the left plot and  $m_{\ell\ell\tau\tau}^{\text{vis}}$  in the right plot, blue histograms), 2) using the FastMTT algorithm to correct for missing momentum carried away by neutrinos in the  $\tau$  lepton decays ( $m_{\tau\tau}^{\text{corr}}$  in the left plot and  $m_{\ell\ell\tau\tau}^{\text{corr}}$  in the right plot, orange histograms), and 3) using the FastMTT algorithm with a mass constraint of 125 GeV for the  $h \rightarrow \tau\tau$  candidate ( $m_{\ell\ell\tau\tau}^{\text{cons}}$  in the right plot, green histogram).

## 4 Data and simulated samples

The data sample analyzed in this search corresponds to an integrated luminosity of  $138 \text{ fb}^{-1}$  from pp collisions at a centre-of-mass energy at 13 TeV, collected with the CMS detector at the LHC.

Simulated signal events with a  $CP$ -odd Higgs boson A produced in gluon-gluon fusion and associated production with b quarks, decaying to a 125 GeV Higgs boson and a Z boson are generated at leading order (LO) precision in the strong coupling constant  $\alpha_S$  using MADGRAPH5\_amc@NLO v2.6.5 [42], assuming a narrow signal width. The generated A boson mass points lie in the range 225 GeV to 1 TeV. The  $A \rightarrow Zh$  decaying to  $\ell\ell\tau\tau$  is simulated with MADSPIN [43]. In the gluon-gluon fusion production mode, up to one additional jet is included in the matrix element calculations, following the MLM matching scheme with parton showers [44].

In the signal event simulation, the value of  $m_h$  is set to 125 GeV and the additional  $CP$ -even H boson,  $CP$ -odd A boson, and charged Higgs boson masses are assumed to be at least 225 GeV.

The discrete  $\mathbb{Z}_2$  symmetry is broken as in the minimal supersymmetric standard model [45], and  $CP$  is enforced to be conserved at tree level in the 2HDM Higgs  $\mathbb{Z}_2$  sector [12].

The background samples consist of all SM processes with non-negligible yield in the signal region, including those with a 125 GeV Higgs boson present. The  $Zh$ ,  $Wh$ , and  $t\bar{t}h$  processes, in which an  $h$  decaying to two  $\tau$  leptons is generated in association with a  $Z$  boson,  $W$  boson, or top quark pair, respectively, are generated at next-to-LO (NLO) precision in  $\alpha_S$  with POWHEG v2.0 [46–51]. The contribution from processes with a  $h$  boson decaying to two  $W$  bosons, produced via  $Wh$  or  $Zh$ , are generated at NLO precision in  $\alpha_S$  using POWHEG and JHUGEN v7.7.2 [52] programs. Contributions from  $h$  produced via gluon-gluon fusion or vector boson fusion, where the  $h$  decays to two  $\tau$  leptons or two  $W$  bosons, is negligible. The  $h$  boson samples are normalized to their inclusive cross sections and the branching fractions used are those recommended by the LHC Higgs Working Group [53], assuming an  $m_h$  mass of 125.38 GeV [10].

The  $gg \rightarrow ZZ$  process is generated at LO precision in  $\alpha_S$  with MCFM v7.0.1 [54]. The  $q\bar{q} \rightarrow VV$  processes, where  $V$  is either a  $W$  or a  $Z$  boson, are generated with NLO precision in  $\alpha_S$  using POWHEG [55] or with MADGRAPH5\_aMC@NLO with the FxFx jet matching and merging scheme [56]. Triboson,  $Z + \text{jets}$ ,  $t\bar{t}W$ , and  $t\bar{t}Z$  production are generated via MADGRAPH5\_aMC@NLO, with the scheme applied either at NLO precision in  $\alpha_S$  exploiting the FxFx jet matching and merging scheme or at LO precision in  $\alpha_S$  with the MLM jet matching and merging scheme. For  $Z + \text{jets}$ , supplementary samples are generated with up to four outgoing partons in the hard interaction to increase the number of simulated events in regions of high signal purity. The  $t\bar{t}$  background processes is generated at NLO precision in  $\alpha_S$  with POWHEG [57]. The  $gg \rightarrow ZZ$ ,  $q\bar{q} \rightarrow VV$ , triboson,  $Z + \text{jets}$ ,  $t\bar{t}$ ,  $t\bar{t}W$ , and  $t\bar{t}Z$  are normalized to their cross sections at NLO precision in  $\alpha_S$  or higher [54, 58–63].

For all simulated samples the NNPDF3.1 [64] parton distribution functions (PDFs) are used for the simulation. Parton showering and hadronization, as well as the  $\tau$  lepton decays, are modeled using version 8.230 of the PYTHIA event generator [65]. The description of the underlying event is parameterized according to the CP5 [66] tunes for the simulation. Additional inclusive inelastic pp collisions generated with PYTHIA are added according to the expected pileup profile in data. All generated events are passed through a GEANT4-based [67] simulation of the CMS detector and reconstructed using the same version of the CMS event reconstruction software used for the data.

## 5 Event selection

Events are selected online using single-lepton triggers targeting leptons resulting from  $Z$  boson decays. The nominal online  $p_T$  thresholds for the single-electron (single-muon) trigger are 25–35 GeV (24–27 GeV), depending on the data-taking period. Events are selected if either of the two leptons assigned to a  $Z \rightarrow ee$  ( $Z \rightarrow \mu\mu$ ) decay satisfies the single-electron (single-muon) trigger. The offline  $p_T$  selection of the triggering lepton is required to be 1 GeV higher than the nominal  $p_T$  threshold of the corresponding trigger. Leptons selected by the trigger are required to geometrically match with a selected offline lepton. Corrections are applied to account for small differences in the trigger selection efficiencies measured in simulation and data.

The light leptons and the  $\tau_h$  candidates that do not pass the online triggers selections are required to have  $p_T > 10$  GeV and  $p_T > 20$  GeV, respectively. Constraints on  $|\eta|$  arising from detector geometry are  $|\eta^e| < 2.5$  for electrons,  $|\eta^\mu| < 2.4$  for muons, and  $|\eta^{\tau_h}| < 2.3$  for  $\tau_h$  candidates. These constraints are applied to all selected electrons and muons of the event whether

or not they pass the online trigger criteria. The light leptons in an event are required to be separated from each other by  $\Delta R > 0.3$ , while the  $\tau_h$  candidates must be separated from each other and from any other lepton by  $\Delta R > 0.5$ . The resulting selected events are made mutually exclusive by discarding events that have additional identified and isolated electrons or muons.

