You may want to look at Tableau Server log files, or need to send them to Tableau Support if you have a problem with your server. Use the `tsm maintenance ziplogs` command to create a zipped archive of log files from all nodes in your installation. By default, Tableau Server

log file archives are gathered in a zip file called `logs.zip`, but you can specify a different file name when you create the archive. You can copy the archive from the server to a local computer and open it there, or send it to Tableau Support.

When you unzip the archive, a directory is created for each node in the cluster, and in that directory are sub-directories for each service or process using this naming convention:

```
<service_name>_<instance>.<version>.<build>
```

If there are multiple instances of a service on a node, there will be multiple directories for that service, one for each instance. For example, if you have two Backgrounders on a node, you will see directories like these:

```
backgrounder_0.<version>.<build>
backgrounder_1.<version>.<build>
```

The specific directories and logs in the zip file depend on what version of Tableau Server you have, and which processes you have configured. For details about processes or services you might find logs for, see [Tableau Server Processes](#).

## Log File Snapshots (Archive Logs)

Tableau Server includes functionality to generate a snapshot of log files for archival purposes. If you plan to clean up and delete old log files as part of regular server maintenance, you may consider archiving log files to an off-server storage location before deleting them.

Or, if you are working with Tableau Support on a case, the support engineer may request a server log file snapshot.

This topic describes:

- How to generate a log file snapshot
- How to send the snapshot directly to Tableau Support from the Tableau Server administration tools
- How to download the snapshot
- How to delete archived logs

Use the TSM web interface

## Tableau Server on Linux Administrator Guide

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Maintenance**.
3. Generate a log file snapshot.
  - a. On the Server Maintenance page, under Log Files, click **Generate Log File Snapshot**.

An options dialog displays:

- b. On the Options page, enter or select the options you want, including a **Description**, time **Range** of log files to be included, and the optional types of logs to be included (**Include Postgres Data**, **Include Recent Crash Dumps**), then click **Generate Log File Snapshot**.

The log file snapshot is saved to a fixed location on the computer where TSM and Tableau Server are installed. If you have a multi-node installation, the snapshot is saved to the initial node of the cluster. The location is specified by the `basefilepath_log_archives` variable.

By default the snapshot is saved to:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/log-archives
```

You can find the current location by querying the `basefilepath.log_archives` setting, and change the location by specifying a new value for `basefilepath.log_archive`. For more information, see [tsm File Paths](#).

4. After you generate the snapshot, you can select it and upload it to Technical Support, download it to your local machine, or delete it:

Log Files

Generate a custom log file snapshot. After Tableau Server has generated the snapshot, you can download the snapshot or upload it to Tableau Technical Support. Generating

| Description  | Created                      | Range  | Size   | Stored in | Status    |
|--|------------------------------|--------|--------|-----------|-----------|
| <input type="radio"/>  | Jun 7, 2018, 6:43:14 PM UTC  | 2 days | 3.7 MB | node1     | Succeeded |
| <input type="radio"/>  | Jun 7, 2018, 10:05:34 PM UTC | 2 days | 230 B  | node1     | Succeeded |
| <input checked="" type="radio"/> Logs generated at 6/19/2018, 7:37:26 AM | Jun 19, 2018, 2:45:53 PM UTC | 2 days | 69 MB  | node1     | Succeeded |

5. To download a local copy of the snapshot or to delete it, select the snapshot under Log Files and then select the appropriate **Action**.

#### Uploading log snapshots for Tableau Support

1. Click the **Maintenance** tab.
2. Select the snapshot you want to send.

Log Files

Generate a custom log file snapshot. After Tableau Server has generated the snapshot, you can download the snapshot or upload it to Tableau Technical Support. Generating

| Description  | Created                      | Range  | Size   | Stored in | Status    |
|--|------------------------------|--------|--------|-----------|-----------|
| <input type="radio"/>  | Jun 7, 2018, 6:43:14 PM UTC  | 2 days | 3.7 MB | node1     | Succeeded |
| <input type="radio"/>  | Jun 7, 2018, 10:05:34 PM UTC | 2 days | 230 B  | node1     | Succeeded |
| <input checked="" type="radio"/> Logs generated at 6/19/2018, 7:37:26 AM | Jun 19, 2018, 2:45:53 PM UTC | 2 days | 69 MB  | node1     | Succeeded |

3. Click **Upload to Technical Support Case**.
4. In the dialog that displays, enter the **Support Case Number** and your **Contact Email**

**Address**, then click **Upload Snapshot**.

Upload To Technical Support Case

Upload your log file snapshot to Tableau Technical Support. Upload time is dependent upon the network connection and size of the log file snapshot. To file a new support case, select the Info icon in the header and then select Support.

Support Case Number

Contact Email Address

You are about to upload the following log file snapshot:

|             |   |
|-------------|---|
| Description | Logs generated at 6/19/2018, 7:37:26 AM |
| Created     | Jun 19, 2018, 2:45:53 PM UTC            |
| Range       | 3 days                                  |
| Size        | 69 MB                                   |

[Tableau Software Privacy Policy](#)

For additional methods to send log archives to Tableau Support, see [Sending Large Files to Tableau](#) in Salesforce Help.

Use the TSM CLI

You create a snapshot archive of Tableau Server log files using the `tsm maintenance zip-logs` command.

By default, this command creates a zip file containing all of the log files. If you are running a distributed installation of Tableau Server, perform this step from the initial node. Logs from all nodes will be included in the zip file.

**Note:** If you cannot run the ziplogs command successfully, you can manually zip the Tableau Server logs. For more information, see [Troubleshoot Tableau Server on Linux](#).

To create a log file snapshot:

1. On the initial node, open a terminal session.
2. Type the following command:

```
tsm maintenance ziplogs -l -f <filename>
```

where `<filename>` is name of the zipped archive file you want to create. Choose a unique name with no spaces. If an existing ziplog with the same file name already exists the creation of the file will fail unless you include the `-o` option to force an overwrite, delete the existing file, or specify a different name in the command.

You can specify a time range for the snapshot and the types of logs to include. For example, if you know when an error occurred, use the `--startdate` and `--enddate` options to capture logs from a few hours before and after the error:

```
tsm maintenance ziplogs -f <filename> --startdate "<mm/dd/yyyy  
H:mm>" --enddate "<mm/dd/yyyy H:mm>"
```

For more information, see `tsm maintenance ziplogs`.

The log file snapshot is saved to a fixed location on the computer where TSM and Tableau Server are installed. If you have a multi-node installation, the snapshot is saved to the initial node of the cluster. The location is specified by the `basefilepath_log_archives` variable.

By default the log file snapshot is saved to:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/log-archives
```

You can find the current location by querying the `basefilepath.log_archives` setting:

```
tsm configuration get -k basefilepath.log_archive
```

and change the location by specifying a new value for `basefilepath.log_archive`:

## Tableau Server on Linux Administrator Guide

```
tsm configuration set -k basefilepath.log_archive -v
"<drive>:/new/directory/path"
```

For more information, see [tsm File Paths](#).

### Sending log archives to Tableau Support

You can send log files to Tableau Support as a part of a customer support case (a customer support case number is required). Before sending a log file, use `tsm maintenance zip-logs` command to combine the log files into a single zip file archive.

- In a terminal session, type the following command:

```
tsm maintenance send-logs -f <zip file name> -c <case number> -
e <email address>
```

where `<case number>` is your support case number, `<email address>` is your contact email for this support case, and `<zip file name>` is the file name of your archive with `.zip` file extension.

For additional methods to send log archives to Tableau Support, see [Sending Large Files to Tableau](#) in Salesforce Help.

### Change Logging Levels

By default, Tableau Services Manager (TSM) and Tableau Server log events at the **Info** level. You can change this if you need to gather more information (if you are working with Tableau Support, for example).

As a best practice you should not increase logging levels except when troubleshooting an issue, as instructed by Support. You should only set a logging level to debug when investigating a specific issue. Changing log levels can have these impacts:

- Increasing the log level to `debug` or `trace` increases the amount of information being logged and can have a significant impact to performance. Reproduce the issue and then reset the logging level back to `info`.
- Setting the log level to `warn` or `error` can reduce the amount of information so much that it is not useful for Tableau Support.

**Note:** When logging at the `DEBUG` level, full environment information is gathered when Tableau starts. This means that if you have any sensitive information in an environment variable, it may be included in a log. Logging at the default `INFO` level only gathers safe environment information.

## Logging Levels

The following logging levels are listed in order of increasing amount of information logged:

- off
- fatal
- error
- warn
- info (the default)
- debug
- trace

## Change Logging Levels

Set logging levels for TSM and Tableau Server processes using **tsm configuration set** configuration keys. The key you use depends on which component of TSM or Tableau Server you want to change the logging level for.

## Dynamic log level configuration

In version 2020.2 we introduced dynamic configuration. The capability has been expanded in subsequent releases. If you are only changing logging levels for one or more of these components, and are running the appropriate version of Tableau, you can change the logging levels without restarting Tableau Server.

These logging levels are dynamically configurable, beginning with these versions:

- 2020.2 - tsm services (`tsm.log.level`) and control application services (`tsm.-controllerapp.log.level`).
- 2020.3 - backgrounder (`backgrounder.log.level`), cluster controller (`cluster-controller.log.level`), data server (`dataserver.log.level`), file store

## Tableau Server on Linux Administrator Guide

- (`filestore.log.level`), data source properties (`tdsservice.log.level`), and VizQL server (`vizqlserver.log.level`).
- 2020.4 - adds interactive microservice container (`tomcatcontainer.log.level`) and application server (`vizportal.log.level`).

### Configuration Keys for Changing Logging Levels

This table includes both dynamically configurable keys and those that are not dynamically configurable.

| Configuration key  | Location of affected logs<br>(path begins with <code>/var/opt/tableau/tableau_server-</code><br><code>/data/tabsvc/logs/</code> )  |
|--|--|
| <p><code>tsm.log.level</code></p> <p>Changes TSM logging levels for: <code>clientfileservice</code>, <code>licenseservice</code>, <code>tabadminagent</code>, <code>tabadmincontroller</code>, <code>tabsvc</code></p> | <p><code>/&lt;service&gt;/&lt;service&gt;_node&lt;n&gt;-&lt;instance&gt;.log</code></p> <p><b>example:</b> <code>/clientfileservice/clientservice_nodel-0.log</code></p>   |
| <p><code>tsm.controlapp.log.level</code></p> <p>Changes TSM logging levels for: control applications</p>   | <p><code>/&lt;service&gt;/control_&lt;service&gt;_node&lt;n&gt;-&lt;instance&gt;.log</code></p> <p><b>examples:</b> <code>/clientfileservice/control_clientservice_nodel-0.log</code></p> <p><code>/filestore/control_filestore_nodel-0.log</code></p> |
| <p><code>&lt;process&gt;.native_api.-log.level</code></p>  | <p><code>/vizqlserver/*.txt</code></p>   |

|  |                          |
|--|--------------------------|
| Valid process names are backgrounder, vizportal, vizqlserver, dataserver |                          |
| <b>Note:</b> These are not dynamically configurable.                     |                          |
| backgrounder.log.level   | /backgrounder/*.log      |
| Changes logging levels for: Backgrounder                                 |                          |
| clustercontroller.log.level  | /clustercontroller/*.log |
| Changes logging levels for: Cluster Controller                           |                          |
| dataserver.log.level   | /dataserver/*.log        |
| Changes logging levels for: Data Server                                  |                          |
| filestore.log.level  | /filestore/*.log         |
| Changes logging levels for: File Store                                   |                          |
| gateway.log.level  | /gateway/*.log           |
| Changes logging levels for: Gateway control processes                    |                          |
| gateway.httpd.loglevel   | /gateway/*.log           |
| <b>Note:</b> added in version 2021.3.0                                   |                          |
| Changes logging levels for: Gateway                                      |                          |
| hyper.log.level  | /hyper/*.log             |
| Changes logging levels for: Hyper  |                          |

## Tableau Server on Linux Administrator Guide

|  |                                     |
|--|-------------------------------------|
| <code>tdsservice.log.level</code>  | <code>/tdsservice/*.log</code>      |
| Changes logging levels for: Data Source Properties service   |                                     |
| <code>tomcatcontainer.log.level</code>   | <code>/tomcatcontainer/*.log</code> |
| Changes logging levels for microservices in: Interactive Microservice Container and Non-Interactive Microservice Container |                                     |
| <code>vizportal.log.level</code>   | <code>/vizportal/*.log</code>       |
| Changes logging levels for: Application Server   |                                     |
| <code>vizqlserver.log.level</code>   | <code>/vizqlserver/*.log</code>     |
| Changes logging levels for: VizQL Server   |                                     |

For more information, see [tsm configuration set Options](#).

If you are only changing dynamically configurable logging levels, you do not need to stop or start the server (for more information, see [Dynamic log level configuration](#) above). If you are changing other logging levels, you may need to stop Tableau Server before changing the logging levels, and restart it afterward. If this is the case, you will be prompted.

On a multi-node installation of Tableau Server, set logging levels from the initial node.

To change the logging level:

1. (Optional for dynamically configurable logging levels in 2020.2.0 and later) Stop Tableau Server by opening a command prompt and typing:

```
tsm stop
```

2. Set the logging level to by typing `tsm configuration set -k <config.key> -v <config_value>`

where `<config.key>` is one of the keys in the above table and `<config_value>` is a valid logging level.

Examples:

- `tsm configuration set -k backgrounder.native_api.log.level -v debug`
- `tsm configuration set -k tsm.log.level -v debug`
- `tsm configuration set -k tsm.controlapp.log.level -v debug`

3. Apply pending changes by running the `tsm pending-changes apply` command.
4. (Optional, only if server is stopped) Start Tableau Server by running the following command:

```
tsm start
```

### Reset Logging Levels

After you reproduce the issue and gather the information related to the issue, reset the logging levels so there is no lingering performance impact and no additional disk space used up.

Reset the logging level back to its default (info) using the appropriate command with a `-d` option. You need to apply pending changes after resetting the level, and if you are resetting logging levels for Tableau Server processes, you may need to stop the server before making the change, and start it after applying the pending changes.

Examples:

- `tsm configuration set -k backgrounder.native_api.log.level -d`
- `tsm configuration set -k tsm.log.level -d`

## Troubleshoot Tableau Server Install and Upgrade

Follow the suggestions in this topic to resolve common issues with Tableau Server. For additional troubleshooting steps based on process status viewed on the Status page, see [Troubleshoot Server Processes](#).

### General Troubleshooting Steps

Many Tableau Server issues can be addressed with some basic steps:

1. Make sure there is enough disk space on each computer running Tableau Server. Limited disk space can cause a failure to install, a failure to upgrade, or problems running Tableau Server.
2. Restart Tableau Server. Issues related to processes not fully started can be resolved by restarting Tableau Server in a controlled way. To restart Tableau Server, use the `tsm restart` command. This will stop all the processes associated with Tableau Server and then restart them.
3. Reindex Tableau Server. Issues related to indexing can be resolved by reindexing Tableau Server. To reindex Tableau Server, use the `tsm maintenance reindex-search` command. For more information, see [Reindexing Tableau Server Search & Browse](#) below.
4. Restart the computer on which Tableau Server is running. Some issues, such as those related to data source connectivity, can be resolved by restarting the server computer.

### Common Tableau Server Install Issues

#### Installation logs location

The install log, `app-install.log`, is located in `/var/opt/tableau/tableau_server-logs`.

The upgrade log, `app-upgrade.log`, is located in `/var/opt/tableau/tableau_server/logs`.

### Multiple install attempts fail

If you attempt to install Tableau Server and the install fails, any subsequent installation attempts are likely to fail unless you run the `tableau-server-obliterate` script to clean Tableau off the computer.

A failed install attempt can leave the computer in a state that causes subsequent attempts to also fail with errors that don't seem directly related to a previous install attempt. One possible error is:

```
Enabling and starting all services
+ services=(appzookeeper* tabadmincontroller* tabsvc* licenseservice*
fnlicenseservice* tabadminagent* clientfileservice*)
+ systemctl_user enable appzookeeper_0.service 'tabadmincontroller*'
'tabsvc*' 'licenseservice*' fnlicenseservice_0.service 'tabadminagent*'
'clientfileservice*'
++ id -ru a_tabadminpoc
+ local unprivileged_uid=222954
+ su -l a_tabadminpoc -c 'XDG_RUNTIME_DIR=/run/user/222954 systemctl
--user enable appzookeeper_0.service tabadmincontroller* tabsvc*
licenseservice* fnlicenseservice_0.service tabadminagent* clientfileservice*'
Failed to execute operation: No such file or directory
```

To fix this problem, run the `tableau-server-obliterate` script to clean up any left over remnants of the previous install attempt and then restart the computer. For more information, see [Running the `tableau-server-obliterate` script](#).

**Important:** If you created a backup of Tableau (`<file>.tsbak`) you want to keep (for example, to restore to your new installation), copy that file to a safe location on another computer to guarantee it is not removed when you clean up your Tableau computer.

## Tableau Server on Linux Administrator Guide

### Install fails due to hardware requirements

Tableau Server cannot install if the computer you are installing on does not meet the minimum hardware requirements. The requirements apply to all computers on which you are installing Tableau Server. For details on minimum hardware requirements, see [Minimum Hardware Requirements and Recommendations for Tableau Server](#).

### Install or upgrade fails due to CPU requirements

Beginning in version 2020.4.0 Tableau Server requires CPUs that support SSE4.2 and POPCNT instruction sets. You cannot install or upgrade Tableau Server 2020.4.0 or later on computers that have CPUs which do not support these instruction sets.

You may see this error message when installing a new installation, or in preparation for upgrading an existing installation:

```
Your computer's processor doesn't meet the minimum requirements that Tableau requires to install the software. If you are using a VM, make sure Processor compatibility mode is off.
```

The SSE4.2 and POPCNT instruction sets have been common for more than 10 years and most newer CPUs support them, but if you get an error related to processor minimum requirements when attempting to install or upgrade Tableau Server on a Virtual Machine (VM), Processor compatibility mode may be enabled on the VM. To successfully install or upgrade Tableau on a VM, make sure the Processor compatibility mode is turned off.

## Common Tableau Server Upgrade Issues

### Upgrade logs location

The upgrade log, `app-upgrade.log`, is located in `/var/opt/tableau/tableau_server/logs`.

### Maps do not display or display incompletely after upgrading

Beginning with Tableau version 2019.2, the internet access requirements changed for maps. If you are upgrading from version 2019.1.x or earlier to version 2019.2.x or later, and maps are

not displaying as expected, confirm that your environment is configured to allow access on port 443 to `mapsconfig.tableau.com` and `api.mapbox.com`.

In version 2019.1.x or earlier, access was necessary to `maps.tableausoftware.com`.

For more details on internet access requirements, see [Communicating with the Internet](#).

Upgrade script error: "Tableau Server Version change validation failed."

When upgrading, if you run the `upgrade-tsm` script from the `scripts.<version_code>` directory for the earlier version, the upgrade will fail with an error:

```
Tableau Server Version change validation failed.  
Tableau Server <version> is already installed.
```

If you get this error, change to the `scripts.<version_code>` directory for the version you just installed and run the script from there.

Upgrade multi-node, initializing additional node fails with "Enter your credentials again" error

If you attempt to initialize an additional node when upgrading Tableau Server and see this error:

```
Enter your credentials again. The credentials you enter must  
provide administrative access to the computer where you generated  
the configuration file.
```

this is an indication that the node is unable to connect to or communicate with the initial node.

This can happen for multiple reasons:

- The credentials you entered are not valid or you mistyped them. The credentials must be for a user who has administrative permissions on the computer where Tableau Server was first installed. You do not need to use the credentials of the user who created the bootstrap file but doing so will ensure you are using valid credentials.
- The local firewall of the computer you are trying to add is not allowing communication to the initial node. For more information, see [Local firewall configuration](#).

## Tableau Server on Linux Administrator Guide

### Upgrading fails due to lack of disk space

If there is not enough disk space for the Tableau Server Setup program to run and do the upgrade, the installation will fail. The amount of disk space required will depend on the size of your repository database and the number and size of your extracts.

To free up disk space:

1. Create a log archive snapshot using the `tsm maintenance ziplogs` command.

After you create the ziplogs file, save it to a safe location that is not part of your Tableau Server installation.

2. Clean up unnecessary files using the `tsm maintenance cleanup` command. For more information, see [Remove Unneeded Files](#).

### Upgrade fails on RebuildSearchIndex job

Beginning with version 2020.1.x, the final step in an upgrade is to rebuild the search index. At this point all services have been upgraded, so if this job fails, you can manually reset the search server by running the `tsm maintenance reset-searchserver` command. You do not need to obliterate and start over.

The error will be:

```
An error occurred while rebuilding search index.
```

To reset the search server :

1. On the initial node, open a terminal session.

This must be a new terminal session because the upgrade script updates system environment for the new version.

2. Rebuild the search index using the `tsm maintenance reset-searchserver` command.

### Upgrade fails on 2022.1 and later

After upgrading Tableau Server 2022.1 (or later), restoring a Tableau Server backup as part of your upgrade process can cause the following error:

*“The backup cannot be restored because Tableau Server uses the new identity service tables by default.”*

This issue occurs because Tableau Server 2022.1 (and later) uses an identity schema that is different from the identity schema used by the backup. To resolve this issue, see [Troubleshoot Issues with the Identity Migration](#).

### Upgrade fails on 2020.4.0 or later

Beginning with version 2020.4.0, the Checkpoint Upgrade feature allows you to retry a failed upgrade. In general, this is most useful for experienced server administrators and IT professionals who are comfortable with Tableau Server log files and are willing to search through them. But the feature can help in all failed upgrades because it allows you to rerun the `upgrade-tsm` script, and the script is run from the last successful step, saving time. For those with experience, it may be possible to identify problems like disk space problems, or permissions issues, correct them, and rerun the upgrade.

If you are upgrading to version 2020.4.0 or later and the upgrade fails, the following steps may help you to complete the upgrade:

- Rerun the `upgrade-tsm` script. Upgrade failures are sometimes a result of timeouts during the upgrade process, and rerunning the script can allow the upgrade to get beyond intermittent or occasional timing issues. This is also a step that is safe to do, and easy. Rerunning the script will do no harm, and at worst, the upgrade will fail again at the same point, but without needing to go through any previous steps.

The script is located in the `\scripts` directory:

```
opt/tableau/tableau_server/packages/scripts.<version_code>/upgrade-tsm
```

## Tableau Server on Linux Administrator Guide

If your Tableau Server upgrade isn't successful when you rerun the `upgrade-tsm` script, and you are comfortable with Tableau Server logs, you can take these additional troubleshooting steps:

- Look at the output of the script in the command window. Useful error messages may help you identify the cause of the upgrade failure and give you some ideas for how to correct the issue.
- Look in the `app-upgrade.log` file. Any errors that are displayed at the command line will also appear in the `app-upgrade.log` file, often with more details.
- Look in the `tabadmincontroller.log` file. Upgrade problems that aren't easily identifiable in the above two instances are likely the result of an issue in a job. The `tabadmincontroller.log` file may have more information that helps you diagnose the issue.

**Note:** For information about log file locations, see [Tableau Server Logs and Log File Locations](#).

### Upgrade fails due to permission problems with the backup/restore file location

With versions of Tableau Server before 2022.1.0, if the file location for the backup/restore file does not have the correct permissions, the upgrade script will fail with an error about not being able to read the backup file or not being able to restore the repository.

Beginning with version 2022.1, the upgrade script confirms the permissions of file location for the backup/restore file before starting the upgrade so the file can be written to and read from the location during the upgrade to the new version of Tableau Server.

The errors will be similar to these:

```
The tableau user does not have permission to read the backup file:  
<backup/restore basefilepath>.
```

```
Repository restore failed.
```

An error occurred during installation.

An error occurred while restoring repository.

The location used by TSM for backup and restore is defined by the `base-filepath.backuprestore` configuration key and has a default that the installation program sets up with correct permissions, but these may be impacted by organization IT rules or if you change the location to one you have created yourself. A new command available starting in 2022.1 allows you to check the permissions on the backup/restore file location immediately after creating it, to avoid any permission-related problems. For details about that command, see `tsm maintenance validate-backup-basefilepath`.

For details about the backup/restore file path, see `tsm File Paths`.

## Common Settings Import Issues

Import of settings file causes "not present on any node" validation error due to missing services

If you are upgrading by installing a new version of Tableau Server and importing a settings file from an earlier version, you may encounter topology validation errors when running the `tsm settings import` command.

This can happen when you export a settings file from an older version of Tableau Server and import it into a new version, and new services have been added to Tableau between the two versions.

Errors will be similar to this (the specific service may be different):

```
>tsm settings import -f 20183-export.json
```

```
Pending topology set.
```

```
There are 1 topology validation errors/warnings.
```

```
Service 'elasticsearch' is not present on any node in the cluster.
Service: Elastic Server
```

To resolve this issue, add any missing services to Tableau Server:

## Tableau Server on Linux Administrator Guide

1. For any service that generated a validation error, add the service with an instance count of 1.

For example, if the Elastic Server is not present in the cluster, set the process instance count to 1 using the service name that appears in the first line of the validation error message:

```
tsm topology set-process -n node1 -pr elasticserver -c 1
```

Repeat this step for each service that results in an error.

2. When you have no more warnings or errors, apply the pending changes:

```
tsm pending-changes apply
```

Your settings should be imported successfully.

Import of settings file causes "configuration value you specified does not match" error

If you are installing a new version of Tableau Server and import a settings file from an earlier version, you may encounter configuration validation errors when running the `tsm settings import` command. These can occur when a settings file includes a configuration value that has since been removed from Tableau.

The error will look similar to this (the configuration key may be different):

```
>tsm settings import -f 20183-export.json
Configuration error: At least one configuration value you specified
does not match a known configuration key. This applies to the fol-
lowing keys: '[features.TsmConfigFileService]'
Use this parameter to override unknown key error: --force-keys
```

To resolve this issue, edit the settings file you are importing to remove the reference to the configuration key or keys in the error:

1. Copy the JSON settings file and save the copy for backup.
2. Open the JSON settings file in a plain text editor.

3. Locate and delete the entire line that includes the key. In this example, `features.TsmConfigFileService`:

```
"configKeys" : {
  "config.version" : 19,
  "tabadmincontroller.port" : "8850",
  "endpoints.enabled" : false,
  "endpoints.health.enabled" : true,
  "features.TsmConfigFileService" : true,
  "tableau_projects.language" : "en",
```

The above is an example of a small section of an exported settings file and is not intended to represent the entire contents of the file.

4. Save the settings file and import it again.

You may encounter additional errors related to topology validation. For information about solving those errors, see [Import of settings file causes "not present on any node" validation error due to missing services above](#).

"You cannot directly modify instances of the Coordination Service" error

This error can occur in two situations:

- When you import a Tableau Server settings file into an installation that has a different Coordination Service topology than the settings file does
- When you attempt to configure the Coordination Service using the `tsm topology set-process` command

If you see this error after importing a settings file:

The Tableau Server settings file has a different Coordination Service topology than the target server does. This can happen if you are upgrading Tableau Server by installing a new version and importing a settings file from an earlier version. If you have not explicitly deployed a Coordination Service ensemble on the target server, it has a single instance of Coordination Service, on the initial node.

To correct this error you can take either correct the mismatch from the command line, or by editing the settings import file. You can also discard all pending changes, deploy the Coordination Service on the target computer to match the settings in the import file, and reimport the settings file.

To correct the mismatch from the command line, for each node that generates an error, use the `tsm topology set-process` command to revert the instance count of Coordination Service.

1. Run the `tsm pending-changes list` command. The output shows you which nodes have changes.
2. Find the node or nodes where the Coordination Service count is changed.

For example, if the settings file had a Coordination Service instance on node2, but the target system did not have any Coordination Service instance on that node, the count for node 2 would show as changed from 0 to 1 by the import of the settings file:

```
C:\Windows\system32>tsm pending-changes list
Configuration
There are no pending configuration changes.
Topology
node2:
        Coordination Service
                                New Instance Count:1
                                Old Instance Count:0
```

3. Use the `tsm topology set-process` command to set the count back to the "Old Instance" value.

For the example above:

```
tsm topology set-process -n node2 -c 0 -pr "Coordination Service"
```

4. Once you have reset any Coordination Service instance count that was changed, apply

pending changes:

```
tsm pending-changes apply
```

If you see the error when setting the process count for Coordination Service manually:

This error can also occur if you attempt to update the Coordination Service directly, using the `tsm topology set-process` command instead of the `tsm topology` commands for managing the Coordination Service. If you tried this:

1. Use the `tsm pending-changes discard` command to discard the pending changes.
2. Use the correct commands for configuring the Coordination Service. For more information, see [Deploy a Coordination Service Ensemble](#) .

## Starting Tableau Server

Tableau Server cannot determine if it fully started

In some instances Tableau Server may report that it could not determine if all components started properly on startup. A message displays: "Unable to determine if all components of the service started properly."

If you see this message after starting, verify that Tableau Server is running as expected by using a `tsm status -v` command.

If the status shows as running ("Status: RUNNING"), then the server successfully started and you can ignore the message. If the status is DEGRADED or STOPPED, see "Tableau Server doesn't start" in the next section.

Tableau Server doesn't start

If Tableau Server does not start or is running in a degraded state, run the `tsm restart` command from a command prompt. This will shut down any processes that are running, and restart Tableau Server.

## Reindexing Tableau Server Search & Browse

Problems that can be solved by rebuilding Search & Browse index

Symptoms of an index that needs to be rebuilt include:

- A blank list of sites when a user attempts to log in
- A blank list of projects when a user tries to select a project
- Missing content (workbooks, views, dashboards)
- Unexpected or inaccurate alerts (for example, an "refresh failed" alert on a workbook that does not include an extract)

If you see any of these behaviors, reset and rebuild the Search & Browse index using the `t-smaintenance reset-searchserver` command.

## Activating Tableau Server

Tableau Server license activation fails

In some instances Tableau Server license activation may fail. Error messages can range from a very generic one:

- `An error has occurred`

To more specific messages:

- `Function flxActCommonLicSpcPopulateFromTS returned error 50030, 71521,`
- `No license found for 'Tableau Server'`

To resolve this issue, try these solutions in the order listed:

Confirm you can access the licensing server

The Tableau licensing service was moved to a new data center on October 6, 2018. This means any environments that required special configuration (static IP safe listing for example) to access `licensing.tableau.com` or `licensing.tableau.com` will need to be updated before you can activate, refresh, or deactivate a Tableau product key.

To test access, type the URL and the port of the licensing server in a browser:

```
https://licensing.tableau.com:443
```

and:

```
https://atr.licensing.tableau.com/_status/healthz
```

If you are able to access the server, a "Test success" message displays for the first server, and an "OK" message displays for the second.

Tableau Server needs to make a connection to the following internet locations for licensing purposes:

- atr.licensing.tableau.com:443
- licensing.tableau.com:443
- register.tableau.com:443
- o.ss2.us
- s.ss2.us
- crt.rootca1.amazontrust.com
- crt.sca1b.amazontrust.com
- crt.sca0a.amazontrust.com
- crt.sca1a.amazontrust.com
- crt.sca2a.amazontrust.com
- crt.sca3a.amazontrust.com
- crt.sca4a.amazontrust.com
- \*.digicert.com

## Tableau Server on Linux Administrator Guide

- `ocsp.*.amazontrust.com`
- `crl.*.amazontrust.com`

Requests to the above domains may be on port 80 or 443. Port 80 is used for certificate validation (revocation, certificate chain, etc). Port 443 is used for SSL connections.

Requests to the `ocsp.*.amazontrust.com` and `crl.*.amazontrust.com` domains are managed by Amazon for certificate revocation information. See [ACM certificate characteristics](#) for more information.

### Verify the date and time

Verify the date and time on the initial Tableau Server computer is correct. If the clock is set to a time and date earlier than the current date, Tableau Server cannot be activated.

### Force the product key to be read again

1. On the initial Tableau Server computer, log on as a user with sudo access.
2. Change to the Tableau Server bin directory. By default this is:

```
/opt/tableau/tableau_server/packages/bin.<version_code>/
```

3. Type the following commands:

```
tsm stop
```

```
./lmreread
```

```
tsm start
```

### Send the contents of trusted storage to Tableau Support

If FlexNet Licensing Services is installed and running but you're still seeing an error, there might be a problem with the Tableau product key information. To resolve this issue, complete the following steps to create a file of the key information located in trusted storage.

1. On the initial Tableau Server computer, log on as a user with sudo access.
2. Type the following command:

```
serveractutil -view > <machine_name>-LicResults.txt
```

This creates the `<machine_name>-LicResults.txt` file in your current directory. If you don't have write permissions for that location and see an error, change to a location where you do have permission to create a file and run the command again.

3. Contact Tableau Support (<http://www.tableau.com/support/request>) and include the `<machine_name>-LicResults.txt` file that you created.

## tabcmd Installation Problems

### Installing tabcmd separately

tabcmd is automatically installed on the initial Tableau Server node when you install Tableau Server, but if you want to run it on another computer, you need to download and install tabcmd separately. For details, see [Install tabcmd](#).

### Problems installing tabcmd on Linux

tabcmd requires Java 11 to run properly. On RHEL-like systems, this will be installed as a dependency when installing tabcmd. On Debian-like systems, you need to install Java 11 separately if it is not already installed.

As of July 2022, Debian distributions are no longer supported. For more information, see [this Tableau Community post](#).

### Java is not installed

If you see errors similar to this when installing tabcmd, confirm that Java 11 is installed on your Linux computer:

```
Cannot find 'java' in your PATH. Install 'java' and make sure it is  
in your PATH to continue.
```

## Tableau Server on Linux Administrator Guide

### Incorrect version of Java is installed

If you see errors similar to these, confirm that Java 11 is installed:

```
Exception in thread "main" java.lang.UnsupportedClassVersionError:  
com/tableausoftware/tabcmd/Tabcmd : Unsupported major.minor version  
52.0
```

or.

```
*** Uncaught exception NoClassDefFoundError: javax/xml-  
1/bind/JAXBException  
*** See the logs for the stacktrace.
```

### systemd User Service Failures

You may receive one of the following errors when upgrading or when running `initialize-tsm` during a fresh installation:

- "Failed to get D-Bus connection: No such file or directory"
- "\$XDG\_RUNTIME\_DIR not found"
- "systemd unit user@<userID> is not running. Check /var/log/messages or /var/log/syslog."

#### Background

As of 2018.1, Tableau Server uses the `systemd` user service to manage processes. This means there is a `systemd` process that runs as the unprivileged user. By default, Tableau Server Setup creates an unprivileged account named `tableau`. The Tableau Server processes are spawned from the `systemd` process and not the system-wide `systemd` process, which runs as root.

**Important:** This troubleshooting note applies primarily to RHEL 7-based distros. However, if you see one of these errors, it's possible that the same issues exist on Ubuntu distros.

The `systemd` user service is not used as commonly as the normal `systemd` process manager. Red Hat disabled the `systemd` user service in RHEL 7 (and thereby all distros that come from RHEL, like CentOS, Oracle Linux 7, Amazon Linux 2). However, RedHat has assured Tableau that running the `systemd` user service is supported as long as the service is re-enabled.

### Upgrading from Tableau Server on Linux 10.5

If you are upgrading from Tableau Server 10.5, check that the unprivileged user has a valid shell and home directory. For Tableau Server 10.5, Tableau deliberately created the unprivileged user with shell set to `/sbin/nologin` and home directory `"/`". If the unprivileged user was created by `initialize-tsm`, then during upgrade to 2018.1 Tableau updates the shell and home directory.

However, if you created the unprivileged user during the initial installation of 10.5, then you will get an error when trying to upgrade.

To fix this, you must set the shell to `/sbin/nologin` and the home directory `"/`", and then run upgrade again.

### Fresh installation error troubleshooting

Verify that the `systemd` user service is running.

Check by running the command, `ps -fww $(pgrep -f "systemd --user")`

If the `systemd` user service is not running, then something prevented it from starting.

Follow this list to troubleshoot:

- Check the logs in `/var/log/messages`
- Run `journalctl`
- Verify that any customization that you may have done to your PAM configuration includes has not removed `pam_systemd.so`.

## Tableau Server on Linux Administrator Guide

If the RHEL 7 PAM file, `/etc/pam.d/system-auth` is missing the following line:

```
-session optional pam_systemd.so
```

then it must be added back for Tableau Server to function.

- If `-session optional pam_systemd.so` is present in your PAM configuration, the user service cannot start, and the error message `$XDG_RUNTIME_DIR not found` is showing in `/var/log/messages`, do not attempt to set the environmental variable. In this scenario, the error is not accurate.

The real error is that the PAM module `pam_systemd.so` is unable to allocate the user session. The default configuration suppresses error messages from `pam_systemd.so`. To surface error messages and debug messages, change the line in `/etc/pam.d/system-auth` from `-session optional pam_systemd.so` to `session optional pam_systemd.so debug`. (Removing the leading hyphen will surface the error messages, and adding `debug` will surface more verbose logging.)

Now you can look in `/var/log/messages`, `/var/log/secure` and `/var/log/audit/audit.log` files to see error messages.

### Example

You may see the following error message:

```
systemd-logind: Failed to mount per-user tmpfs directory /run-  
/user/0: Permission denied
```

In this case, searching the error online leads to the Redhat KB article, <https://access.redhat.com/solutions/2460611>.

The article recommends updating the `selinux-policy` package by running `sudo yum update selinux-policy`.

In some cases, upgrading from version 3.12.X to 3.13.X fixes a `$XDG_RUNTIME_DIR not found` problem. Be sure to run `sudo reboot` after updating the package.

## Troubleshoot Job Failures Due to Service Failures

Beginning in Tableau Server version 2021.1, a new set of error messages help you understand when jobs fail due to an issue with a service. This topic explains the messages and what they can mean.

An error message will display in this format:

```
<nodeId>
<service>_<instanceId>.<version>: <error>
```

There are four categories of errors:

- **Missing status** - If a service is unable to report its status, for example, if a node is down, if tabadminagent is unable to report status, or if a service has failed in a way that results in its dependent services not being able to be installed, this will show up as a "missing status" error.
- **Failed to update configuration** - If a service is unable to update its configuration file, this shows up as a "failure to update configuration" error. This may occur during upgrades, when attempting to apply pending changes to new services. See the service's control app log, `<dataDir>\tabsvc\logs\<service>\control-<service>_<nodeId>-<instanceId>` for more details about the error.
- **Failed to reach the requested state. Current state:<currentState>** - If a service cannot be installed/removed/started/stopped, this results in a "failed to reach requested state" error. This can happen during upgrades when new services are being installed and old ones removed. Possible options for `<currentState>` are: `DEPLOY_FAILED`, `INSTALL_FAILED`, `DISABLE_FAILED`, `ENABLE_FAILED`, `CONFIGURE_FAILED`, `UNINSTALL_FAILED`, `REMOVE_FAILED`. Most common are: `INSTALL_FAILED`, `UNINSTALL_FAILED` and `REMOVE_FAILED`. See the service's control app log, `<dataDir>\tabsvc\logs\<service>\control-<service>_<nodeId>-<instanceId>` for more details about the error.
- **Failed to start/stop. Current status: <currentStatus>** - This occurs if a service that should be running is stopped or if a service that should be stopped continues to run. Possible values in `<currentStatus>` are: `ACTIVE`, `BUSY`, `PASSIVE`, `UNLICENSED`, `DOWN`, `STATUS_UNAVAILABLE` and `DEGRADED`. The first three (`ACTIVE`, `BUSY`, `PASSIVE`) are considered "running" statuses. The last four are a "stopped" status. See

## Tableau Server on Linux Administrator Guide

the main service log, `<dataDir>\tabsvc\logs\<service>\<service>_<nodeId>-<instanceId>.log`, for more details about the error.

An example of an error message is:

```
This job failed due to unexpected error: 'ServiceOperationTimeoutException'
One or more services failed to reach their expected state.
node1:
    vizportal_0.2021.4.0.0: Failed to reach requested state. Current state: INSTALL_FAILED
```

Beginning in version 2021.3, an additional error message has been added for the second and third error types that will match the errors found in the control app logs.

## Troubleshoot Server Sign in Problems

There are several different sign in options between Tableau Services Manager (TSM) and Tableau Server.

- **TSM**—If you are not able to sign into TSM, make sure you are using credentials for a user who has administrative rights to the computer where TSM is installed. This user may or may not also be a Tableau Server administrator. This is true whether you are signing in to the Web UI or the CLI. For more information, see [Sign in to Tableau Services Manager Web UI](#).
- **Tableau Server**—
  - **Administrators:** if you are signing into Tableau Server as an administrator, you must use credentials for a user who has an administrator role in Tableau Server. You create the initial administrator when you first install Tableau, but can add other users as administrators once Tableau is installed and running. For more information, see [Sign in to the Tableau Server Admin Area](#).

- Non-administrative users: If you are signing into Tableau Server as a user, you need to use credentials for a user who has been added to Tableau Server. For more information, see [Sign in to Tableau Server or Tableau Cloud](#).

**Note:** If users with valid credentials are unable to sign into Tableau Server, make sure you have not added a node without applying pending changes. If you have a pending new node, signing into Tableau Server may not be possible.

## Troubleshooting scenarios

### Troubleshoot Licensing

This topic includes instructions for troubleshooting issues related to Tableau Server licensing.

#### Handle an unlicensed server

Tableau offers two licensing models: role-based and core-based. To learn more about role-based and core-based licensing, see [Licensing Overview](#).

role-based licensing requires each active user account to be covered by a license. role-based licenses have a defined capacity, or number of users that they allow. Each user is assigned a unique user name on the server and is required to identify themselves when connecting to the server.

Core-based licensing has no constraints on the number of user accounts in the system, but it does restrict the maximum number of processor cores that Tableau Server can use. You can install Tableau Server on one or more machines to create a cluster, with the restriction that the total number of cores in all the machines does not exceed the number of cores you have licensed and that all of the cores on a particular machine are covered by the license.

## Tableau Server on Linux Administrator Guide

### Unlicensed role-based server

The most common reason for a server that has role-based licensing to be unlicensed is an expired product key or an expired maintenance contract.

### Unlicensed core-based server

A core-based server can become unlicensed for a variety of reasons, such as an expired product key or when Tableau Server nodes running licensed processes cannot contact the Tableau Server node running the License Manager service. To learn more about licensed processes, see [Tableau Server Processes](#).

When the server is unlicensed you may not be able to start or administer the server. You can, however, manage your licenses using the `tsm licenses` command.

### Unlicensed server administrator

All Tableau Server administrators require a user license. Tableau Server administrators will always consume the highest role available. If a Creator product key is activated, the Tableau Server Administrator(s) will take this role. If the highest role available on Tableau Server is an Explorer, the Server Administrator will take the Explorer role. If Creator licenses are added to the server, any existing Server Administrator accounts using Explorer licenses will automatically convert to use Creator licenses.

TSM administrator accounts do not require licenses.

If the license that the server administrator is using expires, then the account will become unlicensed and will be unable to sign in.

Verify the expiration date of your license(s) for the administrators on the server:

- Run `tsm licenses list`.
- Compare the date with the date displayed in the [Tableau Customer Portal](#).
- If the portal does not display the date that you expect, contact [Customer Success](#).
- To renew your license, visit the [Tableau renewal](#) web page.
- Run the `tsm licenses activate` command to activate a new license for the administrator account(s).

If the TSM date matches the portal date and the following refresh operation fails, contact [Tableau Support](#).

If the license for your administrator account has expired or will expire soon, you will need to activate a new license for the account. Alternatively, you can unlicense a non-administrator user to free a license for the server administrator account.

If a Tableau Server administrator is using a Creator, Explorer or Viewer license and their license expires, they will use another license of the same type, if available. If no license seats are available the user will become “unlicensed”.

**Important:** Do not restart Tableau Server until you have activated a new license or transferred a site role for the server administrator account.

## Troubleshoot role-based licensing

This section provides information about resolving issues that can occur when adding the role-based Viewer, Explorer and Creator licenses to Tableau Server or Tableau Cloud, or when these licenses expire. The highest available license type is Creator, followed by Explorer, and finally Viewer. To learn more about role-based licensing, see [Licensing Overview](#).

A user or administrator is unlicensed due to license expiration

To avoid having users unexpectedly become unlicensed or move to another site role, you should always do one of the following before the license that they are currently using expires:

- Renew and activate a replacement license. If a user occupies a Creator, Explorer or viewer license and their license expires, they will use another license of the same type, if available.
- Change the site role of those users to allow the use of a license that is not due to expire.

To learn how site roles can be changed to require a different license, see [Set Users' Site Roles](#).

The reassignment of users to new licenses is governed by the following logic:

- When a Server Administrator user occupies a Creator license and their license expires (with no replacement licenses available), they are reassigned to an Explorer license if any Explorer licenses are available. This license reassignment occurs in order of most recent login. Server Administrators displace other users who might be currently using an Explorer license. If no Creator or Explorer licenses are available a Server Administrator becomes unlicensed.
- When a non-Server Administrator user occupies a Creator license and their license expires (with no replacement licenses available), they become unlicensed. To avoid having these users become unlicensed, change their site role prior to license expiration. This is especially important for users in the Site Administrator Creator site role, who must move to the Site Administrator Explorer site role before their Creator license expires to avoid losing Site Administrator capabilities.
- When a non-Server Administrator user occupies an Explorer or Viewer license and their license expires (with no replacement licenses available), they are upgraded to a higher license type, if licenses of that type are available. Specifically, the following occurs when a license expires:
  - Users who occupy an Explorer license will move to a Creator license, if available (with no change to site role).
  - Users who occupy a Viewer license will move to an Explorer license, if available. If no Explorer licenses are available, these users will move to a Creator license, if available (with no change to site role).
  - If no licenses are available at the higher license types, those users are moved to Unlicensed.

Users are reassigned to a new license as described above in order of most recent login, with lower license types reassigned first (first Viewer, then Explorer, and then Creator).

For example: Two users with a Viewer license, a user with the Creator license, and two Server Administrators with a Creator license all have their licenses expire. Four unexpired Explorer licenses are available for these users. In this situation, the following occurs in the order shown below:

1. The user with a Viewer license who logged in most recently is reassigned to an Explorer license.
2. The second user with a Viewer license is reassigned to an Explorer license.

3. The Server Administrator user with a Creator license who logged in most recently is reassigned to an Explorer license, and then the second Server Administrator with a Creator license is reassigned to the remaining Explorer license.
4. The user with the Creator license becomes unlicensed.

Server Administrator site role is unchanged when using a Creator license

Server Administrators gain Creator capabilities if Creator licenses are available in Tableau Server, with no change to their site role name. All other Tableau Server and Tableau Cloud users gain Creator licenses only if assigned to a site role that includes Creator in its name.

Licenses are not immediately available

When you add a role-based license to Tableau Server, those licenses become available to all users when you restart Tableau Server.

A user with a Viewer license cannot open Tableau Server or Tableau Cloud workbooks from Tableau Desktop

A user with a Viewer license who also has a separate Tableau Desktop license will be unable to open workbooks on Tableau Server or Tableau Cloud using Tableau Desktop. To open workbooks such using Tableau Desktop, that user will need an Explorer or Creator license on Tableau Server or Tableau Cloud.

## Handle an Unlicensed Server Process

There are several status indicators on the Tableau Server Status page that help you understand the state of Tableau Server processes. An orange-color status box, "Unlicensed", indicates that one of the server processes is unable to retrieve the Tableau Server license information.

In the image below, one of the VizQL processes is unlicensed:

**Process Status**  
The real-time status of processes running in Tableau Server.

| Process            | Primary<br>10.32.139.21 | Worker<br>10.32.139.22 |
|--------------------|-------------------------|------------------------|
| Gateway            | ✓                       | ✓                      |
| Application Server | ✓                       | ✓                      |
| API Server         | ✓                       | ✓                      |
| VizQL Server       | ✓ ✓                     | ⚠                      |
| Cache Server       | ✓ ✓                     | ✓ ✓                    |
| Search & Browse    | ✓                       | ✓                      |
| Backgrounder       | ✓                       | ✓                      |
| Data Server        | ✓ ✓                     | ✓ ✓                    |
| Data Engine        | ✓                       | ⊘                      |
| File Store         | ✓                       | ⊘                      |
| Repository         | ✓                       | ⊘                      |

✓ Active
🔄 Busy
⊘ Passive
⚠ Unlicensed
✖ Down
⊘ Status unavailable

There may be several reasons why a process is unable to access licensing information. For example, there may be network issues preventing a process running on an additional node from communicating with the licensing service on the initial node. Or, the unlicensed process may be getting sent more requests than it can accept at a particular moment and can't handle the licensing request. The impact to users depends on which process is unable to confirm its license, and whether there are other instances of the process on one of the server nodes. In the case of the unlicensed VizQL process above, some users may be able to access views while others cannot.

To resolve the problem, **stop**, then **start** Tableau Server.

## Tableau Services Manager (TSM) Command Timeout

When Tableau Server is configured with two instances of the repository and failover to the backup repository occurs, TSM attempts to restart the original repository so that it is available as a backup. If this cannot be done for any reason, subsequent TSM commands can fail due to timeouts while waiting for the original repository to recover.

Commands that can be impacted include:

- `tsm maintenance restore`
- `tsm maintenance reindex-search`
- `tsm reset`
- `tsm security regenerate-internal-tokens`
- `tsm sites export`
- `tsm sites import`

If any of these commands is failing, and you have a repository that is not recovering, remove the repository from the server topology, apply pending changes, and re-add it.

## Troubleshooting Tableau Services Manager (TSM) Backup

### Backup fails to start because services do not start

When you back up Tableau Server, one of the first steps taken is to confirm that key services are running, and, if they are not, to start them. If these services cannot be started:

- Active Repository
- File Store
- Cluster Controller

any attempt to back up Tableau Server will fail with one of the following errors:

```
An error occurred starting one or more of the following services:  
Active Repository, File Store, Cluster Controller.
```

```
One or more of the following services did not start in a timely  
fashion: Active Repository, File Store, Cluster Controller.
```

To successfully back Tableau Server up, make sure these processes can start.

### Cookie Restriction Error

When a user signs in to Tableau Server, a session cookie is stored in their local browser. The stored cookie is how Tableau Server maintains that the signed in user has been authenticated and can access the server. Because the cookie is set with the same domain or sub-domain as

the browser's address bar, it is considered a first-party cookie. If a user's browser is configured to block first-party cookies, they will be unable to sign in to Tableau Server.

When a user signs in to Tableau Server via an embedded view, or in an environment where trusted authentication has been configured, the same thing happens: a cookie is stored. In this case, however, the browser treats the cookie as a third-party cookie. This is because the cookie is set with a domain that's different from the one shown in the browser's address bar. If a user's web browser is set to block third-party cookies, authentication to Tableau Server will fail. To prevent this from occurring, web browsers must be configured to allow third-party cookies.

## Troubleshoot Subscriptions

"The view snapshot in this email could not be properly rendered."

If you receive a subscription with this error message, there could be several reasons:

- **Missing credentials:** Some views are published with embedded credentials. You may receive the above error if the embedded credentials are now out-of-date, or if the view was republished without the embedded credentials.
- **Database temporarily down:** If the view has a live database connection and the database was temporarily down when the subscription was being generated, you might receive the above error.
- **Background process timeout:** By default, the background process that handles subscriptions has a timeout value of 30 minutes per view for the rendering of a view. If rendering a view goes beyond this time limit, the next view in the workbook results in a failed job due to the timeout. In the majority of cases, this default is plenty of time. However, if the background process is handling an extraordinarily large and complex dashboard, that may not be enough time. You can check the Background Tasks for Non Extracts admin view to see if that's the case. To increase the timeout threshold, use the `tsm configuration set subscriptions.timeout` command.

## Can't see images in email

For images of content to display in a subscription email, users subscribed to views, in addition to **View** permissions, must also have **Download Image/PDF** permissions. For more information, see [Permissions](#).

## Can't subscribe

If you can see a view on Tableau Server and it has a subscription icon (✉+) in the upper right corner, you can subscribe to it.

To subscribe to a view, Tableau Server needs to be correctly configured (described in [Manage Subscriptions](#)) and the view you're subscribing to must either have embedded credentials for its data source or not rely on credentials at all. Examples of the latter include a workbook that connects to an extract that isn't being refreshed, or a workbook whose data is in a file that was included with the workbook at publish time. Embedding credentials is a step that happens in Tableau Desktop (see the [Tableau Help](#) for details).

## No subscription icon

It's possible to see a view but be unable to subscribe to it. This can happen because for several reasons:

- **No subscriptions have been scheduled:** If no subscriptions have been scheduled or all subscription schedules are disabled, the subscription icon will not appear. To set a schedule for subscriptions, see [Create or Modify a Schedule](#).
- **The view uses a live database connection:** Views with live database connections, where you're prompted for your database credentials when you first click the view, aren't available for subscription. A subscription includes a view (or workbook), data, and a schedule. To deliver the data required for the view, Tableau Server either needs embedded database credentials or data that doesn't require credentials. Where live database connections are concerned, Tableau Server doesn't have the credentials, only the individual users do. This is why you can only subscribe to views that either don't require credentials or have them embedded.
- **Tableau Server is configured for trusted authentication:** You may also be able to see a view but be unable to subscribe to it (no subscription icon) if Tableau Server is

configured for trusted authentication. See [Ensure Access to Subscriptions](#) for more information.

## Receiving invalid or "broken" subscriptions

If you configured subscriptions on test or development instances of Tableau Server in addition to your in-production instance, disable subscriptions on your non-production instances. Keeping subscriptions enabled on all instances can result in your users receiving subscriptions that appear to be valid, but which don't work, or receiving subscriptions even though they've unsubscribed from the view or workbook.

## Missing attachments

You can add a PDF attachment to your subscription if your administrator has it enabled. If the PDF attachment is missing from your subscription, it might be because the size of the PDF exceeds either the email server size limit or the maximum size limit set by server administrators. In Tableau Server, the maximum size limit for PDF attachments to subscriptions can be adjusted through the tsm configuration option `subscriptions.max_attachment_size_megabytes`. For more information, see [Configure Server Event Notification and Set Up a Site for Subscriptions](#).

Starting in Tableau 2024.1, you can send emails with your own sending server, which will allow you to send attachments with a maximum email size of 10MB.

To enable this feature, navigate to site settings, find the **Customize Email Notifications** section, and check the box next to **Use your SMTP server**.

Note: If you're using your own sending server, Tableau will attempt to send a subscription email with a subset of the attachment that is under the 10MB limit, but this is not guaranteed. If Tableau can't send the attachment, you'll see a message letting you know that the attachment is too large to send.

## Suspended Subscriptions

By default, a subscription is suspended after 5 consecutive subscription failures. To change the threshold number of subscription failures that can occur before they are suspended, use the tsm configuration set option, `backgrounder.subscription_failure_threshold_for_run_prevention`. This sets the threshold for the number of consecutive failed subscriptions necessary before suspending the subscription. This is a server-wide setting.

Only Server administrators can configure the threshold number of subscription failures before a subscription is suspended. For information on setting this threshold, see [Set up a Server for Subscriptions](#).

By default, administrators are not emailed when a subscription is suspended, but can opt-in to suspension emails per site through **My Account Settings**.

Resume suspended subscriptions

Administrators and subscription owners can resume subscriptions in several ways:

- from My Subscription tab in Content Settings
- from the Subscriptions tab per workbook
- from the Subscriptions tab under Tasks (Server Admins only)

When a subscription is resumed, the alert failing count goes back to zero. The next evaluation of the subscription will occur at the next scheduled evaluation time.

Can't set subscription frequency to "When Data Refreshes"

You can set subscriptions to run when an extract refreshes if the workbook uses a connection to a published extract. When creating or modifying a subscription, you might not see a **Frequency** option if the workbook uses:

- More than one extract refresh
- A live data connection

## Subscriptions not arriving ("Error sending email. Can't send command to SMTP host.")

You may see the above error in Windows Event Viewer if subscriptions aren't arriving and your SMTP server is using encrypted (TLS) sessions. To send subscriptions to an SMTP server that is configured with TLS, you must configure secure SMTP on Tableau Server. See [Configure SMTP Setup](#). (If you're experiencing this error, note that Tableau Server will still indicate that subscriptions are being sent in the [Background Tasks for Non Extracts](#) admin view.)

## Missing data quality warnings or sensitivity labels

Data quality warnings and sensitivity labels are included in subscription emails when:

- Tableau Server or Tableau Cloud is licensed with Data Management. For more information, see [About Data Management](#).
- Tableau Catalog is enabled. For more information, see [Enable Tableau Catalog](#).
- In site settings, the check box under **High-Visibility Data Labels in View and Workbook Subscriptions** is selected. (In earlier versions, the check box is under **Data Quality Warnings in Subscriptions**.)

# Server Administrator Reference

You can learn more about Tableau Server processes, ports, and accounts and permissions.

## Tableau Server Processes

This topic describes the options for setting the process configuration. To configure Tableau Server processes, you need to specify which processes and how many instances should run on each node. You do this using the `tsm topology set-process` command. For more information, see [Changing the number of processes on a node](#).

Looking for Tableau Server on Windows? See [Tableau Server Processes](#).

Except where explicitly noted in the table below, applying changes in processes will stop Tableau Server if it is running when you apply those changes. After changes are applied, Tableau Server is returned to the state it was in before process configuration, so if the server was running, it will be restarted.

**Important:** Your process topology will depend on your organizational needs.

## Licensed processes

Some of the processes that are installed as a part of Tableau Server are "licensed" processes. Licensed processes need a valid Tableau Server license in order to run. Other processes that are installed as a part of Tableau Server are not tied to a valid license. This has the following impact:

- Every licensed process needs to regularly contact the Tableau Server License Manager service that runs on the initial Tableau Server computer to verify they are licensed. If they cannot confirm there is a valid license, for example, if the initial node is not available, the process will not run and Tableau Server may not function properly or reliably.
- If you have a core-based Tableau Server license, the cores on any node with a licensed process will count against the total count of licensed cores.

**Note:** If you have Data Management and a core-based license, you will need to understand how the licensed processes will count against the total count of licensed cores that come with each license. For more information, see License Data Management.

The "Licensed" column in the table below identifies those processes that require a valid license, and which impact the count of cores in core-based licenses.

**Tableau Server Processes** These processes have a status of `running` when Tableau

| Server is running, and <code>stopped</code> when Tableau Server is stopped. |   |   |  |           |

## Process workflow

The Tableau Server processes and how they interact depend on what action or activity is taking place. For example, the processes that are used, and how they interact, differ when you publish a workbook from those used when you sign in using SAML. For some interactive

## Tableau Server on Linux Administrator Guide

views on process workflow, see the below workbook. This allows you to select a particular workflow and follow it step by step from start to finish.

**Disclaimer:** This workbook is published on Tableau Public and is not maintained by Tableau documentation. We cannot guarantee that it is up-to-date with the latest version of Tableau Server.

## Tableau Server Administration Agent

The Administration Agent monitors the Coordination Service for changes to configuration or topology and delivers new configurations to each service (configuration) or deploys new services and removes old ones (topology). The Administration Agent also checks each of the services for status and reports this back to the Coordination Service. This process will be automatically configured on each node of the cluster during installation—no explicit configuration is required or possible.

The Administration Agent may also be referred to as the *TSM Administration Agent*.

|                |  |
|----------------|--|
| <b>Process</b> | Administration Agent   |
| <b>Status</b>  | Status of the Administration Agent process is not visible on the Status Page. Use the TSM CLI to view status. For more information, see <a href="#">View Server Process Status</a>   |
| <b>Logging</b> | Logs generated by the the Administration Agent process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/tabadminagent</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

What happens when an Administration Agent process fails? All other Tableau Server processes running on the same node will display as “unavailable” on the TSM status page. Tableau Server will continue to work as expected, however you will not be able to make configuration/topology changes to the cluster. Failed Administration Agent processes automatically restart as long as the computer itself is otherwise healthy. If the Administration Agent doesn’t start up on the node, you can try to start the service manually by running the following command:

```
sudo su -l tableau

systemctl --user start tabadminagent_0
```

## Tableau Server Administration Controller

The Administration Controller process hosts the TSM REST API for configuring and managing your Tableau Server deployment. There can only be a single instance of the Administration Controller in the entire cluster.

This process will be automatically configured on the initial node of the cluster during installation—no explicit configuration is required.

The Administration Controller is also referred to as the *TSM Controller* and the *TSM Administration Controller*.

|                |  |
|----------------|--|
| <b>Process</b> | Administration Controller  |
| <b>Status</b>  | Status of the Administration Controller process is visible on the Status Page, displayed as <b>TSM Controller</b> . For more information, see <a href="#">View Server Process Status</a>   |
| <b>Logging</b> | Logs generated by the Administration Controller process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/tabadmincontroller</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

What happens when the Administration Controller process fails?

If the Administration Controller fails, the Tableau Server cluster should continue to function; however, tsm commands and the TSM web UI will be unavailable. You will not be able to make any changes or updates to the configuration or topology until the Administration Controller is back up and running. Like other TSM services, Administration Controller is automatically restarted if it is stopped or has failed.

If the Administration Controller doesn't start up on the node, you can try to start the service manually by running the following command:

```
sudo su -l tableau  
  
systemctl --user start tabadmincontroller_0
```

## Moving the Administration Controller

If the initial node fails, you need to move the Administration Controller and the Licensing Service to a different node so that Tableau Server can continue to function. For details on how to do this, see [Recover from an Initial Node Failure](#).

## Restarting the Administration Controller

Restart the TSM Administration Controller (as *tableau* system account):

```
sudo su -l tableau -c "systemctl --user restart tabadmincontroller_0.service"
```

**Note:** It may take a few minutes for `tabadmincontroller` to restart. If you attempt to apply pending changes in the next step before the controller has fully restarted, TSM will not be able to connect to the controller. You can verify that the controller is running by using the `tsm status -v` command. Tableau Server Administration Controller should be listed as "is running".

## Tableau Server Application Server

The Application Server (VizPortal) handles the web application and REST API calls. Application Server also supports browsing and searching. To ensure high availability of Application Server, configure instances on each node in the Tableau Server cluster.

|                |  |
|----------------|--|
| <b>Process</b> | Application Server   |
| <b>Status</b>  | Status of the Application Server process is visible on the Status Page. For more information, see <a href="#">View Server Process Status</a>   |
| <b>Logging</b> | Logs generated by the Application Server process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/vizportal</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

## Tableau Server on Linux Administrator Guide

What happens when an Application Server process fails? Requests being handled by that instance will fail, but subsequent requests will be routed to other running Application Server processes. Assuming the node containing the failed Application Server is still running, the failed process should automatically restart within seconds.

### Troubleshooting problems with Application Server

Beginning with version 2024.2.0, admins can enable Activity and Resource Tracing (ART) data to trouble issues with Application Server. The ART data captured provides detailed insights of memory and CPU usage. This can be useful if your server is experiencing Server Resource Manager (SRM) restarts due to native memory saturation with Application Server (VizPortal).

**Important:** When you enable ART, additional entries are written to vizportal java and cpp logs. You should not leave ART enabled after you are finished investigating. Be sure to disable ART to avoid extra disk space usage.

### Enable ART data on Tableau Server

To enable ART data:

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).
2. Run the following tsm commands:
  - a. `tsm configuration set -k vizportal.enable_art -v true`
  - b. `tsm configuration set -k vizportal.log_art_java -v true`
  - c. `tsm configuration set -k vizportal.art_skip_list -v "/v1/reportEventU-  
nau-  
thentic-`

```

ated,/v1/-
getSes-
sionIn-
fo,/v1/hasUn-
seenNo-
tific-
ation-
s,/v1/re-
freshSes-
sion,/v1/-
getViews,/v1/-
getUser-
s,/v1/-
getWork-
book-
s,/v1/-
getView,/v1/-
getServer-
Set-
ting-
sUnauthenticated,/v1/getProjectAncestors,/v1/getWorkbook"

```

d. `tsm restart`

Application Server logs are found here by default:

```
C:\ProgramData\Tableau\Tableau Server\data\tabsvc\logs\vizportal
```

### Disable ATR

Disable ART data after completing your investigation. To disable ART, run the following commands at a command prompt:

1. `tsm configuration set -k vizportal.enable_art -v false`
2. `tsm configuration set -k vizportal.log_art_java -v false`
3. `tsm configuration set -k vizportal.art_skip_list -v ""`
4. `tsm restart`

## Tableau Server Backgrounder Process

The Backgrounder process runs server jobs, including extract refreshes, subscriptions, flow runs, and data driven alerts. Jobs are initiated both from scheduled tasks and when started manually using 'Run Now', REST API, or tabcmd commands.

|                |   |
|----------------|---|
| <b>Process</b> | Backgrounder  |
| <b>Status</b>  | Status of the Backgrounder process is visible on the Status Page. For more information, see <a href="#">View Server Process Status</a>  |
| <b>Logging</b> | Logs generated by the Backgrounder process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/backgrounder</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

What happens if a Backgrounder process goes down? Jobs on the failed Backgrounder process are retried once the Backgrounder process recovers from failure. Most background jobs are scheduled to run periodically, and the same background task will be picked up and performed normally at the next scheduled time by a functioning Backgrounder process.

Failed Backgrounder processes automatically restart as long as the computer itself is otherwise healthy, and the failed jobs will be retried.

To make the Backgrounder process highly available, you should configure one or more instances to run on multiple nodes in the cluster.

### Managing Backgrounder Resources

Backgrounders as mentioned earlier in this topic, run server tasks, and can be resource intensive. There are several ways in which you can manage the resources that Backgrounder needs to run the server tasks:

- Increase the number of instances on a specific node: Backgrounder is single-threaded. It can only launch a single job at a time. Adding more Backgrounder instances to a node

can increase the number of jobs that can be run in parallel on that node, but keep in mind that each job launched can itself use multiple threads. You can add Backgrounder instances up to one half the number of cores. When deciding where and how many Backgrounders to run, consider that each Backgrounder process launched for a job can use multiple threads, so adding Backgrounder instances may limit the effectiveness of each process. Also keep in mind how other server processes will affect each machine's available capacity.

- **Isolate Backgrounder process:** If you are running Tableau Server on a multi-node cluster, you can dedicate one or more nodes for running Backgrounder. For more information, see [Recommended Baseline Configurations](#).
- **Node Roles:** You can also separate the type of jobs or workload that the Backgrounder on a node does. For example, you can have one node dedicated to running extract refreshes only. For more information, see [Workload Management through Node Roles](#).
- **Restricting users from manually running jobs:** Currently users can run extract refreshes, flow run, and subscriptions using the web interface, REST API, and `tabcmd` commands, and can run them at any time of the day. This can take up server resources during times that your server is busy doing other activities. Starting in Tableau Server 2020.1, a new Run Now settings allows the server administrator to choose whether or not to allow users to run jobs manually. By disabling the Run Now option, you have better control over how backgrounders are utilized as well as being able to better predict the load. This does not apply or affect jobs that are generated for scheduled tasks. For more information on configuring this setting, see [Server Settings \(General and Customization\)](#).

- [Improving group synchronization performance](#)

## Tableau Server Cache Server

The Cache Server provides a shared external query cache. It's a cache of key/value pairs which hold information from previous queries to speed up future requests. To make Cache Server highly available, configure one or more Cache Server processes on multiple nodes of the cluster.

|                |  |
|----------------|--|
| <b>Process</b> | Cache Server   |
| <b>Status</b>  | Status of the Cache Server process is visible on the Status Page. For more information, see <a href="#">View Server Process Status</a>   |
| <b>Logging</b> | Logs generated by the Cache Server process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/cacheserver</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

What happens when Cache Server process goes down? The consequences are relatively mild. Tableau Server will still work but actions may take longer as they do not have cached results available. As the queries rerun, the restarted Cache Server gets repopulated, eventually speeding things up for end users. In effect, Cache Server does not have an availability impact; however, it does have an impact on various end user performance scenarios.

To reduce impact on user performance, run multiple processes of this type across the cluster. We recommend you install no more than a maximum of six cache server instances, limiting each node to no more than two. Our testing indicates that installing more than a total of six cache server instances in a Tableau Server installation provides no improvement, and could have a negative impact on performance.

A failed Cache Server process is automatically restarted; as long as the computer itself is otherwise healthy, the Cache Server process will relaunch.

## Tableau Server Client File Service

The Client File Service (CFS) stores and distributes files needed by TSM (e.g. certificates, customization files, etc.). Files that are managed by the Client File Service are renamed and obfuscated before they are distributed across the deployment. This process also parametrizes the

file attributes that are required by Tableau services. As a result, files are not mapped to a single file location on the file system. Be sure you have an off-box backup of all files managed by CFS.

The following files are managed by CFS:

- SAML certificate file
- SAML key file
- SAML IdP metadata file
- OpenID.static.file
- Kerberos.keytab file
- LDAP Kerberos keytab file
- LDAP Kerberos conf file
- Mutual SSL certificate file
- Mutual SSL revocation file
- Customization header logo file
- Customization sign-in logo file
- Customization compact logo file

The following files are not managed or distributed by CFS:

- External SSL files. The certificate and key files for external SSL are stored and managed by the Coordination Service. You do not need to manually distribute these files.
- SSL files for LDAP external identity store. You must distribute the SSL certificate file manually to each node in the cluster. See [Configure Encrypted Channel to LDAP External Identity Store](#).

The Client File Service functions much like the File Store does for files needed by business services. By default, CFS is only installed on the initial node of your Tableau Server installation. To configure CFS to for high availability, we recommend that you configure an instance of CFS on each of the nodes where you deploy the Coordination Service.

In a cluster, if a node that is running your only instance of CFS fails, any files being managed by CFS will be lost, and you will need to repopulate CFS those files by reimporting certs and custom images, and making any related configuration changes.

|                |                     |
|----------------|---------------------|
| <b>Process</b> | Client File Service |
|----------------|---------------------|

|                |   |
|----------------|---|
| <b>Status</b>  | Status of the Client File Service process is not visible on the Status Page. Use the TSM CLI to view status. For more information, see View Server Process Status   |
| <b>Logging</b> | Logs generated by the the Client File Service process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/clientfileservice</code> . For more information, see Tableau Server Logs and Log File Locations |

What happens when a CFS process fails? Nothing, as long as there is still at least one functioning CFS process in the cluster. The controller will redirect file transfer requests to the other working CFS process.

Failed Client File Service processes automatically restart as long as the computer itself is otherwise healthy.

## Tableau Server Collections Service

The Tableau Server Collections service was added in Tableau Server version 2021.2. The Collections service powers the Collections feature. It provides information about collections, and connects with the Content Exploration service to get meta data about collections and items within collections. The Collections service also supports the Favorites feature.

### Server Configuration

The Collections Service is automatically installed on the first node where Application Server (vizportal) is installed.

### Multi-Node Configuration

For high availability and better performance, we recommend you install one instance of the Collections Service on every node that is running the Application Server (vizportal).

|                |   |
|----------------|---|
| <b>Process</b> | Collections Service   |
| <b>Status</b>  | Status of the Collections Service is visible on the Status Page and from the command line using the <code>tsm status -v</code> command. For more information, |

|                |  |
|----------------|--|
|                | see View Server Process Status   |
| <b>Logging</b> | Logs generated by the the Collections Service process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/collections</code> .<br>For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

### Impact if the Collections Service is not running properly

If the Collections Service stops, it should automatically restart as long as the computer itself is otherwise healthy.

### One instance of Collections service

If you have a single instance of the Collections service configured and that instance fails, collections and favorites will not be available.

### Multiple instances of Collections service

If you have a multi-node installation of Tableau Server and have configured instances of the Collections service on multiple nodes, when one instance fails, collections and favorites may not be available to some users.

### Log Files

The Collections Service creates two sets of log files:

- `control_collections*.log`: These logs will contain information about the service starting and being enabled.
- `collections_*.log`: Any errors or problems are logged here.

For more information, see [Tableau Server Logs and Log File Locations](#).

## Tableau Server Content Exploration Service

The Tableau Server Content Exploration Service extends the capabilities of the Search and Browse process and is responsible for indexing all content in Tableau Server. This service is available in Tableau Server 2021.1 and later and required to search and browse external

assets such as databases and tables. Databases and tables are only available if you have [Tableau Catalog](#) enabled.

The Content Exploration Service is applicable to both quick and filtered search. This service is not based on SOLR but depends on the Elastic Search to perform its functions.

### Server Configuration

The Content Exploration Service is automatically installed on the initial node.

### Multi-Node Configuration

For high availability and better performance, we recommend you install at least one instance of the Content Exploration Service on every node that is running the Application Server.

|                |  |
|----------------|--|
| <b>Process</b> | Content Exploration Service  |
| <b>Status</b>  | Status of the Content Exploration Service is visible on the Status Page and can be accessed using the TSM CLI to view. For more information, see <a href="#">View Server Process Status</a>  |
| <b>Logging</b> | Logs generated by the Content Exploration Service are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/contentexploration</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

### What happens when the Content Exploration Service fails?

If the Content Exploration Service stops working, any search requests for the content type it provides would fail to appear on the search results. If multiple instances of the service are installed, subsequent requests are routed to a healthy instance.

A failed Content Exploration service is automatically restarted; as long as the computer itself is otherwise healthy, the service will relaunch.

## Performance Tuning

The Content Exploration Service has the ability to scale up as needed but based on the available memory on the node. However, there is a memory allocation set by default that determines the maximum amount of memory that can be used by the service. While it is not typically recommended that you change this setting if you are seeing performance issues due to insufficient memory allocation, you can run the following commands to change the maximum memory allocation setting.

First, retrieve the current maximum memory allocation by running the following command:

```
tsm configuration get -k contentexploration.vmopts
```

Run the following set command to change the maximum memory allocation by updating the `-Xmx` value, followed by applying the pending changes. Do not change any other options:

```
tsm configuration set -k contentexploration.vmopts -v "-Xmx<new
value>m -XX:+ExitOnOutOfMemoryError -Dspring.profiles.active=monolith"
```

For example:

```
tsm configuration set -k contentexploration.vmopts -v "-Xmx1024m -
XX:+ExitOnOutOfMemoryError -Dspring.profiles.active=monolith"

tsm pending-changes apply
```

## Log Files

The Content Exploration Service creates two sets of log files:

- `control_contentexploration*.log`: These logs will contain information about the service starting and being enabled.
- `contentexploration_*.log`: Any errors or problems are logged here.

For more information, see [Tableau Server Logs and Log File Locations](#).

### Search Accuracy

There are couple of ways the Content Exploration Service is used to make sure that searchable content is kept up to date:

- Whenever content managed by Tableau Server or Tableau Cloud is modified, including permissions, the Content Exploration Service re-indexes the relevant documents to keep its search indexes up to date.
- A system generated Backgrounder task that periodically validates that all content is properly synchronized and re-indexes any discrepancies that are found.

### Re-indexing

During restore, the restore process will initiate a full re-indexing of the content and external assets managed by Tableau Server. The re-indexing process consumes CPU resources which may be noticeable during backup and restore.

## Tableau Server Coordination Service

The Coordination Service is built on [Apache ZooKeeper](#), an open-source project, and coordinates activities on the server, guaranteeing a quorum in the event of a failure, and serving as the source of "truth" regarding the server topology, configuration, and state. The service is installed automatically on the initial Tableau Server node, but no additional instances are installed as you add additional nodes. Because the successful functioning of Tableau Server depends on a properly functioning Coordination Service, we recommend that for server installations of three or more nodes, you add additional instances of the Coordination Service by deploying a new Coordination Service ensemble. This provides redundancy and improved availability in the event that one instance of the Coordination Service has problems.

The hardware for your cluster can have some effect on how well the Coordination Service runs. In particular:

- Memory. The Coordination Service maintains state information in memory. By design, the memory footprint is small, and is typically not a factor in overall server performance.

- Disk speed. Because the service stores state information on disk, it benefits from fast disk speed on the individual node computers.
- Connection speed between nodes. The service communicates continuously between cluster nodes; a fast connection speeds between nodes helps with efficient synchronization.

|                |  |
|----------------|--|
| <b>Process</b> | Coordination Service   |
| <b>Status</b>  | Status of the Coordination Service process is not visible on the Status Page. Use the TSM CLI to view status. For more information, see <a href="#">View Server Process Status</a>   |
| <b>Logging</b> | Logs generated by the the Coordination Service process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/app-zookeeper</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

### Configuration for the Coordination Service

The Coordination Service is installed automatically on the initial node of Tableau Server. If you are running a single-node installation, you do not need to do anything to deploy or configure the Coordination Service. If your installation includes three or more nodes, you'll be prompted to configure a Coordination Service ensemble when you add your third node. This is not required, but is highly recommended as the Coordination Service serves a key function for high availability, acting as the source of "truth" about server topology, configuration, and state.

To configure a Coordination Service ensemble, use the TSM CLI and add the Coordination Service to the nodes you want running it. For details on how to deploy a Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#) .

### The Coordination Service Quorum

To ensure that the Coordination Service can work properly, the service requires a *quorum*—a minimum number of instances of the service. This means that the number of nodes in your

installation impacts how many instances of the Coordination Service you want to configure in your ensemble.

## Number of Coordination Service instances to use

The maximum number of Coordination Service instances you can have in an ensemble on Tableau Server depends on how many Tableau Server nodes you have in your deployment. Configure a Coordination Service ensemble based on these guidelines:

| Total number of server nodes | Recommended number of Coordination Service nodes in ensemble (must be 1, 3, or 5) | Notes  |
|------------------------------|---|--|
| 1-2 nodes                    | 1 node  | This is the default and requires no changes unless you want to move the Coordination Service off your initial node and onto your additional node.  |
| 3-4 nodes                    | 3 nodes   |  |
| 5 or more nodes              | 3 nodes or 5 nodes  | <p>Five is the maximum number of Coordination Service instances you can install. A 3-node Coordination Service ensemble allows for one of the ensemble nodes to fail without causing Tableau Server to fail. A 5-node ensemble allows for two of the ensemble nodes to fail without causing Tableau Server to fail.</p> <p>For most installations, three Coordination Service nodes are adequate, and because of the I/O-intensive nature of the Coordination Service, this is the most performant configuration.</p> <p>If high availability is your absolute priority, you may want to consider deploying a 5-node Coordination Service ensemble. This provides the most redund-</p> |

| Total number of server nodes | Recommended number of Coordination Service nodes in ensemble (must be 1, 3, or 5) | Notes   |
|------------------------------|---|---|
|                              |   | <p>ancy in the event that one or more nodes fail but will require more system resources. A maximum of two of the ensemble nodes can fail without impacting Tableau Server (as long as any other services on the node also exist on still-functioning nodes).</p> <p>To reduce performance impact, locate the Coordination Service on nodes that are running fewer other services or consider using Coordination Service-only nodes. For details, see <a href="#">Configure Tableau Server for High Availability with Coordination Service-Only Nodes</a>.</p> |

If you reduce the number of nodes

If you reduce the nodes in your cluster from three (or more) to two nodes, a warning tells you Tableau Server can no longer support high availability:

A minimum of three Tableau Server nodes are required for high availability. You can add a third node now, or continue with only two nodes. Continuing with only two nodes means Tableau Server will not be highly available. You can always add a third node later. Click OK to continue with 2 nodes, or Cancel to go back and add a node.

If you continue, Tableau Server will run, but you will not have any automatic failover of the repository.

## Tableau Server on Linux Administrator Guide

### Viewing Coordination Service Status

The Coordination Service is not included in the listing when you View Server Process Status.

To see the state of the service, you can use the `tsm status` command:

```
tsm status -v
```

The output from the command shows you whether the service is running:

```
node1: TABLEAUSVR01
Status: RUNNING
'Tableau Server Gateway 0' is running.
'Tableau Server Application Server 0' is running.
'Tableau Server VizQL Server 0' is running.
'Tableau Server VizQL Server 1' is running.
'Tableau Server VizQL Server 2' is running.
'Tableau Server VizQL Server 3' is running.
'Tableau Server Cache Server 0' is running.
'Tableau Server Cache Server 1' is running.
'Tableau Server Coordination Service 0' is running.
'Tableau Server Cluster Controller 0' is running.
'Tableau Server Search And Browse 0' is running.
'Tableau Server Backgrounder 0' is running.
'Tableau Server Backgrounder 1' is running.
'Tableau Server Data Server 0' is running.
'Tableau Server Data Server 1' is running.
'Tableau Server Data Engine 0' is running.
'Tableau Server File Store 0' is running.
'Tableau Server Repository 0' is running (Active Repository).
'Tableau Server Administration Agent 0' is running.
'Tableau Server Administration Controller 0' is running.
'Tableau Server Service Manager 0' is running.
'Tableau Server License Manager 0' is running.
'Tableau Server Client File Service 0' is running.
'Tableau Server Database Maintenance 0' is stopped.
'Tableau Server Backup/Restore 0' is stopped.
```

```
'Tableau Server Site Import/Export 0' is stopped.
```

```
'Tableau Server SAML Service 0' is stopped.
```

## Tableau Server Data Engine

Hyper is Tableau's in-memory Data Engine technology optimized for fast data ingests and analytical query processing on large or complex data sets. Hyper powers the Data Engine in Tableau Server, Tableau Desktop, Tableau Cloud, and Tableau Public. The Data Engine is used when creating, refreshing or querying extracts. It is also used for cross-database joins to support federated data sources with multiple connections.

|                |   |
|----------------|---|
| <b>Process</b> | Data Engine   |
| <b>Status</b>  | Status of the Data Engine process is visible on the Status Page. For more information, see View Server Process Status   |
| <b>Logging</b> | Logs generated by the Data Engine process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/hyper</code> . For more information, see Tableau Server Logs and Log File Locations |

### Memory and CPU usage

The Data Engine is designed to leverage all available CPU and memory on the machine to provide the fastest response times.

### CPU usage

Hyper technology leverages the new instruction sets in CPU and is capable of parallelizing and scaling to all the available cores. Hyper technology is designed to scale to many cores efficiently, and also to maximize the use of each single core as much as possible. This means that you can expect to see up to an average of 75% use of total CPU per hour during query processing. Adding more CPU should result in performance improvement.

**Note:** The 75% hourly average usage is the default, and should be left unchanged unless you are running Data Engine on a dedicated server node. For more information about

running Data Engine on a dedicated node, see [Optimize for Extract Query-Heavy Environments](#).

Modern operating systems such as Microsoft Windows, Apple macOS, and Linux have mechanisms to make sure that even if a CPU is fully used, incoming and other active processes can run simultaneously. In addition, to manage overall resource consumption and to prevent overloading and completely starving other processes running on the machine, the Data Engine monitors itself to stay within the limits set in the Tableau Server Resource Manager (SRM). Tableau Server Resource Manager monitors the resource consumption and notifies Data Engine to reduce the usage when it exceeds the predefined limit.

Since the Data Engine is designed to utilize the available CPU, it is normal to see spikes in CPU usage at times. If however, you see high CPU usage (ex: 95%) for extended periods of time (an hour or more), this can mean a couple of things:

- There is a high load of queries. This can happen if a server is under stress due to overload of multiple client requests and the queries are queuing up. If this happens often, it is an indication that more hardware is required to serve the clients. Adding more CPU in this case should help to improve performance.
- There is one long running query. In this case, the Tableau Server resource Manager will stop long running queries based on the timeout settings. This was also true for the Tableau Server versions earlier than version 10.5

For more information on Tableau Server Resource Manager, see [General Performance Guidelines](#).

## Memory usage

Memory usage of the Data Engine depends on the amount of data required to answer the query. The Data Engine will try to run this in-memory first. A working set memory is allocated to store an intermediate data structure during query processing. In most cases, systems have enough memory to do these types of processing, but if there isn't enough available memory, or

if more than 80% of RAM is utilized, the Data Engine shifts to spooling by temporarily writing to disk. The temporary file get deleted after the query has been answered. Therefore, spooling is an indication that more memory may be needed. Memory usage should be monitored and upgraded appropriately to avoid performance issues caused by spooling.

To manage memory resources on the machine, the maximum memory limit for Data Engine is set by Tableau Server Resource Manager (SRM).

### Server configuration, Scalability, and Performance

- A single instance of Data Engine is automatically installed per node where an instance of File Store, Application Server (VizPortal), VizQLServer, Data Server, or Backgrounder is installed on Tableau Server. The Data Engine can scale by itself and uses as much CPU and memory as needed, thus removing the need for multiple instances of the Data Engine. For more information on the server processes, see Tableau Server Processes.
- The instance of Data Engine installed on the node where File Store is installed is used for querying data for view requests. The instance of Data Engine installed on the node where backgrounder is installed is used for extract creation and refreshes. This is an important consideration when you are doing performance tuning. For more information, see Performance Tuning.
- Data Server, VizQL Server, and the Application Server (VizPortal) all use the local instance of Data Engine to do cross-database joins and create shadow extracts. Shadow extract files are only created when you work with workbooks that are based on non-legacy Excel or text, or statistical files. Tableau creates a shadow extract file in order to load the data more quickly.
- In Tableau Server 10.5 one instance of Data Engine is installed automatically when you install backgrounder. The backgrounder process uses the single instance of Data Engine (hyperd.exe) installed on the same node.

**Important!** There are exceptions to when the Data Engine is installed on the same node as File Store. When File Store is configured external to Tableau Server, Data Engine is no longer installed with File Store. In this configuration where Tableau Server is configured with an External File Store, Data Engine, will continue to be installed with the other process as noted above. In addition, you can also configure Data Engine on a node without other processes - but only when File Store is configured externally. For more information on External File Store, see [Tableau Server External File Store](#).

### Scalability:

You can scale up with the new Data Engine: Since cores are fully utilized, adding more cores makes individual queries execute faster which in turn allows for more queries to execute in less time.

Memory usage should be monitored and upgraded appropriately to avoid the performance issues caused by spooling.

For more information on Scalability, see [Tableau Server Scalability](#).

### Performance:

## Performance benefits

Starting in 10.5, Hyper technology has been integrated with Tableau Data Engine to give you the following key benefits:

- **Faster extract creation:** With Hyper technology, extracts are generated almost as fast as the source system can deliver data, no sorting needed.
- **Support for larger extracts:** Prior to this release, you might have not been able to get all your data into a single extract. With Hyper technology, much larger amounts of data can be included in a single extract.
- **Faster analysis of extracts:** In many cases you will see faster querying of data for larger extracts, or workbooks with complex calculations.

Here are some reasons why the Data Engine powered by Hyper performs better on larger or complex extracts and is optimized for faster querying:

- **Hyper technology is designed to consume data faster.** Unlike in previous versions, the Data Engine does not do any post processing like sorting. With Hyper, post processing steps like sorting are not needed giving the Data Engine the ability to perform better with larger extracts.
- **Hyper technology is memory-optimized.** This means that when needed, all data lives in memory. This results in fast data access times.
- **Hyper technology is CPU optimized.** This means that Data Engine now fully parallelizes the query execution and utilizes available CPU in such a way that query execution time scales almost linearly with the number of cores in the machine.
- **Hyper is a compiling query engine.** Queries are either interpreted or compiled to the machine code for maximum performance and allowing the Data Engine to get most performance out of modern hardware (CPU, large main-memory capacities).
- **Hyper technology uses advanced query optimizations to make queries faster.** Along with many additional advanced techniques such as, materializing min and max values for each column, mini-indices to optimize search ranges, more granular data block-level dictionaries, advanced logic for join and sub-query performance optimizations, the new Data Engine offers many improvements over the previous Tableau Data Engine in terms of performance and scalability.

For more information on performance, start with [General Performance Guidelines](#), and [Performance Tuning](#)

## Tableau Server Data Server

The Data Server manages connections to published data sources on Tableau Server. To make Data Server highly available, configure one or more Data Server processes to run on multiple nodes of the cluster.

|                |  |
|----------------|--|
| <b>Process</b> | Data Server  |
| <b>Status</b>  | Status of the Data Server process is visible on the Status Page. For more information, see <a href="#">View Server Process Status</a>  |
| <b>Logging</b> | Logs generated by the Data Server process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/dataserver</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

What happens if a Data Server process fails? Queries running through the Data Server process will fail, resulting in a failed view rendering, extract refresh, or alert. Subsequent requests, including a retry of the failed operation, should succeed as long as a working Data Server is available to accept rerouted requests.

Tableau Server is not dependent on Data Server to function; however, without a running Data Server, workbooks on the server lose the ability to query or to connect to published data sources. Any view that does not use Data Server for any of its data sources will still function correctly.

## Tableau Server Data Source Properties Service

Introduced in version 2020.1.0, the Tableau Server Data Source Properties service provides metadata for published data source from the Application Server (VizPortal) to client services like Ask Data.

**Note:** Tableau's Ask Data feature was retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2.

One instance of the Data Source Properties service is configured on the initial node of Tableau Server. You can add additional instances on the initial node or on other nodes in a multi-node installation. You are required to configure at least one instance of the Data Source Properties service on any node that has an instance of Application Server.

|                |   |
|----------------|---|
| <b>Process</b> | Data Source Properties Service  |
| <b>Status</b>  | Status of the Data Source Properties Service is visible on the Status Page and from the command line using the <code>tsm status -v</code> command. For more |

|                |  |
|----------------|--|
|                | information, see View Server Process Status  |
| <b>Logging</b> | Logs generated by the Data Source Properties Service are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/tdsservice</code> .<br>For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

### Log files for the Data Source Properties service

The Data Source Properties service creates two sets of log files:

- `control-tdsservice*.log`. These logs will contain information about the service starting and being enabled.
- `tdsservice_*.log`. Any errors or problems are logged here.

For more information, see [Log File Snapshots \(Archive Logs\)](#).

### Data Source Properties service in a multi-node cluster

How you configure the Data Source Properties service in a multi-node cluster depends on how you configure your nodes. In any installation of Tableau Server you must have at least one instance of the service. In addition, you are required to configure at least one instance of Data Source Properties on any node that is configured with the Application Server (VizPortal).

## Tableau Server File Store

This topic describes File Store process when configured to run locally on Tableau Server. However, File Store can be run locally as well as external to Tableau Server. For more information on Tableau Server External File Store, see [Tableau Server External File Store](#).

The Tableau Server File Store process controls the storage of extracts. When File Store is installed, an instance of the Data Engine is also installed unless the node already has an instance of the data engine. In highly available (HA) environments, the File Store ensures that extracts are synchronized to other file store nodes so they are available if one file store node stops running.

|                |            |
|----------------|------------|
| <b>Process</b> | File Store |
|----------------|------------|

|                |  |
|----------------|--|
| <b>Status</b>  | Status of the File Store process is visible on the Status Page. For more information, see <a href="#">View Server Process Status</a>   |
| <b>Logging</b> | Logs generated by the File Store process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/filestore</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

### The decommission Command

If you want or need to remove a File Store instance you need to decommission File Store first using the `tsm topology filestore decommission` command. If you don't decommission File Store before you attempt to remove it, you will be prompted to do so. Decommissioning puts the File Store instance into read-only mode and copies any unique data contained in the instance to the other File Store(s) in the cluster. While a File Store instance is being decommissioned, this shows on the Status page, and once all unique content has been copied to other File Store nodes, the decommissioned node shows as ready to be removed.

### Decommissioning File Store when co-located with the Administrative Controller

Tableau backup is fastest when an instance of File Store is located on the same node as the TSM Administrative Controller. If you are removing an instance of File Store that is co-located with the Controller, you will be warned about the performance impact for backups.

## Tableau Server Gateway Process

The Tableau Server gateway process is an Apache web server component (`httpd.exe`). Its role is to handle requests to the server from all clients—Tableau Desktop, mobile devices, a proxy, a load balancer, etc.

The server runs a single instance of the gateway process; you can't run more than one per machine. The gateway process is required on any node with an instance of VizQL Server or Vizportal.

|                |   |
|----------------|---|
| <b>Process</b> | Gateway   |
| <b>Status</b>  | Status of the Gateway is visible on the Status Page. For more information, see <a href="#">View Server Process Status</a> |

|                |  |
|----------------|--|
| <b>Logging</b> | Logs generated by the repository are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/httpd</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |
|----------------|--|

### Port assignment

By default, the gateway process listens for requests on port 80 (for HTTP requests) and 443 (for SSL requests). When you install Tableau Server on a computer, part of the server configuration makes sure that this port is open in the computer's firewall. If the computer is running a different process that requires port 80 for HTTP, you can change the port assignment for the gateway process during installation. (You cannot change the SSL/HTTPS port.)

If you need to set the HTTP port after installation, then run the following TSM command, where *node* is the node number (for example, `node1`) and *nn* is the new port number:

```
tsm topology set-ports --node-name node --port-name gateway:primary
--port-value nn
```

If you are running Tableau Server with a reverse proxy server, you will need to configure other port and host-related settings on Tableau Server. See [Configuring Proxies and Load Balancers for Tableau Server](#).

### Log files for the gateway process

The gateway process creates two sets of log files:

## Tableau Server on Linux Administrator Guide

- Activity logs. The name for these log files has the format `access.yy_mm_dd_hh_mm_ss.log`.
- Error logs. All errors are logged in a single file named `error.log`.

For more information, see [Log File Snapshots \(Archive Logs\)](#).

### Gateway processes in a cluster

If your server environment is distributed across multiple machines, you can run a single gateway process on each node of the cluster. The most common scenario for running a gateway process on multiple computers in the cluster is that you have a load balancer in front of the cluster. In this scenario, the load balancer distributes requests to any gateway in the cluster. If you need to take a node off line (for example, to perform maintenance on that node), you can disable the load balancer's routing to that machine. When the maintenance is complete, you can re-enable the node on the load balancer.

You must have a gateway process running on at least one computer in the cluster. If you remove the gateway process from the primary server, you must make sure that another computer in the cluster is running the gateway process. You must also make sure that that computer is reachable by clients.

An instance of the gateway process is required on any node that is configured for one of these processes or services: VizQL Server, Vizportal, or Tableau Prep Flow Authoring.

If the Tableau Server is configured to use SSL, you must make sure that the certificate for SSL support is in the same location on each computer in the cluster that has the gateway process running. For more information about using SSL, see [Configure SSL for External HTTP Traffic to and from Tableau Server](#).

Similarly, if the server installation uses a custom logo, the logo must be in the same location on every computer that is running the gateway process.

If you need to change the port number that the gateway process listens on, as explained earlier, you can use the configuration dialog box or run the following command for each worker computer that is running the gateway process:

```
tsm topology set-ports --node-name node --port-name gateway:primary
--port-value nn
```

### Additional information

#### Configuring Proxies and Load Balancers for Tableau Server

##### Add a Load Balancer

## Index and Search Server

The Tableau Server Index and Search Server process, based on OpenSearch, handles fast search, filter, retrieval, and display of content metadata on your Tableau Server site. Beginning with Tableau Server version 2023.3, Index and Search Server completely replaces the Search and Browse process.

### Server Configuration

The Index and Search Server is automatically installed on the initial node.

### Multi-Node Configuration

To configure Index and Search Server for high availability, configure the process on multiple nodes. We recommend you configure an odd number of Index and Search Server instances. On Tableau Server Clusters that have 3 or more nodes, you should configure Index and Search Server on at least three different nodes.

|                |   |
|----------------|---|
| <b>Process</b> | Index and Search Server   |
| <b>Status</b>  | Status of the Index and Search Server is visible on the Status Page and can be accessed using the TSM CLI to view. For more information, see <a href="#">View Server Process Status</a>   |
| <b>Logging</b> | Logs generated by the Index and Search Server are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/index-andsearchserver</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

### What happens when the Index and Search Server fails?

## Tableau Server on Linux Administrator Guide

If Index and Search Server fails, users can still sign in to Tableau Server, however the different content types (workbooks, projects, data sources, and views for example) will not appear in the Home page, the search bar or the Explore page. Existing workbooks and Views should still be accessible and fully functional if accessed from a bookmarked url. The content is not actually missing. Rather, the content is not being returned in the search results; it will be displayed again after the Index and Search Server restarts. A failed Index and Search Server is automatically restarted; as long as the computer itself is otherwise healthy, the service will relaunch.

If more than one Index and Search Server is configured and running on multiple nodes when the failure occurs, requests made to a failed Index and Search Server will also fail, but subsequent requests will be routed to working Index and Search Server instances. Each Index and Search Server instance indexes across all nodes in the cluster, therefore as long as one Index and Search Server instance is running, results will still be returned across all nodes.

### Performance Tuning

The Index and Search Server heap size can be configured by using the `tsm set configuration` command with the `indexandsearchserver.vmopts` option. For more information, see `indexandsearchserver.vmopts`

### Re-indexing

During restore, the restore process will initiate a full re-indexing of the content and external assets managed by Tableau Server. The re-indexing process consumes CPU resources which may be noticeable during backup and restore.

## Tableau Server Internal Data Source Properties Service

The Tableau Server Internal Data Source Properties service was introduced in version 2020.1.0 and communicates with the Data Source Properties service. It is managed internally by Tableau Server, and cannot be configured by an administrator.

An instance of the Internal Data Source Properties service is automatically configured on any node that has an instance of the Data Source Properties service.

|                |  |
|----------------|--|
| <b>Process</b> | Internal Data Source Properties Service  |
| <b>Status</b>  | Status of the Internal Data Source Properties Service is visible on the Status Page and from the command line using the <code>tsm status -v</code> command. For more information, see View Server Process Status                   |
| <b>Logging</b> | Logs generated by the Internal Data Source Properties Service are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/tdsnativeservice</code> . For more information, see Tableau Server Logs and Log File Locations |

Log files for the Internal Data Source Properties service

The Internal Data Source Properties service creates two sets of log files:

- `control-tdsnativeservice_*.log`. These logs will contain information about the service starting and being enabled.
- `nativeapi_tdsnativeservice_*.log`. Any errors or problems are logged here.

For more information, see Log File Snapshots (Archive Logs).

Internal Data Source Properties service in a multi-node cluster

One instance of the Internal Data Source Properties services is added to any node that has an instance of Data Source Properties configured. Because the Internal Data Source Properties service is managed internally by Tableau, there is nothing an administrator can configure related to the service.

## Tableau Server Messaging Service

The Tableau Server messaging service uses Apache ActiveMQ beginning with version 2019.4. This is a publish/subscribe platform that enables secure, scalable, performant, and highly available message-oriented communication for microservices. The Messaging Service is used to support communication between microservices in Tableau Server.

## Tableau Server on Linux Administrator Guide

The server runs a single instance of the Messaging Service by default. In version 2020.1 and later, if you have a multi-node instance of Tableau Server you can configure a second instance of the Messaging Service.

|                |   |
|----------------|---|
| <b>Process</b> | Messaging Service   |
| <b>Status</b>  | Status of the Messaging Service is visible on the Status Page and from the command line using the <code>tsm status -v</code> command. For more information, see <a href="#">View Server Process Status</a>          |
| <b>Logging</b> | Logs generated by the repository are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/activemqserver</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

### Impact if Messaging Service is not running properly

If the Messaging Service stops or fails to start the consequences depend on whether you have one, or two instances of the Messaging Service configured.

### Multiple instances of Messaging Service (multi-node, version 2020.1 and later)

You can configure two instances of the Messaging Service configured if you have version 2020.1 or later, *and* you have a multi-node installation of Tableau Server. In this case, if one instance fails, the other instance handles all traffic, and you can remove and reinstall the failed instance.

### One instance of Messaging Service

If you have a single-node installation of Tableau Server, you are limited to a single instance of the Messaging Service. In this case, if the configured instance fails, Tableau Server will continue to function, but the status will show as "Degraded", and any event message that was sent to the Messaging Service while it was down may be lost, even if the service restarts. Event messages include permission changes to projects.

If the Messaging Service stops, it is automatically restarted as long as the computer itself is otherwise healthy.

## Messaging Service in a multi-node cluster

How you configure the Messaging Service in a multi-node cluster depends on what version of Tableau Server you are running. In all cases, you must run one instance of the Messaging Service.

Starting with version 2020.1, you can run two instances of the service in a multi-node environment. We recommend you run two instances as this provides redundancy. You can add a second instance to any node that does not already have the Messaging Service configured. You cannot add more than a combined total of two instances in your multi-node cluster.

## Tableau Server Metrics Service

### Retirement of the legacy metrics feature

Tableau's legacy metrics feature was retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. In October 2023, Tableau retired the ability to embed legacy metrics in Tableau Cloud and in Tableau Server version 2023.3. With Tableau Pulse, we've developed an improved experience to track metrics and ask questions of your data. For more information, see [Create Metrics with Tableau Pulse](#) to learn about the new experience and [Create and Troubleshoot Metrics \(Retired\)](#) for the retired feature.

The Metrics service is responsible for reading and writing Metric data in Tableau Server. The service is required in order for Metrics to work properly. To make the Metrics service highly available, configure one or more instances of the service to multiple nodes of the cluster. We recommend you configure at least one instance on every node that is running the Application Server (VizPortal).

|                |   |
|----------------|---|
| <b>Process</b> | Metrics Service   |
| <b>Status</b>  | Status of the Metrics Service is visible on the TSM Status Page and from the command line using the <code>tsm status -v</code> command. For more information, see <a href="#">View Server Process Status</a>              |
| <b>Logging</b> | Logs generated by the Metrics Service process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/metrics</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

## Tableau Server on Linux Administrator Guide

### Impact if the Metrics Service fails

The Metrics Service is required for Metrics to function properly on Tableau Server. In order to minimize issues, install multiple instances of the service in your server installation. If you have a single-node instance of Tableau Server, configure at least two instances of the service on your node. If the Metrics Service stops working, any Metrics requests that are in-process will fail. Subsequent requests are routed to a healthy instance of the service.

### Metrics Service in a multi-node cluster

The Metrics Service is required for Metrics to function properly on Tableau Server. In order to minimize issues, install multiple instances of the service in your server installation. In multi-node installations, we recommend you configure at least one instance of the Metrics Service on every node that is running the Application Server (VizPortal). This provides redundancy and maximum performance.

### Log files for the Metrics service

The Metrics Service creates two sets of log files:

- `control-metrics*.log`. These logs will contain information about the service starting and being enabled.
- `metrics_*.log`. Any errors or problems are logged here.

For more information, see [Log File Snapshots \(Archive Logs\)](#).

## Tableau Server Microservice Containers

By default, one instance of the Interactive Microservice Container is added to every node that has Application Server (Vizportal) installed, and one instance of the Non-Interactive Microservice Container is added to every node that has Backgrounder installed. Although you cannot add a Microservice container directly, you can use the TSM CLI to change the number of instances for both Microservice Containers, when necessary. If all instances of Backgrounder or Application Server are removed from a node, the container process is also removed.

## Microservice Containers and the microservices:

- Interactive Microservice Container:
  - MessageBus Microservice
  - Relationship Query Microservice
  - Credentials Service
- Non-Interactive Microservice Container:
  - Relationship Ingestor Microservice
  - External Content Provider Microservice
  - Flow Provider Microservice
  - Content Provider Microservice

## Viewing Microservice Container Status

You can see the status of the Microservice Container processes from the TSM Status page, or from the command line, using the `tsm status -v` command. When you use the TSM Status page to View Server Process Status, the status of each container process is visible, but you cannot see the status of any of the microservices in the containers. When you use the command line, more detail is shown, including the status of each individual microservice.

## Microservice Container Status

The status of a container process depends on the status of the microservices within the container. When all microservices within a container process are running as expected, the container status is *Active* (on the TSM Status page) or *running* (when viewed from the TSM command line). If all microservices within a container process are stopped, the status for the container is *Error* (on the TSM Status page) or *stopped* (from the TSM command line). If a microservice is stopped but at least one other microservice is running, the container status is *Degraded* (on the TSM Status page) or *degraded* (from the TSM command line).

When all microservices within a container process have a status of *running*, the container status is *Active*. If any microservice in a container is in an error state (has a status of

## Tableau Server on Linux Administrator Guide

`stopped` ) the container process status is `degraded`. If all microservices in a container are in an error state, the container status is `error`.

Use the TSM web interface

To view the Microservice Container status from the TSM Status page:

1. Open TSM in a browser:

`http://<tsm-computer-name>:8850`

2. Click **Status**:

The page displays the status for the Interactive Microservice Container and Non-Interactive Microservice Container processes, as well as status for other processes running as part of TSM or Tableau Server.

You cannot see the status of any individual microservice within a container process, but if the container process has a status of Active (a green check), the microservices it contains are all running as expected. To see the status of individual microservices, use the TSM command line.

**Note:** The status of the container processes does not display on the older Tableau Server status page. For details about the two status pages and how they differ, see [View Server Process Status](#).

Use the TSM CLI

To view the Microservice Container status from the TSM command line:

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).
2. Run the following command:

```
tsm status -v
```

The output from the command shows you the status of the container services and the microservices in them:

```
node1: TABLEAUSVR01
Status: RUNNING
'Tableau Server Gateway 0' is running.
'Tableau Server Application Server 0' is running.
'Tableau Server Interactive Microservice Container 0' is running.
'MessageBus Microservice 0' is running.
'Relationship Query Microservice 0' is running.
'Tableau Server VizQL Server 0' is running.
'Tableau Server VizQL Server 1' is running.
'Tableau Server VizQL Server 2' is running.
'Tableau Server VizQL Server 3' is running.
'Tableau Server Cache Server 0' is running.
'Tableau Server Cache Server 1' is running.
'Tableau Server Coordination Service 0' is running.
'Tableau Server Cluster Controller 0' is running.
'Tableau Server Search And Browse 0' is running.
'Tableau Server Backgrounder 0' is running.
'Tableau Server Backgrounder 1' is running.
'Tableau Server Non-Interactive Microservice Container 0' is running.
'Relationship Ingestor Microservice 0' is running.
'External Content Provider Microservice 0' is running.
'Flow Provider Microservice 0' is running.
'Content Provider Microservice 0' is running.
'Tableau Server Data Server 0' is running.
'Tableau Server Data Server 1' is running.
'Tableau Server Data Engine 0' is running.
'Tableau Server File Store 0' is running.
'Tableau Server Repository 0' is running (Active Repository).
'Tableau Server Tableau Prep Conductor 0' is running.
```

## Tableau Server on Linux Administrator Guide

```
'Tableau Server Elastic Server 0' is running.  
'Tableau Server Ask Data 0' is running.  
'Tableau Server Administration Agent 0' is running.  
'Tableau Server Administration Controller 0' is running.  
'Tableau Server Service Manager 0' is running.  
'Tableau Server License Manager 0' is running.  
'Tableau Server Client File Service 0' is running.  
'Tableau Server Database Maintenance 0' is stopped.  
'Tableau Server Backup/Restore 0' is stopped.  
'Tableau Server Site Import/Export 0' is stopped.  
'Tableau Server SAML Service 0' is stopped.  
c:\Program Files\Tableau\Tableau Server-  
\packages\scripts.near.18.1216.1859>
```

## Tableau Server Repository

Tableau Server Repository is a database that stores server data. This data includes information about Tableau Server users, groups and group assignments, permissions, projects, data sources, workbooks, and extract metadata and refresh information.

The Repository is also referred to as the *PostgreSQL* repository or database .

|                |  |
|----------------|--|
| <b>Process</b> | Repository   |
| <b>Status</b>  | Status of the Repository is visible on the Status Page. For more information, see <a href="#">View Server Process Status</a>   |
| <b>Logging</b> | Logs generated by the repository are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/pgsql</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

### Preferred active repository

When you configure Tableau Server you have the option to specify a node as the preferred active repository. When Tableau Server is configured for repository failover, the preferred active repository node is the one used for the active repository. This is an optional step, and if you do

not specify a preferred active repository node, Tableau Server will select the active repository node on startup.

To configure the preferred active repository, use the `tsm configuration set` command to configure the `pgsql.preferred_host` option:

```
tsm configuration set -k pgsql.preferred_host -v "<host_name>"
```

**Note:** The `host_name` is case-sensitive and must match the node name shown in the output of `tsm status -v`.

Configure a preferred active repository node if you want Tableau Server to select a specific node on startup. You might want to do this if you have a particular server you want to use for your active repository (a computer with more disk space or memory for example), or if you are using custom administrative views. Custom administrative views have embedded connection information that refers to the repository for which you created the views. For more information on connecting to the Tableau Server repository, see [Collect Data with the Tableau Server Repository](#)

#### The failoverrepository Command

If failover occurs and your passive repository becomes the active repository, it remains the active repository until either Tableau Server restarts or you use the `tsm topology failover-repository` command to switch back. Specify the repository you want to be the active one, or specify that the preferred active repository (if configured) should be made active again. For more information, see `tsm topology failover-repository`.

## Tableau Server Resource Limits Manager

This process was introduced in Tableau Server 2022.1.

## Tableau Server on Linux Administrator Guide

The Tableau Server Resource Limits Manager tracks background resource usage in relation to the set resource limits to make sure the resource limits are applied correctly.

|                |   |
|----------------|---|
| <b>Process</b> | Resource Limits Manager   |
| <b>Status</b>  | Status of the Resource Limits Manager is visible only in TSM CLI.   |
| <b>Logging</b> | Logs generated by the Content Exploration Service are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/allegro</code> . <ul style="list-style-type: none"><li>• The configuration logs are included in the Backgrounder logs</li><li>• The resource consumptions logs are included in the vizportal logs.</li></ul> For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

The Resource Limits Manager is automatically and by default installed on the initial node of Tableau Server. We do not recommend adding more processes or configuring this on additional nodes of the Tableau Server.

The maximum memory usage is set to 512 MB.

### What happens when the Resource Limits Manager fails?

The resource limits will no longer be applied but the jobs will continue to run using the available Backgrounder resources. The behavior will be similar to the scenario where there are no set resource limits.

You can see the status using the tsm command - `tsm status -v`

## Tableau Server SAML Service

For Tableau Server installations that have site-specific SAML enabled, there will also be a SAML Service instance running on each node that is configured with Application Server. This service is automatically configured when site-specific SAML has been enabled on the server.

- In version 2023.1.x and later, SAML Service on Tableau Server isn't displayed until site SAML is enabled.

- In version 2022.3.x and earlier, SAML Service on Tableau Server is shown as stopped unless site SAML is enabled.

|                |  |
|----------------|--|
| <b>Process</b> | SAML Service   |
| <b>Status</b>  | Status of the SAML Service process is not visible on the Status Page. Use the TSM CLI to view status. For more information, see <a href="#">View Server Process Status</a>   |
| <b>Logging</b> | Logs generated by the the SAML Service process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/samlservice</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

If this process goes into a failed state, then users will not be able to sign in to Tableau Server if the user request is routed to an Application Server on this node. Like other processes, when a node containing the SAML Service fails, the failed process should automatically restart within seconds.

## Tableau Server Search and Browse

**Note:** Starting in version 2023.3, Search and Browse is retired (no longer installed). It is replaced by the Index and Search Server.