The Z boson candidates are reconstructed from pairs of same-flavour and opposite-charge light leptons satisfying  $60 < m_{\ell\ell} < 120$  GeV. In events with multiple Z boson candidates, we choose the one with the mass closest to the Z boson mass. The leptons associated with the  $h \rightarrow \tau\tau$  decay ( $e\tau_h, \mu\tau_h, \tau_h\tau_h$ ) are required to have opposite charge and an isolation requirement of  $I_{\text{rel}}^{e(\mu)} < 0.15$ , whereas other identification requirements are described in Section 3. The  $\tau_h$  candidates associated with the h boson must satisfy the  $\tau_h$  identification with efficiencies detailed in Table 1.

Events with at least one identified b jet, according to the criteria given in Section 3, fall into the *b-tag* category, used to target b quark associated A boson production. All other events are placed into the *no b-tag* category, which is used to target gluon-gluon fusion production of the A boson.

To further improve search sensitivity, the FastMTT algorithm is employed to account for unmeasured momentum carried away by  $\tau$  decay neutrinos. The FastMTT-corrected mass of the  $h \rightarrow \tau\tau$  candidate,  $m_{\tau\tau}^{\text{corr}}$ , is required to be within the 90–160 GeV mass range.

## 6 Modeling of signal and background

Backgrounds with prompt lepton decays (ZZ,  $t\bar{t}Z$ , triboson, and SM processes producing a h boson), and the acceptance of signal processes ( $gg \rightarrow A$  and  $b\bar{b}A$ ) are estimated from simulation. Background processes are scaled by their theoretical cross sections calculated at the highest order available, as described in Section 4, whereas normalizations of signal processes are extracted from fits to data as described in Section 8.

Reducible background, arising from the misidentification of one or both  $\tau$  candidates, is estimated from data. The dominant contributions come from the  $t\bar{t}$ , Z + jets, and WZ + jets processes, where at least one  $\tau$  candidate is mimicked by a hadronic jet. This background is evaluated using a “misidentification factor” method, that involves measuring the probabilities of misidentifying a hadronic jet as a prompt light lepton or  $\tau_h$  candidate. The misidentification factors for electrons, muons, and  $\tau_h$  are measured in a control region dominated by nonprompt or misidentified leptons, and are defined as the fraction of objects passing the nominal selections in the sample of objects passing loose selections. When selecting signal candidate events, any events with  $\tau$  candidates passing loose criteria but failing the nominal criteria are assigned to an application region (AR). They are used along with the misidentification factors to estimate the contribution from the reducible background in the signal region, i.e., the region that contains events with leptons or  $\tau_h$  passing identification and isolation.

An estimate of the background from misidentified leptons and  $\tau_h$  in the signal region is obtained by applying suitably chosen weights to the events selected in the AR. Applied weights

are computed according to the following relations:

$$\begin{aligned} w_1 &= \frac{f_1}{1-f_1}, \\ w_2 &= \frac{f_2}{1-f_2}, \\ w_{12} &= -\frac{f_1 f_2}{(1-f_1)(1-f_2)}, \end{aligned} \quad (3)$$

where: weight  $w_1$  ( $w_2$ ) is applied to events where the first (second)  $\tau$  candidate fails the nominal identification criteria, whereas the second (first)  $\tau$  candidate passes the nominal identification criteria; weight  $w_{12}$  is applied to events where both  $\tau$  candidates fail the nominal identification criteria; and  $f_1$  and  $f_2$  are the misidentification factors of the first and second  $\tau$  candidates. The negative sign of the weight  $w_{12}$  accounts for double counting of events from  $t\bar{t}$  and  $Z + \text{jets}$  processes with both  $\tau$  candidates failing the nominal identification criteria.

The misidentification factors  $f_i$  are measured in event samples that have no overlap with the signal region. A validation region, defined to be orthogonal to the signal and measurement regions, is used to test the robustness of the reducible background estimate. Systematic uncertainties corresponding to the possible differences between the true and estimated reducible background rates in the signal region are estimated from these closure tests.

In this analysis, we use a sample of Drell–Yan (DY) events with an additional hadronic jet that is misidentified as light lepton or  $\tau_h$  candidates. The estimation of misidentification factors relies on reconstructing an opposite-charge, same-flavour lepton pair compatible with a  $Z$  boson, and requiring one additional loosely defined lepton or  $\tau_h$  candidate. The requirements on the leptons associated with the  $Z$  boson are the same as those defined in Section 5, but they must fulfill a more stringent dilepton mass requirement,  $81 < m_{\ell\ell} < 120$  GeV. The lower threshold on the dilepton mass is tightened to suppress the contribution of DY events affected by final-state radiation. These events have typically lower dilepton mass compared to DY events without final-state radiation. After reconstructing the  $Z \rightarrow \ell\ell$  candidate, the misidentification factor is estimated by applying the lepton identification algorithm to the additional loosely identified light lepton or  $\tau_h$  candidate in the event. Orthogonality to the signal region is achieved by rejecting events with extra  $\tau$  candidates (either light lepton or  $\tau_h$ ), passing loose identification criteria. The misidentification factors are measured in different bins of lepton  $p_T$ , and are further split between reconstructed decay modes for the  $\tau_h$  candidate, and for muons and electrons in bins of lepton  $\eta$ , based on the barrel and endcap regions. The events where the  $\tau$  candidates are genuine  $\tau_h$ , electrons, or muons, are estimated from simulation and subtracted from data so that the misidentification factors are measured for genuine hadronic jets only. The misidentification factors obtained for electrons (muons) are <2 (5)% in the barrel and endcap regions for lepton  $p_T > 10$  GeV, whereas for  $\tau_h$  candidates with  $p_T > 20$  GeV the misidentification factors vary between 2 and 20%, depending on the decay mode and discriminator working point.

The measured misidentification factors are validated in another region that consists of events with a  $Z$  boson candidate and two additional  $\tau$  candidates. To ensure that the validation region is not contaminated with signal events or contributions from backgrounds with genuine prompt leptons, the two additional  $\tau$  candidates are required to have the same charge. All other selection criteria are identical to those defining the signal region. The reducible background in the validation region is constructed in the same way as in the nominal analysis. The purity of the reducible background in the validation region amounts to more than 95% in all analyzed channels.

Given the limited statistical power of the data sample in the validation region, the observed data yields and shapes of the  $m_{\ell\ell\tau\tau}^{\text{cons}}$  distribution are compared with the predicted yields and shapes of the reducible background by combining all three data-taking periods. The comparison revealed only modest differences between the observed data and the model of the reducible background. The saturated goodness of fit (GoF) test [68], quantifying consistency of the observed data with the background model, yields  $p$ -values of 0.31, 0.48, and 0.82 for the  $\tau_h\tau_h$ ,  $e\tau_h$ , and  $\mu\tau_h$  channels, respectively. This test is performed using the CMS statistical toolkit COMBINE [69]. The differences between the observed data and the model, together with the statistical uncertainties due to the limited data sample in the validation region are accounted for by assigning a systematic uncertainty in the yield of the reducible background, estimated to be 20–30% depending on the  $h$  decay channel. Given that the comparison is performed for the combined dataset, these uncertainties are correlated among data-taking periods, but uncorrelated among  $h$  decay channels.