Starting in version 2022.3, Search and Browse is deprecated (installed but no longer used by Tableau Server). If you are running Tableau Server version 2022.3 or 2023.1, you *should not configure more than one instance of Search and Browse* for any installation. Configuring more than one instance can, in rare cases, result in stability issues.

The Search & Browse process, based on Apache SOLR (in Tableau Server versions 2020.4 and earlier) and also known as searchserver, handles fast search, filter, retrieval, and display of content metadata on your Tableau Server site. To configure high availability for the Search & Browse process, configure the process on multiple nodes. Starting in Tableau Server version 2021.1, the functionality of the Search and Browse process is enhanced by the Content Exploration Service. For more information, see [Tableau Server Content Exploration Service](#)

|                |  |
|----------------|--|
| <b>Process</b> | Search & Browse  |
| <b>Status</b>  | Status of the Search & Browse process is visible on the Status Page. For more information, see <a href="#">View Server Process Status</a>  |
| <b>Logging</b> | Logs generated by the Search & Browse process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/searchserver</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

What happens if a Search & Browse process fails? Users can still sign in to Tableau Server, but workbook content will appear to be missing. The content is not actually missing. Rather, the content is not being returned in the search results; it will be displayed again after the Search and Browse process restarts.

If more than one Search & Browse process is configured and running on multiple nodes when the failure occurs, requests made to a failed Search & Browse process will also fail, but subsequent requests will be routed to working Search & Browse processes. Each Search & Browse process indexes across all nodes in the cluster, therefore if all but one Search & Browse process fails, results will still be returned across all nodes.

### Tuning the Search & Browse Process

There are several ways you can change how the Search & Browse process works in Tableau Server. In most cases you should not need to change anything, but here are some configuration changes you can make.

#### Search & Browse Max Heap Memory

You can configure Search & Browse options using the `searchserver.javamemopts` configuration key. The most important setting you can configure is the one controlling how large the maximum heap memory should be and specified by the `-Xmx` option. By default this is set by Tableau, based on the available physical memory for the server node running the Search & Browse service. The value should be set as high as possible, based on available physical memory and memory usage, but no higher than 24 GB.

When changing the amount of max heap memory, you need to take into account any other services on the system. If you're running low on memory on the computer running Tableau Server, you should consider adding more memory, or scaling down the topology on the machine. If you are running Search & Browse on a node with few other processes, or with a large amount of physical memory, you can consider increasing the amount used by the search service. If you are running Search & Browse on a node with more than the default number of processes, you should consider decreasing the maximum heap memory allocation to avoid having the service attempt to use more memory than is available.

## Default maximum heap memory allocations

The table below shows the *default* amount of heap memory Tableau allocates to Search & Browse on a server node, based on available memory:

| System memory | SOLR heap memory |
|---------------|------------------|
| <= 16 GB      | 1 GB             |
| <= 32 GB      | 2 GB             |
| <= 64 GB      | 4 GB             |
| <= 128 GB     | 8 GB             |
| > 128 GB      | 16 GB            |

To change the value of max heap memory, set the `-Xmx` value of `search-server.javamemopts` using the `tsm configuration set` command.

First get the current values:

```
C:\WINDOWS\system32>tsm configuration get -k search-
server.javamemopts
-Xmx512m -Xms512m -XX:+ExitOnOutOfMemoryError -XX:-UsePerfData
```

Next, change the value of the `-Xmx` option. Include but do not change all other options:

## Tableau Server on Linux Administrator Guide

```
tsm configuration set -k searchserver.javamemopts -v "-Xmx8g -Xms512m -XX:+ExitOnOutOfMemoryError -XX:-UsePerfData"
```

For more details about the `searchserver.javamemopts` configuration key, see `searchserver.javamemopts`.

### Client session timeouts

You can configure how long Search & Browse clients will wait to establish a connection to the Search & Browse server, and to Coordination Service (Zookeeper). Both timeout values are set to a relatively high value, but if you experience issues browsing to server content, and viz-portal and backgrounder logs show timeouts connecting to SOLR, try increasing these settings. If this has no impact, you may be running into limited resources on the Tableau Server computer.

```
searchserver.connection_timeout_milliseconds  
searchserver.zookeeper_session_timeout_milliseconds
```

To change the values use the `tsm configuration set` command:

```
tsm configuration set -k searchserver.connection_timeout_milliseconds -v
```

For more details about the `searchserver.connection_timeout_milliseconds` configuration key, see `searchserver.connection_timeout_milliseconds`.

### Zookeeper connection health check timeout at startup

When Tableau Server is starting, resource usage is high, especially related to CPU usage. If Search & Browse does not make a connection to Coordination Service (zookeeper), it will fail to start. To account for this, Tableau Server performs a health check on the Coordination Service before starting Search & Browse.

If your Tableau Server computer is especially busy, or if Search & Browse fails to start, increase this timeout value.

An error is written to the control-searchserver.log files when this health check fails: Failed zookeeper health check. Refusing to start SOLR.

To increase the amount of time Tableau Server waits for a successful health check, set the value of searchserver.startup.zookeeper\_healthcheck\_timeout\_ms using the tsm configuration set command.

```
tsm configuration set -k searchserver.startup.zookeeper_
healthcheck_timeout_ms -v <nnnnnn>
```

For more details about the searchserver.startup.zookeeper\_healthcheck\_timeout\_ms configuration key, see searchserver.startup.zookeeper\_healthcheck\_timeout\_ms.

## Tableau Statistical Service

The Tableau Statistical Service manages the statistical engine behind Explain Data and predictive modeling functions on Tableau Server. This service is available in Tableau Server 2022.1 through 2023.1.x.

**Note:** The Statistical Service was retired in version 2023.3.0 and no longer shows up on the status page or in the output of the tsm status command.

### Server configuration

The Tableau Statistical Service is automatically installed on any node where VizQL is installed.

|                |   |
|----------------|---|
| <b>Process</b> | Tableau Statistical Service   |
| <b>Status</b>  | Status of the Tableau Statistical Service process is visible on the Status Page and can be accessed using the TSM CLI to view. For more information, see View Server Process Status |
| <b>Logging</b> | Logs generated by the Tableau Statistical Service process are located in /var/opt/tableau/tableau_  |

|  |  |
|--|--|
|  | <code>server/data/tabsvc/logs/statsservice</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |
|--|--|

### Impact if the Tableau Statistical Service fails

If the Tableau Statistical Service stops working, Explain Data will be unavailable, and views that contain calculations with predictive functions `MODEL_PERCENTILE` and `MODEL_QUANTILE` won't render.

### Performance

If there is increased usage of Explain Data or predictive modeling functions on Tableau Server, you may benefit from installing additional instances of the Tableau Statistical Service on nodes running VizQL. For more information on configuring the topology of a Tableau Server node, see [Configure Nodes](#).

### Log files

The Statistical Service creates two sets of log files:

- `control_statsservice*.log`: These logs will contain information about the service starting and being enabled.
- `stdout_statsservice_*.log`: These logs will contain information about status and errors.

For more information, see [Tableau Server Logs and Log File Locations](#).

## Tableau Server TSM Maintenance Services

There are three TSM Maintenance Services that are installed on every node of the cluster: Database Maintenance, Backup/Restore, and Site Import/Export.

|                  |  |
|------------------|--|
| <b>Processes</b> | Database Maintenance, Backup/Restore, and Site Import/Export.              |
| <b>Status</b>    | Status of the TSM Maintenance services are not visible on the Status Page. |

|                |   |
|----------------|---|
|                | Use the TSM CLI to view status. For more information, see <a href="#">View Server Process Status</a>  |
| <b>Logging</b> | Logs generated by the the Service Manager process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/</code> , in the <code>data-basemaintenance</code> , <code>backuprestore</code> , and <code>siteimportexport</code> directories. For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

These services remain stopped unless a specific maintenance task that requires them is initiated by the administrator. Additional high-availability configuration is not required for these services. These services are used only for maintenance tasks such as backup and restore and should not impact the functioning of Tableau Server for the end users.

## Tableau Server VizQL Server

The VizQL Server loads and renders views, and computes and executes queries. To achieve high availability for the VizQL Server process, configure one or more instances to run on multiple nodes.

|                |  |
|----------------|--|
| <b>Process</b> | VizQL Server   |
| <b>Status</b>  | Status of the VizQL Server process is visible on the Status Page. For more information, see <a href="#">View Server Process Status</a>   |
| <b>Logging</b> | Logs generated by the VizQL Server process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/vizqlserver</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

What happens if a VizQL Server process fails? If there is only one VizQL Server process and it fails, then Tableau Server will no longer be able to render any views. High availability requires configuring redundant VizQL processes. A fairly typical configuration consists of two to four VizQL Server processes on each node.

This simultaneously serves the need for high availability and scalability. If multiple VizQL Server processes are running, then the failure of a single process will result in the failure of

any requests and the loss of session data at the time of its failure. Any future requests will be routed to the other working VizQL Server processes on the Tableau Server cluster.

## Tableau Prep Conductor

The Tableau Prep Conductor process runs flows and processes flows for ingestion by Data Catalog. It leverages the scheduling and tracking functionality of Tableau Server so you can automate running flows to update the flow output. Starting in 2020.4 Data Management is only needed to schedule flows to run on Tableau Server. For more information, see [Tableau Prep Conductor](#).

|                |  |
|----------------|--|

Tableau Prep Conductor uses the following components to run flows:

- **Backgrounder:** Tableau Prep Conductor uses the Backgrounder process to run flows. Backgrounder is single threaded, so each instance of the Backgrounder process on a node can run one flow at a time. By adding more Backgrounders to a node, you can increase the number of flows that can be run in parallel on that node. The Backgrounder processes can be up to half the number of the physical cores of that node.
- **Connectors:** Prep Conductor uses the supported Tableau Data connectors to connect to data. For a list of supported Connectors, see [Supported Connectors](#).
- **Data Engine:** Any changes to data or transformation steps in your flow that cannot be pushed to the underlying data source are processed using the Data Engine process. For example, SQL Server does not natively support regular expressions. When connecting to SQL Server, Tableau Prep lets you write regular expression calculations. [Tableau](#)

Prep Conductor uses Data Engine to temporarily load the data and then perform the regular expression.

#### Performance and Scale Recommendations

- **Isolate flows to a separate node:** Running Tableau Prep Conductor on a separate node will isolate flow workflows from other Tableau workloads. This is highly recommended since Prep flows are CPU and RAM intensive.
- **Manage flow schedules:** You can control flow execution by creating flow schedules. These schedules let you determine when flows run, how frequently they run, the priority of that schedule, and whether to run items in that schedule serially or in parallel.
- **Add resources:** When scaling your Tableau Prep Conductor environment, we recommend scaling up to an 8 physical cores box per node running as many as 4 backgrounders on each. As you need more resources, we recommend adding more nodes to your server environment.

You can monitor user activity and performance of flows using Administrative views. For more information, see [Monitor Flow Health and Performance](#).

#### Topology and Configuration

By default, Tableau Prep Conductor is automatically enabled on a node where backgrounder is enabled. If the node role is set to exclude flows, then Tableau Prep Conductor is not installed on that node. For more information, see [Workload Management through Node Roles](#).

It is recommended that you enable Tableau Prep Conductor on a dedicated node to run flows. For more information, see the following topics:

- For new Tableau Server installations, see [Step 1 \(New Install\): Install Tableau Server with Tableau Prep Conductor](#).
- To enable Tableau Prep Conductor on an existing installation of Tableau Server, see [Step 1 \(Existing Install\): Enable Tableau Prep Conductor](#).

## Tableau Prep Flow Authoring

The Tableau Prep Flow Authoring process provides the interactive Prep Flow experience in the browser, which lets users create and interact with flows on Tableau Server to clean and prepare data. For more information, see [Create and Interact with Flows on the Web](#). It was added in version 2020.4.

|                |   |
|----------------|---|
| <b>Process</b> | Tableau Prep Flow Authoring   |
| <b>Status</b>  | Status of the Tableau Prep Flow Authoring process is visible on the Status Page. For more information, see <a href="#">View Server Process Status</a>   |
| <b>Logging</b> | Logs generated by the Tableau Prep Flow Authoring process are located in <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/flowed-itor</code> . For more information, see <a href="#">Tableau Server Logs and Log File Locations</a> |

Tableau Prep Flow Authoring is enabled by default. It uses these components:

- **Tableau Prep Minerva Service:** Used by Tableau Prep Flow Authoring for querying datasources. By default, it is automatically enabled on a node where Tableau Prep Flow Authoring is enabled.
- **Data Engine:** The Data Engine creates data extracts and processes queries. By default, it is automatically enabled on a node where Tableau Prep Flow Authoring is enabled.
- **Gateway:** The Gateway process handles all requests to Tableau Server from browsers, Tableau Desktop, and other clients. By default, it is automatically enabled on a node where Tableau Prep Flow Authoring is enabled.

### Performance and Scale Recommendations

Tableau Prep Flow Authoring can be CPU and RAM intensive. It is recommended to monitor server and adjust your deployment as necessary by isolating flow authoring to a separate node or adding server resources.

## Isolate flow authoring to a separate node

Running Tableau Prep Flow Authoring on a separate node will isolate flow authoring workflows from other Tableau workloads. If you have a busy server with many extract refreshes, and a lot of viz editing and viewing and you don't want to cause disruption to this workload, then it is recommended to isolate Prep Flow Authoring to its own server node. This means that all flow editing is directed to a dedicated node. For more information see [Configure Nodes](#).

**Note:** Prep Web Authoring uses shared services such as the Application Server (VizPortal), the PostgreSQL repository, the Cache Server, and Hyper. If those services are already at capacity, they might also need additional resources because of the additional Prep Web Authoring load.

If you are running Tableau Server on a multi-node cluster, you can dedicate one or more nodes for running Backgrounder. Using the Backgrounder process, you can isolate background workloads such as Tableau Prep Conductor from all your interactive workloads such as Prep Flow Authoring and VizQL Server. For more information, see [Tableau Server Backgrounder Process](#) and [Workload Management through Node Roles](#).

For core and user-based deployments, it's strongly recommended that at least one node be dedicated to flows for best performance. While you can run flows on any licensed Server core, the additional resource cores purchases should only run Tableau Prep Conductor, and not extract refreshes or VizQL processes.

## Add resources

As you need more resources, you can add more nodes to your server environment. When planning your nodes, several factors can influence your decision on how much additional hardware you need to allocate.

The main things to consider when planning your nodes are:

- The number of concurrent users or concurrent sessions you expect during peak hours. The number of concurrent sessions per user can be set using the TSM option `maestro.sessionmanagement.maxConcurrentSessionPerUser`. For more information, see [tsm configuration set Options](#).
- The number of data input nodes your flows have on average and the amount of data they have. The maximum row sampling limit can be set using the TSM option `maestro.app_settings.sampling_max_row_limit`. For more information, see [tsm configuration set Options](#).
- The complexity of the flows being authored and the number of nodes. Node types like joins, unions, aggregates, and pivots will, in general, require more resources.

### License additional offerings

Additional licenses for Data Management and Advanced Management are required for configuring nodes.

| <b>OFFERING</b>     | <b>Allows you to:</b>  |
|---------------------|--|
| Data Management     | <p>Configure a node to run only flows, or configure a node to run all jobs except flows. Tableau Prep Conductor must be running on the node.</p> <p>The Data Management license includes Tableau Prep Conductor, which enables you to schedule and track flows. The license is for a single Tableau Server deployment, which can be role-based or core-based.</p> <p>As a Creator, Data Management is not required to create and edit flows directly on your server.</p> |
| Advanced Management | <p>Configure where the different types of workloads are processed through node rules. For example, you can run flows on one node and subscriptions and alerts on another node.</p>   |

## Topology and Configuration

To make Tableau Prep Flow Authoring highly available, configure two instances of Tableau Prep Flow Authoring on nodes when enabling it.

Here is an example of a two node configuration:

- Topology
- Security
- User Identity & Access
- Notifications
- Licensing

## Topology

Configure and improve Tableau Server performance by adding or removing nodes and changing process configurations and other settings. [Learn more](#)

## Tableau Server Dynamic Topology Changes

With the introduction of TSM, Tableau Server also introduced the ability to make certain topology changes or updates without restarting the server. These are known as dynamic topology changes, and are possible with the Backgrounder and VizQL Server processes.

You can increase or decrease the number of backgrounder or VizQL Server instances on a node without requiring a Tableau Server restart if the node already has at least one instance of the process running. You must be only changing the number of instances of Backgrounder or

VizQL Server. If you also add or remove another process, or if you are adding the first instance of Backgrounder or VizQL Server to a node or removing the last instance of either from the node, Tableau Server will require a restart.

### Dynamic configuration changes

Beginning with version 2020.2.0 of Tableau Server, certain configuration changes can also be made dynamically using configuration keys. You can make dynamic topology changes at the same time you make dynamic configuration changes, without needing to restart Tableau server. For more information about dynamic configuration changes, see [Tableau Server Release Notes in What's New and Changed for 2020.2 in Tableau Server](#).

### Example Scenarios

To better understand why this might be useful, consider these examples:

- **Backgrounder**—At the end of a sales quarter your sales team is using Tableau Server to keep track of their numbers. Dashboards that depend on extracts are showing sales people how they are doing. Any delay in extract refreshes means your team is not seeing the most up-to-date numbers. You can add additional backgrounders to any node that already has at least one backgrounder or VizQL Server, and increase the throughput of extract refreshes, helping to guarantee the numbers are up-to-date as your team finished up their quarter. Later, after the quarterly push, you can reduce the backgrounder instances again to return Tableau Server to its original configuration.
- **VizQL Server**—Similarly, if Tableau Server is unable to keep up with view refreshes, you can quickly add additional VizQL Server instances to any node that already has at least one instance of either VizQL Server or backgrounder configured. In the above backgrounder example, you might want to remove VizQL Servers temporarily, to accommodate additional backgrounders, and then re-add them back before your users arrive in the morning.

### Making dynamic topology changes

You can make dynamic topology changes using the TSM Web UI, or on the command line. To use the Web UI, sign in to TSM using a browser, and on the Configuration tab, update the number of backgrounder or VizQL Server instances for the node you are updating. For details, see [Configure Nodes](#). To make your changes using the TSM CLI, at a command

prompt, run the `tsm topology set-process` command. For details, see [Changing the number of processes on a node](#).

### Impact of dynamic topology changes

When making dynamic topology changes that remove existing instances of VizQL Server or backgrounder, the instances are removed immediately. Be aware of the following potential impacts to users and currently running jobs:

- **Backgrounder**—Any currently running jobs are terminated. The normal Tableau Server retry logic will restart these jobs, using another backgrounder instance.
- **VizQL Server**—Any currently active sessions are terminated. Users may see an error message. Refreshing the browser should clear the error.

### Best practices

Tableau recommends you test any dynamic topology changes you plan on using, before implementing them in your production environment. This will help you fully understand potential impacts to your users and scheduled refreshes and subscriptions, and allow you to most efficiently take advantage of the flexibility offered by dynamic topology.

### Automating dynamic topology changes

You can automate dynamic topology changes. For example, if you have most of your extract refreshes scheduled overnight, and know your server has extra capacity because users are not signed in, you can use a script or other automated deployment tool to add backgrounder instances when they can be most efficiently used, and then remove them before the start of the work day.

To automatically get the status of processes, use the `tsm status -v` command and parse the output in your script. Alternately, you can use the TSM REST API get server status. The API is currently in alpha. For more details, see [Get server status](#).

A sample script to set four instances of backgrounder on node2 might look like this:

```
echo Adding/Removing Processes
tsm topology set-process -pr backgrounder -n node2 -c 4
tsm pending-changes apply
echo Done!
```

### Additional information

#### Tableau Server Processes

## Server Process Limits

When you reconfigure processes for Tableau Server, there is a limit to the amount that you can increase the number of process instances. By default, the limit is set to eight. If your machine has enough RAM and CPU cores, and you want to go above this limit, you can change the limit using the `service.max_procs` configuration option. For each process instance, Tableau recommends that the machine running the process have at least 1 GB of RAM and 1 logical CPU core.

To change the maximum number of processes allowed:

1. Type the following command, where `number` is the maximum number of process instances you want to allow:

```
tsm configuration set -k service.max_procs -v <number>
```

For example:

```
tsm configuration set -k service.max_procs -v 10
```

2. Next type:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart

behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Tableau Services Manager Ports

The processes and services that make up the components of Tableau Services Manager (TSM) and Tableau Server on Linux use various ports to communicate. By default, most these ports are assigned (mapped) dynamically from a predefined range of ports. The port assignments are made for each service or process when it is installed. You can control what ports are used in a variety of ways.

A small subset of processes do not use dynamic port mapping and behave uniquely. For more information, see [Ports that are not dynamically mapped](#), below.

**Note:** This operation includes steps that you may need to perform using the TSM command line.

### Ephemeral port use

If your operating system is configured to use ephemeral ports, your Tableau traffic may be routed through these, even when configured as described below. This happens at the OS level and is not something you can configure in Tableau. If you want to control port usage, consult your operating system documentation on how to limit ephemeral port usage.

### Firewall requirements

If you are running a firewall on the computer where you will be installing Tableau Server, then you will need to open the following default ports for Tableau Server traffic. All port numbers, except 443 can be changed.

| Port        | TCP/UDP | Used by ...  | TYPE OF INSTALLATION |                                 |
|-------------|---------|--|----------------------|---------------------------------|
|             |         |  | All                  | Distributed / High Availability |
| 80          | TCP     | Gateway  | X                    |                                 |
| 443         | TCP     | SSL. When Tableau Server is configured for SSL, the application server redirects requests to this port. Do not change this port.   | X                    |                                 |
| 8850        | TCP     | Tableau Services Manager.  | X                    |                                 |
| 8060        | TCP     | PostgreSQL database.   | X                    |                                 |
| 8061        | TCP     | PostgreSQL backup verification port  | X                    |                                 |
| 8000-9000   | TCP     | Range of ports reserved by default for dynamic mapping of Tableau processes  |                      | X                               |
| 27000-27009 | TCP     | Range of ports used by Tableau Server for License service. This range must be open on the node running the License service and accessible from other nodes. By default, the initial node runs the License service. | X                    |                                 |

See Configure Local Firewall.

## Port assignment

There are two approaches you can use for port assignment or mapping in TSM:

- **Dynamic port assignment.** This is the default and requires the least intervention by the administrator.

- **Manual port assignment.** This option requires an administrator to individually assign each port.

If you change port assignments and you are running a local firewall, see [Local firewall configuration](#).

## Dynamic port assignment

You can control which ports are used by changing the range of ports available to the dynamic assignment process. Doing this leaves dynamic port assignment in place but restricts the ports that can be chosen. With dynamic port assignment in place, you can still choose to assign ports for certain processes manually. This approach enables you to assign specific ports to specific processes, while leaving the others to be mapped dynamically. Using dynamic mapping, with or without some individually assigned ports is the easiest approach, and should satisfy the requirements of most customers. Dynamically assigned ports are preserved if you export your Tableau Server configuration.

By default, ports are assigned for each service or process from available ports between 8000 to 9000. This assignment takes place when services are installed for the first time on a node. After Tableau Server is initialized, you can see which ports are being used by which services or processes by running this command:

```
tsm topology list-ports
```

If you have a multi-node cluster, ports on all nodes are listed.

### Changing the port range

For organizations that have specific requirements for ports being used, the easiest way to control this is to change the range from which ports are dynamically selected. You need to do this at installation, by specifying a minimum and maximum port for the range in your configuration file.

**Note:** The minimum allowable size of your port range will depend on your server installation and how many services or processes you are running. As a general best practice you should not restrict the range too tightly because port assignment is done by selecting random ports within the range, and if you do not allow a large enough range, selection may fail to find an available port.

To limit the range from which available ports are chosen to those between 8300 and 8600, your configuration file would include an entry similar to this:

```
"configKeys": {
  "ports.range.min": "8300",
  "ports.range.max": "8600"
}
```

### Blocking specific ports within the range

Beginning with version 2021.1.0, you can specify certain ports that are within the dynamically assigned range but should not be used by Tableau. This is useful if you have other software on your Tableau Server computers that rely on ports within the range Tableau is using.

To specify ports within the range that should not be used by TSM and Tableau Server, use the `ports.blocklist` configuration key:

```
tsm configuration set -k ports.blocklist -v <port>[,<port>,<port>]
```

For example:

```
tsm configuration set -k ports.blocklist -v 8000,8088, 8090
```

### Disabling dynamic port assignment

If you need more control of port assignment than you can get through a combination of restricting port range and individually assigning ports, you can disable dynamic port mapping at initial server configuration. Disabling dynamic port mapping requires you to manually assign every port for every process, so we don't recommend this unless you need to control every single port assignment.

If you disable dynamic port mapping, you must configure the port for each process on each node of your installation.

To disable dynamic mapping, your configuration file would include an entry similar to this:

```
"configKeys": {  
  "service.port_remapping.enabled": false  
}
```

**Important:** When you disable dynamic port assignments, the License service port range is not included. This range (27000-27009) must be open on the node running the License service and accessible from other nodes. By default, the initial node runs the License service.

### Manual port assignment

You can disable automatic port assignment entirely and assign a port for each process individually. If you do this, you must assign a port for every process on every node. You can assign ports either in a configuration file, when the processes are first installed, or after installation, using a TSM command. Only ports assigned at process installation are preserved if you export your Tableau Server configuration.

You can specify individual ports for specific processes, whether or not dynamic mapping is enabled. You might do this if you want a process to use a particular port, or if you've disabled dynamic mapping. There are two ways to specify ports for processes: during installation or after installation.

#### Configuring ports during installation

We recommend configuring port assignment during the installation process as described here. Changing ports after installation is a much more labor-intensive process.

To configure ports during installation, create a json file that specifies your port configuration. This process is similar to defining a non-default port range, but instead you specify a particular port for a specific service or process. If you are going to assign specific ports, this approach is

the most robust way to do so because the port mapping is preserved if you export the server configuration and topology settings using the `tsm settings export` command.

To define ports at installation, add information to your configuration file to specify the node (`workerN`), process (`servicename`) and instance ID (`instanceid`), port type (`porttype`), and the port to be used. The format looks like this:

```
workerN.{servicename}_{instanceid}.{porttype}.port:X
```

Where:

- `workerN` is an optional parameter and identifies the node for which the remapping applies. Node numbers start with zero (0).  
We recommend you do not include this parameter unless you need to map different ports for the same service on different nodes. If you leave this parameter off, you can map a service port on the initial node, or map the same service port on multiple nodes.
- `servicename` is the name of the process or service that will use the port.
- `instanceid` is the instance of the process. If you are going to be configuring multiple instances of a process on one node, you would need to increment this value for each instance. Start the `instanceid` at zero (0) and increment it by one (1) for each instance of the process. For services that only install a single instance on any given node, this must be left off.
- `porttype` If setting the primary port, do not include this option.
- `port` is the port the process or service should use.

For example, to set the port for the first instance of the file store process on the initial node to 8500, you would include a configuration file entry similar to this:

```
"configKeys": {
  "filestore_0.port": "8500"
}
```

The example above does not include the optional `workerN` parameter, so sets the port on all nodes in the cluster. It also leaves off the `porttype` option because it is setting the primary filestore port.

**Important:** When specifying port changes with a configuration file, you must include the `--force-keys` parameter with the `tsm settings import` command.

### Configuring ports after installation

If you need to change ports after you have installed Tableau Server, use the `tsm topology set-ports` command. This approach allows you to specify a port for a specific process after that process has been installed. You are restricted by these limits:

- You must set ports individually, on each node.
- After you set an individual port, you must run `tsm restart`.
- The port assignments are not preserved if you need to import a Tableau Server configuration using `tsm settings import`.
- Port names use a different syntax for `tsm` commands than the syntax that is required for `configKeys`. The table at the end of this topic provides a syntax reference.

For example, to set second instance of the file store on the initial node to use port 8500:

```
tsm topology set-ports --node-name node1 --port-name filestore --  
port-value 8500 --instance 2
```

The following example shows how to use shorthand commands to set the JMX ports:

```
tsm topology set-ports -n node1 --port-name vizqlserver:jmx.rmi -pv  
9403 -i 1
```

```
tsm topology set-ports -n node1 --port-name vizqlserver:jmx -pv 9404  
-i 2
```

**Note:** Port entries are not validated when you enter them. Therefore, if you use a port that is already assigned, or if you mistype the syntax for a command, Tableau will not give an error until you restart. After restarting, you may see a generic error, *The reconfigure async job failed*.

If you add an incorrect `portname:type` with a valid port, you cannot delete the incorrect

entry. To update the port, you must reassign an unused port to that value to free up the port again.

### Ports that are not dynamically mapped

The Tableau Server repository uses two ports that are not dynamically mapped. These each have a default port that you can override using the `tsm configuration set` command and a process-specific parameter.

| Port names                             | Port (default) | Description   |
|--|----------------|---|
| <code>pgsql.port</code>                | 8060           | <p>Port for the Tableau Repository (PostgreSQL database).</p> <p>To override this port:</p> <pre>tsm configuration set -k pgsql.-port -v &lt;port&gt;</pre>                 |
| <code>pgsql.verify_restore.port</code> | 8061           | <p>Port for verifying the integrity of a repository backup.</p> <p>to override this port:</p> <pre>tsm configuration set -k pgsql.verify_restore.port -v &lt;port&gt;</pre> |

Because these ports do not use the dynamic port mapping system, they do not show up in the output of the `tsm topology list-ports` command. To see the value of these you need to use the `tsm configuration get -k <config.value>` command. For example:

```
tsm configuration get -k pgsql.port
```

## Controlling port remapping with initialize-tsm

Port assignments are made when services are installed. This means that in order to manually map ports for the TSM-specific processes, you need to assign the ports when you run the initialize-tsm script. The script includes options to specify ports for individual TSM services, as well as options for defining the minimum and maximum of the port range used with dynamic mapping, and you can disable dynamic mapping.

The table below lists the options for ports when running the initialize-tsm script.

**Table: initialize-tsm script port options**

| Script option            | Parameter  | Description  |
|--------------------------|------------|--|
| -i                       | <port>     | Sets the Coordination Service client port.   |
| -e                       | <port>     | Sets the Coordination Service peer port.   |
| -m                       | <port>     | Sets the Coordination Service leader port.   |
| -n                       | <port>     | Sets the TSM agent file transfer port.   |
| -o                       | <port>     | Sets the TSM Controller port.  |
| -l                       | <min-port> | Sets the bottom of the port range used for dynamically mapping ports.  |
| -r                       | <max-port> | Sets the top of the port range used for dynamically mapping ports.   |
| --disable-port-remapping |            | Disables dynamic port mapping. If you do this you must assign ports for every service or process used by TSM and Tableau Server. For more information, |

| Script option | Parameter | Description                       |
|---------------|-----------|-----------------------------------|
|               |           | see Manual port assignment above. |

## Dynamically mapped ports

This table lists the processes or services that use dynamically mapped ports.

| Port names: syntax for json file (configKeys) | Port names: syntax for tsm CLI | Description                       |
|---|--------------------------------|-----------------------------------|
| activemqserver.port                           | activemqserver:primary         | ActiveMQ Service service port.    |
| activemqserver.openwire.port                  | activemqserver:openwire        | ActiveMQ Service openwire port.   |
| appzookeeper_0.client.port                    | appzookeeper:client            | Coordination Service client port. |
| appzookeeper_0.peer.port                      | appzookeeper:peer              | Coordination Service peer port.   |
| appzookeeper_0.leader.port                    | appzookeeper:leader            | Coordination Service leader port. |
| backgrounder_0.port                           | backgrounder                   | Backgrounder primary port.        |
| backgrounder_0.debug.port                     | backgrounder:debug             | Backgrounder debug port.          |
| backgrounder_0.jmx.port                       | backgrounder:jmx               | Backgrounder jmx port.            |

| Port names: syntax for json file (configKeys) | Port names: syntax for tsm CLI       | Description                        |
|---|--------------------------------------|------------------------------------|
| backgrounder_0.jmx.rmi.port                   | backgrounder:jmx.rmi                 | Backgrounder jmx rmi port.         |
| backgrounder_0.recommendations.trainer.port   | backgrounder:recommendations.trainer | Backgrounder recommendations port. |
| backuprestore.port                            | backuprestore                        | Backup/Restore service port.       |
| cacheserver_0.port                            | cacheserver                          | Cache server port.                 |
| clustercontroller.status.port                 | clustercontroller:status             | Cluster Controller status port.    |
| clustercontroller.storage.port                | clustercontroller:storage            | Cluster Controller storage port.   |
| databasemaintenance.port                      | databasemaintenance                  | Database Maintenance port.         |
| dataserver_0.port                             | dataserver                           | Data server primary port.          |
| dataserver_0.debug.port                       | dataserver:debug                     | Data server debug port.            |
| dataserver_0.jmx.port                         | dataserver:jmx                       | Data server jmx port.              |
| dataserver_0.jmx.rmi.port                     | dataserver:jmx.rmi                   | Data server jmx rmi port.          |
| filestore.port                                | filestore                            | File store                         |

| Port names: syntax for json file (configKeys) | Port names: syntax for tsm CLI | Description  |
|---|--------------------------------|--|
|   |                                | primary port.  |
| filestore.status.port                         | filestore:status               | File Store status port.  |
| gateway.port                                  | gateway                        | <p>Gateway port.</p> <p>This defaults to 80, and if that is not available, to 8080. If that is not available, it tries 8000. That sequence is followed whether or not dynamic port assignment is enabled or not. If none of those ports are available and dynamic mapping is enabled, it takes an available port within the defined range. The gateway port must be the same on all nodes in a multi-node cluster, so if port 80 is selected on the initial node this is the</p> |

| Port names: syntax for json file (configKeys) | Port names: syntax for tsm CLI | Description   |
|---|--------------------------------|---|
|   |                                | port that will be used on all nodes and if it is unavailable on one of the other nodes, gateway port selection will fail. |
| hyper.port                                    | hyper                          | Data engine primary port.   |
| hyper.connection.port                         | hyper:connection               | Data engine connection port.  |
| indexandsearchserver.port                     | indexandsearchserver           | Index and Search server primary port.   |
| index-andsearchserver.transport.port          | indexandsearchserver:transport | Index and Search server transport port.   |
| licenseservice.vendor_daemon.port             | licenseservice:vendor_daemon   | License service vendor daemon port. Used for licensing-related communications between nodes in a multi-node installation. |
| samlservice.port                              | samlservice                    | SAML service port.  |

| Port names: syntax for json file (configKeys) | Port names: syntax for tsm CLI     | Description                                 |

| vizportal_0.debug.port                               | vizportal:debug                       | Application server debug port.           |
| vizportal_0.jmx.port                                 | vizportal:jmx                         | Application server jmx port.             |
| vizportal_0.jmx.rmi.port                             | vizportal:jmx.rmi                     | Application server jmx rmi port.         |
| vizqlserver_0.port                                   | vizqlserver                           | VizQL server primary port.               |
| vizqlserver_0.debug.port                             | vizqlserver:debug                     | VizQL server debug port.                 |
| vizqlserver_0.jmx.port                               | vizqlserver:jmx                       | VizQL server jmx port.                   |
| vizqlserver_0.jmx.rmi.port                           | vizqlserver:jmx.rmi                   | VizQL server jmx rmi port.               |

## Enable the JMX Ports

To help you work through a problem with Tableau Server, Tableau Support may ask you to enable the server's JMX ports. These ports can be useful for monitoring and troubleshooting, usually with a tool like JConsole. In versions 2022.1 and later, the JMX ports can be enabled securely and this is the recommended method. In versions earlier than 2022.1, you can only enable the ports unsecured.

### Enable secure JMX ports

Beginning with version 2022.1 of Tableau Server, you can enable JMX ports securely. This procedure explains how to enable secure JMX. To enable JMX in earlier versions, see [Enable unsecured JMX ports](#) below.

To enable secure JMX ports on Tableau Server:

1. Log on as a user with `sudo` access to the computer where TSM is installed.
2. Run this command:

```
tsm maintenance jmx enable
```

The command has several options you can provide when running it. If you do not provide any options when you run the command, you will be prompted for options based on the answers you give.

For example:

```
C:\Windows\system32>tsm maintenance jmx enable
We do not recommend you enable JMX unsecured on a production
environment. Would you like to enable security features for
JMX?
(y/n): y
JMX access is readonly by default. Would you like to add read-
write access?
(y/n): n
Would you like to enable SSL?
```

## Tableau Server on Linux Administrator Guide

```
(y/n): y
Would you like to require client authentication (mTLS)?
(y/n): n
Enabling JMX with the specified settings. This will perform a
server restart. Do you want to continue?
(y/n): y
Starting enable JMX asynchronous job.
```

For more information on the command and its options, see `tsm maintenance jmx enable`.

## Enable unsecured JMX ports

For versions of Tableau Server earlier than 2022.1.0, if you are enabling JMX ports they can only be enabled unsecured.

**Important** Enabling unsecured JMX ports can introduce some security risk. We strongly recommend using secure JMX. If you do not have a version of Tableau Server that supports this, be aware of the risk and mitigate it by limiting access to the JMX ports to the fewest number of clients that's practical for your scenario. You typically limit access using the host's firewall rules, an external security device, or routing rules.

To enable unsecured JMX ports on Tableau Server:

1. **Stop the server.**
2. Enter the following command:

```
tsm configuration set -k service.jmx_enabled -v true
```

3. Apply pending changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

- Restart the Coordination Service and TSM Administration Controller (as `tableau` system account):

```
sudo su -l tableau -c "systemctl --user restart appzookeeper_0.service"
```

```
sudo su -l tableau -c "systemctl --user restart tabadmincontroller_0.service"
```

It may take a few minutes for `tabadmincontroller` to restart. If you attempt to apply pending changes in the next step before the controller has fully restarted, TSM will not be able to connect to the controller. You can verify that the controller is running by using the `tsm status -v` command. Tableau Server Administration Controller should be listed as "is running".

- Start the server.**

#### How the JMX Ports Are Determined

By default, the JMX ports assigned dynamically, from within a range of available ports. For details on how port assignment is done, and how to override dynamic mapping, see [Tableau Services Manager Ports](#).

## ATRDdiag.exe Command Line Reference

You can use the `ATRDdiag` command line utility to manage licensing issues related to the login-based license management and authorization-to-run (ATR) features.

## Synopsis

```
ATRdiag -dumpATR -showAll -showVerbose -product ["Tableau Desktop"]
["Tableau Prep"]["Tableau Server"]

-subProduct {subProduct} -version {version} -setVersion {version}

-container -serverDataPath {path}

-log [Trace][Debug][Info][Warn][Error][Fatal][Off] -status -
deleteAllATRs

-deleteInvalidATRs -deleteATR {atrIdToDelete}

-enableATRFeature -disableATRFeature -enableLBLMFeature -dis-
ableLBLMFeature

-requireLBLMFeature -setDuration {seconds}
```

**Note:** All ATRdiag options are case-insensitive.

## Options

-dumpATR

Display a valid authorization-to-run (ATR) on the command prompt (if present). Use -version/-product/-subProduct/-version to control which ATR is dumped if more than one is valid.

-showAll

Enumerate the contents of the registry to see available ATRs.(some of which might not be valid).

-showVerbose

Enumerate the contents of the registry and use `-version/-product/-sub-Product/-version` to provide per-product.

```
-product ["Tableau Desktop"]["Tableau Prep"]["Tableau Server"]
```

Defaults to "Tableau Desktop". Must specify "Tableau Server" to display Server ATR.

For example: `atrdiag -product "Tableau Server"`

```

  TTL Start: Fri Dec 3 18:01:47 2021
```

```
-subProduct {subProduct}
```

Defaults to "Professional".

```
-container
```

Container mode, only for Tableau Server. Must specify `-product "Tableau Server"`.

```
-serverDataPath
```

The location of Server data under Container mode. Defaults to `"/var/opt/tableau/tableau_server/"`.

```
-version {version}
```

No default; a valid value for this field is "Tableau 2021.1".

```
-setVersion {version}
```

## Tableau Server on Linux Administrator Guide

Persist a default value for `-version`.

```
-log [Trace] [Debug] [Info] [Warn] [Error] [Fatal] [Off]
```

Display ATR log information.

```
-status
```

Provide ATR feature status (enabled or disabled), the license server, and dump the ATR.

```
-deleteAllATRs
```

Remove all ATRs present on the machine.

```
-deleteInvalidATRs
```

Remove all invalid ATRs.

```
-deleteATR {atrIdToDelete}
```

Remove an ATR by ID.

```
-enableATRFeature
```

Turn on the ATR feature. Must run as an administrator. For use on Tableau Desktop only.

```
-disableATRFeature
```

Turn off the ATR feature. Must run as an administrator. For use on Tableau Desktop only.

```
-enableLBLMFeature
```

Turn on login-based license management (LBLM). Must run as an administrator.

`-disableLBLMFeature`

Turn off login-based license management (LBLM). Must run as an administrator.

`-requireLBLMFeature`

Set the login-based license management (LBLM) feature to required. Must run as an administrator.

`-setDuration {seconds}`

Set `ATRRequestedDurationSeconds` to `seconds`. Must run as an administrator.

## Global Options

`-h, --help`

Optional.

Show the command help.

## Help Output for initialize-tsm Script

The following help content is the output when you run the following command:

```
sudo ./initialize-tsm -h
```

The `initialize-tsm` script is installed to `/opt/tableau/tableau_server-  
/packages/scripts.<version_code>/`.

## Output

REQUIRED

`--accepteula` Indicate that you have accepted the End User License Agreement (EULA).

You can find the EULA in `/opt/tableau/tableau_server-  
/packages/docs.<version_code>`

## Tableau Server on Linux Administrator Guide

### OPTIONAL

- `-c config-name` Set the service configuration name.  
If not set, the default is "tabsvc".
- `-d data-directory` Set a custom location for the data directory  
if it's not already set. If not set, the default is  
"/var/opt/tableau/tableau\_server".
- `-b bootstrap-file` Optional. Location of the bootstrap file down-  
loaded from the Tableau Services Manager  
on existing node. Must be provided to join existing Tableau  
Server cluster.
- `-u username` Name of the user with admin privileges on  
existing Tableau Services Manager.  
Required if `-b` option specified.
- `-p password` Password for the Tableau Services Manager  
admin user.  
Note: This option was removed beginning in version 2021.3.0 to  
improve script security.
- `-f` Bypass warning messages.
- `-g administrative` Do NOT add the current user to the "tsmadmin"  
group, used for default access to Tableau Services Manager,  
to the "tableau" group, used for easier access to log files.
- `-a username` The provided username will be used as the  
user to be added  
to the appropriate groups, instead of the user running this  
script. Providing both `-a` and `-g` is not allowed.
- `-q` Quiet, suppress output except for errors and warn-  
ings.

## Tableau Server on Linux Administrator Guide

`--disable-account-creation` Do not create groups or user accounts for Server and TSM authorization. However, the values in: `unprivileged-user` and `unprivileged-group` will still be used in TSM configuration.

`--http_proxy=<value>` Http forward proxy for Tableau Server. Its value should be `http://<proxy_address>:<proxy_port>/`. For example, `--http_proxy=http://1.2.3.4:3128/`  
`y=http://example.com:3128/`

`--https_proxy=<value>` Https forward proxy for Tableau Server. Its value should be `http://<proxy_address>:<proxy_port>/`. For example, `--https_proxy=http://example.com:3128/`. Take care to use `https_proxy` environmental variable. Do not specify the `https_proxy` environmental variable.

`--no_proxy=<value>` Environment variable that directs certain URIs to bypass the forward proxy. For example, `--no_proxy=localhost,127.0.0.1,localaddress,`

`--[no-]activation-service` Specify whether the Tableau authorization-to-run (ATR) service should be used to activate Tableau Server. This option is ideal for cloud-based or virtual machines but is available to anyone who can activate their copy of Tableau Server on their machine. If product activation is a permanent choice that cannot be undone later. If no option is specified, the Tableau authorization-to-run (ATR) service will be used to activate Tableau Server.

## Help Output for upgrade-tsm Script

The following help content is the output when you run the following command:

```
sudo ./upgrade-tsm -h
```

The `upgrade-tsm` script is installed to `/opt/tableau/tableau_server-  
/packages/scripts.<version_code>/`.

## Output

```
Usage: upgrade-tsm --accepteula [optional arguments]
```

```
Upgrade Tableau Server cluster to version <version number>.
This script should be run from any Tableau Server cluster node
after Tableau Server <version number> package
has been installed on all nodes.
```

### REQUIRED

```
--accepteula                                Indicate that you have
accepted the End User License Agreement (EULA).
                                             You can find the EULA in docs directory

-u <value>, --username=<value>              TSM administrator user
name. Required if it is run using a non-TSM administrator
```

## Tableau Server on Linux Administrator Guide

account on the initial node, or if upgrading prior to 2019.2.

`-p <value>, --password=<value>` TSM administrator password.  
Required if the `--username` option is specified.  
If a password is required but not provided, `-p` must be provided for the password.

OPTIONAL

`--debug` Print each command as it is run for debugging purposes. Produces extensive output.

`--trust-admin-controller-cert` Do not validate the server certificate.

`--no-prompt` Suppress script prompts. You will only be prompted for missing required parameters, for example, if you specify a user password. If the script needs to stop or restart Tableau Server without warning or prompting. Use this if you automate the upgrade with a script.

`--external-repository-config-file=filename` Required if upgrading from a Tableau Server that uses a later major version of PostgreSQL to use an external repository. The filename is a configuration file describing a new instance of the external repository. The new instance must be the same type of external service as the current external repository, but with the supported version of PostgreSQL.

`--external-repository-cert-file=filename` Required if upgrading from a Tableau Server

Tableau Server

figured to use an

file for the new

type

with the

that uses a later major version of PostgreSQL

external repository. The filename is an SSL

external repository. The new repository should

of external service as the current external

supported version of PostgreSQL.

## View Server Version

The version of Tableau Server you are running is important. It determines the functionality and capabilities you have access to. Version is also important when you are upgrading, because in some cases how you upgrade depends on which version you are upgrading from, and which version you are upgrading to. Knowing your version is easy, once you understand how to find it.

- Viewing version in Tableau Server—All server users can view the version of Tableau Server from the Help menu in the server web UI.
- Viewing version in Tableau Services Manager (TSM)—TSM administrators can view the versions of TSM and Tableau Server from the TSM command line (CLI).

### Viewing the server version from the Tableau Server web UI

- While logged into Tableau Server, click the information icon (  ) and **About Tableau Server**.

The version of Tableau Server is listed in the About Tableau Server dialog box:

## Viewing the server version and TSM version from the TSM command line

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).
2. Run the following command:

```
tsm version
```

The output displays the versions of Tableau Services Manager (TSM) and Tableau Server.

For example:

```
C:\>tsm version
Tableau Services Manager command line version 20182.18.1214.0751.
Tableau Server version 20182.18.1214.0751.
```

## Short version, long version, and version\_code

In most cases, when you need to know your version number, you need to know the "short" version. This version number displays in the About Tableau Server dialog box and is made up of three parts: major, minor, and maintenance versions. The short version number has this format: `nnnn.n.n`. For example: `2018.2.5`.

A longer version includes the major and minor version numbers, as well as other build-specific information, and has this format: `nnnnn.nn.nnnn.nnnn`, for example: `20182.18.1214.0751`. When you see a reference to `<version_code>` in this documentation, it means this longer version. The most common reference to this `version_code` or long version in the documentation is when we are discussing install locations or paths to the scripts or bin directories.

Tableau Server is installed in a `/packages` directory, with subdirectories that include the long version in the path name. This means that when you are navigating to a location within the `/packages` directory, you need to include the long version. For example, the `/scripts` directory: `/opt/tableau/tableau_server/packages/scripts.<version_code>/`.

For example: `/opt/tableau/tableau_server/packages/scripts.20182.18.1214.0751`

### Finding the long version number

This longer version also displays in the About Tableau Server dialog box, in parentheses:

## Configure Einstein Discovery Integration

Beginning with version 2021.1.0, Tableau Server supports integration with Einstein Discovery, making Einstein Discovery predictions available to authors and viewers of workbooks and dashboards. Starting in version 2021.2.0, Einstein Discovery predictions is also now available when authoring flows on the web.

Einstein Discovery in Tableau is powered by [salesforce.com](https://salesforce.com). Consult your agreement with [salesforce.com](https://salesforce.com) for applicable terms.

To integrate Einstein Discovery with Tableau Server, there are several necessary configuration steps, including some in Tableau Server, and some in the Salesforce org running Einstein Discovery. This overview outlines these steps for Dashboard extensions, Analytics extensions, and Tableau Prep extensions, and provides links to specific topics with steps for completing the server configuration.

For details on how to use Einstein Discovery predictions in Tableau, including licensing and permission requirements, see [Integrate Einstein Discovery Predictions in Tableau](#) in the Tableau Desktop and Web Authoring Help. For information about adding predictions in flows, see [Add Einstein Discovery Predictions to your flow](#).

### Einstein Discovery dashboard extensions

The Einstein Discovery dashboard extension allow workbook authors to surface real-time predictions in Tableau. The dashboard extension delivers predictions interactively, on-demand, using source data in a Tableau workbook and an Einstein Discovery-powered model deployed in Salesforce.

To configure Tableau Server for the Einstein Discovery dashboard extension you need to do the following:

1. In Tableau Server:
  - a. Enable saved OAuth tokens for data connections and extensions in Tableau Server. Allow Saved Access Tokens

- b. Enable Dashboard extensions for the server. See: Manage Dashboard and Viz Extensions in Tableau Server
2. In Salesforce, in the organization running Einstein Discovery:
  - a. Configure CORS in Salesforce.com for Einstein Discover Integration in Tableau Server.
  - b. In Salesforce, in the organization running Tableau CRM, create a connected app. See Step 1: Create a Salesforce connected app.
3. In Tableau Server, configure server for saved SF OAuth credentials using information from the connected app. Step 2: Configure Tableau Server for Salesforce.com OAuth

## Einstein Discovery analytics extensions

The Einstein Discovery analytics extension gives your users the ability to embed predictions directly in Tableau calculated fields. A table calc script requests predictions from a model deployed in Salesforce by passing its associated prediction ID and input data that the model requires. Use Model Manager in Salesforce to auto-generate a Tableau table calculation script, and then paste that script into a calculated field for use in a Tableau workbook.

To configure Tableau Server for either the Einstein Discovery analytics extension you need to do the following:

1. In Tableau Server:
  - a. Enable saved OAuth tokens for data connections and extensions in Tableau Server. Allow Saved Access Tokens
  - b. Enable analytics extensions for the server and configure a connection type. See: Configure Connections with Analytics Extensions
2. In Salesforce, in the organization running Einstein Discovery, create a connected app. See Step 1: Create a Salesforce connected app.
3. In Tableau Server, configure server for saved SF OAuth credentials using information from the connected app. Step 2: Configure Tableau Server for Salesforce.com OAuth

## Einstein Discovery Tableau Prep extensions

*Supported in Tableau Server and Tableau Cloud starting in version 2021.2.0*

The Einstein Discovery Tableau Prep extension enables users to embed Einstein predictions directly in their flows when authoring flows on the web.

To configure Tableau Server or Tableau Cloud for the Einstein Discovery Tableau Prep extension you need to do the following:

1. In Tableau Server:
  - a. Enable saved OAuth tokens for data connections and extensions in Tableau Server. See [Allow Saved Access Tokens](#)
  - b. Enable Tableau Prep Extensions for the server. See [Enable Tableau Prep Extensions](#).
2. In Salesforce, in the organization running Einstein Discovery, create a connected app. See [Step 1: Create a Salesforce connected app](#).
3. In Tableau Server, configure server for saved SF OAuth credentials using information from the connected app. [Step 2: Configure Tableau Server for Salesforce.com OAuth](#)

## Configure CORS in Salesforce.com for Einstein Discover Integration in Tableau Server

In version 2021.1.0 the ability to integrate Einstein Discovery predictions into Tableau Dashboards was added. You can do this using the Einstein Discovery dashboard extension. A prerequisite for this is configuring Cross-Origin Resource Sharing (CORS) in the Salesforce org that hosts Tableau CRM and includes the model and predictions that are going to be used.

This procedure explains how an administrator in a Salesforce.com organization would do this configuration. You can find more information about CORS in the Salesforce documentation, [Configure Salesforce CORS Allowlist](#).

Configure CORS for Einstein Discovery.

**Note:** This procedure documents the process in Salesforce Lightning. If you are using the traditional interface, the navigation may be different but the configuration is the same.

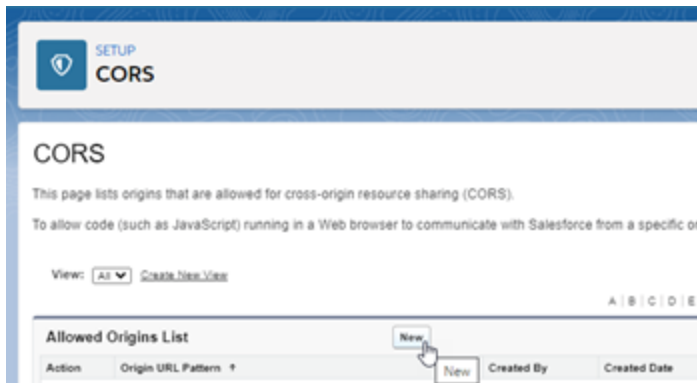

1. Sign in to your Salesforce.com developer account, click your user name in the upper-right, and then select **Setup**.

2. In the left navigation column, search for "cors" and select **CORS**.

3. In **CORS**, in the **Allowed Origins List** section, click **New**.

4. In **CORS Allowed Origin List Edit**, enter the URL of your Tableau server, beginning with "https://".

For more information about the URL pattern, see the Salesforce developer documentation: [https://developer.salesforce.com/docs/atlas.en-us.chat-terapi.meta/chatterapi/extend\\_code\\_cors.htm](https://developer.salesforce.com/docs/atlas.en-us.chat-terapi.meta/chatterapi/extend_code_cors.htm)

5. Click **Save**.

## Configure Connections with Analytics Extensions

Tableau supports a set of functions that your users can use to pass expressions to analytics extensions for integration with R, Python, and Einstein Discovery.

**Note:** You can use R and Python scripts to perform complex cleaning operations in your Tableau Prep flows, but configuration and functionality supported can be different. For information see [Use R and Python Scripts in your Flow](#) in the Tableau Prep help.

This topic describes how to configure sites on Tableau Server with analytics extensions.

Because Tableau Server provides an authentication mechanism, it can be more secure to expose analytics extensions functionality to users through Tableau Server than in Tableau Desktop.

For more information about user scenarios and configuring Tableau Desktop, see [Pass Expressions Analytics Extensions](#), in the *Tableau Desktop and Web Authoring Help*.

The configuration steps in this article are specific to Workbooks. For information about how you can use R and Python scripts to incorporate predictive modeling data into your flow, see [Use R and Python scripts in your flow](#) in the *Tableau Prep Help*.

### Feature change history:

- 2021.2 — You can configure multiple analytics extension connections for each site. (You are limited to a single Einstein Discovery connection per site.)

For information about how to determine analytics extension usage in workbooks, see [Determining analytics extensions usage](#).

- 2021.1 — Einstein Discover is included as an analytics extension option. Einstein Discovery in Tableau is powered by [salesforce.com](#). Consult your agreement with [salesforce.com](#) for applicable terms.
- 2020.2 — You can configure a different analytics extension connection for each site on your server. Prior to this change a single analytics extension configuration applied globally to all sites on the server.
- 2020.1 — This functionality is now called *analytics extensions*. Previously the feature was called "external services."

## Server SSL

To configure SSL for analytics extensions, you must install a valid certificate on the computer running Tableau Server. The certificate must be trusted by the computer running Tableau Server. The certificate Subject field or one of the SAN entries on must exactly match the URI of the analytics extensions service configuration.

## Enable analytics extensions

Before you configure extensions, you must enable analytics extensions server-wide.

1. Sign in to the Tableau Server Admin Area.
  - If you only have a single site (default) on your server, click **Settings**, and then go to Step 2.

- If you have multiple sites on your server:
  - a. Under **All Sites**, click **Manage all sites**.
  - b. Click the **Extensions** tab.
- 2. Scroll to **Analytics Extensions**, select **Enable analytics extensions**, and then click **Save**.

## Configure analytics extensions settings

1. Sign in to the Tableau Server Admin Area.
2. On the Settings page, click the **Extensions** tab and then scroll to **Analytics Extensions**. (On multi-site deployments of Tableau Server, navigate to the site where you want to configure analytics extensions, and then click **Settings>Extensions**.)
3. **Multi-site deployments only:** you must enable Analytics Extensions on each site. Under Analytics Extensions, select **Enable analytics extensions for site**.
4. Under Analytics Extensions, click **Create new connection**.
5. In the **New Connection** dialog, click the connection type you want to add, then enter the configuration settings for your analytics service:

6. The options you need to configure depend on the connection type you choose:
- For an Einstein Discovery connection, click **Enable**.
  - For TabPy, RServer, and Analytics Extensions API connections, enter the following information:
    - **Connection Name** (Required): Specify the server type you are connecting to. RSERVE supports connections to R using the RServe package. TABPY supports connections to Python using TabPy, or to other analytics extensions.
    - **Require SSL** (Recommended): Select this option to encrypt the connection to the analytics service. If you specify a `HTTPS` URL in the **Hostname** field, then you must select this option.
    - **Hostname** (Required): Specify the computer name or URL where the analytics service is running. This field is case sensitive.
    - **Port** (Required): Specify the port for the service.

## Tableau Server on Linux Administrator Guide

- **Sign in with a username and password** (Recommended): Select this option to specify user name and password that is used to authenticate to the analytics service.

7. Click **Create**.

Edit or delete an analytics extension connection

To edit or delete a configuration, navigate to **Analytics Extensions** on the **Extensions** tab of your site.

Click the **Edit** or **Delete** icon and follow the prompts to change the configuration.

## Client requirement: Intermediate certificate chain for Rserve external service

As of Tableau Server version 2020.1, you must install a full certificate chain on Tableau Desktop computers (Windows and Mac) that are connecting to a Rserve external connection through Tableau Server. This requirement is due to how Rserve manages the handshake on secure connections.

Importing a root certificate on the Tableau Desktop is not sufficient, the entire certificate chain must be imported onto the client computer.

## Script errors

Tableau cannot verify that workbooks that use an analytics extension will render properly on Tableau Server. There might be scenarios where a required statistical library is available on a

user's computer but not on the analytics extension instance that Tableau Server is using.

A warning will be displayed when you publish a workbook if it contains views that use an analytics extension.

This worksheet contains external service scripts, which cannot be viewed on the target platform until the administrator configures an external service connection.

## Determining analytics extensions usage

Beginning with version 2021.2, analytics extensions configurations are mapped at the workbook level. This allows administrators to use custom views to query the Tableau Repository and determine which workbooks are using which extensions, and how often they are used.

To do this you need to join the workbook connections table to tables showing workbook usage. For details about creating and using custom administrative views, see [Collect Data with the Tableau Server Repository and Create Custom Administrative Views](#).

## Changing the Identity Store

Infrastructure or business changes may require you to change the identity store on Tableau Server. There are two kinds of identity stores: local and external. When you installed Tableau Server you configured either a local identity store or an external identity store.

When you configure Tableau Server with a local identity store, all user and group information is stored and managed in the Tableau Server repository. In the local identity store scenario, there is no external source for users and groups.

When you configure Tableau Server with an external store, all user and group information is stored and managed by an external directory service. Tableau Server must synchronize with the external identity store so that local copies of the users and groups exist in the Tableau Server repository, but the external identity store is the authoritative source for all user and group data. Examples of external identity stores are OpenLDAP and Active Directory.

For more information about the Tableau identity store, see [Identity Store](#).

You can change from local store to an external store, or you can change from an external store to a local store. In either case, to change the identity store type, you complete these steps:

1. Uninstall and then reinstall of Tableau Server. The procedure for full uninstall and clean install are at the end of this topic.
2. Restore content and permissions.

In these steps the term "restore" does not refer to using the `TSM maintenance restore` command to restore the backup you are making. You cannot restore a backup (`.tsbak`) created on a Tableau Server instance that uses a different identity store than the target Tableau Server. The backup is a best practice safeguard, in case you need to go back to your original Tableau Server configuration.

### Warning

Changing the installation type on Tableau Server can be a complicated and time-consuming process. To avoid data loss or orphaning of content or users, you'll need to plan this process carefully. In all cases, user filters applied to workbooks and data sources will need to be updated manually after the change.

Most importantly, determine how you will transition content and permissions to the new identity store after you reinstall Tableau Server.

## Methods for restoring content and permissions

The following list describes two methods for restoring content and permissions after you reinstall Tableau Server. Select the method that best fits with your environmental requirements.

- **Method 1: Use site export and import**—In this method, you start by exporting each site in your existing deployment. Then, you install the new server and configure it for the new identity store type. You then create new users in the default site on the new server. Finally, you import all the original sites. During the import stage, you can map the

original identities to the new users that you created in the default site.

**Note:** When migrating sites between instances of Tableau Server, the target site must be on a version of Tableau Server that is the equal to or later than the version of Tableau Server for the source site. Both the source and target sites must be from supported versions of Tableau Server.

Because this method exports all content and permissions at each site, it is the best method for organizations that require a high fidelity replica of the content and permissions after the identity store change is complete. Some organizations require an identity store change as the result of an authentication change. In these cases, a different user name syntax is often a requirement in the new model. This method, which includes a process of mapping original user names to new names, provides flexibility for such scenarios.

- **Method 2: Fresh installation; users republish content**—In this method, you install a new version of Tableau Server and select the new identity store type during setup. You also create new sites. You then create users and give them access, and they republish their workbooks and data sources. Unlike the other method, in this one, you do not reuse any of your existing Tableau Server infrastructure.

This method is most appropriate for smaller deployments with fairly autonomous and data savvy users. From an administrative perspective, this method is the simplest, since you're not actively porting over content. However, because you rely entirely on users to republish content, this method may not be successful for large organizations or for those where centralized oversight of content is required.

## User filters

User filters are domain-specific. Therefore, when the domain of Tableau Server changes or authentication type changes, filters no longer function as expected. Although the user filters are generated by Tableau Server, after they are set by the user, the filters are stored in the

workbooks and data sources. Neither of these methods for changing the identity store modifies the contents of the workbooks or data sources.

As you plan the identity store change, you must also include a final task to correct user filtering in all workbooks and data sources with Tableau Desktop.

### User names and the Tableau Identity store

If you are using Method 1, it's helpful to understand how Tableau Server stores user names in the Tableau identity store. Tableau stores all user identities in the repository, which coordinates content permissions and site membership with various services in Tableau Server. Generally, an identity store configured for Active Directory store user names in the format, `domain\username`. Some organizations use a UPN (`jsmith@domain.lan`).

On the other hand, organizations that configure Tableau Server with local identity store usually create standard, truncated user names, such as `jsmith`.

In all cases, these user names are literal strings that must be unique in the Tableau identity store. If you are changing from one identity store type to another, then your target authentication, SSO, or user provisioning solution may require a specific user name format.

Therefore, to maintain all permissions, content, and user viability, one of the following must be true after you change the identity store type:

- The new user names must match the original user names, or
- The original user names must be updated to match a new format.

If an authentication change is driving the identity store change, then the target authentication scheme will likely impose a user name syntax that is different than your original user names. Method 1 includes a process where you can map original user names to new user names.

It's possible that the original user name format will work with the new authentication type. For example, if you used UPN names in a local identity store deployment, you might be able to use the same user names in an Active Directory deployment. You could also use the `domain\username` format for local identity store, as long as users continue to use that format to sign in to Tableau Server.

If you are changing from local identity store to an external Active Directory store, review the topic, [User Management in Deployments with External Identity Stores](#), as part of your planning process.

## Method 1: Use site export and import

You must use the same version of Tableau Server for the export and import operations.

1. Export all sites on your server. See [Export or Import a Site](#).
2. Back up, remove, and then reinstall .
3. Create new users on Tableau Server. You should have a new user that corresponds to each user on the original server.
4. Import the sites that you exported in Step 1. See [Export or Import a Site](#). During import, you will be prompted to map the new users to the original users.

## Method 2: Fresh installation—users republish content

Even if you do not plan to port content as part of your identity store change, we recommend that you back up the server.

1. Back up, remove, and then reinstall .
2. Create users, sites, and groups.
3. Inform your users of the new Tableau Server, provide them with credentials, and allow them to republish their content.

## Back up, remove, and then reinstall

Both methods include the following steps:

1. Back up Tableau Server
2. Remove Tableau Server.
3. Reinstall Tableau Server with the new identity store type.

### Step 1: Back up Tableau Server

As a best practice, you should back up the server before proceeding.

Follow the procedure, [Create a backup using the TSM command line interface \(CLI\)](#). Run the `backup` command with the `-d` option. The `-d` option adds the timestamp.

When you are finished, copy the backup file (.tsbak) to a safe location that is not a part of your Tableau Server installation.

### Step 2: Remove Tableau Server

You must completely remove Tableau Server from the computer. See [Remove Tableau Server from Your Computer](#).

### Step 3: Reinstall Tableau Server with new authentication type

1. Go to the [Tableau Customer Portal](#), sign in with your Tableau user name and password, and then download Tableau Server.
2. Install Tableau Server. See [Install and Configure Tableau Server](#) more information. During installation, you will select the new identity store type. See [Configure Initial Node Settings](#).

## External Identity Store Configuration Reference

Tableau Server supports connecting to an external directory using LDAP. In this scenario, Tableau Server imports users from the external LDAP directory into the Tableau Server repository as system users.

This topic provides a description of all LDAP-related configuration options Tableau Server supports. If you are connecting to Active Directory, we strongly recommend that you automatically configure the LDAP connection with Tableau Server as part of Setup, rather than configuring the connection manually. See [Configure Initial Node Settings](#).

The options listed in this reference can be used for any LDAP-compliant directory. If you do not have experience configuring LDAP, then work with your directory administrator, or with an LDAP expert.

This is a reference topic. For more information about how Tableau Server stores and manages users, start with [Identity Store](#).

## Configuration methods

Configuration parameters that enable Tableau Server to connect to your LDAP directory are stored in `.yaml` files. These files are managed and synchronized by various services in Tableau Server. Updating the `.yaml` files must be done using a Tableau Services Manager (TSM) interface.

Do not attempt to update `.yaml` files directly with a text editor. TSM must manage all updates for proper operation.

The `.yaml` configuration files are composed of key-value pairs. For example, the key, `wgserver.domain.username`, takes a username as a value. This key defines the username that will be used to authenticate to the LDAP directory during the bind operation.

There are four different TSM methods that can set `yaml` key values. The four methods are described here, using the `wgserver.domain.username` key as an example to illustrate the different methods:

- **configKey key-value pairs**—You can update a `.yaml` configuration file key by updating the `wgserver.domain.username` key running `tsm configuration set` Options, or by including the key in a JSON configuration file under a `configKey` entity. See [Configuration File Example](#).

The `configKey` key-value pairs in a JSON configuration file are the same as those used for `tsm configuration set` but they are set differently. This topic refers to both of these methods as *configKey*.

Unlike when using `configEntities` and native `tsm` commands that are described below, `configKey` input is not validated. When you set an option with a `configKey`, the value that you enter is copied as a literal string to the underlying `.yaml` configuration files. For example, for a key where `true` or `false` are the valid inputs, when you configure the key using a `configKey` key-value pair, you can enter an arbitrary string value and it will be saved for the key. In such cases, invalid values will undoubtedly lead to LDAP configuration errors.

We recommend using `configKeys` only when no option exists to set the configuration with the other three options listed below (`configEntities`, a native `tsm` command, or the TSM Web UI). When using `configKeys` be sure to double-check your values and be sure to mind case-sensitivity.

- `configEntities` JSON—You can update a `.yaml` configuration file by passing the `username` option in a `configEntities` JSON.

When you configure a value using `configEntities` options in a JSON file, the values are validated before they are saved. Values are case-sensitive. For details on how to configure a value using `configEntities`, see the `identityStore` Entity example. The JSON file is imported with the `tsm settings import` command. The options available for `configEntities` are a subset of all the `.yaml` key-value pairs.

Validation means that the import command will only succeed if all the values in the JSON file are valid data types. For example, if you enter `no` for a value that only accepts `true` or `false`, then you will receive an error and the configuration is not imported.

You can only import JSON configuration files only as part of the initial configuration. If you need to make LDAP changes after you have imported the JSON configuration file and initialized Tableau Server, do not attempt to re-import the JSON file. Instead, make individual key changes with native `tsm` commands if available, or using `configKeys` and `tsm configuration set`.

- Native `tsm` commands—You can update a `.yaml` configuration file by passing the `ldapuser` option with the *native tsm command* `tsm user-identity-store`. As with `configEntities`, values that you enter with the native `tsm` command are validated before they are saved.

Not all key-value pairs in a `.yaml` file can be set using native `tsm` commands.

- TSM GUI—You can set configuration values during Setup, using the TSM GUI. If you are connecting to Active Directory, and configure the Tableau identity store during Setup, with the GUI, then you are prompted for an account with AD read access. The

`wgserver.domain.username` key is set when you enter credentials.

This scenario only works if you are connecting to Active Directory. Tableau Server does not support arbitrary LDAP configuration as part of the GUI Setup process.

Consider using the [Tableau Identity Store Configuration Tool](#) to generate your LDAP json configuration file. The Tableau Identity Store Configuration Tool will also generate a list of key/value pairs that you can set by running `tsm configuration set` Options. The tool itself is not supported by Tableau. However, using a JSON file created by the tool instead of creating a file manually does not change the supported status of your server.

## Configuring Active Directory

If you are configuring Tableau Server to use Active Directory, we recommend using the TSM Web UI during installation. The TSM Web UI is optimized to configure Tableau Server for Active Directory with the minimum necessary input. See [Configure Initial Node Settings](#).

### Configuration reference table

| con-figEntities option<br>(Options are case sensitive) | Native tsm command | configKey<br>(Used with <code>tsm configuration set</code> command or in the <code>configKeys</code> section of a JSON file) | Scenario             | Notes  |
|--|--------------------|--|----------------------|--|
| type   | N/A                | <code>wgserver.authenticate</code>   | A-D, L-D, A-P, Local | Where you want to store user identity information. Values: <code>local</code> or <code>activedirectory</code> .<br><br>If you want to connect to any LDAP server, enter <code>activedirectory</code> . |

|         |     |  |                                 |   |
|---------|-----|--|---------------------------------|---|
| sslPort | N/A | wgserv-<br>er.domain.ssl_port                        | A-<br>D,<br>L-<br>D-<br>A-<br>P | Use this option to specify the secure port of the LDAP server. We recommend secure LDAP for simple bind. LDAPS is usually port 636.   |
| N/A     | N/A | wgserv-<br>er.-<br>domain.ldap.starttls.e-<br>nabled | A-<br>D,<br>L-<br>D-<br>A-<br>P | <p>Values: <code>true</code> or <code>false</code>.</p> <p>Beginning with version 2021.2, this key is set to <code>true</code> by default when Tableau Server is configured to connect to Active Directory. As a result, simple bind to LDAP directory is encrypted when a valid SSL/TLS certificate is present in the Tableau key store. For more information, see <a href="#">Configure Encrypted Channel to LDAP External Identity Store</a>.</p> <p>This key is set to <code>false</code> by default when Tableau Server is configured to connect to a an arbitrary (but not Active Directory) LDAP server.</p> <p>This key was introduced (but not set) in version 2021.1.</p> |
| port    | N/A | wgserv-<br>er.domain.port                            | A-<br>D,<br>L-<br>D-<br>A-<br>P | Use this option to specify the non-secure port of the LDAP server. Plain-text is usually 389.   |

|          |               |                               |                                 |  |
|----------|---------------|-------------------------------|---------------------------------|--|
| domain   | domain        | wgserv-<br>er.domain.default  | A-<br>D                         | <p>In Active Directory environments, specify the domain where Tableau Server is installed, for example, "example.lan".</p> <p>For non-AD LDAP: the string you enter for this value is displayed in the "Domain" column of user management tools. You can enter an arbitrary string, but the key cannot be blank.</p> <p>This key is redundant with wgserv-er.domain.fqdn. The values for both keys must be the same.</p> <p>Native tsm command: Uses tsm user-identity-store set-connection [options] command.</p> |
| username | ldapuser-name | wgserv-<br>er.domain.username | A-<br>D,<br>L-<br>D-<br>A-<br>P | <p>The user name that you want to use to connect to the directory service.</p> <p>The account that you specify must have permission to query the directory service.</p> <p>For Active Directory, enter the username, for example, jsmith.</p> <p>For LDAP servers, enter the distinguished name (DN) of the user that you want to use to connect. For example, "cn=--</p>  |

|                      |               |  |               |  |
|----------------------|---------------|--|---------------|--|
|                      |               |  |               | <p><code>jsmith,dc=example,dc=lan"</code>.</p> <p>Native tsm command: Uses <code>tsm user-identity-store set-connection [options]</code> command.</p>  |
| password             | ldap-password | wgserv-er.domain.password                | A-D, L-D, A-P | <p>The password of the user account that you will use to connect to the LDAP server.</p> <p>Native tsm command: Uses <code>tsm user-identity-store set-connection [options]</code> command.</p>  |
| directoryServiceType | N/A           | wgserv-er.-domain.-directoryservice.type | A-D, L-D, A-P | <p>The type of LDAP directory service that you want to connect to.</p> <p>Values: <code>activedirectory</code> or <code>openldap</code>.</p>   |
| kerberosPrincipal    | kerbprincipal | wgserv-er.-domain.ldap.principal         | A-D, L-D, A-P | <p>The service principal name for Tableau Server on the host machine. The keytab must have permission for this principal. Do not use the existing system keytab at <code>/etc/krb5.keytab</code>. Rather, we recommend that you register a new service principal name. To see principals in a given keytab, run the <code>klist -k</code> command. See Understanding Keytab Requirements.</p> <p>Native tsm command: Uses <code>tsm user-identity-store set-connection [options]</code> command.</p> |

|                           |           |  |             |   |
|---------------------------|-----------|--|-------------|---|
| hostname                  | host-name | wgserv-er.-domain.ldap.host-name                   | A-D-L-D-A-P | <p>The hostname of the LDAP server. You can enter a hostname or an IP address for this value. The host that you specify here will be used for user-/group queries on the primary domain. In the case where user-/group queries are in other domains, Tableau Server will query DNS to identify the appropriate domain controller.</p> <p>Native tsm command: Uses tsm user-identity-store set-connection [options] command.</p>   |
| member-sRetrievalPageSize | N/A       | wgserv-er.-domain.ldap.members.retrieval.page.size | A-D-L-D-A-P | <p>This option determines the maximum number of results returned by an LDAP query.</p> <p>For example, consider a scenario where Tableau Server is importing an LDAP group that contains 50,000 users. Attempting to import such a large number of users in a single operation is not a best practice. When this option is set to 1500, Tableau Server imports the first 1500 users in the first response. After those users are processed, Tableau Server requests the next 1500 users from the LDAP server, and so forth.</p> <p>We recommend that you modify this option only to accommodate the</p> |

|     |     |  |                                 |   |
|-----|-----|--|---------------------------------|---|
|     |     |  |                                 | requirements of your LDAP server.   |
| N/A | N/A | wgserver.-<br>domain.ldap.-<br>con-<br>nectionpool.enabled | A-<br>D,<br>L-<br>D-<br>A-<br>P | When this options is set to <code>true</code> , Tableau Server will attempt to reuse the same connection when sending queries to the LDAP server. This behavior decreases the overhead of having to re-authenticate with the LDAP server on each new request. Connection pooling only works with simple bind and TSL/SSL bind connections. Connection pooling is not supported for GSSAPI bind connections.   |
| N/A | N/A | wgserver.domain.accept_list                                | A-<br>D                         | Allows connection from Tableau Server to secondary Active Directory domains. A secondary domain is one that Tableau Server connects to for user synchronization, but is a domain where Tableau Server is not installed. To ensure that Tableau Server can connect to other Active Directory domains, you must specify the trusted domains by setting the <code>wgserver.domain.accept_list</code> option with TSM. For more information, see <code>wgserver.domain.accept_list</code> . |
| N/A | N/A | wgserver.domain.whitelist                                  | A-<br>D                         | <b>Important:</b> Deprecated as of version 2020.4.0. Use <code>wgserver.domain.accept_list</code> instead.<br><br>Allows connection from Tableau Server to secondary Active Directory   |

|                |            |                   |               |   |
|----------------|------------|-------------------|---------------|---|
|                |            |                   |               | <p>domains. A secondary domain is one that Tableau Server connects to for user synchronization, but is a domain where Tableau Server is not installed. To ensure that Tableau Server can connect to other Active Directory domains, you must specify the trusted domains by setting the <code>wgserver.domain.whitelist</code> option with TSM. For more information, see <code>wgserver.domain.whitelist</code>.</p> |
| kerberosConfig | kerbconfig | No direct mapping | A-D, L-D, A-P | <p>The path to the Kerberos configuration file on the local computer. If you are installing into Active Directory, we don't recommend using the existing Kerberos configuration file or keytab file that may already be on the domain-joined computer. See Identity Store</p> <p>Native tsm command: Uses <code>tsm user-identity-store set-connection [options]</code> command.</p>                                  |
| kerberosKeytab | kerbkeytab | No direct mapping | A-D, L-D, A-P | <p>The path to the Kerberos keytab file on the local computer. It is recommended that you create a keytab file with keys specifically for Tableau Server service and that you do not share the keytab file with other applications on the computer. For example,</p>  |

|                    |     |  |              |   |
|--------------------|-----|--|--------------|---|
|                    |     |  |              | <p>on Linux, you might place the keytab file in the <code>/var/opt/tableau/keytab</code> directory.</p> <p>Native tsm command: Uses <code>tsm user-identity-store set-connection [options]</code> command.</p>  |
| nickname           | N/A | wgserv-er.domain.nickname                  | A-D, L-D-A-P | <p>The nickname of the domain. This is also referred to as the NetBIOS name in Windows/Active Directory environments. The <code>nickname</code> option is required for all LDAP entities. The value cannot be null. If your organization does not require a nickname/NetBIOS, then pass a blank key, for example: <code>" "</code>.</p> |
| root               | N/A | wgserv-er.domain.ldap.root                 | L-D-A-P      | <p>If you do not use a dc component in the LDAP root or you want to specify a more complex root you need to set the LDAP root. Use the <code>"o=my,-u=root"</code> format. For example, for the domain, <code>example.lan</code>, the root would be <code>"o=example,u=lan"</code>.</p>   |
| server-SideSorting | N/A | wgserv-er.-domain.ldap.server_side_sorting | L-D-A-P      | <p>Whether the LDAP server is configured for server-side sorting of query results. If your LDAP server supports server-side sorting, set this option to <code>true</code>. If you are unsure whether your LDAP server supports this, enter <code>false</code>, as mis-configuration may cause errors.</p>                               |

|                |     |   |         |  |
|----------------|-----|---|---------|--|
| rangeRetrieval | N/A | wgserver.-domain.ldap.range_retrieval     | L-D-A-P | Whether the LDAP server is configured to return a range of query results for a request. This means that groups with many users will be requested in small sets instead of all at once. LDAP servers that support range retrieval will perform better for large queries. If your LDAP server supports range retrieval, set this option to <code>true</code> . If you are unsure whether your LDAP server supports range retrieval, enter <code>false</code> , as misconfiguration may cause errors. |
| bind           | N/A | wgserver.domain.ldap.bind                 | L-D-A-P | The way that you want to secure communication to the directory service. Enter <code>simple</code> for LDAP unless you are connecting to an LDAP server with Kerberos. For Kerberos, enter <code>gssapi</code> .  |
| N/A            | N/A | wgserver.-domain.ldap.domain_custom_ports | L-D-A-P | <p><b>Note:</b> This key is only supported for Tableau Server on Linux.</p> <p>Allows you to map child domains and their LDAP ports. Domain and port are separated by a colon (:) and each domain:port pair is separated by a comma (,) using this format: <code>FQDN1:port,FQDN2:port</code></p> <p><b>Example:</b> <code>tsm configuration set -k wgserver-</code></p>   |

|                       |            |   |         |   |
|-----------------------|------------|---|---------|---|
|                       |            |   |         | <pre>er.domain.ldap.domain_custom_ports -v child-domain1.lan:3269,child-domain2.lan:3269,child-domain3.lan:389</pre>  |
| distinctNameAttribute | N/A        | wgserver.-domain.ldap.dnAttribute       | L-D-A-P | <p>The attribute that stores the distinguished names of users. This attribute is optional, but it greatly improves the performance of LDAP queries.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>Important:</b> Do not set this option as part of the initial configuration. Only set this after you have validated overall LDAP functionality. You must have a dnAttribute set in your organization before setting this key.</p> </div> |
| groupBaseDn           | N/A        | wgserver.-domain.ldap.-group.baseDn     | L-D-A-P | <p>Use this option to specify an alternative root for groups. For example, if all of your group are stored in the base organization called "groups," then enter "o=groups".</p>   |
| N/A                   | classnames | wgserver.-domain.ldap.-group.classnames | L-D-A-P | <p>By default Tableau Server looks for LDAP group object classes containing the string "group". If your LDAP group objects do not fit the default class name, override the default by setting this value. You can</p>   |

|                  |             |  |  |
|------------------|-------------|--|--|
|                  |             |  | <p>provide multiple classnames separated by commas.</p> <p>If your group names include commas, you must escape them with a backslash (\). For example, if you have a group name, <code>groupOfNames, top</code>, then enter <code>"groupOfNames\, top"</code>.</p> <p>Tableau LDAP implementation interprets LDAP objects as either user or group. Therefore, be sure that you are entering the most specific class name. Overlapping class names between users and groups may cause conflicts.</p> <p>Native tsm command: Uses <code>tsm user-identity-store set-group-mappings [options]</code> command.</p> |
| groupBase-Filter | base-filter | wgserv-er.-domain.ldap.-group.baseFilter | <p>L-<br/>D-<br/>A-<br/>P</p> <p>The filter that you want to use for groups of users of Tableau Server. You might specify an object class attribute and an organization unit attribute. For example:</p> <pre>" (&amp;(objectClass=s=groupofNames) (ou=Group)) "</pre> <pre>If " (&amp;(objectClass=s=inetOrgPerson)</pre>   |

|                  |             |   |         |   |
|------------------|-------------|---|---------|---|
|                  |             |   |         | <p>(ou=People) " doesn't work in your LDAP implementation, then specify the base filter that works for your Tableau user base.</p> <p>This is a required key. It cannot be blank.</p> <p>Native tsm command: Uses tsm user-identity-store set-group-mappings [options] command.</p> |
| groupName        | groupname   | wgserv-er.-domain.ldap.-group.name        | L-D-A-P | <p>The attribute that corresponds to group names on your LDAP server.</p> <p>Native tsm command: Uses tsm user-identity-store set-group-mappings [options] command.</p>   |
| groupEmail       | groupemail  | wgserv-er.-domain.ldap.-group.email       | L-D-A-P | <p>The attribute that corresponds to group email addresses on your LDAP server.</p> <p>Native tsm command: Uses tsm user-identity-store set-group-mappings [options] command.</p>   |
| groupDescription | description | wgserv-er.-domain.ldap.-group.description | L-D-A-P | <p>The attribute that corresponds to group descriptions on your LDAP server.</p> <p>Native tsm command: Uses tsm user-identity-store set-group-mappings [options] command.</p>  |

|             |             |   |                     |   |
|-------------|-------------|---|---------------------|---|
| member      | member      | wgserv-<br>er.-<br>domain.ldap.-<br>group.member    | L-<br>D-<br>A-<br>P | Specify the LDAP attribute that contains a list of distinguished names of users that are part of that group.<br><br>Native tsm command: Uses tsm user-identity-store set-group-mappings [options] command.  |
| N/A         | N/A         | wgserv-<br>er.-<br>domain.ldap.-<br>group.memberURL | L-<br>D-<br>A-<br>P | Specify the name of the LDAP attribute that stores the LDAP query for dynamic groups.   |
| user-BaseDn | N/A         | wgserv-<br>er.-<br>domain.ldap.user-<br>.baseDn     | L-<br>D-<br>A-<br>P | Use this option to specify an alternative root for users. For example, if all of your users are stored in the base organization called "users," then enter "o=users".   |
| N/A         | class-names | wgserv-<br>er.-<br>domain.ldap.user-<br>.classnames | L-<br>D-<br>A-<br>P | By default Tableau Server looks for LDAP user object classes containing the string "user" and "inetOrgPerson". If your LDAP user objects do not use these default class names, override the default by setting this value. You can provide multiple classnames separated by commas. For example: "userclass1, userclass2".<br><br>If your names include commas, you must escape them with a backslash (\). For example, if you have a name, Names, top, then enter "Names\, top". |

### Calculated configKeys

The following Kerberos-related configKeys are calculated and set according to multiple environmental inputs. As such, they must be set by the native tsm command or configEntities. Do not attempt to set these configKeys manually.

| Calculated configKey  | To use the native TSM command:   | To use configEntity json:  |
|---|--|--|
| wgserver.domain.ldap.kerberos.conf,<br>cfs.ldap.kerberos.conf     | Set the Kerberos configuration file location with the <code>kerbconfig</code> option of <code>tsm user-identity-store set-connection [options]</code> command. | Set the Kerberos configuration file location with the <code>kerberosConfig configEntity</code> option. |
| wgserver.domain.ldap.kerberos.keytab,<br>cfs.ldap.kerberos.keytab | Set the Kerberos keytab file location with the <code>kerb-keytab</code> option of <code>tsm user-identity-store set-connection [options]</code> command.       | Set the Kerberos keytab file location with the <code>kerberosKeytab configEntity</code> option.        |

### Unsupported configKeys

Some unsupported configKeys are present in underlying .yaml configuration files. The following keys are not intended for standard deployments. Do not configure these keys:

- `wgserver.domain.ldap.kerberos.login`
- `wgserver.domain.ldap.guid`
- `wgserver.domain.fqdn`: this key is redundant with `wgserver.domain.default`. The values for both keys must be the same. Only update `wgserver.domain.fqdn` if the value does not match `wgserver.domain.default`.

## Basic Product Data

By default Tableau products send usage data to Tableau so that we can understand how customers use our software, and gain insights into where they are successful and where they might run into problems that we can address. For example, this data can help us learn where upgrades are commonly failing and allow us to make product changes to address those issues, or identify what portion of our user base needs informed about a security issue that applies to a specific version of Tableau Server. You can disable the sending of this data at installation time, or later. For details on how to do this, see the instructions for [Tableau Desktop](#) or [Tableau Server](#).

Even when you disable the sending of product usage data, certain basic product data is sent to Tableau. This Basic Product Data includes information about products and their processes, including which product or process is running, when they start up, what operating system they are running on, licensing information, which machine or cluster of machines has sent the data (using unique pseudonymized identifiers), and whether the product is configured to send product usage data.

You can disable the sending of Basic Product Data at the machine level, or at the enterprise level, by blocking traffic sent to **`prod.telemetry.tableausoftware.com`**.

### Disabling sharing of Basic Product Data on individual computers

**Important:** This procedure involves modifying your local `hosts` file. If you do not know what this is, you should not change it. You should only make this change if you understand the implications of making changes to the file, know how to change the file, and have made a backup of the file for safety.

Modifying `hosts` files changes network behavior for computers. Detailed instructions for modifying `hosts` files are provided by operating system providers such as Microsoft, Apple or Linux Distributions.

1. Make a copy of your existing `hosts` file and save it to a computer that is not your Tableau computer. This is your backup, in case you need to reverse your changes. Do not start modifying the file until you have made a backup copy of it.
2. Modify your computer's `hosts` file to include these lines:

```
# Stops sending Product Usage to Tableau (prod.telemetry.tableausoftware.com) .  
# Learn more here: http:\\tableau.com\\derived-data  
127.0.0.1    prod.telemetry.tableausoftware.com
```

The first and second lines are comments, explaining the third line.

The third line prevents all traffic to `prod.telemetry.tableausoftware.com` (`http://-prod.telemetry.tableausoftware.com/`) from leaving your local machine by sending it to the Internal host loopback address. The data does not get sent outside the computer.

## Disabling the sharing of Basic Product Data at the enterprise level

To disable sending of Basic Product Data on an enterprise level, modify your Network Firewall to prevent outbound traffic to `prod.telemetry.tableausoftware.com`.

This domain is used by Tableau to receive the Basic Product Data about process launch and shutdown. It is also used for the more general Product Usage Data. Blocking traffic to this domain it you will prevent both kinds of data from being sent.

Traffic to this domain will occur on Ports 80 (for initial registration of our Product Data clients) and on Port 443 (for all subsequent traffic). To completely prevent product data from being sent, block all traffic to this domain.

For details on how to configure your network firewall, refer to your vendor or your internal IT department. Tableau cannot provide these instructions.

# Archived Content

## This is archived content

Deployments on public clouds continue to be supported but the content for third-party public cloud deployments is no longer updated.

For the latest Tableau Server deployment content, see the [Enterprise Deployment Guide](#) and the [Deploy](#) section of Tableau Server help.

For those customers who have access, we recommend Tableau Cloud. For more details, see:

- [Tableau Cloud Trial for Admin](#)
- [Tableau Cloud: Get Started for Admin](#)

## Introduction

Even if you don't have your own infrastructure and server hardware, you can deploy an enterprise-level Tableau Server installation in the cloud. Building a cloud-based solution has many benefits over an on-premises installation. For example, the overall total cost of ownership for

building a Tableau Server solution in the cloud is normally much less than a similar on-premises solution because you don't have to buy all of the expensive hardware. In addition, the cloud can provide better uptime, reliability, and fault-tolerance, especially if you deploy your solution across different regions and availability zones.

Looking for Tableau Server on Windows? See [Self-Host Tableau Server in a Public Cloud Service](#).

You can build and scale your Tableau environment in the following cloud environments:

- **Amazon Web Services** - You install and manage Tableau Server on Amazon Web Services (AWS). For more information, see [Install Tableau Server in the AWS Cloud](#).
- **Google Cloud Platform** - You install and manage Tableau Server on the Google Cloud Platform. For more information, see [Install Tableau Server on the Google Cloud Platform](#).
- **Microsoft Azure** - You install and manage Tableau Server on Microsoft Azure. For more information, see [Install Tableau Server on Microsoft Azure](#).
- **Alibaba Cloud** - You install and manage Tableau Server on Alibaba Cloud. For more information, see [Install Tableau Server in the Alibaba Cloud](#).

## About Tableau Advanced Management on Tableau Server

**Important:** Beginning September 15, 2024, Advanced Management will no longer be sold as an independent add-on option. After September 15, 2024, features and functionality in Advanced Management will be offered via certain license editions. Existing deployments with Advanced Management remain unaffected. More details will be

announced in the coming months. For more information, contact your Sales Account team.

Tableau Advanced Management is a separately licensed collection of features for Tableau Server which provide enhanced security, manageability, and scalability capabilities.

**Note:** Tableau Advanced Management includes several Tableau Server features and two separately installed tools: Tableau Content Migration Tool and the Tableau Resource Monitoring Tool. For more information, see the [feature table](#) later in this topic.

## Advanced Management Licensing Requirements

Advanced Management is licensed on a per Deployment basis, which may be User-Based or Core-Based. A Deployment includes a licensed production Tableau Server installation and two licensed non-production Tableau Server installations that support the production installation. For more information on Deployment, see the [EULA Documentation](#).

- The Advanced Management can only be activated on a licensed Tableau Server Deployment. This means that your Tableau Server must be first activated with a valid key that is either User-Based or Core-Based, before applying the Advanced Management product key. For more information on how to purchase Advanced Management and get the product key, contact your account manager.
- When the product key is active and enabled, you can use all the features that are included in Advanced Management.
- When the Advanced Management product key is removed or deactivated, you will no longer be able to use the features that require a valid Advanced Management license. Any associated data will not be deleted. Each feature might have slight differences on

what happens when the license expires. For more information on the individual features use the links in the table below.

The following table lists the features that are included and require a valid Advanced Management license:

| Feature                                | Description   | Requirements to use the feature  | Version  |
|--|---|--|--|
| About Tableau Resource Monitoring Tool | Provides a comprehensive look at the health of Tableau Server. With the Resource Monitoring Tool you can identify issues that cause slow load times, extract failures, and other critical issues and can help you proactively address the issues that impact end user experience.   | The installation of Tableau Server that you are monitoring must have an Advanced Management license.   | Available in 2019.3 and later. Linux support was introduced in version 2020.4. |
| About Tableau Content Migration Tool   | The Content Migration Tool provides an easy way to copy or migrate content between Tableau Server projects, sites and deployments. You can do this between projects on separate Tableau Server installations (for instance, between a development instance of Tableau Server and a production instance of Tableau Server), or between projects on a single Tableau Server installation. | <ul style="list-style-type: none"> <li>Both the source Tableau Server (Server that you are moving the content from) and the target Tableau Server (Server that you are moving the content to) must have a valid Advanced Management license.</li> <li>The Content</li> </ul> | Available in version 2019.3 and later.   |

| Feature                            | Description  | Requirements to use the feature   | Version   |
|------------------------------------|--|---|---|
| Activity Log                       | The Activity Log writes log events to the vizportal logs folder on the local hard drive for further analysis and auditing.   | Migration Tool must be installed on a version of Microsoft Windows that supports .NET 4.6.1 (Windows 7 or later, Windows Server 2008R2 or later). | Available in version 2022.3 and later.  |
| Tableau Server External Repository | Allows you to deploy Tableau Server Repository external to Tableau Server. The Tableau Server Repository is a PostgreSQL database that stores data about all user interactions, extract refreshes, and more. | The Tableau Server that is using an external repository must have a Advanced Management license.  | Available in version 2019.3 and later.<br>- AWS supported on Tableau Server version 2019.3 and later.<br>- Azure supported on |

| Feature                                | Description  | Requirements to use the feature                                   | Version   |
|--|--|---|---|
| Workload Management through Node Roles | Using node roles, you can configure where certain types of workloads are processed on your Tableau Server installation. The node roles features allows you to dedicate and scale resources to specific workloads (ex: extract refreshes, subscriptions). | The Tableau Server must have a valid Advanced Management license. | Tableau Server version 2020.4 and later.<br><br>Available in version 2019.3 and later.  |
| Tableau Server Key Management System   | Gives you additional functionality to configure Tableau Server to use AWS as the KMS for extract encryption.   | Tableau Server must have a valid Advanced Management license.     | Available in version 2019.3 and later.<br><br>- AWS supported on Tableau Server version 2019.3 and later.<br><br>- Azure supported on Tableau Server version 2021.1 |

| Feature                              | Description   | Requirements to use the feature                               | Version  |
|--------------------------------------|---|---|--|
| Tableau Server External File Store   | Allows you to use network attached storage(NAS) as your File Store. This removes the need to run File Store locally on your Tableau Server  | Tableau Server must have a valid Advanced Management license. | and later.<br>Available in version 2020.1 and later. |
| Tableau Backgrounder Resource Limits | The Tableau Server Resource Limits Manager tracks backgrounder resource usage in relation to the set resource limits to make sure the resource limits are applied correctly.  | Tableau Server must have a valid Advanced Management license. | Available in version 2022.1 and later.               |
| Tableau Server Independent Gateway   | Tableau Server Independent Gateway allows you to install a Tableau Server-managed reverse proxy on a separate computer. Install Independent Gateway in your DMZ to provide security for your Server installation and all your data. The Independent Gateway can be used in a variety of configurations, and can be scaled to meet your client connection demands. | Tableau Server must have a valid Advanced Management license. | Available in version 2022.1 and later.               |

## Activating the Advanced Management license

The Advanced Management license is applied to a Tableau Server Installation and can be used for both User-Based and Core-Based installations.

Here is a quick overview of how you can activate the Advanced Management license on your Tableau Server Installation.

## Use the TSM web interface

1. Open TSM in a browser:

```
https://<tsm-computer-name>:8850
```

2. Click **Licensing** on the **Configuration** tab. Click **Activate License**.
3. Enter or paste your Advanced Management product key and click **Activate**.
4. On the **Register** page, enter your registration information and click **Register**.
5. Follow the prompts and restart Tableau Server after registration is complete.

**Note:** If this is a new Tableau Server installation, and you apply an Advanced Management Key before you apply the Tableau Server product key, you will see an error. You may however, continue the installation and apply the Tableau Server product key using the same steps described above.

## Use the TSM CLI

1. Open a command prompt as administrator on a node in the Tableau Server cluster.
2. Run the following command with your Advanced Management product key to activate the license:

```
tsm licenses activate -k <server-management-add-on-product key>
```

**Note:** If this is a new Tableau Server installation, run the command twice, first with the Tableau Server product key and then with an Advanced Management product key.

3. Apply the changes and restart the Server:

```
tsm pending-changes apply
```

## Who can do this

Only Server Administrators can activate Advanced Management license keys.

## About Tableau Resource Monitoring Tool

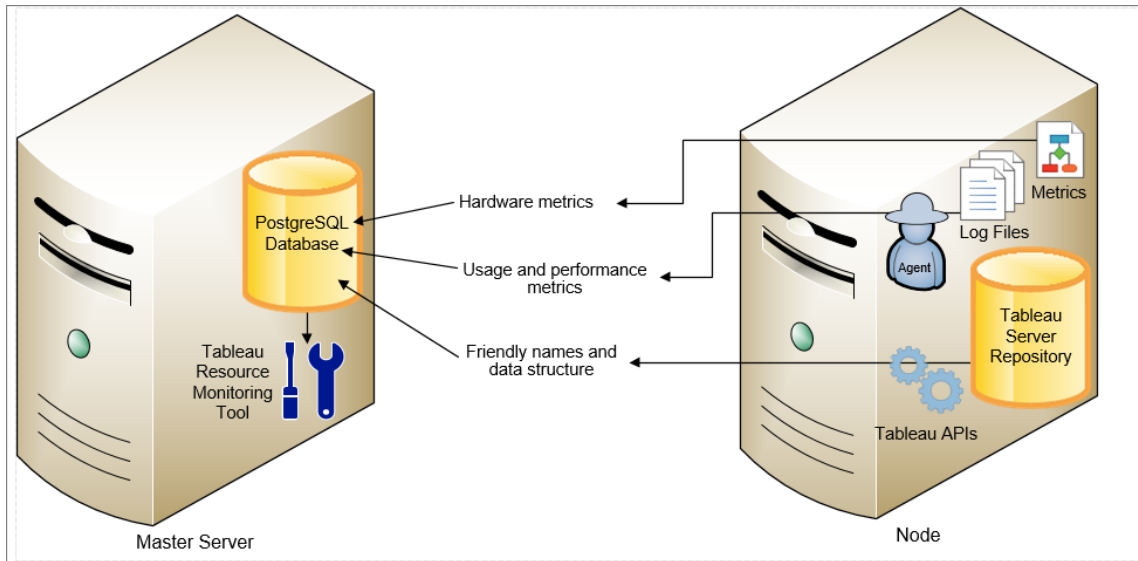

This document gives you an overview of the Tableau Resource Monitoring Tool.

### What is Resource Monitoring Tool?

The Resource Monitoring Tool is a tool that you can use to monitor the health and performance of your Tableau Server. It gathers data from your Tableau Server to provide a comprehensive look at the health of Tableau Server. Using this tool, you can identify the cause of slow load times, extract failures, and other critical issues. To use the Resource Monitoring Tool, you must have the Advanced Management enabled on your server. For more information on the Advanced Management, see [About Tableau Advanced Management on Tableau Server](#)

The Resource Monitoring Tool has two main components: Resource Monitoring Tool Server (RMT Server) and Agent.

- The RMT Server is where the data from Tableau Server is collated and served up through a web interface. This is also where you can configure, monitor, and analyze the health and performance of Tableau Server.
- An Agent runs on each of the nodes in your Tableau cluster to monitor their performance and activity. The following diagram illustrates the interaction between a Tableau Server node and the RMT Server.

## Get Started with Tableau Resource Monitoring Tool

This article will help you get started with Tableau Resource Monitoring Tool. It contains links to other articles about information you need to prepare before installing Resource Monitoring Tool, links to upgrade and other useful resources.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files, and other instances. For more information, see [About Tableau Help](#).

### Pre-Installation

#### Product Compatibility with Tableau Server

The Resource Monitoring Tool can be installed to monitor supported Tableau Server versions.

The table below lists the version compatibility between Resource Monitoring Tool(RMT) and Tableau Server:

| RMT Version | OS support        | Tableau Server Version                              |
|-------------|-------------------|---|
| 2023.3.x    | Windows,<br>Linux | 2021.1.x-2022.1.x , 2022.3.x, 2023.1.x,<br>2023.3.x |
| 2023.1.x    | Windows,<br>Linux | 2021.1.x-2022.1.x , 2022.3.x, 2023.1.x              |
| 2022.3.x    | Windows,<br>Linux | 2021.1.x - 2022.1.x , 2022.3.x                      |
| 2022.1.x    | Windows.<br>Linux | 2021.1.x - 2022.1.x                                 |
| 2021.4.x    | Windows,<br>Linux | 2021.1.x - 2021.4.x                                 |
| 2021.3.x    | Windows,<br>Linux | 2021.1.x - 2021.3.x                                 |
| 2021.2.x    | Windows,<br>Linux | 2021.1.x - 2021.2.x                                 |
| 2021.1.x    | Windows,<br>Linux | 2021.1.x  |

### Resource Monitoring Tool Server (RMT Server) and Agent Compatibility

Generally, we recommend that you install the same version of RMT Server and Agent to be sure that they are compatible. If you have Agents using versions not compatible with the RMT Server version, a critical incident is logged. For more information, see [Agent Incidents](#).

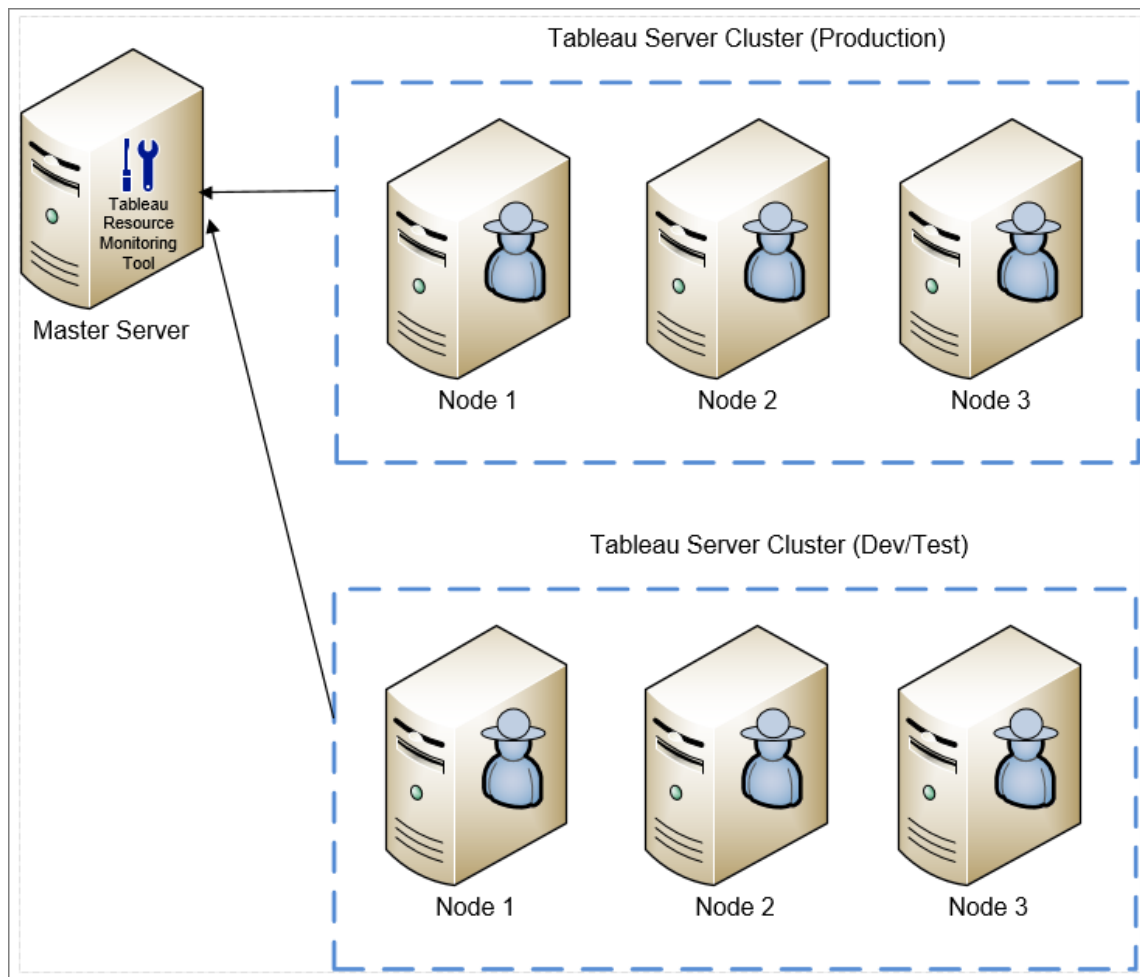

### Concepts and Terms

Get familiar with the concepts and terms used in the Resource Monitoring Tool topics. For more information, see [Concepts](#).

## Setup Architecture

The Resource Monitoring Tool has two main components: Resource Monitoring Tool Server (RMT Server) and Agent. The RMT Server should be installed on its own machine, and the Agent is installed on each node of your Tableau Server Cluster. For a more details about the setup architecture, see [Install the Tableau Resource Monitoring Tool](#).

A high level view of the Resource Monitoring Tool setup. This diagram shows a three node Tableau Server Cluster.

## Tableau Server on Linux Administrator Guide

### Minimum Hardware Requirements and Recommendations for Resource Monitoring Tool

Resource Monitoring Tool handles all of the processing, aggregation, storage, and web interface to the monitoring data collected from your Tableau Server installation. For production use, the machine you install Resource Monitoring Tool on should meet or exceed the minimum hardware recommendations. For more details, see [Minimum Hardware Requirements and Recommendations for Tableau Resource Monitoring Tool](#).

### Pre-Installation Checklist for Resource Monitoring Tool

Before you install Resource Monitoring Tool, review these action items and complete any necessary steps: [Pre-Installation Checklist - Tableau Resource Monitoring Tool](#)

### Troubleshoot

Be sure to check our [Troubleshoot Tableau Resource Monitoring Tool Issues](#) for answers to common questions before contacting support.

### Concepts

This document briefly explains some of Tableau Resource Monitoring Tool core concepts and defines some terminology you will see often.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. However, you may continue to see the terms in CLI commands and options and other instances. For more information, see [About Tableau Help](#).

### Agent

Resource Monitoring Tool Agent runs as a background service on each of your Tableau servers. It must be installed on all the nodes in a Tableau Server installation that you want to monitor.

The agent is a lightweight process that monitors the Tableau activity and general performance of the server it is installed on. It reports those details back to the Resource Monitoring Tool Server.

## Resource Monitoring Tool Server (RMT Server)

The Resource Monitoring Tool Server hosts the web application that users interact with. It also does much of the background processing to collate and monitor the data from the agents. We will use the term **RMT Server** to refer to this component.

## Environment

**Environment** is the term used to refer to a single node Tableau Server installation, or a Tableau Server cluster. In the RMT Server web interface, each node of the Tableau Server is called a **Server**.

Resource Monitoring Tool can monitor multiple Tableau Server installations. For example, you may have both production and staging Tableau Servers. In Resource Monitoring Tool, you can create two environments (*Production* and *Staging*) and monitor both of those Tableau Server clusters.

## Environment Status

The *environment status* indicates the state of the current Tableau environment. The status is determined by the number and type of incidents and the status of Tableau's various processes. The following sections will describe what each status means in these terms.

### OK

No warning or critical incidents have occurred today and there are not currently any failed processes.

### Warning

The Environment is in a **Warning** state when any of the following are true:

## Tableau Server on Linux Administrator Guide

- At least one warning incident has occurred today.
- A process is **Unlicensed**.
- A process is **Offline**.

### Critical

The Environment is in a **Critical** state when any of the following are true:

- At least one critical incident has occurred today.
- The Primary Gateway is **Offline**.
- All instances of a process are **Unlicensed**.
- All instances of a process are **Offline**.

### Server

**Server** is the term used to refer to each of nodes in the Tableau Server installation. Every machine that you install the Resource Monitoring Tool Agent on is considered a Server.

### Pre-Installation Checklist - Tableau Resource Monitoring Tool

#### Machine, Network, and Account Requirements

**Note:** Resource Monitoring Tool (RMT) server and agent are not Federal Information Processing Standard (FIPS) 140-2 compliant, and will not function properly on operating systems running with FIPS mode enabled.

Complete the following prerequisites before installing the Tableau Resource Monitoring Tool.

1. Make sure you have administrative privileges for all computers that will run the Resource Monitoring Tool. This includes the computer running the RMT Server, and all the Tableau Server nodes in the installation you will be monitoring with Resource Monitoring Tool.
2. Open port 5672 to inbound TCP traffic on the computer running the RMT Server

The Resource Monitoring Tool Agent application sends the data that it collects through port 5672, so the machine where the RMT Server is installed will need to allow inbound TCP traffic on that port.

3. Open the following ports:

- Open port 80 to inbound TCP traffic on the computer running the RMT Server

This is the port on which the RMT Server will host the web interface. Note that we can change the port number during installation if there is a 3rd party service already using it. To make the web interface accessible from outside the RMT Server, this port will need to be opened.

- Open port 443 to inbound TCP traffic on the computer running the Resource Monitoring Tool RMT Server.

This is the port on which connections come from the Agent when testing the connection to the RMT Server.

- Open port 5672 and 5671 (TLS connections) to outbound TCP traffic on all Agent nodes.

The Agent application sends the data that it collects to the RMT Server using this port.

- Open port 80 to outbound TCP traffic on all Agent computers.

Periodically, the Agent will make requests to the RMT Server web interface.

- Open port 443 to outbound TCP traffic on all Agent computers.

This is the port on which the Agent tests its connection to the RMT Server.

For more information on ports and communications, see [Tableau Resource Monitoring Tool Communication Ports](#).

4. Verify that all Agent computers can contact the RMT Server.

## Tableau Server on Linux Administrator Guide

The web interface hosted by the RMT Server is bound to a specific hostname or IP address during the setup process. It will only answer requests sent to that specific hostname. For example, if the RMT Server is configured to be hosted at `http://RMTServer/` but the Agents can only contact the RMT Server through `http://myrmt-server.myserver.com/` then the requests will not go through.

5. Gather credentials for a Tableau Server Administrator account.

Resource Monitoring Tool will use the Tableau Server web API to collect information about the content, so it will need credentials for a user that is a Tableau server administrator and can access all sites, projects, etc. We recommend creating one dedicated to Resource Monitoring Tool, but it can be any user that is a Tableau Server administrator.

6. Enable access to the Tableau Server repository database. **This is required starting in version 2022.3.**

Resource Monitoring Tool accesses the repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the "readonly" database user. For details, see [Enable access to the Tableau Server repository](#).

7. If you want to use SSL connections between Resource Monitoring Tool and Tableau Server Repository, make sure Tableau Server is configured to use SSL for internal Postgres connections. For more information, see [Configure SSL for Internal Postgres Communication](#).

The Resource Monitoring Tool allows you to use either the certificate file (`server.crt`) or thumbprint for the SSL connections. The certificate file for the Postgres database is installed to:

```
/var/opt/tableau/tableau_server/data/tabsvc/config/pgsql_<version>/security
```

If you plan to use the certificate file (`server.crt`), copy the certificate file generated by Tableau Server for internal Postgres SSL connections, to the machine where you plan to install the RMT Server. Make sure that the Operating System trusts the certificate.

8. Confirm that the REST API is enabled on Tableau Server (this is the default). Use the `tsm configuration get -k api.server.enabled` command to do this. A return value of `true` means the REST API is enabled. To enable the REST API, use the `tsm configuration set` command. For more information, see `api.server.enabled`.
9. Review the size of Tableau Server logs. Once Agent Server is installed and configured, the Resource Monitoring Tool processes relevant historical data from Tableau Server logs before data is displayed. If there is a large amount of historical log data, it may take a while to process the information. This might result in a delay of processing newer events on the Server.

If you are concerned about the delay, and not having historical information does not concern you, you can do the following to clean up the existing files:

- Remove Unneeded Files, and consider Log File Snapshots (Archive Logs) before you remove log files.

**Note:** Performance data like CPU usage and memory usage are not gathered using historical log data and are collected after Agent is installed and configured so cleaning up historical data does not affect performance data.

10. (optional) Gather connection information for a SMTP server that the RMT Server can access.

If you want email notifications, you need to provide the RMT Server with the server name, username and password (if any), and port number for a SMTP Server that it can use to send the email, and the TLS version. Currently, TLS version 1.2 is required, but

TLS version 1.3 is also supported. If you want to use TLS version 1.3, make sure you have Open SSL 1.1.1f or greater on the machine where RMT Server will be installed. For more information, see Email notifications

### Who can do this

To do all the steps described above you need be an admin on the machine that you are installing Resource Monitoring Tool, and be a Tableau Server Administrator.

### Minimum Hardware Requirements and Recommendations for Tableau Resource Monitoring Tool

Tableau Resource Monitoring Tool handles all of the processing, aggregation, storage, and web interface to the monitoring data collected from your Tableau Server installation.

#### RMT Server Minimum Hardware Recommendations

For production use, the machine that you install Resource Monitoring Tool on should meet or exceed the hardware recommendations below:

- 8 physical CPU cores (16 vCPUs)
- CPUs must support SSE4.2 and POPCNT instruction sets
- 64GB RAM
- 500GB Disk Space for RMT Server
- SSD drive or similar for performance

For RMT Server installations that match the minimum hardware specified above, the Resource Monitoring Tool can provide performance reporting for a Tableau Server deployments serving up to 10,000 views per hour.

For deployments with more view loads per hour, or very high numbers of background jobs, data delays may occur. In these cases, you may need to upgrade your hardware.

#### Resource Monitoring Tool Agent - Resource Utilization

The Resource Monitoring Tool Agent monitors the operating system and Tableau Server processes and log files and sends performance metrics and Tableau log data to the Resource

Monitoring Tool for near real time processing. The Agent needs to be installed on every machine that is running Tableau Server.

On Tableau Server installations that match Minimum Hardware Requirements and Recommendations for Tableau Server, here is what to expect:

- We typically see the Agent using 0-5% CPU on average with infrequent spikes above that. Our performance target is an average of 10% CPU usage or less.
- The agent typically uses 200 MB RAM or less with infrequent spikes during periods of heavier Tableau Server activity.
- A minimum of 10 GB free disk space is recommended for the machine where Agent is installed.

### Installing in a Cloud Environment

Resource Monitoring Tool can be installed on a virtual machine in any cloud environment that you may be using for your Tableau Servers. The virtual machine where RMT Server is installed will need to meet the same minimum hardware requirements [described above](#).

Who can do this

To install Resource Monitoring Tool, you must be all the following:

- Administrator on the machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator.
- Resource Monitoring Tool Administrator.

## Install the Tableau Resource Monitoring Tool

The Tableau Resource Monitoring Tool has two components: RMT Server and Agent.

Resource Monitoring Tool prerequisites and the RMT Server must be installed on dedicated hardware to guarantee they have the necessary resources, and that there is no contention for machine resources with other programs or software. These should not be installed on your Tableau Server computer, except in exceptional cases (for example, for limited demonstration purposes in non-production environments).

Agents are installed on all nodes of Tableau Server that you want to monitor.

The installer for installing Resource Monitoring Tool can be found on the [Advanced Management Download site](#). Download all the files that start with **Tabrmt**.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see [About Tableau Help](#).

### Installation version history

This section calls out significant changes to the installation process. Use this section to understand what changes have been made depending on your current version and the version you are upgrading to.

- Starting in version **2022.3**, you have the option to configure RabbitMQ messaging service and the PostgreSQL database used by Resource Monitoring Tool on a cloud platform. Currently, AWS AMQ for RabbitMQ, and Amazon RDS for PostgreSQL database are supported. With this addition, you can choose to install the repository and message queue service with RMT Server on the same machine or separately on the AWS platform.
- Starting in version **2020.4**, the Resource Monitoring Tool can be installed on Linux machines. Previously Resource Monitoring Tool installation was only supported on Windows machines.
- Starting in **2020.2**, a single installer will install the prerequisites and the RMT Server. You will need only two installers: One for RMT Server that includes prerequisites, and one for installing the Agent.

### Before Installing the Resource Monitoring Tool

- Review the following requirements and instructions:
  - [Minimum Hardware Requirements and Recommendations for Tableau Resource Monitoring Tool](#)
  - [Pre-Installation Checklist - Tableau Resource Monitoring Tool](#)

- The following OS is supported:
  - AlmaLinux:  
  
Version 2023.3.1 and later: AlmaLinux 8.x, AlmaLinux 9.x
  - Amazon Linux:  
  
Version 2023.3.1 and later: Amazon Linux 2, Amazon Linux 2023  
  
Version 2023.3.0 and earlier: Amazon Linux 2
  - CentOS:  
  
Version 2023.3.1 and later: 7.9 and higher (except 8.x), Stream 8.x,  
Stream 9.x  
  
Version 2023.3.0 and earlier: 7.9 and higher (except 8.x)
  - Oracle:  
  
Version 2023.3.1 and later: Oracle 8.x, Oracle 9.x
  - Red Hat Enterprise Linux (RHEL):  
  
Version 2023.3.1 and later: 9.x, 8.3+, 7.3+  
  
Version 2023.3.0: 9.x, 8.3+, 7.3+  
  
Version 2023.1.x and earlier: 8.3+, 7.3+
  - Rocky Linux:  
  
Version 2023.3.1 and later: Rocky Linux 8.x, Rocky Linux 9.x
  - Ubuntu:

## Tableau Server on Linux Administrator Guide

Version 2023.1.0: the latest versions of Ubuntu 16.04 LTS, 18.04 LTS (not 17.04), and 20.04 LTS

Version 2022.3 and earlier: the latest versions of Ubuntu 16.04 LTS and 18.04 LTS (not 17.04)

### **Additional notes on Linux distributions:**

- Red Hat Enterprise Linux (RHEL), CentOS, Oracle Linux, and Amazon Linux distributions are collectively referred to in this documentation as RHEL-like.
- Previous versions of CentOS and Ubuntu are not supported because Tableau Server requires systemd for process management.
- The version of the installer with the file suffix, .deb, installs on Ubuntu distributions.

As of July 2022, Debian distributions are no longer supported. For more information, see [this Tableau Community post](#).

- Custom kernels are not supported.
- Make sure the Tableau Server installation you are going to be monitoring is licensed with the Advanced Management license. You must have a valid Advanced Management license to use the Resource Monitoring Tool.
- Review the size of Tableau Server logs. Once Agent is installed and configured, the Resource Monitoring Tool processes relevant historical data from Tableau Server logs before data is displayed. If there is a large amount of historical log data, it may take a while to process the information which in turn might result in a delay of processing newer events on the Server.

If you are concerned about the delay, and not having historical information does not concern you, you can do the following to clean up the existing files:

- Remove Unneeded Files, and consider Log File Snapshots (Archive Logs) before you remove log files.

**Note:** Performance data like CPU usage and memory usage are not gathered using historical log data and are collected after Agent is installed and configured so cleaning up historical data does not affect performance data.

- Enable the readonly built-in user for Tableau Server Repository. This user is used when installing the Resource Monitoring Tool Agent. **This is required starting in version 2022.3.** For more information, see Collect Data with the Tableau Server Repository.
- Determine if you want to configure the repository and message queue service external to Resource Monitoring Tool.

### Setup Architecture

A high level view of the Resource Monitoring Tool setup. This diagram shows two Tableau Server clusters monitored by the RMT Server.

A detailed view of the Resource Monitoring Tool components installed on the RMT Server and Agent.

## Installation Overview

The RMT Server can be installed on either operating system and does not depend on the operating system that Agent is installed on. This means you can install RMT Server and Agent on different operating systems.

However, Agent is installed on the Tableau Server Cluster nodes, so the operating system choice for the Agent depends on the Tableau Server installation.

You can monitor multiple Tableau Server clusters using the same Resource Monitoring Tool. Each Tableau cluster should be set up as a separate environment.

## External Configuration

The repository and the message queue service can both be hosted external to RMT Server on the AWS platform. For hosting the repository, use the AWS RDS instance and for message queue use AWS AMQ. For more details on the configuration, step-by-step instructions, and other details, see:

## Tableau Server on Linux Administrator Guide

- External Repository for Tableau Resource Monitoring Tool
- External Message Queue Service (RabbitMQ) for Tableau Resource Monitoring Tool

### Installation on Linux

You can install RMT Server and Agent using the command line on Linux operating systems.

Here are the steps to installing Resource Monitoring Tool:

1. Install the RMT Server [using command line](#).

When you start the Resource Monitoring Tool installer, the setup program will install certain programs required to run Resource Monitoring Tool first. The programs installed are RabbitMQ, Erlang, and a dedicated PostgreSQL database. It will then proceed to install the RMT Server.

2. Install the Agent [using command line](#).

Install the Agent on every one of your Tableau Server nodes. The Agent sends information about Tableau Server usage and performance to the RMT Server for reporting.

### HTTPS

As a best practice, you should use HTTPS to protect sensitive information and user credentials.

The **Require HTTPS** setting in the Server configuration is used for communications between the users and the RMT Server. It is also used when you register an Agent. Regular agent communications between Agent and RMT to collect data is done through Rabbit MQ.

Initially, the RMT Server is installed with a self-signed certificate and will use that certificate for HTTPS communication which includes communication during Agent registration. You can use your own certificate to replace the self-signed certificate. This can be done during RMT Server install in the Server Configuration page or after the installation is complete.

### SSL Certificate Mode and Requirements

The resource monitoring tool supports the following modes of using SSL Certificates:

- **Default:** This mode uses the default self-signed certificate supplied by the installer.
- **Local:** This mode allows you to specify a file-based certificate in the `/var/opt/tableau/tabrmt/master/config` folder.

Follow these guidelines and requirements for your certificate:

- You must have a HTTPS certificate (like X.509) for the appropriate domains. This depends on your local security policies and certificate requirements. For example, if the Resource Monitoring Tool is using a CName or SSL passthrough proxy then you might need to use a SAN certificate. For multiple sub-domains, wildcard certificates are supported.
- The Resource Monitoring Tool supports only PKCS #12 and PEM formats.
- The Resource Monitoring Tool web server requires a certificate and a private key, and optionally chain-of-trust.

The private key can be either RSA or DSA.

These can be provided in a single file or grouped files.

- Single file examples:
  - PKCS #12: A single file with the `.pfx` or `.p12` file extensions.
  - PEM: PEM-encoded certificate + private key (plus optionally intermediate CAs chaining up to root CA), in a single file with the `.pem` extension. The items in the file does not have to be in any specific order.
- Grouped file examples:
  - PEM-encoded certificate in a `.crt` or `.cer` file PLUS
  - PEM-encoded private key in a `.key` file PLUS (optionally)
  - PEM-encoded certificate authority in one or more `.ca` files

Default File and Directory locations:

### RMT Server:

- **Installation directory:** `/opt/tableau/tabrmt/master`
- **Configuration file:** `/var/opt/tableau/tabrmt/master/config.json`
- **Logs:** `/var/opt/tableau/tabrmt/master/logs`

### Agent:

- **Installation directory:** `/opt/tableau/tabrmt/agent`
- **Bootstrap:** `/var/opt/tableau/tabrmt/agent/bootstrap`
- **Logs:** `/var/opt/tableau/tabrmt/agent/logs`

Who can do this

To install Resource Monitoring Tool, you must have all the following:

- User account with full sudo access.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

Next Step

Install the RMT Server:

- [Using web interface](#)
- [Using command line](#)

Install the RMT Server Using Web Interface

The Resource Monitoring Tool Server (RMT Server) hosts the web application that users interact with. It also does much of the background processing to collate and monitor the data from the Agents. The RMT Server must be installed on dedicated hardware.

Installation through web interface is currently only supported for Windows Installations. If you want to install on Linux, see [Install the RMT Server Using Command Line](#).

### To install the RMT Server:

There are three main steps to installing the RMT Server:

- Installing the Server software
- Configuring the RMT Server
- Creating a new environment.

The detailed step by step process is described below:

## 1. Installing the Server software:

1. Run the RMT Server setup program.
2. After reading the EULA, select **I agree to the license terms and conditions**, and click **Install**.
3. If the User Account Control dialog opens, click **Yes** to allow the installer to make changes.
4. The RMT Server installer will first install certain prerequisites as the first step. The prerequisites include RabbitMQ, Erlang, and a PostgreSQL database. The PostgreSQL database is used to store usage data gathered from Tableau Server. It will then proceed to install the RMT Server.
5. At the end of the installation, a **Server Configuration** web page opens.

## 2. Configure the RMT Server:

1. The page should already be filled in. Make any updates to the values if needed.

**Note:** Make a note of the **Host Name**. The web interface used to access the RMT Server uses this format: `https://<hostname>`.

2. By default, Resource Monitoring Tool uses a self-signed certificate to use for the HTTPS communications with the RMT Server. To leverage your own certificate, replace the thumbprint value with the one for the certificate you want to use. Check the **Require HTTPS** option if you want to mandate secure HTTPS communications.

Checking the **Require HTTPS** option will also require you to choose a certificate mode and provide additional details if necessary. Mainly there are three options to choose from:

1. **Default:** This mode uses the default self-signed certificate supplied by the installer.
2. **Local:** This mode allows you to specify a file-based certificate in the Resource Monitoring Tool/**config** folder. When **Local** mode is selected,

the **Certificate Name** field becomes available. The options listed will correspond with the certificate file groups located in the **/config** folder.

3. **Store:** This mode allows you to enter the thumbprint of a certificate in the Windows certificate store.

The **Password** field will only be used if the selected certificate requires a password.

3. Test the Server Configuration by clicking **Test Server Configuration**.
4. The **Password** section allows you to configure the password requirements that will apply to the user accounts and will be applied to the Administrative user account you will create a little later.
5. In the **Authentication** section, you can configure the timeout period for the sessions. If the user does not access the session for the set timeout period then the session will expire and they will need to log in again. By default, this is set to 240 minutes. You can also enable the **Sliding Expiration** option to reset the time out period when a session is accessed within the time out period.
6. Click **Save and Restart Server**.
7. When the server has restarted, you are prompted to create an administrative user and password.
8. After signing in using the administrative credentials you just created in the previous step, the Resource Monitoring Tool you will see a message that no Environment has been created. Click **Add an environment** to setup a new environment.

### 3. Create a New Environment:

1. Create a new environment: Fill in the details of the environment, like the name an identifier. The Tableau Server REST API and the Tableau Server Repository configurations are used to communicate with Tableau Server. The Tableau Server Repository configuration is optional, but is a preferred method to access Tableau Server.

You have the option to configure secure encrypted connection when RMT connects to Tableau Server Repository. In order to use SSL connections between

RMT and Tableau Server Repository database, Tableau Server must be configured to use SSL. For more information, see [Configure SSL for Internal Postgres Communication](#).

## 2. Tableau Repository Configuration:

In the **Tableau Repository Configuration** section:

1. In the **SSL Mode** drop down box, select **Prefer SSL** or **Require SSL** to configure SSL connections to Tableau Repository. Choosing **Disable** means SSL will never be used to make Tableau Server Repository connections.

In the **Prefer SSL** mode, the Resource Monitoring Tool will use SSL in the first attempt, and if that fails the subsequently attempts a non-encrypted connection.

In the **Require SSL** mode, if the SSL connection fails, the connections to Tableau Server Repository will fail entirely. In this case, Tableau Server REST API connections will be used to communicate with Tableau Server.

2. You can choose to either supply the thumbprint that was generated by Tableau Server, or copy the **server.crt** file to the Resource Monitoring Tool Master Server machine. If you choose to copy the certificate file, you don't have to supply the thumbprint. For more information, see [Configure Postgres SSL to Allow Direct Connections from Clients](#).
4. Click **Save**. You will see a new section added to the page - **Agent Configuration**. This section allows you to download the bootstrap file needed to install and configure Agents.

**Note:** If you make any updates to the Environment configurations, you must click **Save** before downloading the Bootstrap file.

# Tableau Server on Linux Administrator Guide

## Who can do this

To install Resource Monitoring Tool, you must have all the following:

- Administrator permissions on the machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

## Next Step

### Install the Agent Using the Web Interface

### Install the Agent Using the Web Interface

The Agent is a lightweight process that consumes minimal server resources and sends data to the Resource Monitoring Tool Server (RMT Server). Install the Resource Monitoring Tool Agent on each of your Tableau Server nodes. To install and register an Agent, download the Agent bootstrap configuration file and save it to a location that is accessible from the Resource Monitoring Tool Agent nodes.

Installation through web interface is currently only supported for Windows Installations. If you want to install on Linux, see Install the Agent Using Command Line.

Before you install

- Download the bootstrap file. **Bootstrap files are only valid for 24 hours after downloading. You will need to regenerate the bootstrap file if the one you are using is older than 24 hours.**
- Starting in version 2021.3, Agent registration will need to communicate both through a https endpoint and RabbitMQ to complete the Agent registration. Make sure both ports 443 and 5672 are open for these communications.

Steps to download the Agent bootstrap file

Use the following steps if you have not yet downloaded the bootstrap file from the RMT Server.

1. Using the web interface (*https://<hostname>*) on the RMT Server, from the **Admin** menu, select **Environments**.
2. The bootstrap file can be downloaded directly from the environment overview tab on the home page.

**Note:** If you haven't created an environment as part of the RMT Server setup, follow steps 12- 15 described in the Install the RMT Server Using Web Interface topic.

3. Save the bootstrap configuration file to a location that is accessible from the Tableau Server nodes where you will be installing Resource Monitoring Tool Agent.

Steps to install Agent

**To install the Agent on each of your Tableau Server nodes:**

1. Run the Agent setup program.
2. After reading the EULA, select **I agree to the license terms and conditions**, and click **Next**.

3. On this page, you will have the option of changing the install location and specify the Run As User account for Agent.

If you are planning to install to a non-default location, use the guidelines provided in the Installing to a Non-Default Location. The default location is **C:\Program Files\Tableau\Tableau Resource Monitoring Tool\agent**.

Starting in 2021.4, you must specify a Run As User account for Agent. This account is used to access Tableau Server for gathering monitoring information from Tableau Server nodes.

**For the Agent Run As User account, you must specify the same account that you currently use for the Tableau Server Run As User account.** If the account information you provide is not the same as that on Tableau Server, Agent will not be able to gather the monitoring data on that node.

4. If the **User Account Control** dialog opens, click **Yes** to allow the installer to make changes.
5. When the installer is finished an **Agent Registration** web page opens.

**Tip!** It may take a while for the web page to open. If the web page fails to open for some reason, use the following URL on the machine that you are installing:

<http://localhost:9002/setup/register>

6. Review the information on this page about the Tableau Server log file size, historical data, and the implications. Once you proceed to the next step, you will no longer see this information.

Once Agent is installed and registered, the Resource Monitoring Tool processes relevant historical data from Tableau Server logs before data is displayed. If there is a large amount of historical log data, it may take a while to process the information which in turn might result in a delay of processing newer events on the Server.

If you are concerned about the delay, and not having historical information does not concern you, you can do the following to clean up the existing Tableau log files:

Remove Unneeded Files, and consider Log File Snapshots (Archive Logs) before you remove log files.

**Note:** Performance data like CPU usage and memory usage are not gathered using historical log data and are collected after Agent is installed and configured so cleaning up historical data does not affect performance data.

7. Browse to the location of the bootstrap file you downloaded from the RMT Server. Click **Import Bootstrap File**. **Bootstrap files are only valid for 24 hours after downloading. You will need to regenerate the bootstrap file if the one you are using is older than 24 hours.**
8. Once the import is successfully completed, a web page to enter the Server information is displayed. In the **Tableau Server gateway URL** field, enter the URL you use to access Tableau Server.

Here are some examples on what the URL might look like:

- <https://MarketingServer/> (if you know the server's name)
  - <https://10.0.0.2/> (if you know the server's IP address)
  - <http://10.0.0.4/> (If your Tableau Server is not enabled to use SSL)
9. Enter the user name and password. You can use the admin user credentials that you created when you installed the RMT server. This user name and password is used for communications between RMT Server and Agent.
  10. Click **Test Tableau Server Connection** to verify the Agent is able to reach Tableau Server.

A **Success** message displays to confirm the Agent can connect to Tableau.

11. The **RMT Server URL** field should already be populated from the information in the bootstrap file. This is the URL of the web page used to do administration tasks, monitor performance and other tasks.

Here is an example of what the URL might look like:

- *https://<hostname>*

12. Click **Test RMT Server Connection** to verify the Agent is able to reach the Resource Monitoring Tool RMT Server.

A **Success** message displays to confirm the connection to the RMT Server works.

13. The **RMT Server certificate thumbprint** field should be already be populated using the information in bootstrap file. The bootstrap file you saved should have this and the RMT Server URL information. Enter the RMT Server user name and password. This user must have the **Server/Environment Management** role.

Click **Get Registration Options**.

This takes you to the **Agent Registration - Message Queue** page.

14. Click **Test Message Queue Connection** to verify the message queue connection is working.

A **Success** message displays if the connection works.

**Note:** The **Enable TLS** setting under the message queue section allows you to enable encryption when data is transmitted between the RMT Server and the Agents. It requires additional RabbitMQ setup. For more information, see Encrypted Data Collection.

15. On the final Agent Registration page the environment section should already be filled out. Verify the information and add any Tableau Server node details.
16. Click **Connect to Message Queue**.

17. Click **Register Agent** to complete the agent installation and configuration.

You will see an option to disable the web interface. After registration the web interface is no longer necessary for the agent and can optionally be disabled. If you need to re-enable the web interface, use the following command:

```
rmtadmin set server.web.run true
```

For more information on Resource Monitoring Tool commands, see *rmtadmin Command Line Utility*

18. You can verify that the Agent is connected by navigating to the RMT Server web interface. From the **Admin** menu, select **Environments**, and under environment details you can see the number of Agents that are currently connected.

## Installing Agent on a Multi-Node Tableau Server Installation

1. Follow the steps described above to install the Agent on the Tableau Server initial node to connect to the Resource Monitoring Tool.
2. In the **Server** section on the final registration page, check the **Primary Server** option.
3. On the Tableau Server additional nodes, install the Agent using the same bootstrap file that you used to install Agent on the initial node and follow the steps described above.
4. On the final registration page, in the **Environment** section, select the environment you created when installing the Agent on the initial node.
5. In the **Server** section, select the **New Environment Server** option. The Primary Server option should remain unselected.
6. The agent registration process automatically adds this node to your existing environment.

### Installing to a Non-Default Location

Tableau recommends using `\Tableau\Tableau Resource Monitoring Tool\agent` as the location for the prerequisites. Example non-default location: **D:\Tableau\Tableau Resource Monitoring Tool\agent**.

**To choose a non-default location during installation, use the following steps:**

## Tableau Server on Linux Administrator Guide

1. Run the Agent installer.
2. On the EULA page, choose **Customize**.
3. Under **Setup Options**, in the **Install location** field, enter the location.
4. Continue with Step 2 of the installation as described [Install the Agent Using the Web Interface](#).

### Who can do this

To install Resource Monitoring Tool, you must have all the following:

- Administrator permissions on the machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator site role.

### Next Steps

#### Resource Monitoring Tool Server Configuration

#### Install the RMT Server Using Command Line

The Resource Monitoring Tool Server (RMT Server) hosts the web application that users interact with. It also does much of the background processing to collate and monitor the data from the Agents. The RMT Server must be installed on dedicated hardware.

This topic describes the steps you can use to install the RMT Server using command line. Command line installation is supported on both Windows and Linux operating systems.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see [About Tableau Help](#).

#### Install on Linux

#### To install the RMT Server:

1. Install the RMT Server:
  1. Download the rpm or .deb RMT Server Installer and save it to a location that you can access from the machine where you plan to install the RMT Server.
  2. Login to the machine where you want the RMT Server installed as a user that has sudo access.
  3. Run the following command to install the RMT Server, where <version> is formatted as major-minor-maintenance:

For RHEL like distribution including CentOS:

```
sudo yum install <pathtormtserverinstaller>/Tabrmt-Master-x86_64-<version>.rpm
```

For Ubuntu distributions:

```
sudo apt install ./<pathtormtserverinstaller>/Tabrmt-Master-amd_64-<version>.deb
```

This installs the package and the prerequisites including RabbitMQ, Erlang, and a PostgreSQL database. The PostgreSQL database is used to store usage data gathered from Tableau Server. It will then proceed to install the RMT Server.

2. Initialize RMT Server:

You must explicitly accept the End User License Agreement (EULA) when you initialize RMT Server. You also have the option to specify non-default configurations. To initialize RMT Server with a default configuration, run this command :

```
sudo /opt/tableau/tabrmt/master/install-scripts/initialize-rmt-master --accepteula
```

The EULA can be found in the `/opt/tableau/tabrmt/master/docs` folder.

Beginning in version 2023.1 you can specify a custom Run As account to be used by RMT, as well as other configuration options. By default RMT creates and uses an account called `rmt-master` to run under. To specify a custom Run As account to be used by RMT Server, include the `--unprivileged-user` option when you run the initialization script. For information about all the available switches for the `initialize-rmt-master` script, see RMT Server Initialization Script Options.

### 3. Configure the RMT Server

1. Run the following command as the `tabrmt-master` user:

```
sudo su --login tabrmt-master  
  
rmtadmin master-setup [options]
```

The configuration options can be supplied either through the command prompt, a configuration file. If you do not supply the options, the default values will be applied except for the administrator password. The administrator user name will be set to `admin` and you will be prompted to provide the password.

Example command including the required password parameter:

```
rmtadmin master-setup --admin-username=<name of the admin-  
istrator user> --admin-password=<administrator user pass-  
word>
```

The following table lists the required and some commonly used options to configure the RMT Server. For a full list of the configurations options, see `rmtadmin Command Line Utility`.

**Note:** Require HTTPS option ensures secure communications between the RMT Server and users. When you require HTTPS for communications, you must also select a mode for the certificate that should be used for these communications. The table below includes the various options. To learn more

about these modes and certificates, see [SSL Certificate Mode and Requirements](#)

| Option              | Required?  | Default | Description  |
|---------------------|--|---------|--|
| admin-password      | Yes<br><br>Password can be supplied in the command line or provide a file with the password to use. If neither is provided, you will be prompted for the password. | n/a     | The password for the administrator user.   |
| admin-password-file | No<br><br>Password can be supplied in the command line or provide a file with the password to use. If neither is provided, you will be prompted for the pass-      | n/a     | The file where the password for the administrator user is stored.<br><br><b>Note:</b> <code>tabrmt-master</code> user must have access to this file. |

| Option                       | Required?   | Default   | Description  |
|------------------------------|---|---|--|
|                              | word.   |   |  |
| admin-username               | No  | admin   | The username for the administrator user.   |
| http-port                    | No  | 80  |  |
| require-https                | No  | False   | Redirect http traffic to HTTPS.  |
| https-certificate-mode       | No  | <p><b>"Default"</b></p> <p>Available options:</p> <p>Default</p> <p>Local</p> | <p>The type of certificate search to perform for the HTTPS certificate.</p> <p><b>Default:</b> This mode uses the default self-signed certificate supplied by the installer.</p> <p><b>Local:</b> Allows you to specify a file-based certificate in the <code>/var/opt/tableau/tabrmt/master/config</code> folder.</p> |
| https-certificate-local-name | No  | Null  | The name of the HTTPS certificate file without the file extension.   |
|                              | Note: If not specified, the Resource Monitoring Tool is installed with a self-signed certificate and will |   |  |

| Option                                | Required?                                      | Default | Description  |
|---------------------------------------|--|---------|--|
|                                       | use that certificate for HTTPS communications. |         |  |
| https-certificate-local-password      | No   | Null    | The password to use for the HTTPS certificate.                                 |
| https-certificate-local-password-file | No   | Null    | The path to the file containing the password to use for the HTTPS certificate. |

#### 4. Create an environment

1. Run the following command to create an environment:

```
rmtadmin create-env --name=<myenvironment> --api-user-name=<TableauServer API user name> --api-password=<password for the Tableau Server API user account>
```

Configure the environment using the options available for this command. Here are some key configuration options to consider:

- The Tableau Server REST API and the Tableau Server Repository configurations are used to communicate with Tableau Server. The Tableau Server Repository configuration is optional, but is a preferred method to access Tableau Server.
- You have the option to configure secure encrypted connection when RMT connects to Tableau Server Repository. In order to use SSL connections

between RMT and Tableau Server Repository database, Tableau Server must be configured to use SSL. For more information, see [Configure SSL for Internal Postgres Communication](#).

The following table lists the some of the common options. To see a full list of options, see [rmtadmin Command Line Utility](#) .

| Option         | Required?   | Default | Description   |
|----------------|---|---------|---|
| --name         | Yes   | n/a     | The name of the environment.  |
| --gateway-url  | Yes   | n/a     | URL used to access the Tableau Server gateway.  |
| --version      | Yes   | n/a     | Tableau Server version that this environment will be monitoring.  |
| --api-username | No  | Null    | User name of the account used to connect to Tableau Server APIs. The user account should be a Tableau Server administrator with access to all Tableau Server sites. |
| --api-password | No<br><br>(If you specify the Tableau API user name, you will either provide the password, or specify | Null    | Password of the Tableau Server API user account used to connect to Tableau Server APIs.   |

| Option                | Required?                                     | Default | Description  |
|-----------------------|---|---------|--|
|                       | the file path and file that has the password) |         |  |
| --api-password-file   | No  | Null    | The path to the file and the name of the file containing the password of the Tableau Server API user account.  |
| --repository-server   | Yes   | Null    | This is the server name for the PostgreSQL database that is installed with Tableau Server  |
| --repository-port     | Yes   | Null    | The port number of the Tableau Server Repository database.   |
| --repository-username | Yes   | Null    | <p>Username used to connect to PostgreSQL database installed with the Tableau Server Repository.</p> <p>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the <b>readonly</b> database user. For details, see Enable access to the Tableau Server repository.</p> |

| Option                     | Required? | Default | Description   |
|----------------------------|-----------|---------|---|
| --repository-password      | Yes       | Null    | <p>Password for the user account used to connect to the PostgreSQL database that is installed with the Tableau Server .</p> <p>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the <b>readonly</b> database user. For details, see Enable access to the Tableau Server repository.</p> |
| --repository-password-file | No        | Null    | <p>The path including the file name where the password for the user account used to connect to the PostgreSQL database that is installed with Tableau Server.</p>   |
| --repository-ssl-mode      | No        | Prefer  | <p>Tableau Server Repository SSL Mode:</p> <p><b>Prefer</b> SSL or <b>Require</b> SSL to configure SSL connections to Tableau Repository.</p> <p><b>Disable</b> to never use SSL to make Tableau Server Repository connections.</p>   |

| Option                                   | Required? | Default | Description   |
|--|-----------|---------|---|
| <code>--repository-ssl-thumbprint</code> | No        | Null    | You can choose to either supply the thumbprint that was generated by Tableau Server, or copy the <b>server.crt</b> file to the Resource Monitoring Tool Server (RMT Server) machine. If you choose to copy the certificate file, you don't have to supply the thumbprint. For more information, see <a href="#">Configure Postgres SSL to Allow Direct Connections from Clients</a> . |

2. Download the bootstrap file to a location that can be accessed from the Tableau Server nodes.

```
rmtadmin bootstrap-file --env=<myenvironment> --file-name<The absolute or relative path including the file name>
```

5. **Optional step - only if not using SSD:** The Resource Monitoring Tool is optimized for SSD by default. If you are not using SSD hardware, run the command:

```
sudo /opt/tableau/tabrmt/master/tabrmt-master optimize --no-ssd
```

## Install on Windows

### To install the RMT Server:

1. **Run the RMT Server setup program**
  1. Download the RMT Server installer and save it to a location that you can access from the machine where you plan to install the RMT Server.
  2. Open the command prompt as an administrator.

3. Navigate to the location of the RMT Server installer and run the exe file using the following command

```
Tabrmt-Master-64bit-<version>.exe /silent ACCEPTTEULA=1
```

**Note:** Use the /silent or /quiet switch to run the setup unattended and without displaying any UI or prompts.

The default install folder is usually like this: *C:\Program Files\Tableau\Tableau Resource Monitoring Tool\master*. To provide a different install location run the following command:

```
Tabrmt-Master-64bit-<version>.exe /silent ACCEPTTEULA=1  
InstallFolder="D:\Tableau Resource Monitoring Tool\master"
```

Full list of all the install command properties and switches can be found in [this section](#) below.

This installs the package and the prerequisites including RabbitMQ, Erlang, and a PostgreSQL database. The PostgreSQL database is used to store usage data gathered from Tableau Server. It will then proceed to install the RMT Server.

## 2. Configure the RMT Server.

1. Run the following command and provide the options:

```
rmtadmin master-setup [options]
```

The configuration options can be supplied either through the command prompt, a configuration file. If you do not supply the options, the default values will be applied except for the administrator password. The administrator user name will be set to admin and you will be prompted to provide the password.

Example command including the required password parameter:

```
rmtadmin master-setup --admin-username=<name of the administrator user> --admin-password=<administrator user password>
```

The following table lists the required and some commonly used options used to configure the RMT Server. For a full list of the configurations options, see `rmtadmin` Command Line Utility .

**Note:** Require HTTPS option ensures secure communications between the RMT Server and users. When you require HTTPS for communications, you must also select a mode for the certificate that should be used for these communications. The table below includes the various options. To learn more about these modes and certificates, see [Install the Tableau Resource Monitoring Tool](#)

| Option         | Required?   | Default | Description                              |
|----------------|---|---------|--|
| admin-password | Yes<br><br>Password can be supplied in the command line or provide a file with the password to use. If neither is provided, you will be | n/a     | The password for the administrator user. |

| Option                 | Required?   | Default                                  | Description   |
|------------------------|---|--|---|
|                        | prompted for the password.  |  |   |
| admin-password-file    | No<br><br>Password can be supplied in the command line or provide a file with the password to use. If neither is provided, you will be prompted for the password. | n/a                                      | The file where the password for the administrator user is stored. |
| admin-username         | No  | admin                                    | The username for the administrator user.                          |
| http-port              | No  | 80                                       |   |
| require-https          | No  | False                                    | Redirect http traffic to HTTPS.                                   |
| https-certificate-mode | No  | <b>Default</b><br><br>Available options: | The type of certificate search to perform for the                 |

| Option                             | Required? | Default   | Description  |
|------------------------------------|-----------|---|--|
|                                    |           | <ul style="list-style-type: none"> <li>• Default</li> <li>• Store</li> <li>• Local</li> </ul> | <p>HTTPS certificate.</p> <p><b>Default:</b> This mode uses the default self-signed certificate supplied by the installer.</p> <p><b>Store:</b> This allows you to enter the thumbprint of a certificate in the Windows certificate store.</p> <p><b>Local:</b> Allows you to specify a file-based certificate <i>&lt;installation directory&gt;\config</i> folder. By default this is <i>C:\Program Files\Tableau\Tableau Resource Monitoring Tool\master\config</i>.</p> |
| https-certificate-store-thumbprint | No        | Null  | The HTTPS certificate hash/thumbprint to search for in 'store' certificate mode.   |
| https-certificate-local-name       | No        | Null<br><br>Note: If not specified, the Resource Mon-   | The name of the HTTPS certificate file without the file extension.   |

| Option                                | Required? | Default  | Description  |
|---------------------------------------|-----------|--|--|
|                                       |           | itoring Tool is installed with a self-signed certificate and will use that certificate for HTTPS communications. |  |
| https-certificate-local-password      | No        | Null   | The password to use for the HTTPS certificate.                                 |
| https-certificate-local-password-file | No        | Null   | The path to the file containing the password to use for the HTTPS certificate. |

### 3. Create an environment

1. Run the following command to create an environment:

```
rmtadmin create-env --name=<myenvironment> --api-user-name=<TableauServer API user name> --api-password=<password for the Tableau Server API user account>
```

Configure the environment using the options available for this command. Here are some key configuration options to consider:

- The Tableau Server REST API and the Tableau Server Repository configurations are used to communicate with Tableau Server. The Tableau Server Repository configuration is optional, but is a preferred method to access Tableau Server.
- You have the option to configure secure encrypted connection when RMT connects to Tableau Server Repository. In order to use SSL connections

between RMT and Tableau Server Repository database, Tableau Server must be configured to use SSL. For more information, see [Configure SSL for Internal Postgres Communication](#).

The following table lists the some of the common options. To see a full list of options, see [rmtadmin Command Line Utility](#) .

| Option         | Required?   | Default | Description   |
|----------------|---|---------|---|
| --name         | Yes   | n/a     | The name of the environment.  |
| --gateway-url  | Yes   | n/a     | URL used to access the Tableau Server gateway.  |
| --version      | Yes   | n/a     | Tableau Server version that this environment will be monitoring.  |
| --api-username | No  | Null    | User name of the account used to connect to Tableau Server APIs. The user account should be a Tableau Server administrator with access to all Tableau Server sites. |
| --api-password | No<br><br>(If you specify the Tableau API user name, you will either provide the password, or specify | Null    | Password of the Tableau Server API user account used to connect to Tableau Server APIs.   |

| Option                | Required?                                     | Default | Description  |
|-----------------------|---|---------|--|
|                       | the file path and file that has the password) |         |  |
| --api-password-file   | No  | Null    | The path to the file and the name of the file containing the password of the Tableau Server API user account.  |
| --repository-server   | Yes   | Null    | This is the server name for the PostgreSQL database that is installed with Tableau Server  |
| --repository-port     | Yes   | Null    | The port number of the Tableau Server Repository database.   |
| --repository-username | Yes   | Null    | <p>Username used to connect to PostgreSQL database installed with the Tableau Server Repository.</p> <p>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the <b>readonly</b> database user. For details, see Enable access to the Tableau Server repository.</p> |

| Option                     | Required? | Default | Description   |
|----------------------------|-----------|---------|---|
| --repository-password      | Yes       | Null    | <p>Password for the user account used to connect to the PostgreSQL database that is installed with the Tableau Server .</p> <p>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the <b>readonly</b> database user. For details, see Enable access to the Tableau Server repository.</p> |
| --repository-password-file | No        | Null    | The path including the file name where the password for the user account used to connect to the PostgreSQL database that is installed with Tableau Server.  |
| --repository-ssl-mode      | No        | Prefer  | <p>Tableau Server Repository SSL Mode:</p> <p><b>Prefer SSL</b> or <b>Require SSL</b> to configure SSL connections to Tableau Repository.</p> <p><b>Disable</b> to never use SSL to make Tableau Server Repos-</p>  |

| Option                      | Required? | Default | Description   |
|-----------------------------|-----------|---------|---|
|                             |           |         | itory connections.  |
| --repository-ssl-thumbprint | No        | Null    | You can choose to either supply the thumbprint that was generated by Tableau Server, or copy the <b>server.crt</b> file to the Resource Monitoring Tool Server(RMT Server) machine. If you choose to copy the certificate file, you don't have to supply the thumbprint. For more information, see Configure Postgres SSL to Allow Direct Connections from Clients. |

2. Download the bootstrap file to a location that can be accessed from the Tableau Server nodes.

```
rmtadmin bootstrap-file --env=<myenvironment> --file-name<The absolute or relative path including the file name>
```

## Windows install properties and switches

### Switches:

| Switch                | Description  | Comments  |
|-----------------------|--|---|
| /install   /uninstall | Run Setup to either install or uninstall Resource Monitoring Tool. | Default is to install, displaying UI and all prompts. If no directory is specified using the InstallFolder property on a fresh install, C:\Program Files\Tableau\Tableau Resource Monitoring Tool\master is assumed. If Resource Monitoring Tool is already installed, Setup will assume the same location as the current |

| Switch                             | Description   | Comments  |
|------------------------------------|---|---|
|                                    |   | <p>installation.</p> <p>To completely remove Resource Monitoring Tool including the data directory, use, <code>/uninstall DELTEDATADIR=1</code></p>   |
| <code>/passive</code>              | Run Setup with minimal UI and no prompts.   |   |
| <code>/quiet   /silent</code>      | Run Setup in unattended, fully silent mode. No web interface or prompts are displayed.  | Use either <code>/quiet</code> or <code>/silent</code> , not both.  |
| <code>/norestart</code>            | Run Setup without restarting Windows, even if a restart is necessary.   | In certain rare cases, a restart cannot be suppressed, even when this option is used. This is most likely when an earlier system restart was skipped. For example, if restart was skipped during installation of other software.  |
| <code>/log &lt;log-file&gt;</code> | Log information to the specified file and path. By default log files are created in %TEMP% with a naming convention of <code>Tableau_Resource_Monitoring_Tool_&lt;version_code&gt;</code> . | <p>If no file location is specified, the log file is written to the TEMP folder - <code>C:\Users\&lt;username&gt;\AppData\Local\Temp</code>. Check this log file for errors after installation.</p> <p>For example: <code>&lt;Setup file&gt; /quiet /log="C:\Tableau\Logs\RmtInstall</code></p> |

**Properties:**

| Property   | Description   | Comments   |
|--|---|--|
| <code>InstallFolder=<br/>=&lt;path\to\i-<br/>installation\directory&gt;</code> | Install to the specified non-default install location.  | Specifies the location to install RMT. If not used, RMT is installed to <i>C:\Program Files\Tableau\Tableau Resource Monitoring Tool\master</i> .<br><br>Example: <code>&lt;Setup file&gt; /silent InstallFolder=r="D:\Tableau\Tableau Resource Monitoring Tool\master"</code> |
| <code>ACCEPTTEULA=1 0</code>   | Accept the End User License Agreement (EULA). Required for quiet, silent, and passive install on both initial and additional nodes. 1 | If not included when using /passive, /silent or /quiet, Setup fails silently. If included but set to 0, Setup fails.   |

| Property | Description   | Comments |
|----------|---|----------|
|          | = true, accept the EULA, 0 = false, do not accept the EULA. |          |

Who can do this

To install Resource Monitoring Tool, you must have all the following:

### Windows

- Administrator permissions on the machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

### Linux

- Full sudo access for the user account that is used to install the Agent.
- Resource Monitoring Tool Administrator account

Next Step

Install the Agent Using Command Line

RMT Server Initialization Script Options

After installing the RMT Server you need to initialize the Server. By default the only required flag you must include when running the initialization script is `--accepteula`. Other options

## Tableau Server on Linux Administrator Guide

give you flexibility to customize the installation based on your environment and the security requirements of your enterprise.

`--accepteula`

Required.

Indicates you have read and accepted the terms of the End User License Agreement (EULA).

`-a <username>`

Optional.

Add the provided username to the appropriate groups, instead of the user running the initialize script. This gives the user access to the resources owned by the groups. This is not the same as the Run As user account.

Default: the user running the initialization script

`-f`

Optional.

Bypass warning messages or distribution version check.

`-h | -?`

Optional.

Displays the script's help text.

`-q`

Optional.

Quiet, suppress output except for errors and warnings.

`--debug`

Optional.

Print each command as it is run for debugging purposes. Produces extensive output.

`--default-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that allows authorization to access Tableau RMT Agent. If specified then `--unprivileged-user` must also be specified.

`---disable-account-creation`

**Version:** Added in version 2023.1.0.

Optional.

Accounts/groups, that do not exist, will not be created. If specified, then you must also specify the `--unprivileged-user` parameter and a combination of the `--default-group` and/or other `--rmt-<...>-group` parameters. The user ID and groups those parameters refer to must already exist.

`--rmt-authorized-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the install base install directory and the `install_dir/-prerequisites` folder. If specified then `--unprivileged-user` must also be specified.

**Default:** "rmtmasterapp" or `--default-group` value

## Tableau Server on Linux Administrator Guide

`--rmt-config-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/master/config` directory. If specified then `--unprivileged-user` must also be specified.

**Default:** "rmtmasterconfig" or `--default-group value`

`--rmt-logs-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/master/logs` directory. If specified then `--unprivileged-user` must also be specified.

**Default:** "rmtmasterlogs" or `--default-group value`

`--rmt-openssl-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/prerequisites/openssl` directory.

**Default:** "rmtopenssl" or `--default-group value`

`--rmt-postgres-app-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/prerequisites/postgresql13` directory.

**Default:** "rmtpostgresapp" or `--default-group value`

`--rmt-postgres-data-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/master/logs` directory. If specified then `--unprivileged-user` must also be specified.

**Default:** "rmtmasterlogs" or `--default-group value`

`--rmt-rabbitmq-app-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/prerequisites/rabbitmq` directory.

**Default:** "rmt-rabbitmqapp" or `--default-group value`

`--rmt-rabbitmq-data-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/data/rabbitmq` directory.

**Default:** "rmt-rabbitmqdata" or `--default-group value`

`--unprivileged-user=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the unprivileged user account to run Tableau RMT Master. You cannot change the account after initializing RMT.

**Default:** `"tabrmt-master"`

### Install the Agent Using Command Line

The Agent is a lightweight process that consumes minimal server resources and sends data to the Resource Monitoring Tool Server (RMT Server). Install the Resource Monitoring Tool Agent on each of your Tableau Server nodes. To install and register an Agent, download the Agent bootstrap configuration file and save it to a location that is accessible from the Resource Monitoring Tool Agent nodes.

This topic describes the steps you can use to install the Resource Monitoring Tool Agent using command line. Command line installation is supported on both Windows and Linux operating systems.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see [About Tableau Help](#).

#### Before you install

- Download the bootstrap file and save it to a location that is accessible to the nodes on which you are going to install RMT Agent. **Bootstrap files are only valid for 24 hours after downloading. You will need to regenerate the bootstrap file if the one you are using is older than 24 hours.**
- Starting in version 2021.3, Agent registration will need to communicate both through a https endpoint and RabbitMQ to complete Agent registration. Make sure both ports 443 and 5672 are open for these communications.

#### Install on Linux

**To install and configure the Agent:****1. Install:**

1. Download the .rpm or .deb Agent Installer and save it to a location that you can access from the machine where you plan to install the Agent.
2. Run the following command to install the Agent where <version> is formatted as major-minor-maintenance:

For RHEL like distributions including CentOS:

```
sudo yum install Tabrmt-Agent-x86_64-<version>.rpm
```

For Ubuntu:

```
sudo apt install Tabrmt-Agent-amd64-<version>.deb
```

**2. Initialize RMT Agent:**

You must explicitly accept the End User License Agreement (EULA) when you initialize RMT Agent. You also have the option to specify non-default configurations. To initialize RMT Agent with a default configuration, run this command :

```
sudo /opt/tableau/tabrmt/agent/install-scripts/initialize-rmt-agent --accepteula
```

The EULA can be found in the `/opt/tableau/tabrmt/agent/docs` folder.

Beginning in version 2023.1 you can specify a custom Run As account to be used by RMT, as well as other configuration options. By default RMT creates and uses an account called `rmt-agent` to run under. To specify a custom Run As account to be used by RMT Agent, include the `--unprivileged-user` option when you run the initialization script. For information about all the available switches for the `initialize-rmt-agent` script, see [RMT Agent Initialization Script Options](#).

### 3. Register:

1. Log off and log on as the *tabrmt-agent* user so you can run `rmtadmin` commands which always require that you run as the *tabrmt-agent* user. Also, when you log on again, you create a new session in which group membership changes have taken effect.

```
sudo su --login tabrmt-agent
```

2. Run the following command and provide the path where the bootstrap file is located. Provide a description of the node where the Agent is being installed.

```
rmtadmin register <bootstrap file path\file> --server-name=  
e=<Friendly name of machine> --server-description=<server  
description> --username=<name of the RMT admin user>
```

You will be prompted for the password of the RMT admin user.

**Note:** The *tabrmt-agent* user defaults to run commands from the base working directory: `/var/opt/tableau/tabrmt/agent`, so you must specify the file path accordingly. For example, if you placed the bootstrap file in the `/var/opt/tableau/tabrmt/agent/bootstrap/` folder as recommended, the file path would be `/var/opt/tableau/tabrmt/agent/bootstrap/<bootstrap_file_name>`.

The following table lists the configuration options used to register the Agent:

| Option                        | Required? | Default | Description                         |
|-------------------------------|-----------|---------|-------------------------------------|
| <code>--bootstrap file</code> | Yes       | <none>  | The location of the bootstrap file. |
| <code>--username</code>       | Yes       | <none>  | This is typically the               |

| Option               | Required?   | Default              | Description   |
|----------------------|---|----------------------|---|
|                      |   |                      | admin user you created during RMT Server installation.  |
| --password           | Yes   | <none>               | This is the password for the user account   |
| --password-file      | No  | <none>               | Path including the file name where the password is stored.  |
|                      | Password can be supplied in the command line or a file that contains the password. If neither is provided, you will be prompted for the password. |                      |   |
| -- server-name       | No  | Host name of machine | Name of the computer that has the Agent Installed. If no option is provided, this field will default to the host name of the machine. |
| --server-description | No  | <none>               | Description of the computer that has the Agent installed. If no option is provided, this field will remain blank.                     |

Install on Windows

**To install and configure the Agent:**

## Tableau Server on Linux Administrator Guide

1. Download the bootstrap file to a location that can be accessed from the Tableau Server nodes.

```
rmtadmin bootstrap-file --env=<myenvironment> --filename<The  
absolute or relative path including the file name>
```

2. Run the Agent setup program:

1. Download the Agent installer and save it to a location that you can access from Tableau Server machines.
2. Open the command prompt as an administrator.
3. Navigate to the location of the Agent installer and run the **exe** file using the following command

```
Tabrmt-Agent-64bit-<version>.exe /silent ACCEPTTEULA=1
```

**Note:** Use the /silent or /quiet switch to run the setup unattended and without displaying any UI or prompts.

The default install folder is usually like this: *C:\Program Files\Tableau\Tableau Resource Monitoring Tool\agent*. To provide a different install location run the following command:

```
Tabrmt-Agent-64bit-<version>.exe /silent ACCEPTTEULA=1  
InstallFolder="D:\Tableau Resource Monitoring Tool\agent"
```

3. Register the Agent:

1. Run the following command to register the Agent:

```
rmtadmin register <bootstrap file path\file> --server-name=  
e=<Friendly name of machine> --server-description=<server  
description>
```

The following table lists the configuration options used to register the Agent:

| Option                | Required?   | Default              | Description   |
|-----------------------|---|----------------------|---|
| --bootstrap file      | Yes   | <none>               | The location of the bootstrap file.   |
| --username            | Yes   | <none>               | This is typically the admin user you created during RMT Server installation.  |
| --password            | Yes   | <none>               | This is the password for the user account   |
| --password-file       | No  | <none>               | Path including the file name where the password is stored.  |
|                       | Password can be supplied in the command line or a file that contains the password. If neither is provided, you will be prompted for the password. |                      |   |
| -- server-name        | No  | Host name of machine | Name of the computer that has the Agent Installed. If no option is provided, this field will default to the host name of the machine. |
| -- server-description | No  | <none>               | Description of the computer that has the Agent installed. If no option is   |

| Option | Required? | Default | Description                             |
|--------|-----------|---------|---|
|        |           |         | provided, this field will remain blank. |

## Windows install properties and switches

### Switches:

| Switch           | Description  | Comments                                |
|------------------|--|---|
| /passive         | Run Setup with minimal UI and no prompts.  |   |
| /quiet   /silent | Run Setup in unattended, fully silent mode. No web interface or prompts are displayed. | Use either /quiet or /silent, not both. |

### Properties:

| Property   | Description  | Comments  |
|--|--|---|
| InstallFolder= <code>&lt;path\to\installation\directory&gt;</code> | Install to the specified non-default install location. | Specifies the location to install RMT. If not used, RMT is installed to <i>C:\Program Files\Tableau\Tableau Resource Monitoring Tool\master</i> .<br><br>Example: <code>&lt;Setup file&gt; /silent InstallFolder="D:\Tableau\Tableau</code> |

| Property          | Description  | Comments   |
|-------------------|--|--|
|                   |  | Resource Monitoring Tool\agent"  |
| ACCEPT_EULA=1   0 | Accept the End User License Agreement (EULA). Required for quiet, silent, and passive install on both initial and additional nodes. 1 = true, accept the | If not included when using /passive, /silent or /quiet, Setup fails silently. If included but set to 0, Setup fails. |

| Property | Description                              | Comments |
|----------|--|----------|
|          | EULA, 0 = false, do not accept the EULA. |          |

## Installing Agent on Multi-Node Tableau Server

Run the steps described above on each of the nodes of Tableau Server. On the web interface of the RMT Server you should be able to see all the nodes where the Agent is installed.

Who can do this

To install Resource Monitoring Tool, you must have all the following:

### Windows:

- Administrator permissions on the machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator site role.

### Linux:

- Full sudo access for the user account that is used to install the Agent.

Next Step

Configure Tableau Resource Monitoring Tool

RMT Agent Initialization Script Options

After installing the RMT Agent you need to initialize the Agent. By default the only required flag you must include when running the initialization script is `--accepteula`. Other options give

you flexibility to customize the installation based on your environment and the security requirements of your enterprise.

#### RMT Agent initialization options

`--accepteula`

Required.

Indicates you have read and accepted the terms of the End User License Agreement (EULA).

`-a <username>`

Optional.

Add the provided username to the appropriate groups, instead of the user running the initialize script. This gives the user access to the resources owned by the groups. This is not the same as the Run As user account.

Default: the user running the initialization script

`-f`

Optional.

Bypass warning messages or distribution version check.

`-h | -?`

Optional.

Displays the script's help text.

`-q`

Optional.

Quiet, suppress output except for errors and warnings.

`--debug`

Optional.

Print each command as it is run for debugging purposes. Produces extensive output.

`--default-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that allows authorization to access Tableau RMT Agent. If specified then `--unprivileged-user` must also be specified.

`---disable-account-creation`

**Version:** Added in version 2023.1.0.

Optional.

Accounts/groups, that do not exist, will not be created. If specified, then you must also specify the `--unprivileged-user` parameter and a combination of the `--default-group` and/or other `--rmt-<...>-group` parameters. The user ID and groups those parameters refer to must already exist.

`--rmt-authorized-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the install base install directory and the `install_dir/prerequisites` folder. If specified then `--unprivileged-user` must also be specified.

**Default:** "rmtagentapp" or `--default-group` value

`--rmt-config-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/agent/config` directory. If specified then `--unprivileged-user` must also be specified.

**Default:** "rmtagentconfig" or `--default-group` value

`--rmt-logs-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/agent/logs` directory. If specified then `--unprivileged-user` must also be specified.

**Default:** "rmtagentlogs" or `--default-group` value

`--unprivileged-user=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the unprivileged user account used to run Tableau RMT Agent. You cannot change the account after initializing RMT.

**Default:** "tabrmt-agent"

### External Repository for Tableau Resource Monitoring Tool

The Tableau Resource Monitoring Tool uses a PostgreSQL database as its repository to gather and store Tableau Server monitoring data that is used to provide performance and usage information.

## Tableau Server on Linux Administrator Guide

Before the 2022.3 release, this PostgreSQL repository was automatically installed with the RMT Server, on the same machine as the RMT Server and this was the only option available. Starting in version 2022.3, you can reconfigure RMT Server to use an externally hosted PostgreSQL database instead of the locally installed database. When RMT Server is configured to use an externally hosted PostgreSQL database, we refer to it as the external repository.

The supported platform for hosting the external repository is an AWS RDS instance. Hosting the repository database externally allows you to manage the availability, backups, and disaster recovery of the repository component of the RMT Server.

With the addition of this option to configure an external repository, RMT Server can be configured in the following ways:

- **Continue to use the locally installed repository:** This means that the PostgreSQL database that is automatically installed with RMT Server on the same machine will be used as the repository for RMT Server, and no further changes are made to this configuration.
- **Configure RMT Server to use an external repository:** This means that the PostgreSQL database that RMT uses is hosted external to RMT Server. This requires making some configuration changes post installation. Currently only AWS RDS instances are supported as the hosting platform for PostgreSQL database.

In order to setup and manage the external repository, you should have a good understanding of the AWS RDS platform and PostgreSQL database. We recommend, you use the [documentation on the AWS site](#) for platform related instructions.

You will also need to know how to configure and manage the external repository configuration for Resource Monitoring Tool. This topic will provide you with that information in the sections below.

### New installation of Resource Monitoring Tool

The instructions detailed in this section apply to a new installation of Resource Monitoring Tool. If you have an existing deployment of RMT, and want to move to an external repository configuration, see the Existing Resource Monitoring Tool installation section of this topic.

When you install RMT Server, it automatically installs the repository database on the same machine as the RMT Server. The process to configure the external repository is a post install configuration where you will reconfigure RMT Server to use an externally hosted PostgreSQL database.

Use the following steps to install Resource Monitoring Tool and reconfigure RMT Server to use an external repository:

1. **Create the external repository:** Create an RDS instance to host the external repository with the following recommendations.
  - **Minimum recommended PostgreSQL instance specifications:**
    - db.m6g.2xlarge (8 vcpu, 32 GiB RAM)
    - SSD Storage with 500 GB disk space
  - **Instance configuration values:**
    - Max Worker Processes: Total Logical Processors
    - Max Workers Per Gather:  $\text{Min}(\text{Total Logical Processors} / 2, 4)$
    - Max Parallel Workers: Total Logical Processors
    - Max Parallel Maintenance Workers:  $\text{Min}(\text{Total Logical Processors} / 2, 4)$
    - Shared Buffers: Total Memory / 4
    - Effective Cache Size: 75% of Total Memory
    - Maintenance Work Memory: Total Memory / 16 Linux, Max 2GB - 1MB in Windows
    - Wal Buffers: Derived from Shared Buffers, likely around 16 MB
    - Work Memory: Derived from Shared Buffers and Max Workers Per Gather

To learn how to create and connect to a PostgreSQL DB instance on AWS, see [this page on AWS documentation site](#).

2. **Install RMT:** Follow the instructions [Install the RMT Server Using Command Line](#) to Install RMT Server, but **skip the steps for creating an environment. You will do that later after configuring RMT Server to use the external repository. Note that this will initially install a local PostgreSQL database.**
3. **Test the connection to the external repository:** Test the connection to the new database using `psql`, a PostgreSQL administrative tool that is installed with the RMT Server; Navigate to the 'bin' folder of the locally installed PostgreSQL installation directory.

```
/var/opt/tableau/tabrmt/prerequisites/postgresql<version number>/bin
```

Run the following command to test the connection. Substitute your own value below for **aws\_rds\_servername**, and provide the PostgreSQL password you created in AWS when prompted.

```
psql -h <aws_rds_servername> -p 5432 -d postgres -U postgres
```

If you receive an error at this point and cannot connect successfully, review the parameter values in the command against the values from the AWS RDS console.

Once the connection has been successfully established, you can close the `psql` session with the following command:

```
\q
```

4. Run `rntadmin master-setup` **to configure RMT Server to use the external repository.** Use the following command examples, and edit the command to reflect your Resource Monitoring Tool installation path, AWS RDS instance name, port

number, and the RDS PostgreSQL admin user password:

Navigate to the Resource Monitoring Tool RMT Server installation directory: `sudo /var/opt/tableau/tabrmt/master`

Run the command to configure external repository: `rmtadmin master-setup --db-config=external --db-server=aws_rds_servername --db-port=5432 --db-admin-user-name=postgres --db-admin-password='postgres_user_password'`

5. Now **create an environment** and download the bootstrap file:

- Run the following command to create and environment:

```
rmtadmin create-env --name=<myenvironment> --api-user-name=<TableauServer API user name> --api-password=<password for the Tableau Server API user account>
```

- Download the bootstrap file to register Agents:

```
rmtadmin bootstrap-file --env=<myenvironment> --filename<The absolute or relative path including the filename>
```

The steps are described in full detail here: [Install the RMT Server Using Command Line](#).

6. Follow the instructions [Install the Agent Using Command Line to Install and register Agents on Tableau Server Nodes](#).

### Existing Resource Monitoring Tool installation

In this release, to configure external repo, you will essentially have to start with a new installation of Tableau Resource Monitoring Tool using the steps described in the [above section](#).

### Upgrade best practices

Here are the general steps you need to follow if you want to upgrade Tableau Resource Monitoring Tool and migrate to an external repository at the same time:

### Migration with environment recreation:

1. Upgrade RMT Server and all Agents to 2022.3 or later.
2. Steps through 2-4 are very similar to the steps you would take to do a new install - see [New installation of Resource Monitoring Tool](#) above. This mainly involves:
  - Create an AWS PostgreSQL DB Instance.
  - Configure RMT Server to use the external repository.
  - Recreate environments and re-register all the Agents.
3. Reconfigure any custom configurations.

**Note:** You will lose historical data and also need to reconfigure any custom configurations.

## Upgrading when the new version of RMT requires a major version PostgreSQL upgrade

When there is a change in the PostgreSQL major version requirement for Resource Monitoring Tool, it is a best practice to upgrade the external repository PostgreSQL version first before you upgrade Resource Monitoring Tool. More details are provided below. To see if you should upgrade your external repository PostgreSQL version, see the [product compatibility table](#).

Use the following steps to upgrade RMT and the RDS instance when a PostgreSQL major version upgrade is required

1. Make a backup of your RDS instance. You will need this in case you need to roll back the upgrade. For more information, see [Backing up and restoring an Amazon RDS DB instance](#) topic on the AWS site.
2. Make a copy of the configuration file in the Resource Monitoring Tool directory. The configuration file is located at:  

```
/var/opt/tableau/tabrmt/master/config.json
```
3. Upgrade the RDS instance to the new version of PostgreSQL For more information, see [Upgrading the PostgreSQL DB engine for Amazon RDS](#) topic on the AWS site.
4. Upgrade RMT Server. If the upgrade including the database migration completes successfully, proceed to the next step. If the upgrade fails, see the instructions in this section on how to recover and roll back the upgrade.

5. Upgrade all the Agents on Tableau Server nodes to the new RMT version. For more information, see [Upgrading Resource Monitoring Tool](#).

## Recovering from a failed upgrade

1. Uninstall the upgraded RMT Server.
2. Restore the AWS RDS instance to the version previous to the upgrade. For more information, [Backup up and restoring an Amazon RDS DB instance](#) topic on the AWS site.
3. Replace the config file that you backed up prior to upgrade in the following location. You may have to create this folder as it might have been deleted during uninstall:

```
/var/opt/tableau/tabrmt/master/config.json
```

4. Install RMT Server which installs a local repository.
5. Configure RMT Server to use the external repository: `rmtadmin master-setup --db-config=external --db-server=<aws_rds_servername> --db-port-t=5432 --db-admin-username=postgres --db-admin-password=<postgres_user_password>.`

## RMT and PostgreSQL version compatibility

This table lists RMT version 2022.3 and later only, since the external repository is only available from version 2022.3 and later.

| RMT Version | PostgreSQL Version shipped with RMT | Supported PostgreSQL Version for external repository |
|-------------|-------------------------------------|--|
| 2022.3      | 13.7                                | 13.7   |

Who can do this

To install Resource Monitoring Tool, you must have all the following:

- User account with full sudo access.
- Tableau Server Administrator site role.

- Resource Monitoring Tool Administrator account.

### External Message Queue Service (RabbitMQ) for Tableau Resource Monitoring Tool

The Tableau Resource Monitoring Tool uses RabbitMQ as its message queue service to collect data from Agents and bring them to the RMT Server. This information in the queue is processed and eventually stored in the RMT repository (PostgreSQL database).

Before the 2022.3 release, the RabbitMQ message queue service was automatically installed with the RMT Server and this was the only configuration available. Starting in RMT version 2022.3, you can reconfigure RMT Server to use an externally hosted RabbitMQ service. When RMT Server is configured to use an externally hosted message queue service, we refer to it as the external message queue service.

With this new option added in version 2022.3, RMT Server can be configured in the following ways:

- **Continue to use the locally installed message queue service:** This means that RabbitMQ that is automatically installed with RMT Server on the same machine will be used as the message service for RMT Server, and no further changes are made to this configuration.
- **Configure RMT Server to use an external message queue service:** This means that RabbitMQ that RMT uses is hosted external to RMT Server. Currently only AWS AMQ is supported as the hosting platform for RabbitMQ. Since all messages from the Agents go through RabbitMQ, by hosting this externally frees up resources from the machine where RMT Server is installed.

To setup and manage the external message queue service, you should have a good understanding of the AWS AMQ platform. We recommend reviewing the [documentation on AWS site](#). You will also need to know how to configure and manage the external message queue service for RMT. This topic will provide you with that information in the sections below.

### New installation of Resource Monitoring Tool

The instructions provided in this section apply to a new installation of Resource Monitoring Tool. If you have an existing installation, and want to move your local RabbitMQ to an extern-

ally hosted configuration, see the Existing installations of Tableau Resource Monitoring Tool section of this topic.

Use the following steps to install Tableau Resource monitoring tool and reconfigure RMT Server to use an external message queue service:

1. **Create Amazon AMQ for Rabbit MQ** to host the external message queue service with the following recommendations:
  - For engine type, use RabbitMQ engine. For the version of Rabbit MQ, see the Product compatibility section.
  - Use the same default version as the one used when RabbitMQ is installed locally. For more information, see the product compatibility table.
  - Use a single-Instance broker.
  - Instance specification: mq.m5.large, 2 vCPU/8 GiB RAM.
  - Create a RabbitMQ username/password.

To learn more, see [Working with Amazon MQ for Rabbit MQ](#) on AWS documentation site.

2. **Test the connection from RMT Server** to the message broker by copying the RabbitMQ web console URL from the AWS MQ page, and paste it into a web browser on RMT Server. Log in via the username and password you created when you set up the broker.
3. Follow the instructions in this topic to **install RMT Server**, but **skip the steps for creating an environment. You will do that later after configuring RMT Server to use the external repository.**
4. Run rmtadmin setup as follows to configure the external Rabbit MQ message queue service:

## Tableau Server on Linux Administrator Guide

```
rmtadmin master-setup --mq-config=external --mq-server=aws_amq_
servername --mq-vhost='/' --mq-port=5671 --mq-username=aws_amq_
username --mq-password='aws_amq_password' --mq-tls-certificate-
host=aws_amq_servername
```

### 5. Now create an environment and download the bootstrap file.

- Run the following command to create an environment: `rmtadmin create-env --name=<myenvironment> --api-username=<TableauServer API user name> --api-password=<password for the Tableau Server API user account>`
- Download the bootstrap file to register Agents: `rmtadmin bootstrap-file --env=<myenvironment> --filename<The absolute or relative path including the file name>`

The steps are described in full detail in the [Install the RMT Server Using Command Line](#) topic.

### 6. Re-register Agents on Tableau Server Nodes using the instructions in [Install the Agent Using Command Line](#) topic.

## Existing installations of Tableau Resource Monitoring Tool

In this release, to configure external messaging service, you will essentially have to start with a new installation of Tableau Resource Monitoring Tool using the steps described in the [above section](#).

## Upgrade best practices

Here are the general steps you need to follow if you want to upgrade to a version 2022.3 or later and migrate to using an external message queue service at the same time.

### **Migration with environment recreation:**

1. Upgrade RMT Server and all Agents to 2022.3 or later
2. Create an Amazon AMQ broker service.

3. Configure RMT Server to use the external message queue service
4. Recreate environments and re-register all the Agents
5. Recreate any custom configurations.

**Note:** You will lose some event and hardware processing data and you will also need to reconfigure the incident thresholds

## Upgrade steps with enabling TLS for RabbitMQ

Since the agents in versions earlier than 2022.3 have been communicating using unencrypted connection to the RabbitMQ message queue service, when upgrading to version 2022.3 or later, those agents need to be updated to use the new secure connection details.

The steps to do this are as follows:

1. After completing the upgrade steps described in the above section, stop all agents by running the following command:

```
rmtadmin stop --agent
```

2. Download the bootstrap file for the environment by running the following command:

```
rmtadmin bootstrap-file --env<myenvironment> --filename <The absolute or relative path including the file name>
```

3. Run the following command on each of the machines where the Agent is installed:

```
rmtadmin rotate-mq-certificate <BOOTSTRAP_FILE> --username=<RMT Server Username> --password-file=<RMT Server Password file name>
```

4. Restart each Agent machine after successfully running the `rmtadmin rotate-mq-certificate` command.

## Tableau Server on Linux Administrator Guide

### Product Compatibility

This table lists RMT version 2022.3 and later only, since the external message queue is only available from version 2022.3 and later.

| RMT Ver-<br>sion | RabbitMQ version shipped<br>with RMT | Support RabbitMQ version for external mes-<br>sage queue service |
|------------------|--------------------------------------|--|
| 22.3             | 3.10.5                               | 3.10.5   |

### Who can do this

To install Resource Monitoring Tool, you must have all the following:

- User account with full sudo access.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

### Tableau Resource Monitoring Tool Prerequisites - Licenses

Tableau Resource Monitoring Tool contains the following open source applications:

| RMT Version | OPENSSL Version | ERLANG   | RABBITMQ | POSTGRESQL |
|-------------|-----------------|----------|----------|------------|
| 2020.4      | 1.1.1h          | 22.3     | 3.8.3    | 12.2       |
| 2021.1      | 1.1.1h          | 23.1     | 3.8.9    | 12.4       |
| 2021.2      | 1.1.1i          | 23.2.6   | 3.8.14   | 12.5       |
| 2021.3      | 1.1.1k          | 23.3.1   | 3.8.14   | 12.6       |
| 2021.4      | 1.1.1l          | 24.0.3   | 3.8.19   | 12.6       |
| 2022.1      | 1.1.1l          | 24.1.2   | 3.9.7    | 13.3       |
| 2022.3      | 1.1.1q          | 24.3.4.2 | 3.10.5   | 13.7       |

- **Erlang:** Copyright 2016 Industrial Erlang User Group, Apache 2.0. For more information, see the [Erlang](#) and [Apache 2.0](#) sites.

- **RabbitMQ:** Copyright , MPL 2.0, Copyright (c) 2007-2021 VMware, Inc. or its affiliates. For more information, see [Mozilla Public License](#) site.

Resource Monitoring Tool contains a single modified RabbitMQ source file, which is available upon request.

- **PostgreSQL:** Copyright Portions Copyright © 1996-2021, The PostgreSQL Global Development Group, Portions Copyright © 1994, The Regents of the University of California, PostgreSQL license. For more information, see [PostgreSQL](#) site.
- **OpenSSL:** Copyright (c) 1998-2019 The OpenSSL Project, Copyright (c) 1995-1998 Eric A. Young, Tim J. Hudson, OpenSSL license, double license under both the OpenSSL License and the original SSLeay license. For more information, see [Open SSL License](#).

## Upgrading Resource Monitoring Tool

These instructions are for upgrading an existing installation of Tableau Resource Monitoring Tool.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see [About Tableau Help](#).

**Note:** The Resource Monitoring Tool performs an in-place upgrade, upgrading your current installation to the newer version. Do not uninstall your existing installation **before** upgrading.

### Upgrade Notes

#### Consider the following before you start the upgrade process:

1. If you are planning to move to use an external repository (PostgreSQL) or external message queue service (RabbitMQ), make sure you review the upgrade best practices section in the following topics:

## Tableau Server on Linux Administrator Guide

- Upgrade best practices for external repository
  - Upgrade best practices for external message queue
2. Starting in version 2022.3, Tableau Resource Monitoring Tool has built-in encrypted communications between RMT Server and Agents. However, you will need to run `rmtadmin rotate-mq-certificates` on all the Agents to enable TLS. This applies to RabbitMQ that is configured locally on the same machine as RMT Server. For more details on how to do this, see **Upgrade steps with enabling TLS for RabbitMQ** below.
  3. You may need to reboot the machine during an upgrade. This usually occurs if files are locked and cannot be updated by the installer. If necessary, you will be prompted by the installer. Because of this possibility, you may want to consider doing your upgrades during non-work hours.
  4. Sometimes, the Resource Monitoring Tool will modify the database and in such cases, the upgrade process will include a database migration. In case of a database migration, you will see a message banner at the top of the RMT Server web page with a time estimate for completing the process. An example screen shot is shown below:

> As part of the upgrade process, the Tableau Resource Monitoring Tool database is being migrated to a new format. Current progress: **42% complete**. [Refresh this page](#) for an updated estimate.

On expanding the banner you can review the details of the impact of the upgrade. Changes are unique to each release and the details shown are specific to the release.

∨ As part of the upgrade process, the Tableau Resource Monitoring Tool database is being migrated to a new format. Current progress: **42% complete**. [Refresh this page](#) for an updated estimate.

During migration:

- Averages for events and content pages that existed before the upgrade will show a null value: "--", until the data aggregation is complete.
- Averages for new events and content pages that occurred after the upgrade will initially show as 0 until the data aggregation is complete.

[Learn More](#)

5. The Resource Monitoring Tool is backward compatible with Tableau Server versions, but not forward compatible. This means the Resource Monitoring Tool version should be equal to or greater than the Tableau Server version you are monitoring.

For compatibility reasons, Tableau recommends you upgrade the Resource Monitoring Tool first and then follow with a Tableau Server upgrade. For more information, see [Product Compatibility with Tableau Server](#).

### How to Upgrade the Resource Monitoring Tool

We recommend you do an in-place upgrade of Resource Monitoring Tool. If you uninstall Resource Monitoring Tool and install a new version of the database, it may result in data corruption and you will be prompted to reinstall the previous version and re-do the upgrade process.

1. Log in to the Resource Monitoring Tool in a browser and confirm it is working before starting the upgrade.
2. Copy the new version of the RMT Server package to the RMT Server machine.
3. Copy the new version of the RMT Agent package to the machines where you have RMT Agents installed. RMT Agents are installed on Tableau Server nodes you are monitoring.
4. On each Tableau Server node running the RMT Agent service, switch to the `tabrmt-agent` user and stop the RMT Agent service:

```
sudo su --login tabrmt-agent
rmtadmin stop
exit
```

5. Switch to the `tabrmt-master` user on the RMT Server and stop the RMT Server service using the following command:

```
sudo su --login tabrmt-master
rmtadmin stop
exit
```

6. Wait until there are not any running processes with `tabrmt` in the name before continuing to the next step.

## Tableau Server on Linux Administrator Guide

Once the services have been stopped, it is best practice to check for any Resource Monitoring Tool processes that are running after the services have been stopped: Any with `tabrmt-agent` or `tabrmt-master`. This does not include PostgreSQL or RabbitMQ. You can check the status using the following command:

```
rmtadmin status
```

7. Run the upgrade commands on the RMT Server. This will upgrade the existing version to the new version:

### **For RHEL-like distributions including CentOS:**

```
sudo yum install <pathtomasterserverinstaller>/<tabrmt-master-setup-<version>-x86_64.rpm>
```

```
sudo /opt/tableau/tabrmt/master/install-scripts/upgrade-rmt-master --accepteula
```

### **For Ubuntu distributions:**

```
sudo apt install <pathtomasterserverinstaller>/<tabrmt-master-setup-<version>-amd_64.deb>
```

```
sudo /opt/tableau/tabrmt/master/install-scripts/upgrade-rmt-master --accepteula
```

8. Once the RMT Server has been upgraded, upgrade all the RMT Agents by running the following command:

### **For RHEL-like distributions including CentOS:**

```
sudo yum install <pathtoagentinstaller>/<tabrmt-agent-setup-<version>-x86_64.rpm>
```

```
sudo /opt/tableau/tabrmt/agent/install-scripts/upgrade-rmt-agent --accepteula
```

**For Ubuntu distributions:**

```
sudo apt install <pathtoagentinstaller>/<tabrmt-agent-setup-
<version>-amd_64.deb>
```

```
sudo /opt/tableau/tabrmt/agent/install-scripts/upgrade-rmt-
agent --accepteula
```

9. Confirm the RMT Server and Agents are running. Start the RMT Server and Agents if they do not automatically restart after the upgrade is complete.
10. To verify RMT Agents have been upgraded, log in to Resource Monitoring Tool in a browser and go to the **Admin** menu, select **Environments**, and click the **Edit Environment** icon to see the environment details. In the **Servers** tab, you can see the version of the RMT Agent. This can be useful to determine which RMT Agents have been upgraded when you have a multi-node Tableau Server cluster.

## Upgrade steps with enabling TLS for RabbitMQ

Since the agents in versions earlier than 2022.3 have been communicating using unencrypted connection to the RabbitMQ message queue service, when upgrading to version 2022.3 or later, those agents need to be updated to use the new secure connection details. The steps to do this are as follows:

1. After completing the upgrade steps described in the above section, stop all agents by running the following command:

```
rmtadmin stop --agent
```

2. Download the bootstrap file for the environment by running the following command:

```
rmtadmin bootstrap-file --env<myenvironment> --filename <The
absolute or relative path including the file name>
```

3. Run the following command on each of the machines where the Agent is installed:

## Tableau Server on Linux Administrator Guide

```
rmtadmin rotate-mq-certificate <BOOTSTRAP_FILE> --username=<RMT
Server Username> --password-file=<RMT Server Password file
name>
```

4. Restart each Agent machine after successfully running the `rmtadmin rotate-mq-certificate` command.

### Who can do this

To upgrade Resource Monitoring Tool, you will need to have the following permissions:

- User account with full sudo access.
- Tableau Server Administrator.
- Resource Monitoring Tool Administrator.

## Uninstalling Resource Monitoring Tool

There are two primary "uninstall" scenarios Resource Monitoring Tool supports:

- **Uninstall Resource Monitoring Tool:** Resource Monitoring Tool can be uninstalled using the `remove` command which removes each Tableau Resource Monitoring Tool service from the computer from which you are running the command. It also removes data and Resource Monitoring Tool user accounts and groups, but preserves configuration files, logs, and backup files, by moving them to a temporary directory under the `/opt/tableau/tabrmt/data` folder.
- **Obliterate Resource Monitoring Tool:** If you want to completely remove Resource Monitoring Tool from a computer, you can use a script provided by Tableau to remove Resource Monitoring Tool and all related files. *This removes all data as well as Resource Monitoring Tool components, so should only be done if you know you want to reset the computer to a pre-Tableau state.* You might need to do this if Technical Support recommends this step when troubleshooting an installation problem. Completely remove Resource Monitoring Tool without uninstalling any version first. The script will uninstall all existing versions found on the computer. If you have already uninstalled

your existing version and now want to completely remove Tableau, you can find the script to do so in a temporary location.

Uninstall Resource Monitoring Tool using `remove`:

- For RHEL-like distributions including CentOS:

```
sudo yum remove tabrmt-master
```

```
sudo yum remove tabrmt-agent
```

- For Ubuntu distributions:

```
sudo apt remove tabrmt-master
```

```
sudo apt remove tabrmt-agent
```

Obliterate Resource Monitoring Tool using `tableau-rmt-obliterate` script:

If you run into issues when uninstalling using the `remove` command, you can use the obliterate script provided by Tableau to remove all of the installation files from your computer. By default, the obliterate script is located at `/opt/tableau/tabrmt/master/install-scripts/tableau-rmt-obliterate` on the RMT Server machine and `/opt/tableau/tabrmt/agent/install-scripts/tableau-rmt-obliterate` on Agent machines.

If you already attempted to uninstall Resource Monitoring Tool using the `remove` command, the obliterate script is automatically copied to: `/var/tmp/tableau-rmt-obliterate`

The information to run the script is described below:

1. As the root user, run the following command on the RMT Server machine to completely uninstall RMT Server:

```
/var/tmp/tableau-rmt-obliterate -m -y -y -y
```

## Tableau Server on Linux Administrator Guide

2. As the root user, run the following command on each Agent machine to completely uninstall Agents:

```
/var/tmp/tableau-rmt-obliterate -a -y -y -y
```

You can force remove all the files, including the logs and backups, using the parameters:

-y

Required.

Removes Resource Monitoring Tool from this computer. Must be specified three times (-y-y-y) to confirm.

-m

Required to uninstall RMT Server.

Removes RMT Server.

-a

Required to uninstall Agent.

Removes Resource Monitoring Tool Agent if installed.

-k

Optional.

Does not copy backups to the `logs-temp` directory.

-g

Optional.

Does not copy logs to the logs to the `logs-temp` directory.

Who can do this

To uninstall Resource Monitoring Tool, you must have all the following:

- Administrator permissions on the machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

## Configure Tableau Resource Monitoring Tool

This section includes topics that provide information on how to configure Tableau Resource Monitoring Tool to suit your requirements.

### Resource Monitoring Tool Server Configuration

This topic describes the Resource Monitoring Tool Server (RMT Server) configuration options you can set using the web interface.

### Post install setup configurations

You can update the configurations you specified during the setup.

Following are the two recommended ways to make configuration changes:

- **To do this using the web interface:** On the machine where RMT Server is installed, go to: *http://<hostname>/setup/server*.
- **To do this using command line,** use `rmtadmin master-setup` command with the `--skip-admin-creation` option to make sure you are not prompted to create the admin user post installation. For more information, see `rmtadmin master-setup`.

**Note:** Configuration values are saved in the [configuration file](#). Changes can be made directly to this file, but it is advised to leverage the configuration options in the UI and through the `rmtadmin` command line utility. Changes to the config file will require a restart to be applied.

Here are some examples of the type of updates you might want to do after the initial setup.

## Tableau Server on Linux Administrator Guide

- **Changing SSL Configuration:** The default configuration is set to false. You can change this configuration to require HTTPS. Use the `rmtadmin master-setup` command to update this setting.
- **SSL Certificate Updates:** You might have completed your initial RMT Server setup using the default certification mode for secure communications, and want to update the certification with your own certificate.
- **Changes Ports:** Sometimes you will need to use different port numbers than the default based on your network requirements. To learn more about ports and communications between the various components of Resource Monitoring Tool, see [Tableau Resource Monitoring Tool Communication Ports](#).
- **Update session expiration:** If the user does not access the session for the set timeout period then the session will expire and they will need to log in again. By default, this is set to 240 minutes. You can also enable the **Sliding Expiration** option to reset the time out period when a session is accessed within the time out period.

**Note:** Adding or removing a Tableau Server node: If you add a new node to the Tableau Server Cluster that you are monitoring using Resource Monitoring Tool, you will need to install and register this node. For more information, see [Tableau Server Topology Changes](#).

To do this through command line, use `rmtadmin-master-setup` command. For more information, see [rmtadmin Command Line Utility](#).

You can configure Resource Monitoring Tool by clicking on “Configuration” under the Admin menu. Configuration sections are divided by tabs. To do this using a configuration file, see [RMT Server Configuration File](#).

## Notifications

Notifications can be set at a global level and at the environment level.

You can choose how you want to receive your notifications- through email or Slack, or through both email and Slack.

### **The following applies to both email and Slack notifications:**

Both email and Slack notifications can be set at a global level and at the environment level. To send any notifications, global configurations must be enabled, not just at the environment level. You can also configure different minimum severity levels at which to send notifications - they can be different for email and slack, they can also be different at global and environment levels.

Global configurations are applied to existing environments or any new environments created unless the environment is using custom thresholds.

## Slack notification settings

Slack notifications were introduced in Resource Monitoring Tool version 2022.1.

**Before** you set up Slack notifications in Resource Monitoring Tool, there is some initial setup you need to do in Slack. The full details are described in [this Slack article](#), but here are the main things you will need to do:

1. Create a new or use an existing Slack workspace or app and make sure it is enabled to receive incoming webhooks.
2. Authorize a channel where the notifications should be posted.
3. Copy the Webhook URL that is generated for your workspace.

To set up Slack notification in the Resource Monitoring Tool:

1. From the **Admin** menu, select **Global Configuration**.
2. Under the **Notifications** tab, in the **Slack** section, use the toggle button at the top of the section to enable Slack notifications.

3. Configure the following settings:
  1. **Minimum Severity:** The minimum severity level at which you want to receive Slack notifications.
  2. **Webhook URL:** URL of the incoming webhooks for your Slack workspace. This URL is automatically generated when you enable incoming webhooks for your Slack workspace.
4. Test it using the **Send a Test Message** button to make sure your settings are valid and they work.

To specify the notifications for each environment:

1. From the **Admin** menu, select the environment that you want to modify and choose **Edit Environment**.
2. In the **Notifications** tab, choose **Custom** for configuration type to override the global settings.
3. Set the minimum severity and the Webhook URL
4. Test it using the **Send a Test Message** button to make sure your settings are valid and they work.

## Email notifications

To set up email notification, start by configuring SMTP server settings at the global level. The SMTP server settings configured at the global level are applied automatically to all environments. You can customize certain settings like the minimum severity level and the sender and recipient emails for each environment.

Here are some technical details about how the TLS configuration works:

- RMT Server uses the STARTTLS SMTP option, which upgrades the SMTP connection to TLS after it has been initiated but before the mail content is sent. RMT does not support the REQUIRETLS SMTP option.
- RMT Server uses STARTTLS to encrypt mail in transit to the SMTP server. Whether or not the SMTP server stores the mail encrypted at rest is subject to the SMTP server configuration.

Before you can configure email notifications in the Resource Monitoring Tool, you must have an SMTP server set up and have the following pieces of information:

- **Name** of the SMTP server.
- If you are planning to use encrypted communications, make a note of the **TLS version** that the SMTP server accepts. Currently, **TLS 1.2 is required** by Resource Monitoring Tool and **TLS 1.3 is supported**.
- The **certificate thumbprint** (optional).
- **Port number** for the SMTP server.
- **Username and password** (optional). Needed only if the SMTP server is configured to authenticate using a username and password.
- **Sender and recipient email addresses** that will be used to send and receive notifications.

**To specify the SMTP server settings in the Resource Monitoring Tool:**

1. From the Admin menu, select **Global Configuration**.
2. In the **Notifications** tab in the **Email** section, select the toggle button at the top of the sections to enable email notifications.
  1. Configure the following SMTP server settings:
    1. **Server:** Provide the fully qualified DNS name of the SMTP server.
    2. **Encryption:** Specify whether you want the communications between RMT Server and the SMTP server encrypted. The option you choose will depend on the SMTP server configuration for encryption and your preference for using encrypted communications between RTM Server and the SMTP server.
      1. **Required:** Use this when your SMTP server is enabled to use encrypted communications and you want to make sure communications are always encrypted. When set to required, the connection will always be attempted using encryption. If the SMTP server is not enabled to use encryption, the RMT server will be unable to communicate with the SMTP server.

2. **Preferred:** Use this if you are not sure about the encryption settings of your SMTP server, but prefer that encrypted communications be used when possible. If the SMTP server is not enabled to use encryption, in this case, non-encrypted communication is used.
3. **Disabled:** Use this if your SMTP is not enabled to use encrypted communications. Communications between RMT Server and the SMTP server are not encrypted.

**Note:** If the SMTP server requires encryption, the connection will fail. If the SMTP server is enabled for encryption but does not require it, the connection will succeed.

4. **Options:** This determines how the SMTP server will be verified. You have the following options:
  1. Check Server identity: RMT will verify if the name of the certificate used matches the SMTP server name. If there is no match, the connection will fail.
  2. Trust all hosts: All certificate errors are ignored and overrides the Check Server identity. This should be used only if you are confident that the certificate that the RMT server using is from your server.
5. **TLS version:** The version of TLS that is supported by your SMTP server. There is a default version already selected, but you can select other versions. If multiple TLS versions are selected, the RMT server will use the most secure version compatible with RMT and the SMTP server. TLS version 1.3 requires Open SSL 1.1.1f. If you are planning to use TLS 1.3, make sure the machine where RMT Server is installed has Open SSL 1.1.1f.

6. **Certificate Thumbprint:** This is optional. The SHA1 certificate is used when provided and it must be valid and one that the SMTP server uses. A valid thumbprint will override other certificate errors like expiration dates and Server name mismatches.
7. **Port:** Port setting for the email server.
8. **Username:** Optional. The name of the account used to authenticate to the email server, if the SMTP server is configured with a username and password for authentication.
9. **Password:** Optional. The password for the account used to authenticate to the email server, if the SMTP server is configured with username and password for authentication.
10. **Minimum Severity:** The minimum severity level at which you want to receive email notifications. This will be applied to all environments unless modified at the environment level.
11. **Sender email:** The email address that is used to send the notifications. This will be applied to all environments unless modified at the environment level.
12. **Recipient email(s):** Email addresses of the people who should receive these notifications. This will be applied to all environments unless modified at the environment level.
13. **Test** it using the Send a Test Message button to ensure your settings are valid and can be used to successfully send an email notification.

**To customize the settings for an environment:**

1. From the **Admin** menu, select the environment that you want to modify and choose **Edit Environment**.
2. In the **Notifications** tab, choose **Custom** for configuration type to override the global settings.

3. Set the severity level, and sender and recipient email information.
4. Test it using the Send a Test Message button to make sure your settings are valid and you are able to send an email notification.

## Troubleshoot connection failures

Connection failures can happen due to various reasons, but here are some that could be caused due to configuration issues:

- **Encryption setting errors:** Happens if there is a mismatch of encryption settings between the RMT Server and the SMTP server. For example, if the RMT server is set to require encryption, but the SMTP server is not configured to use encryption. The reverse is also true. If the SMTP server requires encrypted communication and RMT Server is set to disable encryption, the connection will fail.
- **Certificate errors:** When using encrypted communications, things like certificate authority and match between certificate name and the SMTP server are considered unless you choose to explicitly **Trust all hosts** under **Options**.
- **TLS errors:** TLS version support is dependent on the Operating System (OS) on which the RMT Server is installed. Check to see if the version of TLS you selected is supported by the OS. TLS 1.2 is required, but TSL 1.3 is also supported. TLS 1.3 requires Open SSL 1.1.1f or greater. Make sure you have Open SSL 1.1.1f on the machine where RMT Server is installed.

### Incident thresholds

Configure the global incident notification settings. These global thresholds apply to all environments by default unless overridden by the individual environments.

See [Incidents](#) for information on what incident options are available and how to configure them.

### Security

Configure the security settings for Resource Monitoring Tool user accounts.

## Data

By default, Resource Monitoring Tool stores two weeks of detailed activity data and ten years of aggregated reporting data.

**Data Retention:** Detailed activity data from your Tableau Server powers the dashboards and incidents for diagnosis of recent performance incidents. Due to the associated storage and processing requirements, this data is only stored for two weeks by default.

**Reporting Data:** Aggregated activity data from your Tableau Server is stored for reporting purposes (e.g., the [Chargeback](#) report). This data is compact and can easily be stored for many years of historical reporting.

## Advanced

Allows configuration of the Resource Monitoring Tool diagnostic logging levels.

See the [Log Files](#) for more information about logging.

## Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-Environment Management** role.

## RMT Server Configuration File

This topic describes the configuration options you can use using the configuration file. To do this using the web interface, see [Resource Monitoring Tool Server Configuration](#).

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see [About Tableau Help](#).

The configuration file is located at `/var/opt/tableau/tabrmt/master/config.json`.

**Note:** Configuration values are saved in the configuration file. Changes can be made directly to this file, but it is advised to leverage the configuration options in the UI and through the `rmtadmin` command line utility. Changes to the config file will require a restart to be applied.

You will need to restart the RMT Server after making changes to the configuration file.

### Data Retention

By default the Resource Monitoring Tool stores two weeks of detail data and ten years of aggregated reporting data.

This is configurable. Here is an example snippet defining the data retention settings:

```
{
  "db": {
    "cleanup": {
      "afterDays": 14,
      "aggregate": {
        "afterDays": 3650
      }
    }
  }
}
```

### SMTP Configuration

An example `config.json` snippet defining the SMTP information:

```
{
  "smtp": {
    "server": "localhost",
    "port": 25,
    "username": "my-username",
    "password": "my-password",
    "requireSSL": true
  }
}
```

```
}
}
```

The full list of configuration values available in the `smtp` configuration section:

| Key                     | Data Type | Required? | Description  |
|-------------------------|-----------|-----------|--|
| <code>server</code>     | String    | Optional  | The SMTP server to use. Default value: <code>localhost</code>  |
| <code>port</code>       | Number    | Optional  | The SMTP server's port number. Default value: <code>25</code>  |
| <code>username</code>   | String    | Optional  | The username to use if authentication is required by the server.   |
| <code>password</code>   | String    | Optional  | The password to use if authentication is required by the server.   |
| <code>requireSSL</code> | Boolean   | Optional  | <code>true</code> if your SMTP server requires SSL, otherwise <code>false</code> . Default value: <code>false</code> |

### Notification Configuration

An example `config.json` snippet defining the notification information:

```
{
  "notifications": {
    "email": {
      "from": "sender@domain.com",
      "to": "recipient1@domain.com,recipient2@domain.com"
    }
  }
}
```

```
}
```

Global notification information (as shown above) can be overridden per environment in the `environments` section:

```
{
  "environments": {
    "Environment1": {
      "notifications": {
        "email": {
          "from": "sender@domain.com",
          "to": "recipient1@domain.com,recipient2@domain.com"
        }
      }
    }
  }
}
```

The full list of configuration values available in the `notifications.email` configuration section:

| Key                                  | Data Type | Required? | Description  |
|--------------------------------------|-----------|-----------|--|
| <code>from</code>                    | String    | Required  | The sender's email address.  |
| <code>to</code>                      | String    | Required  | The recipient email address (es). Multiple addresses must be separated by commas or semi-colons. |
| <code>minimumIncidentSeverity</code> | String    | Optional  | The minimum incident severity at which emails will be sent.                                      |

| Key | Data Type | Required? | Description   |
|-----|-----------|-----------|---|
|     |           |           | Default value: <code>critical</code> . Also see Tableau Resource Monitoring Tool - Incidents. |

### Histogram Configuration

The boundaries used to generate histograms in the web interface are configurable, using an array of values that represent each boundary.

The full list of configurable histograms in the `monitoring.histograms` section:

| Key                                      | Data Type        | Required? | Description  |
|--|------------------|-----------|--|
| <code>viewLoadDuration</code>            | Array of Numbers | Optional  | The histogram boundaries for view loads. Values are in milliseconds.<br>Default value: <code>[1000, 3000, 6000, 10000]</code>      |
| <code>externalDataRequestDuration</code> | Array of Numbers | Optional  | The histogram boundaries for external data requests. Values are in milliseconds.<br>Default value: <code>[1000, 3000, 6000,</code> |

| Key                    | Data Type        | Required? | Description  |
|------------------------|------------------|-----------|--|
|                        |                  |           | 10000]   |
| backgroundTaskDuration | Array of Numbers | Optional  | The histogram boundaries for background tasks. Values are in milliseconds. Default value: [60000, 300000, 600000, 1800000] |

As an example, to use the following histogram buckets for everything at a global level:

- ≤ 1 second
- > 1 second and ≤ 10 seconds
- > 10 seconds and ≤ 30 seconds
- > 30 seconds

The configuration would look like:

```
{
  "monitoring": {
    "histograms": {
      "viewLoadDuration": [1000, 10000, 30000],
      "externalDataRequestDuration": [1000, 10000, 30000],
      "backgroundTaskDuration": [1000, 10000, 30000]
    }
  }
}
```

Histogram boundaries can also be set per environment. As an example, for an environment whose identifier is “staging-environment” to use the following view histogram buckets:

- ≤ 2.5 seconds
- > 2.5 seconds and ≤ 5 seconds
- > 5 seconds and ≤ 30 seconds
- > 30 seconds and ≤ 1 minute
- > 1 minute and ≤ 10 minutes
- > 10 minutes

The configuration would look like:

```
{
  "environments": {
    "staging-environment": {
      "monitoring": {
        "histograms": {
          "viewLoadDuration": [2500, 5000, 30000, 60000,
600000]
        }
      }
    }
  }
}
```

The “staging-environment” would fall back to the global histogram configuration for background tasks.

## Incident Configuration

See [Incidents](#) for information on what incident options are available and how to configure them.

## RMT ServerLogging

See Tableau Resource Monitoring Tool Log Files.

## Agent

The agent service's configuration file is located at `/var/opt/tableau/tabrmt/master/config.json`

You will need to restart the agent service after making changes to the config file.

## Tableau Server Detection

In almost all situations agents will automatically detect the Tableau Server installation and no configuration is needed beyond the standard [agent setup process](#). If desired, you can however manually configure the Tableau Server information through the `config.json` file.

An example `config.json` snippet defining the Tableau Server information needed to run the agent:

```
{
  "agent": {
    "tableauServer": {
      "override": true,
      "productVersion": 2021.4,
      "applicationDirectory": "/var/opt/tableau/tableau_
server/2021.4"
    }
  }
}
```

The full list of configuration values available in the `agent.tableauServer` configuration section:

| Key                               | Data Type | Required? | Description                                    |
|-----------------------------------|-----------|-----------|--|
| <code>applicationDirectory</code> | String    | Required  | The Tableau Server application root directory. |
| <code>dataDirectory</code>        | String    | Optional  | The directory to get Tableau                   |

| Key                         | Data Type | Required? | Description  |
|-----------------------------|-----------|-----------|--|
|                             |           |           | Server data files.   |
| <code>override</code>       | Boolean   | Optional  | <code>true</code> to have the configuration values take precedent over any automatically detected values.<br><code>false</code> to have the configuration values act as a fallback to the automatically detected values. |
| <code>productVersion</code> | Number    | Required  | The version number of the Tableau Server.  |

## Agent Logging

See Tableau Resource Monitoring Tool Log Files.

### Common

Common configuration values are available in both RMT Server and Agent applications. See application-specific sections for guidance on locating the configuration file.

You will need to restart the application service after making changes to the config file.

### Encrypted Messaging

To enable encrypted messaging, the RabbitMQ server must be first configured to allow TLS. See the [Encrypted Data Collection](#) administrator guide for more details.

When configuring the RMT Server or Agent(s) for encrypted messaging:

## Tableau Server on Linux Administrator Guide

- Both the `enabled` flag and the `certificateHostName` must be configured for encryption to be enabled.
- The `certificateHostName` variable MUST match the canonical name (CN=) on the server certificate or the connection will fail.
- The `port` setting in the `mq` section will likely need to be changed based on the TLS port you configured RabbitMQ.

```
{
  "mq": {
    "port": 5671,
    "tls": {
      "enabled": true,
      "certificateHostName": "foo"
    }
  }
}
```

The full list of configuration values available in the `mq.tls` configuration section:

| Key                              | Data Type | Required? | Description  |
|----------------------------------|-----------|-----------|--|
| <code>enabled</code>             | Boolean   | Optional  | <code>true</code> enables TLS encryption for messaging connections. <code>false</code> uses unencrypted connections for messaging. Default value: <code>false</code> |
| <code>certificateHostName</code> | String    | Optional  | <code>certificateHostName</code> MUST match the canonical name (CN=) of the server certificate or the connection will fail. Default value: ""                        |

Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-Environment Management** role.

## rmtadmin Command Line Utility

Resource Monitoring Tool includes a command line interface, `rmtadmin.cmd`, located in the installation folder. The default installation folder is:

- **RMT Server** `/var/opt/tableau/tabrmt/master/`.
- **Agent:** `/var/opt/tableau/tabrmt/agent/`.

`rmtadmin` is included in both the **RMT Server** and **Agent** installations. Some commands may vary based on whether you are using the RMT Server or Agent `rmtadmin` command line utility. E.g., the `users` command only works from the **RMT Server**. The `ziplogs` command is available everywhere but only includes the log files from the application the command is run on.

**Note:** You must run these commands as the `tabrmt-master` user:

```
sudo su --login tabrmt-master
```

Here are the commands that can be used with the `rmtadmin` command line:

**Note:** The `rmtadmin` commands use both positional parameters and options.

The positional parameters should be specified using only the values. You don't need to specify the actual keyword. The option keyword and the value should be specified using an equal sign.

Example:

```
rmtadmin <command> <positional parameter value> --<option keyword>=<value>
```

- [rmtadmin agents](#)

*In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can cause a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files, and other instances. For more information, see [About Tableau Help](#).*

rmtadmin agents

**Note:** Added in version 2021.2

Lists all the registered Agents on Tableau Server nodes for all environments.

This is useful to see where the Resource Monitoring Tool Agent is installed on Tableau Server.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin agents [options][global option]
```

## Options

`--env`

Optional: Use this option to see the list of Agents for the specific environment. This is the system generated identifier. You can find this by going to **Admin > Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

`--keys`

Optional: includes the agent key in the output.

**Example:** `rmtadmin agents --env=<myenvironmentidentifier> --keys`

`rmtadmin bootstrap-file`

**Note:** Added in version 2021.2

Creates and saves the bootstrap file used to register Agents on Tableau Server nodes.

Bootstrap file will be created and saved to the specified absolute path or relative path. Relative paths are resolved to the current working directory.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin bootstrap-file [options][global option]
```

## Options

`--env`

Required. This is the system generated identifier. You can find this by going to **Admin > Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

The Agent on a Tableau Server node can only registered to one environment at a time.

`--filename`

Optional. The absolute or relative path including the file name. The relative paths are resolved to the current working directory. If not specified, the default output filename is used.

`--force`

Optional. Overwrites the existing file with the same name.

**Example:** `rmtadmin bootstrap-file --env=<myenvironmentidentifier>`

`rmtadmin cleanup`

**Note:** Added in version 2021.2

Deletes the log files that are older than a certain number of days. By default it deletes log files older than 31 days.

**This command on both RMT Server and Agent.**

**Note:** If the Resource Monitoring Tool processes are running, the active log files will not be cleaned up by the command. If you want to be sure that all files are deleted, you will need to stop RMT using the `rmtadmin_stop` command and then run cleanup using the following command, `rmtadmin cleanup --log-files-retention=0`, and then restart the processes using the `rmtadmin_start` command.

## Synopsis

```
rmtadmin cleanup [option][global option]
```

## Option

```
--log-files-retention
```

Optional. Deletes the log files older than the specified number of days.

**Example:** `rmtadmin cleanup --log-files-retention=<number of days>`

```
rmtadmin create-admin-user
```

**Version:** Added in version 2022.1

Creates an initial admin user if no other users exist.

**Note:** Beginning in version 2023.1 you can create multiple admin users.

**This command on only RMT Server.**

## Synopsis

```
rmtadmin create-admin-user [options][global option]
```

## Options

`--username`

Optional. The username for the admin user account. Defaults to "admin" if not specified.

`--password`

Required. The password for the admin user account.

`--password-file`

Optional. The path to the file containing the password for the admin user account. You can use this if you do not want to type in the password directly and have the password stored in a file that can be accessed.

**Example:** `rmtadmin create-admin-user --username<admin user name> --password <password for the admin user account>`

`rmtadmin create-env`

**Note:** Added in version 2021.2

Creates a new environment.

**This command only works on the RMT Server.**

## Synopsis

`rmtadmin create-env [options][global option]`

## Options

| Option              | Required? | Default | Description                  |
|---------------------|-----------|---------|------------------------------|
| <code>--name</code> | Yes       | n/a     | The name of the environment. |

| Option            | Required?  | Default  | Description   |
|-------------------|--|--|---|
| --gateway-url     | Yes  | n/a  | URL used to access the Tableau Server gateway.  |
| --version         | Yes  | n/a  | Tableau Server version that this environment will be monitoring.  |
| --non-interactive | No   | Interactive prompts are enabled by default.                  | Disables all interactive prompts.   |
| --no-test         | No   | API and Repository connection testing is enabled by default. | Disables testing API and repository connections.  |
| --api-username    | No   | Null   | User name of the account used to connect to Tableau Server APIs. The user account should be a Tableau Server administrator with access to all Tableau Server sites. |
| --api-password    | No   | Null   | Password of the Tableau Server API user account used to connect to Tableau Server APIs.   |
|                   | (If you specify the Tableau API user name, you will either provide the password, or specify the file path and file |  |   |

| Option                | Required?              | Default | Description  |
|-----------------------|------------------------|---------|--|
|                       | that has the password) |         |  |
| --api-password-file   | No                     | Null    | The path to the file and the name of the file containing the password of the Tableau Server API user account.  |
| --repository-server   | Yes                    | Null    | This is the server name for the PostgreSQL database that is installed with Tableau Server.   |
| --repository-database | Yes                    | Null    | This is the name of the PostgreSQL database that is installed with Tableau Server.   |
| --repository-port     | Yes                    | Null    | The port number of the Tableau Server Repository database.   |
| --repository-username | Yes                    | Null    | <p>Username used to connect to PostgreSQL database installed with the Tableau Server Repository.</p> <p>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the <b>readonly</b> database user. For details, see Enable access to the Tableau Server repository.</p> |
| --repository-password | Yes                    | Null    | Password for the user account used to connect to the PostgreSQL data-  |

| Option                      | Required?   | Default | Description   |
|-----------------------------|---|---------|---|
|                             |   |         | <p>base that is installed with the Tableau Server .</p> <p>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the <b>readonly</b> database user. For details, see Enable access to the Tableau Server repository.</p> |
| --repository-password-file  | No, but required if you are not providing the password in command prompt or in a script directly. | Null    | The path including the file name where the password for the user account used to connect to the PostgreSQL database that is installed with Tableau Server.  |
| --repository-ssl-mode       | No  | Prefer  | <p>Tableau Server Repository SSL Mode:</p> <p><b>Prefer</b> SSL or <b>Require</b> SSL to configure SSL connections to Tableau Repository.</p> <p><b>Disable</b> to never use SSL to make Tableau Server Repository connections.</p>   |
| --repository-ssl-thumbprint | No  | Null    | When configuring Tableau Server   |

| Option | Required? | Default | Description   |
|--------|-----------|---------|---|
|        |           |         | <p>PostgreSQL to allow direct connections, Tableau Server creates a certificate and keys. You can choose to either supply the thumbprint for the certificate that was generated by Tableau Server, or copy the <b>server.crt</b> file to the Resource Monitoring Tool Server machine. If you choose to copy the certificate file, you don't have to supply the thumbprint. For more information, see <a href="#">Configure Postgres SSL to Allow Direct Connections from Clients</a>.</p> |

**Example:** `rmtadmin create-env --name=<myenvironment> --api-user-name=<TableauServer API user name> --api-password=<password for the Tableau Server API user account> --gateway-url <Tableau Server Gateway URL> --version <Tableau Server version>`

`rmtadmin data-access`

**Note:** Added in version 2022.3

Enables or disables access to PostgreSQL database. Note: Access to PostgreSQL database is required starting in version 2022.3 for Resource Monitoring Tool to successfully gather all monitoring data from Tableau Server.

**This command only works on the RMT Server**

**Note:** The PostgreSQL database must be restarted for this configuration to take effect.

## Synopsis

```
rmtadmin data-access [positional parameter][options] [global
option]
```

## Positional Parameter

mode

Required. The mode that should be used for remote data access to PostgreSQL database. The values should be one of: *None*, *ReadOnly*, *Admin*. When set to *None*, the data access is disabled. *ReadOnly*, and *Admin* specify which user account to use to access the database..

## Options

--

### Example:

```
rmtadmin data-access ReadOnly
```

```
rmtadmin restart --db
```

```
rmtadmin delete-env
```

**Note:** Added in version 2021.2

Deletes a specific environment and all data that has been collected for that environment. It also removes the connection and topology information about the Tableau Server that the environment is monitoring and deregisters all the Resource Monitoring Tool Agents.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin delete-env [positional parameter][options] [global option]
```

## Positional Parameter

env

Required. This is the system generated identifier. This is the system generated identifier. You can find this by going to **Admin > Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

## Options

--confirm

Optional. Confirm that you want to delete the environment. If you do not provide this option, you will be prompted to confirm.

--skip-agent-disconnect

Optional. Skips disconnecting the Agent and continues with deregistering the Agent. Use this option if you think the Agent is inaccessible - For example, if the Tableau Server node has been removed or if the Agent has been uninstalled on that node.

**Example:** `rmtadmin delete-env <myenvironmentidentifier>`

rmtadmin delete-env-data

Permanently deletes all Tableau Server related data collected for a specific environment. Environment configuration, Tableau Server information, and Agent registration will not be removed.

This is useful for clearing all the existing data in an environment without removing the environment itself. After deleting the existing data, new data sent by the Agents will continue to be processed.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin delete-env-data [positional parameter] [option] [global
option]
```

## Positional Parameter

env

The identifier of the environment for which the data should be deleted. This is the system generated identifier. You can find this by going to **Admin > Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

## Option

--confirm

Optional. Confirm that you want to delete the environment data. If you do not provide this option, you will be prompted to confirm.

**Example:** `rmtadmin delete-env-data <myenvironmentidentifier>`

```
rmtadmin delete-server
```

**Note:** Added in version 2021.2

Deletes the configuration information of the Tableau Server node from the environment, deregisters the Agent on that node, and deletes all monitoring data collected specific to that node.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin delete-server [options][global option]
```

## Options

`--env`

Required. The identifier of the environment that the Tableau Server node is connected to. This is the system generated identifier. You can find this by going to **Admin > Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

`--hostname`

Required to delete information about one or more connected to the environment and if **--all** is not specified.

This is the machine name of the Tableau Server node. Use commas to separate multiple values if specifying more than one host name.

`--all`

Optional, but required if **--hostname** is not specified.

Deletes the information for all the Tableau Server nodes connected to the environment.

`--skip-agent-disconnect`

Optional. Skips disconnecting the Agent and continues with deregistering the Agent. Use this option if the Agent is inaccessible- For example, if the node has been removed from Tableau Server or if the Agent has been uninstalled on that node.

`--confirm`

Confirm that you want to delete all the information about the Tableau Server node. If you do not provide this option, you will be prompted to confirm.

**Example:** `rmtadmin delete-server --hostname=<machine name of the Tableau Server node>`

`rmtadmin delete-server-data`

**Note:** Added in version 2021.2

Deletes the data collected from one or more Tableau Server nodes. Data removed only pertains to the nodes that are specified. If you specify *all*, then all the data collected from all the nodes will be deleted. Environment configuration, Tableau Server information, and Agent registrations will not be deleted.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin delete-server-data [options][global option]
```

## Options

`--env`

Required. The identifier of the environment that the Tableau Server node is connected to. This is the system generated identifier. You can find this by going to **Admin > Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

`--hostname`

Required to delete information about on or more connected to the environment and if **--all** is not specified.