The limited statistical power of the data sample in the AR along with the contribution of events with negative weights (Eq. 3), hampers the construction of smooth templates to model the shape of the  $m_{\ell\ell\tau\tau}^{\text{cons}}$  distribution of the reducible background. The shape of the distribution is therefore taken from a data region with same-sign  $\tau$  candidates that pass loose identification and isolation requirements. This region has higher statistical power than the AR region, resulting in a smoother shape for the  $m_{\ell\ell\tau\tau}^{\text{cons}}$  distribution, which is normalized to the estimated yield of the reducible background in the signal region. Consistency of shapes obtained from the statistically limited AR and the region with same-sign  $\tau$  candidates, passing loose identification criteria, is verified with a Kolmogorov-Smirnov test, yielding  $p$ -values between 0.56 and 0.97 depending on the di- $\tau$  decay mode.

## 7 Systematic uncertainties

The dominant systematic uncertainties considered in the analysis are summarized in Table 2.

The uncertainties in the  $\tau_h$  identification efficiency are estimated in  $Z \rightarrow \tau\tau$  and  $W \rightarrow \tau\nu$  decays from control samples. These uncertainties are partially correlated across data-taking years. The size of uncertainties varies in the range of 2–10% per  $\tau_h$ , depending on  $p_T$  and the decay mode of the  $\tau_h$  candidate. The uncertainties in the  $\tau_h$  energy scale amount to 0.5–1.1%, depending on the  $\tau_h$  decay mode. They are predominantly of statistical origin and uncorrelated between data-taking years. Uncertainties in the  $\tau_h$  identification efficiency and momentum scale affect both the normalization of simulated processes and the shape of the  $m_{\ell\ell\tau\tau}^{\text{cons}}$  distribution.

Uncertainties in the identification and isolation efficiencies of electrons and muons are 1.5%, and are correlated across all years. These uncertainties result in normalization variations between 1.5% and 4.5%, depending on the analyzed final state. Uncertainties in the muon momentum scale amount to less than 0.3% and have a negligible impact on the analysis. The uncertainty in the electron energy scale, which is derived from the calibration of the ECAL crystals and applied on an event-by-event basis, is less than 2%. The uncertainty in the single-lepton trigger efficiency results in a normalization uncertainty of about 2% for both single-electron and single-muon triggers.

Uncertainties in both the identification efficiency for  $b$  jets and in the misidentification rates for light-flavour or  $c$  quarks or gluon jets range from the subpercent level to  $\mathcal{O}(10\%)$ , depending on jet flavour and  $p_T$ . The uncertainty in the identification efficiency of  $b$  jets causes variation of 1–4% (0.3–1%) in the normalization of the  $b\bar{b}A$  signal and background processes with genuine

$b$  jets in the  $b$ -tag (*no b*-tag) category. The uncertainty in the misidentification efficiency of the light-flavour, or  $c$  quarks, or gluon jets modifies normalization of the  $gg \rightarrow A$  signal and background processes with no genuine  $b$  jets by 5–10% in the  $b$ -tag category and has an impact of  $\mathcal{O}(0.1\%)$  on the normalization of processes without genuine  $b$  jets in the *no b*-tag category.

An uncertainty related to the energy carried by unclustered particle candidates, which are not contained in jets in the event [41], is propagated on an event-by-event basis to  $p_T^{\text{miss}}$ , resulting in a variation of up to 10% in the shape of the  $m_{\ell\ell\tau\tau}^{\text{cons}}$  distribution. A normalization-altering effect of 1–3% is introduced by this uncertainty by requiring  $90 < m_{\ell\ell\tau\tau}^{\text{corr}} < 160$  GeV. The jet energy scale and resolution affect both the selection efficiencies and shapes of the  $m_{\ell\ell\tau\tau}^{\text{cons}}$  distributions. The jet energy scale is responsible for a 1–3% variation in the number of selected background and signal events; the jet energy resolution contributes an additional 0.5–1%. The calibration accuracy of the unclustered and jet energy scales and jet energy resolution is mainly affected by statistical limitations of the measurements, the time-dependence of the data-taking conditions, and the aging of the detector. For this reason, the respective uncertainties are uncorrelated between data-taking years.

Theoretical uncertainties related to the choice of PDFs, and the renormalization ( $\mu_R$ ) and factorization ( $\mu_F$ ) scales, affecting both the acceptance and cross section of the dominant background processes, are estimated from simulation separately for each process. Uncertainties due to the choice of  $\mu_R$  and  $\mu_F$  in the calculation of the matrix elements are obtained from an independent variation of these scales by factors of 0.5 and 2, omitting the variations where one scale is multiplied by 2 and the corresponding other scale by 0.5. The uncertainties are then obtained from an envelope of these variations. The uncertainties due to PDF variations and the uncertainty in  $\alpha_S$  are obtained following the PDF4LHC recommendations [70], taking the root mean square of the variation of the results when using different replicas of the default NNPDF3.1 set.

Combining  $\mu_R$  and  $\mu_F$  scale uncertainties with the PDF set uncertainty for the  $q\bar{q} \rightarrow ZZ$  process leads to a normalization uncertainty of 5%. For the  $gg \rightarrow ZZ$  process, a normalization uncertainty of 15% is obtained. It covers variations of  $\mu_R$  and  $\mu_F$ , PDF set and  $\alpha_S$  uncertainties, and uncertainty that accounts for effects of interference with the process mediated by the off-shell Higgs boson,  $gg \rightarrow h^* \rightarrow ZZ$  [9, 58]. The uncertainties in cross sections of the  $t\bar{t}Z$  and triboson production amount to 25% [71] and dominate normalization uncertainty for these processes.

The uncertainty in the theoretical calculations of the SM  $h \rightarrow \tau\tau$  branching fraction amounting to 2% [53] is applied to both the signal samples as well as all backgrounds that include the  $h \rightarrow \tau\tau$  process. The inclusive uncertainty for  $Zh$  production related to the PDFs amounts to 1.3%, whereas the uncertainty for the variation of  $\mu_R$  and  $\mu_F$  is 0.9% [53]. For the subleading  $h$  boson processes  $gg \rightarrow h \rightarrow ZZ$ , and  $t\bar{t}h$  the inclusive uncertainties related to the PDFs amount to 3.2 and 3.6% and the uncertainties for the variation of  $\mu_R$  and  $\mu_F$  are 3.9 and 8%, respectively [53].