## Tableau Server on Linux Administrator Guide

This is the machine name of the Tableau Server node. Use commas to separate multiple values if specifying more than one host name.

`--all`

Optional, but required if `--hostname` is not specified.

Deletes the monitoring data for all the Tableau Server nodes connected to the environment.

`--confirm`

Confirm that you want to delete all the monitoring data from the Tableau Server nodes. If you do not provide this option, you will be prompted to confirm.

**Example:** `rmtadmin delete-server-data --all`

`rmtadmin deregister`

**Note:** Added in version 2021.2

Deregisters the Agent from the environment. Monitoring data from this node will no longer be collected. Existing data will remain and not be deleted.

**This command only works when run on the RMT Agent. Run this on the Agent you want to deregister.**

## Synopsis

`rmtadmin deregister [options]`

## Options

`--confirm`

Optional. Confirm that you want to deregister the Agent. This bypasses the confirmation prompt.

`--ignore-master-errors`

Optional. Ignores any errors that occur while communicating with the RTM Server during this process.

**Example:** `rmtadmin deregister --confirm`

`rmtadmin deregister-agent`

**Note:** Added in version 2021.2

Deregisters the specified Agent from the environment. Monitoring data from this node will no longer be collected. Existing data will remain and not be deleted.

**This command only works when run on the RMT Server.**

## Synopsis

```
rmtadmin deregister-agent [options][global option]
```

## Options

`--env`

Required if `--key` is not specified.

This is identifier of the environment where the Agent is currently registered. This is the system generated identifier. This is the system generated identifier. You can find this

by going to **Admin > Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

`--key`

Optional if `--env` is specified.

This is the Agent key. Use commas to separate multiple values. You can get the key values by running the `rmtadmin agents` command.

`--hostname`

Optional. Machine name of the Tableau Server node where the Agent is installed. Use commas to separate multiple values.

`--all`

Optional. Use this option to deregister Agents on all the nodes.

`--ignore-agent-errors`

Optional. Ignores any errors that occur if unable to connect with the Agents during this process.

`--skip-agent-disconnect`

Optional. Skips disconnecting the Agent and continues with deregistering the Agent. Use this option if you think the Agent is inaccessible - For example, if the node has been removed from Tableau Server or if the Agent has been uninstalled on that node.

`--confirm`

Optional. Confirm that you want to deregister the Agents. If you do not provide this option, you will be prompted to confirm.

**Example:** `rmtadmin deregister-agent --env=<myenvironmentidentifier> --all`

`rmtadmin environments`

**Note:** Added in version 2021.2

Lists all the environments on the Resource Monitoring Tool Server.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin environments [global option]
```

```
rmtadmin get
```

Gets the value of a specified configuration key.

**This command can be used both on the RMT Server and Agent.**

## Synopsis

```
rmtadmin get <config.key> [global option]
```

## Positional Parameter

key

Name of the configuration key.

**Example:** `rmtadmin get db:database`

## Supported configuration keys

| Key                                     | Data Type | Applies To           | DEFAULT                             | Description  |
|---|-----------|----------------------|-------------------------------------|--|
| <code>db:database</code>                | String    | RMT Server           | tabrmtdb                            | Name of the PostgreSQL database that RMT uses.   |
| <code>db:readOnlyUsername</code>        | String    | RMT Server           | readonly                            | Username of a PostgreSQL user account which has only read-only access to the RMT data. |
| <code>db:readOnlyPassword</code>        | String    | RMT Server           | Generated by the installer program. | Password of the PostgreSQL read-only user.   |
| <code>mq:tls:certificateHostName</code> | String    | RMT Server and Agent | n/a                                 | Host name in the certificate to use when connecting to RabbitMQ via TLS.               |
| <code>mq:tls:enabled</code>             | Boolean   | RMT Server and Agent | FALSE                               | Enable/disable TLS connection to RabbitMQ.   |
| <code>mq:port</code>                    | Integer   | RMT Server and Agent | 5672                                | RabbitMQ host port number.   |

| Key                         | Data Type | Applies To           | DEFAULT             | Description  |
|-----------------------------|-----------|----------------------|---------------------|--|
| <code>mq:virtualHost</code> | String    | RMT Server and Agent | <code>tabrmt</code> | Connection to the RMT Server or Agent. For Agent, you can modify this setting by registering the Agent with a bootstrap file. For the RMT Server, the value is managed by the installer. |
| <code>server.web.run</code> | Boolean   | Agent                | TRUE                | Enable or disable the Agent's web interface.   |

Use the `set` command to change the current configuration value.

```
rmtadmin help
```

Shows general help about the command line interface and the available commands.

**This command can be used both on the RMT Server and Agent.**

## Synopsis

```
rmtadmin help
```

Show help and usage information for a specific command:

**This command can be used both on the RMT Server and Agent.**

```
rmtadmin help [command]
```

```
rmtadmin master-setup
```

Configures the RMT Server with specified options. Used both during install and post installation configurations.

## Synopsis

```
rmtadmin master-setup [options][global option]
```

The configuration options are listed below:

| Option                | Required?   | Default | Description                              |
|-----------------------|---|---------|--|
| --admin-password      | Yes (Required for initial installation only)<br><br>Password can be supplied in the command line or provide a file with the password to use. If neither is provided, you will be prompted for the password. | n/a     | The password for the administrator user. |
| --admin-password-file | Yes (Required for initial installation only)<br><br>Password can be supplied in the command line or provide a file with the pass-   | n/a     | The password for the administrator user. |

| Option  | Required?  | Default | Description  |
|---|--|---------|--|
|   | word to use. If neither is provided, you will be prompted for the password.  |         |  |
| --admin-user-name   | No   | admin   | The username for the administrator user.           |
| --skip-admin-creation<br><br><b>Added:</b> version 2020.4.0<br><br><b>Retired:</b> version 2022.3.0 | No<br><br>This option must be and only used when you making configuration updates post installation.<br><br>In versions where this option is valid (2020.4.0 - 2022.2.x), if not used during post installation configuration updates, the command will fail and no updates will be made.<br><br>In versions 2022.3.0 and later, the command will create the admin where necessary. | False   | Skip creating the administrator user and password. |

| Option                               | Required? | Default  | Description   |
|--------------------------------------|-----------|--|---|
| --http-port                          | No        | 80   |   |
| --require-https                      | No        | False  | Redirect http traffic to HTTPS.   |
| --https-certificate-mode             | No        | 'Default'<br><br>Available options: <ul style="list-style-type: none"> <li>• Default</li> <li>• Store (Windows only)</li> <li>• Local</li> </ul> | <p>The type of certificate search to perform for the HTTPS certificate.</p> <p><b>Default:</b> This mode uses the default self-signed certificate supplied by the installer.</p> <p><b>Store:</b> This allows you to enter the thumbprint of a certificate in the Windows certificate store.</p> <p><b>Local:</b> Allows you to specify a file-based certificate in the <b>config</b> folder.</p> |
| --https-certificate-store-thumbprint | No        | Null   | The HTTPS certificate hash/thumbprint to search for in 'store' certificate mode.  |
| --https-certificate-local-name       | No        | Null<br><br>Note: If not specified, the Resource Mon-  | The name of the HTTPS certificate file.   |

| Option                                  | Required? | Default   | Description  |
|---|-----------|---|--|
|   |           | Monitoring Tool is installed with a self-signed certificate and will use that certificate for HTTPS communications. |  |
| --https-certificate-local-password      | No        | Null  | The password to use for the HTTPS certificate.   |
| --https-certificate-local-password-file | No        | Null  | The path to the file containing the password to use for the HTTPS certificate.   |
| --confirm                               | No        | Prompt for confirmation.  | Confirms the restart of the RMT Server.  |
| --host                                  | No        | Current configuration value or machine name.  | The preferred URL for accessing the Resource Monitoring Tool server. The server will listen to all the IPs regardless of the host name.                      |
|   |           | <b>Note:</b> We don't recommend changing this value.  |  |
| --db-config=external                    | No        | None.<br>This is only used when the repository is configured external to RMT Server.                                | Use this to configure RMT Server to use an external repository. You do not need to specify this if you want the PostgreSQL database to be installed locally. |

| Option  | Required? | Default   | Description   |
|---|-----------|---|---|
| --db-server   | No        | Current configuration value or installer default. | <p>This is the server name for the PostgreSQL database that is installed with the Resource Monitoring Tool.</p> <p>If you are using an external repository hosted on AWS RDS, this should be the RDS instance name.</p>   |
| --db-ssl-mode<br><br>Version: Added in version 2023.1.0 | No        | Prefer  | <p>This determines the SSL/TLS encryption for the connection to the PostgreSQL database that is installed with the Resource Monitoring Tool.</p> <p>Options are <code>Prefer</code> (the default), <code>VerifyCA</code>, and <code>VerifyFull</code>. For details, see the <a href="#">Npgsql documentation</a>.</p> |
| --db-port   | No        | Current configuration value or installer default. | Port number for the database server.  |
| --db-username   | No        | Current configuration value or                    | Username used to connect to PostgreSQL data-  |

| Option               | Required? | Default  | Description  |
|----------------------|-----------|--|--|
|                      |           | installer default.   | <p>base installed with the Resource Monitoring Tool.</p> <p>If you are using an external repository hosted on AWS RDS, this should be "postgres".</p>  |
| --db-password        | No        | Current configuration value or installer default.  | <p>Password for the user account used to connect to the PostgreSQL database that is installed with the Resource Monitoring Tool.</p> <p>If you are using an external repository hosted on AWS RDS, this is the user password you created when creating the RDS instance.</p> |
| --mq-config=external | No        | None<br>This option is only specified when the messaging service is hosted external to RMT Server. | This option configures RMT Server to use an external Rabbit MQ messaging service.  |
| --mq-server          | No        | Current configuration value or installer default.  | The name of the message queue server.  |

| Option                    | Required? | Default   | Description  |
|---------------------------|-----------|---|--|
| --mq-port                 | No        | Current configuration value or installer default. | The message queue port.  |
| --mq-vhost                | No        | Current configuration value or installer default. | The message queue virtual host.  |
| --mq-username             | No        | Current configuration value or installer default. | The user name used to connect to the message queue.  |
| --mq-password             | No        | Current configuration value or installer default. | The password for the user account used connect to the message queue.   |
| --mq-enable-tls           | No        | Current configuration value or <b>false</b> .     | Requires TLS connection to connect to the message queue.   |
| --mq-tls-certificate-host | No        | Current configuration value or <b>null</b> .      | The canonical name of the message queue server. This must match the name on the certificate.                                       |
| --password-salt           | No        | Random  | A global salt to use to hash the password.<br><br>This applies to the local user accounts created in the Resource Monitoring Tool. |
| --password-min-           | No        | Current con-                                      | The minimum length for   |

| Option                 | Required? | Default                                    | Description   |
|------------------------|-----------|--|---|
| length                 |           | figuration value or <b>10</b> .            | <p>the password.</p> <p>This applies to the local user accounts created in the Resource Monitoring Tool.</p>  |
| --password-min-numeric | No        | Current con-figuration value or <b>1</b> . | <p>The minimum required numeric characters in the password.</p> <p>This applies to the local user accounts created in the Resource Monitoring Tool.</p> |
| --password-min-special | No        | Current con-figuration value or <b>1</b> . | <p>The minimum required special characters in the password.</p> <p>This applies to the local user accounts created in the Resource Monitoring Tool.</p> |
| --password-min-latin   | No        | Current con-figuration value or <b>5</b> . | <p>The minimum required latin characters in the password.</p> <p>This applies to the local user accounts created in the Resource Monitoring Tool.</p>   |

| Option                                     | Required? | Default                                      | Description  |
|--|-----------|--|--|
| <code>--password-require-mixed-case</code> | No        | Current configuration value or <b>true</b> . | Requires mixed case characters in passwords.<br><br>This applies to the local user accounts created in the Resource Monitoring Tool. |
| <code>--auth-timeout-minutes</code>        | No        | Current configuration value or <b>240</b> .  | The number of minutes before the user authentication expires for the session.  |
| <code>--auth-sliding-expiration</code>     | No        | Current configuration or <b>true</b> .       | Whether or not to reset the authentication timeout period with user activity.  |

**Examples:**

**To specify the admin password:** `rmtadmin master-setup --admin-password=<password> --skip-admin-creation`

**To update the port post install:** `rmtadmin master-setup --http-port=8000 --skip-admin-creation`

`rmtadmin passwd`

Resets the password for a specific Resource Monitoring Tool user account.

**This command works only on the RMT Server.**

## Synopsis

```
rmtadmin passwd [positional parameter][global option]
```

## Positional Parameter

```
username
```

Name of the user that you want to change the password for.

**Example:** `rmtadmin passwd <username>`

```
rmtadmin query
```

Executes a raw SQL query against the Resource Monitoring Tool database and saves the results to an output file.

**This command works only on the RMT Server.**

## Synopsis

```
rmtadmin query [positional parameter][options] [global option]
```

## Positional Parameter

```
sql
```

SQL command text to run. You can provide multiple SQL commands. To use a file with the SQL commands, use **@** as a prefix to the name of the file.

## Options

```
--outfile=VALUE
```

Name of the zip file you want to output the query results. Default is *queryresults.zip*

`--force`

Overwrites the existing file.

`--timeout=VALUE`

timeout for the query. Specify this in seconds

`--commit`

Commits any changes made by the SQL command to the database. By default, the SQL command is run as a transaction, but is rolled back at completion.

**Example:** `rmtadmin query <SQLCommand> --outfile=<path and the output file name>`

`rmtadmin register`

**Note:** Added in version 2020.2

Registers the Agent using a bootstrap file. The bootstrap file can be downloaded using the `rmtadmin bootstrap-file` command.

**This command is can only be used on the Agent and should be run on the machine where you want to install the Agent.**

## Synopsis

```
rmtadmin register [options][positional parameter] [global option]
```

## Positional Parameter

`bootstrap`

The file path including the name of the bootstrap file.

## Options

`--username`

Required. Name of the admin user created during the RMT Server installation.

`--password`

Required. Password for the user account.

`--password-file`

Path including the file name that contains the password information. Password can be supplied in the command line or a file that contains the password. If neither is provided, you will be prompted for the password.

`--server-name`

Name of the node where Agent is being installed. It defaults to the machine name if no name is specified.

`--server-description`

Custom description for the Server.

**Example:** `rmtadmin register <bootstrap file name and path> --server-name=<server name>`

`rmtadmin restart`

Restarts the Resource Monitoring Tool applications. When run from the machine where RMT Server is installed, it restarts the RMT Server application. When run on a node where the Agent is installed, it restarts just the Agent application on that particular node.

**This command can be run from both the RMT Server and Agent.**

## Synopsis

```
rmtadmin restart [options] [global option]
```

## Options

At least one option must be specified:

### **RMT Server:**

```
--all
```

Restarts all services.

```
--master
```

Restarts the RMT Server.

```
--mq
```

Restarts the message queue service.

```
--db
```

Restarts the database service.

### **Agent:**

```
--agent
```

Restarts the Agent service running on the machine.

**Example:** `rmtadmin restart --db`

`rmtadmin rotate-mq-certificate`

Rotates the Agent message queue client certificate on the agent machine. Run this command after running `rmtadmin rotate-mq-certificate` on the Server machine.

**This command must be run from the RMT Agent.**

## Synopsis

```
rmtadmin rotate-mq-certificate [options] [positional parameter]
```

## Positional Parameter

`bootstrap`

The file path including the name of the bootstrap file.

## Options

`--username`

Required. The username for the master server.

`--password`

Required. Password for the master server user account.

`--password-file`

Path including the file name that contains the master server password information. Password can be supplied in the command line or a file that contains the password. If neither is provided, you will be prompted for the password.

```
--confirm-restart
```

Confirms service restart and bypasses confirmation prompt.

```
rmtadmin rotate-mq-certificates
```

Rotates message queue server and client certificates on the Server machine.

**This command must be run from the RMT Server.**

## Synopsis

```
rmtadmin rotate-mq-certificates [options]
```

## Options

```
--confirm-restart
```

Confirms service restart and bypasses confirmation prompt.

```
rmtadmin servers
```

**Note:** Added in version 2021.2

Lists all the Tableau Server nodes across all environments or a specific environment.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin servers [positional parameter][global option]
```

## Positional Parameter

`env`

Optional. Specify the identifier of the environment to get a list of Tableau Server nodes registered in that environment. This is the system generated identifier. You can find this by going to **Admin > Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

`rmtadmin service-setup`

**Note:** Added in version 2021.4. Used to install, or update the user credential for Resource Monitoring Tool services including RMT Server, Agent, Rabbit MQ, and PostgreSQL database. This is useful to update service information post-install.

**This command works on both RMT Server and Agent.**

## Synopsis

```
rmtadmin service-setup [positional parameter] [options] [global
option]
```

## Positional Parameter

At least one of the following values must be specified:

`all`

Updates all available services. Can be run on both RMT and Agent. When run on a Tableau Server node, updates the Agent on that node.

`master`

Updates the RMT Server.

agent

Updates the Agent. Can only be run on the Agent (Tableau Server node).

db

Updates the database service. Can only be run on RMT Server.

mq

Updates the message queue service. Can only be run on RMT Server.

## Options

`--confirm`

Optional. Confirm that you want to make updates. Can be run on both RMT and Agent. When run on a Tableau Server node, updates the Agent on that node.

`--append-permissions`

Optional. Appends new permissions. Use this if you do not want to overwrite the existing permissions.

`rmtadmin set`

Sets the value of a specified configuration key.

**This command works both on the RMT Server and Agent.**

## Synopsis

```
rmtadmin set [positional parameter] [global option]
```

## Positional Parameters

key

The configuration key you want to change the value for.

value

The new value you want to use.

**Example:** `rmtadmin set mq:port <port number>` where `mq:port` is the key and the `<port number>` is the value.

## Supported configuration keys

| Key                                     | Data Type | Applies To           | DEFAULT | Description   |
|---|-----------|----------------------|---------|---|
| <code>mq:tls:certificateHostName</code> | String    | RMT Server and Agent | n/a     | Host name in the certificate to use when connecting to RabbitMQ via TLS |
| <code>mq:tls:enabled</code>             | Boolean   | RMT Server and Agent | FALSE   | Enable/disable TLS connection to RabbitMQ                               |
| <code>mq:port</code>                    | Integer   | RMT Server and Agent | 5672    | RabbitMQ host port number.  |
| <code>server.web.run</code>             | Boolean   | Agent                | TRUE    | Enable or disable the Agent's   |

| Key | Data Type | Applies To | DEFAULT | Description    |
|-----|-----------|------------|---------|----------------|
|     |           |            |         | web interface. |

## Options

`--backup`

Creates a backup of the configuration file before making changes.

Use the `get` command to view the current configuration value.

`rmtadmin start`

Starts the Resource Monitoring Tool services. When this is run on the RMT Server, it will start the RMT Server only. When run on an Agent, it will start the Agent on the machine you are running the command from.

**This command works both on the RMT Server and Agent**

## Synopsis

```
rmtadmin start [options] [global option]
```

## Options

At least one option must be specified:

**RMT Server:**

`--all`

Starts all services.

```
--master
```

Starts the RMT Server.

```
--mq
```

Starts the message queue service.

```
--db
```

Starts the database service.

**Agent:**

```
--agent
```

Starts the Agent service running on the machine.

**Example:** `rmtadmin start --all`

```
rmtadmin status
```

Checks the status of the application and running services on the machine you are running this command on. For RMT Server, the status report confirms that the RMT Server is connected to the database and message queue. For Agents, the status report confirms that the agent is connected to the RMT Server.

**This command can be run both on the RMT Server and the Agent.**

This command returns the following:

- Application status (running or not)
- License status
- MQ connection
- Queue details

## Tableau Server on Linux Administrator Guide

- Memory used
- Disk space used
- Tableau server version on machine
- Process topology of Tableau Server that is stored in Agent config file.

Beginning with version 2024.2.0, when run on the RMT Server, the command returns:

- Disk space usage warning if messaging tables in the local database are using more space than the warning threshold (4 GB). For more information, see [Troubleshoot Messaging Tables Disk Usage Warnings](#)

## Synopsis

```
rmtadmin status [global option]
```

```
rmtadmin stop
```

Stops the Resource Monitoring Tool services. When this command is run on the RMT Server, it will only stop the RMT Server. When run on a machine where Agent is installed, it will only stop the Agent on that machine.

**This command can be run both on the RMT Server and the Agent.**

## Synopsis

```
rmtadmin stop [options] [global option]
```

## Options

At least one option must be specified:

### **RMT Server:**

```
--all
```

Stops all services.

```
--master
```

Stops the RMT Server.

```
--mq
```

Stops the message queue service.

```
--db
```

Stops the database service.

**Agent:**

```
--agent
```

Stops the Agent service running on the machine.

**Example:** `rmtadmin stop --db`

```
rmtadmin test-env
```

**Note:** Added in version 2021.2

Tests the various connection points between Resource Monitoring Tool and Tableau Server. This includes testing Tableau Server Repository connection, Tableau Server API connections, and Advanced Management (formerly Server Management Add-on) licensing.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin test-env [positional parameter][global option]
```

## Positional Parameter

`--env`

Optional. The identifier of the environment that the Resource Monitoring Tool is monitoring. This is the system generated identifier. You can find this by going to **Admin > Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

`--force`

Optional. Use this option to update the baseline immediately even if enough data is not available. By default the command will wait for 50 successful loads to calculate the baseline.

`rmtadmin update-baseline`

**Note:** Added in version 2021.4

Updates the baseline for all view loads. Baseline is the 95th percentile of 50 successful initial load times for a view.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin update-baseline [options][global option]
```

## Options

`env`

Required. This is the system generated identifier. You can find this by going to **Admin > Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

```
rmtadmin update-env
```

**Note:** Added in version 2021.2

Updates the environment settings.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin update-env [options][global option]
```

## Options

| Option                         | Required? | Description  |
|--------------------------------|-----------|--|
| <code>--non-interactive</code> | No        | Disables all interactive prompts.  |
| <code>--no-test</code>         | No        | Disables testing API and repository connections.   |
| <code>--name</code>            | Yes       | The name of the environment.   |
| <code>--id</code>              | No        | Identifier of the environment used in web interface URLs.<br><br>This is the system generated identifier. You can find this by going to <b>Admin &gt; Environments &gt; Edit Environment</b> . On this page, in the <b>Environment Details</b> section, you will see the identifier for the environment. |

| Option                | Required? | Description  |
|-----------------------|-----------|--|
| --gateway-url         | No        | URL used to access the Tableau Server gateway.   |
| --version             | No        | Tableau Server version that this environment will be monitoring.   |
| --api-username        | No        | User name of the account used to connect to Tableau Server APIs. The user account should be a Tableau Server administrator with access to all Tableau Server sites.  |
| --api-password        | No        | Password of the Tableau Server API user account used to connect to Tableau Server APIs.  |
| --api-password-file   | No        | The path to the file containing the password of the Tableau Server API user account.   |
| --repository-server   | No        | This is the server name for the PostgreSQL database that is installed with the Resource Monitoring Tool.   |
| --repository-port     | No        | The port number of the Tableau Server Repository database.   |
| --repository-username | No        | <p>Username used to connect to PostgreSQL database installed with the Tableau Server Repository.</p> <p>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the</p> |

| Option                | Required? | Description   |
|-----------------------|-----------|---|
|                       |           | <p>repository must be enabled, with a password set for the <b>readonly</b> database user. For details, see Enable access to the Tableau Server repository.</p>  |
| --repository-password | No        | <p>Password for the user account used to connect to the PostgreSQL database that is installed with the Tableau Server .</p> <p>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the <b>readonly</b> database user. For details, see Enable access to the Tableau Server repository.</p> |
| --repository-password | No        | <p>The path including the file name where the password for the user account used to connect to the PostgreSQL database that is installed with Tableau Server.</p>   |
| --repository-ssl-mode | No        | <p>Tableau Server Repository SSL Mode:</p> <p><b>Prefer</b> SSL or <b>Require</b> SSL to configure SSL connections to Tableau Repository.</p>   |

| Option                      | Required? | Description   |
|-----------------------------|-----------|---|
|                             |           | <b>Disable</b> to never use SSL to make Tableau Server Repository connections.  |
| --repository-ssl-thumbprint | No        | When configuring Tableau Server PostgreSQL to allow direct connections, Tableau Server creates a certificate and keys. You can choose to either supply the thumbprint for the certificate that was generated by Tableau Server, or copy the <b>server.crt</b> file to the Resource Monitoring Tool Server machine. If you choose to copy the certificate file, you don't have to supply the thumbprint. For more information, see <a href="#">Configure Postgres SSL to Allow Direct Connections from Clients</a> . |

**Example:** `rmtadmin update-env --name=<new name>`

`rmtadmin users`

Shows a list of the Resource Monitoring Tool user accounts.

**This command works only on the RMT Server.**

## Synopsis

`rmtadmin users`

```
rmtadmin version
```

Shows the current version information for the RMT Server when run on the RMT Server machine. It shows the current version information of the Agent installed on the machine that you are running the command from.

**This command can be run both on the RMT Server and the Agent.**

## Synopsis

```
rmtadmin version
```

```
rmtadmin ziplogs
```

Creates a ZIP archive file containing the Resource Monitoring Tool log files.

**This command works both on the RMT Server and Agent but only includes the log files from the application the command is run on.**

## Synopsis

```
rmtadmin ziplogs [positional parameter] [option] [global option]
```

## Positional Parameter

```
filename
```

Name of the output zip file. Defaults to log.zip if no name is provided.

## Option

```
--force
```

Overwrites the existing file.

## Tableau Server on Linux Administrator Guide

**Example:** `rmtadmin ziplogs <zip file name> --force`

### Global Option

`--help`

Shows the help for the command.

## Tableau Resource Monitoring Tool Communication Ports

This article lists the communication ports the Tableau Resource Monitoring Tool uses, the default port configuration, and how to change these ports when your network requirements needs them to be different than what is set by default.

### RMT Server

You can change or update the port information using:

- `rmtadmin master-setup` command
- Web interface: From the machine where RMT Server is installed, go to: `http://localhost/setup/server`

## RMT Server Communications

Ports used: 9001, 443, and 80

- Setup initially defaults to port 9001, but changes the default to 80 after initial configuration.
- The SSL self signed certificate on initial installation is for port 443. RMT Server listens on port 80 by default and will attempt to forward traffic to 443 for SSL. Any user specified certificate will also be for port 443.
  - The certificates are used during user traffic to the RMT Server and when the Agent is registered using the Web interface.

- We generally do not recommend changing port 443. If however, you need to change this due to your environment restrictions, you will need to explicitly list the port number when connecting to RMT Server. If you are registering the Agent using the web interface, you must explicitly specify the port number to connect to the RMT Server.
- Port 80 is used for non SSL traffic and can be changed either during initial setup or post installation.
- The RMT Server will reach out directly to the Tableau Server gateway for REST API calls.
- The RMT Server will reach out directly to the Tableau Server repository to query information if PostgreSQL info is supplied (optional). For information about configuring SSL between RMT server and the Tableau Server repository, see Pre-Installation Checklist - Tableau Resource Monitoring Tool.

## RabbitMQ

RabbitMQ is the component (message queue) used to broker information between Agents and the RMT Server.

Ports used: 5671, 5672

- RabbitMQ is installed and listens to port 5671 (TSL), 5672 (non-TSL).
- TLS communication for RabbitMQ is enabled by default.

## PostgreSQL Database

Ports used: 5555

## Tableau Server on Linux Administrator Guide

- PostgreSQL database is installed and listens to port 5555. This cannot be changed.
- PostgreSQL has an `admin` user that is used by the Resource Monitoring Tool. The `readonly` user is used to connect to the Resource Monitoring Tool PostgreSQL database in `.tds` files downloaded from the Resource Monitoring Tool web interface. For more information about downloading the `.tds` files, see [Explore Monitoring Data Using Tableau Data Source Files](#).
- PostgreSQL requires SCRAM-SHA-256 authentication. For more information, see [Explore Monitoring Data Using Tableau Data Source Files](#).

### Agent

Ports used: 9002, 443, 5672

- During installation, the Agent installer opens a web browser that is only used for registration that listens on port 9002.
- If Agent registration is done using the web interface, the registration process uses port 443. If the registration is done using the command line, the registration process goes through RabbitMQ and uses port 5672.

### Manage Users

When you install Resource Monitoring Tool, you create an admin user during configuration. That user has permissions to perform all tasks on the RMT Server. You can later add other users and specify which tasks they are able to perform related to RMT.

#### Add a local user

To add users to RMT, click the **Admin** menu and select **Users** (this option may not be available if you have not configured an environment).

To add a new user in Resource Monitoring Tool:

1. From the **Admin** menu, select **Users**.
2. Click **New User**.

3. Provide a user name, password, and apply the server roles.
4. Click **Save**.

#### Add a delegated user

Beginning in version 2023.1 users can be authenticated using their domain account credentials rather than using a separate password stored locally in RMT. When a user configured for delegated authentication signs into RMT, RMT passes the user and the password they entered to the computer operating system (OS) for verification.

To add a new, delegated user in Resource Monitoring Tool:

1. From the **Admin** menu, select **Users**.
2. Click **New User**. The default is a local user.
3. Select **Operating System (Delegated)**.
4. Provide a **Username**.

Be sure to type *just* the user name. Do not include any domain.

When signing into RMT, the user will provide their standard network password and the OS will verify this.

5. Select the server roles the user should have. For more details about server roles, see below.
6. Click **Save**.

#### Change user authentication

With version 2023.1.0 or later you can change an existing user from one auth type to another.

To change an existing user's authentication:

1. Click the Edit icon.
2. Select the **Authentication Mode** you want:
  - If you are changing to **Operating System (Delegated)** mode, you only need to enter the username (without domain). The user will provide their own password at sign in. And existing password stored in RMT is deleted and cannot be restored.

## Tableau Server on Linux Administrator Guide

- If you are changing to **RMT (Local)** mode, you need to enter a username and password. These are stored locally by RMT.
3. Confirm the **Server Roles** selected for the user.
  4. Click **Save** to save your changes.

### Server Roles in Tableau Resource Monitoring Tool

The Tableau Resource Monitoring Tool has various server roles that you can assign to a user to give them permissions to perform certain tasks.

The following table lists the available roles and what each roles allows the user to do:

| <b>Server Roles</b>           | <b>Role Description</b>                       |
|-------------------------------|---|
| Download Log Bundles          | Download log files.                           |
| Download TDS Files            | Download <b>.tds</b> files.                   |
| Generate Chargeback Reports   | Create chargeback reports.                    |
| Server/Environment Management | Has permissions to update all configurations. |
| User Management               | Create and edit users.                        |
| Webhook Management            | Manage Slack notification settings.           |

## Troubleshoot authentication issues

For details on how to troubleshoot user sign in and authentication issues, see [Troubleshoot User Authentication](#).

### Tableau Resource Monitoring Tool - Incidents

Incidents are reported for events that are unusual and may require human attention. Incidents can be configured for a variety of events either at a global level or can be customized for each environment.

To see current incidents reported for an environment, after selecting an environment, from the **Incidents** menu, select **All Incidents** to see a list of all incidents logged and reported.

You may also receive a notification through email or Slack depending on your settings for notifications. To learn more about how notifications work, see Notifications.

You can generally categorize incidents into two types:

1. Incidents that are set by default and cannot be changed. We will refer to these as “**system-defined incidents**”.
2. Incidents that can be configured by you. We will refer to these as “**configurable incidents**”.

All incidents have an incident severity level. The severity level is something that is specifically defined. For system-defined incidents, Resource Monitoring Tool sets the severity levels, and for configurable incidents, you set the severity level depending on what is right for your environment.

Here is the list of severity levels:

| Severity Level | Key         | Description   |
|----------------|-------------|---|
| Info           | information | When you wish to be informed of an incident that does not cause service disruption. |
| Warning        | warning     | Incidents causing possible service disruptions.                                     |
| Critical       | critical    | Incidents causing major service disruption or the service is down entirely.         |

#### System-defined incidents

The following is a list of system incidents that are set by default and cannot be changed.

| Incident   | Incident Level | Description   |
|------------|----------------|---|
| Agent Down | warning        | An incident is logged and reported when either one or more Agents are down, and the RMT Server is unable to |

| Incident         | Incident Level | Description   |
|------------------|----------------|---|
|                  |                | communicate with the Agent.   |
| Agent Unlicensed | critical       | This can happen if Tableau Server is not properly licensed to use Tableau Resource Monitoring Tool, or due to connection issues. For more information on the possible causes, see Agent Incidents |
| Environment Down | critical       | An incident is logged and reported when Tableau Server is offline.  |

### Configurable incidents

These incidents can be configured based on your environment characteristics and organizational priorities. Following are the events that you can configure severity levels and, or thresholds. The links provide more details on what you can configure for each of the events.

- Extract Failure Incidents
- Hardware Incidents: Includes CPU and memory usage, memory availability, disk space, and disk queue length.
- Hyper Spooling Incidents
- Slow Query Incidents
- Slow Views Incidents

To configure incidents at the global level:

1. From the **Admin** menu, select Global Configuration.
2. In the **Incidents** tab, configure the threshold and severity levels for the incidents.

Global configurations are applied to existing environments or any new environments created unless the environment is using custom thresholds.

### Environment Down Incidents

*Environment Down* incidents will be logged as critical when we detect that your Tableau Server is offline. Following are couple of use cases where Tableau Server is considered offline

by Tableau Resource Monitoring Tool:

- Resource Monitoring Tool is unable to get a response from Tableau Server. Resource Monitoring Tool will retry three times before the incident is logged.
- If Resource Monitoring Tool detects that a process is down across all the nodes, an environment down incident will be logged.

Resource Monitoring Tool polls Tableau Server's `http://{Tableau-ServerUrl}/admin/systeminfo.xml` page every 30 seconds (by default) to check the status. If the 30 second polling interval is not sufficient, increase the interval to 60 seconds. If the status is offline, or does not reply within the set value for three consecutive polling intervals then a critical incident is created.

**Note:** The polling interval cannot be set using the `rmtadmin set` command. This setting can only be changed by editing the `config.json` file."

An example `config.json` snippet is below:

```
{
  "background": {
    "run":true,
    "loglevel":"Information",
    "pollRates": {
      "processStatus": 30000
    }
  }
}
```

| Key                        | Data Type | Required? | Description  |
|----------------------------|-----------|-----------|--|
| <code>processStatus</code> | Number    | Optional  | The amount of time in milliseconds to pause between Tableau Server |

| Key | Data Type | Required? | Description     |
|-----|-----------|-----------|-----------------|
|     |           |           | status polling. |

## Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-Environment Management** role.

Agent Incidents

Agents Unlicensed (critical)

Incompatible Agent Version (critical)

**Agent Message Queue Credential Rotation Failure** (critical)

Agent Down (warning)

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files, and other instances. For more information, see [About Tableau Help](#).

## Agents Unlicensed

**Agents Unlicensed** incidents will be logged as critical when we detect that your Tableau Server has not been properly licensed to use Tableau Resource Monitoring Tool.

To monitor a Tableau Server using the Resource Monitoring Tool your Tableau Server must be licensed with the Tableau Advanced Management.

Agents will no longer collect data in the unlicensed state and send to the RMT Server. You can however, continue to see the data that was previously collected when the environment was properly licensed.

To resolve this issue, license Tableau Server with a valid Advanced Management product key. For more information, see [About Tableau Advanced Management on Tableau Server](#).

**Note:** It may take up to an hour after adding a valid license to Tableau Server, for the incident to be cleared.

There are other possible causes that can cause an **Agents Unlicensed** incident:

- Tableau Server API credentials may not be correct. In the environment configuration page, verify that the username and password are correct and that the account used has the Server Administrator role on Tableau Server.
- Unable to connect to Tableau Server REST API. Make sure that REST API is enabled on Tableau Server and that Tableau Server is running.

To resolve the REST API connectivity issue, from the **Admin** menu, select **Environments**, click **Edit Environment** on the environment you want to modify, and in the **Environment Details** tab, click the **Test Connection** button in the **Tableau Server REST API** section on the right side of the page.

- The RMT Server was unable to connect to Tableau Server, likely due to a network connectivity or similar issue.

## Incompatible Agent Version

Agent incompatible incidents will be logged as critical when one or more Agents in the environment are on a version that is not compatible with the RMT Server version.

To resolve the issue, you need to make sure that the Agent is on a version that is compatible with the current RMT Server version.

Use one of the following to resolve this issue:

We recommend that the RMT Server and all Agents be on the same version.

- If the Agent is on a version that is earlier than the minimum compatible version, then you must upgrade the Agent to at least the minimum compatible version that is listed in the incident report.
- If the Agent is on a version that is later than the RMT Server version, we recommend that you upgrade the RMT Server to that same later version as well. You may need to upgrade other Agents depending on the version that they are currently on.

## Upgrading Agents:

Use the following steps to upgrade the Agent:

1. Copy the Agent package to the machines where you have Agents installed. Agents are installed on Tableau Server nodes that you are monitoring. The Agent should be on the same version as the RMT Server or use a version that is compatible with the RMT Server version. The incident details provides the minimum compatible version.
2. Stop the Resource Monitoring Tool Agent service on all Tableau Server nodes using the following command:

```
rmtadmin stop --agent
```

3. Upgrade all the Agents by running the following command:

### **For RHEL like distributions including CentOS:**

```
sudo yum install <pathtoagentinstaller>/<tabrmt-agent-setup-  
<version>-x86_64.rpm>
```

```
sudo /opt/tableau/tabrmt/agent/install-scripts/upgrade-rmt-  
agent --accepteula
```

### **For Ubuntu and Debian distributions:**

**If you are upgrading from version 2020.4 to 2020.4.1 or later:**

```
touch /tmp/tabrmt-agent-upgrading.txt && sudo apt install <tab-
rmt-agent-setup-<version>-amd_64.deb>
```

```
sudo /opt/tableau/tabrmt/agent/install-scripts/upgrade-rmt-
agent --accepteula
```

**Note:** The touch command is only required when upgrading from 2020.4. If you do not run the touch command before installing the package, your existing version of the Resource Monitoring Tool will be uninstalled before upgrading.

**If you are upgrading from version 2020.4.1 to 2020.4.2 or later:**

```
sudo apt install <pathtoagentinstaller>/<tabrmt-agent-setup-
<version>-amd_64.deb>
```

```
sudo /opt/tableau/tabrmt/agent/install-scripts/upgrade-rmt-
agent --accepteula
```

4. Confirm that the Agent is running and has been upgraded. You can view Agent registration status by navigating to **Admin -> Environments -> Edit the Environment -> servers** tab to see a full list of Tableau Server nodes and the status of the Agent.

## Upgrading RMT Server

Upgrade the RMT Server if one or more Agents are on a later version.

Use the following steps to upgrade RMT Server:

1. Copy the new version of the RMT Server package to the machine where RMT Server is installed.
2. Stop the Resource Monitoring Tool on the RMT server using the following command:

```
rmtadmin stop --master
```

3. Stop the Resource Monitoring Tool Agents on all Tableau Server Nodes using the following command:

## Tableau Server on Linux Administrator Guide

```
rmtadmin stop --agent
```

4. Once the services have been stopped, it is best practice to check for any Resource Monitoring Tool processes that are running after the services have been stopped: Any with `tabrmt-agent` or `tabrmt-master`. This does not include PostgreSQL or RabbitMQ. You can check the status using the following command:

```
rmtadmin status
```

5. Run the upgrade commands on the RMT Server. This will upgrade the existing version to the new version:

### **For RHEL like distributions including CentOS:**

```
sudo yum install <pathtomasterserverinstaller>/<tabrmt-master-setup-<version>-x86_64.rpm>
```

```
sudo /opt/tableau/tabrmt/master/install-scripts/upgrade-rmt-master --accepteula
```

### **For Ubuntu and Debian distributions:**

#### **If you are upgrading from version 2020.4 to 2020.4.1 or later:**

```
touch /tmp/tabrmt-master-upgrading.txt && sudo apt install <tabrmt-master-setup-<version>-amd_64.deb>
```

```
sudo /opt/tableau/tabrmt/master/install-scripts/upgrade-rmt-master --accepteula
```

**Note:** The touch command is only required when upgrading from 2020.4. If you do not run the touch command before installing the package, your existing version of the Resource Monitoring Tool will be uninstalled before upgrading.

#### **If you are upgrading from version 2020.4.1 to 2020.4.2 or later:**

```
sudo apt install <pathtomasterserverinstaller>/<tabrmt-master-  
setup-<version>-amd_64.deb>  
  
sudo /opt/tableau/tabrmt/master/install-scripts/upgrade-rmt-mas-  
ter --accepteula
```

6. Confirm that the Agent and RMT Server are running. Start the Agent and RMT Server if they do not automatically restart after the upgrade is complete.

## Agent Message Queue Credential Rotation Failure

Starting in version 2021.3, as a security best practice, the credentials for connections between Agent and Rabbit MQ must be unique to that Agent. The unique credentials are created during a new installation or updated when upgrading to 2021.3.

During upgrade, if there are network issues, the credential update process can fail, resulting in a critical incident report. This, however, does not interrupt the upgrade process and the upgrade process will continue. After upgrade is complete, the Resource Monitoring tool will retry daily to create the unique credentials. A critical incident report is created for the initial failure and every subsequently failed retry. During this time, Agent will continue to work using the previous credentials until new credentials have been created.

The issue might resolve by itself, but if it persists, do the following:

- Verify that the Agents can connect to RMT Server.
- Check for firewall issues between Agent and RMT Server.

## Agent Down

Agent Down incidents will be logged as warning when the Tableau Resource Monitoring Tool is unable to communicate with the Agents on Tableau Server.

Use the following steps to troubleshoot this issue:

## Tableau Server on Linux Administrator Guide

1. Make sure that the hardware that hosts the Agents is running and available to communicate with the RMT Server.
2. Make sure that the Agent service is successfully registered, and is running. You can view Agent registration status by navigating to **Admin -> Environments -> Edit the Environment -> servers** tab to see a full list of Tableau Server nodes and the status of the Agent.

## Agent polling and incident creation times

- Agent sends a *heartbeat message* to the Resource Monitoring Tool server every 5 minutes.
- The Resource Monitoring Tool server checks to see if the most recent *heartbeat message* from Agent is less than 15 minutes old.
  - If the latest *heartbeat message* received from the Agent is less than 15 minutes old, then the Agent is considered to be online and no incident is created, and any existing **Agent Down** incidents are cleared.
  - If the latest *heartbeat message* received from Agent is more than 15 minutes old, then it is considered to be the first failed attempt. Every minute thereafter, a check is done, two more times. If after three attempts (first attempt and two retries) there is still no recent heartbeat message, then an **Agent Down** incident is created.

**Note:** Based on the polling interval described above, it takes about 17 (15+1+1) minutes for an **Agent down** incident to be created after the Agent is offline.

## Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-Environment Management** role.

Extract Failure Incidents

*Extract Failure* incidents will be logged as a warning when there is an extract failure in Tableau.

## Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-Environment Management** role.

Hardware Incidents

**Hardware** incidents monitor the server itself. These can be used to help identify server issues that may affect Tableau Server's performance.

You can set thresholds for the following issues:

- CPU Usage
- Available Memory
- Memory Usage
- Free Disk Space

The following incidents are configured by default when you install a new Tableau Resource Monitoring Tool:

- When the available disk space falls below 10 GB for 10 minutes or more a warning incident is logged, and when available disk falls below 5 GB for 10 minutes or more, a critical incident is logged.
- When available memory falls below 8 GB for over 10 minutes, a warning incident is logged.
- When the CPU usage for the entire server is 80% or more for 5 minutes, a warning incident is logged.

**Note:** Memory related incidents are configured in binary multiples of bytes.

You can configure thresholds using the RMT Server web interface or by updating the configuration file `config.json`.

## Use the RMT Server web interface

## Tableau Server on Linux Administrator Guide

To set the thresholds for hardware incidents, under the **Admin** menu, select **Configuration**, and go to the **Incidents** tab.

For **CPU Usage**, set the following:

To set the thresholds for hardware incidents, under the **Admin** menu, select **Configuration**, and go to the **Incidents** tab.

| Key                    | Required? | Description  |
|------------------------|-----------|--|
| <b>Severity</b>        | Required  | See <a href="#">Incident Severity Level</a> .  |
| <b>Process</b>         | Required  | The threshold applies to the entire Tableau Server or for a single process as specified.   |
| <b>Start Threshold</b> | Required  | The CPU usage must surpass the value specified before an incident is created and monitored. Set the percent and the duration for this threshold. |
| <b>End Threshold</b>   | Optional  | The CPU usage that must fall below the value specified before an incident is considered resolved.  |

For **Available Memory**, set the following:

| Key                    | Required? | Description  |
|------------------------|-----------|--|
| <b>Severity</b>        | Required  | See <a href="#">Incident Severity Level</a> .  |
| <b>Start Threshold</b> | Required  | The available memory must fall below the value specified before an incident is created and monitored. Set the percent and the duration for this threshold. |
| <b>End Threshold</b>   | Optional  | The available memory must be above the value specified before an incident is considered resolved.  |

For **Memory Usage**, set the following:

| Key                    | Required? | Description   |
|------------------------|-----------|---|
| <b>Severity</b>        | Required  | See <a href="#">Incident Severity Level</a> .   |
| <b>Process</b>         | Required  | The threshold applies to the entire Tableau Server or for a single process as specified.  |
| <b>Start Threshold</b> | Required  | The memory usage must be equal to the value specified before an incident is created and monitored. Set the percent and the duration for this threshold. |
| <b>End Threshold</b>   | Optional  | The memory usage must be below the value specified before an incident is considered resolved.   |

For **Free Disk Space**, set the following:

| Key                    | Required? | Description   |
|------------------------|-----------|---|
| <b>Severity</b>        | Required  | See <a href="#">Incident Severity Level</a> .   |
| <b>Start Threshold</b> | Required  | The free disk space must fall below the value specified before an incident is created and monitored. Set the percent and the duration for this threshold. |
| <b>End Threshold</b>   | Optional  | The free disk space must be above the value specified before an incident is considered resolved.  |

For **Disk Queue Length**, set the following:

| Key                    | Required? | Description  |
|------------------------|-----------|--|
| <b>Severity</b>        | Required  | See <a href="#">Incident Severity Level</a> .  |
| <b>Start Threshold</b> | Required  | The disk queue length must be equal to the value specified before an incident is created and monitored. Set the percent and the duration for this threshold. |
| <b>End Threshold</b>   | Optional  | The disk queue length must be below the value specified before an incident is considered resolved.   |

## Use the configuration file (config.json)

An example `config.json` snippet defining two hardware incidents:

```
{
  "monitoring": {
    "incidents": {
      "triggers": [
        {
          "counter": "DiskSpaceAvailableKB",
          "severity": "warning",
          "threshold": 1048576
        },
        {
          "counter": "ProcessorTimePercent",
          "severity": "warning",
          "threshold": 0.95,
          "thresholdDuration": 300000,
          "endThreshold": 0.90,
          "endThresholdDuration": 5000
        }
      ]
    }
  }
}
```

- The **DiskSpaceAvailableKB** incident will trigger a warning once the available disk space falls below 10 GB.
- The **ProcessorTimePercent** incident will trigger a warning once the CPU has had at least 95% utilization for over 5 minutes. The incident will be considered resolved once the CPU is below 90% utilization for 5 seconds.

The default settings may or may not meet your requirements, and can be changed based on your environment. As an example, for an environment whose identifier was “staging-environment” to trigger a warning when the available disk space falls below 2 GBs, the configuration would look like:

```

{
  "environments": {
    "staging-environment": {
      "monitoring": {
        "incidents": {
          "triggers": [
            {
              "counter": "DiskSpaceAvailableKB",
              "severity": "warning",
              "threshold": 2097152
            }
          ]
        }
      }
    }
  }
}

```

| Key               | Data Type | Required? | Description  |
|-------------------|-----------|-----------|--|
| counter           | String    | Required  | The identifier for the hardware incident to monitor. available options are: <ul style="list-style-type: none"> <li>• ProcessorTimePercent</li> <li>• DiskSpaceAvailableKB</li> <li>• DiskQueueTotalLength</li> <li>• MemoryAvailableKB</li> <li>• MemoryCommittedKB</li> </ul> |
| severity          | String    | Optional  | See <a href="#">Incident Severity Level</a> . Default value: Warning   |
| threshold         | Number    | Required  | The threshold that must be surpassed before an incident is monitored.  |
| thresholdDuration | Number    | Optional  | The amount of time in milliseconds   |

| Key                               | Data Type | Required? | Description   |
|-----------------------------------|-----------|-----------|---|
|                                   |           |           | to monitor the situation before triggering an incident. If not specified, an incident will be triggered as soon as the <code>threshold</code> is reached.   |
| <code>endThreshold</code>         | Number    | Optional  | The threshold that must be surpassed before an incident is considered resolved.   |
| <code>endThresholdDuration</code> | Number    | Optional  | The amount of time in milliseconds to monitor the situation before completing the incident. If not specified, an incident will be resolved as soon as the <code>endThreshold</code> is reached. If <code>endThreshold</code> is not defined, then <code>threshold</code> is used. |

## Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-Environment Management** role.

### Hyper Spooling Incidents

*Hyper Spooling* incidents will be logged as a warning when Hyper queries are spooled to disk. Typically, this happens when there is not enough available memory and the Tableau Server Data Engine process shifts to spooling by temporarily writing to disk. The Tableau Server Data Engine topic describes this in more detail in the memory usage section.

## Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-Environment Management** role.

## Slow Query Incidents

*Slow Query* incidents are triggered when any data query takes too long to complete. By default, a Slow Query incident will trigger a warning if any data query takes at least 30 seconds to execute.

You can configure thresholds using the RMT Server web interface or by updating the configuration file `config.json`.

## Use the RMT Server web interface

To set the thresholds for slow query incidents, under the **Admin** menu, select **Configuration**, and go the **Incidents** tab.

| Key             | Required? | Description  |
|-----------------|-----------|--|
| <b>Severity</b> | Required  | See <a href="#">Incident Severity Level</a> .                                  |
| <b>Duration</b> | Required  | The minimum duration for a query to be considered slow. Values are in seconds. |

## Use the configuration file (config.json)

An example `config.json` snippet defining a Slow Query incident:

```
{
  "monitoring": {
    "incidents": {
      "triggers": [
        {
          "counter": "DataQueryDuration",
          "severity": "critical",
          "threshold": 45000
        }
      ]
    }
  }
}
```

```
}
}
```

This Slow Query incident will trigger if a data query takes at least 45 seconds to execute.

Incidents can be configured per environment. As an example, for an environment whose identifier was “staging-environment” to trigger a warning when a data query takes longer than 30 seconds to execute, the configuration would look like:

```
{
  "environments": {
    "staging-environment": {
      "monitoring": {
        "incidents": {
          "triggers": [
            {
              "counter": "DataQueryDuration",
              "severity": "warning",
              "threshold": 30000
            }
          ]
        }
      }
    }
  }
}
```

| Key       | Data Type | Required? | Description  |
|-----------|-----------|-----------|--|
| counter   | String    | Required  | Slow Query incidents use the DataQueryDuration identifier.           |
| severity  | String    | Optional  | See <a href="#">Incident Severity Level</a> . Default value: Warning |
| threshold | Number    | Required  | The minimum duration for   |

| Key | Data Type | Required? | Description  |
|-----|-----------|-----------|--|
|     |           |           | a query to be considered slow. Values are in milliseconds. |

## Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-Environment Management** role.

Slow Views Incidents

*Slow View* incidents are triggered when any view request takes too long to load.

By default, a slow view incident will trigger a warning if any view request takes at least 1 minute to load.

## Configure Slow View Incident Thresholds

To set the thresholds for slow view incidents, under the **Admin** menu, select **Configuration**, and go the **Incidents** tab.

| Key                  | Required? | Description  |
|----------------------|-----------|--|
| <b>Severity</b>      | Required  | See <a href="#">Incident Severity Level</a> .  |
| <b>Duration</b>      | Required  | The minimum duration for a query to be considered slow. Values are in seconds.   |
| <b>Tableau Users</b> | Required  | This threshold is can be either applied to specific users when they make view requests or for all users. Default is <b>All Users</b> .   |
| <b>Content</b>       | Required  | Content includes workbooks and views. This threshold can be applied to a single view or all views. If a workbook is specified, the threshold would be applied to all the views in that work- |

| Key | Required? | Description  |
|-----|-----------|--|
|     |           | <p>book. To specify a view, use the share URL. For more information, see <a href="#">How View URLs are structured</a>.</p> <p>You can also exclude certain views or workbooks by specifying exceptions.</p> <p>Default is <b>All Views</b></p> |

Only one incident is created per view request. The Resource Monitoring Tool evaluates all of the incident triggers, and if multiple triggers match a specific view request, then the triggers are ranked in order of priority and specificity. The highest ranking trigger is used to create the incident.

For example, a trigger with a severity of critical is ranked higher than a severity of warning.

#### Encrypted Data Collection

To make sure the data collection from Tableau Server to Tableau Resource Monitoring Tool is encrypted, communications between RMT Server and Agents, and connections to Tableau Server Repository have to be enabled to use encrypted messaging.

For versions 2022.3 and later

- If RabbitMQ is installed on the same machine as the RMT Server (local configuration), Tableau Resource Monitoring Tool has built-in encrypted communications between RMT Server and agents. There is no set up required for encryption between RabbitMQ and RMT Server.
- If RabbitMQ is hosted external to RMT Server (external configuration), you must follow the same steps as described in the For versions 2022.2 and earlier section in this topic

You still need to enable and configure [encrypted communications to Tableau Server](#) repository database in both cases stated above.

#### Tableau Repository SSL Configuration

1. Make sure Tableau Server is configured to use SSL connections for internal Postgres connections. For more information, see [Configure SSL for Internal Postgres](#)

Communication. The Resource Monitoring Tool allows you to use either the certificate file or thumbprint for the SSL connections. If you plan to use the certificate file, copy the certificate file generated by Tableau Server for internal Postgres SSL connections, to the machine where you plan to install the RMT Server. For more information, see [Configure Postgres SSL to Allow Direct Connections from Clients](#).

2. On the RMT Server web interface, from the Admin menus, select Environments. Click on the edit environment icon.

In the **Tableau Repository Configuration** section:

1. In the **SSL Mode** drop down box, select **Prefer SSL** or **Require SSL** to configure SSL connections to Tableau Repository. Choosing **Disable** means SSL will never be used to make Tableau Server Repository connections.

In the **Prefer SSL** mode, the Resource Monitoring Tool will use SSL in the first attempt, and if that fails the subsequently attempts a non-encrypted connection.

In the **Require SSL** mode, if the SSL connection fails, the connections to Tableau Server Repository will fail entirely. In this case, Tableau Server REST API connections will be used to communicate with Tableau Server.

2. You can choose to either supply the thumbprint that was generated by Tableau Server, or copy the **server.crt** file to the Resource Monitoring Tool Master Server machine. If you choose to copy the certificate file, you don't have to supply the thumbprint. For more information, see [Configure Postgres SSL to Allow Direct Connections from Clients](#).

For versions 2022.2 and earlier

Encrypted communication between the Agent(s) and RMT Server is possible by performing the following:

- [Configuring RabbitMQ with SSL/TLS certificates.](#)
- [Configuring the RMT Server and agent\(s\) to enable encrypted messaging.](#)
- [Configuring encrypted connections to Tableau Repository.](#)

## Tableau Server on Linux Administrator Guide

### RabbitMQ Setup

For details on RabbitMQ server setup please reference RabbitMQ's documentation for [TLS Setup](#).

### Tableau Resource Monitoring Tool Setup

After RabbitMQ has been configured for TLS all client applications: the Tableau Resource Monitoring Tool RMT Server and all Agents will need to be configured to enable encrypted messaging. Do the following on the RMT Server web interface:

1. On the machine where RMT Server is installed, go to: `http://<hostname>/setup/server`.
2. In the Message Queue section, check the Enable TLS check box, and provide the Certificate Host Name.
3. Update the port information if needed.

When configuring the RMT Server and agent(s) for encrypted messaging:

- Both the `enabled` flag and the `certificateHostName` must be configured for encryption to be enabled.
- The `certificateHostName` variable must match the canonical name (CN=) on the server certificate or the connection will fail.
- The `port` number will likely need to be changed based on the TLS port you configured on RabbitMQ.

**Note:** If the Agents were already registered before SSL was configured, then you must re-register the agent. To do this, download the new bootstrap file and re-register the Agent using the new bootstrap file. For more information on re-registering the Agent, see [Re-registering an Agent](#).

### Who can do this

To configure encrypted data collection you must be both a Tableau Server Administrator and Resource Monitoring Tool.

## Hardware Changes to RMT Server - Tuning PostgreSQL Database

Sometimes you may need to upgrade or change hardware on the machine where RMT Server is installed. Whenever you make any hardware changes, specifically to memory and CPU, it would be beneficial to tune the underlying PostgreSQL database that is installed with the RMT Server.

When you install RMT Server, the setup program configures the PostgreSQL database to optimize the use of available hardware on the machine. Example optimizations include managing the buffer and cache size. When you change the hardware on your machine, it may affect the performance.

Use the following steps to make sure the configuration is updated to reflect the change in hardware:

1. Connect to the RMT Server as a user with complete sudo access.
2. Navigate to the "master" directory and run the following command:

```
sudo /opt/tableau/tabrmt/master/tabrmt-master optimize
```

You should see a message that indicates that the configuration file has been updated. It will also state that a restart of the PostgreSQL service is required for the changes to take effect. The updates to the configuration file does not require downtime of the server.

3. Restart the PostgreSQL database. You can do this during off-work hours when the Resource Monitoring Tool is not in use.

## Tableau Server Topology Changes

This article will help you understand what you need to do when you make certain topology changes to Tableau Server. The changes include: adding or removing a node, adding or removing a process from a node, and changing the number of processes on a node.

### Adding a Node

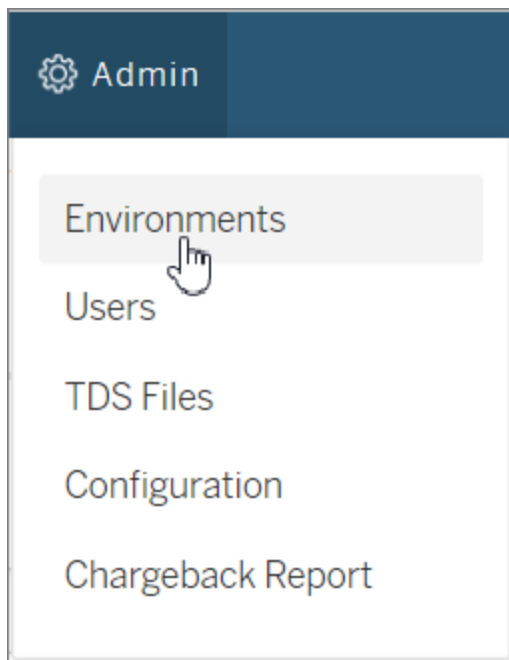

When you add a new node to Tableau Server, you must install the agent on this node. For more information on installing Agent on Tableau Server cluster, see [Install the Tableau Resource Monitoring Tool](#). Until you install the agent, information about this node will not be included in the reports.

### Removing a Node

When you remove an existing node from Tableau Server cluster, you must update the environment on the RMT Server.

#### Use the following steps to update the environment:

1. Log into the RMT Server web interface.
2. From the **Admin** menu, choose **Environments**. Select the environment that should reflect this change.

3. Choose **Edit Environment**. This opens more detailed information about the environment.

4. From the **Servers** tab, select the node that was removed from Tableau Server, and choose **Delete**.

**Note:** The host name should match the name or the IP address of the node.

## Re-registering an Agent

There can be situations when you might want to re-register an Agent. One such use case might be when you want to point one node or the entire Tableau Cluster to a different environment. Another example might be if you had to re-image a Tableau Server node and need to install and re-register the Agent. Use the following instructions to re-register the Agent.

1. On the RMT Server web interface, navigate to **Admin -> Environments**. Select the environment. From the **Servers** tab, click delete to completely remove the Agent

## Tableau Server on Linux Administrator Guide

registration for this node on this environment. This also removes historical monitoring data that has been collected on this node. Use this for scenarios where you are ok with losing the history. For example, if you planning to point this node to a new environment, it might be acceptable to remove the historical data and start fresh.

**Note:** In the RMT Server web interface, each node in a Tableau Server is referred to as a **Server**. The entire Tableau Server constitutes an environment. For more information, see [Concepts](#)

### Who can do this

To make topology changes, you must be both a Tableau Server Administrator and a Resource Monitoring Tool Administrator.

### Tableau Resource Monitoring Tool Log Files

#### Log Files

Tableau Resource Monitoring Tool includes many components. Each component maintains its own set of log files.

By default, 31 log files with a max file size of 1 GB each will be retained in each set. Excess log files beyond that will be deleted automatically.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see [About Tableau Help](#).

## Components

| Component                          | Log File Location                                | Description  |
|------------------------------------|--|--|
|                                    | <code>/var/opt/tableau/tabrmt/master/logs</code> |  |
| Backgrounder                       | <code>background\YYYYMMDD-pts.log</code>         | Logs generated by the general background processor.  |
| Director                           | <code>director\YYYYMMDD-pts.log</code>           | Logs generated by the director background processor. |
| Host                               | <code>host\YYYYMMDD.log</code>                   | Logs generated by the host.                          |
| Web Server                         | <code>web\YYYYMMDD-pts.log</code>                | Logs generated by the web server.                    |
| RabbitMQ (Message Broker)          | <code>rabbitmq/*.log</code>                      | Logs generated by RabbitMQ                           |
| PostgreSQL (local data repository) | <code>pgsql/*.log</code> and <code>/*.csv</code> | Logs generated by the local PostgreSQL database.     |

For advanced troubleshooting, verbose logging can also be enabled for more internal activities. These activity logs are stored in the associated component's log directory.

| Activity      | Log File Location      | Description  |
|---------------|------------------------|--|
| Database      | logs\*\YYYYMMDD-ef.log | Logs of internal database queries. By default, only errors are written to this log. Enable by changing db.logLevel to Debug or higher.       |
| Message Queue | logs\*\YYYYMMDD-mq.log | Logs of internal message queue communication. By default, this log will not be generated. Enable by changing mq.logLevel to Debug or higher. |

Log Level Configuration

Resource Monitoring Tool log levels can be adjusted in the following ways:

- Resource Monitoring Tool web interface: From the Admin menu, navigate to Configuration and select the Advanced tab. You can set the log levels and also specify if you want to include database queries and message queue communications.

Logging levels you can set using the web interface:

| Level  |
|--|
| Default: Includes Information, Warning, Error, and Critical levels                                   |
| Verbose: Includes Information, Warning, Error, Critical (everything in the default) and Debug levels |

- Settings in the `config.json` files. Log levels are configured independently for each component. The default config file paths are below. This may vary depending on your installation folder.

| Install                                | Default Location  |
|--|---|
| Tableau Resource Monitoring Tool       | • <code>/var/opt/tableau/tabrmt/master/config.json</code> |
| Tableau Resource Monitoring Tool Agent | <code>/var/opt/tableau/tabrmt/agent/config.json</code>    |

Logging levels that can be configured using the configuration file:

| Level       |
|-------------|
| Trace       |
| Debug       |
| Information |
| Warning     |
| Error       |
| Critical    |
| None        |

Below is a snippet demonstrating some default log level settings:

```
{
  "db": {
    "logLevel": "Error"
  },
  "mq": {
    "logLevel": "Warning"
  }
}
```

```
    },  
    "server": {  
      "background": {  
        "logLevel": "Information"  
      },  
      "director": {  
        "logLevel": "Information"  
      },  
      "web": {  
        "logLevel": "Information"  
      }  
    }  
  }  
}
```

## Sending Log Files to Tableau Customer Support

If you are working with Tableau Support and they ask you to send log files, zip the files up before you send them:

1. Connect to RMT Server and each server that has the Resource Monitoring ToolAgent installed.
2. Open a command prompt and run: `rmtadmin ziplogs <output file path>`, to create a ZIP archive of the log files.

For more information on sending log files to Tableau, see the [Tableau Knowledge Base](#).

Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-Environment Management** role.

Tableau Log Files

Tableau Resource Monitoring Tool agents monitor the Tableau log files in near real time and send log messages to the RMT Server for processing and reporting.

Below is a list of the specific Tableau log files that are monitored.

All directory paths are relative to the Tableau Server data directory. By default, this is located at: `/var/opt/tableau/tabrmt/data/tabsvc`

| Directory                      | File Name                       |
|--------------------------------|---------------------------------|
| <code>logs\backgrounder</code> | <code>backgrounder-*.log</code> |
| <code>logs\httpd</code>        | <code>*.log</code>              |
| <code>logs\vizportal</code>    | <code>vizportal-*.log</code>    |
| <code>logs\dataserver</code>   | <code>dataserver_*.txt</code>   |
| <code>logs\vizqlserver</code>  | <code>vizqlserver_*.txt</code>  |

## Upgrading Tableau

When upgrading a Tableau Server installation that is monitored by Tableau Resource Monitoring Tool, there are a few additional steps that need to be followed.

Ensure Resource Monitoring Tool supports the new Tableau version

Before upgrading Tableau, you'll want to make sure that the version of Resource Monitoring Tool you have installed supports the version of Tableau that you are upgrading to.

The quickest way to check is to log in to the Resource Monitoring Tool web interface and navigate to the **Admin | Environments** screen. Edit the environment you are upgrading and check the **Tableau Version** drop down for the version you are upgrading to.

## Stop Agents

Resource Monitoring Tool agents should be stopped while you upgrade Tableau Server. Follow these steps on each machine in your Tableau Server cluster:

Run the following command as the `tabrmt-master` user:

```
sudo su --login tabrmt-master
```

```
rmtadmin stop --agent
```

## Tableau Server on Linux Administrator Guide

### Upgrade Tableau

Follow the normal process for upgrading Tableau Server. This process is outlined in [the Tableau Server documentation](#).

### Update Tableau Version in Resource Monitoring Tool

1. Log in to the Resource Monitoring Tool web interface.
2. Go to **Admin | Environments**
3. Edit the environment you upgraded.
4. Modify the **Tableau Version** to match

### Restart Agents

After the upgrade is complete you are ready to restart the Resource Monitoring Tool agents. Follow these steps on each machine in your Tableau Server cluster:

Run the following command as the `tabrmt-master` user:

```
sudo su --login tabrmt-master
```

```
rmtadmin restart --agent
```

### Who can do this

To upgrade Resource Monitoring Tool, you must have all the following:

- Full sudo access for the user on machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

## Monitor Tableau Server Performance

Tableau Resource Monitoring Tool is used to monitor and analyze Tableau Server health and performance. Performance, usage and hardware metrics are collected through the Agents installed on the Tableau Server nodes and sent to the RMT Server. The aggregated and analyzed data is then displayed in the form of charts and views on the web interface of the RMT Server.

The web interface of the RMT Server has built-in charts and views that you can use to identify what is causing slow load times, extract failures, and other critical issues. For more information, see [Monitor Tableau Server Performance with Tableau Resource Monitoring Tool](#).

You can also download the data that is used to create the pre-built charts and explore it further. For more information, see [Explore Monitoring Data Using Tableau Data Source Files](#).

### Monitor Tableau Server Performance with Tableau Resource Monitoring Tool

Tableau Resource Monitoring Tool makes it easy to detect and resolve health and performance problems within your Tableau Server environments. One instance of the Resource Monitoring Tool can provide a single unified interface for administrators to monitor multiple Tableau Servers.

The Resource Monitoring Tool consists of two components:

- Agent, which collects resource usage and performance recording of interactions on Tableau Server.
- RMT Server, which aggregates and displays this performance data in the form of charts on a web interface.

The Resource Monitoring Tool may not be able to provide information for Tableau Server process that are external:

- External Repository: The process status is not monitored and not included in the chartss
- External File Store: The process status is not monitored and the extract file size information is not tracked. The extract failure and time taken to complete is still available.
- External Gateway: The process status is not monitored and not included in the charts.

### Pre-built Charts

The web interface of the RMT Server has built-in dashboards and charts that can be used to identify performance bottlenecks and issues. These built-in charts and metrics can be found on the **Performance**, **Activity**, and **Content** pages. You can also set up alerts (called **incidents**) to report outliers or unusual behavior based on thresholds that you configure.

## Tableau Server on Linux Administrator Guide

Here is a full list of capabilities that the Resource Monitoring Tool offers to help with monitoring your Tableau Server:

| Capability                   | Component   | Where to find it on RMT Server   |
|------------------------------|---|--|
| Configuring Incidents/Alerts | <ul style="list-style-type: none"> <li>Hardware resources at Tableau Server node and process level.</li> <li>View load times.</li> <li>Query times.</li> <li>Tableau Server node down events.</li> </ul>  | <p><b>Admin -&gt; Environments -&gt;Edit Environment -&gt; Incidents or Notifications</b> tabs.</p> <ul style="list-style-type: none"> <li>Use the <b>Incidents</b> tab to configure incident thresholds.</li> <li>Use the <b>Notifications</b> tab to configure when and how you want to receive notifications.</li> </ul>  |
| Hardware Resources           | <ul style="list-style-type: none"> <li>CPU</li> <li>Memory</li> <li>Disk</li> <li>Network</li> </ul>  | <p>For a high level view, go to <b>Performance -&gt; Select environment -&gt;Environment</b></p> <p>For a more detailed view, go to <b>Performance -&gt; Select environment -&gt; Servers</b></p>  |
| Tableau Server Usage         | <ul style="list-style-type: none"> <li>Concurrent users</li> <li>Aggregated view load times across the server</li> <li>Background tasks <ul style="list-style-type: none"> <li>Duration, state, and detailed errors for failed tasks.</li> <li>Log snippets for failed tasks.</li> </ul> </li> <li>Query details <ul style="list-style-type: none"> <li>Duration, state,</li> </ul> </li> </ul> | <p>Most of this information is on the <b>Environment</b> tab of the performance dashboard.</p> <p><b>Performance -&gt; Select environment -&gt;Environment</b></p> <p>To see query details, go to <b>Activity -&gt; Data Queries</b> and select a query for more details.</p> <p>To see log information, go to <b>Activity -&gt;</b> and make a selection from the list to</p> |

| Capability | Component  | Where to find it on RMT Server |
|------------|--|--------------------------------|
|            | <p>and query text for long-running or expensive queries.</p> <ul style="list-style-type: none"> <li>• Log information for:               <ul style="list-style-type: none"> <li>• Individual view load times.</li> <li>• VizQL session information.</li> <li>• Duration of events during view loads.</li> <li>• Query text, load time, and number of rows returned</li> <li>• Background tasks and run times.</li> </ul> </li> </ul> | see more details.              |

### Custom Charts

You can also download the data that is used to create the pre-built charts and explore it further in Tableau. For more information, see [Explore Monitoring Data Using Tableau Data Source Files](#).

### Who can do this

Any Resource Monitoring Tool user can view the charts.

### Tableau Resource Monitoring Tool Performance Charts

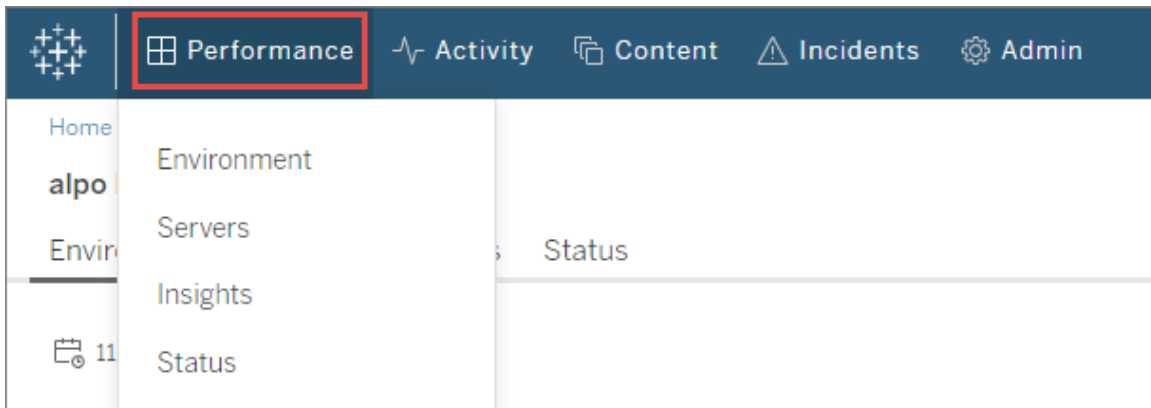

The Tableau Resource Monitoring Tool includes dashboards that help you monitor and analyze various performance metrics like hardware resource usage, user activity, and the status

of Tableau Server processes. They can be useful in identifying performance bottlenecks and the overall health of your Tableau Server.

This topic describes the information on the charts on the **Performance** page. The performance page provides a dashboard view of the overall health of the Tableau Server and includes the following tabs:

1. **Environment:** A dashboard of the performance metrics specific to the environment you selected.
2. **Servers:** Focuses on the hardware resource metrics.
3. **Insights:** Highlights the slowest views and the longest extract refreshes.
4. **Status:** Tableau Server processes status. Information about each process on the nodes whether they are active, busy, or down. This is similar to what you might see on the Tableau Server Settings page.

## Environment Tab

The charts on the environment tab give you an all-up view of the health of the Tableau Server.

- The left side of the page has resource-related metrics: Performance, Tableau Processes, and Background Tasks.
- The right side charts focus on the user activity and the impact: Concurrent Users, Slow View Load Requests, and Total View Load Requests.

### Navigation Tips:

At the top left corner of the page, you can select a time line that is applied to all the charts on

this page. You can also select a time range by selecting a part of a specific chart (range selection).

- When you make a range selection in the hardware performance and background task charts, the time line acts as a filter for all the charts on this tab.
- When you make a range selection in the slow view load, and user activity charts, you will be automatically be navigated to the Activity page which provides more details for the selected time range.

## Performance Chart

The information on this chart shows you the overall health and usage of the hardware resources for each Tableau Server node. The hardware resources included in this chart are CPU, memory, disk queue, and network.

**Note:** Network information is not available and not currently supported for Tableau Server running on Linux.

## Tableau Processes Chart

Use this chart to get more details about a specific node and the processes running on that node. **Starting in 2021.4**, almost all Tableau Server processes are tracked with a few exceptions like cluster controller and process that are configured external to Tableau Server cluster, like the External Repository, External File Store, and Independent Gateway. This chart allows you to identify the processes that are driving CPU or memory utilization on a particular node. The chart is dynamically updated to highlight the top ten processes that are using the most resources on a node for the selected time period.

**Note:** Some Tableau Server sub-processes like tabprotosrv, postgres, and gateway, are not captured by RMT Server and can cause apparent discrepancies between the Performance chart and the sum of all the values from the Tableau Processes chart.

## Background Tasks Chart

The chart is an overview of the volume of background tasks, categorized by the task type. Use the toggle button to see the total number of tasks, the median duration of those tasks, and a histogram that shows you the run-time for the selected time period. This can be a quick way to drill down to see which tasks are taking a long time to run.

## Concurrent Users Chart

This chart shows you the number of users that have been sending requests in the time period that is selected.

**Note:** When you select a portion of this chart, it automatically takes you to the related activity page and shows you the information for that specific time period.

## Slow View Load Requests Chart

This chart uses a **baseline** that is established for each view and is then uses it to compare the time it takes to render that view to determine if the view is taking longer than expected.

**In version 2021.4**, the baseline is established by calculating the median value of the first 10 times a specific workbook is rendered successfully.

**In version 2021.4.1** and later, the baseline is established by calculating the 95th percentile of 50 times a specific workbook is rendered successfully.

Once the baseline is established, every time that same workbook is rendered in the future, the time taken for a workbook to load is then compared to its baseline. Depending on whether the time taken to render the view falls within the expected range or at varying degrees outside of the expected range, they are categorized as follows:

- **Normal:**  $\leq 2x$  baseline
- **Long:**  $> 2x$  baseline

- **Very Long:**  $\geq 4x$  baseline
- **Failed:** Failed to load or resulted in an error

This baseline and the comparisons only apply to initial rendering of the view. It does apply to subsequent actions like filter selections. Also, when you publish a new version of the workbook, it triggers a recalculation of the baseline.

**Note:** When you select a portion of this chart, it automatically takes you to the related activity page and shows you the information for that specific time period.

For a detailed walk through on how to use this chart and investigate performance with view rendering, see [Investigating Slow View Load Requests](#).

## Total View Load Requests Chart

This chart gives you an overall feel for how many views have been rendered over a period of time. This chart is useful to assess the scope of the impact of a particular incident.

**Note:** When you select a portion of this chart, it automatically takes you to the related activity page and shows you the information for that specific time period.

## Server Tab

The charts on this tab provide a more detailed view of the **Performance** chart on the **Environment** tab.

## Insights Tab

### Slowest Views

This chart shows the slowest views ordered by average view load duration. The orange dot indicator represents that view's longest load duration. The time period that is represented here is the full range of data that is available, default is 2 weeks.

### Longest Extract Refreshes

This chart shows the slowest Refresh Extract tasks ordered by duration. Both data source extracts and workbook extracts are considered. They can be distinguished by the icon next to their name. The time period that is represented here is the full range of data that is available, default is 2 weeks.

## Status Tab

This tab lists the Tableau Server processes and their status on each node of the Tableau Server Cluster. This does not include Tableau Server processes that are configured external to Tableau Server cluster like External Repository, External File Store, and Independent Gateway.

## Who can do this

Any Resource Monitoring Tool user can view the charts.

## Related Topics

- [Monitor Tableau Server Performance with Tableau Resource Monitoring Tool](#)
- [Tableau Resource Monitoring Tool Activity Pages](#)
- [Tableau Resource Monitoring Tool Content Pages](#)

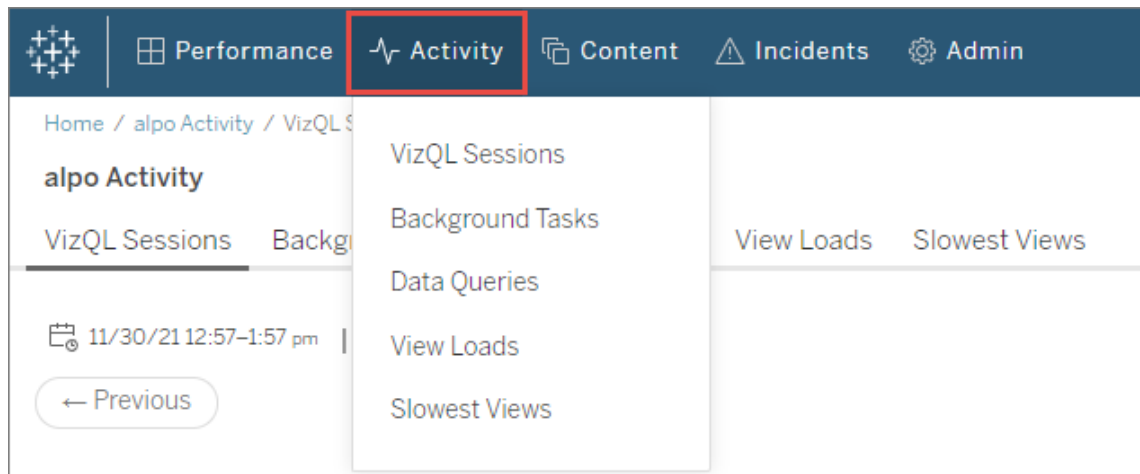

## Tableau Resource Monitoring Tool Activity Pages

The Tableau Resource Monitoring Tool includes dashboards that help you monitor and analyze various performance metrics like hardware resource usage, user activity, and the status of Tableau Server processes. They can be useful in identifying performance bottlenecks and the overall health of your Tableau Server.

This topic describes the information on the **Activity** page. The activity page provides the next level of detail to what is seen on the charts on the **Performance** page. The filter selections on either of these dashboards are carried over to the other so you can see corresponding information as you are trying to identify any performance issues.

The activity page includes detailed information about the following:

- VizQL Sessions
- Background Tasks
- Data Queries
- View Loads
- Slowest Views

## VizQL Sessions

Shows you a list of all the VizQL sessions in the selected time range. A VizQL session is a set of interactions that a user has with a workbook on Tableau Server.

Click a session ID to see a summary chart and more details such as the requests made during the session, request duration, and related workbook sessions. You can also see any related data queries, incidents that have been reported, and the environment activity filtered to the same time period as the VizQL session's time frame.

## Background Tasks

Shows you a list of all the background tasks in the selected time range.

Click the start time of the task to see more details about the background task including a summary that shows you a comparison of the time it took to complete the task versus the average duration of time taken to complete similar tasks. You can also see any related incidents that have been reported and the overall environment activity during the time this task was run.

Click the site name to see more information about the site including the number of workbooks, views, and VizQL sessions for each project on that site.

## Data Queries

Shows you a list of all the data queries during the selected time range.

Click on a query to see query performance details, the full query text, and the connection details.

## View Loads

Shows you the list of rendered views in the selected time range.

The **Load Time Severity Category** filter allows you to filter views are taking much more time to load than normally expected. This uses the same baseline concept and comparisons used on the **Slow View Load Request** Chart. The baseline is established by calculating the median value of the first 10 times a specific workbook is rendered. Once the baseline is established,

every time that same workbook is rendered in the future, the time taken for a workbook to load is then compared to its own baseline.

The categories for the load time severity are as follows:

- **Normal:**  $\leq 2x$  baseline
- **Long:**  $\geq 2x$  baseline
- **Very Long:**  $\geq 4x$  baseline
- **Failed:** Failed to load or resulted in an error
- **Processing:** The baseline calculation is in process and is not yet established.

## Slow Views

Shows you the list of all views that have taken the longest time in descending order. This list is based on average load duration time rather than a comparison against a baseline. You can narrow this list by filtering by duration, publisher, site or a specific view.

- Click on the view to see more details about the load times You can also see any related incidents that have been reported and the overall environment activity during the time this task was run.
- Click on the workbook to see more details about a specific workbook.

## Who can do this

Any Resource Monitoring Tool user can view the charts.

## Related Topics

- Monitor Tableau Server Performance with Tableau Resource Monitoring Tool
- Tableau Resource Monitoring Tool Performance Charts

Tableau Resource Monitoring Tool Content Pages

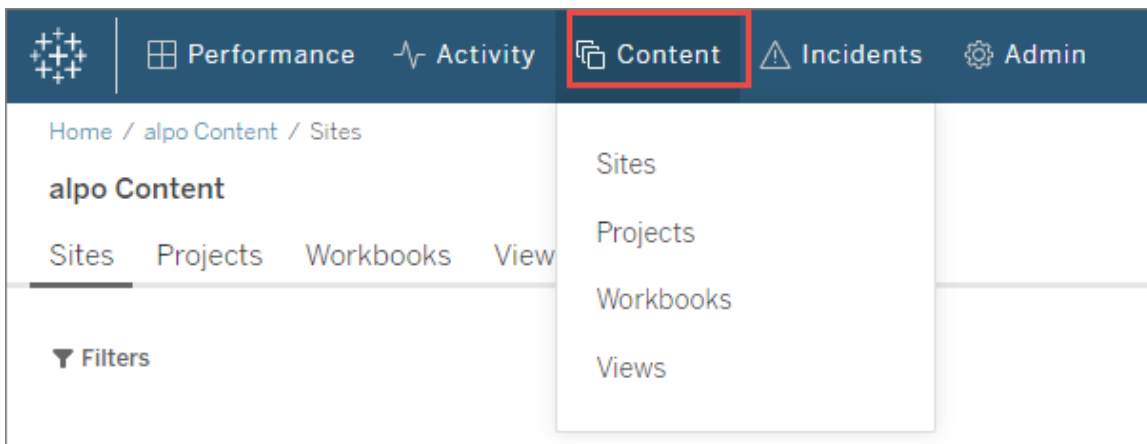

The Tableau Resource Monitoring Tool includes dashboards that help you monitor and analyze various performance metrics like hardware resource usage, user activity, and the status of Tableau Server processes. They can be useful in identifying performance bottlenecks and the overall health of your Tableau Server.

This topic describes the information on the charts on the **Content** page. This page is the main way to look at the details for a specific content item. It is a useful place to start when you need to investigate performance for a specific workbook or a view.

The content page includes detailed information about the following:

- Tableau Sites
- Projects in each Tableau Site
- Workbooks
- Views

You can see performance metrics for the VizQL sessions, data queries related to a project, workbook, or a view. You can also see any related incidents specific to workbooks or views.

## Sites

Shows you a list of sites on your Tableau Server environment including the total number of projects, workbooks, and VizQL sessions.

## Projects

Shows you a list of all the projects on a site. Click on the project to see a list of all the workbooks, views, and related VizQL sessions, and data queries.

## Workbooks

Shows you a list of all the workbooks on a site. Click on a workbook to see the load times, VizQL session information, related data queries, and any reported incidents specific to this workbook.

## Views

Shows you a list of all the Views on a site. Click on view to see the load times for the view, VizQL session information, related data queries, and any reported incidents specific to the view.

## Who can do this

Any Resource Monitoring Tool user can view the charts.

### Investigating Slow View Load Requests

The **Slow View Load Requests** chart on the performance page is a useful metric to understand the performance of views and the resulting impact on user interactions on Tableau Server.

The Slow View Load Requests chart shows when views are rendering more slowly than normal on Tableau Server. To do this, the chart uses a **baseline** that is established for each view and is then uses it to compare the time it takes to render that view to determine if the view is taking longer than expected.

**In version 2021.4**, the baseline is established by calculating the median value of the first 10 times a specific workbook is rendered successfully.

**In version 2021.4.1** and later, the baseline is established by calculating the 95th percentile of 50 times a specific workbook is rendered successfully.

Once the baseline is established, every time that same workbook is rendered in the future, the time taken for a workbook to load is then compared to its baseline. Depending on whether the time taken to render the view falls within the expected range or at varying degrees outside of the expected range, they are categorized as follows:

- **Normal:**  $\leq 2x$  baseline
- **Long:**  $\geq 2x$  baseline
- **Very Long:**  $\geq 4x$  baseline
- **Failed:** Failed to load or resulted in an error

**Note:** This baseline and the comparisons only apply to initial rendering of the view. It does apply to subsequent actions like filter selections. Also, when you publish a new version of the workbook, it triggers a recalculation of the baseline.

The chart shows the percentage of view loads that are outside of the normal range for the selected time range. So, if you see yellow (Long) or red (Very Long) spikes on this chart, that is the first indication that there is likely a problem.

**Tip:** Selecting the “Past 48 hours” time range might be a good place to start as it will give you some context on activity in the past versus current.

The **Concurrent Users** and the **Total View Load Requests** charts on the same page can be used to see the scope of the impact resulting from slow view loads in the same time range. You can also use the **Tableau Processes** chart to identify any correlations between the slow view load performance and resource usage - like for example, you might see high VizQL Server resource usage on specific nodes during the same time that you are seeing spikes in the **Slow View Load Requests** chart.

If you see a spike in the slow view load request chart, you can then start to drill down further to identify what might be causing the issue - whether the problem is due to a single view or a much broader issue. To do this, within the **Slow View Load Requests** chart, select a range to include a large portion of the slow views. This will take you to the **View Loads** activity page, showing you view load requests for the same time frame.

Filter by **Load Time Severity Category** and select the appropriate category for the view loads you want to investigate.

The screenshot shows the Tableau Server interface with the "View Loads" tab selected. The top navigation bar includes "VizQL Sessions", "Background Tasks", "Data Queries", "View Loads", and "Slowest Views". Below the navigation bar, the date and time range "12/1/21 3:47-4:05 pm" is displayed. A "Filters" dropdown menu is open, showing options: "Duration", "Load Time Severity Category" (highlighted with a red box), "Site", "User", "View", and "Clear All". On the right side, the "Workbook" section lists "Default", "Escalations Official", and "Escalation Eligibility Check (AF)".

The list should indicate which views might have caused the chart results and can be understood in the following ways:

**Multiple views:** If the list shows multiple views, this is likely a broader issue with Tableau Server. Go back to the performance page, and take a look at the **Performance**, and **Tableau Server Processes** chart to investigate the resource usage. The **Status** tab on the performance page will show the status of the processes whether they are active, busy, or down. Look for the VizQL Server, Data Server, and the Data Engine processes on this list.

**Same view:** If the list is mostly one single view, this could mean that there is an issue with that view or workbook. Further investigation might be needed to see what might be causing the problem. Click on the **view name** in the list to see more information about load times, related data queries, and VizQL sessions.

**Important!** On the **Load Times** chart, if the average load time is consistent even when adjusting the date range to span just before and after the spike began, it means that the baseline calculation was likely created when view loads were heavily cached, causing subsequent view loads to be considered 'slow'. This scenario does not reflect an issue with Tableau Server or the view. If this is the case, you can trigger a recalculation of the baseline by publishing a new version of the workbook.

Here are some resources to help with performance troubleshooting for a specific view:

- [Optimize Workbook Performance](#)
- [Record and Analyze Workbook Performance](#)

## Who can do this

Any Resource Monitoring Tool user can view the charts.

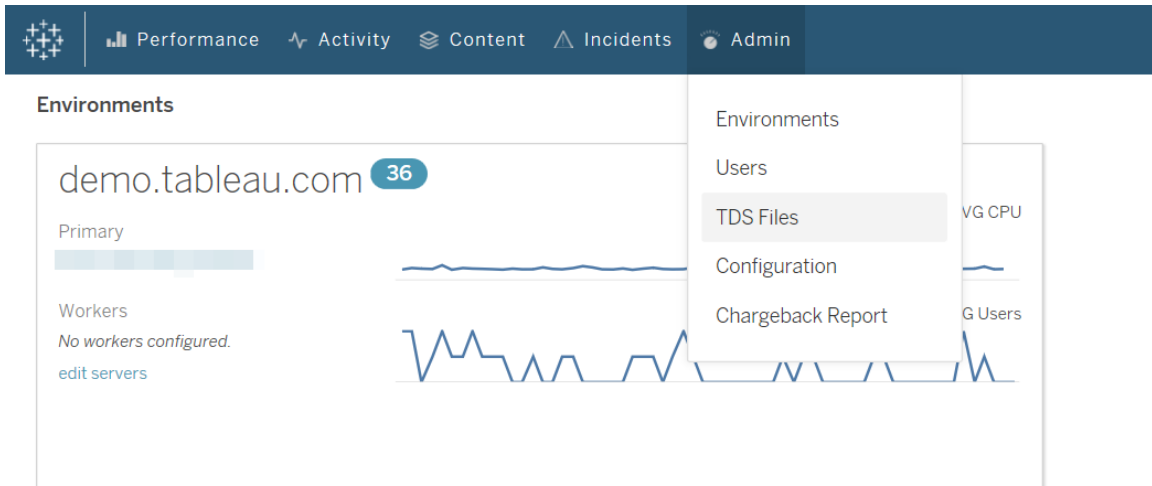

Tools used in Data Collection

Below is a list of the specific classes used to collect monitoring data :

| Class   | Command             | Monitoring Category |
|---|---------------------|---------------------|
| <code>LinuxSystemCpuCollector</code>          | <code>top</code>    | CPU                 |
| <code>LinuxProcessPerformanceCollector</code> | <code>top</code>    | Process             |
| <code>LinuxSystemMemoryCollector</code>       | <code>free</code>   | Memory              |
| <code>LinuxDiskQueueLengthCollector</code>    | <code>iostat</code> | Disk                |
| <code>LinuxDiskUsageCollector</code>          | <code>df</code>     | Disk                |

Explore Monitoring Data Using Tableau Data Source Files

The Tableau Resource Monitoring Tool includes built-in charts that you can use to monitor and analyze Tableau Server health and performance. The data Tableau Resource Monitoring Tool leverages can be downloaded as Tableau data source (.tds) files for exploration within Tableau Desktop. You can download the .tds files from the **Admin** menu using the Resource Monitoring Tool web interface. This methods works for both local and external repository configurations.

The following is a list of Tableau data source (.tds) files you can download:

- **Background Tasks:** Includes information about scheduled background tasks like extract refreshes, subscriptions, and flows.
- **Data Queries:** Information about all queries executed by Tableau Server.
- **Gateway Requests:** HTTP requests handled by Tableau Server including VizQL Server session details.
- **Incidents:** Incidents recorded by the Resource Monitoring Tool .
- **Server Performance:** Tableau Server hardware and process information that is gathered by the Resource Monitoring Tool.
- **Tableau Entities:** Information about the Tableau Server sites, projects, workbooks, and views gathered by the Resource Monitoring Tool.

#### Requirements

- Encryption used is SCRAM-SHA-256 which is supported by Tableau Desktop 2020.4 and later.

Enable access to the Resource Monitoring Tool PostgreSQL database

The Tableau data source (.tds) file contains a connection to the Resource Monitoring Tool PostgreSQL database. Before you can connect to a downloaded .tds file, you need to enable access for the `readonly` user to the Resource Monitoring Tool PostgreSQL database. Once the `readonly` user has access, you can then use the `readonly` username and password to

connect to the Resource Monitoring Tool PostgreSQL database from the .tds file in Tableau Desktop.

## Resource Monitoring Tool versions 2022.3 and later:

### Resource Monitoring Tool with local repository:

1. On the RMT Server machine, enable access to the Resource Monitoring Tool PostgreSQL database for the `readonly` user:

```
rmtadmin data-access ReadOnly
```

2. Restart the Resource Monitoring Tool PostgreSQL database for the configuration change to take effect:

```
rmtadmin restart --db
```

3. Retrieve the password for the `readonly` user:

```
rmtadmin get db.readOnlyPassword
```

### Resource Monitoring Tool with external repository:

You must configure the RDS instance to allow access from Tableau Desktop. Retrieve the username and password for the Resource Monitoring Tool PostgreSQL database and use it to download .tds files. For more information see the [documentation on AWS site](#).

## Resource Monitoring Tool versions 2022.2 and earlier:

1. Open the `postgresql.conf` file. By default, the file is located at: `/var/opt/tableau/tabrmt/data/postgresql<version>`
2. Update `Listen_addresses = 'localhost'` to `Listen_addresses = '*'`.

**Note:** You must remove the '#' from this line.

## Tableau Server on Linux Administrator Guide

3. Open the `pg_hba.conf` file. This file is also located in the same directory as the `postgresql.conf` file. By default the file is located at: `/var/opt/tableau/tabrmt/data/postgresql<version>`

4. Add the following to the end of the `pg_hba.conf` file and then save the file:

```
host all all 0.0.0.0/0 scram-sha-256  
  
host all all ::/0 scram-sha-256
```

5. Restart the Resource Monitoring Tool PostgreSQL database for the configuration changes to take effect:

```
rmtadmin restart --db
```

6. Retrieve the password for the `readonly` user:

```
rmtadmin get db.readOnlyPassword
```

### Connect to the RMT .tds files from Tableau Desktop

After access to the Resource Monitoring Tool PostgreSQL database has been enabled for the `readonly` user, you can then connect to the downloaded `.tds` files from Tableau Desktop.

1. In Tableau Desktop, go to **File > Open** and select the `.tds` file downloaded from the Resource Monitoring Tool web interface.

**Note:** You might need to install the PostgreSQL database drivers. You can download drivers from [www.tableau.com/support/drivers](http://www.tableau.com/support/drivers).

If Tableau Desktop does not automatically connect to the Resource Monitoring Tool Postgres database after opening the `.tds` file, you might need to manually enter the `readonly` username and password into the edit connection window in Tableau Desktop.

Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Download TDS Files** server role.

### Chargeback Reports

Chargeback reports show usage on a per-project or per-site basis and are available for allowed users through the **Admin** menu. The report is generated as a Tableau workbook using a generated extract, allowing you to modify the report or reuse the extract as needed.

The **Chargeback Overview** worksheet shows a breakdown of various metrics based on site and/or project:

### Overview

Dollar amounts can be customized using the total cost field, and by adjusting the cost weights for each metric.

Clicking on a project or site navigates to a customized invoice-style detail report for that project/site:

# Tableau Server on Linux Administrator Guide

## Detail

### Security

User access is controlled through the **Generate Chargeback Reports** server role.

### Data Generation

Data for the chargeback report is aggregated at the daily level, with the following metrics included in the data set:

| Metric                 | Description  |
|------------------------|--|
| Extract File Usage     | The size, in Kilobytes, of extract files is collected once per day. For the default report this is simply totaled across the time period for ratio/comparison purposes between projects/sites. |
| Extract Query Duration | The length of time, in milliseconds, that queries running against extract files ran, totaled per day.  |

| Metric                        | Description  |
|-------------------------------|--|
| Extract Refresh Task Duration | The length of time, in milliseconds, that extract refresh background tasks ran, totaled per day.   |
| Query Duration                | The length of time, in milliseconds, that queries ran, totaled per day. This includes both extract and non-extract queries.  |
| View Request Duration         | The length of time, in milliseconds, that requests to render views ran, totaled per day. This includes the duration of any data queries that blocked view rendering. |

## Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-Environment Management** role.

## Troubleshoot Tableau Resource Monitoring Tool Issues

This section includes articles that describe troubleshooting steps and tips. If you have any questions or encounter other issues not described here, contact [Tableau customer support](#).

### Troubleshoot Missing Hardware Performance Data

Processor (CPU) usage, memory usage, disk queue, and network performance stats are considered hardware performance data in the Tableau Resource Monitoring Tool. The most common places to see this data are:

- On the **Environment Overview** dashboard in the Performance and Tableau Processes charts
- On the **Servers** dashboard

This data is reported in near-real-time by the Resource Monitoring Tool agent processes running on each of your Tableau Server machines.

## Tableau Server on Linux Administrator Guide

If these charts show no data for an extended period of time, this may be due to the following reasons:

1. Tableau Server is not licensed correctly. This may be due to missing Advanced Management licensed to use Tableau Resource Monitoring Tool with Tableau Server. Make sure Tableau Server has the required license. For more information on Advanced Management license, see [About Tableau Advanced Management on Tableau Server](#).
2. Connectivity issues between Agent and Tableau Server. Use the steps below to troubleshoot and isolate these issues.

### Step 1: Check the Agent connection status

First, check that the Agents are currently connected to the Resource Monitoring Tool. The Agents send a regular heartbeat message to the RMT Server to indicate their connection status.

1. Log in to the Resource Monitoring Tool as an administrator.
2. Navigate to the **Admin > Environments** page.
3. Click the Edit link for the environment that is missing performance data.
4. Locate the **Servers** list and ensure that each server shows the Agent Service as **Connected**. You can hover over the **Connected** status for a timestamp of when the last heartbeat message was received.

### Step 2: Ensure the Agent is running

If the Agent shows as **Disconnected** in the Resource Monitoring Tool, then the Agent's Windows service may not be running.

1. Connect to the machine the agent is running on.
2. Ensure that the Tableau Resource Monitoring Tool Agent Windows service is running.

### Step 3: Ensure the Agent is configured correctly

If the agent shows as **Disconnected** in the Resource Monitoring Tool, but the service is running, then the agent may not be able to reach the Resource Monitoring Tool's message queue.

1. Connect to the machine the agent is running on.
2. Navigate to the agent's installation folder. For example: `/opt/tableau/tabrmt/agent`
3. Run the `rmtadmin status` command.

The `rmtadmin status` command will test the agent's connectivity to the message queue and the Resource Monitoring Tool's RMT Server.

#### Step 4: Restart the Agent

In some cases, the Agent may be running and all status indicators show success but the agent continues to not send hardware performance data. This is a known issue that can result from transient connectivity errors between the Agent and the message queue. For example, when restarting the message queue server or during brief network interruptions.

To ensure this isn't the case, restart the Agent and wait a few minutes to confirm whether the performance data is working again.

1. Connect to the machine the Agent is running on.
2. Restart the Tableau Resource Monitoring Tool Agent Windows service.
3. Ensure the service starts successfully.
4. Wait at least 10 minutes and then log in to Resource Monitoring Tool and check Servers dashboard to see if any hardware performance data has been received.

#### Step 5: Verify Run As account configuration

Ensure the run-as accounts for the agents are configured to use the same run-as account that Tableau Server uses to connect to Tableau Server and get the performance and CPU data. It must be the same account that Tableau Server is configured with. Make sure this account has permissions to access Tableau Server logs.

#### Step 6: Contact Support

If, after following the above steps the issue is still not resolved, please contact support.

The support team will need a copy of the Resource Monitoring Tool log files from the RMT Server and from each of the agents that are having connection issues. For more information on how to collect log files and sending them to Tableau customer support, see [Sending Log Files to Tableau Customer Support](#).

Who can do this

Resource Monitoring Tool Administrators.

## Tableau Server on Linux Administrator Guide

### Troubleshoot RMT Server Service Interruptions

You may be experiencing service interruptions due to RMT Server stopping on a regular basis. This is most likely because Resource Monitoring Tool has been configured with service accounts that do not conform to your internal IT policies. Many IT departments employ automation tools that will revoke privileges on accounts that are deemed non-compliant with their standards, and are the cause for the service interruptions.

**Temporary solution:** Restart RMT Server by running `rmtadmin start -master`.

**Long term solution:** You can either configure the Resource Monitoring Tool to run under an account that is compliant with your internal governance policies (recommended), or alternatively, work with your IT department to obtain an exception from the policy.

Who can do this

You need to be a Administrator on the machine and be a Resource Monitoring Tool Administrator in order to make configuration and database changes.

### Troubleshoot Unknown Status of Tableau Server Processes

Under certain conditions you might see that the status of a Tableau Server process as reported as **Unknown**. This is often due to a change in the process configuration in Tableau Server which has not yet been updated in Tableau Resource Monitoring Tool.

**Note:** After updating any configuration, it may take a few minutes for the status reported by the Resource Monitoring Tool to refresh. By default, the Resource Monitoring Tool checks the Tableau Server status every 15 seconds but it may be longer if you configured it to check less frequently.

Use the following troubleshooting steps to resolve this issue:

### Step 1: Check Tableau Server Environment Settings

The Resource Monitoring Tool connects to Tableau Server for monitoring and data collection. If the Tableau Server is upgraded, or the Tableau Server credentials expire then Resource Monitoring Tool will not be able to monitor it as expected.

To confirm that the Resource Monitoring Tool is able to connect to your Tableau Server:

1. Go to **Admin > Environments list** page.
2. Edit the environment that is having the issue.
3. Confirm that the selected Tableau Server version is correct. When you upgrade your Tableau Server you may need to update the version in the Resource Monitoring Tool.
4. Test the Tableau Server REST API connection using the “Test Connection” button.

Optionally, test the Tableau Repository connection using the “Test Connection” button.

### Step 2: Update Tableau Server Machines and Processes

To correctly monitor a Tableau Server, the Resource Monitoring Tool needs to be configured with a complete record of your Tableau Server machine names and process ports. This information is automatically gathered when creating a new environment but may need manually updated if the Tableau Server configuration is changed.

1. Go to the **Admin > Environments** page.
2. Edit the environment that is having the issue.
3. Confirm that the list of **Servers** contains your initial node/gateway Tableau Server machine as well as all additional node machines.
4. Follow the steps below to confirm that each server is configured correctly.

### Step 3: Update Machine Name

1. Open this Tableau Server URL: *http://<your TableauServer URL>/admin/systeminfo.xml*.
2. Compare and update the Resource Monitoring Tool configuration with this page to ensure it is up-to-date:
  - Update the server’s Host Name to exactly match the `<machine name="{HOST NAME}"/>` attribute value.

## Tableau Server on Linux Administrator Guide

### Step 4: Contact Support

If, after following the above steps the issue is still not resolved, contact [Tableau customer support](#).

VizQL Session details page says the VizQL process is unknown

HTTP requests for a Tableau view are linked to the VizQL process (the actual VizQL PID) that last locked the request's VizQL session ID.

In some cases we may not be able to find a matching VizQL process (PID) and in these cases you will see a message on the view session details page that the VizQL process is unknown.

This can happen in a few rare cases:

- The Tableau cluster has been modified with the addition of a new VizQL worker instance.
- Tableau adjusting the VizQL process's port number to avoid a conflict with another process.

If this happens, sign in to the Resource Monitoring Tool and navigate to the environment admin screen. You'll want to check the process definitions for your servers. Ensure that VizQL processes are defined on the expected servers and with the correct port numbers.

Who can do this

To troubleshoot Tableau Server processes issues, you need to be both a Tableau Server Administrator and a Resource Monitoring Tool Administrator.

Troubleshoot User Authentication

When a Resource Management Tool user is unable to sign in to RMT, there are a few different reasons why this might happen. Your troubleshooting steps depend on what version of RMT you are using, and what kind of authentication the user is configured for.

Troubleshoot RMT user authentication issues

When a user is unable to sign into Resource Management Tool, troubleshoot the problem by verifying the following:

- Is the user name they are entering added as a user in RMT?
- What type of authentication does the user have in RMT?
  - **Local:** If the user has local auth, reset the password and give them the new one.
  - **Delegated** (Version 2023.1.0 and later):
    - If the user has delegated auth, make sure their user name is correctly entered into RMT. It should not include the domain either before or after the user name:
      - **Correct:** <username>
      - **Incorrect:** <subnet.network>\<username> or <username@<subnet>.<network>
    - Have the user confirm their credentials by signing into another system that uses their domain credentials.
    - Make sure the user is not locked out due to excessive failed sign in attempts (this is not something RMT handles; they'll need to work with their IT help desk on this).

#### Using logs to troubleshoot authentication problems

Logs for authentication issues can be found at: `\[Install Directory]\master\logs\web\tabrmt_YYYYMMDD.log`.

#### Error strings to look for:

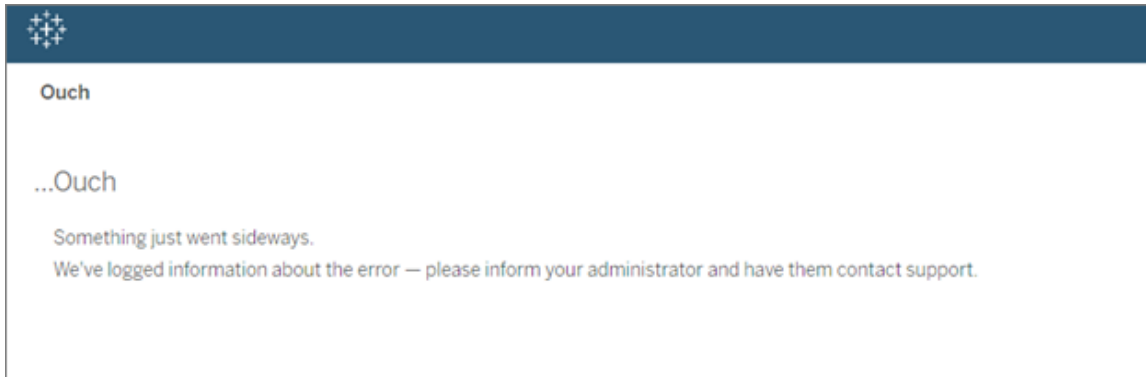

- "Invalid password for user" - A user entered the valid username, mapped to an RMT user assigned Local authentication, but provided an invalid password.
- "User failed to provide the correct password" - A user entered the correct username, mapped to an RMT user assigned delegated authentication, but provided an invalid password.
- "Executing action method \"Tableau.PowerTools.Server.Master.Web.Controllers.AuthenticationController.Login" - A sign in attempt is being made.

#### Who can do this

You need to be a Administrator on the machine and be a Resource Monitoring Tool Administrator in order to troubleshoot user authentication issues.

### Troubleshoot Web Interface Timeouts

When you try to navigate to the Tableau Resource Monitoring Tool web interface, you see the following error:

This can happen when the load time takes longer than the default 30 seconds threshold. The load time can be affected by the following:

- The size of the underlying PostgreSQL database.
- If RMT is connected to Tableau Server environments that push the current scale that RMT can support, this may also have an affect on the load times.
- Port conflict. Make sure the port Resource Monitoring Tool is suing is not in conflict with the ports that Tableau Server is using.

To resolve this issue you can either change the data retention time period or change the threshold to greater than 30 seconds.

#### **To change the data retention time period, use the following steps:**

1. Navigate to the Configuration UI as described in [this topic](#).
2. Navigate to the Data tab.

There are two types of Data Configurations:

- Data retention that is set to 2 weeks by default. It includes detailed activity data and the data displayed in the charts.

- Reporting data that is set to 10 year time period by default. It includes aggregated historical data and data used for chargeback reports.
3. Tableau recommends changing the data retention time period to 1 week.

To change the timeout threshold, use the following steps:

1. Log into the machine where the RMT Server is installed.
2. Find the "master" configuration file. The file when installed in the default location can be found at:

```
/var/opt/tableau/tabrmt/master/config.json
```

3. Add or change the key: **db:timeoutSeconds**

If you need to reduce the size of the PostgreSQL database immediately, Use the `rmtadmin` command line utility to delete the data. For more information, see [rmtadmin Command Line Utility](#) .

Who can do this

You need to be a Administrator on the machine and be a Resource Monitoring Tool Administrator in order to make configuration and database changes.

### Troubleshoot Messaging Tables Disk Usage Warnings

In rare situations you may see a disk space usage warning at the command line after running the `rmtadmin status` command:

```
Internal RMT messaging tables total disk usage is now: <nn.nn> KB.
```

A message displays when disk space reaches or exceeds the warning threshold of 4 GB.

The database usually cleans up unnecessary tables automatically, but if this warning displays, take the following steps to clean up the tables manually:

1. Stop RMT Server:

```
rmtadmin stop
```

## Tableau Server on Linux Administrator Guide

2. Start the database service:

```
rmtadmin start --db
```

3. Clean up the unnecessary tables:

```
rmtadmin query "DROP SCHEMA hangfire CASCADE;" --outfile=drop_
hangfire_schema_output.zip --commit
```

4. Start RMT Server:

```
rmtadmin start
```

Who can do this

You need to be a Resource Monitoring Tool Administrator in order to run the necessary commands.

## Upgrade Power Tools for Server to Tableau Resource Monitoring Tool

Power Tools Server has been rebranded to Tableau Resource Monitoring Tool. The installer has been changed to reflect this rebranding and new ownership. This means the product will install side-by-side with the legacy InterWorks product instead of upgrading it in place.

The 2019.3 version of Power Tools Server (now named the Tableau Resource Monitoring Tool) requires a license key. For information about activating the license key, see [Tableau Resource Monitoring Tool Legacy License Key Activation](#).

Follow these steps to upgrade to Resource Monitoring ToolThe recommended steps to upgrade are:

1. Stop all installed InterWorks agents.
2. Wait for the data processing to complete.
3. Stop and uninstall InterWorks master server.
4. Run the Tableau RMT Server installer to install Tableau RMT server.

5. Stop Tableau RMT server.
6. Copy over *config/config.json* from InterWorks RMT Server directory to Tableau RMT Server directory.
7. If you are using Postgres as your database, the following steps are necessary for the database to function with the security improvements in 2019.3. If using any other database, skip to step 8.

Postgres SQL Update Instructions:

- Locate the *postgres pg\_hba.config* file. It will be at *<PTS installation directory>\data\postgresql\pg\_hba.config*.
  - Edit the *pg\_hba.config* file, entries at the end will look like this: host all all 127.0.0.1/32 trust. Change the last column for all lines from **trust** to **md5**. So the new line should look like this: host all all 127.0.0.1/32 md5.
  - Save the *pg\_hba.config* file.
  - Restart the PTS postgresql service.
8. Restart Tableau RMT Server.
  9. Run the Tableau Agent installers to install Tableau agents.
  10. Stop Tableau Agents.
  11. Copy over *config/config.json* from InterWorks agent directory to Tableau Agent directory.
  12. Once the Tableau Resource Monitoring Tool installation is complete, and you have confirmed it is working as expected, uninstall the InterWorks/Tableau Power Tools for Server.

## Tableau Server on Linux Administrator Guide

### Tableau Resource Monitoring Tool Legacy License Key Activation

The 2019.3 version of Power Tools Server (now named the Tableau Resource Monitoring Tool) requires a license key. The instructions below provide the steps to activate this key:

1. The license key will be passed over as a file in format *.dat*.
2. The *.dat* file needs to be added to the config directory of the Master Server.

*The default location is: C:\Program Files\Tableau\Tableau Resource Monitoring Tool\master\config.*

3. Restart the Master Server service:

Navigate to **Windows Server Manager** and restart the **Tableau Resource Monitoring Tool** service.

## About Tableau Content Migration Tool

This set of articles guides you through setting up, using, and maintaining the Tableau Content Migration Tool.

### What is Content Migration Tool?

The Content Migration Tool provides an easy way to copy or migrate content between Tableau Server sites. You can do this between sites on a single Tableau Server installation, or if you have user-based licensing, between sites on separate installations (for example, between a development instance of Tableau Server and a production installation). The Content Migration Tool user interface walks you through the steps necessary to build a "migration plan" that you can use once or as a template for multiple migrations.

Before migrating content, we recommend reviewing the [Content Governance](#) section in Tableau Blueprint.

## Help and Support

If you have problems that you cannot solve with this documentation, contact [Tableau Technical Support](#).

## Getting Started with Tableau Content Migration Tool

This article will help you get started with the Tableau Content Migration Tool. It contains links to other articles about information you need to prepare before installing the Content Migration Tool, and steps to design a migration plan and upgrade existing installations.

### Pre-installation

#### Installation requirements

The Content Migration Tool can only be installed on Windows operating systems. Before installing, you must be able to connect to the Tableau source site (the site you are migrating from) and the destination site (the site you are migrating to) from the computer where Content Migration Tool is installed. Both the source and destination sites must have a valid [Advanced Management](#) license. For more information about installing and upgrading Content Migration Tool, see [Install Tableau Content Migration Tool](#).

#### Compatibility with Tableau Server

The Content Migration Tool supports content migration for Tableau Server versions 2019.3 and later.

The table lists compatible versions of Tableau Server based on the installed version of Content Migration Tool.

| CMT Version | Tableau Server Version |
|-------------|------------------------|
| 2024.1x     | 2022.1x - 2024.1x      |
| 2023.1.x    | 2021.2.x - 2023.1.x    |
| 2022.4.x    | 2021.1.x - 2022.4.x    |

| CMT Version | Tableau Server Version |
|-------------|------------------------|
| 2022.3.x    | 2020.4.x - 2022.3.x    |
| 2022.2.x    | 2020.3.x - 2022.2.x    |
| 2022.1.x    | 2020.2.x - 2022.1.x    |
| 2021.4.x    | 2020.1.x - 2021.4.x    |
| 2021.3.x    | 2019.4.x - 2021.3.x    |
| 2021.2.x    | 2019.3.x - 2021.2.x    |
| 2021.1.x    | 2019.3.x - 2021.1.x    |
| 2020.4.x    | 2019.3.x - 2020.4.x    |
| 2020.3.x    | 2019.3.x - 2020.3.x    |

#### Compatibility with Tableau Cloud

Content Migration Tool version 2022.2.1 and later support content migration for all Tableau Cloud deployments. We recommend installing the most recent version from the [Tableau Advanced Management](#) downloads page to take advantage of the latest features and fixes.

#### Compatibility with Tableau content

The Content Migration Tool supports migrating workbooks and published data sources saved in the eight most recent versions of Tableau. While you can migrate existing data sources, only data sources that use the connection types in the table below can be changed and modified during migration. For more information, see [Data Source Transformations in Migration Plans: Workbooks and Migration Plans: Published Data Sources](#).

|                   |                         |                            |
|-------------------|-------------------------|----------------------------|
| Action Matrix     | Google Drive            | Pivotal Greenplum Database |
| Action Vectorwise | HortonWorks Hadoop Hive | PostgreSQL                 |
| Amazon Athena     | HP Vertica              | Progress OpenEdge          |

|                     |                             |                               |
|---------------------|-----------------------------|-------------------------------|
| Amazon Aurora       | IBM DB2                     | Salesforce                    |
| Amazon EMR          | IBM Netezza                 | SAP HANA                      |
| Amazon Redshift     | Map R Hadoop Hive           | SAP Sybase ASE                |
| Apache Drill        | Microsoft Access            | SAP Sybase IQ                 |
| Aster Database      | Microsoft Analysis Services | Snowflake                     |
| Box                 | Microsoft Excel             | Spark SQL                     |
| Cloudera Hadoop     | Microsoft Excel Direct      | Statistical File              |
| Delimited Text File | Microsoft OneDrive          | Tableau Extract               |
| EXASOL              | Microsoft SQL Server        | Tableau Published Data Source |
| Firebird            | MySQL                       | Teradata                      |
| Google Analytics    | OData                       | Text File                     |
| Google BigQuery     | Oracle                      | Web Data Connector            |

## Post-installation

### Limitations when migrating content

Before you start, make sure you understand the limitations when migrating content using the Content Migration Tool. For more information, see [Migration Limitations](#).

### Create a migration plan

The Content Migration Tool walks you through migrating content across projects on a single site, to a new site on the same Tableau Server instance, and to sites that exist on different Tableau Server instances. The plan you create can be saved and used again for future migrations. For more information, see [Migration Plan Overview](#).

## Install Tableau Content Migration Tool

Installing Tableau Content Migration Tool is straightforward and easy.

### Installation requirements

The Content Migration Tool tool is run from a Windows computer and can connect to Tableau Cloud sites and Tableau Server 19.3 and later with a valid Advanced Management license. For more information about compatible versions, see [Getting Started with Tableau Content Migration Tool](#).

The computer that you install Content Migration Tool on must meet the requirements below:

- Microsoft Windows 10 or newer (x64)
- Intel Core i3 or AMD Ryzen 3 (Dual Core)
- 4 GB memory or larger
- Can connect to the source and destination sites. Both sites must have a valid [Advanced Management](#) license to migrate content.
- 2 GB HDD or larger. The drive where the `\temp` folder resides must have enough disk space to hold a copy of all content being migrated in a single migration. All content is stored locally on the disk and deleted when the migration is complete.
- Have enough free disk space to hold the application and its logs.

In addition, confirm that the REST API is enabled on Tableau Server (this is the default). Use the `tsm configuration get -k api.server.enabled` command to confirm this. A return value of `true` means the REST API is enabled. To enable the REST API, use the `tsm configuration set` command. For more information, see [api.server.enabled](#).

### Install Content Migration Tool

To install the Content Migration Tool:

1. Download the Content Migration Tool installer (`Tabcmt-64bit-<version>.exe`) for your version of Tableau Server from the [Tableau Advanced Management](#) downloads page.

2. Run the Content Migration Tool Setup program.

**Note:** Running the Content Migration Tool Setup program overwrites the previous version.

3. After reading the EULA, select **I agree to the license terms and conditions**, and click **Install**.
4. If the User Account Control dialog opens, click **Yes** to allow the installer to make changes.

### Upgrade Content Migration Tool

Upgrading to the latest version of Content Migration Tool ensures that you can take advantage of the latest features and fixes included with each new version.

#### **Important:**

- Running the Content Migration Tool Setup program overwrites the previous version.
- Content Migration Tool doesn't support side-by-side installation of previous versions.

To upgrade Content Migration Tool:

1. Log on to the machine where Content Migration Tool is installed. If there are instances of Content Migration Tool open, save your migration plan and exit the application.
2. Follow the steps listed in [Install Content Migration Tool](#) to download the latest installer and complete the upgrade.

### Install Content Migration Tool from the command line

You can install Content Migration Tool from the command line if you're a local administrator on the machine.

#### Install switches

Specify one or more switches in the command line for the installer. For example:

```
Tabcmt-64bit-2022-3-0.exe /quiet /norestart
```

| Switch   | Description  | Comments   |
|--|--|--|
| <code>/install repair uninstall /layout "&lt;directory&gt;"</code> | Run Setup to either install, repair, or uninstall Content Migration Tool, or with <code>/layout</code> , create a complete local copy of the installation bundle in the directory specified. | Default is to install, displaying UI and all prompts. If no directory is specified on a fresh install, <code>C:\Program Files\Tableau\Tableau Content Migration Tool</code> is assumed. If Content Migration Tool is already installed, Setup assumes the same location as the current installation. |
| <code>/passive</code>  | Run Setup with minimal UI and no prompts.  | Content Migration Tool doesn't start automatically when installed in <code>/passive</code> mode. To start Content Migration Tool, open the application manually.   |
| <code>/quiet /silent</code>  | Run Setup in unattended, fully silent mode. No UI or prompts are displayed.  | Content Migration Tool doesn't start automatically when installed in <code>/silent</code> or <code>/quiet</code> mode. To start Content Migration Tool, open the application manually.<br><br><b>Note:</b> Use either <code>/silent</code> or <code>/quiet</code> , not both.                        |
| <code>/norestart</code>  | Run Setup without restarting Windows, even if a restart is necessary.  | <b>Note:</b> In certain rare cases, a restart cannot be suppressed, even when this option is used. This is most likely when an earlier system restart was skipped, for example, during installation of other software.   |

Who can do this

A user with Administrator access on the machine.

## Using Tableau Content Migration Tool

The following steps are designed to guide you through using the Tableau Content Migration Tool:

- Migration Plan Overview
  - Migration Plans: Sites
  - Migration Plans: Source Projects
  - Migration Plans: Workbooks
  - Migration Plans: Published Data Sources
  - Migration Plans: Permissions and Ownership
  - Migration Plans: Migration Scripts
  - Migration Plans: Plan Options
- Using the Tableau Content Migration Tool Console Runner

## Tableau Content Migration Tool Use Cases

Tableau Content Migration Tool as the name suggests, is primarily used for moving Tableau Server content from one site to another. However, there are many features in the tool that makes it ideal for accomplishing several tasks related to content migration and maintenance.

**Note:** In many of the use cases we use the term migration to describe moving content from one environment, site, or project to another. However, technically the Content Migration Tool copies content and does not automatically delete or archive the original or source content.

The information below describes some common use cases where you can leverage the Content Migration Tool.

### Content promotion

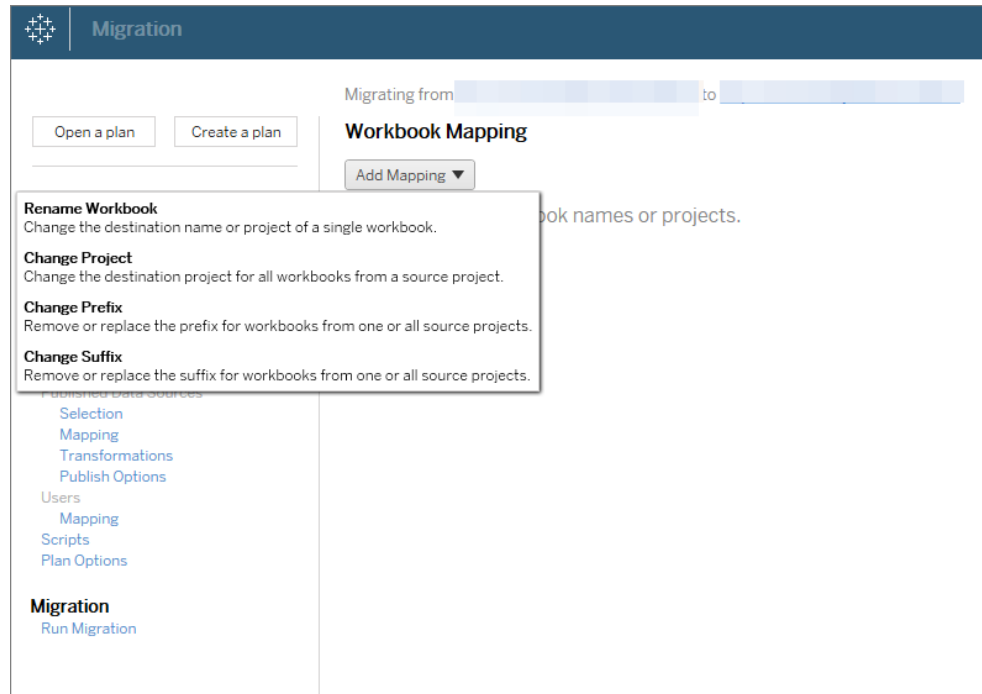

You can use the Content Migration Tool to create content for development sites and then perform routine migrations to promote content to staging or production environments.

#### **Use the following steps to promote content to production environments:**

1. **Create a plan** and select the site used for development as the source and the staging or production site as the destination. For more information, see [Create a Plan in Migration Plan Overview](#) topic.

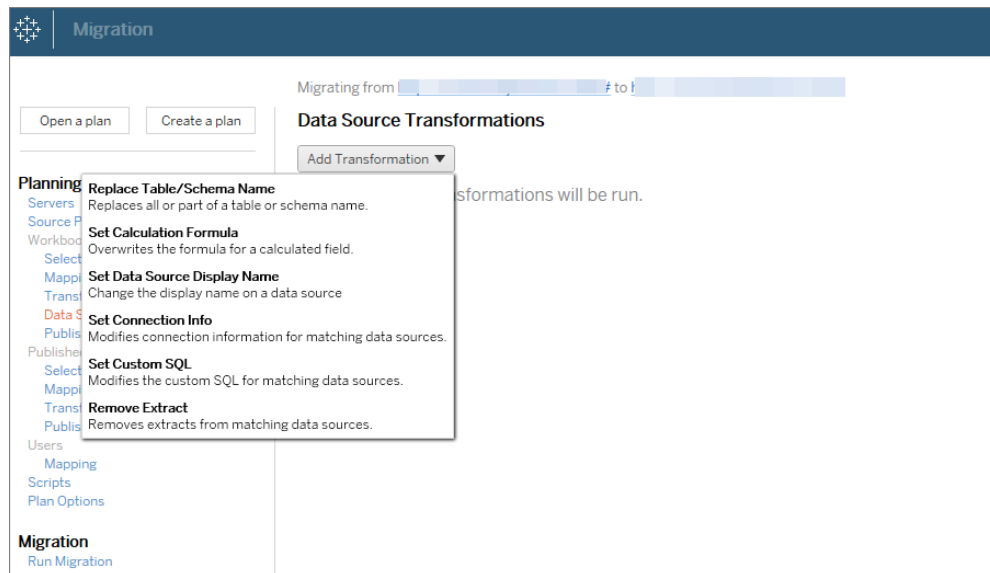

When migrating your workbooks between two projects on the same site, your sign-in credentials for the source and destination may be similar or identical. In this scenario, we recommend using personal access tokens for a more reusable connection. For more information, see [Personal Access Tokens](#).

2. **Select the content** you want to migrate from your source site. You can select entire projects, specific workbooks and data sources, and user permissions. For more information, see [Planning in Migration Plan Overview](#) topic.
3. If you need to make any **changes or transformations** to the content during this migration, you can configure that in the plan as well. This is referred to as **Mapping**. The types of mapping you can make include:
  - **Changes to workbooks:** Includes renaming workbooks and changing the destination project. For a full list of workbook transformations, see [Migration Plans: Workbooks](#).

- **Changes to data sources:** Includes replacing table or schema names, settings calculation formulas, and setting connection information. For a full list of data source transformations, see Migration Plans: Workbooks (embedded data sources) and Migration Plans: Published Data Sources (published data sources).

- **Changes to Users:** Includes domain, user, and group name changes in the destination.
4. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.
  5. **To schedule** this to run regularly, you can [script this as a job](#) using the Content Migration Tool Runner and schedule it. For more information on using the Content Migration Tool Runner, see [Using the Tableau Content Migration Tool Console Runner](#).

### Tailoring content for customers

When working in a consulting scenario, you can customize content for each of your customers using the Content Migration Tool. Each workbook functions as a template for your migration plan, allowing you to apply styling (text, images, etc.) and replace data sources for specific customers.

### Use the following steps to customize content for your customers:

1. **Create a plan** and select the production site as the source and the customer site as the destination. For more information, see [Create a Plan in Migration Plan Overview](#) topic.

2. **In the Workbooks** step of the Migration Plan, use workbook mappings and transformations to customize your content. Below are two examples of frequently used transformations. For a full list of workbook transformations, see Migration Plans: Workbooks.
  - To personalize content, you can use the **Replace Image** and **Replace Text** transformations to update the workbook with a customer's company name and logo.
  - When it comes to data sources, you can use the **Replace Table/Schema Name** or **Set Custom SQL** transformations to modify content for your customer.
3. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.

### Environment migration

You can use the Content Migration Tool to migrate content between Tableau Server environments.

### Use the following steps to migrate content between Tableau deployments:

1. **Create a plan** and **select the site** you want to migrate from as your source. For more information, see Create a Plan in Migration Plan Overview topic.
2. **Select the content** you want to migrate from your source site. You can select entire projects, specific workbooks and data sources, and user permissions.
3. **Create user permissions mappings** to customize and secure content. For more information, see Migration Plans: Permissions and Ownership.

4. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.

### Tips

- Before you perform an environment migration, make sure you understand the Migration Limitations when using the Content Migration Tool.
- You can migrate your content in stages, test and validate content iteratively before final migration is complete. There is no server downtime when you use this method of migration. It can be a replacement for Site import/export.
- Content Migration Tool migration does not handle embedded credentials, subscriptions, and custom views. These will have to be migrated manually.

### External content sharing

You can use the Content Migration Tool to share internal content with external collaborators, without allowing access to your site. This keeps your data secure and allows you to publish only select workbooks and data sources. Once content has been shared, collaborators sign in

to their Tableau Server site to view and make changes, without affecting content stored on your internal server.

Before you continue, make sure the content you share is compatible between the internal (source) and external (destination) sites. The external site should be running the same version of Tableau as the internal site or later. For more information about compatibility, see [Make Workbooks Compatible Between Versions](#) in Tableau Desktop help.

**Use the following steps to share content externally:**

1. **Work with** the external site administrator to determine a user account that has publishing rights on the site. You will use this user account to create the migration plan. For more information, see [Set Users' Site Roles and Permissions](#).
2. **Prepare internal content.** As a best practice, we recommend separating content on the internal server to a project, with locked permissions and strict governance rules. Workbooks and data sources should be clearly labeled to indicate the content is for external use. For more information, see [Use Projects to Manage Content Access](#).

**Note:** Content shared with external sites must use data extracts unless the data source is publicly accessible. For information about creating extracts and replacing data sources, see [Extract Your Data](#) and [Replace Data Sources](#) in Tableau Desktop help.

If you have implemented row level security, those data sources must be updated to reflect user filters and other details for the external site. For more information about row level security, see [Restrict Access at the Data Row Level](#) in Tableau Desktop help.

3. **Create a plan** and select the internal site as the source and the external site as the destination. For more information, see [Create a Plan in Migration Plan Overview](#) topic.

4. **Select the content** you want to share with the external site. You can select entire projects, specific workbooks and data sources, and user permissions.
5. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.

#### Validating database migrations

This use case is when you intend to validate content after a migration of the underlying databases. One example of database migration is moving from SQL Server to Snowflake. CMT can help you validate the content built from both data sources is the same before you finalize your migration, but it cannot perform the actual database migration.

#### Use the following steps to validate database migrations:

1. **Create a plan** and select the Tableau site to use as your source. In this example, we describe a migration between projects on the same Tableau site, so select the same site for your destination. For more information, see [Create a Plan in Migration Plan Overview](#) topic.
2. **Configure the migration** to copy your content to a new project. Let's call the **source** project as **Project A**, and the new or the **destination** project as **Project B**.
  - Changes to workbooks: Create a workbook mapping to change Project A to Project B. For a full list of workbook transformations, see [Migration Plans: Workbooks](#).
  - Changes to data sources: Create a data source mapping to change the Project A to Project B. For a full list of data source transformations, see [Migration Plans: Published Data Sources](#).
3. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.
4. **Update the content** in **Project B** with the new database connections or replace the data sources. This needs to be done manually by authoring.

5. **Test each workbook** in **Project A** with the copy in **Project B** and review for any inconsistencies in the data due to the change in data source.
6. Once you have confirmed everything is working as expected, **overwrite the content** in Project A with the updated content in Project B.

**Note:** If the content already exists in the destination project and you do not select the **Overwrite Newer Workbooks** and **Overwrite Newer Data Sources** publish options, the content will not be copied to the destination project.

### Geographical content migration

If you are maintaining a geographically distributed, multi-site environment, you will need some of this content to be shared and accessible across all the servers. This use case describes how to migrate content between servers in different geographies. The server can be in the same country or across continents.

#### **Best Practices:**

- We recommend prioritizing the content that you most need. Content Migration Tool shouldn't be used to copy entire server environments to multiple geographies.
- We recommend migrating content in one direction only meaning Primary to Secondary. Here we use the term Primary to indicate the source site and Secondary to indicate the destination. You can have one or more destination by creating multiple migration plans.

#### **Use the following steps to migrate between Tableau Server that are distributed in different geographies:**

1. **Create a plan** and select the Primary site as the source and the secondary site as the destination. For more information, see Create a Plan in Migration Plan Overview topic.
2. **Select content** that you want to share between the Primary and Secondary.

3. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.
4. **To schedule** this to run on regularly, you can **script this as a job** using the Content Migration Tool Runner and schedule it. For more information on using the Content Migration Tool Runner, see, Using the Tableau Content Migration Tool Console Runner.
5. **Review the content** on the source **periodically** to determine if new items should be added to the migration plan.

### Consolidate sites

If you need to combine the content of multiple sites into a single site (if, for example, organizational restructuring has changed how your sites should be arranged), you can use the Content Migration Tool to do this.

**Note:** Before consolidating sites, make sure you understand the limitations when migrating content using the Content Migration Tool. For more information, see Migration Limitations.

Use the following steps to copy all the workbooks and data sources from one site to another:

1. Create a plan and select the site you want to consolidate as the source. For more information, see Create a Plan in Migration Plan Overview topic.
2. On the Source Projects page, select **All Projects** and click **Next**.

If a project with the same name exists on the destination site, the content will be migrated to the same folder.

3. On the Project Options page, select your preferences for the destination site and click **Next**.

If the content already exists in the destination project and you do not select the overwrite option, the content will not be copied to the destination project.

4. On the Workbook Selection screen, select **All Workbooks**.
5. (Optional) If you are copying published data sources:
  - From the left navigation menu, under Published Data Sources, click **Selection**.
  - Select **All Data Sources**.
6. Click **Run Migration** and review the migration plan. When you're ready, click **Run** at the bottom of the screen to run the migration.

Repeat these steps until you've consolidated all sites. For more information, see Planning in Migration Plan Overview topic.

#### Maintenance tasks

You can use the Content Migration Tool to perform a variety of maintenance tasks.

#### Tagging stale content

Using the Content Migration Tool, you can manage archiving stale content. For example, you can build a plan that runs on a regular schedule that can automatically pick up content tagged as Stale Content and move it to an Archive project. After a certain amount of time, the content in this project can be purged from the system. For more information see, Migration Plans: Workbooks.

#### Restoring content

You can use the Content Migration Tool to restore content removed (accidentally or purposefully) from the production Tableau Server with content from a backup server. The restoration process is simple and does not require downtime, compared to restoring with a backup file.

**Use the following steps to restore content from a backup server:**

## Tableau Server on Linux Administrator Guide

1. **Create a plan** and select the backup Tableau Server as the source and the production server as the destination. For more information, see [Create a Plan in Migration Plan Overview](#) topic.
2. **Select the content** you want to restore from the backup Tableau Server.
3. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.
4. **Review the content** on the production server.

### Partial backup

Once you have a backup Tableau Server environment, you can use the Content Migration Tool to transfer new content from production to the backup Tableau Server. If you have not configured a backup Tableau Server environment, see the [Disaster Recovery for Tableau Server](#) whitepaper for more information.

#### Notes:

- Before you perform a partial backup, make sure you understand the Migration Limitations when using the Content Migration Tool. You may still need to periodically perform a full backup and restore to backup all Tableau Server content. For more information, see [Perform a Full Backup and Restore of Tableau Server](#).
- The Content Migration Tool shouldn't be used to perform your first backup.

### Use the following steps to perform a partial backup of your content:

1. **Create a plan** and select the backup Tableau Server as the source and the production server as the destination. For more information, see [Create a Plan in Migration Plan Overview](#) topic.
2. **Select the content** you want to backup. You can select entire projects, specific workbooks and data sources, and user permissions. To migrate only new content, make sure

the publish options **Overwrite Newer Workbooks** and **Overwrite Newer Data Sources** are not selected. For more information, see Migration Plans: Workbooks.

3. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.
4. **To schedule** this to run on a regular basis, you can script this as a job using the Content Migration Tool Runner and schedule it. For more information on using the Content Migration Tool Runner, see Using the Tableau Content Migration Tool Console Runner.

## Migration Plan Overview

Tableau Content Migration Tool creates a streamlined process for migrating Tableau content between sites and projects. The easy-to-follow plan can be audited, is repeatable, and works via a batch process so any number of workbooks and data sources can be migrated in a simple and efficient process.

The Content Migration Tool will display contextual tips to walk you through creating or editing a migration plan. Once you select the source and destination sites, a summary of your migration will be displayed at the top of the screen as follows:

Migrating from <http://admin@win-vj23dhvudie:80/#/site/Accounting-sandbox> to <http://admin@win-vj23dhvudie:80/#/site/Accounting>

### Limitations when migrating content

Before you start, make sure you understand the limitations when migrating content using the Content Migration Tool. For more information, see Migration Limitations.

### Encryption keys

Each migration plan file is generated with an encryption key unique to the application that created the plan. Encryption keys can be shared if the migration plan needs to be run through an application that did not originally generate the file. When sharing encryption keys, you will need to overwrite the existing key in the application to run the migration plan. To view your encryption key, select **Help > Settings**.

If you will be using the Content Migration Tool Console Runner for migration plans, you must specify the encryption key using the `tabcmt-runner encryption` command before running the plan. For more information, see Using the Tableau Content Migration Tool Console Runner.

### Migration process

#### Step 1: Start

The core of the migration process is creating a plan, which you can save and re-use for future migrations or modify and update as needed. The first step is choosing whether to create a new plan, or select a previously saved plan.

To create a new plan, click **Create New Plan**. If you already created a migration plan and want to use it, click **Browse for a Plan**.

By default, all of your saved migration plans will be stored in the `Tableau Content Migration Tool Plans` folder in your My Documents folder. All migration plans are saved with a `.tcmx` extension, with recently accessed plans listed separately to make them easy to select:

| Recent Plans   | Last Updated      |
|--|-------------------|
| <b>DefaultToDefault2.tcmx</b><br>C:\Users\jsmith\Documents\Tableau Content Migration Tool Plans\DefaultToDefault2.tcmx | 7/12/2019 6:25 PM |

You can select a recently accessed plan and duplicate it to modify the plan and save it as a new plan. Select the plan you want to copy and click **Duplicate**.

## Step 2: Planning

The Content Migration Tool guides you through building or editing your migration plan in six steps.

Click on each step for detailed instructions:

- Migration Plans: Sites
- Migration Plans: Source Projects
- Migration Plans: Workbooks
- Migration Plans: Published Data Sources
- Migration Plans: Permissions and Ownership
- Migration Plans: Migration Scripts
- Migration Plans: Plan Options

## Step 3: Migration

Once you have completed your plan, you are now ready to run the batch process for migration. When you reach the final step of the migration, a plan summary displays for your verification:

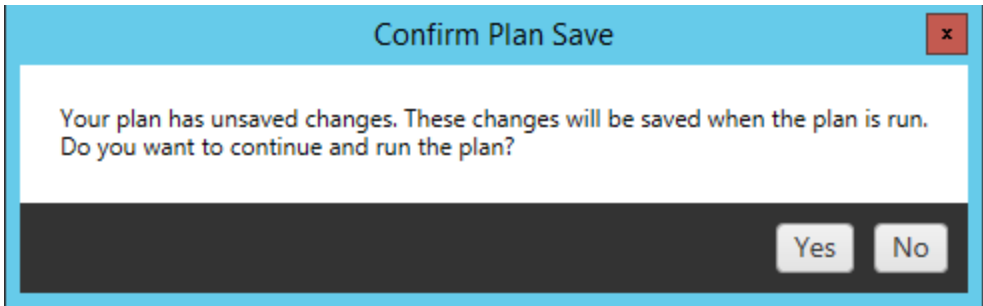

### Review

Need help? 

|                         |   |
|-------------------------|---|
| Source:                 | http://admin@win-vj23dhvudie:80/#/site/Accounting-sandbox |
| Destination:            | http://admin@win-vj23dhvudie:80/#/site/Accounting         |
| Projects:               | Default<br>Mkt-Q3<br>Mkt-Q4                               |
| Workbooks:              | Test Data - 2019 [Project: Mkt-Q4]                        |
| Published Data Sources: | All data sources  |
| Auto Archive:           | No  |

If you want to change any aspects of your plan, you can click on a section in the left sidebar to go directly to that phase. When you are ready, click **Run** to begin your migration.

When you click **Run**, the migration tool will prompt you about any unsaved elements of your plan. By default, any unsaved elements will be saved when you click **Yes**. Remember you can always keep your previous plan without making any changes by duplicating it during the Start phase of the migration process.

Your migration plan will run and a status bar displays for the overall plan progress and each workbook being sent to the destination server.

**Running...**Need help? 

Downloading Source Workbooks

Test Data - 2019

When the plan finishes running, you can click the tabs at the bottom of the screen for more information about the migration.

## Published workbooks

**Published Workbooks** details the newly published workbooks and the projects where they were migrated.

| Published Workbooks | Published Data Sources | Output | Errors and Warnings                    |
|---------------------|------------------------|--------|--|
| Workbook            | Project                |        |  |
| Test Data - 2019    | Mkt-Q4                 |        | <a href="#">View on Tableau Server</a> |

## Published data sources

**Published Data Sources** details the newly published data sources and the projects where they were migrated.

## Output

The **Output** tab details the migration log of your plan.

You can save this log by clicking **Save Log**.

## Errors and warnings

The **Errors and Warnings** tab highlights any problems that occurred during the migration.

|   | Message  | Workbook or Data Source | Project |
|---|--|-------------------------|---------|
| ⊗ | Destination project [Mkt-Q4] does not exist. To avoid this error, enable automatic destination project creation in Options or create the project manually. |                         |         |
| ⊗ | Migration failed.  |                         |         |

You can correct these and rerun your plan. When you have completed your migration and saved your plan, click **Done** to finish.

### Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see [Permissions](#).

### Migration Limitations

There are certain limitations to migrations when using the Tableau Content Migration Tool. Before creating your migration plan, review the sections below to learn about version compatibility and content that will not be migrated.

#### Compatibility with Tableau content

The Content Migration Tool supports migrating workbooks and published data sources saved in the eight most recent versions of Tableau. Workbooks and published data sources saved before version 2018.1.x are not supported by CMT. For more information, see [Getting Started with Tableau Content Migration Tool](#).

#### Configurations

The following configurations are not migrated to the destination site when using the Content Migration Tool.

- [Users](#)
- [Groups](#)
- [Site settings \(custom logos, view recommendations, etc.\)](#)

#### Data connections

While you can migrate existing data sources, only data sources that use the connection types in the table below can be changed and modified during migration. For more information, see

## Tableau Server on Linux Administrator Guide

Data Source Transformations in Migration Plans: Workbooks and Migration Plans: Published Data Sources.

|                     |                             |                             |
|---------------------|-----------------------------|-----------------------------|
| Action Matrix       | Google Drive                | Pivotal Greenplum Database  |
| Action Vectorwise   | HortonWorks Hadoop Hive     | PostgreSQL                  |
| Amazon Athena       | HP Vertica                  | Progress OpenEdge           |
| Amazon Aurora       | IBM DB2                     | Salesforce                  |

| Aster Database      | Microsoft Analysis Services | Snowflake                   |
| Box                 | Microsoft Excel             | Spark SQL                   |
| Cloudera Hadoop     | Microsoft Excel Direct      | Statistical File            |
| Delimited Text File | Microsoft OneDrive          | Tableau Extracts            |
| EXASOL              | Microsoft SQL Server        | Tableau Server Data Sources |
| Firebird            | MySQL                       | Teradata                    |
| Google Analytics    | OData                       | Text File                   |
| Google BigQuery     | Oracle                      | Web Data Connector          |
| Google Cloud SQL    | Oracle Essbase              | Other Databases (ODBC)      |

Unsupported content

The following content is not migrated to the destination site when using the Content Migration Tool and will require additional configuration.

| Content                        | Action required  |
|--------------------------------|--|
| Ask Data lenses                | Users must recreate Ask Data lenses on the destination site. For more information, see <a href="#">Create Lenses that Focus Ask Data for Specific Audiences</a> .  |
| Collections                    | Users must recreate collections on the destination site. For more information, see <a href="#">Collections</a> in Tableau Desktop help.  |
| Comments                       | Users must re-add comments to views on the destination site. For more information, see <a href="#">Comment on Views</a> in Tableau Desktop help.   |
| Custom views                   | Users must recreate custom views on the destination site. For more information, see <a href="#">Use Custom Views</a> in Tableau Desktop help.  |
| Data roles                     | Users must recreate data roles on the destination site. For more information see <a href="#">Use Data Roles to Validate your Data</a> in Tableau Prep Builder help.  |
| Data source certifications     | <p>If you have the following site roles and capabilities, you can certify data sources on the destination site.</p> <ul style="list-style-type: none"> <li>• Site Administrator Creator</li> <li>• Creator or Explorer (can publish) with Project Leader capability on the project containing the data source</li> </ul> <p>For more information, see <a href="#">Use Certification to Help Users Find Trusted Data</a>.</p> |
| Data-driven alerts             | <p>Users must recreate data-driven alerts for dashboards and views on the destination site. After data-driven alerts are created, anyone with access to the view can add themselves to existing alerts.</p> <p>For more information, see <a href="#">Send Data-Driven Alerts from Tableau Cloud or Tableau Server</a> in Tableau Desktop help.</p>   |
| Descriptions for workbooks and | If you own the content item or have the appropriate permissions, you can edit the item's description on the destination site. For more inform-   |

|   |  |
|---|--|
| data sources  | ation, see <a href="#">Add or edit descriptions</a> in Tableau Desktop help.   |
| Embedded credentials  | <p>For security purposes, Tableau Server removes embedded credentials from data sources during the download process.</p> <ul style="list-style-type: none"><li>• To include embedded credentials when migrating from Tableau Server to Tableau Cloud, use the Migrate Embedded Credentials for Workbooks and Migrate Embedded Credentials for Data Source publish options. For more information, see <a href="#">Migrate Workbooks and Data Sources with Embedded Credentials</a>.</li><li>• To include embedded credentials when publishing to Tableau Server sites, use the Set Connection Info data source transformation. For more information, see <a href="#">Migration Plans: Published Data Sources</a>.</li></ul> |
| <p><b>Note:</b> CMT does not support embedded credential migration for OAuth connections. To migrate OAuth credentials, use the Set Connection Info data source transformation.</p> |  |
| External assets   | Customized attributes for external assets are not migrated to the destination site. For example, tags, certifications, data quality warnings, descriptions, permissions, user contacts, tables, and columns must be recreated. For more information, see <a href="#">Manage Permissions for External Assets</a> .  |
| Extract refresh schedules   | Extract refresh schedules cannot be migrated to Tableau Cloud destination sites. To refresh data on Tableau Cloud, you can run extract refreshes manually or create new extract refresh schedules. For more information, see <a href="#">Schedule Refreshes on Tableau Cloud</a> .   |
| Favorites   | Users must reselect their favorite content on the destination site. For more information, see <a href="#">Mark Favorites</a> in Tableau Desktop help.  |
| Flows   | To run flows on a schedule, users must republish flows to the des-   |

destination site with Tableau Prep. For more information, see [Publish a Flow to Tableau Server or Tableau Cloud](#) in Tableau Prep help.

|                                    |   |
|------------------------------------|---|
| Incremental extract refreshes      | Incremental extract refreshes are changed to full extract refreshes on the destination site. Users must reconfigure incremental refreshes in Tableau Desktop and publish extracts to the destination site after migration. For more information, see <a href="#">Refresh Extracts</a> in Tableau Desktop help.  |
| Metrics                            | The historical values for metrics are removed from views, and users must recreate metrics on the destination site. For more information, see <a href="#">Create and Troubleshoot Metrics (Retired)</a> . The legacy Metrics feature was retired in February 2024 for Tableau Cloud and in Tableau Server version 2024.2. For more information, see <a href="#">Create and Troubleshoot Metrics (Retired)</a> .  |
| Revision history                   | To migrate previous versions of workbooks to the destination site, users must download the versions they wish to keep and republish the workbook to the destination site. For more information see <a href="#">Work with Content Revisions</a> in Tableau Desktop help.   |
| Subscriptions                      | Users must resubscribe to views and workbooks on the destination site. For more information, see <a href="#">Create a Subscription to a View or Workbook</a> .  |
| Thumbnails for workbooks and views | <p>Workbooks and views that are migrated using the Content Migration Tool will retain their original thumbnails, even if the migration plan includes transformations that result in the views being rendered differently (for example, if data connections change).</p> <p>To update thumbnails, edit the workbook or view on the destination site and re-save it. For more information, see <a href="#">Edit Tableau Views on the Web</a> in Tableau Desktop help.</p> |
| Virtual connections                | Users must recreate virtual connections on the destination site. For more information, see <a href="#">Create a Virtual Connection</a> .  |

### Migration Plans: Sites

The first step when creating a migration plan in the Tableau Content Migration Tool is to sign in to the source and destination sites.

In the Sites section of the planning phase, you'll sign in to the source and destination sites. The permissions of the user credentials you use govern the sites and projects you see when creating a migration plan. You can only migrate content that the user has access to.

The screenshot shows a user interface for configuring migration sites. It is divided into two main sections: 'Source' on the left and 'Destination' on the right. Each section contains a large rectangular area with the text 'Select a connection for your source' (or 'destination') centered inside. Below this text, in each section, is a button labeled 'Sign in to Tableau'.

### Required permissions and licenses

The user account(s) used to sign in to the source and destination sites must have an Explorer role or higher, and the following permissions for the content you want to migrate:

- View
- Download Workbook/Save a Copy
- Optional: Administrator (to select workbooks, to access a user list)

Both the source and destination sites must have a valid Advanced Management license. For more information, see [About Tableau Advanced Management on Tableau Server](#).

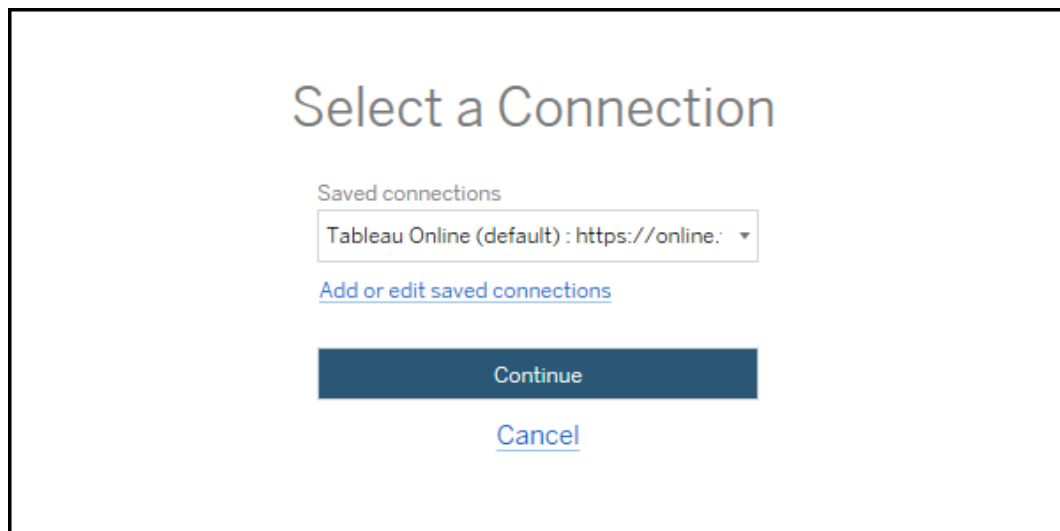

## Step 1: Source

Here is the starting point of the migration. Sign in to Tableau Server , then select your *site* to use as the source. Sites are independent silos of workbooks, data, and user lists created within Tableau to group related content for selected users. You can only migrate content from one site at a time.

## Sign in to the source site

Use the steps below to sign in to Tableau Cloud or Tableau Server. For more information about signing in to Tableau Cloud with Single Sign-On and Tableau with MFA, see [Sign In to Tableau Cloud](#).

1. Click **Sign in to Tableau**.
2. In the **Select a Connection** dialog window, select a saved connection and click **Continue**.

If no connections are available, click **Add or edit saved connections** to add a new connection. For more information, see [Saved connections](#).

3. Enter your username and password, and click **Sign In**.

If your server is configured for SAML or Single Sign-On, you are redirected to the Identity Provider sign-in page to complete the authentication process.

4. Select the site you want to use.

To change the source server or update your site selection, click **Select a different source**.

### Step 2: Destination

Repeat the sign-in process for the destination site (the site you are migrating content to).

If you are migrating your workbooks between two projects on the same Tableau site, your sign-in credentials for the source and destination site will be identical (including the server URL and site name).

### Saved connections

Using saved connections allow you to quickly sign in to the source and destination sites by creating a reusable connection. When adding a saved connection, you must specify the preferred sign-in method for your site.

As of 2021.2, the Content Migration Tool supports the following sign-in methods:

- **Personal access tokens:** Allows users to create long-lived authentication tokens for improved security, auditing, and automation of migration plans. Personal access tokens let users sign in without requiring interactive login in the Content Migration Tool. For more information, see [Personal Access Tokens](#).

- **Browser-based sign-in:** Users enter their credentials and complete authentication through an embedded web browser. This option may be similar to how you usually authenticate to Tableau.
- **Username and password sign-in:** Users authenticate through the Content Migration Tool instead of an embedded browser window. This option passes credentials to the server using Tableau REST APIs. You can use username and password sign-in to authenticate to migration plans created before version 2020.3 and when troubleshooting issues that prevent the use of browser-based sign-in.

## Add or edit saved connections

A link to **Add or edit saved connections** is displayed at the bottom of the Content Migration Tool, and when signing in to the source and destination sites. Clicking this link will open the **Manage Tableau Connections** window.

**Manage Tableau Connection** [x]

New Connection

Connection A  
Connection B  
Connection C

Connection name

Server URL

Use personal access token  
 Use browser-based sign-in  
 Use username/password sign-in

Personal access token name

Personal access token secret

Site name (from URL)

Close

Use the steps below to add a saved connection:

1. On the **Manage Tableau Connections** window, click **New Connection**, or select an existing connection to make changes.
2. Enter a **Connection Name** (name to describe your server) and the **Server URL**.

If you don't include a prefix for the Server URL, the Content Migration Tool will use `http://`.

3. Select the sign-in method for your connection.

If you're using personal access tokens, see [Add saved connections with personal access tokens](#).

4. Click **Save**.

After you create a saved connection, it's listed in the Select a Connection window next time you sign in to the source and destination sites.

## Add saved connections with personal access tokens

Adding a saved connection with a personal access token requires more information than other sign-in methods. You will need to create a new personal access token on the source and destination sites to begin. Personal access tokens should not be shared between applications. For more information, see [Personal Access Tokens](#).

## Creating personal access tokens

1. In a web browser, sign in to your Tableau site.
2. At the top of the page, click your profile image or initials, and then select **My Account Settings**.

3. Under **Personal Access Tokens**, enter a descriptive name for your token in the **Token Name** field, and then click **Create new token**.
4. In the resulting window, click **Copy to clipboard** and then close the window.
5. Paste the token secret to a file. Store the file in a safe location.

## Adding personal access tokens

1. In the Content Migration Tool, click **Add or edit saved connections**.
2. On the **Manage Tableau Connections** window, enter a **Connection name** and the **Server URL**.

If you are connecting to Tableau Cloud, you must enter the full pod URL of your site. For example, `https://10ay.online.tableau.com`. Your pod is shown in the first portion of the site URL after signing in to Tableau Cloud.

3. Enter the **Personal access token name** and **Personal access token secret**, obtained when creating a personal access token in the previous section.
4. In the **Site name** field, enter the site name as it appears in the URL, without spaces. This is different than the friendly site name. For example, "Site A" would be "sitea" in a browser URL.
5. Click **Save**.

Step 3: Continue to the next step

After successfully signing in to both source and destination sites, click **Next** to continue to the Migration Plans: Source Projects section of the planning phase.

Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and

**Publish** capabilities for target projects on the destination site. For more information, see Permissions.

### Migration Plans: Source Projects

The next step in creating a migration plan in the Tableau Content Migration Tool is to select the source projects. Source projects are the projects the workbooks and published data sources will be migrated from. The projects you choose determine which workbooks are available to migrate in the next step of the migration plan.

Step 1: Select your source project

There are two options when selecting source projects, **All Projects**, and **Specific Projects**:

#### Source Projects

Need help? 

All Projects  Specific Projects

 Refresh

Workbooks and data sources from **all projects** will be available for migration.

The **All Projects** option selects all projects from the source site you specified in the Servers step. The **Specific Projects** option allows you to select specific projects from the source site.

**Note:** Source projects must contain workbooks or data sources. Content Migration Tool will not migrate empty projects.

#### Source Projects

Need help? 

All Projects  Specific Projects

 Refresh

Select All (3 of 4 selected)

- Default
- Mkt-Q3
- Mkt-Q4
- Tableau Samples

You can select each project individually or use the **Select All** button and then clear selections for the projects you don't want to include. If you make any changes on the source site while on this step, you can use the **Refresh** button to update the projects list.

## Step 2: Select project options

Once the source projects are selected, select which project options to apply for the destination location. There are options to create projects that don't exist, in addition to copying project permissions and ownership from the source location. To assign new content ownership based on user mappings, select **Apply User Mappings**.

### Project Options

Need help?

Create Destination Projects

Copy Project Permissions

#### Content Owner Settings

Copy Project Owner

Apply User Mappings

- **Create Destination Projects:** Automatically create projects that don't exist in the destination location. Content Migration Tool will not create destination projects if the source project is empty or no workbooks or data sources are selected. By default, attempts to migrate to a non-existent project will result in a failed migration.
- **Copy Project Permissions:** Copy source project permissions as closely as possible.
- **Copy Project Owner:** Copy project ownership settings from the source location to assign the project owner.
- **Apply User Mappings:** Apply user mappings to assign content ownership of projects in the destination location. Content ownership won't be applied if the destination project

already exists. For more information, see [Migration Plans: Permissions and Ownership](#).

### Step 3: Continue to the next step

After selecting the source projects, click **Next** to continue to the Migration Plans: Workbooks section of the planning phase. If you are migrating workbooks between two projects on the same Tableau site, you'll choose your destination project in the next section.

### Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see [Permissions](#).

### Migration Plans: Workbooks

You have successfully signed in to your source and destination sites and selected projects. The next step is to prepare your workbooks for migration.

**Note:** If your workbooks or data sources include extracts, be sure you read and understand the information in [Migrate Workbooks and Data Sources with Extracts](#).

### Step 1: Workbook selection

All of the workbooks in the source site and selected projects appear on the **Workbook Selection** screen.

**Workbook Selection**Need help? 
 Specific Workbooks
  Rule Based
  All Workbooks

 Refresh

 Unselect All (9 of 9 selected)

If you make any changes to the workbooks in the source site while on this step, you can click **Refresh** to update the workbook listings. There are several different ways to select these workbooks.

## Specific Workbooks Selection

There are three buttons in the **Specific** section. Any choices from the Basic section will immediately include the specifically selected workbook in the migration plan. Alternately, you can individually select specific workbooks by clicking on each one.

## Select All

This button will select or clear selection of all the workbooks in the site. If additional workbooks are added to the site after the plan is saved, they will not be automatically added the next time the plan is used.

## Display:

### Thumbnails

The default view shows your workbooks in thumbnail previews to help you differentiate each of them. In this view, mousing over the thumbnail will show previews of the other worksheets and dashboards within that workbook.

### List

The list view is a more succinct listing that also provides additional information, including Workbook Name, Project, Tableau Version, and Last Modified.

Clicking on any of the column headers will sort the workbooks appropriately. Also, mousing over any of the workbooks will also provide a floating preview of the worksheets and dashboards within that workbook. List view is particularly useful if you have a large amount of workbooks in a site.

## Rule Based Selection

You can use **Rule Based** selection to choose workbooks based on specific criteria. Rule-based options will create workbook selection criteria to be used when the migration plan is run. Be aware that selecting "all" in any of the **Rule Based** options is different than the **Specific Workbooks** selection. A rule-based "all" selection will always include all workbooks, so any newly added workbooks are included in future migrations.

In projects

Tagged with [Click to add tag...](#)

Published by

The **Rule Based** radio button allows you to select workbooks by using the following options:

### Workbooks in projects

This menu allows you to select workbooks from specific projects.

### Workbooks tagged with

This menu allows you to select workbooks by their tags.

### Workbooks published by

This menu allows you to select workbooks by their author.

With each option, you can select individually or multiple by clicking on the option next to each entry. All selected workbooks will appear in the **Selection Description** box.

## All Workbooks Selection

The last option is to select the **All Workbooks** radio button, which selects all workbooks in all projects in the site.

Using the **All Workbooks** radio button is different than selecting all of the workbooks using the **Specific Workbook** method because it will use every workbook in the source site each time the migration plan is used in the future.

Specific Workbooks  Rule Based  All Workbooks

---

All workbooks in all projects

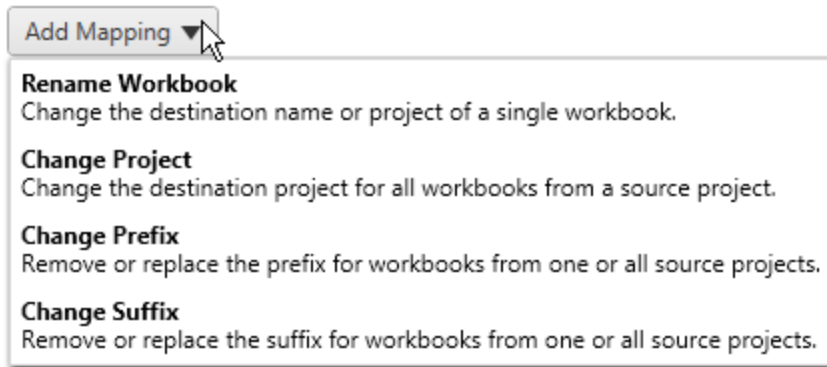

When you are satisfied with your workbook selections, click **Next**.

### Step 2: Workbook mapping

You can now map your selected workbooks from the source file to the destination file. Mapping allows you to rename source workbooks as they are migrated and choose different destinations. You can also add mapping to change the project, prefix, or suffix for the workbooks as well. Projects can be added to the Destination in this section as well.

If you make no changes here, then the selected workbooks will simply be migrated with the same name and into the same project as the source. If you have not defined projects in your destination site, then they will be migrated into the Default project. To add workbook mapping click the **Add Mapping** button. The following options will appear in the mapping area.

## Rename Workbook

This transformation allows you to filter by the **Source** project and select the desired workbook(s) to rename. In the **Destination** field, select which project you would like the workbook to be directed to and enter the desired name.

## Change Project

By default, the workbooks are migrated to the same project in the destination. This mapping allows you to change the destination project for all workbooks from a source project.

## Add Project

When renaming the workbook or changing the project, the **Add New** option allows you to create a destination project without having to sign in to the destination site and create the project manually. You can create both projects and nested projects using the **Add New** dialog box.

## Change Prefix

This allows you to remove or replace the prefix for workbooks from one or all source projects.

## Change Suffix

Like the prefix mapping, you can remove or replace the suffix for workbooks from one or all source projects.

Step 3: Workbook transformations

You can change and modify your workbooks by using the Transformation step.

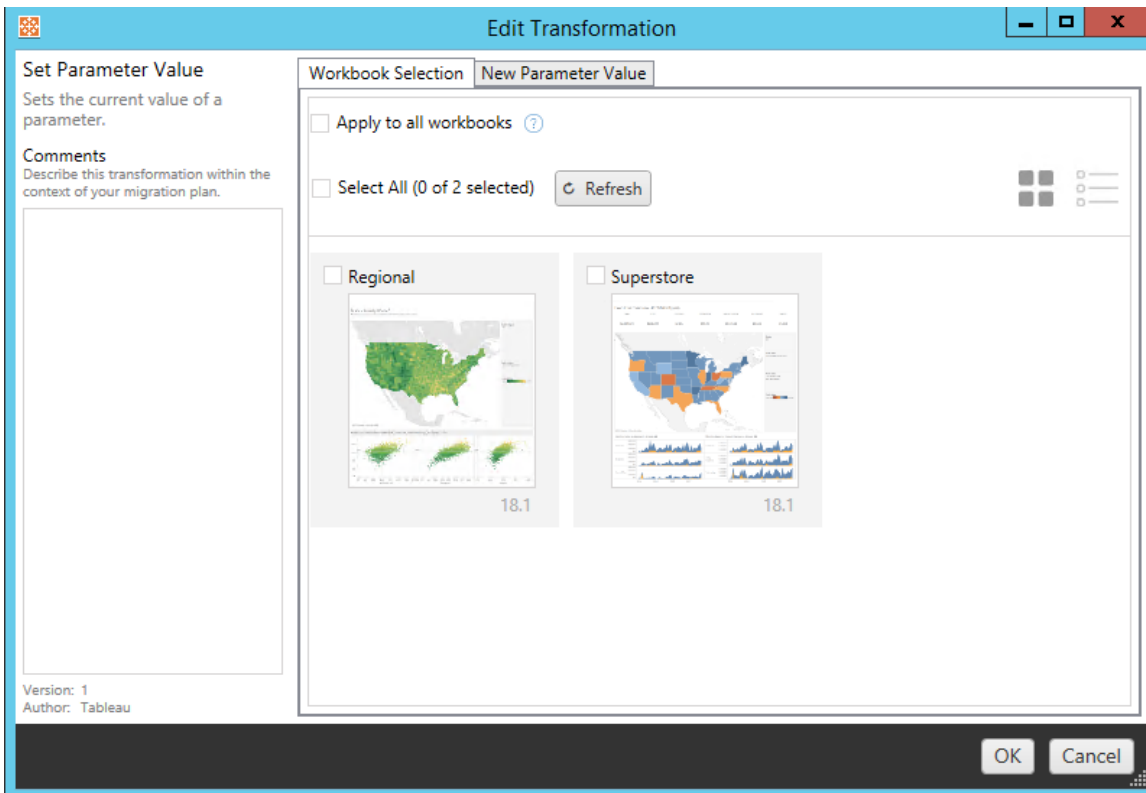

Transformations modify your workbooks in a specified manner. Additional transformations can be included via plug-ins or will be added in future versions of the application. Click on the **Add Transformation** drop-down menu to see the selection of Transformations currently available.

### Workbook Transformations

Selecting any of the transformations will bring up the Edit Transformation window, which will allow you to customize it to your selected workbooks. All transformations will be completed in the order that they are listed from top to bottom.

For all of the different types of transformations, there are two basic steps. The first step is to make your selection for the transformation. In this case, select the workbook(s) you want to transform. The selection area is similar to the Workbook Selection section of the Planning phase with all of the features of the Basic selection radio button: **Select/Unselect All**, **Refresh**, **Thumbnail Display**, and **List Display**. At the top of the list, you can select **Select All** workbooks, which is an option to automatically select all workbooks for future transformations. You can also **Refresh** the workbook display window to reflect any changes or updates to the source site.

The second step is to use the options tab to enter the specific selections for whichever transformation you select.

Each of the workbook transformations have different values to be entered on the options tab, and the tab will have different names, depending on the transformation you're editing:

## Action URL Replacement

Replace part or all of an URL action inside of the workbook using this transformation. On the options tab, enter the text that should be matched and its replacement value.

|                    |                      |
|--------------------|----------------------|
| <b>Match</b>       | <input type="text"/> |
| <b>Replacement</b> | <input type="text"/> |

**Example:**

URL: `www.exampledev.com`

Match: dev

Replacement: Prod

Result: www.exampleProd.com

## Set Parameter Value

Define a new parameter. On the options tab, enter the name of the Parameter, the data type from the drop-down menu, and the value.

|                |                                    |
|----------------|------------------------------------|
| Parameter Name | <input type="text"/>               |
| Data Type      | <input type="text" value="Float"/> |
| Value          | <input type="text" value="0"/>     |

## Remove Images

Remove any images (such as a watermark) in the selected workbooks by entering in the file name on the options tab. There is an additional check box to receive a warning during migration if no image is found.

|                                     |   |
|-------------------------------------|---|
| File Name                           | <input type="text"/>                                  |
| <input checked="" type="checkbox"/> | Warn when no matching images are found in a workbook. |

## Remove Tooltip Commands

Remove all of the tooltip commands from the selected workbooks. There are no additional options to define for this transformation.

## Replace Images

Replace images embedded in the selected workbooks. On the options tab, enter the file name of the current image and the replacement image. You can replace images using a local file path or URL.

|  |                      |
|--|----------------------|
| File Name  | <input type="text"/> |
| Replacement Image URL  | <input type="text"/> |
| <input type="checkbox"/> Warn when no matching images are found in a workbook. |                      |

### Example:

File Name: `image.png`

Replacement Image URL: `https://www.exampledev.com/replacementImage.png`

## Zoom Control Visibility

Set the visibility mode from the drop-down menu: **Automatic**, **Show on Hover**, or **Hide** on the options tab.

|                 |  |
|-----------------|--|
| Visibility Mode | <input type="text" value="Automatic"/> |
|-----------------|--|

## Web Page URL Replacement

Replace part or all of a web page URL used on dashboards using this transformation. On the options tab, enter the text that should be matched and its replacement value.

|             |                      |
|-------------|----------------------|
| Match       | <input type="text"/> |
| Replacement | <input type="text"/> |

### Example:

URL: `www.exampledev.com`

Match: `dev`

Replacement: `Prod`

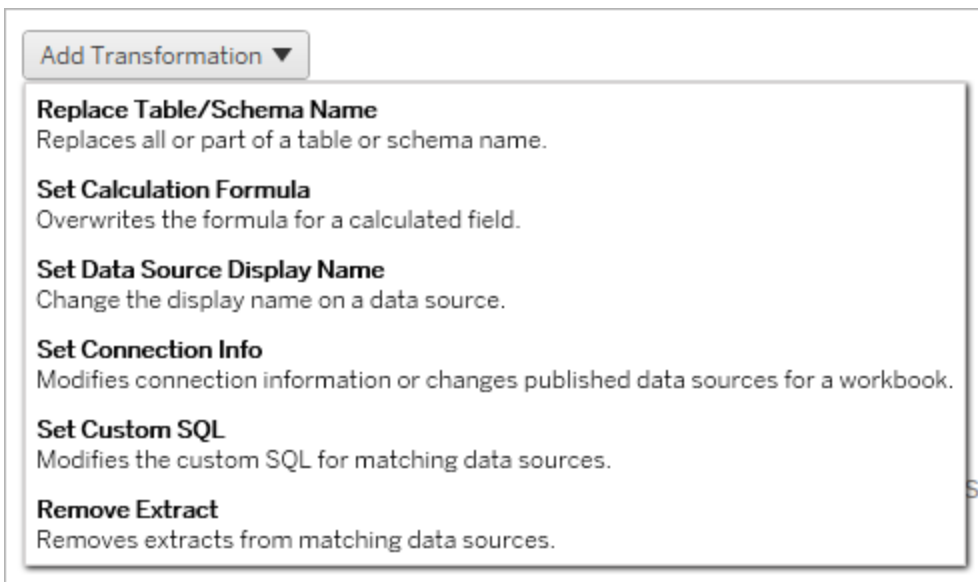

Result: `www.exampleProd.com`

#### Step 4: Data source transformations

The next step in planning your workbooks for your enterprise migration are your data source transformations. It is similar in function to the Workbook Transformations step. These are for data sources that are packaged within the workbooks. Published data sources are handled in a different step in the process.

Click on the **Add Transformation** drop-down menu and the following options will appear:

Selecting any of the data source transformations will bring up the Edit Transformation window, which will allow you to customize it to your selected data sources. All transformations will be completed in the order that they are listed from top to bottom.

For all of the different types of data source transformations, there are two basic steps. The first step is to enter in the match criteria for the desired data source. Depending on which connection type you select, more fields will appear on the **Match Criteria** tab.

The screenshot shows the 'Edit Transformation' dialog box. The 'Match Criteria' tab is active, displaying the following fields:

- Data Source Name: (Match Any)
- Connection Type: (Match Any)
- With or without an extract: (Dropdown menu)

A 'Preview Matching Connections' button is located below the 'Connection Type' dropdown. The dialog also includes a 'Set Connection Info' section on the left and 'OK' and 'Cancel' buttons at the bottom right.

Click on the **Preview Source Connections** to find any connections that match the criteria entered.

## Tableau Server on Linux Administrator Guide

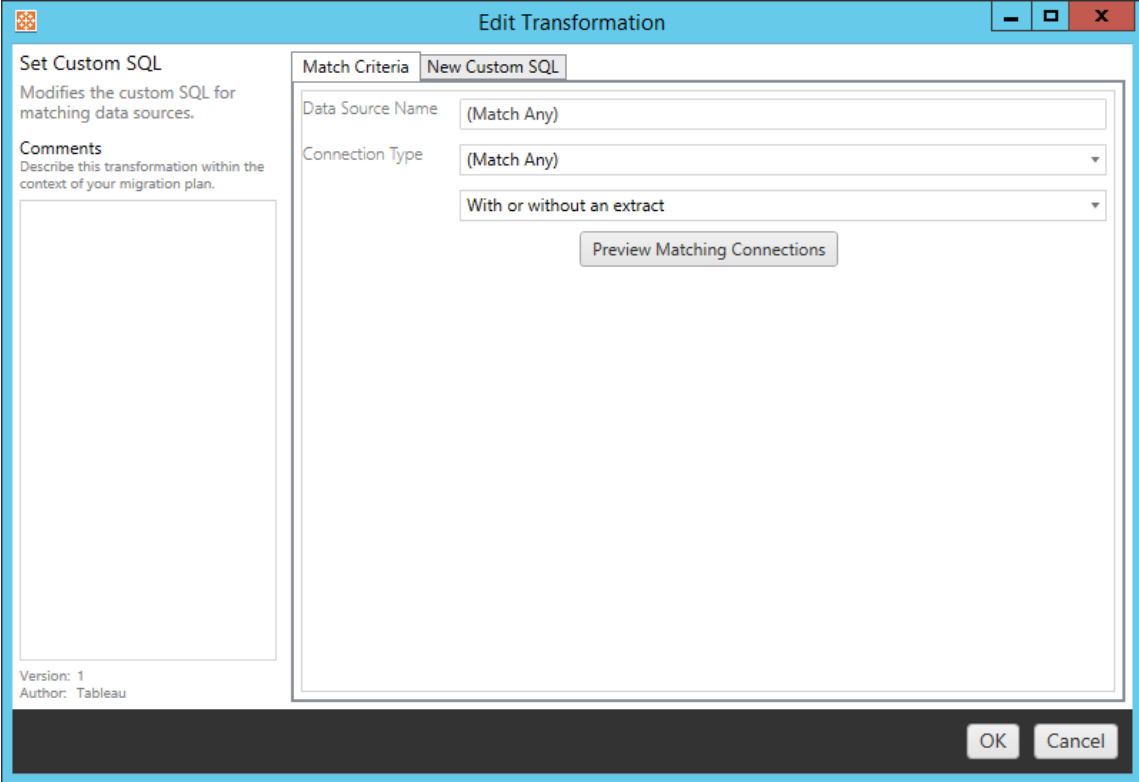

| Workbook       | Data Source                         | Project | Match |  |
|----------------|-------------------------------------|---------|-------|--|
| Internet Usage | Sheet1 (Internet-Penetration.xlsx)  | Default | True  |  |
| Shark Week     | Shark Attacks (Shark Attacks.xlsx)  | Default | True  |  |
| Shark Week     | Fattest Countries (Shark Attacks.xl | Default | True  |  |
| Shark Week     | Sheet1 (Country-Military.xlsx)      | Default | True  |  |
| Shark Week     | BMI (Shark Attacks.xlsx)            | Default | True  |  |
| World Cup      | Sheet2 (World Cup.xlsx)             | Default | True  |  |
| World Cup      | Sheet1 (World Cup - England.xlsx)   | Default | True  |  |

Show All Data Sources

Close

The second step is to use the options tab to enter the specific selections for whichever transformation you select.

Each of the data source transformations have different values to be entered on the options tab:

### Set Calculation Formula

On the options tab, you can replace the calculation for a column.

|             |  |
|-------------|--|
| Column Name |  |
| Formula     |  |

## Set Connection Info

On the **New Connection Values** tab, enter the authentication method and connection details for the new data source. Depending on which connection type you select, more fields will appear.

### Change published data sources with CMT

As of version 2022.1, select the **Tableau Server (Published Data Source)** connection type to change the published data source for a workbook. This can reduce the manual steps required when migrating workbooks between Tableau environments, for example, promoting content from development to production.

To change the published data source, select a data source from the drop-down menu and enter the **Tableau Username** for authentication. The user must exist on the destination site and have the Connect capability for the published data source.

- For file-based data sources, users will access the workbook and see data based on permissions of the specified Tableau user.
- For all other data sources, users are prompted for their own database credentials when the view or workbook loads.

If Tableau Username isn't specified, only users with the Connect capability can see data in the workbook.

|                       |                      |
|-----------------------|----------------------|
| Published Data Source | (No Change) ▼        |
| Tableau Username      | <input type="text"/> |

## Set Custom SQL

On the **New Custom SQL** tab, enter the name of the custom SQL query you want to modify for **Match Query Name**. The query name must match the custom SQL query name from the phys-

ical layer of the data source. If these names don't match, the transformation will fail. For more information about data modeling and the physical layer, see [The Tableau Data Model](#).

After entering the query name, enter the desired **Custom SQL** in the text field. Be aware that custom SQL can negatively impact the performance of your workbooks if improperly used.

The image shows a form with two input fields. The first field is labeled 'Match Query Name' and is empty. The second field is labeled 'Custom SQL' and contains the number '1' at the beginning of a line, with a vertical dashed line to its left. The 'Custom SQL' field has a small upward-pointing arrow on its right side, indicating it is a text area.

## Remove Extract

There is no options tab for this transformation, simply enter in the **Match Criteria** information and the extract will be removed during migration.

In addition, on each of the transformations you can enter notes in the **Comments** section on the left-hand side of the **Edit Transformation** window.

## Apply Saved Credentials

Deprecated in version 2022.3. Use the Set Connection Info data source transformation instead.

On the options tab, enter the **Tableau Username** and corresponding **Saved Credentials Username** for the data connection. You can only apply saved credentials for existing data connections on the Account Settings page of your Tableau site. For more information, see [Manage Saved Credentials for Data Connections](#).

The image shows two input fields. The first field is labeled 'Tableau Username' with a blue question mark icon to its right. The second field is labeled 'Saved Credentials Username'. Both fields are empty.

### Step 5: Publish options

The final step in the Workbooks phase is to select publish options and create transformations for tags, extract refresh schedules, and permissions.

#### Workbook Publish Options

- Reset Dashboard Selections [?](#)
- Overwrite Newer Workbooks [?](#)
- Copy Workbook Permissions [?](#)
- Copy Extract Refresh Schedules [?](#)

#### Content Owner Settings

- Copy Workbook Owner [?](#)
- Apply User Mappings [?](#)

Add Option ▼

No additional publish options.

### Reset Dashboard Selections

This option deselects all objects on dashboards.

### Overwrite Newer Workbooks

If checked, a workbook will be migrated even if it will overwrite a workbook that has been created at the same time or more recently than the moved workbook

### Copy Workbook Permissions

When selected, the migration tool will attempt to match source workbook permissions as closely as possible.

## Copy Extract Refresh Schedules

When selected, the migration tool will attempt to set the destination workbook extract refresh schedule(s) to schedules matching the source's name.

**Note:** Extract refresh schedules cannot be created in Tableau Cloud. This option is not available if the destination is a Tableau Cloud site. For more information, see [Migration Limitations](#).

## Copy Embedded Credentials for Workbooks

Copy the embedded credentials for data sources embedded in workbooks. Only available when migrating from Tableau Server to Tableau Cloud sites. For more information, see [Migrate Workbooks and Data Sources with Embedded Credentials](#).

**Note:** CMT does not support embedded credential migration for OAuth connections. To migrate OAuth credentials to the destination site, use the [Set Connection Info](#) data source transformation.

## Copy Workbook Owner

Copy workbook owner settings from the source location to assign the workbook owner. If unselected, the Content Migration Tool user is given ownership of the workbook in the destination location.

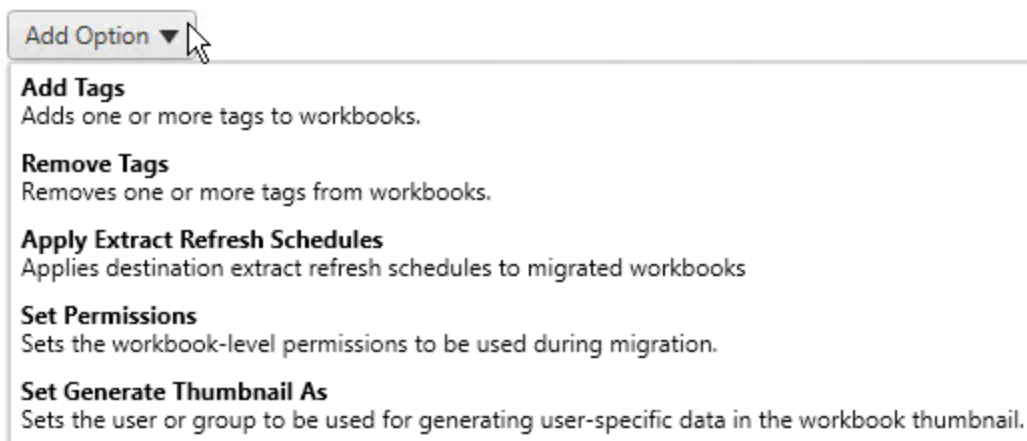

## Apply User Mappings

Apply user mappings to assign content ownership. Select this option if there are differences in username syntax in the destination location. For more information, see [Migration Plans: Permissions and Ownership](#).

## Add Option

Click on the **Add Option** drop-down menu for the different types of transformations you can add:

For all of the different types of transformations, there are two basic steps. The first step is to make your selection for the transformation. In this case, select the workbook(s) you want to transform. The selection area is similar to the Workbook Selection section of the Planning phase with all of the features of the Basic selection radio button: **Select/Unselect All**, **Refresh**, **Thumbnail Display**, and **List Display**. At the top of the list, you can select **Select All** workbooks, which is an option to automatically select all workbooks for future transformations. You can also **Refresh** the workbook display window to reflect any changes or updates to the source site.

The second step is to use the options tab to enter the specific selections for whichever transformation you select. **Note:** The options tab will have different names, depending on which transformation you are editing.

## Add Tags

This allows you to add one or more tags to the workbook. If you hover your mouse over a previously entered tag, a blue “X” will appear to allow deletion.

## Remove Tags

This allows you to add one or more tags to the workbook. If you hover your mouse over a previously entered tag, a blue “X” will appear to allow deletion. You can also choose to remove the tag from the source or destination workbooks.

## Apply Extract Refresh Schedules

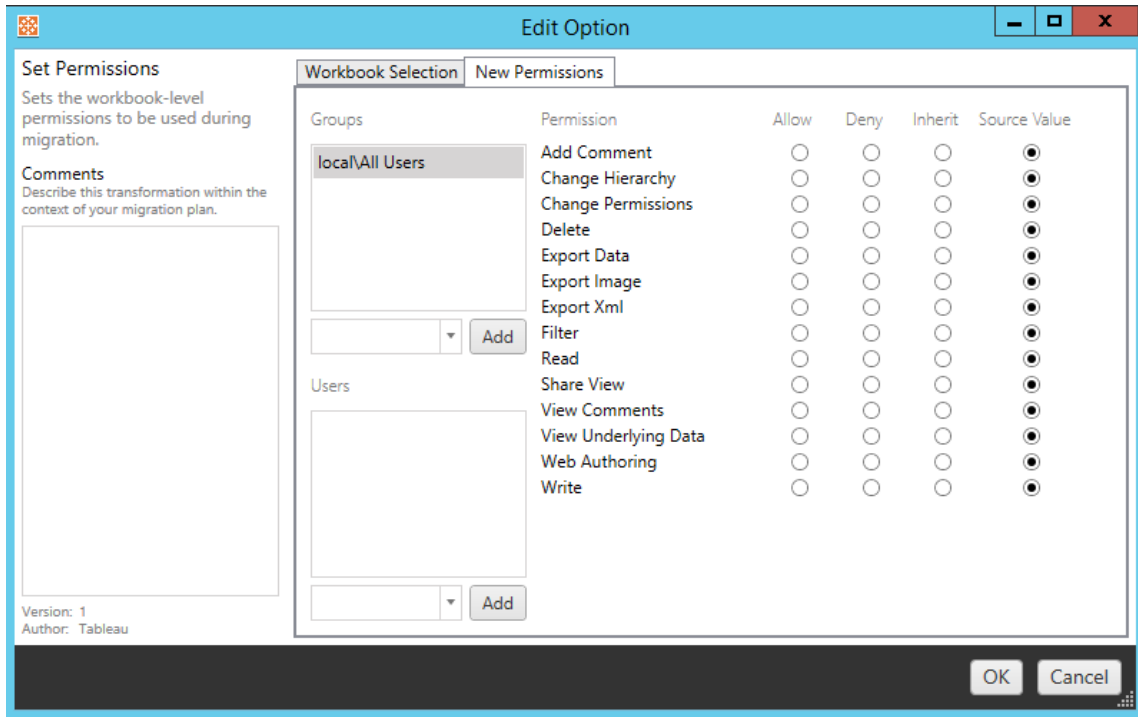

Here you can apply destination extract refresh schedules to migrated workbooks. The list of schedules generated are from the destination.

**Note:** Extract refresh schedules cannot be created in Tableau Cloud. This option is not available if the destination is a Tableau Cloud site. For more information, see Migration Limitations.

## Set Permissions

This transformation is to edit the permissions for the selected workbooks. Enter in a Group or User and then click **Add**. Adjust the permissions as desired. The four different options are to **Allow** the permission, **Deny** the permission, **Inherit**, or to keep the **Source Value**.

## Set Generate Thumbnail As

This allows you to set the **User** or **Group** to be used for generating user-specific data in the workbook thumbnail after being migrated. Each option has a drop down to select the desired user or group.

Step 6: Continue to the next step

After selecting your workbooks and preferences, click **Next** to continue to the Migration Plans: Published Data Sources section of the planning phase.

Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see Permissions.

Migration Plans: Published Data Sources

The next step of creating a migration plan in the Tableau Content Migration Tool is to select, map, and add any transformations to your published data sources. The process is very similar to the Workbooks step of the planning phase, particularly the data source mapping step.

**Note:** If your workbooks or data sources include extracts, be sure you read and understand the information in *Migrate Workbooks and Data Sources with Extracts*.

## Step 1: Selection

Starting the Published Data Sources phase of the migration plan, you'll select any data sources you want to include in the migration plan:

**Data Source Selection** Need help? 

Specific Data Sources
  Rule Based
  All Data Sources
 Refresh 

Unselect All (1 of 1 selected)

|                                     | Name                  | Project |
|-------------------------------------|-----------------------|---------|
| <input checked="" type="checkbox"/> | Sheet1 (state_plates) | Mkt-Q3  |

The data sources will only be selected at the moment of migration. You have two methods of selection. Use **Specific Data Sources** to choose one or more published data sources. Click **Refresh** to reload the list of published data sources available.

The second option is **All Data Sources**, which selects every data source in the source site.

## Step 2: Mapping

The next step is to map your source data sources to the new destination. This is similar in functionality to mapping workbooks.

**Data Source Mapping** Need help? 

Add Mapping 

No changes to data source names or projects.

If you make no changes here, then the selected data sources will simply be deployed with the

same name and project as the source. To add data source mapping click **Add Mapping**. The following options will appear in the mapping area.

|                        | Name  | Project              | Destination Name | Destination Project  |
|------------------------|---|----------------------|------------------|----------------------|
| <a href="#">Delete</a> | (All Selected Data S <input type="text"/> ) | <input type="text"/> | (Same As Source) | <input type="text"/> |

The entry has the following options:

## Delete

Clicking the **Delete** link will delete this mapping entry.

## Name

Use the **Name** menu to select the data source you wish to map. You can select **(All Selected Data Sources)** to choose all of the data sources.

## Project

The **Project** is the project of the associated data source names.

## Destination Name

By default, the Content Migration Tool will use the same **Destination Name(Same As Source)**, keeping the original name in the Source file, but you can type in a new name here for the destination folder.

## Destination Project

If your destination projects have already been created on your site, you can choose which project to place your migrated workbooks or click **Add New** to create a new project. You can create different project destinations for individual data sources.

|                        | Name                | Project   | Destination Name | Destination Project                                       |
|------------------------|---------------------|-----------|------------------|---|
| <a href="#">Delete</a> | (:d Data Sources) ▾ | Default ▾ | (Same As Source) | Default ▾   |
|                        |                     |           |                  | <a href="#">Add New</a><br>Accounting<br>Default<br>Sales |

In most situations if multiple mapping entries exist for a single data source, a validation error will be displayed and must be fixed to continue. There is one important exception to this – a data source may match both a specific selection and a project-wide mapping entry. In this instance, the more specific entry will be used.

When you have completed all of the data source mapping necessary, click **Next** to continue.

### Step 3: Data source transformations

You can modify your data sources by using the transformation option. Click **Add Transformation** to see the list of transformations available.

Selecting any of the data source transformations opens the **Edit Transformation** window. Use this to customize your selected data sources. Transformations are executed in the order they are listed, from top to bottom.

For most data source transformations, there are two basic steps. The first step is to enter in the **Match Criteria** for the desired data source. Depending on which connection type you select, more fields will appear on the **Match Criteria** tab.

The second step depends on which transformation type you are adding. Each of the data source transformations have different values to be entered on the second tab.

You can add notes in the **Comments** section on the left side of the **Edit Transformation** window for each of the transformations you add.

## Replace Table/Schema Name

On the **Options** tab, you can replace all or part of a table or schema name.

## Set Calculation Formula

On the **New Calculation Formula** tab, you can replace the calculation for a column.

|             |                      |
|-------------|----------------------|
| Column Name | <input type="text"/> |
| Formula     | <input type="text"/> |

## Set Connection Info

On the **New Connection Values** tab, enter the authentication method and connection details for the new data source. Depending on which connection type you select, more fields will appear.

|           |                      |
|-----------|----------------------|
| File Path | <input type="text"/> |
|-----------|----------------------|

## Set Custom SQL

On the **New Custom SQL** tab, enter the name of the custom SQL query you want to modify for **Match Query Name**. The query name must match the custom SQL query name from the physical layer of the data source. If these names don't match, the transformation will fail. For more information about data modeling and the physical layer, see [The Tableau Data Model](#).

After entering the query name, enter the desired **Custom SQL** in the text field. Be aware that custom SQL can negatively impact the performance of your workbooks if improperly used.

|                  |  |   |                      |
|------------------|--|---|----------------------|
| Match Query Name | <input type="text"/>   |   |                      |
| Custom SQL       | <table border="1"><tr><td>1</td><td><input type="text"/></td></tr></table> | 1 | <input type="text"/> |
| 1                | <input type="text"/>   |   |                      |

## Remove Extract

There is no **Options** tab for this transformation. Type the **Match Criteria** information and the extract will be removed during migration.

## Use Tableau Bridge

There is no **Options** tab for this transformation. Type the **Match Criteria** information and data sources that are within a private network (inaccessible to the public internet) will be allowed to refresh using Tableau Bridge.

The destination Tableau Cloud site must have Tableau Bridge configured before migrating data sources. For information about Tableau Bridge, see [Use Tableau Bridge](#) in Tableau Cloud help. After the migration, data sources will need to be assigned a refresh schedule through Tableau Cloud.

## Apply Saved Credentials

Deprecated in version 2022.3. Use the Set Connection Info data source transformation instead.

On the options tab, enter the **Tableau Username** and corresponding **Saved Credentials Username** for the data connection. You can only apply saved credentials for existing data connections on the Account Settings page of your Tableau site. For more information, see [Manage Saved Credentials for Data Connections](#).

|  |                      |
|--|----------------------|
| Tableau Username  | <input type="text"/> |
| Saved Credentials Username   | <input type="text"/> |

### Step 4: Publish options

The final step in the Published Data Source phase is to create transformations for permissions and tags and finalize the publish options specific to the data sources.

## Data Source Publish Options

Overwrite Newer Data Sources [?](#)

Copy Data Source Permissions [?](#)

Copy Extract Refresh Schedules [?](#)

### Content Owner Settings

Copy Data Source Owner [?](#)

Apply User Mappings [?](#)

Add Option ▼

No additional publish options.

## Overwrite Newer Data Sources

If selected, a data source will be published even if it will overwrite a data source that has been updated more recently.

## Copy Data Source Permissions

When selected, the migration tool will attempt to match source published data source permissions as closely as possible.

## Copy Extract Refresh Schedules

When selected, the migration tool will attempt to set the destination data source extract refresh schedule to schedules matching the source's name.

**Note:** Extract refresh schedules cannot be created in Tableau Cloud. This option is not available if the destination is a Tableau Cloud site. For more information, see Migration Limitations.

## Copy Embedded Credentials for Data Sources

Copy the embedded credentials for published data sources. Only available when migrating from Tableau Server to Tableau Cloud sites. For more information, see [Migrate Workbooks and Data Sources with Embedded Credentials](#).

**Note:** CMT does not support embedded credential migration for OAuth connections. To migrate OAuth credentials to the destination site, use the [Set Connection Info](#) data source transformation.

## Copy Data Source Owner

Copy data source owner settings from the source location to assign the data source owner. If unselected, the Content Migration Tool user is given ownership of the data source in the destination location.

## Apply User Mappings

Apply user mappings to assign content ownership. Select this option if there are differences in username syntax in the destination location. For more information, see [Migration Plans: Permissions and Ownership](#).

## Add Options

Click on the **Add Option** drop-down menu for the different types of transformations you can add:

**Add Option** ▼

- Remove Tags**  
Removes one or more tags from published data sources.
- Add Tags**  
Adds one or more tags to published data sources.
- Apply Extract Refresh Schedules**  
Applies destination extract refresh schedules to migrated data sources
- Set Permissions**  
Sets the published data source-level permissions to be used during migration.

For all of the different types of transformations, there are two basic steps. The first step is to make your selection for the transformation. In this case, select the data source(s) you want to transform. At the top of the list, you can select **Apply to all published data sources**, which is an option to automatically select all data sources for future transformations. You can also **Refresh** the data source display window to reflect any changes or updates to the source site.

The second step is to enter the specific selections for the transformation you select.

## Remove Tags

Once the data sources you would like to remove tags from are selected, enter any tags you want to remove by entering them into the field at the bottom and click **Add**. From this screen, you can also select to remove from the source or destination data sources. If you want to remove a previously entered tag, click on it and press the delete key.

## Add Tags

After selecting the data sources desired, enter any tags you want to assign by entering them into the field at the bottom and click **Add**. If you want to remove a tag, click on it and press the delete key.

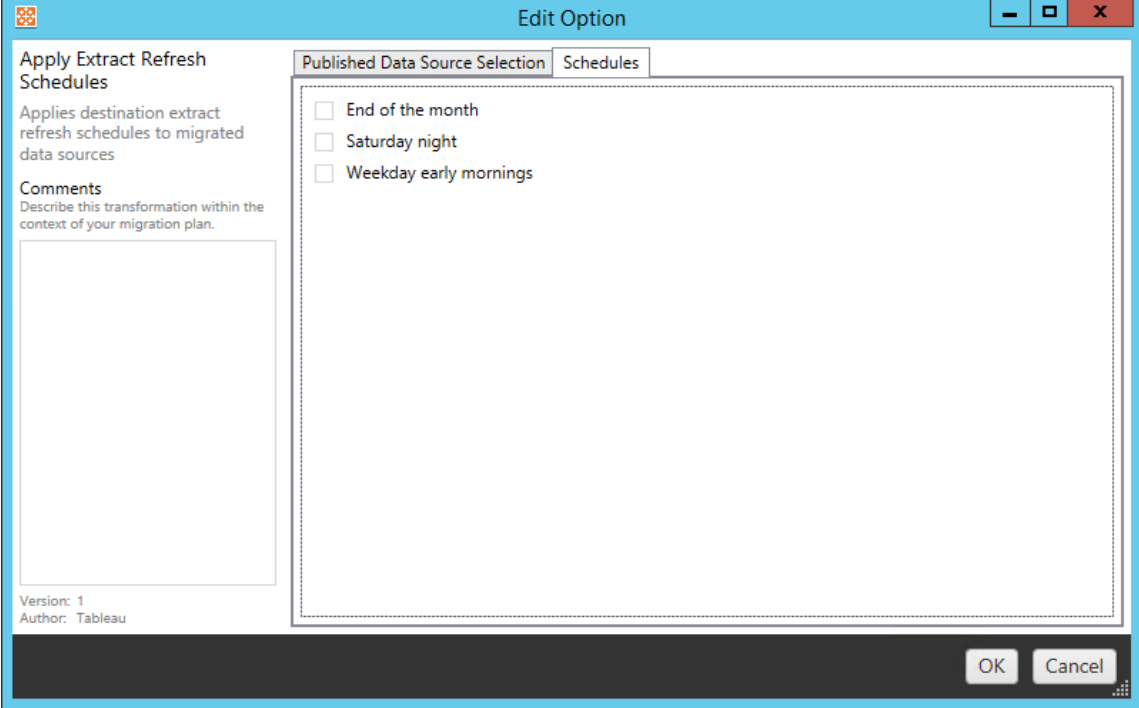

In addition, on each of the transformations you can enter notes in the **Comments** section on the left-hand side of the Edit Transformation window.

## Apply Extract Refresh Schedules

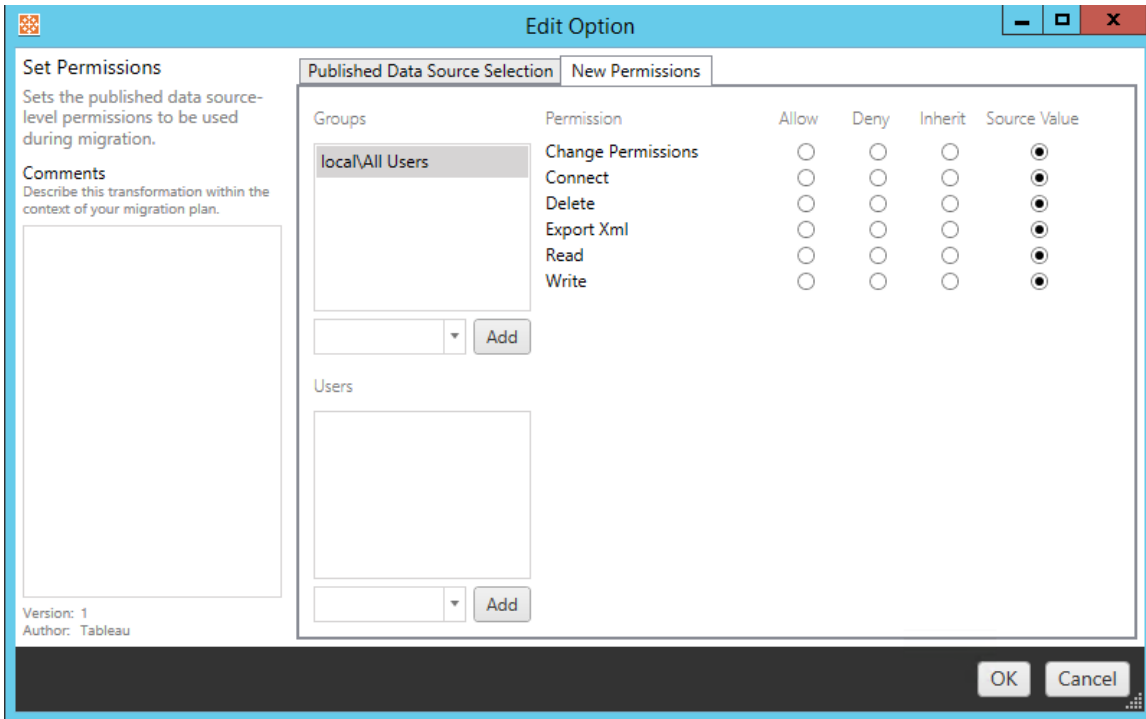

This transformation applies destination extract refresh schedules to migrated data sources. The list of schedules generated are from the destination.

**Note:** Extract refresh schedules cannot be created in Tableau Cloud. This option is not available if the destination is a Tableau Cloud site. For more information, see Migration Limitations.

## Set Permissions

The last type of transformation is to edit the permissions for the selected data sources. Enter in a Group or User and click **Add**. Adjust the permissions as desired. The four different options are to **Allow** the permission, **Deny** the permission, **Inherit**, or to keep the **Source Value**.

Step 5: Continue to the next step

When you are ready, click **Next** to continue to the Migration Plans: Permissions and Ownership section of the planning phase.

Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see [Permissions](#).

Migration Plans: Permissions and Ownership

The Content Migration Tool allows you to replicate workbook and data source permissions to Tableau environments in different network domains or have differences in username or group syntax. You can create user permissions mappings to customize and secure content after it has been published to the destination location. Mappings are applied if **Copy Project Permissions**, **Copy Workbook Permissions**, or **Copy Data Source Permissions** have been selected earlier in the planning phase, along with **Apply User Mappings**.

For more information, see Migration Plans: Source Projects, Migration Plans: Workbooks, and Migration Plans: Published Data Sources.

### Mapping limitations

- Content Migration Tool will stop the migration process if it fails to find the mapped user or group in the destination location. Subsequent user or group permissions mappings are not checked after the first failure, and the plan must be run again.
- Content Migration Tool cannot replicate permissions if the source content has permissions for multiple users and groups with identical names. This only occurs when there are duplicate user or group names sourced from separate domains.

### Step 1: Add mapping

To add user permissions mapping, click **Add Mapping** and select whether to change the name of a domain, user, group or to import mappings from a comma-separated values (CSV) file. If Content Migration Tool is unable to match a permission in the destination location, the source content will not be migrated.

## Domain Mapping

Domain permissions mapping applies to all users and groups in the destination location. If you are unsure about the source or destination domain, you can check the user and group

pages on your Tableau site. If local user provisioning has been selected, the domain must be specified as `local`.

## User Mapping

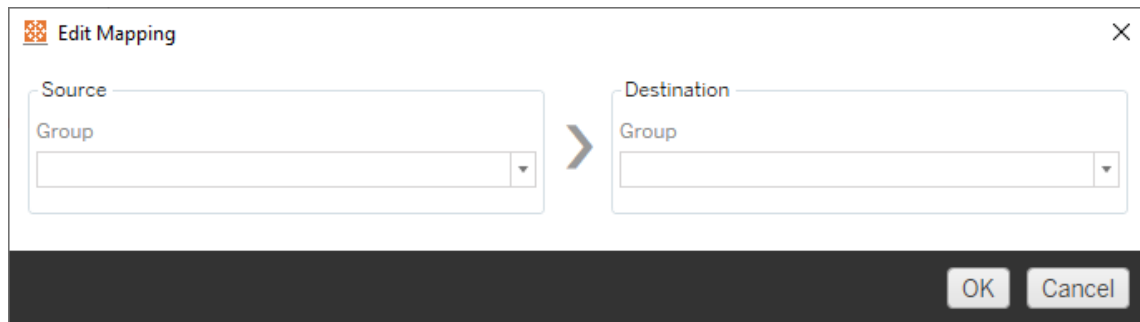

User permissions mapping automatically populates a list of users from the source and destination locations using the syntax `domain\user`. You cannot enter and save the names of users that don't exist.

**Note:** When migrating between projects on the same site, the destination location and list of users will be the same. You can use mappings to update content ownership from `User_A` to `User_B` on the site.

## Group Mapping

Group permissions mapping automatically populates a list of users from the source and destination locations using the syntax `domain\group`. You cannot enter and save the names of groups that don't exist.

Import mappings from a CSV file

Starting in version 2021.4, you can import a CSV file containing domain, user, and group mappings to quickly prepare your data for migration. Importing mappings can reduce the manual steps required to run a migration plan by allowing you to create and edit your mappings in bulk outside of Content Migration Tool. To import mappings, select **Import from File** from the Add Mapping menu.

## CSV file format requirements

When you create a CSV file to import mappings, make sure that the file meets the following requirements:

- The file does not include column headings. Tableau assumes that every line represents a mapping.
- The file contains three comma-separated values per row: mapping type, source domain/user/group, and destination domain/user/group.
- Include the domain for user names and groups if the server uses Active Directory authentication or "local" if a local identity store is used.

You must specify "domain," "user," or "group" for mapping type, as shown in the following table. The source and destination columns provide example syntax for Active Directory and a local identity store. Actual values in the CSV file will vary depending on your organization.

| Mapping Type | Source                                      | Destination                                 |
|--------------|---|---|
| domain       | <domain>                                    | <domain>                                    |
| user         | <domain>\<user name><br>local\<user name>   | <domain>\<user name><br>local\<user name>   |
| group        | <domain>\<group name><br>local\<group name> | <domain>\<group name><br>local\<group name> |

## Import user permissions mappings

To import user permissions mappings in the Content Migration Tool:

1. Click **Add Mapping** and select **Import from File**.
2. In the dialogue window, click **Export CSV** to export a .csv file containing all users and groups from the source site. Edit the resulting file in a text editor to add mappings for the destination site.

If you already have a mapping file, skip to step 3.

**Note:** The exported CSV file doesn't include domains from the source site. Domains must be added manually to the CSV to create domain mappings.

3. Click **Import Mappings** and select the mapping file you want to import.

Content Migration Tool will validate the mappings for errors when importing the file. If errors are detected, you must fix each error in the CSV file and then import it again.

## CSV import example

The following example shows a CSV file that contains multiple mapping types.

```
user,local\hwilson,companyx.lan\henry.wilson
user,local\jjohnson,companyx.lan\janna.johnson
user,local\mkim,companyx.lan\michele.kim
user,local\fsuzuki,companyx.lan\fred.suzuki
user,local\awang,companyx.lan\alan.wang
user,local\snguyen,companyx.lan\susan.nguyen
user,local\lrodriguez,companyx.lan\laura.rodriguez
user,local\agarcia,companyx.lan\ashley.garcia
group,local\All Users,companyx.lan\All Users
group,local\Finance Team,companyx.lan\Finance Group
domain,dev.mycompany,prod.mycompany
```

A preview window is displayed while importing the CSV that shows mappings removed, added or updated, unchanged, and ignored. Review that the mapping changes are correct and click **Accept**.

**Import from File** ✕

Review the table to make sure mapping changes are correct before continuing.

Removed: 5

| Mapping      | Description                                    |
|--------------|--|
| User Mapping | Match "local\User_5" to "local\Company_User_5" |
| User Mapping | Match "local\User_6" to "local\Company_User_6" |
| User Mapping | Match "local\User_7" to "local\Company_User_7" |
| User Mapping | Match "local\User_8" to "local\Company_User_8" |
| User Mapping | Match "local\User_9" to "local\Company_User_9" |

Added or updated: 9

| Mapping      | Description                                      |
|--------------|--|
| User Mapping | Match "local\User_15" to "local\Company_User_15" |
| User Mapping | Match "local\User_18" to "local\Company_User_18" |
| User Mapping | Match "local\User_20" to "local\Company_User_20" |
| User Mapping | Match "local\User_23" to "local\Company_User_23" |
| User Mapping | Match "local\User_3" to "local\Company_User_3"   |
| User Mapping | Match "local\User_26" to "local\Company_User_26" |

Unchanged: 18

| Mapping      | Description                                      |
|--------------|--|
| User Mapping | Match "local\User_1" to "local\Company_User_1"   |
| User Mapping | Match "local\User_10" to "local\Company_User_10" |
| User Mapping | Match "local\User_11" to "local\Company_User_11" |
| User Mapping | Match "local\User_12" to "local\Company_User_12" |
| User Mapping | Match "local\User_13" to "local\Company_User_13" |
| User Mapping | Match "local\User_14" to "local\Company_User_14" |

Ignored: 6

| Mapping       | Description  |
|---------------|--|
| User Mapping  | Match "local\Service_User_1" to "local\Company_Service_User_1" |
| Group Mapping | Match "sales_group" to "sales_west_group"                      |
| User Mapping  | Match "local\User_40" to "local\Company_User_40"               |
| User Mapping  | Match "local\User_41" to "local\Company_User_41"               |
| User Mapping  | Match "local\User_42" to "local\Company_User_42"               |
| User Mapping  | Match "local\User_43" to "local\Company_User_43"               |

Once the mappings are imported successfully, you can edit, delete, or change the mapping order as described in Step 2.

### Step 2: Change mapping order

After a permissions mapping is created, you can change the order using the **Up** or **Down** options to determine when it will be handled during the migration. When a domain, user, or group is handled in a permissions mapping, any subsequent permissions mappings for the source domain, user, or group will be ignored.

In the example below, permissions for `User_A` are mapped to `User_B`. Content Migration Tool will ignore the second permissions mapping because `User_A` has already been handled.

|   | Mapping      | Description                            |
|---|--------------|--|
| <a href="#">Edit</a> <a href="#">Delete</a> <a href="#">Up</a> <a href="#">Down</a> | User Mapping | Match "local\User_A" to "local\User_B" |
| <a href="#">Edit</a> <a href="#">Delete</a> <a href="#">Up</a> <a href="#">Down</a> | User Mapping | Match "local\User_A" to "local\User_C" |

In the example below, the first permissions mapping associates the domain for all users to `prod`. Content Migration Tool will ignore the second permissions mapping because the domain for `User_A` has already been handled.

|   | Mapping        | Description                    |
|---|----------------|--------------------------------|
| <a href="#">Edit</a> <a href="#">Delete</a> <a href="#">Up</a> <a href="#">Down</a> | Domain Mapping | Match "local" to "prod"        |
| <a href="#">Edit</a> <a href="#">Delete</a> <a href="#">Up</a> <a href="#">Down</a> | User Mapping   | Match "User_A" to "dev\User_B" |

### Step 3: Continue to next step

When you are ready, click **Next** to continue to the Migration Plans: Migration Scripts section of the planning phase.

Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see Permissions.

### Migration Plans: Migration Scripts

The next step of creating a migration plan in the Tableau Content Migration Tool is to create any scripts you want to run with your plan before or after migration.

#### Step 1: Pre-Migration

The **Run Pre Migration** section of the screen is dedicated to scripts that will run before the migration.

The screenshot shows a configuration panel titled "Run Pre Migration". At the top left is an unchecked checkbox labeled "Enable" with a help icon. Below it are four rows of input fields, each with a help icon: "Working Directory" (text input, browse button "...", and "Reset" button), "Run" (dropdown menu showing "Executable with parameters"), "Command Executable" (text input, browse button "..."), and "Command Parameters" (text input).

Each field has a help icon you can get information from by moving your cursor over it. To start with your pre-migration scripts, select **Enable**, which will then activate the fields below.

### Working Directory

This is the working directory for the script. The default directory is the same folder as the migration plan. Click on the browse button to select a different folder. The **Reset** button will restore the current migration plan folder as the working directory.

## Run

This drop down allows you to choose either to run a custom script or an executable with parameters.

### Command Executable

If you selected **Executable with Parameters** from the **Run** menu, this field will appear. This is the file path to the command executable to run before migration. Type it in directly or use the browse button to find the executable. This is a required field.

### Command Parameters

If you selected **Executable with Parameters** from the Run drop-down menu, this field will appear. Enter in command line parameters here to use with the command executable.

### Script

If you selected **Custom script** from the **Run** menu, enter in your pre-migration script here. It will be executed as a \*.cmd file. This is a required field.

### Step 2: Post-Migration

The **Run Post Migration** half of the screen is dedicated to scripts that will run after migration.

**Run Post Migration**

**Enable** ?

Working Directory ?  ... Reset ?

Run ?  ▼

Command Executable ?  ...

Command Parameters ?

Each field has a help icon you can get information from by moving your cursor over it. To start with your post-migration scripts, select **Enable**, which will then activate the fields below.

## Working Directory

This is the working directory for the script. The default directory is the same folder as the migration plan. Click on the browse button to select a different folder. The **Reset** button will restore the current migration plan folder as the working directory.

## Run

This drop down allows you to choose either to run a custom script or an executable with parameters.

## Command Executable

If you selected **Executable with Parameters** from the **Run** menu, this field will appear. This is the file path to the command executable to run before migration. Type it in directly or use the browse button to find the executable. This is a required field.

## Command Parameters

If you selected **Executable with Parameters** from the **Run** menu, this field displays. Enter in command line parameters here to use with the command executable.

## Script

If you selected **Custom script** from the **Run** menu, enter in your post-migration script here. It will be executed as a \*.cmd file. This is a required field.

Step 3: Continue to Next Step

When you are ready, click **Next**.

Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see [Permissions](#).

### Migration Plans: Plan Options

The last step of creating a migration plan in the Tableau Content Migration Tool is configuring the plan options.

#### Step 1: Configure options

The **Plan Name** is the name of the plan as it will appear in Content Migration Tool. We recommend using a user-friendly name for your plan name.

The following are available options:

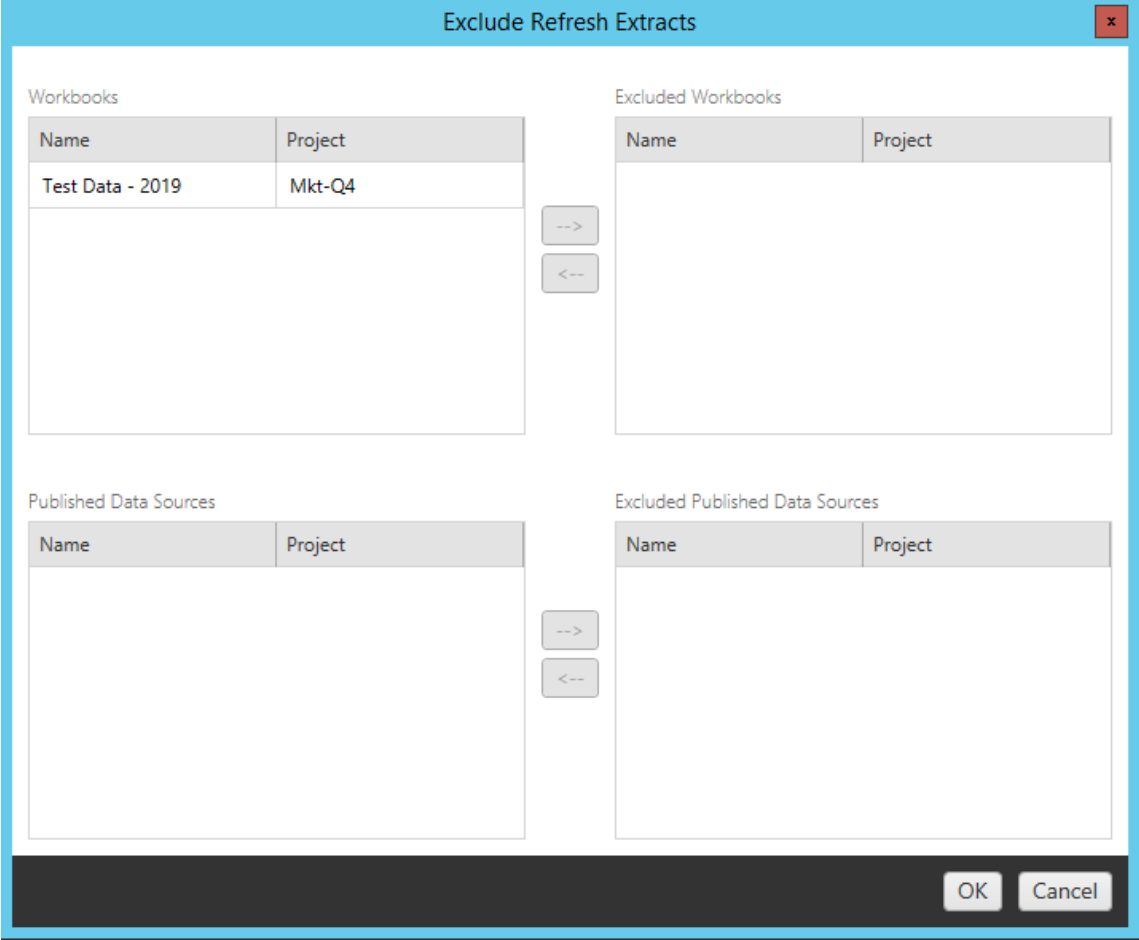

- **Refresh Extracts After Migration:** If selected, data extracts will be refreshed immediately after migration if Content Migration Tool detects they have been modified during migration. Click the **Filter** link to exclude specific extracts. For more information, see [Exclude extract refreshes](#) below.
- **Automatically create Extract Refresh Schedules that do not Exist:** Automatically creates destination extract schedules that do not exist. If not checked, source schedules that do not exist on the destination server will not be copied.

- **Continue Migration if Workbook or Data Source Fails:** If checked, errors migrating a workbook or data source will not cause the migration to stop. The errors will be logged and the migration will continue. Errors during version control will always stop the migration.
- **Continue Migration if Permission or Ownership Mapping Fails:** If checked, errors copying permissions or ownership will not cause the migration to stop. The errors will be logged and the migration will continue.

## Exclude extract refreshes

By clicking **Filter** next to **Refresh Extracts After Migration**, you can choose the workbooks or published data sources that will not be refreshed automatically. Use the arrow buttons to select the items you want to exclude, and click **OK**.

Step 2: Version control

These options allow you to avoid losing the existing workbooks in the destination site that might be replaced by the migrated workbooks.

Select **Enable** to save previous versions of your content. You can choose to archive workbooks and/or published data sources. Once version control is enabled, you must select a project from the **Archive To** menu, which lists all of the projects in your destination site. We recommend creating a separate archive project to store your versioned content. Click the refresh button to display any projects that have been added or modified on the site.

#### Step 3: Save plan

Once you have selected your plan options, click **Save Plan** to save your plan for future use. The plan will be saved to the `Documents\Tableau Content Migration Tool Plans` folder on your local machine.

#### Step 4: Continue to next step

When you are ready, click **Verify & Run** to end the Planning phase and prepare to run your plan.

#### Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see [Permissions](#).

## Migrate Workbooks and Data Sources with Extracts

Tableau Server users can publish extracts which are copies, or subsets of the original data. These extracts may be embedded in a workbook or a data source. By default, when you use the Tableau Content Migration Tool to migrate a workbook or data source that contains an extract, that extract is migrated along with the workbook or data source that contains it. The Content Migration Tool gives you a couple options for controlling this behavior:

- **Switching to a Live Connection**

You can add the **Remove Extract** transformation to your migration plan to remove the extract from your workbook or data source during migration. As always, the source workbook or data source will not be modified. The copy of the workbook or data source migrated to the destination site will have the extract removed from it. This effectively switches the data connection back to a live connection.

- **Refreshing Extracts after Migration**

You can enable the **Refresh Extracts After Migration** option in your migration plan to have an immediate extract refresh task scheduled after the workbook or data source is migrated.

We don't recommend using the **Refresh Extracts After Migration** option if your migration plan also uses the **Set Connection Info** transformation to change the data connection to point to a different set of data (for example, a different database server or database). When you change the connection information to point to different data and use the **Refresh Extracts After Migration** option, this can unintentionally expose data in a way that is a potential security issue.

For more information, see [Option 3: Refresh Extracts After Migration](#).

## Changing data connections that use extracts

Tableau data connections are either live connections that directly query a data source, or they are extracts of a data source. Extracts are copies or subsets of the original data and can be

embedded in a workbook or data source. When present, the views will query data from the extract instead of the underlying data source.

Commonly, you'll want to modify the data source connection during the migration so that it points to a different database on the destination site than it did on the source site.

For example, if you are migrating a workbook from your staging site to your production site, you will likely want to update the data connections inside the workbook to connect to your production database. You can implement this by using the **Set Connection Info** transformation in your migration plan. Now you have a migration plan which copies a workbook from staging to production and updates the data connections to point to the production database.

If your workbook uses an extract, additional work is required. In this scenario, the workbook will be migrated and the live data connection updated. However, the views will still show data from the staging database since it still contains the staging database extract - copied from the source (staging) site. There are a few ways to address this.

### Option 1: Use Published Data Sources

You can change your workbooks so that they use published data sources instead. This way, the extract will be managed as part of the published data source and migrating updates to the workbooks that use that data source can be simplified by not having to worry about the connection to the live database or the data extract.

### Option 2: Remove the Extract During Migration

You can add a **Remove Extract** transformation to your migration plan. This will remove the extract from your workbook, effectively switching the data source to a live connection.

### Option 3: Refresh the Extract After Migration

You can use the **Refresh Extracts After Migration** option in your migration plan. This will migrate the extract along with the workbook but will schedule an immediate extract refresh task for that workbook after the migration is complete.

This option is usually not recommended when used in combination with a **Set Connection Info** transformation because of potential security issues that it can introduce.

The issue is that the migrated workbook on your destination site will still show the old (source) extract data for the period between the completion of migration and the completion of the extract refresh task. If the extract refresh task fails, then the old/source extract data will remain until the extract is refreshed.

In a scenario like we've outlined above, migrating from a staging to production environment, this may be acceptable but you should be aware that the users of your workbooks may not be aware that the workbook is showing old/staging data due it being recently migrated and the extract not being refreshed yet.

In other scenarios where you may be using **Set Connection Info** to change data connections to point to a different set of customer or client data, this could introduce serious security issues where the workbook's extract contains data from a different client or customer until the extract has been refreshed post-migration.

One way to mitigate this issue is to implement a 2-stage migration. This approach requires you to create two migration plans, one for each step described below and ensures the workbooks and data sources have an up-t-o-date extract before they are accessible.

- **Stage 1:** Migrate your content to a project on your destination site that only administrators have access to. This migration allows you to use the **Refresh the Extract After Migration** option along with the **Set Connection Info** transformation to update the data connection, because no unauthorized users will have an opportunity to see the old data, even if the extract refresh fails.
- **Stage 2:** After stage 1 is complete and you confirm there is a successful extract refresh, run a second migration plan to migrate the content from the stage 1 destination to the final destination where it is visible to end-users.

### Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see [Permissions](#).

### Migrate Workbooks and Data Sources with Embedded Credentials

Starting in version 2023.1, authorized users can migrate workbooks and published data sources with embedded credentials from Tableau Server to Tableau Cloud. Additional configuration is required before migrating with Content Migration Tool.

**Note:** Content Migration Tool does not support embedded credential migration for OAuth connections. For more information, see [Migration Limitations](#).

### Overview

Migrating embedded credentials using Content Migration Tool (CMT) is available when connecting to Tableau Server as the source site and Tableau Cloud as the destination site. Both sites must have an [Advanced Management](#) license.

Now that we've covered the requirements, let's discuss how migration works. You'll need to work closely with the Tableau Cloud site administrator and TSM administrator (sometimes the same person) to allow the feature and authorize a site user. After the feature is activated, the authorized site user builds a migration plan and selects the publish options *Migrate Embedded Credentials for Workbooks* and *Migrate Embedded Credentials for Data Sources*.

When running the migration plan, all required content credentials are transmitted in an encrypted content manifest from Tableau Server to Tableau Cloud. As CMT publishes content, the destination Tableau Cloud site embeds matched credentials securely from the manifest into the content (workbooks or published data sources). Any problems that occur during migration will appear in the Errors and Warnings tab in CMT. For more information, see [Migration Plan Overview](#).

## Allow embedded credential migration

Use the following steps to allow embedded credential migration from Tableau Server to Tableau Cloud.

## Tableau Cloud

1. Open a browser window and sign in to Tableau Cloud as a site administrator.
2. Select **Settings > General**, and scroll down to **Manage Content Migration**.

3. Click **Create new key** to generate an encryption key pair.

**Note:** The public key is only displayed once. If you lose the key before completing the configuration, you'll need to generate a new key.

4. In the resulting window, click **Copy to clipboard** and then close the window.
5. Paste the public key to a file and store it in a safe location. The TSM administrator will use the public key to allow migration. You can view the public key expiration date on the Settings page.

## TSM Command Line Interface

1. Open a command prompt with an account that is a member of the `tsmadmin` group on a node in the cluster.

2. Use `tsm security authorize-credential-migration` to allow embedded credential migration to the Tableau Cloud site. For more information, see `tsm security`.