For the MSSM parameter scan, theoretical uncertainties in the  $gg \rightarrow A$  and  $b\bar{b}A$  cross sections are accounted for as described in Ref. [72]. This includes uncertainties in  $\mu_R$ ,  $\mu_F$ , PDFs, and  $\alpha_S$ . Uncertainties are evaluated separately for each  $m_A$ - $\tan\beta$  point under consideration. They are typically 5–20% (10–25%) for  $gg \rightarrow A$  ( $b\bar{b}A$ ) production.

Uncertainties in the estimated yield of background with misidentified leptons comprise two components. Statistical uncertainties arise from the limited statistical power of the data sample in the AR. These are the dominant uncertainties in the analysis and they range between 10–20% (20–40%) in the *no b*-tag (*b*-tag) category and are uncorrelated between channels, event categories and data-taking periods. Uncertainties related to the misidentification factor method

are estimated in the side band region with same-sign  $\tau$  pairs, as described in Section 6. Normalization uncertainties of 20–30% are assigned to the estimated yield of this background. They are correlated between data-taking periods and event categories but uncorrelated across di- $\tau$  final states.

The integrated luminosities of the 2016, 2017, and 2018 data-taking periods are known with uncertainties in the 1.2–2.5% range [73–75], while the total integrated luminosity for the years 2016–2018 has an uncertainty of 1.6%. Uncertainties related to the finite number of simulated events, referred to in Table 2 as bin-by-bin statistical uncertainties, are taken into account using the Barlow-Beeston “lite” method [69, 76, 77]. They are considered for all bins of the distributions used to extract the results. They are uncorrelated across different samples and across bins of a single distribution.

The uncertainty in the predicted yield of the reducible background and theoretical uncertainties in cross sections of the  $q\bar{q} \rightarrow ZZ$ ,  $gg \rightarrow ZZ$  and  $t\bar{t}Z$  processes are the dominant factors limiting sensitivity of the search. Their combined effect reduces sensitivity of the analysis by 15–20% (20–25%) in terms of expected upper limits on the rate of the  $gg \rightarrow A$  ( $b\bar{b}A$ ) process.

## 8 Results

The discriminating variable for this analysis is  $m_{\ell\ell\tau\tau}^{\text{cons}}$ , the mass of the four-lepton final state where four-vector of the  $h \rightarrow \tau\tau$  candidate is reconstructed by the FastMTT algorithm with the mass constraint  $m_{\tau\tau} = 125$  GeV. Six final states corresponding to each combination of  $Z \rightarrow ee, \mu\mu$  and  $h \rightarrow e\tau_h, \mu\tau_h, \tau_h\tau_h$  decays are considered. Each final state comprises two event categories, *no b-tag* and *b-tag*, as described in Section 5. Data are examined for the presence of signal using the CMS statistical analysis toolkit COMBINE [69], which is based on the ROOFIT [78] and ROOSTATS [79] frameworks.

The signal extraction is performed with a simultaneous binned likelihood fit, combining 36  $m_{\ell\ell\tau\tau}^{\text{cons}}$  distributions, which corresponds to 6 analyzed final states times 2 event categories times 3 data-taking periods. The likelihood used to infer the signal has the following form:

$$\mathcal{L}\left(\{k_i\}, \{\mu_s\}, \{\theta_j\}\right) = \prod_i \mathcal{P}\left(k_i | \sum_s \mu_s S_{si}(\{\theta_j\}) + \sum_b B_{bi}(\{\theta_j\})\right) \prod_j \mathcal{C}(\tilde{\theta}_j | \theta_j), \quad (4)$$

where  $i$  labels the bins of the discriminating distributions, split by the final state, signal category (*no b-tag* or *b-tag*), and data-taking year. The function  $\mathcal{P}(k_i | \sum_s \mu_s S_{si}(\{\theta_j\}) + \sum_b B_{bi}(\{\theta_j\}))$  corresponds to the Poisson probability to observe  $k_i$  events in bin  $i$  for a prediction of  $\sum_s \mu_s S_{si}$  signal and  $\sum_b B_{bi}$  background events. The predictions for  $S_{si}$  and  $B_{bi}$  are obtained from the signal and background models. The parameters  $\mu_s$  act as linear scaling factors of the corresponding signal  $s$ . Systematic uncertainties are incorporated in the form of constraint terms for additional nuisance parameters  $\{\theta_j\}$  in the likelihood, appearing as a product with predefined probability density functions  $\mathcal{C}(\tilde{\theta}_j | \theta_j)$ , where  $\tilde{\theta}_j$  corresponds to the nominal value for  $\theta_j$ . The predefined uncertainties in the  $\tilde{\theta}_j$ , as discussed in Section 7, may be constrained by the fit to the data.

The test statistic used for the inference of the signal is the profile likelihood ratio as discussed in Ref. [80]:

$$q_{\mu_s} = -2 \ln \left( \frac{\mathcal{L}(\{k_i\} | \sum_s \mu_s S_{si}(\{\hat{\theta}_{j,\mu_s}\}) + \sum_b B_{bi}(\{\hat{\theta}_{j,\mu_s}\}))}{\mathcal{L}(\{k_i\} | \sum_s \hat{\mu}_s S_{si}(\{\hat{\theta}_{j,\hat{\mu}_s}\}) + \sum_b B_{bi}(\{\hat{\theta}_{j,\hat{\mu}_s}\}))} \right), \quad 0 \leq \hat{\mu}_s \leq \mu_s, \quad (5)$$

Table 2: Dominant sources of systematic uncertainty are considered in this analysis. The symbol  $\dagger$  indicates uncertainties that affect both the shape and normalization of the final  $m_{\ell\ell\tau\tau}^{\text{cons}}$  distributions. Uncertainties without  $\dagger$  affect only normalization. The magnitude column indicates an approximation of the associated change in normalization. The uncertainties in each group are listed in descending order of their impact on the analysis sensitivity.