```
tsm security authorize-credential-migration --source-site-url-namespace <Tableau Server site ID> --destination-site-url-namespace <Tableau Cloud site ID> --destination-server-url <Tableau Cloud site url> --authorized-migration-runner <username> --destination-public-encryption-key <public key>
```

**Note:** When running TSM commands from a remote node, use `tsm login` to authenticate a session with the Tableau Server Administration Controller service before running `tsm security authorize-credential-migration`.

3. (Optional) Use `tsm security cancel-credential-migrations` to cancel granted authorizations. By default, migration authorization will expire in 7 days or the number of days specified with the `--expiration-time-in-days` option.

## Content Migration Tool

1. Open Content Migration Tool and select **Create New Plan** or **Browse for a Plan**.
2. On the Sites page, click **Sign in to Tableau**, and connect to Tableau Server as the source and Tableau Cloud as the destination. Embedded credential migration is only available when migrating from Tableau Server to Tableau Cloud.
3. Build your migration plan and select the following Publish Options:
  - On the Workbook Publish Options page, select **Migrate Embedded Credentials for Workbooks**. For more information, see Migration Plans: Workbooks.
  - On the Data Source Publish Options page, select **Migrate Embedded Credentials for Data Sources**. For more information, see Migration Plans: Published Data Sources.
4. When you are ready, click **Verify & Run** to start the migration.

The workbooks and published data sources you selected are migrated to your Tableau Cloud site and should not prompt for authentication. If you experience issues while migrating embedded credentials, see [Troubleshooting](#).

## Troubleshooting

This section includes some common migration issues you might encounter and suggestions to resolve them.

## There is no option to migrate embedded credentials

You can only migrate embedded credentials from a Tableau Server to a Tableau Cloud site. Tableau Server and Content Migration Tool must be running versions 2023.1 or later. For more information, see [Install Tableau Content Migration Tool](#).

## Migrating embedded credentials failed

In the [Errors and Warnings](#) tab of CMT, you may receive an error indicating that migrating the embedded credentials failed. This can occur when the public key used to authorize migration has expired.

As a Tableau Cloud site administrator, go to the Settings page and verify that the public key is valid. You'll have to create a new encryption pair to authorize the migration if the public key expires. For more information, see [Allow embedded credential migration](#).

Who can do this?

- Tableau Cloud site administrator and TSM administrator are required to allow embedded credential migration.
- The authorized site user must have an Explorer role or higher. They must also have View and Download/Save a Copy capabilities for workbooks on the source site and View and Publish capabilities for target projects on the destination site.

For more information, see [Permissions](#).

## Using the Tableau Content Migration Tool Console Runner

The Tableau Content Migration Tool includes a command-line utility for running migrations, `tabcmt-runner.exe`, located in the installation folder. The default installation folder is `%PROGRAMFILES%\Tableau\Tableau Content Migration Tool`.

**Note:** The `tabcmt-runner.exe` utility is not the same as the `tabcmt.cmd` command line utility which is used to configure the Content Migration Tool graphical application. For more information about `tabcmt.cmd`, see [Using the Tableau Content Migration Tool Command Line Interface](#).

### Usage:

- `tabcmt-runner [options] <plan_file.tcmx>`
- `tabcmt-runner license --remove`
- `tabcmt-runner license <new license key>`
- `tabcmt-runner license <license file path> [--passphrase=<license file passphrase>]`
- `tabcmt-runner encryption --reset`
- `tabcmt-runner encryption <new_key>`
- `tabcmt-runner improvement [on|off]`
- `tabcmt-runner --help`
- `tabcmt-runner --version`
- `tabcmt-runner script-warning [on|off]`

### Options:

- `--version`
- `--help`
- `--quiet`
- `--info`
- `--logfile=VALUE`
- `--src-user=VALUE`
- `--src-password=VALUE`
- `--dest-user=VALUE`
- `--dest-password=VALUE`

- `--https=VALUE`
- `--allow-scripts`

### Run Plan

Executes a migration plan immediately.

```
tabcmt-runner [options] <plan file>
```

Available options:

- `--logfile=<file name>` sets the file name to log output to
- `--https=<secure|legacy>` sets the HTTPS mode
- `--quiet` disables logging to stdout
- `--src-user=<username>` sets the username of the source connection
- `--src-password=<password>` sets the password of the source connection
- `--dest-user=<username>` sets the username of the destination connection
- `--dest-password=<password>` sets the password of the destination connection

Exit codes:

- 0 indicates that the migration was successful.
- 1 indicates that the migration was successful but warning messages were logged.
- 2 indicates that the migration failed. Specific errors will be included in the log output.

### Show Plan Summary

Shows a summary of the migration plan and then exits.

```
tabcmt-runner --info <plan file>
```

### help

Shows usage information for the command line utility.

```
tabcmt-runner --help
```

### version

Shows the current application version information.

```
tabcmt-runner --version
```

### encryption

Reset the encryption key, or specify a new one. You must specify the encryption key before using the `tabcmt-runner` utility, even if you already done so from the Content Migration Tool UI.

```
tabcmt-runner encryption <new_key> | --reset
```

### improvement

Default value: `on`

Enables or disables collection of anonymous usage information by the application. This information is completely anonymous and is sent periodically to Tableau to help us improve Content Migration Tool.

## Examples

Show whether the improvement program is enabled or disabled:

```
tabcmt-runner improvement
```

Enable or disable the improvement program:

```
tabcmt-runner improvement <on|off>
```

### license

Deprecated in July 2022.

This command is only applicable for legacy licenses. Manages a legacy application license for the current user. When using a legacy key, to use the `tabcmt-runner` utility you must activate the license using this command, even if you already activated it from the Content Migration Tool UI.

## Examples

Show the current license information:

```
tabcmt-runner license
```

Set/activate a serial key or offline license key:

```
tabcmt-runner license <key>
```

Remove/deactivate the current license:

```
tabcmt-runner license --remove
```

Set/activate using a license file:

```
tabcmt-runner license <file path> [--passphrase=<password>]
```

script-warning

Default value: on

Shows a warning message when running a migration plan that includes migration scripts.

**Note:** This command updates your selection on the Settings page. For more information, see Tableau Content Migration Tool Settings.

## Examples

Show if script warning is turned on or off.

```
tabcmd-runner script-warning
```

Turn script warning on or off

```
tabcmd-runner script-warning <on|off>
```

If turned on, you must include the option `--allow-scripts` to execute migration plans.

```
tabcmd-runner --allow-scripts <plan file>
```

Who can do this

To use the console runner, you must have all the following:

- Administrator permissions on the Content Migration Tool machine.
- Tableau site user account with an Explorer role or higher.

## Tableau Server on Linux Administrator Guide

- View and Download Workbook/Save a Copy permissions on the source site.
- Publishing rights for the destination site.

### Example: Scripting Migration Plans

**Note:** This topic includes a sample script you can use as the basis for scripting a multi-plan migration that satisfies your needs and environment. This script is intended to be used as a sample only, and not to be run as-is. For detailed instructions on using the console runner, see [Using the Tableau Content Migration Tool Console Runner](#).

Tableau Content Migration Tool command line utility for running migrations can be used to automate the running of a migration plan from an external scheduler (such as Windows Task Scheduler) or from a custom script. The console runner only runs one migration plan (stored in a .edt file) at a time. If you have a group of migration plans you want to run as a group, then you can use a custom script in combination with the Content Migration Tool console runner.

The example below is written in PowerShell and uses the console runner to execute a list of migration plans as a group.

The following example code demonstrates:

- Running multiple migration plans as a group using the console runner.
- Optionally halting deployment of the group of plans immediately when any single migration in the group fails.
- Using the console runner's exit code to determine whether the migration failed or logged warnings.

```
# List of migration plans to execute as a group.
$planFiles = @(
    'customer 1.tcmx',
    'customer 2.tcmx'
)

# True or false whether to continue with the next plan if a
```

```

migration fails.
$continueOnFailure = $false

# Path to the CMT console runner executable
$runnerExe = 'C:\Program Files (x86)\Tableau\Tableau Content Migration Tool\tabcmt-runner.exe'

# Store the exit code from the previously run migration plan.
$lastResult = -1

# Loop through and run each migration plan one at a time.
$planFiles | % {
    $file = $_

    if ($lastResult -ge 2 -and -not($continueOnFailure)) {
        Write-Warning "Skipping plan because previous migration failed.
`nSkipped plan: $file"
        return
    }

    Write-Verbose "Running migration plan: $file"
    & $runnerExe $file
    $lastResult = $LASTEXITCODE

    if ($lastResult -ge 2) {
        Write-Error "Migration failed. See output or log file for error
details.`nPlan: $file" -ErrorAction 'Continue'
    }
    elseif ($lastResult -eq 1) {
        Write-Warning "Migration completed with warnings. See output or
log file for warning details.`nPlan: $file"
    }
}
}

```

#### Who can do this

To script migration plans, you must have all the following:

## Tableau Server on Linux Administrator Guide

- Administrator permissions on the Content Migration Tool machine.
- Tableau site user account with an Explorer role or higher.
- View and Download Workbook/Save a Copy permissions on the source site.
- Publishing rights for the destination site.

## Using the Tableau Content Migration Tool Command Line Interface

The Tableau Content Migration Tool includes a command line interface, `tabcmt.cmd`, located in the installation folder. The default installation folder is `%PROGRAMFILES%\Tableau\Tableau Content Migration Tool (32-bit Windows)` or `%PROGRAMFILES(x86)%\Tableau\Tableau Content Migration Tool (64-bit Windows)`.

**Note:** The `tabcmt.cmd` utility is not the same as the Content Migration Tool console runner, `tabcmt-runner.exe`. The console runner is a separate command line utility used for running migrations from the command line. For information on using the Content Migration Tool console runner, see [Using the Tableau Content Migration Tool Console Runner](#).

Here are the commands that can be used with the `tabcmt` command line:

- `migrate`
- `help`
- `update`
- `version`

`migrate`

Opens a migration plan file to the migrate step in the GUI:

```
tabcmt migrate <plan file>
```

`help`

Shows general help about the command line interface and the available commands.

Examples

Show all commands available:

```
tabcmt help
```

Show help and usage information for a specific command:

```
tabcmt help <command>
```

## license

Deprecated in July 2022.

This command is only applicable for legacy licenses. Manages the application license for the current user.

### Examples

Show the current license information:

```
tabcmt license
```

Remove/deactivate the current license:

```
edt license remove
```

Set/activate a serial key or offline license key:

```
tabcmt license <key>
```

Set/activate using a license file:

```
tabcmt license <file path> [--passphrase=<password>]
```

## update

Manages the options for application updates.

### Examples

Show the current update settings:

```
tabcmt update
```

Enable or disable the automatic update notifications:

```
tabcmt update --disabled=<true|false>
```

## Tableau Server on Linux Administrator Guide

Set the URL to detect/download updates from:

```
tabcmt update --url=<url>
```

Enable or disable showing beta updates. Set to false to only show stable release updates.

```
tabcmt update --beta=<true|false>
```

version

Shows the current application version information.

```
tabcmt version
```

Who can do this

To use the command line interface, you must have all the following:

- Administrator permissions on the Content Migration Tool machine.
- Tableau site user account with an Explorer role or higher.
- View and Download Workbook/Save a Copy permissions on the source site.
- Publishing rights for the destination site.

## Tableau Content Migration Tool Settings

The Tableau Content Migration Tool default settings work in most cases, but you can change these if you need to, or if you are working with Tableau Support and they ask you to make changes.

To view or update the Content Migration Tool settings:

1. Open Content Migration Tool.
2. Click **Help > Settings**. The Settings dialog opens:

**Diagnostics**—Click **Open Log Folder** to open the logs location. Here you can view the logs, and zip them up if you need to send them to Tableau. For more information, see [Tableau Content Migration Tool Log Files](#).

Select **Enable Network Tracing** if you are working with Support and they ask you to include a network trace in the logs. This applies until you clear the option or restart the Content Migration Tool.

**Security**—The encryption key is automatically generated on installation. If you change the encryption key, any migration plans with embedded passwords that were created with the previous key cannot be opened. If you have multiple installations of Tableau Content Migration Tool and want to share migration plans, you need to make sure the encryption key used by each instance of the tool is the same.

**Migration Scripts**—By default, a warning is displayed when running a migration plan that includes migration scripts or executables. Other users can edit these files, so verify that they're safe before running the migration. Toggling this setting on and off will also update your warning preference for the console runner. For more information, see [Using the Tableau Content Migration Tool Console Runner](#).

**Tuning**—In almost all cases you can leave these set to the defaults. If you are working with Support, they may ask you to change these settings.

**Temporary Files**—Select a location for temporary files if you want to change the default. This is the location where content is copied during a migration. You may want to change this if the default location does not have enough space to temporarily hold migrated content.

**Networking**—Selecting **Allow Legacy HTTPS Connections** gives you the ability to connect to Tableau Server installations running with older HTTPS configurations (for example, SSL v3). This is not recommended.

Who can do this

Typically, the tasks listed above can only be done by a user with Administrator access on the machine where Content Migration Tool is installed.

## Tableau Content Migration Tool Log Files

Tableau Content Migration Tool generates log files when you run migrations. These can be helpful for troubleshooting problems.

**Note:** For information on all the Content Migration Tool settings, see Tableau Content Migration Tool Settings.

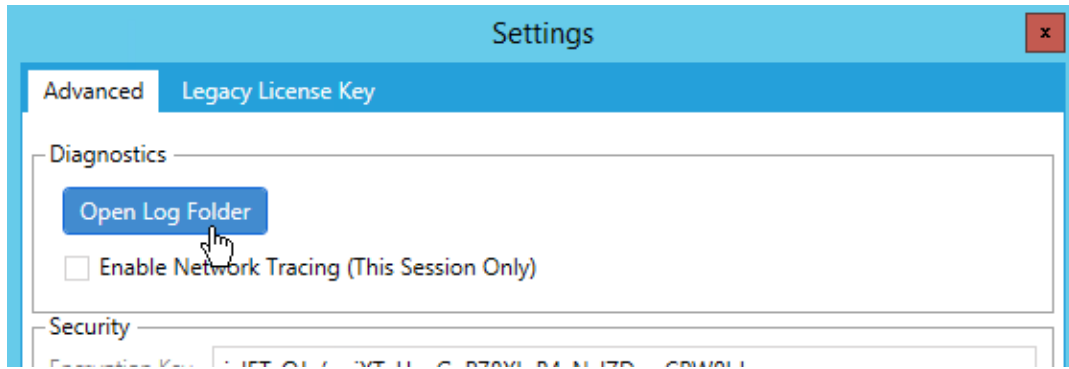

### Content Migration Tool Log File Location

To find the Content Migration Tool log files from within the Content Migration Tool:

1. Start Content Migration Tool.
2. Click **Help** and **Settings**:

3. In the **Settings** dialog, click **Open Log Folder**:

A window opens with the log files.

If you are working with Tableau Support and they ask you to send log files, zip the files up before you send them. For more information on sending log files to Tableau, see the [Tableau Knowledge Base](#).

Who can do this

Typically, the tasks listed above can only be done by a user with Administrator access on the machine.

## Activity Log

If you have Tableau Server with Advanced Management, activity log files are automatically recorded for detailed analysis and auditing. These logs are stored in the `backgrounder`, `dataserver`, `vizportal`, and `vizqlserver` folders on the local hard drive, using the default path `/var/opt/tableau/tableau_server/data/tabsvc/logs/`. Within each directory, find files named `cepp-canonical-events_*.log` that record events and operations.

With the Activity Log, you can:

- View detailed event data for Tableau Server.
- Capture compliance information and keep track of who is doing what on your Tableau sites.

- Audit permissions changes including:
  - Adding or removing users from a group.
  - Moving a piece of content from one project to another.
  - Explicitly changing the permissions on a piece of content.

You can track permissions change events are essential for implementing a robust book of controls on your Tableau environment. These controls are useful for compliance use cases.

Supplement the information provided by Admin Insights and Admin Views to track site activity and usage metrics.

All events include a timestamp and the ID of the actor that performed the event. If relevant, the ID of the piece of affected content is included with the event.

You can use tools like Splunk or Amazon Cloudwatch to examine the Activity Log. You can use these tools to query log fields and answer questions like:

- What were the 10 actions last taken by a particular user.
- Who last performed an event on a piece of content.
- What was the last action taken on a piece of content.

## Audit Permissions Using the Activity Log

Permission auditing allows system administrators to monitor which users have modified access controls to Tableau content. There are two ways to modify access control: *explicit* changes (by changing permission capabilities on a project or content item) and *effective* changes (by changing user site roles, group membership, moving content, and so on). All of these changes are recorded, so administrators can certify that security and access controls are maintained.

For more information about how permission rules are evaluated, see Effective permissions.

### Log format

Every action that modifies user or group access to content will get a log entry. Each log entry is structured in a JSON format, with specific keys representing different pieces of information. A log entry contains two parts:

- **Metadata:** Contains information about when and where an action occurred and what user performed the action.
- **Action:** Contains information about what piece of content had its permissions changed, what capabilities were changed, and to what values the capabilities were changed.

**Note:** Activity Log records changes made through the Permissions Dialog UI and REST API. For more information about API methods, see [Permissions Methods](#).

The Activity Log entries are not formatted, and the keys are not sorted in any particular order in the logs. When auditing permissions, you can combine Activity Log data with other data sources to link IDs to names and make the events easier to interpret.

### Example

The following is an example log entry showing a group was allowed to connect to a data source.

```
{
  event: {
    actorUserId: 39872
    actorUserLuid: "4e6b42bf-9040-4e60-b326-1c56a4fb96f8"
    authorizableType: "DATASOURCE"
    capabilityId: 32
    capabilityValue: "connect"
    contentId: 2099835
    contentName: "Superstore ExtractNeal3"
    eventTime: "2023-01-31T22:44:23.650058Z"
    granteeId: 22
    granteeLuid: "dae0717a-d524-436d-b469-fadeaa22a5dd"
```

```

granteeType: "Group"
granteeValue: "GROUP_ALLOW"
initiatingUserId: 39872
initiatingUserLuid: "4e6b42bf-9040-4e60-b326-1c56a4fb96f8"
isError: false
metadata: {
    applicableToOnline: true
    applicableToServer: true
    comment: "Update Permissions"
    customerAccessible: true
    eventCategory: "security"
    eventType: "update_permissions"
    eventVersion: "1.0"
    internalAccessible: false
}
permissionType: explicit"
siteLuid: "b45e272d-10c7-49d5-9037-e53ce47dbf4e"
}
traceUuid: "3a108a2f-c0ac-4ac7-a5f8-29zf7e064ae1"
}

```

The log entry captures essential information regarding the event, including:

- `eventType` shows an update permissions event occurred
- `permissionType` shows an explicit change to permissions
- `contentId` shows the ID of the content that was modified
- `authorizableType` shows the content type, in this case, a data source
- `capabilityValue` shows the capability that was changed
- `granteeId` shows the grantee that was affected
- `actorUserId` shows the ID of the user who performed the change
- `eventTime` shows the date and time of the change

## Events

Log entries contain various event types for permissions changes, such as `content_owner_change` when the content owner changes or `delete_permissions` when an explicit permission rule is deleted on content. For more information about event types, attributes, and when they're recorded, see Activity Log Event Type Reference.

## Activity Log Event Type Reference

The following tables describe the Activity Log event types and attributes.

### Event type details

The following content describes each event type in Activity Log. Use the alphabetically sorted list of event types on the right, or **ctrl/cmd-f** to go directly to keywords you have in mind.

**Note:** Timestamps for events are recorded in ISO 8601 UTC.

### Common attributes

The following table contains common attributes for all Activity Log events. For event-specific attributes, review the individual event tables.

| Attribute Name   | Type    | Description  |
|------------------|---------|--|
| actorUserId      | integer | ID of the user who performed the action that initiated the event   |
| actorUserLuid    | string  | LUID of the user who performed the action that initiated the event   |
| eventTime        | string  | Timestamp when the event occurred  |
| initiatingUserId | integer | ID of the initiating user. For impersonation, it's the ID of the administrative user who initiated impersonation. For standard login, the value is the same as <code>userId</code> . |

|                    |         |   |
|--------------------|---------|---|
| initiatingUserLuid | string  | LUID of the initiating user. For impersonation, it's the LUID of the administrative user who initiated impersonation. For standard login, the value is the same as userLuid.                                      |
| licensingRoleName  | string  | Name of the user's licensing role when the event occurred   |
| serviceName        | string  | Name of service that initiated the event, such as vizportal, vizqlserver, or sitesaml.  |
| siteLuid           | string  | LUID of the Tableau site where the event occurred   |
| siteRoleId         | integer | The user's site role ID. The value 0 = SiteAdministratorExplorer, 1 = SupportUser, 2 = Explorer-CanPublish, 3 = Explorer, 7 = Guest, 8 = Unlicensed, 9 = Viewer, 10 = Creator, and 11 = SiteAdministratorCreator. |
| systemAdminLevel   | integer | Indicates if the user is a system administrator. The value 10 = System Admin and 0 = Not a system admin.  |

#### add\_delete\_user\_to\_group

The `add_delete_user_to_group` event is logged when a user is added or removed from a group.

| Attribute Name | Type    | Description  |
|----------------|---------|--|
| groupId        | integer | The ID of the group  |
| groupLuid      | string  | The LUID of the group  |
| groupOperation | string  | Group operation, either add or delete user to a group                              |
| isError        | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| userId         | integer | The ID of the user   |

|          |        |                      |
|----------|--------|----------------------|
| userLuid | string | The LUID of the user |
|----------|--------|----------------------|

background\_job

The `background_job` event logs information about jobs run as background tasks. For each job, an event is created to record its various states, including initiation time, queueing, start time, and success or failure.

| Attribute Name     | Type    | Description  |
|--------------------|---------|--|
| args               | string  | Arguments of the job   |
| duration           | long    | Duration of the job  |
| eventInitiatedTime | string  | Start time of the job  |
| eventState         | string  | State of the job   |
| isRunNow           | bool    | Indicates whether the job was initiated manually, by clicking the “Run Now” option on the site or using REST API, or if it was triggered by a schedule.<br><br><b>Note:</b> Starting in April 2024, jobs triggered by a schedule ( <code>False</code> ) include data for all attributes listed in the table. Attributes for jobs initiated manually ( <code>True</code> ) are under active development, and tentatively scheduled for inclusion in a future release. |
| jobId              | integer | ID of the job  |
| jobLuid            | string  | LUID of the job  |
| jobType            | string  | Identifies the background job type associated with the event<br><br><b>Note:</b> Starting in April 2024, only the <code>IncrementExtracts</code> , <code>RefreshExtracts</code> , and  |

|                  |         |  |
|------------------|---------|--|
|                  |         | RefreshExtractsViaBridge jobs include data for all attributes listed in the table. Attributes for other job types are under active development, and tentatively scheduled for inclusion in a future release.       |
| notes            | string  | Notes of the job   |
| objLuid          | string  | Some tasks are specific to a particular workbook or data source. In such cases, the object_luid is the primary key of the relevant item, in either the workbooks or data sources tables, as indicated by obj_type. |
| objName          | string  | Name of the associated object. Used in conjunction with obj_luid, as described there.  |
| objOwnerLuid     | string  | A foreign key reference to the user who owns the job target object   |
| objOwnerName     | string  | Name of the user who owns the job target object  |
| objRepositoryUrl | string  | Uniquely identifies a workbook or data source and is used when referencing the object in a URL. The value is derived from the ASCII characters in the workbook or data source name.                                |
| objRevision      | string  | The revision number. Starts with 1.0 and increments by 0.1 with each republication.  |
| objSize          | integer | The number of bytes used in storing the job target object information  |
| objType          | string  | Either a workbook or data source. Used in conjunction with obj_luid.   |
| podName          | string  | Name of the Tableau pod that handled the job   |
| projectLuid      | string  | A foreign key reference to the project in which the job target object exists   |

Tableau Server on Linux Administrator Guide

|                   |         |   |
|-------------------|---------|---|
| projectName       | string  | Name of the project that contains the job target object                                   |
| projectOwnerEmail | string  | Email address of the user who owns the project containing the job target object           |
| projectOwnerLuid  | string  | A foreign key reference to the user who owns the project containing the job target object |
| scheduleLuid      | string  | Schedule LUID of the task; may be null if the job was manually started                    |
| scheduleName      | string  | Schedule name of the task; may be null if the job was manually started                    |
| siteId            | integer | ID of the site  |
| siteName          | string  | Name of the Tableau site  |
| taskId            | integer | ID of the task; may be null if the job was manually started.                              |
| taskLuid          | string  | LUID of the task; may be null if the job was manually started.                            |
| timeZone          | integer | Time zone of the job  |

content\_owner\_change

The `content_owner_change` event is logged when the content owner changes.

| Attribute Name | Type    | Description   |
|----------------|---------|---|
| contentId      | integer | The ID of the content that had the owner changed            |
| contentLuid    | string  | LUID of the content that had the owner changed              |
| contentName    | string  | Name of the content that had the owner changed              |
| contentType    | string  | The type of content, such as data source, workbook, or view |

|              |         |  |
|--------------|---------|--|
| isError      | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| newOwnerId   | integer | The ID of the new content owner  |
| newOwnerLuid | string  | The LUID of the new content owner  |
| oldOwnerId   | integer | The ID of the old content owner  |
| oldOwnerLuid | string  | The LUID of the old content owner  |

### create\_delete\_group

The `create_delete_group` event is logged when a group is created or deleted.

| Attribute Name | Type    | Description  |
|----------------|---------|--|
| groupDomain    | string  | The domain of the group, such as local   |
| groupId        | integer | The ID of the group  |
| groupLuid      | string  | The The LUID of the group  |
| groupName      | string  | The name of the group that had its permissions changed                             |
| groupOperation | string  | Group operation, either create or delete   |
| isError        | boolean | Indicates if the audit scenario was completed successfully or failed with an error |

### create\_permissions

The `create_permissions` event is logged when a new explicit permission rule is created.

| Attribute Name   | Type    | Description  |
|------------------|---------|--|
| authorizableType | string  | The type of content that had its permissions changed, such as a project or workbook                                  |
| capabilityId     | integer | The ID of the capability. A capability is the ability to perform actions on content, such as view, filter, download, |

|                 |         |  |
|-----------------|---------|--|
|                 |         | or delete  |
| capabilityValue | string  | Description of the capability  |
| contentId       | integer | The ID of the content that had the permissions updated                             |
| contentLuid     | string  | The LUID of the content item   |
| contentName     | string  | The name of the content that had the permissions updated                           |
| granteeId       | integer | The ID of the grantee  |
| granteeLuid     | string  | The LUID of the grantee  |
| granteeType     | string  | The type of grantee, either user or group  |
| granteeValue    | string  | The updated permissions value, such as 'user allow' or 'group allow'               |
| isError         | boolean | Indicates if the audit scenario was completed successfully or failed with an error |

`delete_all_permissions`

The `delete_all_permissions` event is logged when all explicit permission rules for content are deleted, typically when content is deleted.

| Attribute Name   | Type    | Description   |
|------------------|---------|---|
| authorizableType | string  | The type of content that had its permissions changed, such as a project or workbook |
| contentId        | integer | The ID of the content that had the permissions updated                              |
| contentLuid      | string  | The LUID of the content   |
| contentName      | string  | The name of the content that had the permissions updated                            |
| isError          | boolean | Indicates if the audit scenario was completed suc-                                  |

|  |  |                                   |
|--|--|-----------------------------------|
|  |  | cessfully or failed with an error |
|--|--|-----------------------------------|

**delete\_permissions**

The `delete_permissions` event is logged when an explicit permission rule is deleted on content.

| Attribute Name   | Type    | Description  |
|------------------|---------|--|
| authorizableType | string  | The type of content that had its permissions changed, such as a project or workbook  |
| capabilityId     | integer | The ID of the capability. A capability is the ability to perform actions on content, such as view, filter, download, or delete |
| capabilityValue  | string  | Description of the capability  |
| contentId        | integer | The ID of the content that had the permissions updated   |
| contentLuid      | string  | The LUID of the content  |
| contentName      | string  | The name of the content that had the permissions updated   |
| granteeId        | integer | The ID of the grantee  |
| granteeLuid      | string  | The LUID of the grantee  |
| granteeType      | string  | The type of grantee, either user or group  |
| granteeValue     | string  | The updated permissions value, such as 'user allow' or 'group allow'   |
| isError          | boolean | Indicates if the audit scenario was completed successfully or failed with an error   |

`delete_permissions_grantee`

The `delete_permissions_grantee` event is logged when all explicit permission rules for a user are deleted, typically when the user is deleted.

| Attribute Name | Type    | Description  |
|----------------|---------|--|
| granteeId      | integer | The ID of the grantee  |
| granteeLuid    | string  | The LUID of the grantee  |
| granteeType    | string  | The type of grantee, either user or group  |
| isError        | boolean | Indicates if the audit scenario was completed successfully or failed with an error |

`display_sheet_tabs`

The `display_sheet_tabs` event is logged when the "Tabbed Views" value is updated on a workbook.

| Attribute Name | Type    | Description  |
|----------------|---------|--|
| displayTabs    | boolean | Indicates whether sheets of the workbook are displayed as tabs or not              |
| isError        | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| workbookId     | integer | The ID of the workbook   |

`move_content`

The `move_content` event is logged when content is moved, for example, moving a workbook between projects.

| Attribute Name | Type    | Description                                      |
|----------------|---------|--|
| contentId      | integer | The ID of the content that had the owner changed |

|                  |         |  |
|------------------|---------|--|
| contentLuid      | string  | LUID of the content that had the owner changed                                     |
| contentName      | string  | Name of the content that had the owner changed                                     |
| contentType      | string  | The type of content, such as data source, workbook, or view                        |
| isError          | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| newContainerLuid | string  | LUID of the new container  |
| newContainerType | string  | The new container type, such as a project  |
| oldContainerLuid | string  | LUID of the previous container   |
| oldContainerType | string  | The previous container type, such as a project                                     |

#### project\_lock\_unlock

The `project_lock_unlock` event is logged when project permissions are locked or unlocked.

| Attribute Name         | Type    | Description  |
|------------------------|---------|--|
| controllingProjectLuid | string  | LUID of the project that controls permissions for the nested project               |
| isError                | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| projectLuid            | string  | LUID of the project  |
| projectOperation       | string  | Project operation, either lock or unlock   |

#### site\_storage\_usage

The `site_storage_usage` event logs the total storage capacity of the site in bytes, the amount of storage used, and the percentage of the total consumed. Administrators can use

this data to proactively monitor storage consumption and take action before reaching the site's storage limit.

| Attribute Name                  | Type    | Description  |
|---------------------------------|---------|--|
| actorUsername                   | string  | Username of the user who performed the action that initiated the event             |
| initiatingUsername              | string  | Username of the initiating user  |
| isError                         | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| totalPercentageStorageQuotaUsed | float   | Total percentage of storage usage  |
| totalStorageQuotaLimit          | long    | Total storage capacity in bytes  |
| totalStorageQuotaUsed           | long    | Total storage used in bytes  |

update\_permissions

The `update_permissions` event is logged when an explicit permission rule is updated for a content item.

| Attribute Name   | Type    | Description  |
|------------------|---------|--|
| authorizableType | string  | The type of content that had its permissions changed, such as a project or workbook  |
| capabilityId     | integer | The ID of the capability. A capability is the ability to perform actions on content, such as view, filter, download, or delete |
| capabilityValue  | string  | Description of the capability  |
| contentId        | integer | The ID of the content that had the permissions updated   |
| contentLuid      | string  | The LUID of the content  |

|                |         |  |
|----------------|---------|--|
| contentName    | string  | The name of the content that had the permissions updated                           |
| granteeId      | integer | The ID of the grantee  |
| granteeLuid    | string  | The LUID of the grantee  |
| granteeType    | string  | The type of grantee, either user or group  |
| granteeValue   | string  | The updated permissions value, such as 'user allow' or 'group allow'               |
| isError        | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| permissionType | string  | The permission type, either explicit or unspecified                                |

#### update\_permissions\_template

The `update_permissions_template` event is logged when a permission template for a project is updated.

| Attribute Name   | Type    | Description  |
|------------------|---------|--|
| authorizableType | string  | The type of content that had its permissions changed, such as a project or workbook  |
| capabilityId     | integer | The ID of the capability. A capability is the ability to perform actions on content, such as view, filter, download, or delete |
| capabilityValue  | string  | Description of the capability  |
| contentId        | integer | The ID of the content that had the permissions updated   |
| contentLuid      | string  | The LUID of the content  |
| contentName      | string  | The name of the content that had the permissions updated   |

|                |         |   |
|----------------|---------|---|
| granteeId      | integer | The ID of the grantee   |
| granteeLuid    | string  | The LUID of the grantee   |
| granteeType    | string  | The type of grantee, either user or group   |
| granteeValue   | string  | The updated permissions value, such as 'user allow' or 'group allow'                        |
| isError        | boolean | Indicates if the audit scenario was completed successfully or failed with an error          |
| permissionType | string  | The permission type, either explicit or unspecified   |
| templateType   | string  | The type of permission template used to change permissions, such as workbook or data source |

#### user\_create\_delete

The `user_create_delete` event is logged when a user is created or deleted.

| Attribute Name | Type    | Description   |
|----------------|---------|---|
| forUserName    | string  | The name of the user whose account was either created, updated or deleted                 |
| isError        | boolean | Indicates if the audit scenario was completed successfully or failed with an error        |
| siteRole       | string  | Site role of the user. Determines the maximum level of access a user can have on the site |
| targetUserId   | integer | The ID of the user whose account was either created, updated, or deleted                  |
| targetUserLuid | string  | The LUID of the user whose account was either created, updated, or deleted                |
| userOperation  | string  | The action performed on a user, either create, delete, or site role change                |

## Tableau Server Key Management System

Tableau Server has three Key Management System (KMS) options that allow you to enable encryption at rest. One is a local option that is available with all installations of Tableau Server. Two additional options require Advanced Management (formerly Server Management add-on), but allow you to use a different KMS.

Beginning in version 2019.3, Tableau Server added these KMS options:

- A local KMS that is available with all installations. This is described below.
- An AWS-based KMS that comes as part of Advanced Management. For details, see [AWS Key Management System](#).

Beginning in version 2021.1, Tableau Server added another KMS option:

- An Azure-based KMS that comes as part of Advanced Management. For details, see [Azure Key Vault](#).

### Tableau Server local KMS

The Tableau Server local KMS uses the secret storage capability described in [Manage Server Secrets](#) to encrypt and store the master extract key. In this scenario, the Java keystore serves as the root of the key hierarchy. The Java keystore is installed with Tableau Server. Access to the master key is managed by native file system authorization mechanisms by the operating system. In the default configuration, the Tableau Server local KMS is used for encrypted extracts. The key hierarchy for local KMS and encrypted extracts is illustrated here:

## Troubleshoot configuration

### Multi-node misconfiguration

In a multi-node setup for AWS KMS, the `tsm security kms status` command may report healthy (OK) status, even if another node in the cluster is misconfigured. The KMS status check only reports on the node where the Tableau Server Administration Controller process is running and does not report on the other nodes in the cluster. By default the Tableau Server Administration Controller process runs on the initial node in the cluster.

Therefore, if another node is misconfigured such that Tableau Server is unable to access the AWS CMK, those nodes may report Error states for various services, which will fail to start.

If some services fail to start after you have set KMS to the AWS mode, then run the following command to revert to local mode: `tsm security kms set-mode local`.

### Regenerate RMK and MEK on Tableau Server

To regenerate the root master key and the master encryption keys on Tableau Server, run the `tsm security regenerate-internal-tokens` command.

## AWS Key Management System

Tableau Server has three Key Management System (KMS) options that allow you to enable encryption at rest. Two of these require Advanced Management (formerly Server Management add-on), while a local one is available with all installations of Tableau Server.

Beginning in version 2019.3, Tableau Server added these KMS options:

- A local KMS that is available with all installations. For details, see [Tableau Server Key Management System](#).
- An AWS-based KMS that comes as part of Advanced Management. This is described below.

Beginning in version 2021.1, Tableau Server added another KMS option:

- An Azure-based KMS that comes as part of Advanced Management. For details, see [Azure Key Vault](#).

With the release of version 2019.3, Tableau Server supports the AWS key management system (KMS) as part of Advanced Management.

### AWS KMS for encryption at rest

AWS KMS is available as part of Advanced Management in Tableau Server. For more information see [About Tableau Advanced Management on Tableau Server](#).

If your organization is deploying Data Extract Encryption at Rest, then you may optionally configure Tableau Server to use AWS as the KMS for extract encryption. To enable AWS KMS, you must deploy Tableau Server in AWS EC2. In the AWS scenario, Tableau Server uses the AWS KMS customer master key (CMK) to generate an [AWS data key](#). Tableau Server uses the AWS data key as the root master key for all encrypted extracts. However, even when configured for AWS KMS, the native Java keystore and local KMS are still used for secure storage of secrets on Tableau Server. The AWS KMS is only used to encrypt the root master key for encrypted extracts.

Using AWS to encrypt the master root key provides better security properties by not storing the master key under the same permissions as the extracts.

The key hierarchy when Tableau Server is configured with AWS KMS

Configure AWS KMS for Tableau Server encrypted extracts

To use the AWS customer master key (CMK) to encrypt the root key in the Tableau Server KMS hierarchy, you must configure Tableau Server as described in this section.

Before you begin, verify that you meet the following requirements:

- Tableau Server must be deployed in AWS EC2
- Tableau Server must be configured with a Advanced Management license. See About Tableau Advanced Management on Tableau Server.
- You must have administrative control of a customer master key (CMK) created in AWS Key Management Service

Step 1: Create CMK and set key policy for Tableau Server in AWS

The following procedures are performed in the AWS KMS service. References are included to AWS documentation.

1. Create the CMK that you will use for Tableau Server. See the AWS topic, [Creating Keys](#).

## 2. Update the server instance's IAM role.

Tableau Server needs to be able to authenticate with AWS KMS using the instance's IAM role. The role needs to have a policy attached to it. The policy should be giving the instance permissions to call the "GenerateDataKey" and "Decrypt" actions on the CMK. See [IAM Roles for Amazon EC2](#).

In a multinode deployment of Tableau Server, all nodes of the server must be running under roles that have this policy (or equivalent) attached. You can assign the same role to all nodes in the cluster.

## 3. At a minimum, the CMK must have a key policy where the `Effect` is set to `Allow` the `Principal` (the IAM role that is attached to the server instances) the `Action: GenerateDataKey` and `Decrypt`. See [Using Key Policies in AWS KMS](#).

### Step 2: Collect AWS configuration parameters

You will need the full ARN string from AWS KMS. This string is in the "General configuration" section of the AWS KMS management pages. The ARN is presented in this format:

`arn:aws:kms:<region>:<account>:key/<CMK_ID>`, for example, `arn:aws:kms:us-west-2:867530990073:key/1abc23de-fg45-6hij-7k89-110mn1234567`.

You will also need to specify the AWS region, which is also included in the ARN string. In the example above, the region is `us-west-2`. The region is where your KMS instance resides. In the next step, you will need to specify a region as shown in the `Region` column in the [Amazon API Gateway table](#).

### Step 3: Configure Tableau Server for AWS KMS

Run the following command on Tableau Server. This command will restart the server:

- `tsm security kms set-mode aws --aws-region "<region>" --key-arn "arn:aws:kms:<region>:<account_number>:key/<CMK_ID>"`

The `--key-arn` option takes a direct string copy from the ARN in the "General configuration" section of the AWS KMS management pages.

## Tableau Server on Linux Administrator Guide

For example, if your AWS KMS instance is running in us-west-2 region, your account number is 867530990073, and your CMK key is 1abc23de-fg45-6hij-7k89-110mn1234567, then the command would be as follows:

```
tsm security kms set-mode aws --aws-region "us-west-2" --key-arn "arn:aws:kms:us-west-2:867530990073:key/1abc23de-fg45-6hij-7k89-110mn1234567"
```

### Step 4: Enable encryption at rest

See [Extract Encryption at Rest](#).

### Step 5: Validate installation

1. Run the following command:

```
tsm security kms status
```

The following information may be returned:

- The ARN (ID) of the customer master key (CMK)
  - The region the CMK is in
  - The ID of the root master key (RMK) in use. The RMK is a key that is encrypted by the CMK. Tableau Server decrypts the CMK by making calls to AWS KMS. The RMK is then used to encrypt/decrypt the master extract key (MEK). The RMK can change, but there will be only one at a time.
  - KMS stores a collection of master extract keys (MEKs). Each MEK has:
    - An ID, for example, 8ddd70df-be67-4dbf-9c35-1f0aa2421521
    - Either a "encrypt or decrypt key" or "decrypt-only key" status. If a key is "encrypt or decrypt", Tableau Server will encrypt new data with it. Otherwise, the key will only be used for decryption
    - A creation timestamp, for example, "Created at: 2019-05-29T23:46:54Z."
    - First transition to encrypt and decrypt: a timestamp indicating when the key became an encrypt or decrypt key.
    - Transition to decrypt-only: a timestamp indicating when the key transitioned to decrypt-only.
2. View logs after you encrypt and decrypt extracts:

- Publish extracts to your site and then encrypt them. See Extract Encryption at Rest.
- Access the extracts with Tableau Desktop or with Web Authoring on a browser (this will decrypt the extracts for use).
- Search the `vizqlserver_node` log files for the `AwsKmsEncryptionEnvelopeAccessor` and `AwsKmsEncryptionEnvelope` strings. The default location of the logs are at `/var/opt/tableau/tableau_server/data/tabsvc/logs/`

Log entry examples that indicate successful configuration include the following:

- Decrypted the RMK with ID `1abc23de-fg45-6hij-7k89-110mn1234567` using the CMK with ARN `arn:aws:kms:us-west-2:867530990073:key/1234567d-a6ba-451b-adf6-3179911b760f`
- Using RMK with ID `1abc23de-fg45-6hij-7k89-110mn1234567` to decrypt KMS store

For publishing and extract refreshes related to KMS, search the backgrounder logs. For more information about logs, see [Tableau Server Logs and Log File Locations](#).

## Troubleshoot configuration

### Multi-node misconfiguration

In a multi-node setup for AWS KMS, the `tsm security kms status` command may report healthy (OK) status, even if another node in the cluster is misconfigured. The KMS status check only reports on the node where the Tableau Server Administration Controller process is running and does not report on the other nodes in the cluster. By default the Tableau Server Administration Controller process runs on the initial node in the cluster.

Therefore, if another node is misconfigured such that Tableau Server is unable to access the AWS CMK, those nodes may report Error states for various services, which will fail to start.

## Tableau Server on Linux Administrator Guide

If some services fail to start after you have set KMS to the AWS mode, then run the following command to revert to local mode: `tsm security kms set-mode local`.

### Refresh AWS CMK

Refreshing the AWS CMK is a task that you perform with AWS. By default, the AWS CMK will refresh once a year. See the AWS topic, [How Automatic Key Rotation Works](#). Since the ARN and region do not change, you do not need to update the KMS configuration on Tableau Server for normal CMK refresh scenarios.

After AWS CMK refreshes, you must regenerate the internal RMK and MEKs on Tableau Server. You should also re-encrypt all extracts with the new CMK:

1. Run the `tsm security regenerate-internal-tokens` command to regenerate all internal keys on Tableau Server, including the RMK and MEKs used for extract encryption.
2. Run `tabcmd reencryptextracts <site-name>` to re-encrypt extracts on a given site. Run this command on every site where you are storing encrypted extracts. Depending on the number of encrypted extracts on the site, this operation could consume significant server processing load. Consider running this operation outside of business hours. See [Extract Encryption at Rest](#).

### Regenerate RMK and MEK on Tableau Server

To regenerate the root master key and the master encryption keys on Tableau Server, run the `tsm security regenerate-internal-tokens` command.

### Back up and restore with AWS KMS

A server backup can be taken in AWS mode with no additional configurations or procedures. The backup contains encrypted copies of the RMK and MEKs. Decrypting the keys requires access and control of the AWS CMK.

For the restore scenario, the server being restored to can be in either KMS mode, including Local. The only requirement is that the server the backup is being restored to has decrypt access to the CMK the backup itself used.

Upon restore, the MEKs from the backup are imported as decrypt-only keys. The RMK is not migrated over. A new RMK is generated as part of the installation/restore process.

## Azure Key Vault

Tableau Server has three Key Management System (KMS) options that allow you to enable encryption at rest. Two of these require Advanced Management (formerly Server Management add-on), while a local one is available with all installations of Tableau Server.

Beginning in version 2019.3, Tableau Server added these KMS options:

- A local KMS that is available with all installations. For details, see [Tableau Server Key Management System](#).
- An AWS-based KMS that comes as part of Advanced Management. For details, see [AWS Key Management System](#).

Beginning in version 2021.1, Tableau Server added another KMS option:

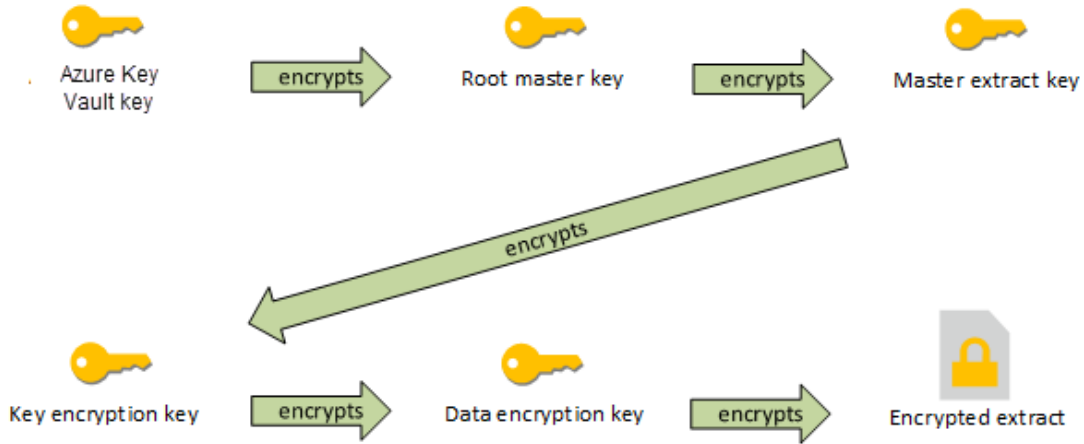

- An Azure-based KMS that comes as part of Advanced Management. This is described below.

### Azure Key Vault for encryption at rest

Azure Key Vault is available as part of Advanced Management to Tableau Server beginning in version 2021.1.0. For more information see [About Tableau Advanced Management on Tableau Server](#).

If your organization is deploying Data Extract Encryption at Rest, then you may optionally configure Tableau Server to use Azure Key Vault as the KMS for extract encryption. To enable Azure Key Vault, you must deploy Tableau Server in Azure. In the Azure scenario, Tableau Server uses the Azure Key Vault to encrypt the root master key (RMK) for all encrypted extracts. However, even when configured for Azure Key Vault, the Tableau Server native Java keystore and local KMS are still used for secure storage of secrets on Tableau Server. The Azure Key Vault is only used to encrypt the root master key for encrypted extracts.

The key hierarchy when Tableau Server is configured with Azure Key Vault

Configure Azure Key Vault for Tableau Server encrypted extracts

To use the Azure Key Vault to encrypt the root key in the Tableau Server KMS hierarchy, you must configure Tableau Server as described in this section.

Before you begin, verify that you meet the following requirements:

- Tableau Server must be deployed in Azure.
- Tableau Server must be configured with a Advanced Management license. See [About Tableau Advanced Management on Tableau Server](#).
- You must have administrative control over the key vault in Azure where the key resides.

Step 1: Create a key vault and key for Tableau Server in Azure

The following procedures are performed in the Azure Key Vault service. References are included to Azure documentation.

1. Create the key vault that you will use for Tableau Server. See the Azure topic, [Create a key vault](#).
2. Create a key in the vault. See the Azure topic, [Manage keys and secrets](#).

The key must be an asymmetric, RSA type, but can be any size (Tableau Server does not care about the key size). We recommend you use the Principle of Least Privilege to have maximum security.

Tableau requires permissions to perform the GET, UNWRAP KEY, and WRAP KEY commands operations and we recommend you allow access for only these operations for least privilege. Assign the access policy to the VM you are running Tableau Server on.

In a multi-node deployment of Tableau Server, the access policy must be assigned to all nodes of the server cluster.

#### Step 2: Collect Azure configuration parameters

You will need the key vault name and the key name from Azure.

#### Step 3: Configure Tableau Server for Azure Key Vault

Run the following command on Tableau Server. This command will restart the server:

- `tsm security kms set-mode azure --vault-name "<vault name>" --key-name "<key name>"`

The `--vault-name` and `--key-name` options a direct string copies from your Azure key vault.

For example, if your Azure key vault is named `tabsrv-keyvault` and your key is `tabsrv-sandbox-key01`, then the command would be as follows:

```
tsm security kms set-mode azure --vault-name "tabsrv-keyvault"
--key-name "tabsrv-sandbox-key01"
```

#### Step 4: Enable encryption at rest

See [Extract Encryption at Rest](#).

### Step 5: Validate installation

1. Run the following command:

```
tsm security kms status
```

The following information may be returned:

- Status: OK (indicates the Key Vault is accessible by the controller node):
  - Mode: Azure Key Vault
  - Vault name: <key\_vault\_name>
  - Azure Key Vault key name: <key\_name>
  - List of available UUIDs for MEKs indicating which key is active
  - Error information if the KMS data is not accessible
2. View logs after you encrypt and decrypt extracts:
    - Publish extracts to your site and then encrypt them. See [Extract Encryption at Rest](#).
    - Access the extracts with Tableau Desktop or with Web Authoring on a browser (this will decrypt the extracts for use).
    - Search the `vizqlserver_node` log files for the `AzureKeyVaultEnvelopeAccessor` and `AzureKeyVaultEnvelope` strings. The default location of the logs are at `/var/opt/tableau/tableau_server-  
/data/tabsvc/logs/`

For publishing and extract refreshes related to the Azure Key Vault, search the background logs. For more information about logs, see [Tableau Server Logs and Log File Locations](#).

### Troubleshoot configuration

#### Multi-node misconfiguration

In a multi-node setup for Azure Key Vault, the `tsm security kms status` command may report healthy (OK) status, even if another node in the cluster is misconfigured. The KMS status check only reports on the node where the Tableau Server Administration Controller

process is running. It does not report on the other nodes in the cluster. By default the Tableau Server Administration Controller process runs on the initial node in the cluster.

Therefore, if another node is misconfigured so that Tableau Server is unable to access the Azure key, those nodes may report Error states for various services, which will fail to start.

If some services fail to start after you have set KMS to the "azure" mode, then run the following command to revert to local mode: `tsm security kms set-mode local`.

### Refresh Azure Key

You refresh the Azure key in Azure. There is no required or scheduled key refresh period. You can refresh your key by creating a new key version in Azure. Because the Key Vault name and Key Name do not change, you do not need to update the KMS configuration on Tableau Server for normal Azure Key refresh scenarios.

### Back up and restore with Azure Key Vault

A server backup can be taken in Azure Key Vault mode with no additional configurations or procedures. The backup contains encrypted copies of the RMK and MEKs. Decrypting the keys requires access and control of the Azure Key Vault.

For the restore scenario, the server being restored to can be in either Azure Key Vault or Local KMS mode. The only requirement is that the server to which the backup is being restored has access to the Azure Key Vault the backup itself used.

## Tableau Server External File Store

This topic provides an overview of Tableau Server External File Store.

Tableau Server File Store stores extracts and workbook revisions. Typically, Tableau Server File Store is a built-in Tableau Server process that is installed locally on Tableau Server. Starting in Tableau Server 2020.1, you can configure Tableau Server to use an external storage to store the File Store data. The external storage must be a network share, a dedicated file storage that enables multiple users and heterogeneous client devices to retrieve data from a centralized disk capacity. This can be a Server Message Block (SMB) for Windows or a Network

## Tableau Server on Linux Administrator Guide

File System (NFS) for Linux installations. Users on a local area network (LAN) access the shared storage via a standard Ethernet connection.

With this new feature, Tableau Server can now be configured in two ways:

- Install File Store locally, meaning File Store is installed on the Tableau Server nodes.
- Use External File Store (Beginning in 2020.1).

### Why use External File Store?

Using external storage has the following key benefits over installing File Store locally:

- **Centralized location:** When File Store is installed locally, the data needs to be replicated across multiple File Store nodes, which will consume network bandwidth. Moving data to a centralized location will eliminate the need for running File Store on multiple nodes in a Tableau cluster and replication between the nodes. This also reduces the disk space requirements on an individual node and also reduce the network bandwidth usage since the data will not be replicated on multiple nodes.
- **Improving backup time:** Snapshot backup technologies are efficient, and by using snapshot backup of the Tableau Data, you can expect to significantly reduce the amount of time it takes to do a Tableau backup.

### Managing External File Store

#### License Management

To configure External File Store, you must first enable this feature using Advanced Management product keys. For more information, see [About Tableau Advanced Management on Tableau Server](#). If you don't have an Advanced Management key activated or if the license is expired, you will see the following behavior:

- If you try to configure Tableau Server with External File Store during installation, you will see an error message, but you will be able to continue the installation and Tableau Server File Store will be installed locally.
- If you are already using External File Store, and the Advanced Management license expires, you will see the following behavior:
  - The server will fail on restart.
  - Backups will fail.

- If you no longer have a valid Advanced Management license, but have a valid Tableau Server license, you can migrate the External File Store to local File Store, to get your server up and running again. For more information on how to migrate from external repository to local repository, see [Reconfigure File Store](#).

### Supported Migration Scenarios

- Moving File Store installed locally on Tableau Server to an external managed storage (network attached storage).
- Move File Store from external managed storage to Tableau Server.

### Backup and Restore

Backup on Tableau Server with External File Store is different than how you would create backup when File Store is installed locally. For more information on how to do backup and restore on Tableau Server with External File Store, see [Backup and Restore with External File Store](#).

### Upgrade Considerations

There are no special steps necessary when upgrading Tableau Server configured with an External File Store. You can follow the normal upgrade process.

### High Availability Considerations

Tableau Server does not manage or setup high availability for the External File Store. Your managed storage may have solutions to support redundancy and high availability.

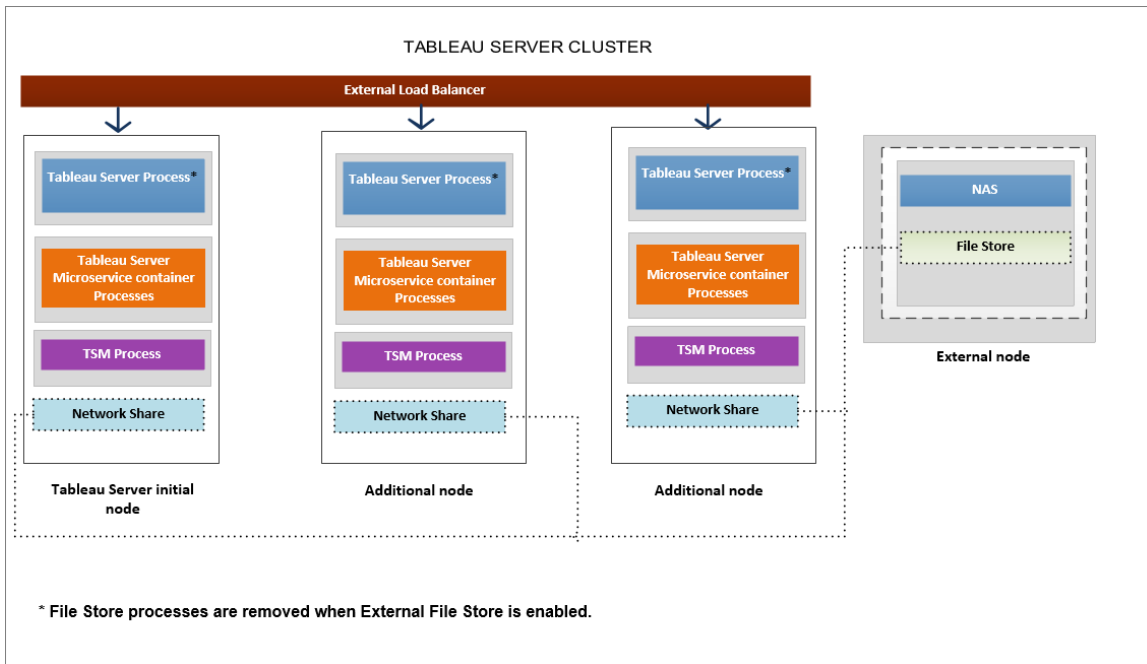

## Topology

When you configure Tableau Server with External File Store, you will no longer run File Store locally. The Server status page will indicate that the File Store process is on an external node.

When File Store is configured external to Tableau Server, Data Engine and File Store are no longer co-located. During setup, Data Engine will continue to be automatically installed with other processes as described in [Tableau Server Data Engine](#), except for File Store. However, when you have Tableau Server configured with External File Store, you will be able to install Data Engine on a separate node without any other processes.

When File Store is configured externally, Data Engine will access the File Store data (extracts) on the storage system across the network. To make sure that your overall system performs to your requirements, there are a few things you must consider for your network and storage system. For more information, see Performance Considerations for External File Store.

The diagram below is a summarized version of the Tableau Server topology with External File Store.

The diagram below is a detailed version of the Tableau Server topology with External File Store and shows all the processes installed on each node.

## Next

Install Tableau Server with External File Store

## Install Tableau Server with External File Store

This topic walks you through the process of configuring network share as your Tableau Server File Store for a new installation. If you are trying to do this on an existing installation of Tableau Server that has File Store running locally, see Reconfigure File Store .

### Prerequisites

- You must use Tableau Server 2020.1 or later.
- You must have network share that you can use as your storage option. For recommendations on the storage solution, see Performance Considerations for External File Store.

Use **NFS** for Linux installations.

Estimating the storage size: You must take into account the amount of storage needed for publishing and refreshing extracts. In addition, you must also take into account the repository backup size unless you specifically choose the option to do your repository backup separately as described in the Option 2: Back up repository separately topic.

- Extracts:
  - Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.
  - Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.
- Repository Backup:
  - To obtain an estimate of the repository data, check the size of `<data directory>/pgsql/data/base directory`.
  - To obtain the exact size of the repository data, open the backup file and use the size of the `workgroup.pg_dump` file.
- You must have a valid Advanced Management license activated on your server. To learn more about Advanced Management, see About Tableau Advanced Management on Tableau Server.

## Install Tableau Server with External File Store

You can install Tableau Server with File Store using a network share to store Tableau Server data. This solution replaces the need for running the File Store process locally. To learn more about this solution and its benefits, see [Tableau Server External File Store](#).

Use the following steps to install your Tableau Server with External File Store during install:

### Step 1: Configure a network share

On your file server:

1. Create and share a directory to use as the Tableau Server External File Store.
2. Make sure the network share is accessible as a directory in the same location on all the Tableau Server nodes.
3. Create the tableau directory in your network share and give full access to **tableau user** and **tableau group**. The tableau user will need read and write permissions to the directory on the network share. We recommend calling the directory '**tableau**'.

```
/mnt/<network share>/tableau/
```

4. **Validate that the network share is configured properly:** From Tableau Server run a command to write to a network share and confirm that you are able to write to it.

### Step 2: Download and install TSM

1. Download the appropriate installer based on the distribution of Linux you are using.
2. Log on as a user with sudo access to the computer where you want to install Tableau Server.
3. Download the .rpm or .deb installer package.
4. Navigate to the directory where you copied the .rpm or .deb package.
5. Use the package manager to install the Tableau Server.
  - On **RHEL-like** distributions, including CentOS, you have the option to install Tableau Server to a non-default location.

## Tableau Server on Linux Administrator Guide

- **Default location**—To install to the default location (`/opt/tableau/tableau_server`), run the following commands:

```
sudo yum update
```

```
sudo yum install tableau-server-<version>.x86_64.rpm
```

- **Non-default location**—to install to a non-default location, you must use `rpm -i`. You will also need to install all dependent packages. See the note below.

Run the following command:

```
sudo rpm -i--prefix/preferred/install/path tableau-server.rpm
```

**Note:** When you use `yum` to install Tableau Server, all dependent packages are automatically downloaded and installed. This is the preferred method for installing Tableau Server. If you want to install to a non-default location, or your organization does not allow you to use `yum` and you must install using `rpm -i`, you must also install all dependent packages separately. For information about installing dependent packages, see [Installing Tableau Server on an Air-Gapped Computer Running Linux](#).

- **On Ubuntu and Debian**, run the following commands:

```
sudo apt-get update
```

```
sudo apt-get -y install gdebi-core
```

```
sudo gdebi -n tableau-server-<version>_amd64.deb
```

### Step 3: Initialize TSM

1. Run the following script to start TSM:

```
sudo ./initialize-tsm --accepteula --<optional_parameters>
```

The only required parameter for the initialize-tsm script is `--accepteula`. You must include this parameter to accept the Tableau Server End User License Agreement (EULA). The EULA is available in the following location:

```
/opt/tableau/tableau_server/packages/docs.<version_code>/Commercial_EULA.txt
```

2. Log off and log on again to the terminal before you configure Tableau Server.

When you log on again, you create a new session in which group membership changes have taken effect. The new session also has access to the environment variables added by the initialize-tsm script.

Alternatively, you can run the following command to update your path for the current session (but not to update your group membership):

```
source /etc/profile.d/tableau_server.sh
```

#### Step 4: Activate and register Tableau Server

Provide the Tableau Server Key and the Advanced Management key in the activate step. You will need to run the following command twice, first with the Tableau Server product key and then with the Advanced Management product key:

```
tsm licenses activate -k <product key>
```

#### Step 5. Enable External File Store

Configuring Tableau Server with external repository can only be done using TSM CLI.

1. Enable the network storage feature using the following tsm commands:

```
tsm topology external-services storage enable --network-share  
/mnt/<network share name>/tableau
```

The setup program automatically creates the following directory structure in the share:

#### **PostgreSQL data backups:**

*tableau\_data/tabsvc/pg\_backups*

**Note:** This directory will be created the first time you create a backup.

**Extracts and workbook revisions:**

*tableau\_data tabsvc/dataengine/extracts*

*tableau\_data/tabsvc/dataengine/revisions*

Step 6: Configure the initial node settings

Follow the instructions provided in the Configure Initial Node Settings topic.

Step 7: Complete the install

You must create the initial administrative account for Tableau Server.

- If you configured a local identity store during setup, then specify a name and password that you want to use.
- If you configured a LDAP or Active Directory identity store during setup, then you must specify a user account that is a member of the directory.

To create the initial user, run the following `tabcmd` command:

```
tabcmd initialuser --server localhost:80 --username '<new-admin-user-name>'
```

After you run the command, the shell will prompt for an administrative password.

Step 8: Post-installation tasks

After you have created the Tableau Server administrator account, continue your deployment by working through the configuration steps described in the Post Installation Tasks topics.

Who can do this

Tableau Server Administrators can install and configure Tableau Server and External File Store. In addition, you must have permissions and access to configure the network share to use with Tableau Server.

Next

Backup and Restore with External File Store

## Reconfigure File Store

Your Tableau Server may be configured with a locally running File Store or an External File Store. This topic describes the steps needed to reconfigure your existing Tableau Server:

- [Reconfigure your Tableau Server to use External File Store](#). This will move your File Store to a network share.
- [Reconfigure your Tableau Server to run File Store locally](#). This will move your File Store from the external storage to your Tableau Server.
- [Configure your Tableau Server to use a different storage](#). An example of this might be when your current network share is at the end of life and you need to use a new network share with new hardware.

Reconfigure Tableau Server with External File Store

Prerequisites

- Tableau Server should be version 2020.1 or later.
- You must have a network share to use as the external storage.

Use **NFS** for Linux installations.

Storage and network considerations: See Performance Considerations for External File Store.

## Tableau Server on Linux Administrator Guide

Estimating the storage size: You must take into account the amount of storage needed for publishing and refreshing extracts. In addition, you must also take into account the repository backup size unless you specifically choose the option to do your repository backup separately as described in the Option 2: Back up repository separately topic.

- Extracts:
  - Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.
  - Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.
- Repository Backup:
  - To obtain an estimate of the repository data, check the size of `<data directory>/pgsql/data/base` directory.
  - To obtain the exact size of the repository data, open the backup file and use the size of the `workgroup.pg_dump` file.
- Tableau Server should have a valid and activated Advanced Management license.

### Step 1: Upgrade Tableau Server

Upgrade your Tableau Server to 2020.1 or later: Upgrading from 2018.1 and Later (Linux) . If your Tableau Server is already on version 2020.1 or later, you can skip this step.

### Step 2: Activate the Advanced Management license

1. View Server Licenses to make sure you have a Advanced Management license activated on your Tableau Server.
2. If you don't have a Advanced Management on your Tableau Server, use the following `tsm` command to activate the license. Provide the Advanced Management key as your

product key:

```
tsm licenses activate -k <product key>
```

### Step 3: Configure File Store to use an external storage

After completing the upgrade and verifying the licenses, configure Tableau Server with External File Store. This will move any existing data from your local File Store to the external storage of your choice.

1. Configure a network share. On the File Server:
  - Create and share a directory to host the files
  - On all the Tableau Server nodes, map the network share or use a UNC path.
2. Create a tableau directory in your network share and give full access to **tableau user** and **tableau group**. The tableau user will need read and write permissions to the directory on the network share. We recommend calling the directory **tableau**.
3. Enable the network share feature using the following tsm commands:

```
tsm topology external-services storage enable --network-share
/mnt/<network share name>/tableau
```

The setup program automatically creates the following directory structure and will move the data from the local File Store to the external storage. The local File Stores will be automatically decommissioned during this process.

#### **Extracts and workbook revisions:**

```
tableau_data tabsvc/dataengine/extracts
```

```
tableau_data/tabsvc/dataengine/revisions
```

#### **PostgreSQL data backups:**

*tableau\_data/tabsvc/pg\_backups*

**Note:** This directory will be created the first time you create a backup.

### Reconfigure Tableau Server to use local File Store

1. Stop Tableau Server by running the following command:

```
tsm stop
```

2. Run the following command to move the File Store data from the external storage to Tableau Server:

```
tsm topology external-services storage disable -fsn <node1,  
node2>
```

3. Start Tableau Server by running the following command:

```
tsm start
```

For a Tableau Server cluster, specify the nodes where File Store should be installed. The data is copied to the first node specified in the command and then replicated to the other nodes.

**Note:** When moving File Store from external to local, make sure Data Engine process is not installed by itself on a separate node and is installed along with one of the core services which include File Store, Application Server (VizPortal), VizQL Server, Data Server, and Backgrounder.

Typically, when you install Tableau Server Data Engine installation happens automatically and is installed on the nodes that have one or more of the core services. However, when you configure Tableau Server to use external storage, you will have the ability to manually install Data Engine on a node on its own without co-locating with the core processes.

If you currently have a Data Engine process installed on a separate node, you can either

choose to install File Store on that node or remove Data Engine from that node, before running the disable command. If you install File Store on a node that currently does not have Data Engine installed, Data Engine will be added automatically.

If you have a Data Engine only node when you run the disable command, it will result in an error.

### Configure Tableau Server to use a different external storage

1. Configure the new network share. On the File Server:
  1. Create and share a directory to host the files.
  2. On all the Tableau Server nodes, map the network share or use a UNC path.
2. Create a tableau directory in your network share and give full access to **tableau user** and **tableau group**. The tableau user will need read and write permissions to the directory on the network share. We recommend calling the directory **tableau**.
3. Stop Tableau Server by running the following command:

```
tsm stop
```

4. Run the following command to configure Tableau Server to use the new network share:

```
tsm topology external-services storage switch-share --network-share /mnt/<newshare>/tableau
```

5. Start Tableau Server by running the following command:

```
tsm start
```

Who can do this

Tableau Server Administrators can move File Store locations. In addition, you will need access to the external storage that is used for the External File Store.

### Backup and Restore with External File Store

When you have External File Store enabled on your Tableau Server, you cannot use the `t-sm maintenance backup` command to do a backup of the Tableau Server repository and File Store Data. Instead, use a "snapshot" backup process to create a point in time snapshot of your network share.

- Tableau Server configured with External File Store
- Tableau Server configured with External File Store and External Repository

Backup strategies:

The backup strategy you use depends on your recovery plan. The snapshot backup process may not be sufficient by itself as it only creates a backup of the File Store (and repository data if requested), and there are other configurations and settings that you may need in order to do a full recovery.

**Important:** We strongly recommend disabling scheduled tasks before you perform an upgrade. This includes all updates to data content and should be done before you create your pre-upgrade backup. This may involve disabling jobs that are triggered outside of Tableau Server, such as those initiated through REST API-based extract refreshes or using `tabcmd`.

Here are some scenarios that illustrate when the snapshot backup process may or may not be enough:

- **Standby Tableau Server**—If you maintain a standby Tableau Server to use if your production Server is down, creating a snapshot backup and restoring it to your standby server on a regular schedule may be sufficient. Your backup schedule should be based on your recovery point objective.
- **New Tableau Server, existing configuration not needed**—If you plan to use a new Tableau Server installation in case of a disaster, but don't necessarily need to use the configurations and settings from your existing Tableau Server installation you can install a fresh instance of Tableau Server and use the snapshot to restore your data.
- **New Tableau Server, existing configuration needed**—If you plan to use a new Tableau Server installation that includes your existing configurations and settings as well as your backed up data, you need additional files in along with the snapshot backup. To do a full backup including all the configurations and settings, follow these instructions:
  1. Export topology and configuration data. This exports most of the Tableau Server configuration and topology. For more information, see [Perform a Full Backup and Restore of Tableau Server](#).
  2. Create a network share snapshot of the File Store (and repository data, if desired) as described in the [Backup and Restore with External File Store](#) section of this topic.
  3. Document the settings that are not included in the export. These include values for system user accounts, coordination service deployment configuration, and customized settings. For more information, see [Perform a Full Backup and Restore of Tableau Server](#).

#### Tableau Server configured with External File Store

When you have Tableau Server configured with an External File Store your backup process needs to include creating a point-in-time snapshot backup of the network share with the External File Store. The following procedure describes how to do this.

**Note:** If you have both an External File Store and an external repository, see [Tableau Server configured with External File Store and External Repository](#).

### Creating a snapshot backup

Use the following steps to create a snapshot backup:

1. Prepare for the snapshot backup.

Run the following command to create a repository backup file and temporarily copy it to the network share. Tableau Server continues to operate normally during the snapshot prepare process. To ensure a consistent snapshot, the internal process that deletes unused extracts will be paused. This process will resume once you complete the backup process described in a later step.

```
tsm maintenance snapshot-backup prepare
```

You should see the following message when the prepare step is complete: **Preparation for snapshot backup succeeded.**

Confirm that the repository backup file was created on the network share.

**Note:** The prepare step creates a backup file of the repository and KMS and Asset keys. If you are using a cloud solution for your encryption key solution, you will need access to the CMK used to decrypt the keys which is necessary for restore. For more information on encryption key solution with AWS, see [AWS Key Management System](#). For more information on encryption key solution with Azure, see [Azure Key Vault](#).

2. Create a snapshot of your network share.

Use the appropriate process to create a snapshot of your network share. The snapshot is a read-only version of the share, taken at a particular point in time. This will include your File Store data, along with the repository backup file that was temporarily copied to the share in the previous step. The steps you take to create this network share snapshot depend on your network. See your networking documentation for details.

3. Complete the snapshot backup process.

Run the following command to complete the backup process and restart the paused internal processes. This removes the temporary repository backup file that was copied to your network share.

```
tsm maintenance snapshot-backup complete
```

Confirm that the temporary repository backup file was removed from the network share.

### Restoring a snapshot backup

These steps apply to both single node and multi-node Tableau Server installations.

1. Stop Tableau Server.

At the command prompt, run the following command:

```
tsm stop
```

2. Restore your File Store data by restoring your network share snapshot to your network. Your specific steps will depend on your network.
3. Restore the repository data.

Use the following command to restore the repository data:

```
tsm maintenance snapshot-backup restore
```

**Note:** If you are using a cloud solution for your encryption key solution, make sure the server where the backup is being restored has decrypt access to the cloud instance where the CMK is deployed.

4. Restart Tableau Server.

At a command prompt, run the following command:

```
tsm start
```

### Tableau Server configured with External File Store and External Repository

When you have Tableau Server configured with both an External File Store and an external repository, there are special steps you need to take to create a backup. These include creating a point-in-time snapshot backup of the network share with the External File Store, and may include separately backing up your external repository. The following procedure describes how to do this.

**Note:** If you have an External File Store but are using the default repository, see Tableau Server configured with External File Store.

### Backing up the repository

When you have both an External File Store and an external repository, you have two options for backing up the repository data. There are reasons why you might choose each of these:

- Include the repository backup with the network share snapshot:

Ease of management. You do not have to do a separate backup of the repository, and the backup is in sync with the File Store data.

- Back up the repository independently:

Doing a backup of an External Repository separately can be faster, especially if you are using a cloud solution that allows for snapshot backups of the instance. The size of the backup file can significantly impact the time it takes to prepare for a network share snapshot.

Option 1: Include repository backup with network share snapshot

## Create a snapshot backup

1. Prepare for the snapshot backup.

Run the following command to create a repository backup file and temporarily copy it to the network share. Tableau Server continues to operate normally during the snapshot prepare process. To ensure a consistent snapshot, the internal process that deletes unused extracts will be paused. This process will resume once you complete the backup process described in a later step.

```
tsm maintenance snapshot-backup prepare --include-pg-backup
```

**Note:** Starting in 2021.1, if you have both External File Store and External Repository enabled, you *must* use the `--include-pg-backup` option to create the repository backup. If you are upgrading from a version earlier than 2021.1 and you have scripts to run or schedule your backups, and want to continue to include the repository backup, add the `--include-pg-backup` option in the prepare command as shown above. For versions prior to 2021.1 you do not need the option, the repository backup is automatically included.

You should see the following message when the prepare step is complete: **Preparation for snapshot backup succeeded.**

Confirm that the repository backup file was created on the network share.

**Note:** The prepare step creates a backup of the repository and KMS and Asset keys. If you are using a cloud solution for your encryption key solution, you will need access to the CMK used to decrypt the keys which is necessary for restore. For more information on encryption key solution with AWS, see [AWS Key](#)

Management System. For more information on encryption key solution with Azure, see Azure Key Vault.

2. Create a snapshot of your network share.

Use the appropriate process to create a snapshot of your network share. The snapshot is a read-only version of the share, taken at a particular point in time. This will include your File Store data, along with the repository backup file that was temporarily copied to the share in the previous step. The steps you take to create this network share snapshot depend on your network. See your networking documentation for details.

3. Complete the snapshot backup process.

Run the following command to complete the backup process and restart the paused internal processes. This also removes the temporary repository backup file that was copied to your network share.

```
tsm maintenance snapshot-backup complete
```

### Restoring a snapshot backup

These steps apply to both single node and multi-node Tableau Server installations.

**Important:** If you perform Blue/Green upgrades or manually upgrade Tableau Server 2021.4 (or earlier) using the **tsm maintenance (backup and restore)** method, you must enable `legacy-identity-mode` before you can restore to Tableau Server 2022.1 (or later). For more information, see [Troubleshoot Issues with the Identity Migration](#).

1. Stop Tableau Server.

At the command prompt, run the following command:

```
tsm stop
```

2. Restore your File Store data by restoring your network share snapshot to your network. Your specific steps will depend on your network.
3. Restore the repository data.

Use the following command to restore the repository data:

```
tsm maintenance snapshot-backup restore
```

**Note:** If you are using a cloud solution for your encryption key solution, make sure the server where the backup is being restored has decrypt access to the cloud instance where the CMK is deployed.

4. Restart Tableau Server.

At a command prompt, run the following command:

```
tsm start
```

#### Option 2: Back up repository separately

This option is recommended only when the host platform for the External Repository allows you to do snapshot backup. If you are using Azure as your host platform, we recommend using Option 1.

## Create snapshot backups

1. Prepare for the snapshot backup.

Run the following command to create a repository backup file and temporarily copy it to the network share. Tableau Server continues to operate normally during the snapshot prepare process. To ensure a consistent snapshot, the internal process that deletes unused extracts will be paused. This process will resume once you complete the backup process described in a later step.

```
tsm maintenance snapshot-backup prepare
```

You should see the following message when the prepare step is complete: **Preparation for snapshot backup succeeded.**

**Note:** The prepare step creates a backup of the KMS and Asset keys. If you are using a cloud solution for your encryption key solution, you will need access to the CMK used to decrypt the keys which is necessary for restore. For more information on encryption key solution with AWS, see [AWS Key Management System](#). For more information on encryption key solution with Azure, see [Azure Key Vault](#).

2. Create a snapshot of your network share.

Use the appropriate process to create a snapshot of your network share. The snapshot is a read-only version of the share, taken at a particular point in time. This will include your File Store data. The steps you take to create this network share snapshot depend on your network. See your networking documentation for details.

3. Create a backup of the repository: Use the backup technology of platform where you are hosting your external repository to create a backup.

**Important:** The snapshot of the network share and the Repository backup must be completed within 3 hours and 30 minutes after completing the Prepare step (step 1). This is to make sure that the File Store and the Repository backups are in sync and to allow the restore to work properly.

For more information on creating a snapshot of AWS DB instance, see [Creating a DB snapshot](#).

For more information on creating a backup of Azure DB instance, see [Backup and Restore on Flexible Server](#) (PostgreSQL 12 and later) or [Backup and Restore on Single Server](#) (PostgreSQL 11 or earlier).

**Note:** If you are using a cloud solution for your encryption key solution, make sure the server where the backup is being restored has decrypt access to cloud instance where CMK is deployed.

4. Complete the snapshot backup process.

Run the following command to complete the backup process and restart the paused internal processes.

```
tsm maintenance snapshot-backup complete
```

## Restoring a snapshot backup

These steps apply to both single node and multi-node Tableau Server installations.

1. Use the database backup of your External Repository. If you are using a cloud platform to host your Repository, this generally requires that you create a new database instance into which you restore the backup.

For detailed instructions on creating a new instance, see the option for your hosting solution in [Install External Repository](#).

2. Use the instructions in Step 1 of the [Install Tableau Server with External PostgreSQL Repository](#) topic to create a configuration file for the new instance.
3. Stop Tableau Server.

At the command prompt, run the following command:

```
tsm stop
```

4. If the restore of the external repository requires a new database instance, use the following command to point Tableau Server to the new database instance:

## Tableau Server on Linux Administrator Guide

```
tsm topology external-services repository replace-host -f <file-name>.json -c <ssl certificate file>.pem
```

The `.json` file is the configuration file you created in Step 2. The certificate file is the SSL certificate you downloaded from the new database instance.

5. Restore your File Store data by restoring your network share snapshot to your network. Your specific steps will depend on your network.

**Note:** Some technologies require you to create a new network share when doing a restore. If this applies to your network attached storage, you can do your restore **before** stopping the Tableau Server. If you are restoring the File Store data to a new network share, you must configure Tableau Server to use the new network share. For more information, see [Configure Tableau Server to use a different external storage](#).

6. Run the following command to restore the KMS and Asset keys:

```
tsm maintenance snapshot-backup restore
```

**Note:** If you are using a cloud solution for your encryption key solution, make sure the server where the backup is being restored has decrypt access to cloud instance where CMK is deployed.

7. Run the following command to restart Tableau Server:

```
tsm start
```

### Who can do this

Tableau Server Administrators can backup and restore Tableau Server. In addition you must have permission to access and perform snapshot backups on the external storage.

## Performance Considerations for External File Store

This topic lists the factors you must consider when you have External File Store to make sure you have optimal performance.

In this scenario where File Store is configured external to Tableau Server, you are storing the extracts on a network share. This means that Tableau Server will be accessing this data across the network. To ensure optimal performance, we recommend the following:

- Use Enterprise grade storage system to ensure reliability and high data access performance.
- The storage system supports enough read IOPS:
  - Use Solid State Drives. If using spinning disks is the only option, use the fastest and as many as possible.
- The network infrastructure supports the following:
  - At least 10 GB Ethernet to support high speed data transfers between Tableau Server and the storage system.
  - No more than 10 millisecond storage latency between Tableau Server and the storage system.

The above recommendations are based on testing done by the Tableau team. Your requirements and performance may vary. We highly recommend that you create your own benchmarks to assess the performance and determine resource requirements.

When creating benchmarks, consider overall performance of Tableau Server with workbook load times as one of the key metrics. This is especially relevant to this configuration since External File Store mostly impacts extract based workbooks.

You can use [Tabjolt](#) to do your benchmarks.

Who can do this

Tableau Server Administrators monitor Tableau Server performance. However, there are network, hardware, and storage considerations that might either need access to make configuration changes to these resources. You may also choose to work with your network administrator to make any changes if you don't have access to these resources.

## Tableau Server External Repository

The Tableau Server Repository is a PostgreSQL database that stores data about all user interactions, extract refreshes, and more.

The repository can be installed as locally on the same nodes as the Tableau Server or installed externally:

**Local repository:** The PostgreSQL Database is installed and deployed locally, meaning it is deployed along with Tableau Server.

**External repository:** The PostgreSQL Database is deployed externally. The external repository can be installed on Amazon RDS, Azure Database, Google Cloud, or as a stand-alone installation.

For more information about what Tableau Server Repository is in general, see:

- [Workgroups Database](#)
- [Collect Data with the Tableau Server Repository](#)

The supported hosts for the external repository are:

- Amazon RDS - Beginning in version 2019.3
- Azure Database - Beginning in version 2020.4
- Stand-alone PostgreSQL Instance - Beginning in version 2021.2
- Google Cloud SQL for PostgreSQL Instance - Beginning in version 2021.4

This topic is an overview of the Tableau Server external repository.

### External Repository Considerations

Both Amazon RDS and Azure Database offer better scalability, reliability, high availability and security built-in for PostgreSQL. By integrating more closely with these cloud offerings, you will be able to take advantage of these additional benefits.

If you are setting up a stand-alone PostgreSQL instance, you must set up and manage high availability and scale as needed.

## Cloud Platform

When using a cloud platform to host your external repository, you have the option of running PostgreSQL instances on hosted infrastructure and managing them yourself or choosing the fully managed service option.

- **Self-managed:** Setting up and managing PostgreSQL instances on hosted infrastructure yourself. For example, if you are using AWS as your cloud platform, you can use EC2 instances to run, manage and maintain PostgreSQL instances.
- **Fully managed:** Select a fully managed service. For example, if you are using AWS as your cloud platform, you can use the RDS option to host your external repository.

One of the key considerations when making a choice between self-managed and fully managed is that in a self-managed option you have the most control but with it comes the responsibility of maintaining the VMs and many database administrative tasks. A fully managed option offers ease of setup, configuration management, and maintenance.

Here is a more comprehensive list of things to consider when choosing between the two:

- Setup and maintenance requirements.
- High availability and disaster recovery options
- Performance, Scalability, and Monitoring capabilities
- Security maintenance
- Operational costs, service costs, personnel costs.

Here is an example of how the two options can be compared for Azure on the Microsoft site:

[Choose the right PostgreSQL server option in Azure,](#)

## Requirements

- Your Tableau Server must be using the following versions:
  - 2019.3 or later to use with AWS
  - 2020.4 or later to use with Azure.

For the right version of PostgreSQL to use, see [Azure Database for PostgreSQL Flexible Server](#) .

## Tableau Server on Linux Administrator Guide

- 2021.2 or later to use with stand-alone PostgreSQL instance. (Can be used for on-premises, Azure VM, or AWS EC2 installations).
- 2021.4 or later to use with Google Cloud for both PostgreSQL Instance or a stand-alone PostgreSQL on Google Cloud VM.
- Your Tableau Server must have the Advanced Management keys activated.
- Depending on where you are planning to host the External Repository, you will need to be familiar with one of the following:
  - Amazon RDS Database setup and management.
  - Azure Database setup and management.
  - PostgreSQL database setup and management as a standalone installation.
  - Google Cloud PostgreSQL instance setup and management

## Versioning

You must be running the correct version of PostgreSQL for standalone Tableau Server repository. The following table shows Tableau Server version compatibility.

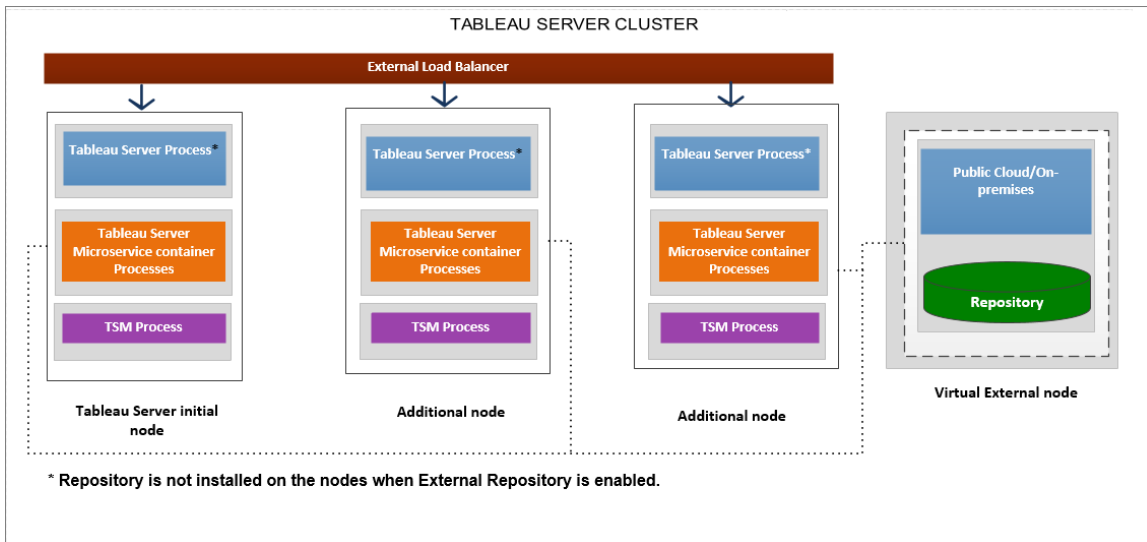

**Note:** The maximum compatibility version for any Tableau Server version is the minimum major version or any minor update to that. For example, if the PostgreSQL minimum compatible version is 13.4, the maximum compatible version is 13.x where <x> is equal or higher than 4.

| Tableau Server versions | PostgreSQL minimum compatible versions |
|-------------------------|--|
| 2021.2.3 - 2021.2.8     | 12.6                                   |
| 2021.3.0 - 2021.3.7     |  |
| 2021.4.0 - 2021.4.3     |  |
| 2021.2.10 - 2021.2.14   | 12.8                                   |
| 2021.3.8 - 2021.3.13    |  |

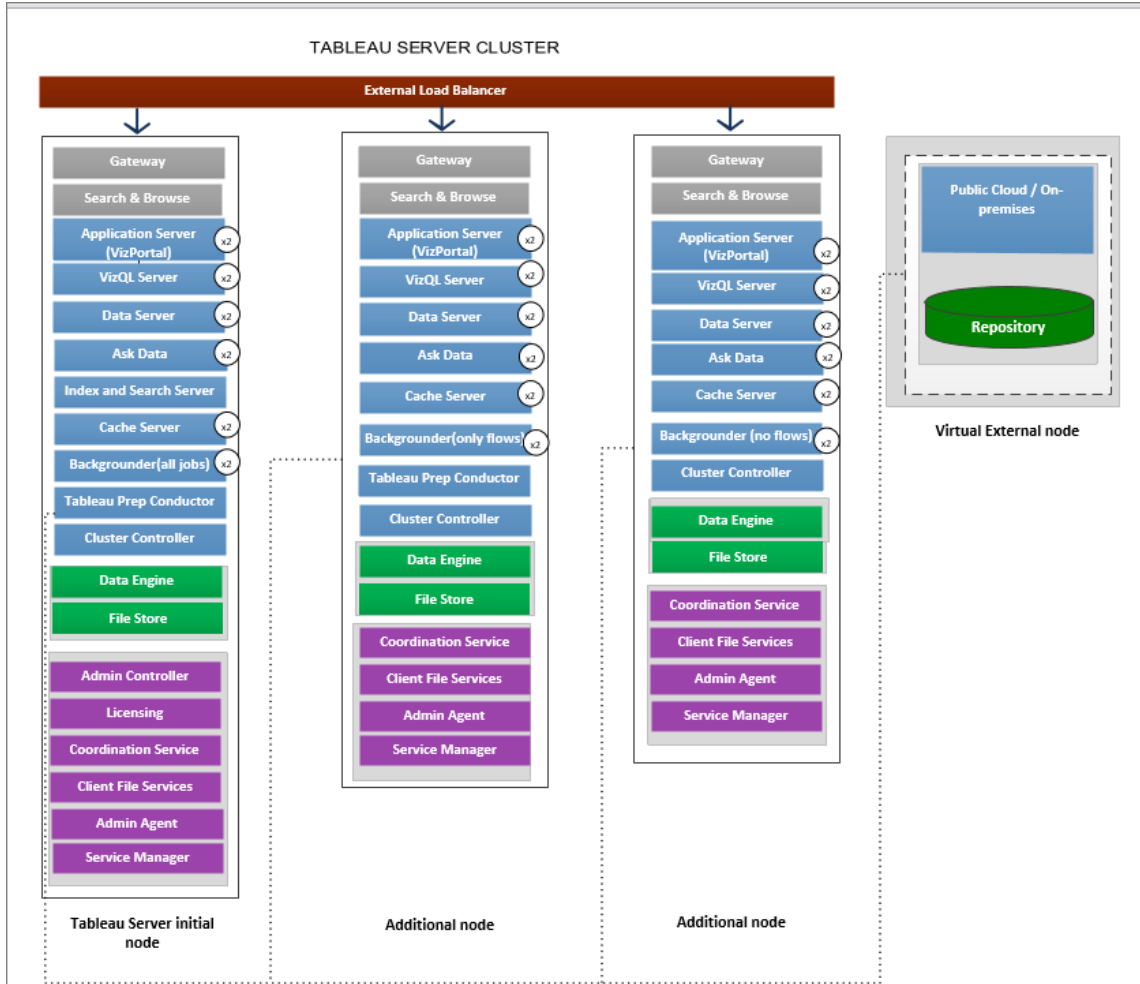

|                       |       |
|-----------------------|-------|
| 2021.4.4 - 2021.4.8   |       |
| 2021.2.15 - 2021.2.16 | 12.10 |
| 2021.3.14 - 2021.3.15 |       |
| 2021.4.9 - 2021.4.10  |       |
| 2021.2.17 - 2021.2.18 | 12.11 |
| 2021.3.16 - 2021.3.17 |       |
| 2021.4.11 - 2021.4.12 |       |
| 2021.3.26             | 12.15 |
| 2021.4.23             |       |
| 2022.1.0              | 13.3  |
| 2022.1.1 - 2022.1.3   | 13.4  |
| 2022.1.4 - 2022.1.6   | 13.6  |
| 2022.1.7 - 2022.1.16  | 13.7  |
| 2022.3.0 - 2022.3.7   |       |
| 2023.1.0 - 2023.1.4   |       |
| 2022.1.17 - 2022.1.19 | 13.11 |
| 2022.3.8 - 2022.3.11  |       |
| 2023.1.5 - 2023.1.7   |       |
| 2023.3.0 - 2023.3.3   |       |
| 2024.0 - 2024.x       | 15.6  |

## Topology

The diagram below is a summarized version of the Tableau Server topology with External Repository.

The diagram below is a detailed version of the Tableau Server topology with External Repository and shows all the processes installed on each node.

## Managing the External Repository

### License Management

To enable this feature you must first activate the Advanced Management product keys on Tableau Server. For more information, see [About Tableau Advanced Management on Tableau Server](#). If you don't have the Advanced Management keys activated or if the licenses is expired, you will see the following behavior:

- If you try to configure Tableau Server to use external repository during installation, you will see an error message, but you will be able to continue the installation and Tableau

## Tableau Server on Linux Administrator Guide

Server Repository will be installed locally. For single server installations, the repository is installed on the same machine as Tableau Server. For multi-node installations, the repository is installed on one of the nodes of your Tableau Server cluster.

- If you are already using an external Tableau Server Repository on your Tableau Server installation, and the Advanced Management license expires, the server will fail on restart. If you no longer have a valid Advanced Management license, but have a valid Tableau Server license, you will still be able to create a backup. You can also migrate the external repository to local repository which does not require the Advanced Management license, to get your server up and running again. For more information on how to migrate from external repository to local repository, see [Re-Configure Tableau Server Repository](#).

### Supported Migration Scenarios

- Moving your repository from local to external.
- Moving your repository from external to local.

### Backup and Restore

#### **If you have only External Repository configured:**

The backup and restore process remains is the same for both local and external repository and as described in the [Back up Tableau Server Data](#) topic.

- The backup and restore commands work in the same manner for both local and external repository. Backup in the case where Tableau Server uses external repository requires more disk space for backup, so you should keep that in mind when configuring your disk space.
- The default and other supported locations for storing the backup file are the same whether it the repository is local or external.

The following exceptions apply to Tableau Servers using external repository:

- Any custom user accounts that are created in the external Tableau Server repository will be included in the restore, but the passwords for the custom user accounts will not be. The passwords will have to be reconfigured after restore is complete. Custom user accounts are PostgreSQL database user accounts, used by SQL or other database client software to connect to the PostgreSQL database.

**Note:** These custom accounts will be disabled as a security measure, but this can be reconfigured.

- Configuration and topology should not be included in the backup. For more information on how to export configuration and topology settings, see [Perform a Full Backup and Restore of Tableau Server](#).

#### **If you have both External Repository and External File Store configured:**

You have a couple of options if you have both External Repository and External File Store configured for your Tableau Server. These options allow you to take advantage of the snapshot backup capabilities of the cloud platforms you might be using to host the External Repository and File Store. For more information, and detailed step by step instructions, see [Backup and Restore with External File Store](#).

#### SSL Connections

You have the option to require or not require TLS/SSL connections from Tableau Server to the External Repository.

If you do not need to use encrypted connections, you must configure the External Repository to allow unencrypted connections, and use the `--no-ssl` option when you configure the External Repository for Tableau Server. For more information, see `tsm topology external-services repository enable`.

If you want to enable or disable SSL at a later time, post installation, use the [tsm security repository-ssl enable](#) or [tsm security repository-ssl disable](#). This option is available starting in 2021.4.

### Updating the SSL Certificate

If as part of a planned expiration of the SSL certificate of the RDS or Azure Database, Google Cloud PostgreSQL instance, or a stand-alone PostgreSQL instance, you need to update the instance with the new certificate file, you will also need to update Tableau Server settings to use the new certificate file. You can do this by downloading the latest file and running the *tsm topology external-services repository replace-host* command and providing the new certificate file.

### High Availability Considerations

Tableau Server does not manage or setup high availability for the external repository.

- **AWS:** Amazon RDS offers features that can be used to provide high availability and manage failover. For more information, see [Amazon RDS High Availability](#).
- **Azure:** Azure offers features that can be used to provide high availability and manage failover. For more information, see [Azure Database High Availability](#).
- **Google Cloud:** Google Cloud offers features that can be used to provide high availability and manage failover. For more information, see [Google Cloud High Availability](#).
- **Stand-alone PostgreSQL instance:** PostgreSQL offers several features that can be used to provide high availability and manage failover. For more information, see [PostgreSQL High Availability](#).

### Upgrade considerations

This applies only if you are using the External Repository configuration with Tableau Server.

If you are using an External Repository, you may need to take additional steps when upgrading:

- **No version change**—If there is no version change in PostgreSQL, there are no special actions required.
- **Minor version change**—If there is a minor version change in PostgreSQL, you need to upgrade your external repository before upgrading Tableau Server. In most cases there

are in-place methods for doing so. The method you use depends on the location of your repository and is beyond the scope of this documentation.

- **Major version change**—If there is a major version change in PostgreSQL, you need to follow the steps described in [Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL](#).

Steps include:

1. Creating a new instance of PostgreSQL DB. For more information, see:
  - [Create a PostgreSQL DB Instance on AWS Relational Database Service \(RDS\)](#)
  - [Create a Azure Database PostgreSQL Instance on Azure](#)
  - [Create a Cloud SQL for PostgreSQL instance on Google Cloud](#)
  - [Create a PostgreSQL Database as a Stand-alone Installation](#)
2. Creating a configuration file and download the SSI certificate file for the new instance that you created in Step 1.

During upgrade, you will need to point Tableau Server to the new instance using the configuration file. The upgrade process will migrate the content from your current external repository to your new instance. For more details, see [Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL](#).

## Monitoring the Status of the Repository

TSM status page will show the Tableau Server external service as an additional node for your Tableau Server installation.

# Tableau Server on Linux Administrator Guide

| Process                                | node1                               | external                            |
|--|-------------------------------------|-------------------------------------|
| Gateway                                | <input checked="" type="checkbox"/> |                                     |
| Application Server                     | <input checked="" type="checkbox"/> |                                     |
| Interactive Microservice Container     | <input checked="" type="checkbox"/> |                                     |
| VizQL Server                           | <input checked="" type="checkbox"/> |                                     |
| Cache Server                           | <input checked="" type="checkbox"/> |                                     |
| Cluster Controller                     | <input checked="" type="checkbox"/> |                                     |
| Search & Browse                        | <input checked="" type="checkbox"/> |                                     |
| Backgrounder                           | <input checked="" type="checkbox"/> |                                     |
| Non-interactive Microservice Container | <input checked="" type="checkbox"/> |                                     |
| Data Server                            | <input checked="" type="checkbox"/> |                                     |
| Data Engine                            | <input checked="" type="checkbox"/> |                                     |
| File Store                             | <input checked="" type="checkbox"/> |                                     |
| Repository                             |                                     | <input checked="" type="checkbox"/> |
| Tableau Prep Conductor                 |                                     |                                     |
| Ask Data                               | <input checked="" type="checkbox"/> |                                     |
| Elastic Server                         | <input checked="" type="checkbox"/> |                                     |
| TSM Controller                         | <input checked="" type="checkbox"/> |                                     |
| License Server                         | <input checked="" type="checkbox"/> |                                     |

The topology tab indicates whether there are Tableau Server external services configured:

**Add a Node**

**Step 1**  
Download the node bootstrap configuration file and locate your Tableau Server installer. The same installer can be used to install multiple nodes. Having trouble finding the installer?  
[Download Bootstrap File](#)

**Step 2**  
Run the node installer on the new node, and when prompted, provide the configuration file. Tableau Services Manager will detect the new node and display it on the Topology page.  
[Learn more about adding, removing, and managing nodes in Tableau Services Manager.](#)

## Getting Logs

Tableau Server logs will not include logs from the external repository. Use the following ways to get the logs specific to your instance:

- **AWS:** For information on setting up logging for your Amazon RDS PostgreSQL instance, see [PostgreSQL Database Log Files](#).
- **Azure:** For information on setting up logging for your Azure Database for PostgreSQL instance see [Logs in Azure Database for PostgreSQL](#).
- **Google Cloud:** For information on how to view and query logs for your PostgreSQL instance, see [Cloud SQL logging](#).
- **Stand alone PostgreSQL Instance:** For information on setting up logging for your stand alone PostgreSQL instance, see [Error Reporting and Logging](#).

## Next Steps

- You can use one of the following to create a PostgreSQL database instance:
  - Create a PostgreSQL DB Instance on AWS Relational Database Service (RDS)
  - Create a Azure Database PostgreSQL Instance on Azure
  - Create a PostgreSQL Instance on Google Cloud
  - Create a PostgreSQL Database as a Stand-alone Installation
- Install Tableau Server with External PostgreSQL Repository
- Re-Configure Tableau Server Repository
  - Migrate from local to external
  - Migrate from external to local

## Create a PostgreSQL DB Instance on AWS Relational Database Service (RDS)

Beginning in version 2019.3, you can host your External Repository on the AWS Cloud Platform. This topic describes how to create a AWS RDS PostgreSQL DB instance to use as your Tableau Server external repository.

To see a full list of hosts that you can use for the your external repository, see [Tableau Server External Repository](#).

### Requirements and Recommendations

- At a minimum use an instance with 8vCPUs and 32GB RAM. This is the minimum recommended AWS RDS instance size to use for Tableau Server external repository, but the exact requirements will vary with your requirements and usage. We recommend using 16 vCPUs and 128GB RAM Amazon RDS memory optimized instance types for good performance.

You can start with a smaller instance type and if you find later that you need a larger instance type, you can upgrade your existing RDS instance. For more information, see [Upgrading your RDS Instance](#) .

Secure communication between Tableau Server and the external PostgreSQL DB instance using SSL connections is **not** required but recommended.

- The PostgreSQL DB instance must be reachable by all nodes in the Tableau Server cluster. One of the ways you can do this is by making the PostgreSQL DB instance a member of a security group that has the necessary permissions to be accessed by all the nodes in the Tableau Server cluster.
- The version of PostgreSQL should match the version used by Tableau Server when installed locally. Tableau Server 2020.4 uses PostgreSQL version 12.
- Tableau auto-generates passwords for internal use by internal database users. These passwords are 32 characters long and consist of lower-case letters and numbers. They cannot be accessed or configured by an admin. Your external PostgreSQL instance may allow you to set a password policy (this will depend on the platform you are using). If you specify a policy that includes character types other than numbers and lower-case letters, this can cause errors while configuring Tableau Server to use the external repository.

## Create a PostgreSQL DB instance on Amazon RDS

### Step 1: Create a parameter group

PostgreSQL parameters that you set for a local PostgreSQL instance in the *postgresql.conf* file are maintained in the DB parameter group for your DB instance. When you create a DB instance, the parameters in the associated DB parameter group are loaded.

From the Tableau Server perspective, most of the parameters can be set to defaults. You can modify the parameter values if you have specific performance or logging requirements, but we strongly recommend that the following parameters be left to default values and not be changed:

- `standard_conforming_strings`
- `escape_string_warning`

We also recommend the value for the `work_mem` be set to at least 16384 to help avoid performance issues.

For more information and a full list of PostgreSQL Parameters, see [Working with PostgreSQL Parameters](#), on the AWS site.

### Step 2: Create a PostgreSQL DB instance on Amazon RDS

To create a new PostgreSQL DB instance, follow the instructions provided on the [Amazon documentation site](#).

Following are configuration options and the recommended values for the new PostgreSQL DB instance:

- **Instance Specifications**
  - Use the parameter group created in **Step 1**.
  - Use the compatible version of PostgreSQL for the version of Tableau Server you are using. For a full list of PostgreSQL versions compatible with Tableau Server versions, see Product Compatibility.
  - Use DB instance class that is `db.m4.2xlarge` or larger.
  - Allocate at least 100GB of storage.

- Storage type and Provisioned IOPS: leave default (recommendations may change depending on load testing).

- **Settings**

- You **must** use **rails** as the master username.

**This is a requirement for the external repository to work properly with Tableau Server.**

- Pick a password that meets AWS's requirements.

- **Network and Security**

- Make sure that the RDS instance can be reached by all the Tableau Server nodes. This most often involves creating a security group that allows access from the nodes.

- **Database Options**

- Don't create an initial database. The Database name should be left blank, as Tableau Server will create the needed databases in the RDS instance.
- The port can be anything, but we recommend leaving it as the default 5432.
- Set the DB Parameter Group to the one created in **Step 1**.
- Leave the IAM DB authentication as disabled.

- **Encryption**

- You can choose whether or not you want encryption.

- **Backup**

- This is for AWS's automated backups, not Tableau Server's backups. You can specify the settings that meets the requirements.

- **Monitoring**

- You can specify the settings based on your requirements.
- **Log Exports**
  - You can specify the settings based on your requirements.
- **Maintenance**
  - Disable auto minor version upgrade. Tableau Server is built to use a specific version of PostgreSQL. and you will be prompted to upgrade the PostgreSQL version if needed, during Tableau Server Upgrade.
- **Delete Protection**
  - You can specify the settings based on your requirements.

### Step 3: Get the PostgreSQL DB Instance Endpoint

After creating the PostgreSQL database instance, you can't use it until it's completed initialization by AWS and this can take several minutes. Once the instance is ready, get the endpoint information that you will use to configure Tableau Server to use this instance for the Tableau Server Repository.

### Step 4: Download the SSL certificate file (.pem file)

Secure connections between Tableau Server and the External Repository using SSL is **not** required, but recommended.

If you want to set up secure connections between Tableau Server and the External Repository, you will need the .pem file when you configure Tableau Server to use the external DB instance for your Tableau Server Repository. For more information, see [Using SSL to Encrypt the Connection to a DB Instance](#).

If you do not need to use secure connections between Tableau Server and External Repository, you need to configure the RDS instance to allow unencrypted connections.

**Important:** If as part of a planned expiration of the SSL certificate of the RDS instance, you need to update your RDS instance with the new certificate file, you also need to update

## Tableau Server on Linux Administrator Guide

Tableau Server settings to use the new certificate file. You can do this by downloading the latest file and running the `tsm topology external-services repository replace-host` command and providing the new certificate file.

### Configuring High Availability for your PostgreSQL DB

Tableau Server does not manage or setup high availability for the external repository. Amazon RDS offers high availability features that can be used to provide high availability, manage fail-over, etc. For more information, see [Amazon RDS High Availability](#).

### Disaster Recovery for your PostgreSQL DB

In the event of a disaster, you may need to setup a new RDS instance. There are other scenarios where you may need to recover from an issue with the RDS instance. For example, when you upgrade your Tableau Server, you might also need to upgrade the PostgreSQL version on your RDS instance. In the event that your PostgreSQL upgrade is not successful you might have to use a new RDS instance. In such scenarios, to configure your Tableau Server to use the new RDS instance, use the following steps:

1. **Restore the snapshot to a new RDS instance.** AWS does not support restoring a snapshot to an existing RDS instance. For more on RDS snapshot backup and restore, see [Amazon RDS Backup and Restore](#).
2. **Create a new JSON settings file** containing connection information for the new RDS instance. For more information on creating a JSON settings file, see **Step 1** in [Install Tableau Server with External PostgreSQL Repository](#).
3. **Use the `tsm topology external-services repository replace-host` command** to point your Tableau Server to the new RDS instance.

For more information on the `tsm topology external-services repository replace-host` command, see [tsm topology](#).

### Who can do this

Only Tableau Server Administrators can configure Tableau Server to use the external repository. You will also need an AWS account to create a RDS instance.

## Next Steps

For new installs: Install Tableau Server with External PostgreSQL Repository

If you want to configure your existing Tableau Server to use an external repository, see [Re-Configure Tableau Server Repository](#).

## Create a Azure Database PostgreSQL Instance on Azure

Beginning in version 2020.4, you can host your External Repository on the Azure Cloud Platform. This topic describes how to create a Azure Database for PostgreSQL instance to use as your Tableau Server external repository.

### Requirements and Recommendations

- We recommend that you use 8 vCore memory optimized server with 50 GB of storage for Tableau Server external repository, but the exact requirements will vary with your requirements and usage. If you already have a Tableau Server, review the usage of your existing repository to determine your storage needs.

You can also scale your resources if you find that you need more. For more information, see [Scaling your PostgreSQL Azure Database resources](#).

- Secure communications between Tableau Server and the external PostgreSQL DB instance using SSL is recommended, but not a requirement.

If you do not want to use secure connections between Tableau Server and External Repository, you should configure the Azure Database to allow unencrypted connections.

- The PostgreSQL DB instance must be reachable by all nodes in the Tableau Server cluster. The database instance must be set up to allow connections from all the Tableau Server nodes. There are two ways to set this up:
  - This is most secure way: Configure Azure Database for PostgreSQL instance to only allow private access via the Virtual Network service endpoint. For more

information, see [Use Virtual Network service endpoints and rules for Azure Database for PostgreSQL](#) and [Create and Manage VNet service endpoints](#).

You may also want to review the [overview topic](#) on Azure virtual networks.

- Alternatively Azure Database for PostgreSQL can be configured to allow connections from a range of public IP addresses. This method exposes the Azure Database endpoint to public access on the internet.
- When setting up the Azure Database instance, we recommend using **postgres** as the Administrator user name. If you choose to use a different user name, make sure that the user name does not start with **pg**, or **azure**. The user name also cannot be **rails**, **tbladmin**, **tableau**, **readonly**, or **tbladminviews**.
- The version of PostgreSQL should match the version used by Tableau Server when installed locally. Tableau Server 2020.4 uses PostgreSQL version 12.
- Tableau auto-generates passwords for internal use by internal database users. These passwords are 32 characters long and consist of lower-case letters and numbers. They cannot be accessed or configured by an admin. Your external PostgreSQL instance may allow you to set a password policy (this will depend on the platform you are using). If you specify a policy that includes character types other than numbers and lower-case letters, this can cause errors while configuring Tableau Server to use the external repository.

### Create a Database PostgreSQL instance on Azure

#### Step 1: Create a delegated subnet for the Azure Database for PostgreSQL instance

This step is a prerequisite for setting up private access for your networking option when you create the instance. Setting up private access to the database is a must for secure communications. This let the virtual machines created anywhere in that Virtual Network to connect to the database instance, but none outside of the Virtual Network is able to do so.

On the same virtual network where you are currently hosting your Tableau Server, create a new delegated subnet for the Azure Database instance. For more information on setting up

private access see [Networking Options for Azure Database for PostgreSQL - Flexible Server](#) on the Azure website.

Step 2: Create an Azure Database for PostgreSQL instance

To create a new Azure Database for PostgreSQL, follow the instructions provided on the [Azure documentation site](#).

Following are configuration options and the recommended values for the new PostgreSQL DB instance:

- **Server Details**

- Specify None as the Data source to create a new server.
- For Admin user name, we recommend using **postgres** as the Administrator user name. If you choose to use a different user name, make sure that the user name does not start with **pg**, or **azure**. The user name also cannot be **rails**, **tbl-wgadmin**, **tableau**, **readonly**, or **tbladminviews**.
- Pick a password that meets Azure's requirements.
- Use the compatible version of PostgreSQL for the version of Tableau Server you are using. For a full list of PostgreSQL versions compatible with Tableau Server versions, see Product Compatibility.
- Allocate at least 512GB of storage.

- **Compute and Storage**

- At a minimum, use Flexible Server with General Purpose computer tier, and Standard\_D8s\_v3 (8 vCores, 32 GB RAM) compute size.

- **Network Options**

- Select Private Access (Virtual Network). This ensures private and secure communications for the database.

- **High availability**

- Enable the high availability option per your requirements.

- **Backup**

## Tableau Server on Linux Administrator Guide

- Set the retention period per your requirements. This is for Azure automated backups, not Tableau Server's backups. You can specify the settings that meets the requirements.

### Step 3: Configure a server-level firewall rule

Once the database is created, configure a server-level firewall rule to allow access to the Tableau Server nodes.

Make sure that the Database instance can be reached by all the Tableau Server nodes using the dedicated subnet described in Step 1.

### Step 4: Configure the Azure Database for PostgreSQL Instance.

From the Tableau Server perspective, most of the parameters values for the instance can be set to defaults. You can modify the parameter values if you have specific performance or logging requirements, but we strongly recommend that the following parameters be left to default values and not be changed:

- `standard_conforming_strings`
- `escape_string_warning`

We also recommend the value for the `work_mem` be set to at least 16384 to help avoid performance issues.

For information on how to configure server parameters, see this [Azure documentation](#).

### Step 5: Get the PostgreSQL DB Instance Endpoint

Once the instance is ready, get the endpoint information that you will use to configure Tableau Server to use this instance for the Tableau Server Repository.

### Step 6: Download the SSL certificate file

Secure communications between Tableau Server and the External Repository using SSL is **not** required but recommended.

If you want to set up secure connections between Tableau Server and the External Repository, download the certificate file. You will need this certificate file when you configure Tableau Server to use this external repository. For more information, see [Configure TLS connectivity for Azure Database for PostgreSQL](#).

If you do not need to use secure connections between Tableau Server and External Repository, configure the Azure Database instance to allow unencrypted connections.

#### Configuring High Availability for your PostgreSQL DB

Tableau Server does not manage or setup high availability for the external repository. Azure offers high availability features that can be used to provide high availability. For more information, see [Azure Database High Availability](#).

#### Disaster Recovery for your PostgreSQL DB

In the event of a disaster, you may need to setup a new Azure Database for PostgreSQL instance. There are other scenarios where you may need to recover from an issue with the database instance. In such scenarios, to configure your Tableau Server to use the new Azure Database instance, use the following steps:

1. **Restore the backup to a new Azure Database instance.** In Azure Database for PostgreSQL, performing a restore creates a new server from the original server's backups. For more on Azure Database for PostgreSQL backup and restore, see [Azure Database for PostgreSQL Backup and Restore](#).
2. **Create a new JSON settings file** containing connection information for the new Azure Database for PostgreSQL instance. For more information on creating a JSON settings file, see **Step 1** in [Install Tableau Server with External PostgreSQL Repository](#).
3. **Use the `tsm topology external-services repository replace-host command`** to point your Tableau Server to the new Azure Database for PostgreSQL instance.

## Tableau Server on Linux Administrator Guide

For more information on the `tsm topology external-services repository replace-host` command, see [tsm topology](#).

### Who can do this

Only Tableau Server Administrators can configure Tableau Server to use the external repository. You will also need an Azure account to create the Azure Database.

### Next Steps

For new installs: [Install Tableau Server with External PostgreSQL Repository](#)

If you want to configure your existing Tableau Server to use an external repository, see [Re-Configure Tableau Server Repository](#).

## Create a PostgreSQL Instance on Google Cloud

Beginning in version 2021.4, you can host Tableau Server External Repository on the Google Cloud Platform. This topic describes how to create a PostgreSQL instance on Google Cloud to use as your Tableau Server external repository.

To see a full list of hosts that you can use for your external repository, see [Tableau Server External Repository](#).

### Requirements and Recommendations

- At a minimum, use high memory machine type with 8vCPUs and 32GB RAM. This is the minimum recommended PostgreSQL instance size to use for Tableau Server external repository, but the exact requirements will vary with your requirements and usage. We recommend high memory instance type with 16 vCPUs and 128GB RAM for good performance in most scenarios.
- Secure communication between Tableau Server and the external PostgreSQL DB instance using SSL connections is not required but recommended.

- The PostgreSQL instance must be reachable by all nodes in the Tableau Server cluster. One of the ways you can do this is by making the PostgreSQL instance a member of a security group that has the necessary permissions to be accessed by all the nodes in the Tableau Server cluster.
- The version of PostgreSQL must should be a supported version. For more information, see Product Compatibility for supported version information.
- Tableau auto-generates passwords for internal use by internal database users. These passwords are 32 characters long and consist of lower-case letters and numbers. They cannot be accessed or configured by an admin. Your external PostgreSQL instance may allow you to set a password policy (this will depend on the platform you are using). If you specify a policy that includes character types other than numbers and lower-case letters, this can cause errors while configuring Tableau Server to use the external repository.

#### Create a Database PostgreSQL instance on Google Cloud

##### Step 1: Create a new PostgreSQL instance

Create a PostgreSQL instance using the directions provided on the Google website, [here](#).

We recommend using a high memory machine type, with 16 vCPUs, and 128GB RAM.

##### Step 2: Configure database flags for your PostgreSQL Instance

From the Tableau Server perspective, most of the parameters values for the instance can be set to defaults. You can modify the parameter values if you have specific performance or logging requirements, but we strongly recommend that the following parameters be left to default values and not be changed:

- `standard_conforming_strings`
- `escape_string_warning`

We also recommend the value for the `work_mem` be set to at least 16384 to help avoid performance issues.

## Tableau Server on Linux Administrator Guide

For more information on database flags, see [this topic](#) on the Google website.

### Step 3: Get the PostgreSQL DB Instance Endpoint

Once the instance is ready, get the endpoint information that you will use to configure Tableau Server to use this instance for the Tableau Server Repository.

### Step 4: Download the SSL certificate file

Secure communications between Tableau Server and the External Repository using SSL is not required but recommended.

To setup secure connections between Tableau Server and the External Repository, you must use the certificate file when you configure Tableau Server to use this external repository. For more information, see [Configuring SSL/TLS certificates](#) on the Google website.

### Configuring High Availability for your PostgreSQL DB

Tableau Server does not manage or setup high availability for the external repository. Google Cloud offers high availability features that can be used to provide high availability. For more information, see [Enable High Availability on an Instance](#) on the Google website.

### Disaster Recovery for your PostgreSQL DB

In the event of a disaster, you may need to set up a new PostgreSQL Database for the PostgreSQL instance. There are other scenarios where you may need to recover from an issue with the database instance. In such scenarios, to configure your Tableau Server to use the new PostgreSQL instance, use the following steps:

1. **Restore the backup to a new PostgreSQL instance.** In the Google Cloud platform, you can choose to either restore to the same instance or create a new instance. For more information, see [Restoring an instance](#) on the Google website.

We recommend creating a new instance and do the following steps to recover.

2. If this is a new instance, **Create a new JSON settings file** containing connection information for the new Azure Database for PostgreSQL instance. For more information

on creating a JSON settings file, see **Step 1** in [Install Tableau Server with External PostgreSQL Repository](#).

3. **Use the `tsm topology external-services repository replace-host` command** to point your Tableau Server to the new Azure Database for PostgreSQL instance.

For more information on the `tsm topology external-services repository replace-host` command, see [tsm topology](#).

#### Who can do this

Only Tableau Server Administrators can configure Tableau Server to use the external repository. You will also need an Google Cloud account to create the PostgreSQL database instance.

#### Next Steps

For new installs: [Install Tableau Server with External PostgreSQL Repository](#)

If you want to configure your existing Tableau Server to use an external repository, see [Re-Configure Tableau Server Repository](#).

## Create a PostgreSQL Database as a Stand-alone Installation

Beginning in version 2021.2, you can host the Tableau Server repository separately as a stand alone installation. This is different from using a managed cloud service such as AWS RDS, or Azure Database. This configuration can be done on-premises, on AWS EC2, or on an Azure VM. Such an installation of the Tableau Server Repository will be referred to as stand-alone External Repository.

To see a full list of hosts that you can use for the your external repository, see [Tableau Server External Repository](#).

This topic provides guidance on the requirements and configurations that are necessary for Tableau Server to connect to a PostgreSQL installation and use it as the Tableau Server External Repository. This topic does not provide you with the detailed instructions on how to

install PostgreSQL. We recommend that you follow the [documentation on the PostgreSQL site](#) for this information.

### Requirements and Recommendations

- **Hardware Recommendations:** CPU and storage depend on your requirements. For smaller installations, you should have at least 50 GB of disk storage, and a quad processor (or 4 virtual cores) system with 32 gig of RAM. Review the guidance in [this topic](#) to calculate the disk space requirements for backup and restore. The general recommendation is to start with more hardware resources and scale back after monitoring.
- **Networking:** The PostgreSQL database instance must be reachable from all nodes in the Tableau Server cluster. One of the ways you can do this is by making the PostgreSQL database instance a member of a security group that has the necessary permissions to be accessed by all the nodes in the Tableau Server cluster.
- **Version Compatibility:** The version of PostgreSQL should match the version of the Tableau Server Repository when installed locally. For more information about compatibility, see Product Compatibility.
- **Security:** Secure connections between Tableau Server and the External Repository using SSL is **not** required, but recommended.

If you do not want to set up secure connections between Tableau Server and External Repository, you should configure the stand-alone PostgreSQL Database to allow unencrypted connections.

### Create a stand-alone PostgreSQL Database Instance

#### Step 1: Install and initialize PostgreSQL

1. Use the [PostgreSQL documentation](#) to install PostgreSQL database instance to serve as the External Repository for Tableau Server. You may want to set up a PostgreSQL database cluster to meet any high availability requirements you may have.
2. Install the contrib package that includes the uuid-ossdp extension. This module is used to

generate the UUIDS that Tableau Server uses for keys in the database.

### 3. Initialize the PostgreSQL instance.

#### Step 1: Configure your PostgreSQL Instance

You will be using two configuration files to configure your PostgreSQL instance:

- `pg_hba`: This is the configuration file for host-based authentication.
- `postgresql.conf`: This is the general server configuration file.

By default these files are located here:

`/var/lib/pgsql/12/data` (This may be different depending on the distribution)

## Super User Settings

Choose a user name that meets your requirements. We recommend using **postgres** as the Administrator user name. If you choose to use a different user name, make sure that the user name does not start with **pg**. The user name also cannot be **rails**, **tblwgadmin**, **tableau**, **readonly**, or **tbladminviews**.

**This is a requirement for the external repository to work properly with Tableau Server.**

## Network and Security

Make sure that the database instance can be reached by all the Tableau Server nodes. This most often involves creating a security group that allows access from the nodes.

## Database Options

The port can be anything, but we recommend leaving it as the default 5432.

## Update Parameters

From the Tableau Server perspective, most of the parameters values for the instance can be set to defaults. You can modify the parameter values if you have specific performance or log-

ging requirements, but we strongly recommend that the following parameters be set to default values and not be changed:

- `standard_conforming_strings`
- `escape_string_warning`

We also recommend the value for the `work_mem` be set to at least `16384` to help avoid performance issues.

## Configure remote connections

Use the following steps to make updates to the configuration files:

1. By default, the configuration in the `postgresql.conf` is configured to only listen to local connections. Enable remote connections by making the following changes in the connections and authentication section of the `postgresql.conf` file:

Add this line to allow remote connections:

```
listen_addresses = '*'
```

2. Restart the PostgreSQL instance.

## Configure SSL

Secure connections between Tableau Server and the External Repository is **not** required, but recommended.

To configure encrypted connections between Tableau Server and the External Repository, follow the guidance and the detailed steps described below:

When configuring Tableau Server to use the stand-alone PostgreSQL database instance, you will need to provide a trusted root certificate authority (CA) which is used to verify the connection to the server. Ideally, the stand-alone PostgreSQL instance's server certificate should specify a resolvable hostname so Tableau Server can use `sslmode`, **verify-full**. This mode verifies that the PostgreSQL server's certificate was signed by a trusted CA and that the hostname in the PostgreSQL Server's certificate matches the hostname used to connect to the

PostgreSQL instance. However, if that is not possible, `sslmode, verify-ca` will just verify that the Postgres server's certificate was signed by a trusted CA.

The following procedure provides the general steps to generating a root CA certificate on the PostgreSQL Server. For more detailed information, read the [SSL documentation](#) on the PostgreSQL website (The link points to version 12):

1. Generate signing root certificate authority (CA) key.
2. Create the root CA certificate.
3. Create the certificate and related key (for example - `server.csr` and `server.key`) for the PostgreSQL Server. The subject name for the certificate must match the DNS name of the PostgreSQL Server. The subject name is set with the `-subj` option with the format `"/CN=<private DNS name>".`
4. Sign the new certificate with the CA certificate that you created in step 2.
5. Copy the crt and key files to the data directory (`/pgsql/<version>/data`).
6. The `pg_hba.conf` file controls the connections to the database. Add the following line to allow remote connections. For example:

```
host all all 10.0.0.0/8 md5
```

7. To enable SSL add or update the `postgresql.conf` file with:

```
ssl = on
```

To restrict connections to only SSL only, use `hostssl` instead of `host`.

### High Availability and Disaster Recovery

Tableau Server does not manage or setup high availability for the external repository. PostgreSQL database supports several solutions for these purposes including replication and log-shipping. For more information, see the [high availability documentation](#) on the PostgreSQL website.

In the event of a disaster, if you need to setup a new PostgreSQL instance, make sure to follow these steps to configure Tableau Server to use the new instance.

1. **Create a new JSON settings file** containing connection information for the new RDS instance. For more information on creating a JSON settings file, see **Step 1** in [Install Tableau Server with External PostgreSQL Repository](#).
2. **Use the `tsm topology external-services repository replace-host` command** to point your Tableau Server to the new PostgreSQL instance.

For more information on the `tsm topology external-services repository replace-host` command, see [tsm topology](#).

### Who can do this

Only Tableau Server Administrators can configure Tableau Server to use the external repository. If you are using AWS EC2 or Azure VM to set up a stand-alone External Repository, you need to have accounts to access these platforms.

## Install Tableau Server with External PostgreSQL Repository

This topic describes how to install and configure Tableau Server to use an external service for Tableau Server Repository.

### Before you install

- You must have the Advanced Management license activated on your Tableau Server to make sure your environment has the appropriate license to use external repository. For more information about Advanced Management, see [About Tableau Advanced Management on Tableau Server](#).
- Your Tableau Server environment must be one of the following:
  - Public Cloud Services:
    - AWS cloud services.
    - Azure cloud services. For more information on Tableau Server installation on Azure, see [Install Tableau Server on Microsoft Azure](#).

- Google cloud services. For more information on Tableau Server installation on Google Cloud, see [Install Tableau Server for Healthcare on the Google Cloud Platform](#).
- On-premises: This is Tableau Server running on the hardware located in your organization or company and not on a public cloud.
- You must have an instance of PostgreSQL database install and ready. You will also need the endpoint of your PostgreSQL DB instance.
  - Tableau Server on **AWS**
    - For a fully managed Server option, using Amazon RDS, follow the guidance detailed in [Create a PostgreSQL DB Instance on AWS Relational Database Service \(RDS\)](#).
    - For a self-managed Server option: Use AWS EC2, and [Create a PostgreSQL Database as a Stand-alone Installation](#)
  - Tableau Server on **Azure**:
    - For a fully managed Server option using Azure DB, see [Create a Azure Database PostgreSQL Instance on Azure](#).
    - For a self-managed Server option use Azure VM, and [Create a PostgreSQL Database as a Stand-alone Installation](#) .
  - Tableau Server on **Google Cloud**:
    - For a fully managed Server option using Google Cloud PostgreSQL instance, follow the guidance in [Create a PostgreSQL Instance on Google Cloud](#)
    - For a self-managed Server option use Google Cloud VM, and [Create a PostgreSQL Database as a Stand-alone Installation](#)
  - If you are installing this on-premises, see [Create a PostgreSQL Database as a Stand-alone Installation](#)

- Download the SSL certificate:

Secure connections between Tableau Server and the External Repository are **not** required, but recommended.

If you want to set up SSL connections for communications between Tableau Server and the External Repository, do the following:

## Tableau Server on Linux Administrator Guide

- Amazon RDS: See [Using SSL to Encrypt the Connection to a DB Instance](#).
- Azure Database for PostgreSQL: See [Configure TLS connectivity for Azure Database for PostgreSQL](#).
- Google Cloud database: See [Configure SSL/TLS certificates](#).
- Stand alone PostgreSQL database: The CA certificate that you used to configure SSL for the database should be copied to the Tableau Server initial node. For more information on configuring SSL for your PostgreSQL database, see [Configure SSL](#).

### Install and Configure Tableau Server

#### Step 1: Create a configuration file

Create a json file with the following configuration settings:

```
{
  "flavor": "<flavor name>",
  "masterUsername": "<admin user name>",
  "masterPassword": "<password>",
  "host": "<instance host name>",
  "port": 5432
}
```

- **flavor:** This is the type of external service you are going to use for Tableau Server repository.
  - Amazon RDS: use "rds"
  - Azure Database: use "azure"
  - Google Cloud Database: use "gcp"
  - Stand-alone PostgreSQL database: use "generic"

- **masterUsername:**

- Amazon RDS: Use "rails" for the user name. This is the user that you specified when creating the RDS instance.

You must use "rails" as the masterUsername. This is required for the external repository to work with Tableau Server properly.

- Azure Database, Google Cloud PostgreSQL instance, or Standalone PostgreSQL Database: Choose a user name that meets your requirements. We recommend using **postgres** as the Administrator user name. If you choose to use a different user name, make sure that the user name does not start with **pg**, or **azure**. The user name also cannot be **rails**, **tblwgadmin**, **tableau**, **readonly**, or **tbladminviews**.
- **masterPassword**: This is the same password you specified when creating the PostgreSQL database instance.
- **host**: This is the endpoint of your PostgreSQL database instance.
- **port**: The database port you specified when creating the PostgreSQL DB instance.

## Step 2: Install Tableau Server and Configure the External Repository

### Using TSM CLI:

1. Install and Initialize TSM: Follow the instructions provided in this topic and complete steps 1-5 which runs the setup program and installs TSM.
2. Activate and Register Tableau Server: Provide the Tableau Server Key and the Advanced Management key in the activate step. You will need to run the following command twice, first with the Tableau Server product key and then with the Advanced Management product key:

```
tsm licenses activate -k <product key>
```

3. Configure Initial Node Settings: Follow the instructions provided in the topic to configure the initial node settings.

Important! Do not run the **Initialize and Start Tableau Server** step when you configure the initial node. After completing the other steps in the Configure Initial Node Settings topic, return to this page and follow the rest of the instructions.

4. Configure Tableau Server to use the external repository by using the following commands:

## Tableau Server on Linux Administrator Guide

- Specify the external repository settings using the json file that you created in the previous step:

```
tsm topology external-services repository enable -f <file-name>.json -c <ssl certificate file>
```

The json file is the file that you created in the first step with the configuration settings.

**Note:** The SSL certificate is needed only if you are using encrypted connections between Tableau Server and the External Repository. If this is not a must for you, you must specify the `--no-ssl` option. In this case, the `tsm` command would look like this:

```
tsm topology external-services repository enable -f <file-name>.json --no-ssl
```

- Apply the changes:

```
tsm pending-changes apply
```

### Step 3: Complete tsm Initialize

To initialize and start Tableau Server:

```
tsm initialize --start-server --request-timeout 1800
```

### Step 4: Complete the install

Add an Administrator Account and complete the installation.

Who can do this

Tableau Server Administrators can install and configure Tableau Server.

## Re-Configure Tableau Server Repository

Your Tableau Server may be configured to use either a local or an external repository. This topic describes the steps needed to reconfigure your existing Tableau Server with one of the

following options:

- Move a local Tableau Server Repository to an external repository and configure your Tableau Server to use an external repository.
- Move the external Tableau Server Repository to your local Tableau Server installation, and configure your Tableau Server to use the local repository. This means that the Tableau Server repository will be installed on the same machine or machines as your Tableau Server.

To learn more about these options and external repositories, see [Tableau Server External Repository](#).

#### Move local repository to external

Tableau Server must be stopped to migrate from a local repository to an external repository.

Use the following steps to move Tableau Server Repository from local to external:

1. Activate the Advanced Management product key on your Tableau Server if it is not already activated. Advanced Management license is required to configure your Tableau Server with an external repository.
2. Configure Amazon PostgreSQL DB instance to use as the external repository.
  1. Amazon: Create a PostgreSQL DB Instance on AWS Relational Database Service (RDS).
  2. Azure Database: Create a Azure Database PostgreSQL Instance on Azure.
  3. Google Cloud Database: Create a PostgreSQL Instance on Google Cloud
  4. Stand-alone PostgreSQL Instance: Create a PostgreSQL Database as a Stand-alone Installation .
3. Create a json file with the following configuration settings:

```
{
  "flavor": "<flavor name>",
  "masterUsername": "<admin user name>",
  "masterPassword": "<password>",
  "host": "<instance host name>",
```

```
"port":5432  
}
```

- **flavor:** This is the type of external service you are going to use for Tableau Server repository.
  - Amazon RDS: use "rds"
  - Azure Database: use "azure"
  - Google Cloud Database: use "gcp"
  - Stand-alone PostgreSQL database: use "generic"
- **masterUsername:**
  - **Amazon RDS:** Use "rails" for the user name. This is the user that you specified when creating the RDS instance.

You must use "rails" as the masterUsername. This is required for the external repository to work with Tableau Server properly.
  - **Azure Database, Google Cloud instance, and Stand-alone PostgreSQL instance:** Choose a user name that meets your requirements. We recommend using **postgres** as the Administrator user name. If you choose to use a different user name, make sure that the user name does not start with **pg**, or **azure**. The user name also cannot be **rails**, **tblwgadmin**, **tableau**, **readonly**, or **tbladminviews**.
- **masterPassword:** This is the same password you specified when creating the PostgreSQL database instance.
- **host:** This is the endpoint of your PostgreSQL database instance.
- **port:** The database port you specified when creating the PostgreSQL DB instance.

4. Run the following TSM CLI command to configure Tableau Server to use external repository:

```
tsm topology external-services repository enable -f file.json -  
c <ssl certificate file>.pem
```

**Note:** The SSL certificate is needed only if you are using encrypted connections between Tableau Server and the External Repository. If this is not a requirement for you, you must specify the `--no-ssl` option. In this case, the `tsm` command would look like this:

```
tsm topology external-services repository enable -f <file-  
name>.json --no-ssl
```

The json file is the file that you created in the first step with the configuration settings. The SSL certificate file can be downloaded as described in [this topic](#).

Running the above command will migrate the local repository to your new external PostgreSQL DB instance.

#### Move external repository to local

Use the following steps to move Tableau Server Repository from external location to the local installation:

1. Run the following TSM CLI command to move the repository to a specific node:

```
tsm topology external-services repository disable -n nodeN
```

2. If you are setting up HA for your repository, install the repository on a second node. For more information, see [Example: Install and Configure a Three-Node HA Cluster](#).

**Note:** To install the repository on a second node, you must run the command described in the previous step first. The first step migrates your external repository to the local repository. You can then install the repository on a second node on your Tableau Server.

Who can do this

Tableau Server Administrators can reconfigure external repository. You will also need to have access to create PostgreSQL database instance on Amazon or Azure.

### Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL

When there is a change in the PostgreSQL major version requirement for Tableau Server, there are some specific instructions you must follow to ensure that your Tableau Server upgrade is successful. For example, Tableau Server 2020.4 requires that the repository use PostgreSQL version 12. This is a major version change from PostgreSQL version 9.x used in Tableau Server versions earlier than 2020.4. So if you are upgrading from an earlier version of Tableau Server to version 2020.4 or later, you will need to take the steps described in the following sections to complete the upgrade.

This topic also includes the product compatibility between PostgreSQL and Tableau Server.

Before you upgrade

You cannot do an in-place upgrade to update the PostgreSQL version on your existing PostgreSQL DB instance on Amazon RDS or Azure Database for PostgreSQL DB. Instead, you must create a new instance and point the Tableau Server to the new instance during upgrade. Use the following information to create a new instance and prepare for the upgrade:

1. Create a new instance of PostgreSQL Database instance:
  1. Create a PostgreSQL DB Instance on AWS Relational Database Service (RDS)
  2. Create a Azure Database PostgreSQL Instance on Azure
  3. Create a PostgreSQL Instance on Google Cloud
  4. Create a PostgreSQL Database as a Stand-alone Installation
2. SSL connections are **not** required but recommended. If you want to setup SSL connections for communications between Tableau Server and the External Repository, do the following:
  - **Amazon RDS:** See [Using SSL to Encrypt the Connection to a DB Instance](#).
  - **Azure Database:** See [Configure TLS connectivity for Azure Database for PostgreSQL](#).

- **Google Cloud Instance:** See [Configuring SSL/TLS certificates](#)
- **Stand-alone PostgreSQL Instance:** See [Configure SSL](#) .

3. Create a configuration file for the new instance you created in step 1.

Create a json file with the following configuration settings:

```
{
  "flavor": "<flavor name>",
  "masterUsername": "<admin user name>",
  "masterPassword": "<password>",
  "host": "<instance host name>",
  "port": 5432
}
```

- **flavor:** This is the type of external service you are going to use for Tableau Server repository.
  - Amazon RDS: use "rds"
  - Azure Database: use "azure"
  - Google Cloud Database: use "gcp"
  - Stand-alone PostgreSQL database: use "generic"
- **masterUsername:**
  - **Amazon RDS:** Use "rails" for the user name. This is the user that you specified when creating the RDS instance.
 

You must use "rails" as the masterUsername. This is required for the external repository to work with Tableau Server properly.
  - **Azure Database, Google Cloud Instance or Stand-alone PostgreSQL Instance:** Choose a user name that meets your requirements. We recommend using **postgres** as the Administrator user name. If you choose to use a different user name, make sure that the user name does not start with **pg**, or **azure**. The user name also cannot be **rails**, **tblwgadmin**, **tableau**, **readonly**, or **tbladminviews**.

## Tableau Server on Linux Administrator Guide

- **masterPassword:** This is the same password you specified when creating the PostgreSQL database instance.
- **host:** This is the endpoint of your PostgreSQL database instance.
- **port:** The database port you specified when creating the PostgreSQL DB instance. Default port for PostgreSQL is 5432.

## Tableau Server Upgrade

**Note:** If you are using Tableau Server External Repository, you must upgrade Tableau server using the command line option.

The following are the high level steps of how to specify the external repository parameters when running the upgrade script.

For a full walk-through of Tableau Server upgrade process, see [Upgrading from earlier versions](#)

1. On the Tableau Server, open a command prompt as administrator.

**Note:** You must open a new command window because the Setup program updates the path for the new installation.

2. Navigate to the scripts folder for your new installation.

By default:

```
/opt/tableau/tableau_server/packages/scripts.<version_code>/
```

3. Run the upgrade script and specify the configuration file and the SSL certificate:

```
upgrade-tsm --external-repository-config-file=<json config file> --external-repository-cert-file=<SSL certificate file>
```

## Product Compatibility

The table below lists the version of PostgreSQL that is supported with Tableau Server. Use this table to determine the version of PostgreSQL to install for your External Repository.

**Amazon RDS support:** External Repository using Amazon RDS is supported on Tableau Server versions 2019.3 and later.

**Azure Database support:** External Repository using Azure Database instance is supported on Tableau Server versions 2020.4 and later.

**Google Cloud support:** External Repository using Google Cloud SQL instance is supported on Tableau Server versions 2021.4 and later.

**Stand alone PostgreSQL instance support:** External Repository using a stand alone installation of PostgreSQL database is supported on Tableau Server versions 2021.2 and later.

Google Cloud Platform support: External Repository using a PostgreSQL instance on Google Cloud Platform is supported on Tableau Server versions 2021.4 and later.

| Tableau Server versions | PostgreSQL minimum compatible versions |
|-------------------------|--|
| 2021.2.3 - 2021.2.8     | 12.6                                   |
| 2021.3.0 - 2021.3.7     |  |
| 2021.4.0 - 2021.4.3     |  |
| 2021.2.10 - 2021.2.14   | 12.8                                   |
| 2021.3.8 - 2021.3.13    |  |
| 2021.4.4 - 2021.4.8     |  |
| 2021.2.15 - 2021.2.16   | 12.10                                  |
| 2021.3.14 - 2021.3.15   |  |

|                       |       |
|-----------------------|-------|
| 2021.4.9 - 2021.4.10  |       |
| 2021.2.17 - 2021.2.18 | 12.11 |
| 2021.3.16 - 2021.3.17 |       |
| 2021.4.11 - 2021.4.12 |       |
| 2021.3.26             | 12.15 |
| 2021.4.23             |       |
| 2022.1.0              | 13.3  |
| 2022.1.1 - 2022.1.3   | 13.4  |
| 2022.1.4 - 2022.1.6   | 13.6  |
| 2022.1.7 - 2022.1.16  | 13.7  |
| 2022.3.0 - 2022.3.7   |       |
| 2023.1.0 - 2023.1.4   |       |
| 2022.1.17 - 2022.1.19 | 13.11 |
| 2022.3.8 - 2022.3.11  |       |
| 2023.1.5 - 2023.1.7   |       |
| 2023.3.0 - 2023.3.3   |       |
| 2024.0 - 2024.x       | 15.6  |

## Legacy compatibility

The table below includes two columns:

1. PostgreSQL version shipped with Tableau Server, which is the version that is installed with Tableau Server for local Repositories.

## 2. All PostgreSQL versions supported for External Repository.

**Notes:**

- For PostgreSQL versions earlier than version 10, the first two digits indicate the major version, and the minor version is represented by the last digit. For example, in the version 9.4.1, 9.4 indicates the major version and the .1 indicates the minor version.
- For PostgreSQL versions 10 or later, the first digit indicates the major version, and the minor version is the represented by the last digit. For example, in the version 11.1, 11 is the major version and .1 is the minor version.
- A PostgreSQL version with a major version equal to, and a minor version greater than, the Postgres version shipped with Tableau server is always acceptable for use with the external repository, along with any explicitly allowed older versions.

| Tableau Server Version   | PostgreSQL Version (Shipped with Tableau Server) | Alternate PostgreSQL Versions supported for External Repository |
|--------------------------|--|---|
| 2019.3 -<br>2019.3.3     | 9.6.11   | 9.6.x, where x is greater than 11                               |
| 2019.3.4 -<br>2019.3.10  | 9.6.15   | 9.6.x, where x is greater than 15                               |
| 2019.3.11 -<br>2019.3.14 | 9.6.17   | 9.6.15, or 9.6.x, where x greater than 17                       |
| 2019.4 -<br>2019.4.1     | 9.6.14   | 9.6.x, where x is greater than 14                               |
| 2019.4.2 -<br>2019.4.6   | 9.6.15   | 9.6.x, where x is greater than 15                               |
| 2019.4.7 -<br>2019.4.13  | 9.6.17   | 9.6.15, or 9.6.x, where x is greater than 17                    |
| 2020.1 -                 | 9.6.15   | 9.6.x, where x is greater than 15                               |

|                        |        |  |
|------------------------|--------|--|
| 2020.1.6               |        |  |
| 2020.1.7 -<br>2020.3.2 | 9.6.17 | 9.6.15, or 9.6.x, where x is greater than 17 |
| 2020.4 -<br>2021.4     | 12.8   | 12.8, or 12.x, where x is greater than 8     |
| 2022.1 and<br>later    | 13.3   | 13.3 or 13.x, where x is greater than 3      |

Who can do this

Tableau Server Administrators can upgrade and configure Tableau Server.

## Upgrading your RDS Instance

If you find that the current RDS instance you are using to host Tableau repository is a performance bottleneck, you can upgrade your RDS instance to a larger size. This topic describes the steps that you can use to upgrade your RDS instance.

1. Back up Tableau Server Data.
2. Stop Tableau Server:
 

```
tsm stop
```
3. After confirming that the server has shutdown, sign in to the AWS Management Console and open the Amazon RDS console at
 

```
https://console.aws.amazon.com/rds/.
```
4. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
5. Choose **Modify**. The Modify DB Instance page appears.
6. Modify your RDS instance by setting the DB instance class to the one you want.
7. Choose **Apply immediately** to make sure that the changes are applied right away. For more detailed information, see [Modifying a DB Instance Running the PostgreSQL Database Engine](#) on AWS documentation site.

8. Monitor the status of the RDS instance in the AWS console. It may take a while, but when the status shows as Available, you can start Tableau Server and resume normal operations:

```
tsm start
```

Who can do this

Tableau Server Administrator who has have access to the Amazon RDS account can perform all the steps required to upgrade the Amazon RDS instance.

## Workload Management through Node Roles

Using node roles, you can configure where certain types of workloads are processed on your Tableau Server installation. The node roles features allows you to dedicate and scale resources to specific workloads. You can configure node roles for Backgrounder and File Store.

The Backgrounder node role specifies the type of background tasks that should run on a node, whereas the File Store node role specifies the type extract workload that should run on a node. Both node roles are specified at a node level. Although these node roles can work independently to optimize selected workload, the two node roles in combination can be used to specialize server nodes to preferentially execute selected workloads to optimize performance extract heavy workloads. This combination is discussed in more detail later in the File Store node roles section.

### Backgrounder node roles

The Backgrounder process runs Tableau Server tasks, including extract refreshes, subscriptions, flow tasks, 'Run Now' tasks, and tasks initiated from *tabcmd*. Running all these tasks can use a lot of machine resources. If you have more than one Backgrounder node in your cluster, you can manage your Backgrounder workload by specifying the type of tasks a Backgrounder can run on a node using the Backgrounder node role feature.

## Tableau Server on Linux Administrator Guide

This configuration option is currently available only through TSM CLI commands and is only useful on multi-node clusters. If you have only one node, the Backgrounder is set to run all tasks by default and that cannot be changed.

### Using Backgrounder node roles

The Backgrounder node role feature is intended to give you more control and governance over where certain type of Backgrounder workloads are processed in your Tableau Server installation and allows you to dedicate and scale resources to specific workloads.

For example, if your deployment is heavy on extract and users are running a lot of extract refreshes or encryption jobs, it could be beneficial to dedicate a node to extract refreshes. Similarly, in the case of subscriptions, if your Tableau Server installation processes a lot of subscriptions and you want to ensure that other jobs do not take resources from subscriptions, then you can dedicate a node to subscriptions. In these cases, you would also want to dedicate other backgrounder nodes to workloads other than extract refreshes or subscriptions.

To support high availability, Tableau recommends having multiple nodes that are dedicated towards a specific workload. For example, if you dedicate a node to extract refreshes, you should also configure a second node to process extract refresh workload. This way if a node dedicated to extract refreshes becomes unavailable, extract refreshes can still be processed by the other node.

### Configuration options

| <b>Configuration</b> | <b>Jobs</b>   |
|----------------------|---|
| all-jobs (default)   | All Tableau Server jobs   |
| flows                | Flow run jobs.  |
| no-flows             | All jobs except flows.  |
| extract-refreshes    | Jobs that are created for:<br><br>Incremental refreshes, full refreshes, encryption and decryption of all extracts including extracts that flow outputs create. |

|  |   |
|--|---|
| subscriptions                          | Subscription jobs   |
| system                                 | System maintenance jobs that interact with other Tableau Server processes. For example, cleaning crashed jobs, reaping database events, and syncing Active Directory. |
| extract-refreshes-and-subscriptions    | Extract-refreshes, encryption and decryption of all extracts including extracts that flow outputs generate, and subscription jobs.                                    |
| no-extract-refreshes                   | All jobs except extract-refreshes, extract encryption and decryption of all extracts including extracts created from flow outputs.                                    |
| no-subscriptions                       | All jobs except subscriptions.  |
| no-extract-refreshes-and-subscriptions | All jobs except extract-refreshes, encryption and decryption of all extracts including extracts created from flow outputs, and subscriptions.                         |
| no-system                              | All jobs except system maintenance jobs.  |

For more information on how to use the tsm commands to set the node role, see tsm topology.

**Note:** Making configurations to node roles require a restart of the server and will require some downtime. For more information, see tsm pending-changes.

### License requirements

Configuring a node to do only a specific type of tasks, like, flows, extract refreshes, and subscriptions, you must have one of the following licenses activated on your Tableau Server:

- To configure a node to run flows, you must have a valid Data Management license activated on your server, and have Tableau Prep Conductor running on that node. To learn more about Tableau Prep Conductor, see Tableau Prep Conductor.

## Tableau Server on Linux Administrator Guide

- To configure a node to run extract refreshes, subscriptions, and any combination related to extract refreshes and subscriptions you must have a valid Advanced Management license activated on your Tableau Server. If the license expires or is deactivated, you will see an error any time you make a change to the Server configuration. For more information on Advanced Management, see [About Tableau Advanced Management on Tableau Server](#).

### Important!

While flows, extract refreshes, and subscriptions can be expensive and resource heavy, they are not the only jobs that may require dedicated resources. In the **all jobs** group, there are a variety of System jobs that the Backgrounder executes, such as thumbnail generation for workbooks. Make sure that the nodes that run jobs other than extract refreshes, subscriptions, or flows have enough machine resources.

For more information on configuring node roles using TSM commands, see [tsm topology set-node-role](#).

### Considerations

There are some rules you must consider when configuring Backgrounder node roles, which are listed below:

- Only one node role configuration can be set for a node at a time. You cannot configure multiple node roles on a node.
- To configure a node role, there must be at least one Backgrounder process on that node.
- If you have only one Backgrounder node, you must configure this node to run all jobs. This is the default configuration and does not require additional licensing.
- If you have more than one Backgrounder node, combined, they must be configured to handle all jobs. This can be achieved in the following ways:

- Configure one of the nodes to run all jobs using the all jobs option. This is the easiest and most straightforward way.
- Using one of the exception configurations on one of the nodes:
  - no-flows
  - no-subscriptions
  - no-extract-refreshes
  - no-extract-refreshes-and-subscriptions

For example, in a cluster where there are three backgrounders, you could have one node configured to run flows, one to run subscriptions and extract refreshes, and one to run all jobs except flows, subscription and extract refreshes.

**Note:** The ability to specify node roles to run flows, or run all jobs except flows, or run all jobs was introduced in 2019.1.

## File Store node roles

The Tableau Server File Store controls the storage of extracts. There are three broad categories of workloads that are extract dependent.

| Extract Workload | Execution Service |
|------------------|-------------------|
| Refresh          | Backgrounder      |
| Query            | Data Engine       |
| Backup/Restore   | Backup/Restore    |

File Store node role management in combination with Backgrounder node role management gives server admins the ability to specialize server nodes to preferentially execute selected workloads to optimize performance of all categories of extract heavy workloads.

## Tableau Server on Linux Administrator Guide

It is possible to specialize a node to execute extract query workloads through a topology that has only stand-alone Data Engine nodes. For more information, see [Optimize for Extract Query-Heavy Environments](#). However, this is at the expense of extract refresh workloads, which are executed by Backgrounder nodes. With the topology-based isolation approach, extract refresh heavy Backgrounder workloads can get slower as none of the Backgrounder nodes have a File Store and thus all extract refresh traffic goes over the network.

With the File Store Node Role configuration option, it is possible to designate certain server nodes that process extract queries to be preferentially selected from the list of server nodes that can do so. This helps speed up workloads such as backup and extract refreshes by allowing server admins to enable File Store on Backgrounder server nodes, which prevents extract queries from running on these nodes. This feature is useful if you have an extract-heavy query workload and an extract-heavy refresh workload and want to achieve optimal extract query and refresh performance.

Guidelines to optimize for extract refresh and backup or restore workloads.

Start from a topology with specialized Data Engine nodes (see [Optimize for Extract Query-Heavy Environments](#)).

**Note:** In the below diagram and procedure, node 1 is Initial Node, node 2 is Additional Node 1, node 3 is Additional Node 2, and node 4 is Additional Node 3.

| Process            | Initial Node | Additional Node 1 | Additional Node 2 | Additional Node 3 |
|--------------------|--------------|-------------------|-------------------|-------------------|
| Cluster Controller | ✓            | ✓                 | ✓                 | ✓                 |
| Gateway            | ✓            | ✓                 |                   |                   |
| Application Server | ✓            | ✓                 |                   |                   |
| VizQL Server       | ✓ ✓          | ✓ ✓               |                   |                   |
| Cache Server       | ✓ ✓          | ✓ ✓               |                   |                   |
| Search & Browse    | ✓            | ✓                 |                   |                   |
| Backgrounder       | ✓ ✓ ✓ ✓      | ✓ ✓ ✓ ✓           |                   |                   |
| Data Server        | ✓ ✓          | ✓ ✓               |                   |                   |
| Data Engine        | ✓            | ✓                 | ✓                 | ✓                 |
| File Store         |              |                   | ✓                 | ✓                 |
| Repository         | ✓            | ✗                 |                   |                   |

### Topology 1 - Dedicated Data Engine Nodes

1. Add File Store to Node 1.

```
tsm topology set-process -n node1 -pr filestore -c 1
```

2. Designate Node 3 and Node 4 to preferentially execute extract-query workloads

```
tsm topology set-node-role -n node3, node4 -r extract-queries
```

3. Designate Node 1 to preferentially execute extract-refresh workloads.

```
tsm topology set-node-role -n node1 -r extract-refreshes
```

4. Designate Node 2 to preferentially execute non-extract-refresh workloads.

```
tsm topology set-node-role -n node2 -r no-extract-refreshes
```

5. Apply pending changes.

```
tsm pending-changes apply
```

## Tableau Server on Linux Administrator Guide

| Process            | Initial Node | Additional Node 1 | Additional Node 2 | Additional Node 3 |
|--------------------|--------------|-------------------|-------------------|-------------------|
| Cluster Controller | ✓            | ✓                 | ✓                 | ✓                 |
| Gateway            | ✓            | ✓                 |                   |                   |
| Application Server | ✓            | ✓                 |                   |                   |
| VizQL Server       | ✓ ✓          | ✓ ✓               |                   |                   |
| Cache Server       | ✓ ✓          | ✓ ✓               |                   |                   |
| Search & Browse    | ✓            | ✓                 |                   |                   |
| Backgrounder       | ✓ ✓ ✓ ✓      | ✓ ✓ ✓ ✓           |                   |                   |
| Data Server        | ✓ ✓          | ✓ ✓               |                   |                   |
| Data Engine        | ✓            | ✓                 | ✓                 | ✓                 |
| File Store         | ✓            |                   | ✓                 | ✓                 |
| Repository         | ✓            | ✗                 |                   |                   |

### Topology 2 - Extra File Store Node

**Note:** In your Tableau Server deployment, adding File Store roles to existing nodes will temporarily increase network I/O between all File Store nodes while the new File Store is being synchronized. The duration of this operation is dependent on the volume of data on the File Store and the network bandwidth capacity. The status of synchronization can be monitored using the TSM Web GUI. If you are adding more than one File Store to your deployment, it is recommended to add them consecutively and wait for the initial synchronization to complete in between each File Store addition.

### Fine tune extract query workload management

When extract queries for email subscriptions and metric alerts are running at the same time that users are interactively viewing extract-based visualizations, users may experience slower than normal viz load times. Use the following node roles to fine tune how these workloads are prioritized.

| Node role to use             | Type of extract query workload | Example                               |
|------------------------------|--------------------------------|---------------------------------------|
| <code>extract-queries</code> | scheduled                      | email subscriptions and metric alerts |

|  |                          |  |
|--|--------------------------|--|
| <code>extract-queries-interactive</code> | <code>interactive</code> | users viewing an extract-based visualization |
|--|--------------------------|--|

If your server deployment is seeing growth in email subscriptions and metric alerts, you can add nodes and assign the `extract-queries` node role, which makes them more available to handle subscriptions and alerts.

If your server deployment is seeing growth in users viewing extract-based visualizations, you can add nodes and assign the `extract-queries-interactive` node role, which makes them prioritize interactive extract queries to reduce extract-based viz load times. The `extract-queries-interactive` node role is a preference and not strict isolation. This means that queries will be routed to nodes that have the `extract-queries-interactive` node role assigned. If you have multiple nodes with the `extract-queries-interactive` role, queries will be routed based on node health.

For example, add a node and designate it to preferentially execute `extract-queries-interactive` workloads.

- `tsm topology set-node-role -n node4 -r extract-queries-interactive`

#### Configuration options

| Configuration                            | Jobs   |
|--|--|
| <code>all-jobs</code> (default)          | All Tableau Server jobs  |
| <code>extract-queries</code>             | Jobs that are created for extract queries. The nodes selected will run as <code>all-jobs</code> and will prioritize the processing of extract queries.   |
| <code>extract-queries-interactive</code> | Jobs that are created for extract queries. The nodes selected will run as <code>all-jobs</code> and will prioritize the processing of interactive extract queries, such as those that run when a user is looking at their screen and waiting for an extract-based dashboard to load. This is an advanced setting and it should only be used if the cluster has a heavy subscription and alert job workload that causes users to experience |

|  |  |
|--|--|
|  | degraded performance on viz load times that run around the same time as scheduled loads. |
|--|--|

For more information on configuring node roles using TSM commands, see `tsm topology set-node-role`.

### License requirements

To configure a node to run extract queries you must have a valid Advanced Management license activated on your Tableau Server.

## How to see node roles

Use the following command to see what node roles are currently configured on Tableau Server:

```
tsm topology list-nodes -v
```

## Who can do this

Tableau Server Administrators can configure node roles and activate any required product keys.

## Tableau Server Independent Gateway

This topic provides an overview of Tableau Server Independent Gateway.

Independent Gateway is a reverse proxy server and load balancer based on Apache httpd. It uses the same Apache httpd version as the Tableau Server Gateway process internal to Tableau Server cluster, but it is suitable for deployment in a network DMZ. Because Independent Gateway is a part of Tableau Server, it is managed by TSM and does not need separate configuration.

Its configuration has full knowledge of the topology of externally accessible Tableau Server components, and is updated when the cluster topology changes. After a simple Independent

Gateway installation process, configuration choices are made centrally using Tableau Services Manager (TSM) configuration items.

With this feature, Tableau Server can now be configured in two ways:

- Install Tableau Server in a self-contained installation. Any reverse proxy needs to be installed and managed separately.
- Install Tableau Server and install Independent Gateway as a reverse proxy that is managed by Tableau Server (version 2022.1 and later).

## Why use Independent Gateway?

Using Independent Gateway has the following benefits over installing a separate reverse proxy:

- **Fully supported:** The Independent Gateway is part of a Tableau Server installation, and is fully supported by Tableau.
- **Tableau Server aware:** When you use a separate reverse proxy, it needs to be updated when the topology of Tableau Server changes. Independent Gateway is fully aware of all externally-callable Tableau Server components, and is updated when these change.

## Managing Independent Gateway

### License Management

To use Independent Gateway you must first enable this feature using Advanced Management product keys in Tableau Server. There is no licensing done on the Independent Gateway node. For more information, see [About Tableau Advanced Management on Tableau Server](#).

If you don't have an Advanced Management key activated or if the license is expired, you will see the following behavior:

- If you try to configure Tableau Server with Independent Gateway it will fail.
- If you are already using Independent Gateway, and the Advanced Management license expires, the server will fail on restart.

### Backup and Restore

There is no impact to backup or restore with Independent Gateway. A backup or restore of Tableau Server will not include any information or configuration for Independent Gateway. If you use the backup to create a new installation of Tableau, you will need to separately install, configure, and enable Independent Gateway for the new Tableau Server installation.

### High Availability Considerations

You can install multiple instances of Independent Gateway to provide robust high availability in your reverse proxy. You might also want to increase the number of Independent Gateway nodes if you have large numbers of client sessions accessing Tableau.

## Topology

When you configure Tableau Server with Independent Gateway, you no longer need to set up and configure a separate reverse proxy. Independent Gateway will appear on the TSM status page as an external service.

**Note:** The status page and the status output on the CLI will only show a single instance of Independent Gateway, even if you have installed multiple Independent Gateway nodes.

## Next

Install Tableau Server with Independent Gateway

## Install Tableau Server with Independent Gateway

This topic walks you through the process of installing Tableau Server Independent Gateway.

Following this process will result in a Independent Gateway configuration with a direct connection to the backend Tableau Sever deployment. You can learn more about *direct vs relay* connection modes in the topic, [Configure Tableau Server with Independent Gateway](#).

## Prerequisites

- You must have a dedicated server with at least 2 cores (4 vCPUs), 8 GB of RAM, and 100 GB free disk space.
- You must use Tableau Server 2022.1 or later.
- You must use an installer for Tableau Server Independent Gateway with a major version (**2022.1** for example) that matches the version of Tableau Server. We recommend maintenance versions (2022.1.1 or 2022.1.5 for example) match as well, but this is not a requirement. If "static assets" change between versions and versions do not match, you may see some unexpected image impact. For example, maps may not be up-to-date if Independent Gateway is an earlier version than Tableau Server.
- You must have a valid Advanced Management license activated in Tableau Server. To learn more about Advanced Management, see [About Tableau Advanced Management on Tableau Server](#).
- By default, the Independent Gateway must be able to communicate with the backend Tableau Server deployment on ports 80 and 21319 during installation. You can change these default ports during initialization as described later in this topic.
- Verify that your Tableau Server deployment is complete and healthy before installing and configuring Independent Gateway.
- Verify that you are not running any other web-aware applications on the computer where you are installing Independent Gateway. For example if Apache httpd is installed on the computer, uninstall it, or configure `httpd` so that it is not actively listening on port 80.

## Install Tableau Server and Independent Gateway

Installing Independent Gateway is done using a standalone installation package that includes "tsig" as part of the file name to distinguish it from the full Tableau Server installer. We strongly recommend you install Independent Gateway after installing Tableau Server and confirming that it is functioning as expected. To install you must be the root user (or be able to sudo to root). You can install one or more instances of Independent Gateway, but each instance of Independent Gateway must be installed separately. If you are installing multiple instances for high availability or to distribute a heavy client load, repeat the installation steps for each instance.

After installation, you are prompted to run a script called `initialize-tsig` to complete the installation. The script takes information you provide using parameters, and configures

## Tableau Server on Linux Administrator Guide

Independent Gateway. Once Independent Gateway is fully installed, you need to run a TSM command on the initial Tableau Server node to configure the server with details about the instance of Independent Gateway.

The IG installation consists of these steps:

- Run the platform-specific installer.
- Run the post-install script.
- Enable the Independent Gateway instance using TSM.

### Step 1: Download and install Tableau Server

1. **Install and Initialize TSM:** Follow the instructions provided in this topic and complete steps 1-5 which runs the setup program and installs TSM.
2. **Activate and Register Tableau Server:** Provide the Tableau Server Key and the Advanced Management key in the activate step. You will need to run the following command twice, first with the Tableau Server product key and then with the Advanced Management product key:  

```
tsm licenses activate -k <product key>
```
3. **Configure Initial Node Settings:** Follow the instructions provided in the topic to configure the initial node settings.

### Step 2: Download and install Independent Gateway

Install Tableau Server Independent Gateway with your distribution's package manager, then run a script to initialize Independent Gateway. The script is included with the installed package.

Independent Gateway is installed in the `/opt` directory.

1. Log on as a user with `sudo` access to the computer where you want to install Independent Gateway.

**Note:** To avoid possible complications, we recommend a user account that does not include any special characters (for example, non-ASCII, "+", "-"). These may cause problems, including a failure to fully install Independent Gateway, depending on how your environment is configured.

2. Download the `.rpm` or `.deb` installer package from the [Tableau Server Downloads and Release Notes](#) page.
3. Navigate to the directory where you copied the `.rpm` or `.deb` package.
4. Use the package manager to install the Independent Gateway package.

Do not install to a location using a symbolic link or to a directory on a Network File System (NFS) volume. Run the following commands to install Independent Gateway, where `<version>` is formatted as major-minor-maintenance (example: 2022-1-0).

- On RHEL-like distributions, including CentOS:

```
sudo yum update

sudo yum install tableau-tsig-<version>.x86_64.rpm
```

- On Ubuntu:

```
sudo apt-get update
sudo apt-get upgrade
sudo apt-get -y install gdebi-core
sudo gdebi -n tableau-tsig-<version>_amd64.deb
```

## Initialize Tableau Server Independent Gateway

The next step is to run the `initialize-tsig` script.

1. Navigate to the `scripts` directory:

```
cd /opt/tableau/tableau_tsig/packages/scripts.<version_code>/
```

2. Run the following script to initialize and start Independent Gateway:

```
sudo ./initialize-tsig --accepteula -c <ts_cluster_location> --  
<optional_parameters>
```

The only required parameters for the `initialize-tsig` script are `--accepteula` and `-c`.

- **--accepteula** - You must include this parameter to accept the Tableau End User License Agreement (EULA). A link to the EULA is available in the following location:

```
/opt/tableau/tableau_tsig/packages/docs.<version_code>/
```

- **-c** - You must include this parameter to specify the network location of all the nodes in the Tableau Server cluster. These nodes may be sending "housekeeping" requests to the Independent Gateway. Wild cards and subnet masks can be used to specify multiple nodes. To specify multiple addresses, separate addresses by spaces and use quotes around the complete set. Values must be provided in one of the forms acceptable to the Apache `httpd mod_authz_host` "Require" directive. For more information, see [https://httpd.apache.org/docs/2.4/mod/mod\\_authz\\_host.html](https://httpd.apache.org/docs/2.4/mod/mod_authz_host.html).

All other parameters, for example default ports used by HTTP and the housekeeping process, are optional and if left off will be given default values. Review the parameters and their default values before running the script: Help Output for `initialize-tsig` Script.

### Step 3: Enable Independent Gateway in Tableau Server

The last step of installing and configuring Independent Gateway is to enable Independent Gateway in Tableau Server. To do this, use the TSM command `tsm topology external-services gateway enable -c <file>` with a JSON file that identifies the Independent Gateway instance or instances, and provides Tableau Server with the details necessary for communication between the server and the Independent Gateway.

Tableau Server must be in a stopped state to enable Independent Gateway.

## The Independent Gateway JSON file contents

The JSON file that you use to enable the instances of Independent Gateway on Tableau Server needs to contain the following:

- **id**—The id value must match the `tsig_instance_id` for the particular instance. If you did not provide this, the default is the fully qualified domain name of the Independent Gateway computer, in lowercase. The value in the json file must match the output of the `hostname` command.
- **host**—The host value must be a DNS-resolvable name for the Independent Gateway computer that can be resolved by the Tableau Server nodes using DNS.
- **port**—The port must match the housekeeping port (`tsig_housekeeping_port`) specified on the Independent Gateway instance. If you did not provide this during initialization, the default is "21319".
- **protocol**—The protocol must be the same as the housekeeping protocol (`tsig_housekeeping_port_protocol`) specified on the Independent Gateway instance. If you did not provide this during initialization, the default is "http".
- **authsecret**—The authsecret must match the secret created by the initialization script on the Independent Gateway instance.

## The Independent Gateway auth secret

The initialization script creates a unique, shared secret on each Independent Gateway computer. You need this secret to enable Independent Gateway in Tableau Server. Copy the secret and include it in your JSON file as the "authsecret".

The shared secret is located in the `tsighk-auth.conf` file here:

```
/var/opt/tableau/tableau_tsig/config/tsighk-auth.conf
```

## Independent Gateway JSON file example

The JSON file should be in the format below. This example JSON file shows default values where there are defaults. Your file should have use the actual values that match your installation of Independent Gateway and your organization.

```
{
  "independentGateways": [
```

## Tableau Server on Linux Administrator Guide

```
{
  "id": "<mycomputer.example.com>",
  "host": "<DNS name of Independent Gateway computer>",
  "port": "21319",
  "protocol": "http",
  "authsecret": "<shared-secret01>"
},
{
  "id": "<mycomputer2.example.com>",
  "host": "<DNS name of second Independent Gateway computer>",
  "port": "21319",
  "protocol": "http",
  "authsecret": "<shared-secret02>"
}
]
```

### Enabling Independent Gateway in Tableau Server

To complete the installation of Independent Gateway , you need to enable it using TSM.

1. Copy the JSON configuration file to the initial node of Tableau Server.
2. On the initial node, open a command prompt using an account that is a member of the `tsmadmin` group.
3. Run the following commands to stop Tableau Server, enable Independent Gateway using the json configuration file, and restart the server:

```
tsm stop
tsm topology external-services gateway enable -c tsig.json
tsm start
```

### Step 4: Verify Independent Gateway in Tableau Server

You should be able to navigate to the Tableau Server sign-in page by entering the address of the Independent Gateway in a browser.

If there is a firewall between the Independent Gateway and the backend Tableau Server deployment, then you will need to open the ports for the Tableau Server processes for direct connection. See [Direct connection](#) for more information.

Alternatively, you may choose to minimize port requirements by configuring Independent Gateway for a relay connection. See [Relay connection](#) for more information.

## Configure Tableau Server with Independent Gateway

This topic describes how to configure Tableau Server with Independent Gateway for different connection scenarios and for a custom authentication module.

For installation procedure, see [Install Tableau Server with Independent Gateway](#).

For an end-to-end deployment example running on Tableau Server for Linux in AWS, see [Configuring Web Tier](#) in the Enterprise Deployment Guide.

### Direct vs relay connection

The Independent Gateway can communicate directly with the back-end Tableau Server processes over multiple ports. We refer to this communication as *direct* connection.

Alternatively, you can configure Independent Gateway to relay client communication over a single port to the gateway process on Tableau Server. We refer to this as a *relay* connection.

The TSM configuration key that sets the connection type is `gateway.tsig.proxy_tls_optional`.

The following sections describe how these connections differ and how to set them.

### Direct connection

In this configuration, the Independent Gateway communicates directly with the backend processes on Tableau Server over multiple ports. This requires that you open the ports between the firewall that separates Independent Gateway from the Tableau Server back end deployment.

The current implementation of Independent Gateway does not support TLS connections on these processes.

A direct connection allows Independent Gateway to communicate with the backend Tableau Server processes without proxying through the Gateway process. Direct connection provides better performance than the alternative relay connection.

### Configuration

Direct connection is the default configuration. As such you do not need to run a command to set it. However, should you need to reset to the default direct connection, run the following commands:

```
tsm configuration set -k gateway.tsig.proxy_tls_optional -v all --  
force-keys  
tsm pending-changes apply
```

### Manage port ingress

After installation, Independent Gateway must be able to communicate with Tableau Server over multiple ports. These ports are dynamically assigned during setup and are in the range, TCP 8000-9000. The specific ports and corresponding processes used to communicate to Tableau Server are written to a CSV file on the computer running Independent Gateway at `TSIG_DATA/config/httpd/proxy_targets.csv`.

**In a default installation:** `/var/opt/tableau/tableau_tsig/config/httpd/proxy_targets.csv`.

Use `proxy_targets.csv` to set or automate port ingress configuration through your network to Tableau Server. We recommend automating port ingress configuration since the ports may change if the topology Tableau Server deployment changes. Adding nodes or reconfiguring processes on the Tableau Server deployment will trigger changes to the port access required by Independent Gateway.

## Relay connection

In a relay connection configuration, the Independent Gateway does not connect directly to the backend processes. Instead, the Independent Gateway relays communication to the Gateway process on the backend Tableau Server deployment over HTTP. This relay process results in an extra hop and therefore degrades performance as compared to the direct connection configuration.

One benefit of configuring Independent Gateway as a relay connection is to secure traffic with TLS. See [Configure TLS on Independent Gateway](#).

## Configuration

To configure Independent Gateway for relay connection to Tableau Server, run the following commands:

```
tsm configuration set -k gateway.tsig.proxy_tls_optional -v none --force-keys
tsm pending-changes apply
```

## Housekeeping protocol

Both direct and relay connections require communication with the Tableau Server housekeeping (HK) protocol. The HK process maintains configuration state between the backend Tableau Server deployment and the Independent Gateway. During installation the Tableau Server must be able to communicate with Independent Gateway over port 21319.

Housekeeping protocol communication details:

- The HK requests check Independent Gateway status and update configuration as needed. There is no customer data in these requests. The configurations do not include passwords or other secrets.
- The configuration files do contain details about the Tableau Server cluster topology so that Independent Gateway can perform reverse proxy functions. Cluster topology configuration can be considered sensitive because the configuration could provide targeting information to an attacker. Note that such configuration data would only be useful to attackers who could then access the Tableau Server cluster.

## Tableau Server on Linux Administrator Guide

- The configuration update files include a check of the hashed contents. This provides an extra layer of security to validate the integrity of the configuration files that are used to update Independent Gateway.

By default, the HK process uses TCP 21319.

Beginning with Tableau Server 2022.1.2, TLS is supported on HK connection. See [Configure TLS on Independent Gateway](#).

### Change the HK port

You can change the port used by the HK protocol as part of the Independent Gateway initialization. See [Help Output for initialize-tsig Script](#).

If you have already installed Independent Gateway, you can change the port by updating the `TSIG_HK_PORT` value in `environment.bash`.

By default, `environment.bash` is located at `/etc/opt/tableau/tableau_tsig`.

After you have updated the file you must restart `tsig-httpd`:

```
sudo su - tableau-tsig
systemctl --user restart tsig-httpd
exit
```

### Log file locations

The most useful log entries on Tableau Server are in the `tabadminagent` log file directory. However, if you are running Tableau Server in a cluster, you must look on each instance to locate the latest `tabadminagent` logs.

On the Independent Gateway, the following log files are written to the `TSIG_DATA/logs/` directory.

By default, this is at the path `/var/opt/tableau/tableau_tsig/logs`:

- `access.log`: Independent Gateway will write to `access.log` for logging that is generated by the `httpd.conf.stub` configuration. Timestamped log files (e.g. `access_date.log`) are generated by `httpd.conf` configuration.

- `error.log`
- `startup.log`

These logs are also relayed verbatim to the Tableau Server deployment and stored in sub-directories of the Cluster Controller logs directory. As such, the Independent Gateway logs are included in the ziplog file generated by `tsm maintenance ziplogs` command.

## Troubleshooting

For troubleshooting tips, see [Troubleshooting Tableau Server Independent Gateway](#) in the Enterprise Deployment Guide (EDG). The EDG provides example deployment of Tableau Server on Linux. The troubleshooting steps are useful for Windows or Linux versions of Tableau Server.

## Configure Authentication Module with Independent Gateway

A common security practice is to allow only authenticated requests to pass through the inner firewall of the DMZ servers. The Independent Gateway supports the traditional Tableau Server authentication methods, but it also includes configuration properties that allow integrating an Apache httpd loadable module for custom authentication.

For example, by configuring SAML on Tableau Server and configuring a custom authentication module, you can require all users to authenticate with your IdP at the Independent Gateway. Only those users who are authenticated will then be able to access Tableau Server, which can then authenticate and authorize user access.

For a more detailed explanation of this authentication scheme, see [Pre-authentication with an AuthN module](#) in the Enterprise Deployment Guide.

To configure the authentication module, you must complete the following steps:

1. Generate authentication module configuration files. When setup is complete, each module and its configuration directives will be treated as Include options making the included files logically part of the overall httpd configuration.
2. Copy the configuration files to each computer running Independent Gateway. All files must be copied to the same locations on each Independent Gateway computer. Each file maps to a configuration property that is managed by Tableau Server.

3. Set the configuration properties with the `tsm configuration set` command on Tableau Server.

Do not edit the `httpd` configuration file (`httpd.conf`) on the Independent Gateway, since Independent Gateway includes logic to update `httpd` configuration based on changes made with TSM commands on Tableau Server.

#### Example authentication module configuration

For an end-to-end authentication module configuration example, see [Example authentication configuration: SAML with external IdP](#) in the Enterprise Deployment Guide. The example describes how to setup and configure SAML with Okta IdP and Mellon authentication module for a Tableau Server on Linux deployment running in AWS. Although the example describes the process for Linux, the configuration example is also useful for Tableau Server on Windows.

#### Configuration properties

The following table describes the various configuration files that you may reference. Each file maps to a configuration property that is set on Tableau Server. You only need to define the properties necessary to formulate your custom authentication configuration. Skip any configuration properties that are not needed.

| Configuration property                             | Description   |
|--|---|
| <code>gateway.tsig.authn_module_block</code>       | Appears at the end of the set of normally loaded Apache <code>httpd</code> modules. The intent is that the file includes one or more <code>LoadModule</code> directives. The modules themselves should be identified with full paths. |
| <code>gateway.tsig.authn_global_block</code>       | Appears after all of the <code>LoadModule</code> references and before most other Apache <code>httpd</code> directives. The intent is to provide a place for any configuration directives needed by the custom module.                |
| <code>gateway.tsig.authn_globalbottom_block</code> | Appears at the very bottom of the configuration file, again at the global level. The intent is to provide a   |

|                                      |  |
|--------------------------------------|--|
|                                      | place for any configuration directives needed by the custom module that must specifically come after various other directives. (You are unlikely to need this.)  |
| gateway.tsig.authn_location_block    | Appears inside a <code>&lt;Location "/"&gt;</code> block, covering all URL paths.  |
| gateway.tsig.authn_directory_block   | This appears inside a <code>&lt;Directory "/"&gt;</code> block, covering all paths to files served by the Independent Gateway. (You are unlikely to need this. Most files served by Independent Gateway are non-sensitive static assets, like images and JavaScript files.)                        |
| gateway.tsig.authn_virtualhost_block | Appears inside one or two <code>&lt;VirtualHost&gt;</code> blocks: one for TLS (if enabled) and one for non-TLS. If configured, the same file is included in both places. If you need to distinguish the two cases, you can use the standard Apache <code>httpd HTTPS</code> environment variable. |

#### The `<Location "/tsighk">` block

In addition to the expected `<Location "/">` block for normal request traffic, there is also a `<Location "/tsighk">` block used to service internal Independent Gateway house-keeping (HK) requests. These HK requests have their own authentication guards and will not work with typical custom SSO solutions.

You may need to explicitly exclude your custom module from attempting authentication for the HK URL path.

To determine whether you need to exclude your module, first configure the module. Then look for HK requests in the Independent Gateway access log. You should see at least a status check once or twice a minute. If those requests are receiving a 200 response code, things are probably OK. On the other hand, if those requests receive a 3xx response code (redirecting to your custom authentication provider), then you need to do something about it.

Possible solutions include:

## Tableau Server on Linux Administrator Guide

- The `<Location "/tsighk">` block contains the directive `AuthType None`, and that may be sufficient.
- The Independent Gateway `httpd.conf` has the standard Apache `httpd` directive `ProxyPreserveHost On`. If there is an unusual circumstance that requires it to be `Off` or some other value, that value can be set with the TSM configuration item `gateway.tsig.proxypreservehost`.
- You might need some module-specific directives to disable your authentication module for `<Location "/tsighk">`. You can't directly modify that block in the `httpd.conf` file. Instead, you can make another `<Location "/tsighk">` block in your `gateway.tsig.authn_global_block` file and let Apache `httpd` logically merge them. For example, some versions of `mod_auth_mellon`, a popular open source authentication module, requires `MellonEnable Off` for sections where it doesn't apply, even if `AuthType None` is set in those sections.
- When creating an additional `<Location "/tsighk">` section, as described in the previous bullet, you may find that the order of appearance of the various sections in the `httpd.conf` file makes a difference in how they affect each other. The standard `<Location "/tsighk">` section appears before the standard `<Location "/">` section. If your experimentation shows that some different order is needed, you might have to define another `<Location "/">` section in your `gateway.tsig.authn_global_block` block in addition to another `<Location "/tsighk">` section, in which case you might not need anything in a `gateway.tsig.authn_location_block` block.

### Troubleshoot custom authentication module configuration

A handy way to understand how the Independent Gateway will compose the `httpd.conf` file is to set the TSM configuration items with values that point to empty files on your Independent Gateway computers. (The files must exist, but they can be empty.) You can then look at the Independent Gateway's `httpd.conf` file to get a concrete understanding of where the `Include` directives for the various configuration files will actually appear.

Configuration problems in the Independent Gateway `httpd.conf` can result in the `tsig-httpd` service being unable to start. Other configuration problems may interfere with receiving configuration updates from the Independent Gateway companion service on the Tableau Server cluster. One way to recover, after you've fixed whatever caused the problem, is to copy `TSIG_DATA/config/httpd.conf.stub` to `TSIG_DATA/config/httpd.conf`, and then restart the `tsig-httpd` service.

For more troubleshooting tips, see [Troubleshooting Tableau Server Independent Gateway](#) in the Enterprise Deployment Guide (EDG). The EDG provides example deployment of Tableau Server on Linux. The troubleshooting steps are useful for Windows or Linux versions of Tableau Server.

### Configure TLS on Independent Gateway

TLS support for Independent Gateway is in Tableau Server 2022.1.2 and later.

Both Tableau Server and Tableau Server Independent Gateway use the SSL module (`mod_ssl`) built with OpenSSL to implement Transport Layer Security (TLS) features.

Because of its complexity and security-sensitive nature, we recommend that TLS configuration is planned and implemented by an IT professional who is familiar TLS on Apache `httpd`.

In many cases, we use "SSL" in the names of things for compatibility with existing TSM or Apache `httpd` configuration properties or concepts. "SSL" actually refers to protocol versions now considered insecure and obsolete. However, the legacy name persists and is often used interchangeably with TLS as convention. Tableau Server and Independent Gateway do not support SSL-era protocols.

### TLS configuration example

For an end-to-end TLS configuration example, see [Configure SSL/TLS from load balancer to Tableau Server](#) in the Enterprise Deployment Guide. The topic shows a step-by-step example of configuring TLS on Tableau Server on Linux in an AWS deployment. Although the example describes the process for Linux, the configuration example is also useful for Tableau Server on Windows.

### TLS configuration overview

You can configure TLS for HTTPS on any of the following sections of the internet-to-Tableau Server path:

- From the external network (internet or front-end load balancer) to Independent Gateway

- From Independent Gateway to Tableau Server
- For housekeeping (HK) process from Tableau Server to Independent Gateway

This topic provides procedures to configure each of these hops.

You will need to make configuration changes to Independent Gateway computers and to the Tableau Server cluster.

## Certificate requirements and considerations

The certificate requirements for Independent Gateway are the same as those specified for Tableau Server "external SSL." See [SSL certificate requirements](#).

Other considerations:

- To simplify certificate management and deployment, and as a security best practice, we recommend using certificates generated by a major trusted third party certificate authority (CA). Alternatively, you may generate self-signed certificates or use certificates from a PKI for TLS. In this case, pay attention to the configuration options for trusting CA certificates and validating certificates.
- If your implementation requires the use of a certificate chain file, see the Knowledge Base article, [Configure TLS on Independent Gateway when using a certificate that has a certificate chain](#).
- If you are running multiple instances of Independent Gateway, then you must distribute certificates to each computer in the same location (file path).
- If you are running a Tableau Server deployment with more than one node, certificates that you upload with TSM commands are automatically distributed across the nodes. Run all TSM commands on the initial node.

### Global TLS configurations

The following configurations are global. The configuration options below refer to configuration keys that must set with the `tsm configuration set` command. The commands must include the `--force-keys` option.

It's unlikely that you will need to change these values.

Note that each pair of keys shares the same naming format, where the string, `tsig`, sets the value for the Independent Gateway. The key that does *not* include the string, `tsig`, sets the value for the gateway process on the Tableau Server cluster.

If you do not set a value for the `tsig` key, then the default Tableau Server gateway value will be used.

`gateway.tsig.httpd.socache` or `gateway.httpd.socache`

**Default:** `shmcb`

**Alternate value:** `dbm`

The storage type of the inter-process SSL Session Cache. For more information about the `shmcb` and `dbm` storage types, see [SSLSessionCache Directive](#) on Apache website.

`gateway.tsig.httpd.shmcb.size` or `gateway.httpd.shmcb.size`

**Default:** `2048000`

Amount of memory, in bytes, to use for the circular buffer when using `shmcb` storage type.

**Note:** Another global key is `gateway.tsig.ssl.key.passphrase.dialog`. If applicable, there is only a single configuration for `gateway.tsig.ssl.key.passphrase.dialog`. By design, it collects passphrases for all encrypted private key files in the configuration. The applicable sections later in this topic describe the use of this key.

### External TLS to Independent Gateway

The process of configuring external connections to terminate TLS on the Independent Gateway servers is conceptually similar to how "external SSL" is configured for a Tableau Server cluster. The mechanics are different. TSM does not automatically distribute certificate and

key material to Independent Gateway nodes. Additionally, Independent Gateway does not automatically provide a way to supply the optional TLS key passphrase on startup.

The following steps describe how to configure TLS from external source to Independent Gateway computers.

## Step 1: Distribute files to Independent Gateway computers

1. Place certificates and related files in a location and with permissions that allow the Independent Gateway service (tsg-httpd) to read them. We recommend restricting access to the key files such that only the Independent Gateway service can read them.
2. Place all files, certificates, and keys in exactly the same locations on all Independent Gateway computers. Place the files outside of the `TSIG_INSTALL` and `TSIG_DATA` paths so that they do not get removed if you reinstall or upgrade Independent Gateway.

## Step 2: Update environment variables on Independent Gateway computers

On each Independent Gateway computer, set the `TSIG_PORT` and `TSIG_PROTOCOL` environment variables to `443` (by convention, but any unused TCP port number is supported) and `https` respectively.

Change these values by updating the `TSIG_PORT` and `TSIG_PROTOCOL` environment variables in `environment.bash`.

By default, `environment.bash` is located at `/etc/opt/tableau/tableau_tsig`.

After you have updated the file you must restart `tsg-httpd`:

```
sudo su - tableau-tsig
systemctl --user restart tsg-httpd
exit
```

## Step 3: Set TLS configuration properties on Tableau Server

Most of the TSM configuration keys in the following table are derived from Apache httpd directives. As such, the configuration values for these TSM configuration keys map directly to the valid values for the corresponding Apache directive. Links to corresponding directives are included in the following table.

In some cases, the configuration will use fallback configurations if a particular key is not set. These are called out in the table below.

The configuration options in the following table refer to configuration keys that you must set with the `tsm configuration set` command. All commands must include the `--force-keys` option. For example:

```
tsm configuration set -k gateway.tsig.ssl.enabled -v true --force-keys
```

After you have set the configuration keys, you must run `tsm pending-changes apply`.

| Configuration property                       | Description  | Corresponding Apache directive        |
|--|--|---------------------------------------|
| <code>gateway.tsig.ssl.enabled</code>        | Required.<br><br>Enables TLS. Must be set to <code>true</code> .   | N/A                                   |
| <code>gateway.tsig.ssl.cert.file_name</code> | Required.<br><br>Path + file name of the certificate file for Independent Gateway. For example, <code>/etc/ssl/certs/tsig-ssl.crt</code> . | <a href="#">SSLCertificateFile</a>    |
| <code>gateway.tsig.ssl.key.file_name</code>  | Required.  | <a href="#">SSLCertificateKeyFile</a> |

|   |   |  |
|---|---|--|
|   | <p>Path + file name of the certificate key file for Independent Gateway. For example, <code>/etc/ssl/keys/tsig-ssl.key</code>.</p>  |  |
| <p>gateway.tsig.ssl.key.passphrase.dialog</p>                                     | <p>If your key requires a passphrase, then you must configure this key with the correct string expected by the Apache httpd <code>SSLPassPhraseDialog</code> directive. Do not enter the literal passphrase for this key. Refer to the Apache documentation for information about how to configure this key.</p> <p>This configuration is global for Independent Gateway.</p> | <p><a href="#">SSLPassPhraseDialog</a></p> |
| <p>gateway.tsig.ssl.protocols</p> <p>Fallback: <code>ssl.protocols</code></p>     | <p>Specify supported versions of SSL/TLS. See Security Hardening Checklist for more information about default configuration.</p>  | <p><a href="#">SSLProtocols</a></p>        |
| <p>gateway.tsig.ssl.ciphersuite</p> <p>Fallback: <code>ssl.ciphersuite</code></p> | <p>Specifies ciphers that the client is permitted to negotiate for SSL connection.</p>  | <p><a href="#">SSLCipherSuite</a></p>      |
| <p>gateway.tsig.ssl.client_certificate_login.required</p>                         | <p>Set this value to <code>true</code> to enable mutual TLS on this connection.</p> <p>You must also set the <code>gateway.tsig.ssl.cacert.file</code></p>  | <p>N/A</p>                                 |

|                                     |   |                      |
|-------------------------------------|---|----------------------|
|                                     | property as specified below.  |                      |
| gateway.tsig.ssl.cacert.file        | Specifies the file containing the concatenated CA certificates for client authentication process.   | SSLCACertificateFile |
| gateway.tsig.ssl.revocation.file    | Specifies the file containing the concatenated CA revocation lists for clients that connect to Independent Gateway.                                       | SSLCARevocationFile  |
| gateway.tsig.ssl.redirect           | When Independent Gateway has been configured for TLS, this option forces client requests from port 80 (default) to redirect to TLS.<br><br>Default: true. | N/A                  |
| gateway.tsig.ssl.redirect_from_port | When gateway.tsig.ssl.redirect is set to true, this option allows you to specify the port from which traffic is redirected.<br><br>Default: 80.           | N/A                  |

### Independent Gateway to Tableau Server

This section describes how to encrypt the connection between the Independent Gateway and Tableau Server.

## Step 1: Configure and enable TLS on Tableau Server

See Configure SSL for External HTTP Traffic to and from Tableau Server.

Note that "SSL" is actually a TLS implementation, and "external" refers to an external connection to Tableau Server. In this scenario, the Independent Gateway is the "external" connection.

We recommend enabling and verifying that clients can connect with TLS directly to Tableau Server before configuring Independent Gateway.

## Step 2: Distribute certificate files on Independent Gateway computers

You will need to distribute certificate files on the Independent Gateway computers if either of the following are true:

- You are using self-signed or PKI certificates for the TLS certificates on the Tableau Server deployment.
- You are enabling mutual TLS on the connection from Independent Gateway to Tableau Server.

As with all TLS-related files on Independent Gateway computers, you must put the files in the same paths on each computer. All file names for TLS shared files must also be the same.

## Step 3: Set TLS configuration properties on Tableau Server

Most of the TSM configuration keys in the following table are derived from Apache httpd directives. As such, the configuration values for these TSM configuration keys map directly to the valid values for the corresponding Apache directive. Links to corresponding directives are included in the following table.

In some cases, the configuration will use fallback configurations if a particular key is not set. These are called out in the table below.

The configuration options in the following table refer to configuration keys that you must set with the `tsm configuration set` command. All commands must include the `--force-keys` option. For example:

```
tsm configuration set -k gateway.tsig.ssl.enabled -v true --force-keys
```

After you have set the configuration keys, you must run `tsm pending-changes apply`.

| Configuration property                                      | Description   | Corresponding Apache directive            |
|---|---|---|
| gateway.tsig.ssl.proxy.certificatefile                      | If your organization uses a self-signed or PKI-generated TLS certificate for Tableau Server, then you must specify a path to the root CA certificate file. This root CA certificate file must be stored on the Independent Gateway computers. | <a href="#">SSLProxyCACertificateFile</a> |
| gateway.tsig.ssl.proxy.protocols<br>Fallback: ssl.protocols | Specify supported versions of SSL/TLS. See Security Hardening Checklist for more information about default configuration.   | <a href="#">SSLProtocols</a>              |

|  |  |                                       |
|--|--|---------------------------------------|
| <p>gateway.tsig.ssl.proxy.ciphersuite</p> <p>Fallback: ssl.ciphersuite</p> | <p>Specifies ciphers that the client is permitted to negotiate for SSL connection.</p>   | <p>SSLCipherSuite</p>                 |
| <p>gateway.tsig.ssl.proxy.machinecertificatefile</p>                       | <p>For mutual TLS. Specifies the file containing concatenated certificate-key pairs for authentication of the Independent Gateway to Tableau Server.</p> | <p>SSLProxyMachineCertificateFile</p> |
| <p>gateway.tsig.ssl.proxy.verify</p>                                       | <p>Specify whether Independent Gateway should verify the certificate presented by Tableau Server.</p> <p>Defaults to require.</p>                        | <p>SSLProxyVerify</p>                 |

|  |  |   |
|--|--|---|
| gateway.tsig.ssl.proxy.checkpeername   | Specify whether Independent Gateway inspects Tableau Server certificate to verify that subject name matches server name.<br><br>Defaults to <code>off</code> . | <a href="#">SSLProxyCheckPeerName</a>   |
| gateway.tsig.ssl.proxy.checkpeerexpire | Specify whether Independent Gateway inspects Tableau Server certificate to verify expiry:<br><br>Defaults to <code>off</code> .                                | <a href="#">SSLProxyCheckPeerExpire</a> |

## Step 4: Upload root CA certificate to Tableau Server

If the TLS certificate that you are using on the Independent Gateway computers is a self-signed or PKI-generated certificate then you must perform this additional step. If the TLS certificate that you are using on the Independent Gateway computer is a certificate from a trusted third-party certificate authority, then you can skip this step.

Copy the root CA certificate used for the Independent Gateway computers to the initial node of Tableau Sever, and then run the following commands:

```
tsm security custom-cert add -c <root-certificate-file-name>.pem  
tsm pending-changes apply
```

### Housekeeping connection between Tableau Server and Independent Gateway

The housekeeping (HK) process maintains configuration state between the backend Tableau Server deployment and the Independent Gateway.

When Independent Gateway is installed, the default configuration provides an unencrypted HTTP connection. Independent Gateway listens for housekeeping requests originating in the Tableau Server cluster (as you defined it during installation).

If you are running multiple instances of Independent Gateway, then all servers must accept housekeeping requests with TLS or all without TLS. This section describes how to configure HK connection for TLS. This process requires restarting Tableau Server and will result in downtime.

As with the previous TLS scenarios described above, many of the configuration changes for HK connection are set on configuration properties managed by the Tableau Server cluster. However, HK TLS configuration requires additional steps on Independent Gateway.

## Step 1: Distribute files to Independent Gateway computers

If you have enabled TLS with external network and Independent Gateway, you may use the same certificate and key files for the HK connection.

If you are using the same assets, then the only other certificate file that you need to distribute is the root CA certificate for the certificate used by Tableau Server. If the TLS certificate presented by Tableau Server is generated by a trusted third-party CA, then you do not need to copy a root CA certificate to the Independent Gateway computers.

1. Place certificates and related files in a location and with permissions that allow the Independent Gateway service (tsig-httpd) to read them. We recommend restricting access to the key files such that only the Independent Gateway service can read them.

2. Place all files, certificates, and keys in exactly the same locations on all Independent Gateway computers.

## Step 2: Import Independent Gateway root CA certificate into Tableau Server trust store

If the TLS certificate that you are using on the Independent Gateway computers is a self-signed or PKI-generated certificate then you must perform this additional step. If the TLS certificate that you are using on the Independent Gateway computer is a certificate from a trusted third-party certificate authority, then you can skip this step.

You may only upload one root CA certificate to Tableau Server. Therefore, if you have already uploaded a root CA certificate, then the same root CA certificate must sign the certificate that you will be using for HK connection.

Copy the root CA certificate used for the Independent Gateway computers to the initial node of Tableau Server, and then run the following commands:

```
tsm security custom-cert add -c <root-certificate-file-name>.pem
tsm pending-changes apply
```

## Step 3: Update environment variables on Independent Gateway computers

On each Independent Gateway computer, set the `TSIG_HK_PROTOCOL` environmental variable to `https`. You may specify an alternative port for HK (default is 21319) by setting the `TSIG_HK_PORT` environment variable as well.

Change these values by updating the `TSIG_HK_PORT` and `TSIG_HK_PROTOCOL` environment variables in `environment.bash`.

By default, `environment.bash` is located at `/etc/opt/tableau/tableau_tsig`.

After you have updated the file you must restart `tsig-httpd`:

## Tableau Server on Linux Administrator Guide

```
sudo su - tableau-tsig
systemctl --user restart tsig-httpd
exit
```

### Step 4: Update httpd.conf.stub on Independent Gateway

You must update the `httpd.conf.stub` file on each Independent Gateway server. The `httpd.conf.stub` file is used to seed the global `httpd` configuration.

The file is located at `TSIG_DATA/config/httpd.conf.stub`.

In a default installation: `/var/opt/tableau/tableau_tsig/-config/httpd.conf.stub`.

1. Open the `httpd.conf.stub` file in a text editor. You must update the `<VirtualHost *:${TSIG_HK_PORT}>` block with HK configuration details. The following example shows the required changes:

```
<VirtualHost *:${TSIG_HK_PORT}>
  SSLEngine on
  #TLS# SSLHonorCipherOrder on
  #TLS# SSLCompression off
  SSLCertificateFile /etc/ssl/certs/tsig-ssl.crt
  SSLCertificateKeyFile /etc/ssl/private/tsig-ssl.key
  SSLCACertificateFile /etc/ssl/certs/rootTS-CACert.pem
  #TLS# SSLCARevocationFile /path/to/file
</VirtualHost>
```

#### Notes:

- By default, each line in the `<VirtualHost *:${TSIG_HK_PORT}>` block is commented out by the string, `#TLS#`. To "enable" a line in the block, delete the `#TLS#` string at the beginning of the line.
- As with all `httpd` configurations, each referenced file requires an absolute path to the file.
- `SSLCACertificateFile` specifies the root CA certificate for the CA that generates the certificate presented by Tableau Server. You only need to set this if the TLS certificate used by Tableau Server is self-signed or generated by a PKI.

2. Stop the `tsig-httpd` service.

```
sudo su - tableau-tsig
systemctl --user stop tsig-httpd
exit
```

You will start receiving failed status checks at this point, indicating in TSM that your Independent Gateway component is degraded.

3. Copy `httpd.conf.stub` to `httpd.conf`.

The `httpd.conf` file is in the same directory. Overwrite the `httpd.conf` file with the `httpd.conf.stub` file.

```
cp httpd.conf.stub httpd.conf
```

4. Start the `tsig-httpd` service.

```
sudo su - tableau-tsig
systemctl --user start tsig-httpd
exit
```

You will continue receiving failed status checks at this point, indicating in TSM that your Independent Gateway component is degraded. These status checks will fail until you have completed the configuration as described in the following steps.

## Step 5: Set TLS configuration properties on Tableau Server

Applying the configuration changes requires a restart of the server. To avoid long timeout times, we recommend stopping the server before applying changes that you set here. In Step 6, you will run an update command and then restart TSM. Stopping TSM at this phase of the configuration results in a shorter downtime.

1. Stop TSM. Run the following command:

```
tsm stop
```

- Most of the TSM configuration keys in the following table are derived from Apache httpd directives. As such, the configuration values for these TSM configuration keys map directly to the valid values for the corresponding Apache directive. Links to corresponding directives are included in the following table.

There are TSM configuration property names that include the `hk` node in the prefix: `gateway.tsig.hk.xyz.abc`. If set, these values are used for the HK TLS configuration. If not set, many configuration properties will use the fallback to `gateway.tsig.xyz.abc`, which themselves may or may not fall back to `gateway.xyz.abc`. The fallback configuration property is listed when relevant.

The configuration options in the following table refer to configuration keys that you must set with the `tsm configuration set` command. All commands must include the `--force-keys` option. For example:

```
tsm configuration set -k gateway.tsig.hk.ssl.enabled -v true --force-keys
```

| Configuration property   | Description   | Corresponding Apache directive        |
|--|---|---------------------------------------|
| <code>gateway.tsig.hk.ssl.enabled</code><br><br>(No fallback)  | Required.<br><br>Enables TLS. Must be set to <code>true</code> .  | N/A                                   |
| <code>gateway.tsig.hk.ssl.cert.file_name</code><br><br>Fallback:<br><br><code>gateway.tsig.ssl.cert.file_name</code> | Path + file name of the certificate file for Independent Gateway. For example, <code>/etc/ssl/certs/tsig-ssl.crt</code> . | <a href="#">SSLCertificateFile</a>    |
| <code>gateway.tsig.hk.ssl.key.file_name</code>   | Path + file name of the certificate key file for Independent  | <a href="#">SSLCertificateKeyFile</a> |

|   |  |  |
|---|--|--|
| <p>Fallback:</p> <p>gateway.tsig.ssl.key.file_name</p>  | <p>Gateway. For example, <code>/etc/ssl/keys/tsig-ssl.key</code>.</p>  |  |
| <p>gateway.tsig.ssl.key.passphrase.dialog</p> <p>(Global property)</p>  | <p>If your key requires a passphrase, then you must configure this key with the correct string expected by the Apache httpd <code>SSLPassPhraseDialog</code> directive.</p> <p>This configuration is global for Independent Gateway.</p> | <p><a href="#">SSLPassPhraseDialog</a></p> |
| <p>gateway.tsig.hk.ssl.protocols</p> <p>Fallbacks:</p> <p>gateway.tsig.ssl.protocols</p> <p>ssl.protocols</p>       | <p>Specify supported versions of SSL/TLS. See Security Hardening Checklist for more information about default configuration.</p>   | <p><a href="#">SSLProtocols</a></p>        |

| gate-<br>way.tsig.hk.ssl.revocation.file<br><br>Fallback:<br><br>gate-<br>way.tsig.hk.ssl.revocation.file | Specifies the file containing the concatenated CA revocation lists for clients that connect to Independent Gateway. | <b>SSLCARevocationFile</b>  |

3. Apply changes. Run the following command:

```
tsm pending-changes apply.
```

## Step 6 Update Independent Gateway JSON configuration file

The final step is to update the Independent Gateway configuration with a JSON file reflecting the switch to `https` and, if applicable, other port numbers.

Refer to the installation topic for more information about editing this file. See Step 3: Enable Independent Gateway in Tableau Server.

After you have updated the JSON file, run the following commands:

```
tsm topology external-services gateway update -c tsig.json
tsm start
```

### Troubleshooting

For troubleshooting tips, see [Troubleshooting Tableau Server Independent Gateway](#) in the Enterprise Deployment Guide (EDG). The EDG provides example deployment of Tableau

Server on Linux. The troubleshooting steps are useful for Windows or Linux versions of Tableau Server.

## Upgrade Tableau Server Independent Gateway

This topic walks you through the process of upgrading Tableau Server Independent Gateway. The process described in this topic is the same for all version upgrades. This means you can use this process for major version (for example, 2022.1 to 2023.1) and maintenance version (2022.1.1 to 2023.1.1) upgrades.

You must use an installer for Tableau Server Independent Gateway with a major version that matches the version of Tableau Server. We recommend maintenance versions (2022.1.1 or 2022.1.2 for example) match as well, but this is not a requirement. If "static assets" change between versions and versions do not match, you may see some unexpected image impact. For example, maps may not be up-to-date if Independent Gateway is an earlier version than Tableau Server.-

### Overview

The upgrade process for Independent Gateway is actually a process of uninstalling then reinstalling the software. However, you can minimize configuration and overall downtime by following the process as described in this topic.

The process described in this topic assumes that you have a functional deployment of Tableau Server and Tableau Server Independent Gateway running. If you are upgrading the backend Tableau Server deployment as part of your upgrade, we recommend upgrading the Independent Gateway server(s) first, validating basic connectivity with a Tableau client, then proceeding with Tableau Server upgrade.

The steps detailed in this topic are summarized here:

1. Copy some existing files for use during upgrade.
2. Run the obliterate script to remove Independent Gateway.
3. Install new version of Independent Gateway.
4. Optional: Overwrite tsighk-auth file with original copy.
5. Update TLS settings.

## Tableau Server on Linux Administrator Guide

6. Optional: Update back end Tableau Server
7. Restart Independent Gateway service.

### Step 1: Copy files for reference

You may need to reference the configuration settings stored in the following files. Copy these files to a secure and accessible location (file paths are default location):

- `/var/opt/tableau/tableau_tsig/config/tsighk-auth.conf`
- `/var/opt/tableau/tableau_tsig/config/httpd.conf.stub`
- `/etc/opt/tableau/tableau_tsig/environment.bash`

### Step 2: Obliterate Independent Gateway

To remove Independent Gateway from the server(s), run the `tableau-tsig-obliterate` script:

1. On the initial node, open a terminal session.
2. Run the `tableau-tsig-obliterate` script:

```
sudo /opt/tableau/tableau_tsig/packages/scripts.<version_
code>/tableau-tsig-obliterate -y -y -y
```

3. Restart the computer.

### Step 3: Install Independent Gateway

Download the version of Independent Gateway that you want to upgrade to and then follow the same installation procedure as described in the topic, [Install Tableau Server with Independent Gateway](#).

As with the original installation, you will need to specify initialization settings as part of set up. To use the same values, reference the `enviornment.bash` file that you copied in step 1. Do not overwrite the new bash file with the original.

**Step 4: (Optional) Overwrite tsighk-auth file with original copy**

The `tsighk-auth` file is a configuration file that stores a unique string called the `authsecret`. The `authsecret` is used to verify that the back end Tableau Server is communicating with a trusted instance of Independent Gateway. When you set up the original instance of Independent Gateway, you had to update a configuration file on the back end Tableau Server with the `authsecret`.

If your security policy allows, you can continue to use the original `authsecret` on Independent Gateway. Doing so avoids the process of updating and restarting the back end Tableau Server with a new `authsecret`.

To maintain the original `authsecret`, overwrite the `tsighk-auth.conf` file (located at `/var/opt/tableau/tableau_tsig/config/tsighk-auth.conf`) with the copy that you saved in step 1.

If your security policy requires that you refresh the `authsecret`, then make note of the new `authsecret` that was generated by the installation process. You will update the back end Tableau Server with the new `authsecret` later in the process.

**Step 5: Update housekeeping TLS settings**

If you did not configure TLS for housekeeping (HK) communication between Independent Gateway instance(s) and the back end Tableau Server deployment, then you can skip this step.

If you configured HK TLS, then you must manually copy the configuration from the original `httpd.conf.stub` file into the file located at `/var/opt/tableau/tableau_tsig/-config/httpd.conf.stub`). Do not overwrite the new file with original file, as the newer file may include other settings.

1. Update the relevant TLS configuration settings in the following block:

```
<VirtualHost *:${TSIG_HK_PORT}>
  SSLEngine on
  #TLS# SSLHonorCipherOrder on
```

## Tableau Server on Linux Administrator Guide

```
#TLS# SSLCompression off
SSLCertificateFile /etc/ssl/certs/tsig-ssl.crt
SSLCertificateKeyFile /etc/ssl/private/tsig-ssl.key
SSLCACertificateFile /etc/ssl/certs/rootTS-CACert.pem
#TLS# SSLCARevocationFile /path/to/file
</VirtualHost>
```

For more information about these settings, see [Configure TLS on Independent Gateway](#).

2. When you have finished updating `httpd.conf.stub`, save it.
3. Copy `httpd.conf.stub` and then save to overwrite `httpd.conf` in the same directory.

### Step 6: (Optional) Update back-end Tableau Server deployment

If you copied the original authsecret file (`tsighk-auth.conf`) to the new instance of Independent Gateway as described in step 4, then you may skip this step.

If you are refreshing the authsecret in the back end Tableau Server deployment, then you must update the `tsig.json` file on the initial node with the new authsecret. See [Install Tableau Server with Independent Gateway](#). When you are finished, run the following TSM commands:

```
tsm stop
tsm topology external-services gateway update -c tsig.json
tsm start
```

### Step 7: Restart the tsig-httpd service

When you have finished with the configuration, restart the `tsig-httpd` service.

```
sudo su - tableau-tsig
systemctl --user restart tsig-httpd
exit
```

## Uninstall Tableau Server Independent Gateway

This topic walks you through the process of uninstalling Tableau Server Independent Gateway.

### Uninstalling Independent Gateway

Uninstalling Independent Gateway is a two step process:

1. Disable the Independent Gateway instance in Tableau Server using TSM.

To disable Independent Gateway in Tableau Server, run this command at the command prompt of the initial Tableau Server node:

```
tsm topology external-services gateway disable
```

2. Uninstall the Independent Gateway instance you are upgrading from the computer it is running on.

To uninstall Independent Gateway from a Linux computer, run the `tableau-tsig-obliterate` script in the `/opt/tableau/tableau_tsig/packages/scripts.<version_code>` directory. This will entirely remove Independent Gateway from the computer.