Source of uncertainty	Magnitude	Process
Experimental uncertainties		
$\tau_h$ id. $^\dagger$	2–10%	all simulations
$\mu$ trigger	2%	all simulations
$\mu$ id. & isolation	1.5–4.5%	all simulations
e trigger	2%	all simulations
e id. & isolation	1.5–4.5%	all simulations
limited MC event count	bin-by-bin uncertainties	all simulations
$\tau_h$ energy scale $^\dagger$	0.5–1.5%	all simulations
integrated luminosity	<2%	all simulations
e energy scale $^\dagger$	1–2%	all simulations
b jet identification efficiency	1–4%	all simulations
b jet misidentification rate	5–10%	all simulations
jet energy scale $^\dagger$	1–3%	all simulations
$\vec{p}_T^{\text{miss}}$ unclustered energy scale $^\dagger$	1–3%	all simulations
jet energy resolution $^\dagger$	<1%	all simulations
Uncertainties in reducible background estimate		
normalization uncertainty	30%	misidentified $\tau$ leptons
	20%	e $\tau_h$ channel
	20%	$\mu \tau_h$ channel
event count in AR	20–40%	$\tau_h \tau_h$ channel
	10–20%	( <i>b</i> -tag category)
		(no <i>b</i> -tag category)
Theoretical uncertainties in background estimate		
$q\bar{q} \rightarrow ZZ$ normalization	5%	$q\bar{q} \rightarrow ZZ$
$gg \rightarrow ZZ$ normalization	15%	$gg \rightarrow ZZ$
$t\bar{t}Z$ normalization	25%	$t\bar{t}Z$
triboson normalization	25%	triboson
$\mu_F$ and $\mu_R$ scales	1–8%	Higgs bkg.
theoretical uncertainty in $\mathcal{B}(h \rightarrow \tau\tau)$	<2%	$gg \rightarrow A, b\bar{b}A, \text{Higgs bkg.}$
PDFs	1.3–3.6%	Higgs bkg.
Theoretical uncertainties in the signal estimate (applied in the MSSM interpretation)		
signal cross section		
$(\mu_F, \mu_R \text{ scale, PDFs, } \alpha_S)$	5–20% (10–25%)	$gg \rightarrow A (b\bar{b}A)$

where  $\mu_s$  are tested values of the parameters of interest (POIs);  $\hat{\theta}_{j,\mu_s}$  are the values of the nuisance parameters that maximize the likelihood function for specified values of  $\mu_s$ , i.e. these are conditional maximum likelihood estimators of  $\theta_j$  and thus are functions of  $\mu_s$ ;  $\hat{\mu}_s$  and  $\hat{\theta}_{j,\hat{\mu}_s}$  are unconditional maximum likelihood estimators of POIs and nuisance parameters. The index of  $q_{\mu_s}$  indicates that the test statistic is evaluated for specified values of  $\mu_s$ .

Compared to the unbinned approach, the binned likelihood fit does not require introduction of analytical probability density functions for description of the background and signal models, thereby simplifying statistical inference. The likelihood function is rigorously defined and properly accounts for the analysis bins with zero observed yields. The background and signal models are represented as binned templates derived from simulated samples or sideband region in data as described in Section 6. The binning has been optimised to maintain high sensitivity in the entire probed range of  $m_A$  while ensuring reasonable statistical population across all bins of the final discriminant in the combined background template, with the statistical uncertainty ranging between 0.5% and 30%.

The statistical model includes two POIs: the rate of  $gg \rightarrow A$  production and the rate of  $b\bar{b}A$  production. Constraints on the production rates of the signal processes are derived using the modified frequentist  $CL_s$  method [81, 82].

The  $m_{\ell\ell\tau\tau}^{\text{cons}}$  distributions, combined across all search channels, are presented in Fig. 3. The distributions are shown separately for *no b-tag* and *b-tag* categories.

Figure 3: The reconstructed four-lepton mass,  $m_{\ell\ell\tau\tau}^{\text{cons}}$ , in the *no b-tag* (left plot) and *b-tag* (right plot) categories. Background distributions are shown after performing a maximum likelihood fit to data under a background-only hypothesis. Signal samples corresponding to the  $gg \rightarrow A$  and  $b\bar{b}A$  production modes of a pseudoscalar Higgs boson with a mass of  $m_A = 350$  GeV, are overlaid to illustrate the expected signal contribution. Signal yields are computed by setting  $\sigma\mathcal{B}(A \rightarrow Zh)$  to a benchmark value of 1 pb for both  $gg \rightarrow A$  and  $b\bar{b}A$  processes. Hatched bands indicate uncertainties in the total background. Contents of each bin along with the corresponding uncertainties are divided by the bin width.

Expected and observed event yields in the final selected sample are reported in Table 3.

Table 3: Expected and observed yields in the final selected sample. The  $Z \rightarrow ee$  and  $Z \rightarrow \mu\mu$  samples and all three data-taking periods are combined for the final results. Numbers are reported individually for *no b-tag* and *b-tag* categories and three analyzed di- $\tau$  decay modes:  $e\tau_h$ ,  $\mu\tau_h$ , and  $\tau_h\tau_h$ , combining  $Z \rightarrow ee, \mu\mu$  channels and three data-taking years. Background yields and related uncertainties are obtained after performing a maximum likelihood fit to the data under a background-only hypothesis. Signal yields are computed for representative chosen mass hypotheses of  $m_A = 250, 350, 500$ , and  $800\text{ GeV}$ , by setting  $\sigma\mathcal{B}(A \rightarrow Zh)$  to a benchmark value of  $1\text{ pb}$  for both the  $gg \rightarrow A$  and  $b\bar{b}A$  processes.

Process	no b-tag			b-tag		
	$e\tau_h$	$\mu\tau_h$	$\tau_h\tau_h$	$e\tau_h$	$\mu\tau_h$	$\tau_h\tau_h$
ZZ	$25.6 \pm 3.4$	$36.4 \pm 4.1$	$41.9 \pm 5.2$	$0.75 \pm 0.13$	$1.09 \pm 0.18$	$1.28 \pm 0.21$
reducible	$18.7 \pm 5.2$	$14.8 \pm 3.4$	$33.5 \pm 8.4$	$3.41 \pm 1.09$	$1.69 \pm 0.49$	$1.21 \pm 0.35$
other	$4.4 \pm 1.1$	$6.6 \pm 1.5$	$7.0 \pm 1.5$	$0.99 \pm 0.26$	$1.43 \pm 0.37$	$0.68 \pm 0.17$
total bkg.	$48.7 \pm 6.4$	$57.8 \pm 5.6$	$82.4 \pm 9.9$	$5.15 \pm 1.14$	$4.21 \pm 0.68$	$3.17 \pm 0.47$
observed	58	57	81	4	2	4
$gg \rightarrow A$ (250 GeV)	4.70	6.84	8.66	0.16	0.24	0.30
$b\bar{b}A$ (250 GeV)	3.70	5.44	7.04	1.24	1.72	2.26
$gg \rightarrow A$ (350 GeV)	6.66	9.54	12.36	0.24	0.34	0.44
$b\bar{b}A$ (350 GeV)	5.10	7.34	9.40	1.88	2.64	3.40
$gg \rightarrow A$ (500 GeV)	8.94	12.68	16.44	0.38	0.52	0.68
$b\bar{b}A$ (500 GeV)	6.74	9.38	12.38	2.72	3.78	4.98
$gg \rightarrow A$ (800 GeV)	11.90	16.76	22.20	0.56	0.76	1.06
$b\bar{b}A$ (800 GeV)	8.72	12.28	16.38	3.82	5.26	7.14

It should be noted that  $b$  jets in the  $b\bar{b}A$  process have relatively soft  $p_T$  spectrum, and about two-thirds of  $b\bar{b}A$  events have  $b$  jets outside the acceptance of  $b$  tagging algorithm. As a consequence, about 75% of selected  $b\bar{b}A$  events contribute to the *no b-tag* category, with the remaining 25% assigned to the *b-tag* category.

The statistical inference did not reveal any evidence for the presence of a signal. The compatibility of the observed distributions of the  $m_{\ell\ell\tau\tau}^{\text{cons}}$  discriminant with a null hypothesis is evaluated with a GoF test, confronting data against a background-only expectation. The  $p$ -value returned by a GoF test based on the saturated model for the test statistics [68], is 0.89. The results of the analysis are used to constrain the rate of the signal processes. The upper limits at 95% confidence level (CL) on the  $A$  production cross section times branching fraction of  $A \rightarrow Zh$  are shown in Fig. 4 for all channels combined. The statistical inference is performed with one POI, corresponding to the rate of the probed process, whereas the rate of the other process is fixed to zero. This interpretation targets BSM scenarios, where one of the two processes, either  $gg \rightarrow A$  or  $b\bar{b}A$ , prevails, whereas contribution of the other process to the signal is negligible. The example of such scenarios is given by Type-II 2HDM, where at low  $\tan\beta$  values the  $A$  boson production is dominated by the  $gg \rightarrow A$  process, while the  $b\bar{b}A$  process has vanishing cross section. The branching fraction of the  $h \rightarrow \tau\tau$  decay is set to the value predicted in the SM,  $\mathcal{B}(h \rightarrow \tau\tau) = 0.062$  [53]. The observed (expected) limits range from  $0.049$  ( $0.060$ ) pb at  $m_A = 1\text{ TeV}$  to  $1.02$  ( $0.79$ ) pb at  $m_A = 250$  ( $225$ ) GeV for the  $gg \rightarrow A$  process. For the  $b\bar{b}A$  process, the observed (expected) limits range from  $0.053$  ( $0.059$ ) pb at  $m_A = 1\text{ TeV}$  to  $0.79$  ( $0.61$ ) pb at  $m_A = 250$  ( $225$ ) GeV.

Figure 4: The expected and observed upper limits at 95% CL on the production cross section times branching fraction of the  $A \rightarrow Zh$  decay for  $gg \rightarrow A$  (left plot) and  $bb\bar{A}$  (right plot) processes as functions of  $m_A$ . The limits for the  $gg \rightarrow A$  ( $bb\bar{A}$ ) process are derived with the rate of other process fixed to zero. The branching fraction of the  $h \rightarrow \tau\tau$  decay is set to the value predicted in the SM,  $\mathcal{B}(h \rightarrow \tau\tau) = 0.062$  [53].

Results of the search are also provided in terms of two-dimensional constraints on the cross section times branching fraction,  $\sigma\mathcal{B}(A \rightarrow Zh)$ , for the  $gg \rightarrow A$  and  $bb\bar{A}$  production mechanisms. Constraints are derived assuming that the rates of  $gg \rightarrow A$  and  $bb\bar{A}$  processes are nonnegative. Figures 5 and 6 present 68% and 95% CL contours for eight representative  $m_A$  hypotheses. For each  $m_A$ ,  $\sigma\mathcal{B}(A \rightarrow Zh)$  values are scanned in two dimensions, corresponding to the  $gg \rightarrow A$  and  $bb\bar{A}$  production mechanisms. At each scanned point,  $-2\log L$  is calculated, defined as the negative-log-likelihood (NLL) of the conditional fit to the background-only Asimov and observed datasets. The minimal value of the NLL in the scanned domain of nonnegative values of  $\sigma(gg \rightarrow A)\mathcal{B}(A \rightarrow Zh)$  and  $\sigma(bb\bar{A})\mathcal{B}(A \rightarrow Zh)$  defines the best fit point. For each scanned point, the difference between the NLL at a given point and the minimal value of NLL,  $-2\Delta(\log L)$ , is then computed. The 68% and 95% CL boundaries are found at  $-2\Delta(\log L)$  values of 2.30 and 5.99, respectively. Maximum-likelihood fits to the background-only Asimov dataset are performed to extract 68% and 95% CL expected contours in the absence of signal. Fits to data are performed to determine the observed 68% and 95% CL contours.

The results of this analysis are also interpreted as constraints on the parameters  $\tan\beta$  and  $m_A$  within the  $M_{h,\text{EFT}}^{125}$  MSSM benchmark scenario [17]. For this scenario the Higgs boson masses, mixing angle  $\alpha$ , and effective Yukawa couplings have been calculated with the FEYNHIGGS [83–90] program. Branching fractions for the  $A \rightarrow Zh$  and  $h \rightarrow \tau\tau$  decays have been obtained from a combination of the FEYNHIGGS and HDECAY [91] programs, as described in Ref. [72] following the prescriptions given in Refs. [53, 92, 93]. For the  $gg \rightarrow A$  process the cross sections are obtained with SUSHI 1.7.0 [94, 95], which includes NLO corrections in  $\alpha_S$  for the t- and b-quark contributions to the cross section [96, 97], NNLO corrections in  $\alpha_S$  in the heavy t quark limit, for the t quark contribution [98–102], and next-to-NNLO contributions in  $\alpha_S$  for h production [103–105]. Electroweak corrections mediated by light-flavour quarks are included at two-loop accuracy reweighting the SM results of Refs. [106, 107]. Cross sections for the  $bb\bar{A}$  process rely on matched predictions [108–111], which are based on the calculation at NNLO in  $\alpha_S$  in the five-flavour scheme [112] and the calculation at NLO in  $\alpha_S$  in the four-flavor scheme [113, 114].

At low  $\tan\beta$  values, the  $A \rightarrow Zh$  decay dominates the natural decay width of A in the  $m_A$  range from 220 to 350 GeV. For higher values of  $m_A$  decays  $A \rightarrow t\bar{t}$  become dominant. For

Figure 5: Two-dimensional constraints on the cross section times branching fraction for the two production mechanisms. The confidence level intervals are derived for mass hypotheses of  $m_A = 250$  (upper left plot), 300 (upper right plot), 350 (lower left plot), and 400 GeV (lower right plot). The branching fraction of the  $h \rightarrow \tau\tau$  decay is set to the value predicted in the SM,  $\mathcal{B}(h \rightarrow \tau\tau) = 0.062$  [53]. Computation of the best fit point and determination of the observed and expected 68% and 95% CL contours are described in the text.

Figure 6: Same as Fig. 5 but for mass hypotheses of  $m_A = 500$  (upper left plot),  $600$  (upper right plot),  $800$  (lower left plot) and  $1000 \text{ GeV}$  (lower right plot). The branching fraction of the  $h \rightarrow \tau\tau$  decay is set to the value predicted in the SM,  $B(h \rightarrow \tau\tau) = 0.062$  [53]. Computation of the best-fit point and determination of the observed and expected 68% and 95% CL contours are described in the text.

$\tan\beta \lesssim 4$ , the A boson is produced mainly via gluon-gluon fusion process, but at higher  $\tan\beta$  values associated production with bottom quarks takes over.

To derive exclusion contours at 95% CL, a scan in the  $m_A$ - $\tan\beta$  plane is performed. Signal yields are determined based on the theoretical predictions for  $\sigma(gg \rightarrow A)$ ,  $\sigma(b\bar{b}A)$ ,  $\mathcal{B}(A \rightarrow Zh)$  and  $\mathcal{B}(h \rightarrow \tau\tau)$  at a given tested  $m_A$ - $\tan\beta$  point, and the  $CL_s$  value [82] is computed. Those points where  $CL_s$  falls below 5% define the 95% CL exclusion contour for the benchmark scenario under consideration. Observed and expected lower limits at 95% CL on  $\tan\beta$  as functions of  $m_A$  are presented in Fig. 7. Observed (expected) limits on  $\tan\beta$  range from 1.4 (1.5) at  $m_A = 375$  GeV to 4.0 (3.9) at  $m_A = 325$  GeV. This analysis excludes  $\tan\beta$  values below 2.2 at 95% CL in the mass range from 225 to 350 GeV. At higher probed values of  $m_A$ ,  $A \rightarrow t\bar{t}$  decay becomes kinematically allowed and suppresses  $A \rightarrow Zh$  decay, significantly reducing the sensitivity of this search.

Figure 7: Lower 95% CL limit on  $\tan\beta$  as a function of  $m_A$  in the  $M_{h,EFT}^{125}$  MSSM scenario. Values below the black solid line are excluded at 95% CL.

## 9 Summary

A search is presented for the decay of a heavy pseudoscalar boson A to a Z boson and 125 GeV Higgs boson, h, in final states with two  $\tau$  leptons and two light leptons (ee,  $\mu\mu$ ). The study is based on proton-proton collision data collected by the CMS experiment at  $\sqrt{s} = 13$  TeV, corresponding to an integrated luminosity of  $138 \text{ fb}^{-1}$ . The analysis probes the gluon-gluon fusion process,  $gg \rightarrow A$ , and bottom quark associated production,  $b\bar{b}A$ . No evidence for a signal is found in the data. Upper limits at 95% confidence level are derived on the product of the cross section and branching fraction of the  $A \rightarrow Zh$  decay under the assumption that the

scalar state  $h$  has the properties of the 125 GeV SM Higgs boson. Observed limits range from 0.049 (0.053) pb at  $m_A = 1$  TeV to 1.02 (0.79) pb at  $m_A = 250$  GeV for the  $gg \rightarrow A(\bar{b}\bar{b}A)$  process.

The results of the search are also interpreted in terms of constraints on  $\tan\beta$  as a function of  $m_A$  within the  $M_{h,\text{EFT}}^{125}$  MSSM benchmark scenario. Values of  $\tan\beta$  below 2.2 are excluded at 95% CL in the mass range of  $225 < m_A < 350$  GeV.

The present analysis supersedes the previous search for the  $A \rightarrow Zh$  decay carried out by the CMS Collaboration in the  $(Z \rightarrow v\bar{v}/\ell\ell)(h \rightarrow b\bar{b})$  and  $(Z \rightarrow \ell\ell)(h \rightarrow \tau\tau)$  channels (where  $\ell = e, \mu$ ) [20, 22] on proton-proton collision data collected at  $\sqrt{s} = 13$  TeV and corresponding to an integrated luminosity of  $36 \text{ fb}^{-1}$ .

## Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centres and personnel of the Worldwide LHC Computing Grid and other centres for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC, the CMS detector, and the supporting computing infrastructure provided by the following funding agencies: SC (Armenia), BMBWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP (Brazil); MES and BNSF (Bulgaria); CERN; CAS, MoST, and NSFC (China); MINCIENCIAS (Colombia); MSES and CSF (Croatia); RIF (Cyprus); SENESCYT (Ecuador); ERC PRG, RVTT3 and MoER TK202 (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); SRNSF (Georgia); BMBF, DFG, and HGF (Germany); GSRI (Greece); NKFIH (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); MES (Latvia); LMTLT (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MOS (Montenegro); MBIE (New Zealand); PAEC (Pakistan); MES and NSC (Poland); FCT (Portugal); MESTD (Serbia); MCIN/AEI and PCTI (Spain); MOSTR (Sri Lanka); Swiss Funding Agencies (Switzerland); MST (Taipei); MHESI and NSTDA (Thailand); TUBITAK and TENMAK (Turkey); NASU (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

<sup>†</sup>: Deceased

<sup>1</sup>Also at Yerevan State University, Yerevan, Armenia

<sup>2</sup>Also at TU Wien, Vienna, Austria

<sup>3</sup>Also at Ghent University, Ghent, Belgium

<sup>4</sup>Also at Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

<sup>5</sup>Also at FACAMP - Faculdades de Campinas, Sao Paulo, Brazil

<sup>6</sup>Also at Universidade Estadual de Campinas, Campinas, Brazil

<sup>7</sup>Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil

<sup>8</sup>Also at University of Chinese Academy of Sciences, Beijing, China

<sup>9</sup>Also at China Center of Advanced Science and Technology, Beijing, China

<sup>10</sup>Also at University of Chinese Academy of Sciences, Beijing, China

<sup>11</sup>Also at China Spallation Neutron Source, Guangdong, China

<sup>12</sup>Now at Henan Normal University, Xinxiang, China

<sup>13</sup>Also at University of Shanghai for Science and Technology, Shanghai, China

<sup>14</sup>Now at The University of Iowa, Iowa City, Iowa, USA

<sup>15</sup>Also at an institute formerly covered by a cooperation agreement with CERN

<sup>16</sup>Also at Helwan University, Cairo, Egypt

<sup>17</sup>Now at Zewail City of Science and Technology, Zewail, Egypt

<sup>18</sup>Now at British University in Egypt, Cairo, Egypt

<sup>19</sup>Now at Cairo University, Cairo, Egypt

<sup>20</sup>Also at Purdue University, West Lafayette, Indiana, USA

<sup>21</sup>Also at Université de Haute Alsace, Mulhouse, France

<sup>22</sup>Also at Istinye University, Istanbul, Turkey

<sup>23</sup>Also at an international laboratory covered by a cooperation agreement with CERN

<sup>24</sup>Also at The University of the State of Amazonas, Manaus, Brazil

<sup>25</sup>Also at University of Hamburg, Hamburg, Germany

<sup>26</sup>Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany

<sup>27</sup>Also at Bergische University Wuppertal (BUW), Wuppertal, Germany

<sup>28</sup>Also at Brandenburg University of Technology, Cottbus, Germany

<sup>29</sup>Also at Forschungszentrum Jülich, Juelich, Germany

<sup>30</sup>Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland

<sup>31</sup>Also at HUN-REN ATOMKI - Institute of Nuclear Research, Debrecen, Hungary

<sup>32</sup>Now at Universitatea Babes-Bolyai - Facultatea de Fizica, Cluj-Napoca, Romania

<sup>33</sup>Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary

<sup>34</sup>Also at HUN-REN Wigner Research Centre for Physics, Budapest, Hungary

<sup>35</sup>Also at Physics Department, Faculty of Science, Assiut University, Assiut, Egypt

<sup>36</sup>Also at Punjab Agricultural University, Ludhiana, India

<sup>37</sup>Also at University of Visva-Bharati, Santiniketan, India

<sup>38</sup>Also at Indian Institute of Science (IISc), Bangalore, India

<sup>39</sup>Also at Amity University Uttar Pradesh, Noida, India

<sup>40</sup>Also at IIT Bhubaneswar, Bhubaneswar, India

- <sup>41</sup>Also at Institute of Physics, Bhubaneswar, India  
<sup>42</sup>Also at University of Hyderabad, Hyderabad, India  
<sup>43</sup>Also at Deutsches Elektronen-Synchrotron, Hamburg, Germany  
<sup>44</sup>Also at Isfahan University of Technology, Isfahan, Iran  
<sup>45</sup>Also at Sharif University of Technology, Tehran, Iran  
<sup>46</sup>Also at Department of Physics, University of Science and Technology of Mazandaran, Behshahr, Iran  
<sup>47</sup>Also at Department of Physics, Faculty of Science, Arak University, ARAK, Iran  
<sup>48</sup>Also at Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Bologna, Italy  
<sup>49</sup>Also at Centro Siciliano di Fisica Nucleare e di Struttura Della Materia, Catania, Italy  
<sup>50</sup>Also at Università degli Studi Guglielmo Marconi, Roma, Italy  
<sup>51</sup>Also at Scuola Superiore Meridionale, Università di Napoli 'Federico II', Napoli, Italy  
<sup>52</sup>Also at Fermi National Accelerator Laboratory, Batavia, Illinois, USA  
<sup>53</sup>Also at Lulea University of Technology, Lulea, Sweden  
<sup>54</sup>Also at Consiglio Nazionale delle Ricerche - Istituto Officina dei Materiali, Perugia, Italy  
<sup>55</sup>Also at Institut de Physique des 2 Infinis de Lyon (IP2I), Villeurbanne, France  
<sup>56</sup>Also at Department of Applied Physics, Faculty of Science and Technology, Universiti Kebangsaan Malaysia, Bangi, Malaysia  
<sup>57</sup>Also at Consejo Nacional de Ciencia y Tecnología, Mexico City, Mexico  
<sup>58</sup>Also at Trincomalee Campus, Eastern University, Sri Lanka, Nilaveli, Sri Lanka  
<sup>59</sup>Also at Saegis Campus, Nugegoda, Sri Lanka  
<sup>60</sup>Also at National and Kapodistrian University of Athens, Athens, Greece  
<sup>61</sup>Also at Ecole Polytechnique Fédérale Lausanne, Lausanne, Switzerland  
<sup>62</sup>Also at Universität Zürich, Zurich, Switzerland  
<sup>63</sup>Also at Stefan Meyer Institute for Subatomic Physics, Vienna, Austria  
<sup>64</sup>Also at Laboratoire d'Annecy-le-Vieux de Physique des Particules, IN2P3-CNRS, Annecy-le-Vieux, France  
<sup>65</sup>Also at Near East University, Research Center of Experimental Health Science, Mersin, Turkey  
<sup>66</sup>Also at Konya Technical University, Konya, Turkey  
<sup>67</sup>Also at Izmir Bakircay University, Izmir, Turkey  
<sup>68</sup>Also at Adiyaman University, Adiyaman, Turkey  
<sup>69</sup>Also at Bozok Universitetesi Rektörlüğü, Yozgat, Turkey  
<sup>70</sup>Also at Marmara University, Istanbul, Turkey  
<sup>71</sup>Also at Milli Savunma University, Istanbul, Turkey  
<sup>72</sup>Also at Kafkas University, Kars, Turkey  
<sup>73</sup>Now at Istanbul Okan University, Istanbul, Turkey  
<sup>74</sup>Also at Hacettepe University, Ankara, Turkey  
<sup>75</sup>Also at Erzincan Binali Yıldırım University, Erzincan, Turkey  
<sup>76</sup>Also at Istanbul University - Cerrahpasa, Faculty of Engineering, Istanbul, Turkey  
<sup>77</sup>Also at Yildiz Technical University, Istanbul, Turkey  
<sup>78</sup>Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom  
<sup>79</sup>Also at IPPP Durham University, Durham, United Kingdom  
<sup>80</sup>Also at Monash University, Faculty of Science, Clayton, Australia  
<sup>81</sup>Also at Università di Torino, Torino, Italy  
<sup>82</sup>Also at Bethel University, St. Paul, Minnesota, USA  
<sup>83</sup>Also at Karamanoğlu Mehmetbey University, Karaman, Turkey

---

<sup>84</sup>Also at California Institute of Technology, Pasadena, California, USA

<sup>85</sup>Also at United States Naval Academy, Annapolis, Maryland, USA

<sup>86</sup>Also at Ain Shams University, Cairo, Egypt

<sup>87</sup>Also at Bingol University, Bingol, Turkey

<sup>88</sup>Also at Georgian Technical University, Tbilisi, Georgia

<sup>89</sup>Also at Sinop University, Sinop, Turkey

<sup>90</sup>Also at Erciyes University, Kayseri, Turkey

<sup>91</sup>Also at Horia Hulubei National Institute of Physics and Nuclear Engineering (IFIN-HH), Bucharest, Romania

<sup>92</sup>Now at another institute formerly covered by a cooperation agreement with CERN

<sup>93</sup>Also at Texas A&M University at Qatar, Doha, Qatar

<sup>94</sup>Also at Kyungpook National University, Daegu, Korea

<sup>95</sup>Also at Yerevan Physics Institute, Yerevan, Armenia

<sup>96</sup>Also at another international laboratory covered by a cooperation agreement with CERN

<sup>97</sup>Also at Imperial College, London, United Kingdom

<sup>98</sup>Also at Institute of Nuclear Physics of the Uzbekistan Academy of Sciences, Tashkent, Uzbekistan

<sup>99</sup>Also at another institute formerly covered by a cooperation agreement with CERN