```
sudo /opt/tableau/tableau_tsig/packages/scripts.<version_code>/tableau-tsig-obliterate -y -y -y
```

To uninstall an instance of Independent Gateway, remove it from the server cluster using TSM, and then, after Tableau Server is fully reconfigured, uninstall Independent Gateway from the computer where it was installed. When you use TSM to remove the instance from Tableau Server, TSM no longer sends any communication to the Independent Gateway instance, so Independent Gateway is unaware of any configuration changes. but the Independent Gateway continues to respond based on the last known configuration and Tableau Server continues to accept those responses. You also need to remove the Independent Gateway instance from the computer it is running on.

## Help Output for initialize-tsig Script

The following help content is the output when you run the following command:

```
sudo ./initialize-tsig -h
```

The initialize-tsig script is installed to `/opt/tableau/tableau_tsig/packages/scripts.<version_code>/`.

### Output

#### REQUIRED

`--accepteula` Indicate that you have accepted the End User License Agreement (EULA).

You can find a link to the EULA in `/opt/tableau/tableau_tsig/packages/docs.<version_code>`

`-c <ts_cluster_location>`

The network location of all nodes in the Tableau Server cluster. These may send

"housekeeping" requests to the TSIG node. The locations must be one of the forms

that are acceptable to Apache httpd `mod_authz_host "Require" directive` as described at [https://httpd.apache.org/docs/2.4/mod/mod\\_authz\\_host.html](https://httpd.apache.org/docs/2.4/mod/mod_authz_host.html). Use quotes if there are embedded spaces.

#### OPTIONAL

`-i <tsig_instance_id>` A unique identifier for the TSIG instance.  
Default: The computer name.

`-p <tsig_external_port>`

Port listening for external requests.  
Default: 80.

## Tableau Server on Linux Administrator Guide

- `-t <tsig_external_port_protocol>`  
Protocol used for external requests. Options are "http" or "https".  
Default: "http".
- `-k <tsig_housekeeping_port>`  
Port listening for housekeeping requests from Tableau Server.  
Default: 21319.
- `-s <tsig_housekeeping_port_protocol>`  
Protocol used for housekeeping requests. Options are "http" or "https".  
Default: "http".
- `-d data-dir`  
Set a custom location for the data directory if it's not already set. If not set, the default is "/var/opt/tableau/tableau\_tsig".
- `-f`  
Bypass warning messages and distribution version checks.
- `-g`  
Do not add the current user to the "tableau-tsig" group. Use this for easier access to log files and runtime files.
- `-a <username>`  
Name of the user to be added to the appropriate groups instead of the current user running the script. You cannot use both `-g` and `-a`.
- `-q`  
Quiet, suppress output except for errors and warnings.
- `--unprivileged-user=<name>`  
Name of the unprivileged account to run Tableau Server Independent Gateway.  
Default: "tableau-tsig".

## Tableau Server on Linux Administrator Guide

`--disable-account-creation`

Do not create groups or user accounts for Tableau Server Independent Gateway.

However, the values in: `unprivileged-user` will still be used in TSIG configuration.

## Tableau Server Backgrounder Resource Limits

Tableau Server Backgrounder resource limits feature was introduced in Tableau Server 2022.1.

### Overview and Concepts

#### What it is

The Backgrounder resource limits feature gives you the ability to manage Backgrounder resources and control how they are used. Starting in 2022.1, you can set limits on the number of background jobs that can run at the same time on a site. You can also specify the number of Backgrounder hours that a site can use to run jobs per day.

Default limits can be applied to all sites, but you can also set custom limits per site. This gives you the ability to manage the Backgrounder resources based on the specific requirements for a site.

#### When to use it

Use this feature when you want to make sure the resources are used where it is most needed. More importantly, you can prevent a single site from consuming a lot of backgrounder resources thus impacting job completion or job queue time on other sites.

If you are currently experiencing unbalanced Backgrounder resource usage or delays in background job completions, use this feature to optimize resource usage that is right for your organizational needs and content priorities.

#### Requirements and recommendations

1. This feature requires that Tableau Server be enabled with a **Advanced Management** license.
2. A new Tableau Server process called **Resource Limits Manager** is required to enforce the set resource limits. When you install or upgrade to Tableau Server 2022.1 or later, this process is automatically configured on the initial node.
  - We recommend having at least 5 Backgrounder processes in total running on Tableau Server for Backgrounder resource limits feature to run optimally. The default configuration and topology recommendations are described in detail in the Tableau Server Resource Limits Manager.
  - We do not recommend adding more Resource Limits Manager processes to your Tableau Server. The automatically installed process on the initial node is sufficient.

#### Terminology and concepts

- **Site job limits:** The background jobs concurrency and run time limits for a site.
- **Default site limits:** The default jobs concurrency and run time limits for a site.
- **Custom site limits:** Site limits specific to that site.
- **Job type:** Same as the task type. Includes extract refreshes, subscriptions, and flows.
- **Concurrent jobs limits:** The maximum number of jobs of a specific type that can run at the same time. The maximum number is equal to the total number of Backgrounder processes deployed on the Server.
- **Daily limit:** The daily limit includes run time limits and the reset time.
- **Runtime limit:** This is the total number of Backgrounder job hours allotted for a site per day. The maximum number is equal to the total number of Backgrounder processes deployed on the Server multiplied by 24, 24 being the number of hours in a full day.
- **Reset time:** The time at which the daily limits are reset. This is automatically set to midnight UTC and cannot be changed.
- **No limit:** This is the same as if there are no resource limits configured. In this case, the jobs on a site that can run in parallel could use all the available backgrounder processes on Tableau Server.

## What you can do

### **As a Tableau Server administrator,**

1. You can specify concurrency jobs limit for each task type - extract refreshes, subscriptions, and flows. This limit controls the number of background jobs on a site that can be run at the same time, for a given task type. The limits are unique to each task type, meaning you can set different limits for extract refreshes, subscriptions, and flows.
2. You can specify the number of Backgrounder hours a site can use to run jobs in a 24 hour period - the daily job run time limit. Unlike the concurrency jobs limit, the daily job run time limit is cumulative across all task types.
3. You can find out how many Backgrounder hours have been used by a site in the last 24 hour time period.
4. You can see when a job is delayed due to set concurrency limits.
5. You can identify when a job is canceled due to lack of available Backgrounder resources.

You can see the job status and details on the [Managing Background Jobs in Tableau Server](#) page.

**As a task owner,** you will receive an e-mail when your background job is canceled because the site reached its daily run time limit.

## How to set Backgrounder resource limits

Tableau Server does not automatically set any resource limits. Until you configure resource limits, there is no resource limitation on backgrounder resource usage.

To set resource limits for the first time or make changes thereafter, navigate to the **Settings** page, and select the **Resource Limits** tab.

**You can only configure custom limits once you have configured the default limits.**

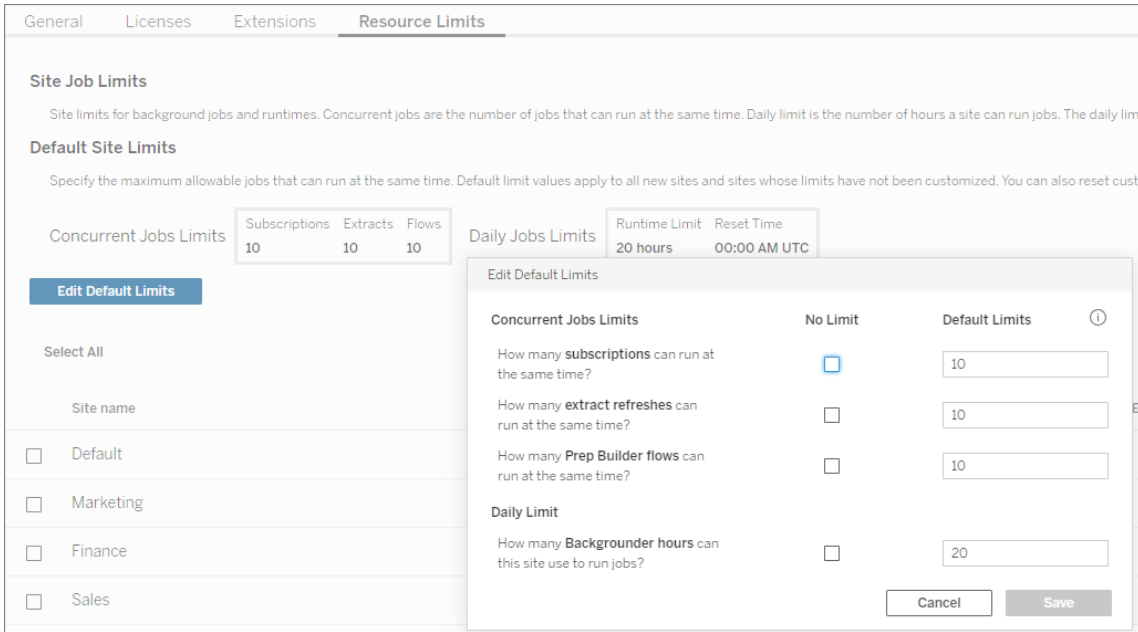

## Default site limits

Default site limits are set at the server level so they can be applied to all sites. Changes to default site limits apply to all new sites and any existing sites that are set to use default limits. Sites that have custom limits will not be affected by this change.

- **Concurrent Jobs Limits** and the **Daily Runtime Limits** must be specified in whole numbers.
- Changes to default site limits are effective immediately and do not require a server restart.

To set default limits for the first time, on the **Resource Limits** tab, select **Set Default Limits**. If you are making updates to existing default limits, select **Edit Default Limits**.

### Custom site limits

For certain sites, you may need more or fewer resources than the default limits. This depends on the amount of content you have on the site and their importance to your business operations. When the default values are not the right capacity for a site, you can set custom resource limits for that site. Custom site limits can exceed default limits.

- **Concurrent Jobs Limits** and the **Daily Runtime Limits** must be specified in whole numbers.
- Changes to custom site limits are effective immediately and do not require a server restart.

To configure custom limits for a site, on the **Resource limits tab**, under **Actions**, click the ellipses and select **Customize Site Limits**.

| Site name | Actions | Configuration            | Subscriptions | Extracts | Flows | Runtime limits | Actual runtime (since reset) | Jobs                |
|-----------|---------|--------------------------|---------------|----------|-------|----------------|------------------------------|---------------------|
| Default   | ...     | Default                  | 10            | 10       | 10    | 20 hours       | 20.2 hours                   | Default Jobs Page   |
| Marketing | ...     | Customize Site Limits... | 83            | 13       | 84    | 47 hours       | 47.0 hours                   | Marketing Jobs Page |
| Finance   | ...     | Custom                   | 87            | 24       | 84    | 92 hours       | 0.0 hours                    | Finance Jobs Page   |

### What happens after you configure resource limits

Once you set the resource limits for your sites, Tableau Server monitors and keeps track of the background resource usage, and makes sure the appropriate limits are enforced.

Jobs are placed in a queue when the site is at its maximum concurrency limit and will not run until a job that is currently running on that site is complete, and Background capacity becomes available.

If after 12 hours there is still no concurrency resource available, then jobs that are still pending will be removed from the queue. At the end of the daily run time limit, **any pending jobs will be canceled for the day** and the task owner will receive a notification.

This feature requires that Tableau Server is activated with a valid Server Management license without which the limits are not enforced. If the license is invalid or deactivated for any reason, previously configured limits are saved and will be enforced once the license issue has been resolved.

## When to make adjustments to the resource limits

*Before making configuration changes, make sure that Tableau Server is running and is in a good state.*

You can use the [jobs](#) page to identify jobs that are pending or canceled, and then determine which of those were due to resource limits.

Here are some patterns to monitor and make adjustments to the resource limits:

- If you are seeing that one or more jobs on a site are consistently getting canceled, you may need to increase the daily run time limits.
- If you are seeing that jobs on a site are consistently getting canceled early in the day, it probably means that the daily job run time is not enough for that site.
- If you are consistently seeing several jobs of a particular type stay pending over a period of time, you may want to consider increasing the concurrent jobs limits for that task type. Alternately consider scheduling the tasks over different time periods so everything is not running at the same time. Also, you may want to consider creating schedules that are spread over a longer period, so tasks are not all scheduled to run too closely to one another.
- If you don't want to change the resource limits in the situations described above, you can choose to adjust the frequency of when the jobs are scheduled to run. For example, if the job is scheduled to run every hour, adjust it to run on a less frequent schedule.

Who can do this

Tableau Server Administrators can configure resource limits.

A Tableau Server user who owns extract refresh, subscription, or flow run tasks will receive email notifications when their jobs are canceled.

# Dynamic Scaling in a Container - Tableau Server Backgrounders

## Introduction

The dynamic scaling of Backgrounder in a container enables various scaling strategies to be applied to backgrounder and scheduled jobs in Tableau Server. Autoscaling in this context means services can be independently scaled to handle variable task loads without requiring human intervention or impacting uptime of other server systems. The Tableau Server Containers which contain complete nodes of Tableau Server processes will continue to run as monolithic systems. Instead a smaller set of decoupled independent container services which comprise the "backgrounder" service role will be dynamically scalable and handle computational load that would normally be handled by Tableau Server Containers. Backgrounder services are responsible for processing system tasks that include refreshing/creating extracts, sending subscriptions, checking data alerts, and many maintenance jobs. If there are times, for example, where it would be advantageous to refresh a large number of datasets or compute a swath of computationally expensive data alerts, you can now leverage Kubernetes to scale up compute power to complete those tasks efficiently. This guide covers the configuration and deployment requirements for Autoscaling Backgrounders in Kubernetes. This document is a supplement to the Tableau Server in a Container documentation.

## Prerequisites

Autoscaling Backgrounders is only available in Kubernetes and is based on Tableau Server in Containers. In order to use the autoscaling backgrounders feature, you must satisfy certain prerequisite:

- Tableau Server must be licensed for Advanced Management. For more information, see [About Tableau Advanced Management on Tableau Server](#).
- You must be using Role-based licensing. Core licenses are not supported. For details on licensing, see [Understanding License Models and Product Keys](#).
- The following Advanced Management features must be enabled:
  - Tableau Server External File Store
  - Tableau Server External Repository

- You must have a Kubernetes cluster version 1.20 or later and understand how to use and manage it.

## Limitations

- This feature only works as a part of a Linux-based deployment.
- Flow jobs are not supported on the autoscaling backgrounders. Flow jobs will be handled by the backgrounder services that continue to run in the Tableau Server container.

## Creating Tableau Server and Backgrounder Pod Images

The first step for using autoscaling backgrounders in containers is to create the service images that comprise the Tableau Server installation. These images will include the Tableau Server image, as well as images for the separate backgrounder and supporting services. You use the same build tool that is used to create the comprehensive all-in-one Tableau Server container image, but the tool must be version 2022.3.0 or later, you must have an Advanced Management license, and you need to use a special flag when building the images.

1. To create the service images, run this command:

```
build-image --accepteula -i <installer> --backgrounder-images
```

This creates the Tableau Server and four new images. These additional images contain individual services that comprise the new autoscalable backgrounder pod.

The `docker images` command lists the images created in the local docker repository:

```
hyper                20214.21.1117.1006
52fd9843c178        10 seconds ago
gateway              20214.21.1117.1006
2308e602a2a3        11 seconds ago
backgrounder         20214.21.1117.1006
4540e459cf23        12 seconds ago
dataserver           20214.21.1117.1006
c5345ed47f51        12 seconds ago
```

## Tableau Server on Linux Administrator Guide

```
tableau_server_image          20214.21.1117.1006  
b27817047dd1    7 minutes ago
```

The hyper, gateway, backgrounder, and dataserver images comprise the new Backgrounder pod. Custom drivers, installation scripts, and properties will be shared across all five of these images. For more information, see [Customizing the image](#).

2. Publish all of these images to your internal image repository for deployment.

## Deployment Guide

The following information provides context for how to deploy Tableau Server in a Container and with Autoscaling Backgrounders. This information assumes you already understand and know how to deploy Tableau Server in a self-container container. For more information, see [Tableau Server in a Container](#). The three Kubernetes configuration files in the [Kubernetes Configuration](#) section are templates that can be used to set up the deployment. The other sections in this guide cover the requirements and details of the deployment.

Deployment of Tableau Server and Autoscaling Backgrounders should be as simple as deploying the populated Kubernetes Configuration files at the bottom of the guide:

```
kubectl apply -f <tableau-kubeconfig-dir>
```

### Backgrounder Jobs

Backgrounder pods assist the Tableau Server in a Container compute additional scheduled workloads in parallel. Backgrounder handles extract refresh, subscription, alert, flow, and system workloads. Distributing jobs among backgrounder pods means there will be more compute resources available for Tableau Server to handle other tasks, like interactive user activities like rendering workbooks and dashboards. Flow jobs are the only type of backgrounder job that does not run in the backgrounder. For details about Backgrounder jobs, see [Managing Background Jobs in Tableau Server](#).

Backgrounder pods can handle any kind of load, except flow jobs, which must be run in the main Tableau Server containers, which continue to run the backgrounder service.

The Node Roles feature give users the flexibility to dedicate backgrounder pods for specific type of jobs. This feature is an extension of the Node Roles Feature on Tableau server. The detailed description about different node roles can be found here. Note, by default flow jobs are disabled on the backgrounder pods (i.e. the role is set to "no-flows") since the backgrounder pods are unable to run flow jobs.

To setup up node roles for backgrounder, you need to set the environment variable `NODE_ROLES` as part of kubeconfig for the container running backgrounder service. For example to set backgrounder to run only extract-refresh jobs, set up `NODE_ROLES` environment variable to extract-refreshes as shown below:

### NODE\_ROLE\_CONFIG

containers:

```

- name: backgrounder
  image: <backgrounder_image> # Backgrounder Image
  ports:
  - containerPort: 8600
  volumeMounts:
  - name: logmount
    mountPath: /var/log/tableau
  - name: clone-volume
    mountPath: /docker/clone
  - name: dataengine-volume
    mountPath: /docker/dataengine
  - name: temp
    mountPath: /var/opt/tableau/tableau_server-
/data/tabsvc/temp
  env:
  - name: ROOT_LOG_DIR
    value: /var/log/tableau
  - name: CLONE_ARTIFACT_DIR
    value: /docker/clone/clone-artifacts
  - name: FILESTORE_MOUNT_PATH
    value: /docker/dataengine
  - name: NODE_ROLES
    value: extract-refreshes

```

## Tableau Server on Linux Administrator Guide

The Tableau Server pods will have at least one backgrounder configured in their topology, which is required to ensure there is always a place to run backgrounder jobs. By default, TSM will require that there must be a backgrounder able to handle every role of background job. In some scenarios, you may want to have backgrounder pods handle all jobs of a particular type. To do so, you must set the Server configuration key `topology.roles_handle_all_jobs_constraint_disabled` to `true`, which will disable the requirement that the TSM topology handle all job types. With this parameter set, the backgrounder role for the Tableau Server backgrounder instance could be set to `no-extract-refreshes` and the role for the backgrounder pods could be set to `extract-refreshes`, which would ensure that all extract refresh jobs run only on the backgrounder pods.

**Note:** Disabling this constraint allows you to configure roles such that some job types are never scheduled. The role configuration of TSM backgrounders and backgrounder jobs must be set carefully because TSM will no longer be verifying that all backgrounder job types can be scheduled.

### Tableau Server in a Container Pods

The containers with Tableau Server as part of the autoscaling backgrounder pods deploy in almost the same way that our existing Tableau Server in a Container does. There are a few key requirement changes:

- A network file share is *required* to transfer configuration between the Tableau Server container and the backgrounder pods.
- You must enable and use the External Filestore feature. This also requires a dedicated network file share.

### Backgrounder Pods

Backgrounder pods consist of four independent service containers working together: **gateway**, **hyper**, **dataserver**, and **backgrounder**. You may deploy these pods like typical independent Kubernetes container pods. The pods have the following requirements:

- Backgrounder pods must be able to reach the Tableau Server node using hostname DNS resolution.
- External Filestore and Clone network file shares must be provided.

**Note:** Backgrounder pods are configured with an init-container to wait until the Tableau Server container has successfully produced clone configuration output before proceeding to run.

## Logs

Backgrounder pod services (like Tableau Server) still write logs predominately to disk. Because the backgrounder pods can be scaled in and out, they are ephemeral so it is essential to ensure that logs are stored off of the pods. Many customers with existing K8s environments will already be using a log aggregation service of some type to collect the logs from the pods they deploy. Examples of log aggregation services are Splunk, and fluentd. We strongly recommend that customers use some sort of log aggregation service to collect the logs from their backgrounder pods. To make log management easier, the kubeconfig we provide configures each service in the pod to write to a shared log volume. The path of the directory in each service container is specified by the `ROOT_LOG_DIR` environment variable.

If you need to open a support case and provide logs, you will provide two sets of logs: ziplogs gathered from the main Server containers, and logs from the backgrounder pods (either retrieved from your log aggregation service, or using the manual process below).

For customers that are unable to use a log aggregation service, logs can be retrieved manually from the pods.

**Note:** Logs from any pod that did not use a Persistent Volume Claim for the volume containing the logs will be lost when the pod is scaled down!

All the relevant logs are available at the `/var/log/tableau` directory (configurable via the `ROOT_LOG_DIR` environment variable) inside the backgrounder pod. We highly recommend you mount a PersistentVolumeClaim at this location so that logs are available when the pod dies.

## Tableau Server on Linux Administrator Guide

Collecting logs when the backgrounder pod is running:

Create a tar file of the logs inside the container:

```
kubectl exec -it <backgrounder-pod-name> -- bash -c "tar -czf /docker/user/backgrounder-pod-logs.tar.gz /var/log/tableau"
```

Copy the tarfile to outside the container:

```
kubectl cp <backgrounder-pod-name>:docker/user/backgrounder-pod-logs.tar.gz ./backgrounder-pod-logs.tar.gz
```

Collecting logs when the backgrounder pod has exited (or failed to start)

Attach any long-running pod with PersistentVolumeClaim mount which is used for backgrounder pod deployment logs. One example configuration:

```
apiVersion: v1
kind: Pod
metadata:
  name: <name>
  namespace: <namespace>
spec:
  containers:
  - name: get-logs-pod
    image: busybox:1.28
    securityContext:
      runAsUser: 0
      allowPrivilegeEscalation: true
    command: ['sh', '-c', "while ;; do sleep 5; done"]
    volumeMounts:
    - name: logmount
      mountPath: /var/log/tableau
  restartPolicy: Never
  volumes:
  - name: logmount
    persistentVolumeClaim:
      claimName: logvolume
```

Create a tar file of the logs inside container:

```
kubectl exec -it <backgrounder-pod-name> -- bash -c "tar -czf /backgrounder-pod-logs.tar.gz /var/log/tableau"
```

Copy the tarfile to outside the container:

```
kubectl cp <backgrounder-pod-name>:/backgrounder-pod-logs.tar.gz ./backgrounder-pod-logs.tar.gz
```

## Live Configuration Changes

If you make configuration changes in Tableau Server in a Container (for example using the `tsm` command line) and want those configuration changes to be represented in Backgrounder pods, you need to run the `tsm settings clone` command to produce a new set of clone configuration files ("clone payload").

1. Use TSM to make configuration changes in the Tableau Server in a Container pod and apply the configuration changes to the server.
2. Run the following command in the Tableau Server in a Container pod:

```
## Run this command in the Tableau Server in a Container pod.
tsm settings clone -d $CLONE_ARTIFACT_DIR
```

This command creates a new set of configuration files and writes it to the Clone NFS drive location.

3. Redeploy your backgrounder pods. The pods should be configured to use the Clone NFS drive and will pick up the new configuration.

## Scaling Strategies

Backgrounder pods can be scaled in Kubernetes using a variety of techniques and strategies. We provide an example scaling strategy that changes Backgrounder pod pool size based on a time schedule.

Note that CPU and memory utilization are **not** good metrics for scaling Backgrounder pods. Memory and CPU utilization do not accurately portray the overall load demand on the cluster. For example, a Backgrounder pod could be at max utilization to refresh an extract, but there

are no additional jobs waiting in the Backgrounder job queue. In this case autoscaling would not improve job throughput.

### Scheduled Scaling

Standard Kubernetes mechanisms using cron jobs allow you to schedule a scaling solution.

An example Kubernetes configuration for this is provided in the Kubernetes Configuration section below.

## Kubernetes Configuration

### New Environment Variables

In addition to the standard Tableau Server container environment variables (see Initial Configuration Options), there are some new required environment variables that must be set in the Kubernetes Configuration.

| Environment Variable | Recommended Value             | Description  |
|----------------------|-------------------------------|--|
| FILESTORE_MOUNT_PATH | /docker/dataengine            | External Filestore directory mount location. This directory should point to the dataengine NFS directory mounted inside each deployed Tableau container. For more information about External Filestore, see Tableau Server External File Store. The value should be the same for the Tableau Server in a Container pod and the Backgrounder pod. |
| CLONE_ARTIFACT_DIR   | /docker/clone/clone-artifacts | Clone configuration directory mount location. This directory should point to an NFS directory mounted inside each Tableau container. Tableau Server will output configuration data that Backgrounder Pods consume to   |

| Environment Variable | Recommended Value | Description   |
|----------------------|-------------------|---|
|                      |                   | become members of the cluster.  |
| ROOT_LOG_DIR         | /var/log/tableau  | (Backgrounder pods only)<br><br>Common log directory location for all services running in a backgrounder pod. |

### Backgrounder Pod Ports

Backgrounder pods consist of four services, each by default is set to run on a specified port. If you want to change the port the service attaches to inside the container, you need to supply the key that corresponds to the service's port assignment. This kind of configuration should not be necessary in most cases, unless there is a sidecar container or some other additional component that is being added to the pod and conflicts with a service's port.

| Port Environment Variable | Default |
|---------------------------|---------|
| BACKGROUNDER_PORT         | 8600    |
| DATASERVER_PORT           | 8400    |
| HYPER_PORT                | 8200    |
| GATEWAY_PORT              | 8080    |

Datasever also uses port 8300, which cannot be reconfigured.

### Shared Network Directory

This deployment of Tableau Server requires two network shares to function properly. Note in all Tableau Server and Backgrounder od Kubernetes configuration templates these network directories are present:

## Tableau Server on Linux Administrator Guide

- **Dataengine Directory** (`FILESTORE_MOUNT_PATH`): Backgrounder Pods require the External Filestore feature. This network share contains extracts and other file-based artifacts that will be shared between Tableau Server and Backgrounder Pods.
- **Clone Directory** (`CLONE_ARTIFACT_DIR`): Tableau Server writes static connection and configuration information to a network share. Backgrounder pods will consume this information to become members of the Tableau Server cluster. In future pre-releases this configuration will be incorporated into the standard life cycle of Kubernetes configuration.

**Important:** If you want to redeploy the cluster entirely (including a new Tableau Server Container), you must purge the contents of the clone NFS mount (otherwise backgrounder pods will attempt to attach to the old server).

## Kubernetes Configuration Examples

**Note:** The configuration examples include use of a readiness probe. You can use the readiness probe when your Tableau Server Container deployment is a single-node TSM deployment (the deployment can include multiple backgrounder pods). You cannot use a readiness probe with multi-node Tableau Server in a Container deployments.

### Kubernetes Job to clean Clone Configuration (Optional)

This is a convenience Kubernetes job you might use during testing. If you want to clear out the clone configuration produced by Tableau Server in a Container between distinct deployment runs, you can run a job like this to clean the NFS.

```
apiVersion: batch/v1
kind: Job
metadata:
```

```

name: delete-clone-artifacts-job
namespace: manatee-cluster
spec:
  template:
    spec:
      containers:
      - name: delete-clone-artifacts
        image: busybox:1.28
        command: ['sh', '-c', "rm -rf ${CLONE_ARTIFACT_DIR}"]
        env:
        - name: CLONE_ARTIFACT_DIR
          value: /docker/clone/clone-artifacts
        securityContext:
          runAsUser: 0
        allowPrivilegeEscalation: true
        volumeMounts:
        - name: clone-volume
          mountPath: /docker/clone
          restartPolicy: Never
        volumes:
        - name: clone-volume
          nfs:
            server: <nfs_ip> # IP for shared NFS directory for clone output
            path: /clone

```

## About Data Management

**Important:** Beginning September 15, 2024, Data Management will no longer be sold as an independent add-on option. After September 15, 2024, features and functionality in Data Management will be offered via certain license editions. Existing deployments with

Data Management remain unaffected. More details will be announced in the coming months. For more information, contact your Sales Account team.

Data Management is a collection of features and functionality that helps customers manage Tableau content and data assets in their Tableau Server or Tableau Cloud environment.

Starting in Tableau Server 2019.1, Tableau Prep Conductor is available for on-premise Tableau Server deployments, and in version 2019.3, Tableau Prep Conductor is available for Tableau Cloud deployments. You can use Tableau Prep Conductor to schedule and monitor flows.

Starting in Tableau 2019.3, Tableau Catalog is included in Data Management, making a variety of additional features available to you in the data management space. You can use Tableau Catalog to discover data, curate data assets, communicate data quality, perform impact analysis, and trace the lineage of data used in Tableau content.

Starting in Tableau 2021.4, more governance and security features are added to Data Management: virtual connections and data policies. Using the virtual connection editor, you can create:

- Virtual connections that provide a sharable central access point to data.
- Data policies to apply row-level security at the connection level.

Tableau Catalog, Tableau Prep Conductor, virtual connections, and data policies are licensed through Data Management. For more information about licensing, see [License Data Management](#).

To purchase Data Management, contact your account manager.

## Data Management Features

The following table lists the features for Data Management, which includes:

- Tableau Catalog
- Tableau Prep Conductor

- Virtual connections
- Data policies

## Tableau Catalog

These features require Data Management with [Tableau Catalog enabled](#).

| Feature                                      | Description   |
|--|---|
| Permissions on metadata                      | Tableau Catalog enables you to control who can see and manage external assets and what metadata is shown through lineage by setting permissions.  |
| Expanded connect experience - data discovery | Whether you author in the web or in <a href="#">Tableau Desktop</a> , you can now search for and connect to the specific databases and tables used by published data sources and workbooks on your <a href="#">Tableau Server</a> or <a href="#">Tableau Cloud</a> site.                      |
| <a href="#">Expanded search</a>              | Tableau Catalog expands search to include results based on columns, databases, and tables.  |
| <a href="#">Tag external assets</a>          | You can categorize items on Tableau Server and Tableau Cloud with tags, helping users to filter external assets (databases, files, tables, and columns).  |
| <a href="#">Certify databases and tables</a> | Help users find trusted data that meets the standards you set by certifying databases and tables.   |
| <a href="#">Set data quality warnings</a>    | You can set warnings to alert users to data quality issues, such as stale or deprecated data.   |
| <a href="#">Lineage and impact analysis</a>  | The Lineage tool traces the source of your data. You can use it to analyze the impact of changes to your data, identify which users might be impacted, and <a href="#">email owners</a> of a workbook, data source, or flow, or contacts for a database or table, about data-related updates. |
| <a href="#">Data Details</a>                 | Enable users to better understand a published visualization by seeing information about the data used.  |

| Feature                                    | Description  |   |
|--|--|---|
| <a href="#">Add descriptions to assets</a> | Help users find the data they're looking for by adding descriptions to databases, tables, and columns. |   |
| Developer resources                        | <a href="#">Tableau REST API - metadata methods</a>  | Programmatically add, update, and remove external assets; and add additional metadata to Tableau content and external assets like descriptions.   |
|  | <a href="#">Tableau Metadata API</a>   | Programmatically query metadata from the content published to Tableau Server or Tableau Cloud. Programmatically update certain metadata using the <a href="#">metadata methods</a> in the Tableau Server REST API.<br><b>Note:</b> The Metadata API does not require Data Management. |
|  | <a href="#">GraphiQL</a>   | Explore and test queries against the Metadata API schema using an interactive in-browser tool called GraphiQL.<br><b>Note:</b> GraphiQL does not require Data Management.   |

## Tableau Prep Conductor

These features require Data Management with Tableau Prep Conductor enabled on [Tableau Server](#) or [Tableau Cloud](#).

| Feature  | Description   |
|--|---|
| <a href="#">Schedule Flow Tasks</a> in the <a href="#">Tableau Cloud</a> or <a href="#">Tableau Server</a> help. | You can create scheduled flow tasks to run a flow at a specific time or on a recurring basis.   |
| Monitor Flow Health and Performance  | Set up email notifications at the site or server level when flows fail, view and resume suspended flow tasks, and view errors and alerts. |

| Feature   | Description  |
|---|--|
| Administrative Views for Flows                  | Use Administrative Views to monitor the activities related to flows, performance history, and the disk space used at the server or site level. |
| Tableau REST API - <a href="#">flow methods</a> | Programmatically schedule flows.   |

## Virtual connections and data policies

These features require Data Management.

| Feature   | Description  |
|---|--|
| Create a Virtual Connection                         | A Tableau content type that enables you to create a shareable re-usable connection to curated data.  |
| Create a Data Policy for Row-Level Security         | Use the virtual connection editor to create data policies with policy conditions that apply row-level security to the data at the connection level.      |
| Test Row-Level Security with Preview as User        | Test the data policy with Preview as user to ensure that users can see only their data.  |
| Schedule Extract Refreshes for a Virtual Connection | Create an extract refresh schedule for the tables in your connection, ensuring that the data is fresh for any content that uses that virtual connection. |

## License Data Management

Data Management includes Tableau Catalog, Tableau Prep Conductor, virtual connections, and data policies. Contact your account manager (or go to the [Tableau pricing](#) page) to purchase Data Management.

Data Management can only be activated on a licensed Tableau Server Deployment. A Deployment includes a licensed production Tableau Server installation and licensed non-production Tableau Server installations that support the production installation. For more information on Deployment, see the [EULA Documentation](#).

### Tableau Prep Conductor

After you purchase and license Data Management, you must enable Prep Conductor on Tableau Server. For more information, see [Enable and Configure Tableau Prep Conductor on Tableau Server](#).

- When Data Management is active and enabled, you can schedule flows in Tableau Server or Tableau Cloud and monitor flows.
- When Data Management is removed or deactivated, or if the Data Management license expires, then the ability to schedule flows is disabled.
- If your Tableau Server or Tableau Cloud license is still active and valid, you can download the flows using the Tableau Server REST API. For more information, see [Flow Methods](#).

### Tableau Catalog

After you purchase and license Data Management, you must enable Catalog on Tableau Server. For more information, see [Enable Tableau Catalog](#).

- When Data Management is active and enabled, you can use Tableau Catalog to discover data, curate data assets, perform impact analysis, and trace the lineage of data used in Tableau content.
- When Data Management is removed, deactivated, or the license expires, the information remains on the server. The Tableau Catalog-specific information is then only accessible using the Tableau Metadata API; it no longer appears in the product. For more information, see the [Metadata API](#).
- When Data Management is removed, deactivated, or the license expires, the write APIs for all new Tableau Catalog information (for example, table descriptions, data quality warnings, column descriptions) are disabled. You can still read information using the Metadata API, however permissions on tables and databases can't be explicitly managed in the product.

## Virtual connections and data policies

After you purchase and license Data Management for Tableau, virtual connections and data policies are automatically enabled.

- When Data Management is active and enabled, you can use virtual connections to create sharable resources that provide a central access point to data. You can also create data policies that enable you to filter data for users using centralized row-level security.
- When Data Management is removed, deactivated, or the license expires, the information remains on the server but is not accessible.
- When Data Management is reactivated, the information is restored on the server and becomes accessible.

## How Data Management licensing works

A Tableau Server Deployment may be user-based or core-based, depending on which license you purchase.

### User-Based

A User-Based license metric allows you to deploy Tableau Server on a single computer or on multiple computers in a cluster. Each user that accesses Tableau Server must be licensed. Administrators add users and license them. The first Creator or Explorer product key that you add to Tableau Server activates Tableau Server and will be used by a Server Administrator.

The Data Management product key enables the included features at the deployment level, and those features are licensed for all the users that are already licensed for Tableau Server.

### Core-Based

A Core-Based license metric imposes no constraints on the number of user accounts in Tableau Server. Instead, the license specifies the maximum number of computer cores on which you can run Tableau Server.

**Note:** When you purchase and use core-based licensing, you must apply both the Data Management product key and the Resource Core product key to your Tableau

Deployment. The first key allows flows to be run on Tableau Server through the Tableau Prep Conductor and the second key adds the additional cores for the Tableau Prep Conductor nodes. All product keys are available through the [Customer Portal](#).

Typically, the total number of cores in all the computers should not exceed the total number that the Tableau Server license allows. When you add the Data Management product key to your Tableau server, it includes a specific number of Tableau Prep Conductor cores. In this scenario, the total number of cores on all computers should not exceed the total number that the Tableau Server license and the Data Management license together allow.

In this topic we will refer to the cores licensed through Tableau Server license as Tableau Server cores, and the cores licensed through Data Management as Tableau Prep Conductor cores.

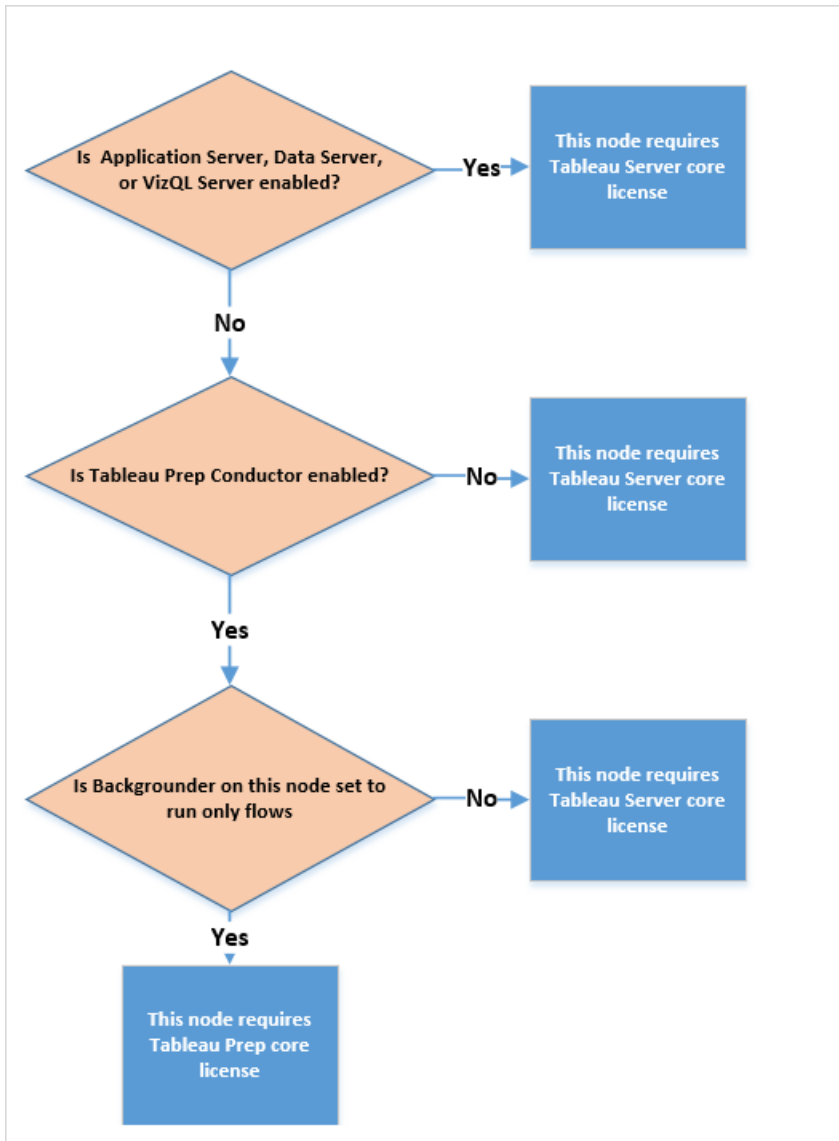

Here are some concepts that apply to how licensing is applied in a Core-Based metric:

- A node can be licensed by only one of type—Tableau Server Cores or Tableau Prep Conductor cores.
- The Tableau Prep Conductor cores are applied to any node that is dedicated to running Tableau Prep Conductor and when the Backgrounder on that node is set to run only flow background jobs. In this case, the total number of cores on this node cannot exceed the number of cores that the Data Management license allows. If this node has any other licensed process besides Tableau Prep Conductor, Backgrounder and Data Engine enabled, then this node will require and use a Tableau Server core license.
- As mentioned above, the Backgrounder node role also affects which license is used by a node. For example, if the Backgrounder node role is set to run jobs of all types (this is the default), then this node will be licensed through the Tableau Server cores. For more information on node roles, see [Node Roles in Tableau Server](#).

See the following table and decision flow to understand how a node is licensed:

| <b>If a node has...</b> | <b>the core on the node is counted towards...</b> | <b>the node is licensed using...</b> |
|-------------------------|---|--------------------------------------|
|-------------------------|---|--------------------------------------|

|   |   |   |
|---|---|---|
| <p>one of the following processes enabled:</p> <ul style="list-style-type: none"> <li>• Application Server</li> <li>• Backgrounder (node role is set to run all jobs)</li> <li>• File Store</li> <li>• Data Server</li> <li>• VizQL Server</li> </ul> | <p>Total count of Tableau Server cores.</p>   | <p>Tableau Server cores.</p>  |
| <p>only the following processes enabled:</p> <ul style="list-style-type: none"> <li>• Tableau Prep Conductor</li> <li>• Backgrounder (node role is set to run only flows)</li> <li>• Data Engine</li> </ul>   | <p>Total number of Tableau Prep Cores purchased through Data Management.</p> <div style="background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p><b>Note:</b> If there are no Tableau Prep Conductor cores available, but Tableau Server cores are available, then Tableau Server cores are used.</p> </div> | <p>Tableau Prep Cores included in Data Management.</p> <div style="background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p><b>Note:</b> If there are no Tableau Prep Conductor cores available, but Tableau Server cores are available, then Tableau Server cores are used.</p> </div> |

For more information about licensed processes, see [Tableau Server Processes](#).

To learn more about Tableau Server licensing, see [Tableau Server Licensing Overview](#).

## Tableau Prep Conductor

Tableau Prep Conductor enables you to leverage the scheduling and tracking functionality available in Tableau Server to run your flows automatically to update the flow output. Tableau

Prep Conductor is part of Tableau Data Management introduced in Tableau Server version 2019.1 and must be enabled to schedule your flows to run.

For more information about the Tableau Prep Conductor process on Tableau Server, see [Tableau Prep Conductor](#)

**Note:** Starting in version 2020.4, the Data Management license is required to run flows on a schedule and when using REST API to run flows.

Data Management isn't required to publish flows and manually run them on the web, and as a Creator, create and edit flows directly on your server.

Flows created in Tableau Prep Builder must be published to Tableau Server before they can be scheduled to run.

Publishing flows is similar to publishing data sources and workbooks with Tableau Desktop. You can package files with the flow or specify a direct connection to data sources to update the flow input as data changes. If your flow connects to databases, specify the authentication type and set credentials to access the data.

You can also publish a flow to share it with others or to continue editing it on the web. For example, publish an incomplete flow to Tableau Server and then open the flow on the web in Edit mode to continue working on it. You could also create a flow with only Input steps (that are properly configured) and share it with co-workers who can then download the flow to their computers and create and publish their own flows.

For flows to run they must include output steps and have no errors or incompatible features. For more information about publishing a flow, see [Publish a Flow to Tableau Server or Tableau Cloud](#). For more information about incompatibility, see [Version Compatibility with Tableau Prep](#).

Keeping track of the health of your flows is easy. If a flow fails to run due to errors, such as a calculation that isn't valid or a connection failed, you can fix the error right in Tableau Server.

## Tableau Server on Linux Administrator Guide

You can edit the connection or edit the flow to fix the error, then republish it to pick up where you left off.

The following table shows the flow management features that are available with and without the Data Management and Tableau Prep Conductor enabled.

| <b>Data Management with Tableau Prep Conductor enabled</b>   | <b>No Data Management</b>   |
|--|---|
| <ul style="list-style-type: none"><li>• View and monitor the details about your flow, including recent activity in the <b>Content</b> pages.</li><li>• Edit your flow (starting in version 2020.4).</li><li>• View the results of the flow runs and any errors in the <b>Run History</b> tab.</li><li>• Use <b>Administrative Views</b> to monitor server and site activity including a new view that tracks flow performance history.</li><li>• Run flows using REST API.</li><li>• View detailed alerts for failed flow runs.</li><li>• Set up email notification alerts to send emails to flow owners notifying them when the flow failed to run and why.</li></ul> <p>For more information about setting up alerts, <a href="#">Monitor Flow Health and Performance</a>.</p> | <ul style="list-style-type: none"><li>• View the details about your flow, including recent activity in the <b>Content</b> pages.</li><li>• Edit your flow (starting in version 2020.4).</li><li>• View and edit your connections on the <b>Connections</b> tab.</li></ul> |

## Enabling Tableau Prep Conductor on Tableau Server

Before you can start publishing flows to your Tableau Server, there are server-level and site-level settings you must configure or verify to prepare your Tableau Server to allow publishing, scheduling and monitoring flows.

Review the following topics to understand Tableau Prep Conductor licensing, and learn how to enable Tableau Prep Conductor:

- [Enable and Configure Tableau Prep Conductor on Tableau Server](#): This topic provides step-by-step instructions on how to enable and configure Tableau Prep Conductor, and preparing your Tableau Server to allow publishing, scheduling, managing, and maintaining flows.
- [License Data Management](#)

## About the Flow Workspace

After you publish your flow you can schedule tasks or linked tasks (version 2021.3 and later) in Tableau Server to automatically run your flows on a regular basis to keep your output data fresh. You can also run your flows manually at any time (no Data Management required).

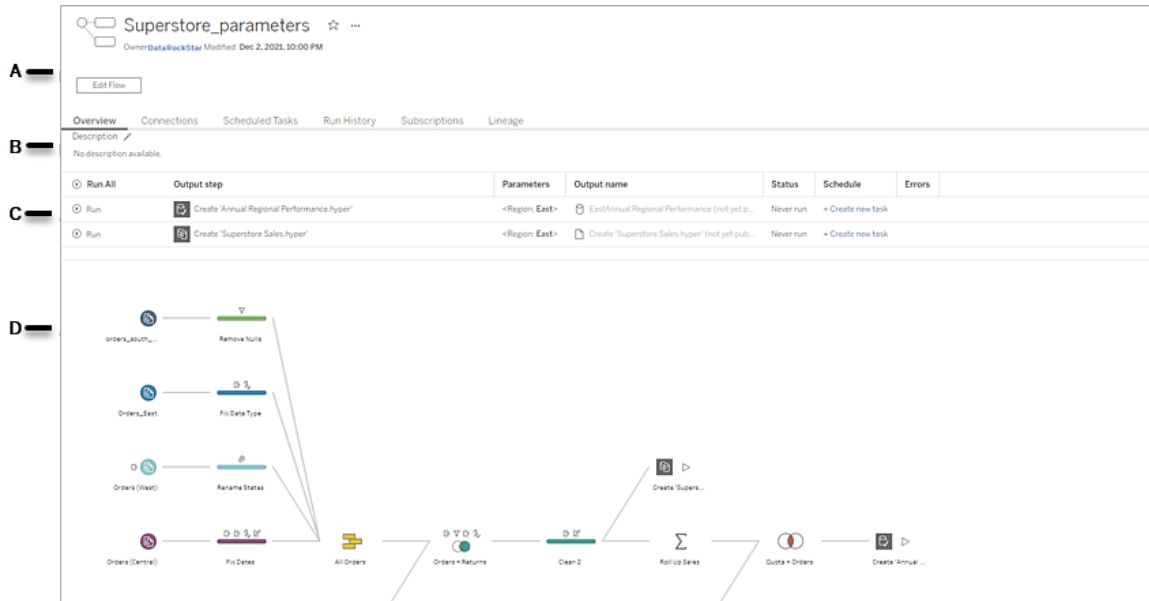

Tableau Prep Conductor leverages much of the same functionality for managing flows that you might see when managing workbooks or data sources from Tableau Desktop in Tableau Server. For example, just like extract refreshes, scheduled flow tasks and on-demand flow runs are queued as background tasks. But when it comes to working with flows, there are a few differences.

### Flow Overview page

The flow **Overview** page is the main landing page where you can view data about your flow and schedule, monitor, and maintain the flow. If you don't have the Data Management, you will have different options.

Open the flow **Overview** page by clicking on a flow in your list. You can navigate there from **Content > Explore > All Flows** or by opening the project that contains your flows.

# Tableau Server on Linux Administrator Guide

A. The header lists the name of the flow, the flow owner and the date that the flow was last modified. Starting in version 2020.4, click **Edit** to edit existing flows.

Add a flow to your favorites, or from the **More actions** ... menu you can also edit, run, download the flow, set permissions, change the flow owner, restore previous flow versions, and more.

B. View and edit the flow description and set tags to help others find the flows they are looking for.

C. View the output steps for a flow along with any parameters applied to the flow (version 2021.4 and later), the status of the last update, any schedule the output is assigned to, and any errors from the last flow run. You can also click the **Run** button to run all output steps or individual output steps on-demand.

|                          |   |
|--------------------------|---|
| <p><b>Parameters</b></p> | <p>If the flow includes user parameters, the parameter value last run in the flow is shown and you can see all generated outputs in the <b>Output</b> column. When the flow is run, you'll be prompted to enter the parameter values.</p> |
|--------------------------|---|

|                 |   |
|-----------------|---|
|                 | <p>System parameters (version 2023.2 and later) are automatically generated at flow run time and the type of system parameter is shown in the <b>Parameters</b> column. To see the last system parameter value applied to the flow, edit the flow.</p> <p>For more information about using parameters in flows, see <a href="#">Create and Use Parameters in Flows</a> in the Tableau Prep help.</p>  |
| <b>Status</b>   | <p>After a flow has run successfully, outputs that are data sources become links that you can click to open the <b>Data Source</b> page to view more information about the data source or edit the flow input connection.</p>   |
| <b>Schedule</b> | <p>In the <b>Schedule</b> field, view the scheduled tasks that the output step is assigned to. A flow output can be assigned to one or more tasks.</p> <p>If no schedule has been assigned yet, click <b>Create new task</b> to add the output step to a schedule. To immediately run the flow to update a specific output step, click the <b>Run</b>  button on the left-hand side of the row.</p>   |
| <b>Errors</b>   | <p>If the flow has errors, the flow run will fail. Connectivity errors can be resolved directly by navigating to the <b>Connections</b> tab for the flow and editing the input connections.</p> <p>To resolve any other flow errors, edit the flow then republish it and try running the flow again. If you are using an earlier version of Tableau Prep Builder, from the <b>More actions</b>  menu, you can also download and open the flow in Tableau Prep Builder, then republish it and try running the flow again.</p> |

D. View an image of the flow.

## Tableau Server on Linux Administrator Guide

### Flow Overview page without the Data Management

If you don't have the Data Management installed on your server, you can still publish flows to Tableau Server, but you will see fewer options to manage your flow.

### Flow Connections page

View both the input and output locations for a flow, connection types, authentication settings, input and output steps and any connectivity errors. You can set authentication settings when publishing a flow. For more information, see [Publish a Flow](#).

For database input types, click the **More actions** ... menu for an input connection to edit the connection and change the server name, port, user name and password.

| Connects to   | Connection type     | Authentication | Username | Input steps   | Output Steps | Errors |
|---|---------------------|----------------|----------|---------------|--------------|--------|
| <input type="checkbox"/> Crane Job Forecast 2018.xlsx | Microsoft Excel     | None           |          | Aluminum...   |              |        |
| <input type="checkbox"/> Age of Cranes.csv            | Text file           | None           |          | Age of Cra... |              |        |
| <input type="checkbox"/> https://server               | Tableau Server Site |                |          |               | Output 2     |        |
| <input type="checkbox"/> https://server               | Tableau Server Site |                |          |               | Output       |        |

### Flow Scheduled Tasks page (Data Management required)

View any schedules that the flow is assigned to, the outputs that are included in those schedules, and any parameters applied to the flow (version 2021.4 and later). As an administrator, you can click the schedule link to open the **Schedules** page and see a list of flows that are assigned to that schedule. For more information about assigning flows to a schedule, see *Schedule Flow Tasks* in the [Tableau Cloud](#) or [Tableau Server](#) help.

To view the outputs on a schedule or the tasks assigned to a linked task (version 2021.3 and later), click the links in the **Schedule type** column.

You can also add new tasks or manage existing ones from this page. To take action on an existing task, select the check box on a task card then click the **Actions** drop-down menu to run, edit, or delete the task.

If the flow fails to run after a configured number of consecutive attempts, the flow is automatically suspended.

You can see that status on the **Overview** tab as well as this tab. You can resume suspended tasks from this menu.

For information about how to set the threshold for suspended flow tasks, see [Step 5: Optional Server Configurations](#). For more information about suspended flow tasks, see [View and resolve errors](#).

**Note:** The Scheduled Tasks page for flows was redesigned in version 2021.3. Your view may look different depending on your server version.

### Schedules page

On the **Schedules** page, you can view the flows assigned to a schedule and the details about the flow runs. If the schedule includes linked tasks (version 2021.3 and later) the number of flows included in the linked tasks is shown.

You can run the schedule on-demand and run all flows assigned to it. You can also select one or more flows, then use the **Actions** menu to change the flow schedule or priority, delete selected flows from the schedule or resume suspended flows.

For information about how to set up a schedule, see [Step 3: Create Schedules for Flow Tasks](#).

| Run Flow - First of the month 1:00AM   |         |              |          |           |                      |                      |                          |
|--|---------|--------------|----------|-----------|----------------------|----------------------|--------------------------|
| Schedule: Every 1 <sup>st</sup> day of the month, at 1:00 AM (UTC-08:00) America/Los_Angeles (next run at: Oct 1, 2021, 1:00 AM) |         |              |          |           |                      |                      |                          |
| Flows 18 Details   |         |              |          |           |                      |                      |                          |
| Select All   |         |              |          |           |                      |                      |                          |
| Flow   | Actions | Output steps | Priority | Status    | Last Run             | Next Scheduled Run   | Errors                   |
| <input type="checkbox"/> <a href="#">Superstore_2020.1.RC</a>  | ...     | 2 outputs    | 50       | Suspended | Never                | Disabled             |                          |
| <input type="checkbox"/> <a href="#">2019.4.Itcv2.Postgres.JDBC</a>  | ...     | 1 output     | 50       | Succeeded | Sep 1, 2021, 1:01 AM | Oct 1, 2021, 1:00 AM |                          |

### Flow Run History (Data Management required)

See, search, and sort through a list of historical runs for a flow. This page also includes details about the flow run such as run type, parameter values applied to flows included in each flow run (version 2021.4 and later), duration and number of rows that were generated.

If the flow output has an error, hover over the error to view the messages. If applicable, click the **Go to Connections** link in the error message to navigate to the **Connections** page to fix connectivity errors. You can also edit the flow directly to fix any errors, or click **Download the flow** to download and fix flow errors in Tableau Prep Builder, then republish the flow to continue to manage it using Tableau Prep Conductor.

**Note:** The run history for a flow will persist unless the flow is deleted.

## Tableau Server on Linux Administrator Guide

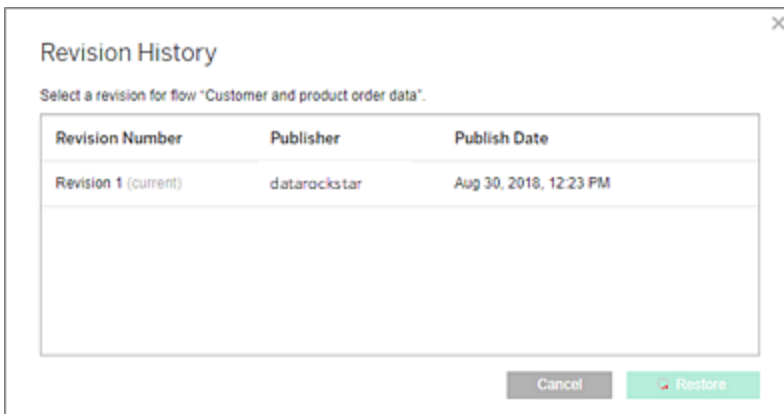

The screenshot shows the 'Run History' tab for a flow named 'Superstore\_parameters'. The table lists several failed runs with error details.

| Output step                                | Run type     | Parameters     | Run start             | Run end               | Duration | Status | Rows generated | Errors   |
|--|--------------|----------------|-----------------------|-----------------------|----------|--------|----------------|----------|
| Create 'Annual Regional Performance.hyper' | Full refresh | <Region: East> | Dec 3, 2021, 3:01 PM  | Dec 3, 2021, 3:01 PM  | 00:00:04 | Failed | 0              | 1 error  |
| Create 'Superstore Sales.hyper'            | Full refresh | <Region: East> | Dec 3, 2021, 3:01 PM  | Dec 3, 2021, 3:01 PM  | 00:00:04 | Failed | 0              | 2 errors |
| Create 'Annual Regional Performance.hyper' | Full refresh | <Region: East> | Dec 3, 2021, 1:00 PM  | Dec 3, 2021, 1:00 PM  | 00:00:03 | Failed | 0              | 1 error  |
| Create 'Superstore Sales.hyper'            | Full refresh | <Region: East> | Dec 3, 2021, 1:00 PM  | Dec 3, 2021, 1:00 PM  | 00:00:03 | Failed | 0              | 2 errors |
| Create 'Superstore Sales.hyper'            | Full refresh | <Region: East> | Dec 3, 2021, 11:00 AM | Dec 3, 2021, 11:00 AM | 00:00:03 | Failed | 0              | 2 errors |
| Create 'Annual Regional Performance.hyper' | Full refresh | <Region: East> | Dec 3, 2021, 11:00 AM | Dec 3, 2021, 11:00 AM | 00:00:03 | Failed | 0              | 1 error  |

**2 errors**  
The output file path is not valid or you don't have permissions to write to the file. Check permissions, verify this file path is in the tablelist, or use a valid output file path. Learn more  
There is an error in one or more steps in the flow. Edit the flow, resolve the errors then republish it and run the flow again.  
Download the flow

### Flow Revision History

If you need to revert a flow to a previous version, from the **More actions** ... menu for the flow, select **Revision History**. On the **Revision History** dialog, select the flow version from the list that you want to revert to.

Who can do this

Server Administrators can activate Data Management license keys.

Server administrators can enable Tableau Prep Conductor.

Creators can create, edit, and run flows manually. If the Data Management is installed, creators can run flows on a schedule.

## Enable and Configure Tableau Prep Conductor on Tableau Server

*Supported in Tableau Server version 2019.1 and later.*

Tableau Prep Conductor is licensed through Data Management, on a per Deployment basis, which is User-Based or Core-Based. A Deployment includes a licensed production Tableau Server installation and licensed non-production Tableau Server installations that support the production installation. For more information on Deployment, see the [Tableau Deployment Guide](#).

For more information on how Tableau Prep Conductor licensing works, see License Data Management.

### Server Topology

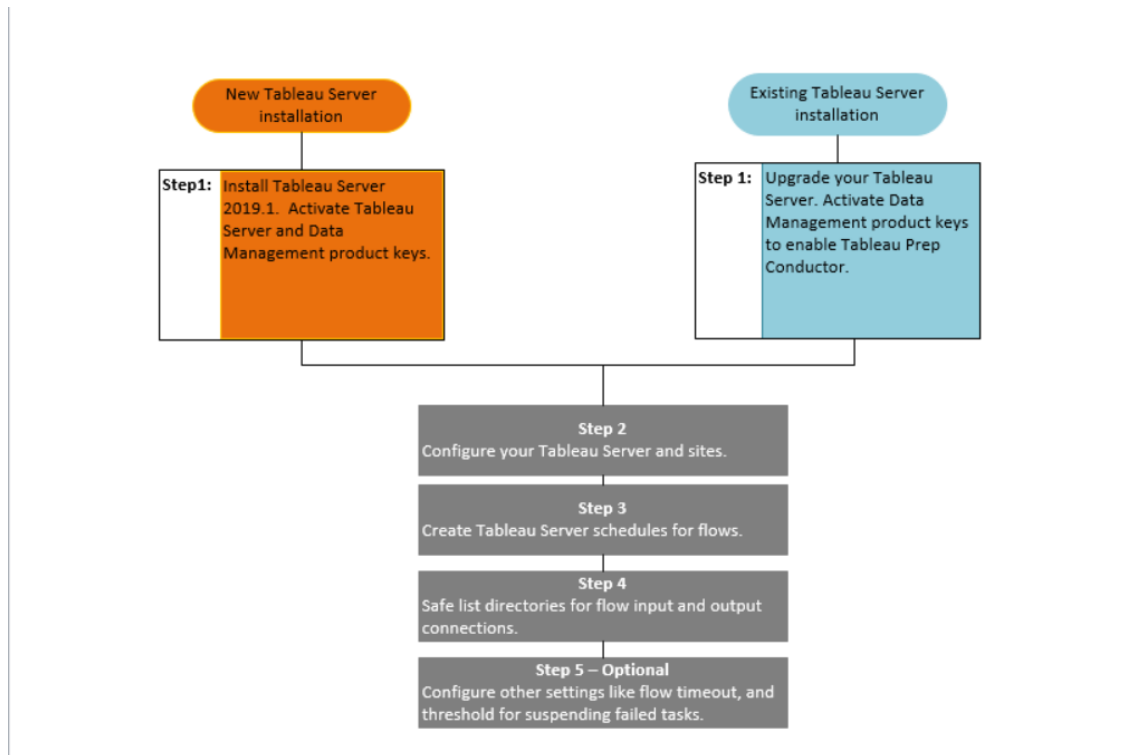

When you install Tableau Server and enable Tableau Prep Conductor, using the Data Management product key, Tableau Prep Conductor is automatically enabled by default by the setup program.

For multi-node installations, by default, one instance of Tableau Prep Conductor is enabled on any node that has backgrounder installed. In the example below, Tableau Prep Conductor is enabled on node 2 and 3 where the backgrounders are also enabled, but not on node 1,4, and 5.

# Tableau Server on Linux Administrator Guide

|  <span>STATUS</span> <span>MAINTENANCE</span> <span>CONFIGURATION</span> |         |         |         |       |       |

| Ask Data  | ✓       |         |         |       |       |
| Elastic Server  | ✓       |         |         |       |       |

Below is a visual representation of that work-flow:

Next step:

New Tableau Server Installations: Step 1 (New Install): Install Tableau Server with Tableau Prep Conductor

Existing Tableau Server Installations: Step 1 (Existing Install): Enable Tableau Prep Conductor

Who can do this

Server administrators can install Tableau Server and enable Tableau Prep Conductor.

Server-level settings can be configured by Tableau Server administrators, and site-level settings can be configured by Tableau Server and Site administrators.

Step 1 (New Install): Install Tableau Server with Tableau Prep Conductor

This topic describes how to Tableau Prep conductor on a new installation of Tableau Server.

Tableau Prep Conductor is supported only on Tableau Server versions 2019.1 or later.

## Tableau Server on Linux Administrator Guide

Tableau Prep Conductor is licensed through Data Management, on a per Deployment basis. A Deployment includes a licensed production Tableau Server installation and licensed non-production Tableau Server installations that support the production installation. For more information on Deployment, see the [Tableau Deployment Guide](#).

Before you install

The recommended topology for a production Tableau Server installation is a dedicated node for running flows. If you are currently planning to have a single node Tableau Server installation it is recommend that you add a second node and dedicate it to run flows.

- Review the hardware recommendations for Tableau Server and Tableau Prep conductor.
  - [Minimum Hardware Requirements and Recommendations for Tableau Server installation on Windows](#).
  - [Minimum Hardware Requirements and Recommendations for Tableau Server installation on Linux](#).

Install Tableau Server and enable Tableau Prep Conductor

Use the instructions provided in the following topics to install Tableau Server.

[Windows: Install Tableau Server](#)

[Linux: Install Tableau Server topic](#)

When you get to the **Activate** step, use the Tableau Server product keys to activate Tableau Server.

All product keys are available through the [Customer Portal](#).

## Configure public gateway settings

If your Tableau Server is set up with one of the following:

- Load balancer to distribute requests across gateways.
- Reverse proxy to authenticate external (internet) client requests and offloading SSL-based encryption.

You must configure the following public gateway settings:

```
tsm configuration set -k gateway.public.host -v <name> (This should be  
the URL that your users are using to access Tableau Server)
```

```
tsm configuration set -k gateway.public.port -v 443
```

For more information on configuring gateway settings, see [Configuring Proxies for Tableau Server](#).

## Enable Tableau Prep Conductor

Use the following steps to add the Data Management product key to your Tableau Server:

**Note:** This process requires a restart of the Tableau Server.

**Note:** If you are using core-based licensing, you must apply both the Data Management product key and the Resource Core product key to your Tableau Deployment. The first key allows flows to be run on Tableau Server through the Tableau Prep Conductor and the second key adds the additional cores for the Tableau Prep Conductor nodes. All product keys are available through the [Customer Portal](#).

1. If the computer where you are running Tableau Server has been configured to connect to the internet through a forward proxy, follow the procedure in the topic, [Configure Product Key Operations with Forward Proxy](#), before continuing.
2. Open TSM in a browser:

```
https://<tsm-computer-name>:8850
```

3. Click **Licensing** on the **Configuration** tab and click **Activate License**.
4. Enter or paste your **Data Management product key** and click **Activate**.
5. On the Register page, enter your information into the fields and click **Register**.
6. Follow the prompts and restart Tableau Server after registration is complete.

## Verify Tableau Prep Conductor is enabled and running

When you activate the Data Management product key, a single instance of Tableau Prep Conductor is automatically enabled on any node that has Backgrounder enabled.

**Use the following steps to verify that it is enabled and running:**

1. Open a browser and enter the Tableau Server URL, and append the dedicated TSM web UI port. Here are some examples of what the URL might look like:

`https://localhost:8850/` (if you're working directly on the server computer)

`https://MarketingServer:8850/` (if you know the server's name)

`https://10.0.0.2:8850/` (if you know the server's IP address)

In the sign-in page that appears, enter your administrator user name and password.

**Note:** Tableau Server creates and configures a self-signed certificate during the installation process. This certificate is used to encrypt traffic to the TSM Web UI. Because it's a self-signed certificate, your browser will not trust it by default. Therefore, your browser will display a warning about the trustworthiness of the certificate before allowing you to connect.

2. In the Tableau Services Manager web interface, click the **Status** tab to see the status.

- If Tableau Prep Conductor is enabled and running, you should see Tableau Prep Conductor in the list of processes as **Active** on at least on one node. If Tableau Prep Conductor is not enabled, you will see Tableau Prep Conductor in the list of processes, but with no status information for any of the nodes.

**Tableau Prep Conductor not enabled:**

The screenshot shows the Tableau Server Status page with the 'STATUS' tab selected. The 'Tableau Prep Conductor' row is highlighted with a red box, and it shows no status indicators for any of the three nodes (node1, node2, node3).

| Process                                | node1   | node2 | node3 |
|--|---------|-------|-------|
| Gateway                                | ✓       |       |       |
| Application Server                     | ✓       |       |       |
| Interactive Microservice Container     | ✓       |       |       |
| VizQL Server                           | ✓ ✓ ✓ ✓ |       |       |
| Cache Server                           | ✓ ✓     |       |       |
| Cluster Controller                     | ✓       | ✓     | ✓     |
| Search & Browse                        | ✓       |       |       |
| Backgrounder                           | ✓ ✓     |       | ✓ ✓   |
| Non-Interactive Microservice Container | ✓       |       | ✓     |
| Data Server                            | ✓ ✓     |       |       |
| Data Engine                            | ✓       | ✓     | ✓     |
| File Store                             | ✓       | ✓     |       |
| Repository                             | ✓       |       |       |
| Tableau Prep Conductor                 |         |       |       |
| Ask Data                               | ✓       |       |       |
| Elastic Server                         | ✓       |       |       |
| TSM Controller                         | ✓       |       |       |
| License Server                         | ✓       |       |       |

Legend: ✓ Active, ⌘ Busy, ⚠ Degraded, ❌ Error, ✖ Stopped

**Tableau Prep Conductor enabled and running. In the image below Tableau Prep Conductor is enabled on node1 and node3:**

# Tableau Server on Linux Administrator Guide

| Process                                | node1   | node2 | node3 |

Refresh Status Active Busy Degraded Error Stopped

## Dedicate a node for Tableau Prep Conductor

On the node you are planning to dedicate to running flows, enable Backgrounder process if it is not already enabled. It is recommended that you do not run other processes like VizQL server on this node.

Because you are dedicating this node to running flows, you must configure Backgrounder to run only flow tasks. By default, the Backgrounder process runs tasks of all types, including flows, extract refreshes, and subscriptions. For more information, see [Node Roles in Tableau Server](#).

Run the following tsm commands on that dedicated node to run only flow tasks:

1. Run the following command to allow Backgrounders on this node to run only flow tasks.

```
tsm topology set-node-role -n node1 -r flows
```

2. Set the node role on the initial node to no flows. The backgrounders on this node will run all jobs except flows:

```
tsm topology set-node-role -n nodel -r no-flows
```

3. Apply the changes and restart Tableau Server:

```
tsm pending-changes apply
```

## Multi-node installations

If you have more than 2 nodes in your Tableau Server installation, you can choose to configure other nodes to run all tasks other than flows:

1. Restrict a node to not allow flows. This command removes Tableau Prep Conductor from this node and Backgrounders on this node will not run flow tasks.

```
tsm topology set-node-role -n nodel -r no-flows
```

2. Apply the changes and restart Tableau Server:

```
tsm pending-changes apply
```

Next step

Step 2: Configure Flow Settings for your Tableau Server

## Who can do this

Server administrators can install Tableau Server and enable Tableau Prep Conductor.

Step 1 (Existing Install): Enable Tableau Prep Conductor

This topic describes how to enable Tableau Prep conductor on your existing installation of Tableau Server.

## Tableau Server on Linux Administrator Guide

Tableau Prep Conductor is supported only on Tableau Server versions 2019.1 or later. If you are using Tableau Server 2018.3 or earlier, you must first upgrade your Tableau Server to 2019.1 before enabling Tableau Prep Conductor on your Tableau Server installation.

Tableau Prep Conductor is licensed through Data Management, on a per Deployment basis, which is User-Based or Core-Based. A Deployment includes a licensed production Tableau Server installation and licensed non-production Tableau Server installations that support the production installation. For more information on Deployment, see the [Tableau Deployment Guide](#).

This topic describes how to enable Tableau Prep conductor on your existing installation of Tableau Server.

Before you upgrade

### Prepare for upgrade:

- [Know before you upgrade](#)
- [Licensing Tableau Prep Conductor](#)
- [Tableau Server Hardware Requirements and Recommendations](#)

### Configure public gateway settings

If your Tableau Server is set up with one of the following:

- Load balancer to distribute requests across gateways.
- Reverse proxy to authenticate external (internet) client requests and offloading SSL-based encryption.

You must configure the following public gateway settings:

```
tsm configuration set -k gateway.public.host -v <name> (This should be the URL that your users are using to access Tableau Server)
```

```
tsm configuration set -k gateway.public.port -v 443
```

For more information on configuring gateway settings, see [Configuring Proxies for Tableau Server](#).

## Tableau Server Installations using User-Based licenses

The recommended topology for a production Tableau Server installation is a dedicated node for running flows. For more information, see [Minimum Hardware Requirements and Recommendations for Tableau Server](#).

## Tableau Server single-node installations

If you currently have a single node Tableau Server installation, it is recommended that you add a second node and dedicate it to running flows.

1. Run upgrade on your current Tableau Server installation using the information in the topics below:
  - [Windows](#)
  - [Linux](#)

When you get to the **Activate** step, use the Tableau Server product keys to activate Tableau Server.

All product keys are available through the [Customer Portal](#).

2. After completing the installation, add the Data Management product key to enable Tableau Prep Conductor on your node. The Data Management product key, like your other server keys, are available through the [Customer Portal](#).
  - In the Tableau Services Manager web interface, click **Licensing** on the **Configuration** tab and click **Activate License**.
  - Enter or paste your new product key and click **Activate**.
  - On the **Register** page, enter your information into the fields and click **Register**.

## Tableau Server on Linux Administrator Guide

3. You will be prompted to restart the server. Restart the server and verify that Tableau Prep Conductor is enabled and running.
  - In the Tableau Services Manager web interface, click the **Status** tab to see the status. If Tableau Prep Conductor is enabled and running, you should see Tableau Prep Conductor in the list of processes as **Active**. If Tableau Prep Conductor is not enabled, you will see Tableau Prep Conductor in the list of processes, but with no status information.

### Tableau Prep Conductor not enabled:

The screenshot shows the Tableau Services Manager interface with the 'STATUS' tab selected. The page displays a list of processes for 'node1'. The 'Tableau Prep Conductor' process is highlighted with a red box and has no status icon, indicating it is not enabled or running. Other processes like Gateway, Application Server, and Data Server show green checkmarks, indicating they are active.

| Process                                | node1   |
|--|---------|
| Gateway                                | ✓       |
| Application Server                     | ✓       |
| Interactive Microservice Container     | ✓       |
| VisQL Server                           | ✓ ✓ ✓ ✓ |
| Cache Server                           | ✓ ✓     |
| Cluster Controller                     | ✓       |
| Search & Browse                        | ✓       |
| Backgroundler                          | ✓ ✓     |
| Non-Interactive Microservice Container | ✓       |
| Data Server                            | ✓ ✓     |

Refresh Status

Active | Busy | Degraded | Error | Stopped

4. Add a second node to your Tableau Server installation. The installer will enable certain required processes like the Cluster Controller. Enable Backgrounder process on it as it is required to run scheduled flow tasks. When you enable the Backgrounder process, the installer automatically enables a single instance of Data Engine and Tableau Prep Conductor on the node. Do not add any other processes on this node.
5. Run the following commands to dedicate this node to do only flow tasks. For more information on node roles, see [Node Roles in Tableau Server](#).

- Get the nodeID for your dedicated node to see the list of services on each node:

```
tsm topology list-nodes -v.
```

- Set the node role for the dedicated node using the nodeID that you got from running the command described above:

```
tsm topology set-node-role -n <nodeID> -r flows.
```

- Apply the changes, and restart the server:

```
tsm pending-changes apply.
```

## Tableau Server on Linux Administrator Guide

- Review the status to ensure that all the processes are up and running and configured correctly:

```
tsm status -v.
```

You have successfully added Tableau Prep Conductor to your Tableau Server installation.

## Tableau Server multi-node installations

1. Run upgrade on your current Tableau Server Installation using the information in the topics below:

- [Windows](#)
- [Linux](#)

When you get to the **Activate** step, use the Tableau Server product keys to activate Tableau Server.

All product keys are available through the [Customer Portal](#).

2. After completing the installation, add the Data Management product key to enable Tableau Prep Conductor. Tableau Prep Conductor is automatically enabled on the nodes where you already have the Backgrounder process enabled. The Data Management product key, like your other server keys, are available through the [Customer Portal](#).
  - In the Tableau Services Manager web interface, click **Licensing** on the **Configuration** tab and click **Activate License**.
  - Enter or paste your new product key and click **Activate**.
  - On the **Register** page, enter your information into the fields and click **Register**.
3. You will be prompted to restart the server. Restart the server and verify that Tableau Prep Conductor is enabled and is running.

- In the Tableau Services Manager web interface, click the **Status** tab to see the status of all the processes. If Tableau Prep Conductor is enabled and running, you should see Tableau Prep Conductor in the list of processes as **Active**. If Tableau Prep Conductor is not enabled, you will see Tableau Prep Conductor in the list of processes, but with no status information.

**Tableau Prep Conductor not enabled:**

The screenshot shows the Tableau Services Manager interface with the 'STATUS' tab selected. A table lists various processes across three nodes (node1, node2, node3). The 'Tableau Prep Conductor' row is highlighted with a red box and shows no status icons, indicating it is not enabled. Other processes like Gateway, Application Server, and VizQL Server show active status with green checkmarks.

| Process                                | node1 | node2 | node3 |
|--|-------|-------|-------|
| Gateway                                | ✓     |       |       |
| Application Server                     | ✓     |       |       |
| Interactive Microservice Container     | ✓     |       |       |
| VizQL Server                           | ✓✓✓✓  |       |       |

| File Store                             | ✓       | ✓     |       |
| Repository                             | ✓       |       |       |
| Tableau Prep Conductor                 | ✓       |       | ✓     |
| Ask Data                               | ✓       |       |       |
| Elastic Server                         | ✓       |       |       |
| TSM Controller                         | ✓       |       |       |
| License Server                         | ✓       |       |       |

Legend: ✓ Active, ⌚ Busy, ⚠ Degraded, ✖ Error, ☒ Stopped

4. Add a new node to your Tableau Server installation. The installer will enable certain required processes like the Cluster Controller. Enable Backgrounder process on it as it is required to run scheduled flow tasks. When you enable the Backgrounder process, the installer automatically enables a single instance of Data Engine and Tableau Prep Conductor on the node. Do not add any other processes on this node.

**Note:** The dedicated node counts towards the total count of the Coordination Service ensemble. You may need to deploy a Coordination Service on the new node depending on the total number of nodes you have in your cluster including the new dedicated node. For more information, see [Deploy a Coordination Service Ensemble](#).

5. Run the following command to dedicate this node to only doing flow related operations. For more information on node roles, see [Node Roles in Tableau Server](#).

- Get the nodeID for your dedicated node to see the list of services on each node:
  - `tsm topology list-nodes -v.`
  - Set the node role for the dedicated node using the nodeID that you got from running the command described above:
  - `tsm topology set-node-role -n <nodeID> -r flows.`
  - Apply the changes and restart the server:
  - `tsm pending-changes apply.`
  - Review the status to ensure that all the processes are up and running and configured correctly:
  - `tsm status -v.`
6. At this stage, you may have Tableau Prep Conductor enabled on other nodes. By default, the Backgrounder process on a node performs all tasks of all types including flow tasks. To isolate Tableau Prep Conductor and flow tasks to only certain nodes, you can configure the Backgrounders to do one of the following:
- To run only flow tasks: `tsm topology set-node-role -n <nodeID> -r flows.`
  - To run all other tasks except flows: `tsm topology set-node-role -n <nodeID> -r no-flows.`

You have successfully added Tableau Prep Conductor to your Tableau Server installation.

#### Tableau Server Installations using Core-Based licenses

The recommended topology for a production Tableau Server installation is a dedicated node for running flows. For more information, see [Minimum Hardware Requirements and Recommendations for Tableau Server](#).

Data Management for Core-Based licenses includes product keys that enable Tableau Prep Conductor for your Tableau Server, and Tableau Prep Conductor cores that comes in units of four. The Tableau Prep Conductor cores should be applied to the node dedicated to running the flows. These product keys, like your other server keys, are available through the [Customer Portal](#).

To learn more about Tableau Prep Conductor licensing, see [Licensing Tableau Prep Conductor for Tableau Server](#).

## Tableau Server single-node installations

If you currently have a single node Tableau Server installation, it is recommended that you add a second node and dedicate it to running flows.

1. Run upgrade on your current Tableau Server Installation using the information in the topics below:
  - [Windows](#)
  - [Linux](#)
2. Activate the product keys. This will enable Tableau Prep Conductor on the nodes where you already have the Backgrounder process enabled. When you are using core-based licensing, you must apply both the Data Management product key and the Resource Core product key to your Tableau Deployment. The first key allows flows to be run on Tableau Server through the Tableau Prep Conductor and the second key adds the additional cores for the Tableau Prep Conductor nodes. All product keys are available through the [Customer Portal](#).
  - In the Tableau Services Manager web interface, click **Licensing** on the **Configuration** tab and click **Activate License**.
  - Enter or paste your new product key and click **Activate**.
  - On the **Register** page, enter your information into the fields and click **Register**.
3. You will be prompted to restart the server. Restart the server and verify that Tableau Prep Conductor is enabled and is running.
  - In the Tableau Services Manager web interface, click the **Status** tab to see the status. If Tableau Prep Conductor is enabled and running, you should see Tableau Prep Conductor in the list of processes as **Active**. If Tableau Prep Conductor is not enabled, you will see Tableau Prep Conductor in the list of processes, but with no status information.

**Tableau Prep Conductor not enabled:**

The screenshot shows the Tableau Server status page for 'node1'. The 'Tableau Prep Conductor' process is highlighted with a red box and has a green checkmark, indicating it is enabled but not running. Other processes like Gateway, Application Server, and Data Engine are also shown with green checkmarks.

| Process                                | Status |
|--|--------|
| Gateway                                | Active |
| Application Server                     | Active |
| Interactive Microservice Container     | Active |
| VizQL Server                           | Active |
| Cache Server                           | Active |
| Cluster Controller                     | Active |
| Search & Browse                        | Active |
| Backgrounder                           | Active |
| Non-Interactive Microservice Container | Active |
| Data Server                            | Active |
| Data Engine                            | Active |
| File Store                             | Active |
| Repository                             | Active |
| Tableau Prep Conductor                 | Active |
| Ask Data                               | Active |
| Elastic Server                         | Active |
| TSM Controller                         | Active |
| License Server                         | Active |

**Tableau Prep Conductor enabled and running:**

The screenshot shows the Tableau Server status page for 'node1'. The 'Tableau Prep Conductor' process is highlighted with a red box and has a green checkmark, indicating it is enabled and running. Other processes like Gateway, Application Server, and Data Engine are also shown with green checkmarks.

| Process                                | Status |
|--|--------|
| Gateway                                | Active |
| Application Server                     | Active |
| Interactive Microservice Container     | Active |
| VizQL Server                           | Active |
| Cache Server                           | Active |
| Cluster Controller                     | Active |
| Search & Browse                        | Active |
| Backgrounder                           | Active |
| Non-Interactive Microservice Container | Active |
| Data Server                            | Active |
| Data Engine                            | Active |
| File Store                             | Active |
| Repository                             | Active |
| Tableau Prep Conductor                 | Active |
| Ask Data                               | Active |
| Elastic Server                         | Active |
| TSM Controller                         | Active |
| License Server                         | Active |

4. Add a second node to your Tableau Server installation. The installer will enable certain required processes like the Cluster Controller. Enable Backgrounder process on it as it is required to run scheduled flow tasks. When you enable the Backgrounder process, the installer automatically enables a single instance of Data Engine and Tableau Prep Conductor on the node. Do not add any other processes on this node.

**Important:** The number of physical cores on this machine must be equal to, or less than the Tableau Prep Conductor cores you purchased. For example, if you purchased four Tableau Prep Conductor cores, your node can only have up to four physical cores. To understand about how Tableau Prep Conductor licensing works, see [Licensing Tableau Prep Conductor for Tableau Server](#).

5. Run the following commands to dedicate this node to only doing flow tasks. For more information on node roles, see [Node Roles in Tableau Server](#).

- Get the nodeID for your dedicated node to see the list of services on each node:

```
tsm topology list-nodes -v.
```

- Set the node role for the dedicated node using the nodeID that you got from running the command described above:

```
tsm topology set-node-role -n <nodeID> -r flows.
```

- Apply the changes and restart the server: `tsm pending-changes apply`.
- Review the status to ensure that all the processes are up and running and configured correctly:

```
tsm status -v.
```

You have successfully added Tableau Prep Conductor to your Tableau Server installation.

## Tableau Server multi-node installations

1. Run upgrade on your current Tableau Server installation using the information in the topics below:
  - [Windows](#)
  - [Linux](#)

2. Activate the product keys. This will enable Tableau Prep Conductor on the nodes where you already have the Backgrounder process enabled. When you are using core-based licensing, you must apply both the Data Management product key and the Resource Core product key to your Tableau Deployment. The first key allows flows to be run on Tableau Server through the Tableau Prep Conductor and the second key adds the additional cores for the Tableau Prep Conductor nodes. All product keys are available through the [Customer Portal](#).
  - In the Tableau Services Manager web interface, click **Licensing** on the **Configuration** tab and click **Activate License**.
  - Enter or paste your new product key and click **Activate**.
  - On the **Register** page, enter your information into the fields and click **Register**.
3. You will be prompted to restart the server. Restart the server and verify that Tableau Prep Conductor is enabled and is running.
  - In the Tableau Services Manager web interface, click the **Status** tab to see the status. If Tableau Prep Conductor is enabled and running, you should see Tableau Prep Conductor in the list of processes as **Active**. If Tableau Prep Conductor is not enabled, you will see Tableau Prep Conductor in the list of processes, but with no status information.

**Tableau Prep Conductor not enabled:**

Refresh Status Active Busy Degraded Error Stopped

4. Add a new node to your Tableau Server installation. A dedicated node to run flow related operations is recommended for production Tableau Server installations. The installer will enable certain required processes like the Cluster Controller. Enable Backgrounder process on it as it is required to run scheduled flow tasks. When you enable the Backgrounder process, the installer automatically enables a single instance of Data Engine on the node. Do not add any other processes on this node.

**Note:** The dedicated node counts towards the total count of the Coordination Service ensemble. You may need to deploy a Coordination Service on the new node depending on the total number of nodes you have in your cluster including the new dedicated node. For more information, see [Deploy a Coordination Service Ensemble](#).

**Important:**

The number of physical cores on this machine must be equal to, or less than the Tableau Prep Conductor cores you purchased. For example, if you purchased four Tableau Prep Conductor cores, your node can only have up to four physical cores. To understand about how Tableau Prep Conductor licensing works, see [Licensing Tableau Prep Conductor for Tableau Server](#).

5. Run the following commands to dedicate this node to only doing flow tasks. This will enable Tableau Prep Conductor on your new node. For more information, see [Node Roles in Tableau Server](#).
  - Get the nodeID for your dedicated node to see the list of services on each node:

```
tsm topology list-nodes -v.
```
  - Set the node role for the dedicated node using the nodeID that you got from running the command described above:

## Tableau Server on Linux Administrator Guide

```
tsm topology set-node-role -n nodeID -r flows.
```

- Apply the changes and restart the server:

```
tsm pending-changes apply.
```

- Review the status to ensure that all the processes are up and running and configured correctly:

```
tsm status -v.
```

6. At this stage, you may have Tableau Prep Conductor enabled on other nodes that have the Backgrounder process. By default, the Backgrounder process on a node performs all tasks of all types including flow tasks. To isolate Tableau Prep Conductor and flow operations to only certain nodes, you can configure the backgrounders to do one of the following:

- To run only flow tasks:

```
tsm topology set-node-role -n <nodeID> -r flows.
```

- To run all other tasks except flows:

```
tsm topology set-node-role -n <nodeID> -r no-flows.
```

Next step

Step 2: Configure Flow Settings for your Tableau Server.

## Who can do this

Tableau Server Administrators can install or upgrade Tableau Server, and enable Tableau Prep Conductor on Tableau Server.

Step 2: Configure Flow Settings for your Tableau Server

This topic describes the various flow settings that you can configure for your Tableau Server. For more information about the different settings needed to enable web authoring for flows,

see [Create and Interact with Flows on the Web](#).

## Publishing, Scheduling, and Credential Settings

When you activate Tableau Prep Conductor using the Data Management product key, Tableau Prep Conductor is enabled for the entire Tableau Server installation. You can further modify and customize the setting for sites.

Use the following instructions to configure settings related to flows for all your sites or for individual sites:

Use the following instructions to sign in to Tableau Server Admin pages:

- Windows: [Tableau Server Admin Pages](#).
- Linux: [Tableau Server Admin Pages](#).

### Configure whether publishing and scheduling flow should be allowed for a site:

1. **Enable users to publish and schedule flows:** This setting is enabled by default when you enable Tableau Prep Conductor. If you have multiple sites, you can selectively turn off Tableau Prep for Server for individual sites. If you disable this setting for a site that once allowed flows, see [Implication of disabling Tableau Prep Conductor](#) for more information.

On the **General** page under **Settings**, scroll to the **Tableau Prep Conductor** section and clear the **Allow users to schedule and monitor flows** check box.

2. **Enable users to link flow runs together using Linked Tasks (version 2021.3 and later):** Enable users to schedule flow tasks to run one after the other. Starting in version 2022.1, this option is enabled by default. In prior versions, administrators needed to enable this feature first.

If you have multiple sites, you can selectively turn off **Linked Tasks** for individual sites, but the option must first be enabled at the **Server Settings** level.

If the setting is turned off after linked tasks are scheduled, any tasks that are running will complete and the scheduled linked tasks are hidden and no longer show on the **Scheduled Tasks** tab.

### 3. Embed Credentials

**-Allow publishers to embed credentials in a data source, flow or workbook:** This setting allows publishers to attach passwords to published flows that will automatically authenticate web users.

**-Allow publishers to schedule flow runs and data extract refreshes:** This option is only available if setting above is enabled. When this setting is enabled, publishers will see scheduling options in the Publish dialog box.

## Implication of disabling Tableau Prep Conductor

If you disable Tableau Prep Conductor after using it for a while, you will not be able to see the flows, schedules, tasks, and other things related to flows. The following table gives you more information on what you can and cannot see when you disable Tableau Prep for Server completely or only for specific sites:

|  | Prep not enabled at Server level | Prep enabled at Server level, but disabled for a site | Prep enabled for both Server and site |
|--|----------------------------------|---|---------------------------------------|
| Show flows                                 | Yes                              | Yes   | Yes                                   |
| Show tasks/schedules in Server view        | No                               | Yes   | Yes                                   |
| Show tasks/schedules in Site view          | No                               | No  | Yes                                   |
| Show Site setting (only for Server Admins) | Yes (disabled)                   | Yes   | Yes                                   |

|                          |   |     |     |
|--------------------------|---|-----|-----|
| <b>Show TSM status</b>   | Yes (Tableau Prep Conductor is not shown) | Yes | Yes |
| <b>Show TSM settings</b> | Yes (disabled)                            | Yes | Yes |

**Important:** Scheduled tasks will continue to run even when Tableau Prep Conductor is disabled for that site, but will fail.

Configure notifications for flow failures

You can configure Tableau Server to send email notifications for flow run failures. The notifications are sent for failures that occur when running the flows through either a scheduled task, linked task, or a manual run using the **Run now** menu option. You must first enable the server-wide setting, and then configure at the site level.

## To enable the server-wide email notification

You can either use the Tableau Services Manager (TSM) web interface or TSM CLI as described below:

### Use the TSM web interface

1. Open TSM in a browser:  
  
<https://<tsm-computer-name>:8850>.
2. Click **Notifications** on the **Configuration** tab and click **Email Server**.
3. Enter the email server information.
4. Click the **Events** tab.

5. Under **Content Updates**, select **Send emails when flow runs, encryption jobs, or scheduled refreshes fail** if not already turned on by default.
6. Click **Save Pending Changes** after you've entered your configuration information.
7. Click **Apply Changes and Restart**.

## Use the TSM CLI

The notification values can be set individually with the `tsm configuration set` command:

Windows: [tsm configuration](#).

Linux: [tsm configuration](#).

### Set notification values

Use the `tsm configuration set` command with the following syntax to

to enable flow failure notifications, run the following command:

```
tsm configuration set -k backgrounder.notifications_enabled -v true
```

**Note:** This will enable email notification for both extract refresh failures and flow failures.

After you are done setting values, you must run the following command:

```
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in the case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior.

## To configure notification for a site:

On the **General** page under **Settings**, scroll to the **Manage Notifications** setting and select the notification types that you want site users to receive.

You can receive notifications as an email, on the Tableau site, or in your Slack workspace if your administrator has connected your site to Slack. For more information, see [Site Settings Reference](#).

|   | On Tableau                          | Email                               | Slack                               |
|---|-------------------------------------|-------------------------------------|-------------------------------------|
| <b>Manage Notifications</b>                               |                                     |                                     |                                     |
| Allow or disable notifications for all of your site users |                                     |                                     |                                     |
| <b>Collaboration</b>                                      |                                     |                                     |                                     |
| Comment mentions  | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Share   | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Data alerts   |                                     | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| <b>Systems Status</b>                                     |                                     |                                     |                                     |
| Flow runs   | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Extract jobs  | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |                                     |
| Webhooks  |                                     | <input checked="" type="checkbox"/> |                                     |

If grayed out, the notification option is disabled for use.

**Note:** Recreate your notifications settings when upgrading from 2020.4 or earlier to 2021.1 and later. Older notifications settings are not automatically moved to the Manage Notifications setting.

Next step

Step 3: Create Schedules for Flow Tasks

## Who can do this

Tableau Server Administrators can configure server and site level settings. Tableau Site Administrators can configure site level settings.

Step 3: Create Schedules for Flow Tasks

Create a new schedule:

1. On the **Schedules** tab, click **New Schedule**.

2. Enter the following information in the **New Schedule** dialog box and click **Create**.
  - **Name:** Enter a descriptive name for the schedule. Typically, this includes the description of the schedule frequency.
  - **Type:** Select Flow as the task type.
  - **Priority:** You can define a default priority from 1 to 100, where 1 is the highest priority. This value will be assigned to the tasks by default. If two tasks are pending in the queue, the one with the higher priority runs first.
  - **Execution:** Choose whether a schedule will run in parallel or serially. Schedules that run in parallel run on all available background processes so that they can complete faster.
  - **Linked Tasks (version 2021.3 and later):** Select the check box if the schedule can be used to schedule flows to run one after the other. Linked tasks require a **Parallel** execution method.

Starting in version 2022.1, this option is enabled by default. In prior versions, the Server Administrator must first enable linked tasks for the server before you can configure schedules to support linked tasks. For more information, see Step 2: Configure Flow Settings for your Tableau Server

- **Frequency:** You can define an hourly, daily, weekly, or monthly schedule.

Next step

Step 4: Safe list Input and Output locations

## Who can do this

Tableau Server Administrators can create and modify schedules. Schedules are created at the server level and apply across all the sites on a server.

Step 4: Safe list Input and Output locations

This topic describes the rules that apply to this feature and how to safe list the directories on your network.

Flow input and output connections may need to connect to databases or files in the directories on your network. You must safe list the directories you want to allow access to. Input and Output connections will only be allowed to connect to data in the safe listed locations. By default, no connections are allowed.

**Note:** You can still publish the flows and any data that is embedded in the flow file (tfx) to Tableau Server, but the flow will fail to run if the directories aren't included in your organization's safe list.

#### How to safe list input and output locations

The following rules apply and must be considered when configuring this setting:

- The directory paths should be accessible by Tableau Server. These paths are verified during server startup and at flow run time and are **not** verified at the time of publishing the flow to Tableau Server.
- Network directory paths have to be absolute and cannot contain wildcards or other path traversing symbols. For example, `\\myhost\myShare\*` **or** `\\myhost\myShare*` are invalid paths and would result in all the paths as disallowed. The correct way to safe-list any folder under *myShare* would be `\\myhost\myShare` **or** `\\myhost\myShare\`.

**Note:** The `\\myhost\myShare` configuration will not allow `\\myhost\myShare1`. In order to safe list both of these folders safe list them as `\\myhost\myShare; \\myhost\myShare1`.

- **Windows:**

- The value can be either `*`, (for example, `tsm configuration set -k maestro.input.allowed_paths -v "*"`) to allow any network directory, or a specified list of network directory paths, delimited by a semicolon (;). If you specify a list of directory paths, be sure to specify particular directories rather than the root of the file share.

- If the path contains spaces or special characters you will have to either use single or double quotes. Whether you use single or double quotes depends on the shell that you are using.
- No local directory paths are allowed even when the value is set to `*`.
- To save flow output to a network share, you must first [configure a Run As user](#) service account on Tableau Server. You cannot save flows to a network share using the default system account. Then configure the target directory on the network share for Full Control permissions for the Run As user account you created.

Depending on how your organization manages nested folder permissions, you may need to grant additional permissions in the folder hierarchy, with a minimum of Read, Write, Execute, Delete, and List Folder permission, to allow the Run As user account access to the target folder.

- **Linux:**

- The value can be either `*`, (for example, `tsm configuration set -k maestro.input.allowed_paths -v "*"`) meaning that any path, including local (with the exception of some system paths configured using `"native_api.internal_disallowed_paths"`), or a list of paths, delimited by a semicolon (`;`).
- You must be using a kernel version equal to or later than 4.7. Safe listing to or from a network share is not supported on kernel versions earlier than 4.7. On earlier versions, when the output is written to a network share, hyper fails to output files, resulting in flows failing at runtime. When reading input files from a network share on earlier versions, flow executions fail. To check the kernel version, in the Linux terminal, type the command `uname -r`. This will display the full version of the kernel you are running on the Linux machine. Note that for Red Hat Enterprise Linux, kernel version 4.7 and later is only available with Red Hat Enterprise Linux version 8.

- To save flow output to a network share, the local Linux account that has access to Tableau Server resources must be given Full Control permissions to the target directory on the network share. If a path is both on the flows allowed list and internal\_disallowed list, internal\_disallowed takes precedence.

The mount points for both input and output paths used by flows must to be configured using the `native_api.unc_mountpoints` configuration key. For example:

```
tsm configuration set -k native_api.unc_mountpoints -v  
'mountpoints'
```

For information about configuring this, see this Tableau Knowledge Base article: [Tableau Server on Linux - How to Connect to a Windows Shared Directory](#).

Use the following commands to create a list of allowed network directory paths:

### For input connections:

```
tsm configuration set -k maestro.input.allowed_paths -v your_net-  
workdirectory_path_1;your_networkdirectory_path_2
```

```
tsm pending-changes apply
```

### For output connections:

```
tsm configuration set -k maestro.output.allowed_paths -v your_net-  
workdirectory_path_1;your_networkdirectory_path_2
```

```
tsm pending-changes apply
```

### Important:

These commands overwrite existing information and replace it with the new information you provided. If you want to add a new location to an existing list, you must provide a list of all the locations, existing, and the new one you want to add. Use the following commands to see the current list of input and output locations:

```
tsm configuration get -k maestro.input.allowed_paths  
tsm configuration get -k maestro.output.allowed_paths
```

Next step

Step 5: Optional Server Configurations

## Who can do this

On Windows, members of the local computer Administrators group can run *tsm* commands.

On Linux, members of the **tsmadmin** group can run *tsm* commands. The **tsmadmin** group can be configured using the *tsm.authorized.groups* setting.

Step 5: Optional Server Configurations

The options described in this topic are not required to enable flow publishing and scheduling flows on Tableau Server. They can be used to customizing your environment according to your requirements.

Set the timeout period for flows

You can set time limits for how long a flow can run to make sure that subsequent tasks are not held up due to stalled tasks. The following two *tsm* command options determine how long a flow task can run before the flow background task is canceled. These two commands together determine the total timeout value for flow tasks.

The `backgrounder.default_timeout.run_flow` sets the number of seconds before a flow run task is canceled.

For example:

```
tsm configuration set -k backgrounder.default_timeout.run_flow -v
<new value>
```

```
tsm pending-changes apply
```

(Default value: 14400 seconds or 4 hours)

The `backgrounder.extra_timeout_in_seconds` command sets the number of seconds beyond the setting in `backgrounder.querylimit` before a background job is

canceled. This setting makes sure that a stalled job does not hold up subsequent jobs. The setting applies to processes listed in `backgrounder.timeout_tasks`.

For example:

```
tsm configuration set -k backgrounder.extra_timeout_in_seconds -v  
<value>
```

(Default value: 1800 seconds or 30 minutes)

Check the available resources on the server running flows. It's recommended that you have a dedicated node for Tableau Prep Conductor.

### Set the threshold for suspended flow tasks

By default, a flow task is suspended after 5 consecutive flow task failures. To change the threshold number of flow task failures that can occur before they are suspended, use the following `tsm configuration set` command:

```
tsm configuration set -k backgrounder.flow_failure_threshold_for_  
run_prevention -v <number>
```

This sets the threshold for the number of consecutive failed flow tasks necessary before suspending the tasks. This is a server-wide setting.

## Who can do this

Tableau Server administrators can make changes to server configurations.

## Schedule Flow Tasks

**Note:** Flows can be scheduled to run on Tableau Cloud or Tableau Server using Tableau Prep Conductor. Prep Conductor is licensed through Data Management on a per deployment basis. After you purchase and license Data Management, you must enable Prep Conductor.

Starting in version 2020.4.1, you no longer need the Data Management license to publish flows to the web. As a Creator, you can also create and edit flows directly on your server. For more information authoring flows on the web, see [Tableau Prep on the Web](#).

**Note:** With the 2024.1 release, changes were introduced for flow schedules on Tableau Cloud. The Schedules tab on the left navigation pane has been removed and you can now create custom schedules directly from your flows Scheduled Tasks tab.

To schedule flows to run at a specific time or on a recurring basis you can create scheduled tasks. Scheduled tasks rely on pre-configured schedules. Schedules are created by the System Administrator. For information about how to create schedules on Tableau Server, see [Step 3: Create Schedules for Flow Tasks](#) in the Tableau Server help.

Starting in version 2021.3, you can link flow runs together when scheduling tasks to run flows one after the other. For more information, see [Schedule linked tasks](#) in this topic.

Starting in version 2022.1, you can also run linked tasks via the REST API using the new flow methods **Query Linked Tasks**, **Query Single Linked Tasks**, and **Run Linked Task Now**. For more information, see [Flow Methods](#) in the Tableau REST API help.

### Running flows that include parameters

Starting in version 2021.4, you can include user parameters in your flows to make flows more dynamic. When the flow runs, you are prompted to enter your parameter values. When setting up flows on a schedule, you specify parameter values at that time.

You must specify the parameter values for any required parameters. For optional parameters, you can enter those values as well, or accept the current (default) value for the parameter. For

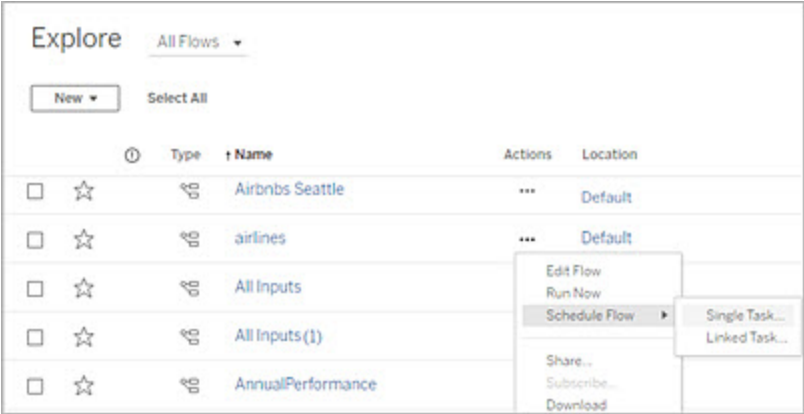

more information about running flows with parameters, see [Run flows on a schedule](#) in the Tableau Prep help.

Starting in Tableau Prep Builder and Tableau Cloud version 2023.2, you can apply date or time system parameters to flow output names for file and published data source output types. The start time is automatically added to the flow output name.

**Note:** Your administrator must enable the **Flow Parameter** server and site settings on your server before you can run flows that include parameters in Tableau Server or Tableau Cloud. For more information, see **Create and Interact with Flows on the Web** in the [Tableau Server](#) or [Tableau Cloud](#) help.

### Schedule a flow task

1. Do one of the following:
  - (version 2022.1 and later) From the **Explore** page, in **List** view, in the **Actions** menu, select **Schedule Flow > Single Task**. If you select a flow in the list, you can also use the top **Actions** menu.

- From the **Overview** page for the flow, **Scheduled Tasks** tab, click **New Task** or click the drop-down and select **Single Task**.

If the output step isn't assigned to a task, you can also create a new task from the **Overview** page. On that page, in the **Schedules** field, click **Create new task**.

2. In the **New Task** dialog, on the **Single Task (New Task** in prior releases) tab, select a schedule from the drop-down list.

3. Select one of the following options:

- **Automatically include all output steps for this flow:**(default) Select this option to include all current and future output steps for this flow in the scheduled task. As new output steps are added to the flow over time, they are automatically included in the schedule when it runs.
- **Select the output steps to include in this task:** Select this option and manually select the output steps to include in this scheduled task.

To include all output steps in the flow task, select the check box next to **Output Steps**. This area can't be edited if the **Automatically include all output steps for this flow** radio button is selected. Select the other radio button to enable this section.

| Output steps                               | Output name                     | Location            | Refresh Type |
|--|---------------------------------|---------------------|--------------|
| Create 'Annual Regional Performance.hyper' | Annual perf_test                | Tableau Server Site | Full refresh |
| Create 'Superstore Sales.hyper'            | Create 'Superstore Sales.hyper' | Tableau Data Engine |              |

4. (version 2020.2.1 and later) Select a **Refresh Type**. For more information about these settings, see [Refresh Flow Data Using Incremental Refresh](#).

**Note:** Starting in version 2020.2.1 and later, if one input is configured to use incremental refresh and it is associated with multiple outputs, those outputs must be run together and must use the same refresh type. Otherwise the flow will fail.

- **Full refresh** (default): Refresh all data and create or append data to your table based on the flow output setting.
- **Incremental refresh**: Refresh only the new rows and create or append data to your table based on the flow output setting. The incremental refresh option is only available when the flow is configured to use this refresh type.

**Note:** Tableau Prep Conductor runs a full refresh for all outputs regardless of the run option you select if no existing output is found. Subsequent flow runs will use the incremental refresh process and retrieve and process only your new rows unless incremental refresh configuration data is missing or the existing output is removed.

New Task

Single Task    Linked Tasks

Select a schedule to run the flow "My Superstore".

Run Flow - Every night - 11:00PM - All days of the week, at 11:00 PM (UTC-08:00) America/Los\_Angeles

Automatically include all output steps for this flow.  
 Select the output steps to include in this task.

| Output steps | Output name               | Location            | Refresh Type |
|--------------|---------------------------|---------------------|--------------|
| Output       | Orders>Returns_Superstore | Tableau Server Site | Full refresh |

Send email when done

Cancel    Create Task

**Full refresh**  
All rows will be processed.

**Incremental refresh**  
Only new rows will be processed.  
Outputs without incremental refresh enabled will be run as a full refresh.

5. (optional) If you are the flow owner, select **Send email when done** to notify users when the flow is successful. For more information about how to send email notifications on flow runs, see [Notify Users of Successful Flow Runs](#).
6. (version 2021.4 and later) If your flows include parameters, enter any required or optional parameter values. You must enter required values for the flow to run.

7. Click **Create Task** to create the scheduled task.

Schedule linked tasks

*Supported in Tableau Server and Tableau Cloud version 2021.3.0 and later.*

**Note:** Starting in version 2022.1, Linked tasks functionality is enabled by default. Server and Site Administrators can turn off this functionality on the **Settings** page and on flow schedules in the **Schedules** dialog. In previous versions, Server Administrators must first enable this functionality to use and manage it. For more information, see Step 2: Configure Flow Settings for your Tableau Server and Step 3: Create Schedules for Flow Tasks.

Use the **Linked Tasks** option to schedule up to 20 flows to run sequentially, one after the other. Easily set up your flow list by selecting your schedule, then select downstream flows to run in the order you choose.

Flows run in the order specified in the list. Use the menu to move flows around in your list or add new upstream or downstream flows to the list at any time.

Select the outputs that you want to include in the flow run and configure the settings to tell Tableau what to do with remaining flows in the schedule when the previous flow run fails.

1. Do one of the following:

- (version 2022.1 and later) From the **Explore** page, in **List** view, in the **Actions** menu, select **Schedule Flow > Linked Task**. If you select multiple flows in the list, you can also use the top **Actions** menu.

- From the **Overview** page for the flow, **Scheduled Tasks** tab, click **New Task** and select the **Linked Task** tab, or click the drop-down and select **Linked Task**.

If the output step isn't assigned to a task, you can also create a new task from the **Overview** page. On that page, in the **Schedules** field, click **Create new task**.

2. In the **New Task** dialog, on the **Linked Tasks** tab, select a schedule from the drop-down list. Only schedules that are enabled for linked tasks are shown.

3. Click the **Select output steps** drop-down to select the flow outputs to run. By default, all flow outputs are included. To select specific outputs, clear the **Include all current and future output steps for this flow** check box.

The flow where the task is initiated is automatically set as the first flow to run, but you can use the menu to change the run order after you add other flows to your list.

4. Select your refresh type from the following options:

**Note:** If one input is configured to use incremental refresh and it is associated with multiple outputs, those outputs must be run together and must use the same refresh type. Otherwise the flow will fail.

- **Full refresh** (default): Refresh all data and create or append data to your table based on the flow output setting.
- **Incremental refresh:** Refresh only the new rows and create or append data to your table based on the flow output setting. The incremental refresh option is only available when the flow is configured to use this refresh type. For more information, see [Refresh Flow Data Using Incremental Refresh](#).

**Note:** Tableau Prep Conductor runs a full refresh for all outputs regardless of the run option you select if no existing output is found. Subsequent flow runs will use the incremental refresh process and retrieve and process only your new rows unless incremental refresh configuration data is missing or the existing output is removed.

5. (optional) If you are the flow owner, select **Send email when done** to notify users when the flow is successful. For more information about how to send email notifications on flow runs, see [Notify Users of Successful Flow Runs](#).
6. Set your flow failure options:
  - **Add data quality warning:** Select the check box to set a warning message on the flow so that users of the data are aware of issues. The message remains until the flow runs successfully. If the flow already has a data quality warning, this option shows selected and can't be turned off.

**Note:** In version 2021.4 and earlier, click the **Flow run monitoring** icon  to open the **Data Quality Warning** dialog.

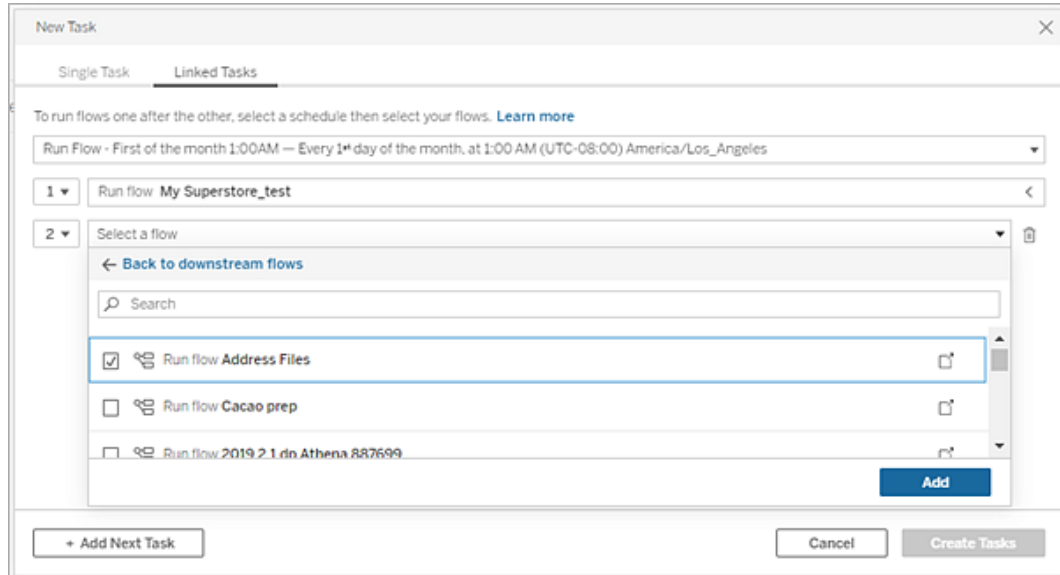

- **Stop remaining tasks:** Select this option to prevent the downstream tasks in the list from being queued to run.
  - **Email me:** Email notifications are automatically sent to the flow owner and the linked task creator when the flow fails, is suspended, or is canceled.
7. (version 2021.4 and later) If your flows include parameters, enter any required or optional parameter values. You must enter required values for the flow to run.

- Click the drop-down for the 2nd task to add your next flow. Flows that use the previous flow's outputs are shown automatically or click **View all flows** to see all available flows.

Select one or more flows and click **Add** or click **Add Next Task** to add more flow run tasks to your list.

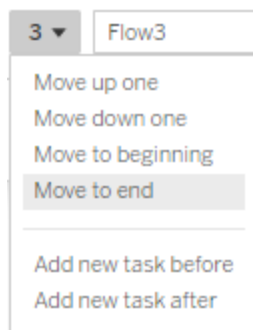

If you don't have permission to run the flow, you must contact the flow owner to grant permissions before adding the flow to your list.

- Repeat steps 3-5 to configure your flow run options.

**Note:** In version 2021.4 and earlier, click the **Edit** icon  next to your new flow to expand the Options pane.

- (Optional) Click the drop-down next to any numbered task to open the menu to change the order of your flow tasks or insert new tasks between existing tasks.

- Click **Create Tasks** to create the scheduled linked tasks.

### Who can do this

- The Server administrator can do this on all sites on the server. The Site administrator can do this on sites they have access to if the site settings to allow users to publish and schedule tasks is enabled.
- For linked tasks, the Server administrator can do this on all sites where the server settings to allow users to schedule linked tasks is enabled. The Site administrator can do this on sites they have access to if the site settings to allow users to schedule linked tasks is enabled.
- Flow owners and project leaders with the Creator site role can create flow tasks for flows or projects that they own respectively.

Site administrators, flow owners, and project leaders can create flow tasks for the flows and projects that they own respectively. Only the Creator site role and above can create or edit a flow task.

For more information, see [Set Users' Site Roles](#) and [Content Ownership and Permissions](#)

## Notify Users of Successful Flow Runs

*Supported in Tableau Prep Builder version 2021.4.1 and later and in Tableau Server and Tableau Cloud version 2021.4 and later. Data Management is required to use this feature.*

Flow owners can subscribe themselves, individual users, and groups to email notifications for information about scheduled tasks for successful flow runs. The email includes links to data within the Tableau environment, or you can optionally include the details of the flow run in attached Excel and CSV files.

Flow subscriptions are added to scheduled tasks for flows. You can add flow subscriptions when you create a new flow task or to an existing flow task. Email notifications are sent when the scheduled task is completed successfully.

Configure the site settings for flow subscriptions

By default, the **Flow Subscriptions** site setting for sending and receiving email notifications is enabled.

## Flow Subscriptions

Flow owners can schedule and send emails with flow output data to themselves and others. [Learn more](#)

- Let users send or receive emails that include flow output data
- Attach .csv and .xlsx flow output files. This option sends data outside of Tableau and is not recommended

- The **Let users send or receive emails that include flow output data** option allows the flow owner to receive, and subscribe users and groups to successful flow run notifications. From the notification email, users can access the full data source or view the flow details from within Tableau.
- (Not recommended) The **Attach .csv and .xlsx flow output files** option lets the flow owner attach files to notification emails. The email recipients must be added to the Tableau server or site, however, the files contain the data source and can be exposed outside of the Tableau system. This option is available only for on-premise environments.

### Publish the Flow

Publish the flow output as either a file, database table, or data source. Consider the following when saving the flow:

- (On-premise only) When publishing you can save the output as a file or as a database table and choose to attach either a .csv or .xlsx file type to the email.
- When publishing and saving the output as a published data source, the email notification provides a link to the flow in Tableau. Files cannot be attached to the email.
- When choosing to save as a file output, you must use a network share and the output and input location must be included in a safe list. For more information, see [Step 4: Safe list Input and Output locations](#).
- Flow subscriptions are supported on Windows and Linux. The following restrictions apply to flow subscriptions on Linux:

- File outputs must be output to a Windows server.
  - For flows that output to a file, use the UNC format for the path: `\\server\path\file-name`. Do not use a local drive letter.
  - The mounted path must be safe listed.
- When attaching files to an email, the file limit is approximately 25 MB for Tableau Cloud. When using an on-premise Tableau Server, you configure the size of attachment files.

#### Add a flow subscription

1. As the owner of the flow, select a published flow in Tableau Server or Tableau Cloud that you want to add subscriptions to for email notifications.
2. You can add subscriptions to a new or existing task:
  - If you are adding a subscription to a new task:
    1. Click **Scheduled Tasks > New Task**.
    2. In the New Task dialog select a schedule to run the flow from the **Select a schedule** drop-down list.
    3. Enable **Send email when done**
  - If you are adding a subscription to an existing task:
    1. Click **Subscriptions > Subscribe**.
    2. In the **Add Flow Subscriptions** dialog, select a schedule from the **Frequency** drop-down list.
3. In the **Send to** field, start typing the name of the user or group to populate the field. Select the users and groups that you want to send a notification to.  
  
Users and groups must be added to the Tableau environment by the administrator.
4. (Optional) To be included in the notification, check the **Send to me** box.
5. (Optional) In the **Subject** field, customize the default email subject line for the flow run notification.
6. (Optional) Add information about the flow run in the **Email message** text box.

7. Click **Include output data** and select the type of output that you want to include in the email.
  - If you published your flow as a file or database table output you can choose to attach .csv or .xlsx files containing the data source to the email. This is not recommended because data can be exposed outside of the Tableau system.

- If you published your flow as a data source, you can choose to include the link to the data source. Attaching files to the email is not supported.

8. If you are adding a subscription to an existing task, click **Subscribe**.

### Unsubscribe from a flow subscription

To unsubscribe from notifications from the email, follow these steps.

1. Click **Unsubscribe** from the bottom of a subscription email.
2. As the flow owner, Sign in to Tableau Server or Tableau Cloud. At the top of the page, click the **Notifications** icon.
3. Expand the ... menu, then select **Remove notification**.

To unsubscribe and remove the subscription as the flow owner, follow these steps.

1. Click **Subscriptions**.
2. Open the published flow in Tableau Server or Tableau Cloud.
3. From the list of flow subscriptions, click the selection box for the flow you want to unsubscribe from.

#### 4. Select **Actions** > **Unsubscribe**.

#### View Subscriptions

You can view your current flow subscriptions in Tableau Server or Tableau Cloud.

- From the **Subscriptions** tab on the **Overview** page of the flow, you can see the list of current subscriptions.
- From the **Subscriptions** tab on the **Tasks** page, you can see the list of subscriptions along with subscriptions to workbooks.

#### Resume suspended flow subscriptions

Sometimes, subscriptions fail because of an issue with the flow. If a subscription fails more than five times, you'll receive a notification email that your scheduled flow task has been suspended.

From the flow Overview page, you can see when a scheduled flow task fails.

| Overview                  | Connections | Scheduled Tasks | Run History                    | Subscriptions                 | Lineage               |
|---------------------------|-------------|-----------------|--------------------------------|-------------------------------|-----------------------|
| Description               |             |                 |                                |                               |                       |
| No description available. |             |                 |                                |                               |                       |
| Run All                   | Output step | Output name     | Status                         | Schedule                      | Errors                |
| Run                       | Output      | Output          | Failed: Nov 15, 2021, 3:00 ... | Run Flow - Every night - 11:0 | <a href="#">Error</a> |

There are a few ways to resume a suspended flow task. If you're flow owner:

- From the My Content area of Tableau web pages, an icon appears in the Last update column to indicate that the subscription is suspended. Select ... > **Resume Scheduled Tasks** to resume.

## Tableau Server on Linux Administrator Guide

- From the Scheduled Tasks page, an icon appears in the last update column to indicate that the subscription is suspended. Select the flow, then click **Actions > Resume**.

Access the flow data from a notification email

Depending on how the flow notification was configured, you can access the data source and file attachments from the notification email.

- Click View Flow to open the flow in Tableau Server or Tableau Cloud.
- Click the attachment file to view the flow data.

### Who can do this

- Flow owners can create flow notification subscriptions for flows that they own.
- To receive notifications, users and groups must be added to the Tableau environment by the administrator.

For more information, review the following articles:

- Windows: [Set Users' Site Roles](#) and [Content Permissions and Ownership](#)
- Linux: [Set Users' Site Roles](#) and [Content Permissions and Ownership](#)

## Manage a Flow

Once you publish a flow to Tableau Server or Tableau Cloud, you can manage your flows and make changes to them as necessary. This topic describes the various actions you can take to manage your flows.

**Note:** The content in this topic applies to both Tableau Server and Tableau Cloud, exceptions are called out specifically.

### Managing your flows

#### Following is a list of actions you can take to manage your flows:

- **Create flows:** Starting in version 2020.4, as a Creator you can create flows directly on the web. From the **Home** page, click **Create > Flow** or from the **Explore** page, click **New > Flow**. For more information, see [Tableau Prep on the Web](#).
- **Edit flows:** Starting in version 2020.4, as a Creator you can edit flows directly on the web. Navigate to the list of flows, select **Actions** and click **Edit Flow**, or open a flow and click the **Edit** button.

When you edit a flow, your changes are moved to a draft state. When you're finished, publish your flow to commit your changes and create a new version of the flow. For more information, see [Autosave and working with drafts](#).

- **Run flows:** You can manually run a flow in addition to creating scheduled flows tasks that run at a specific time.

**Note:** The Data Management is not required to manually run flows, but is required to schedule flows to run.

- Navigate to the list of flows, select one or more flows you want to run, select **Actions** and click **Run Now**.

- **Tag:** Tags are keywords you can create for flows to help you find, filter, and categorize content. Authors can add tags to flows when they publish it. But you can also add tags to any workbook, view, or data source that you are allowed to access and you can delete any tags you have added. You can add a tag to a list of flows.

Navigate to the list of flows, select one or more items you want to tag, select **Actions** and click **Tag**. To add a tag to a specific flow you can do it from the list of flows as described above. Open the Flow, from the Overview tab, select **Actions**, and click **Tag**.

- **Change Owner:** Administrators and flow owners can change owners, and only to themselves.
- **Permissions:** You can set permissions for users and specify if they can perform edit actions like save, download, move to a different project and delete. In addition, you can specify who can view and run the flow.
- **Download:** You can download a flow to view or modify it using Tableau Prep Builder. To download a flow, you need download permissions. You'll have that by default if you are the owner, but you might need to add it for other users.
- **Revision History:** When you make a change to the flow, and republish it to the same project with the same name, a new version of the flow is created. You can view the revision history by selecting revision history from the actions menu. Flow owners have permissions to restore a previous version of a flow.
- **Move:** You can move flows between projects. To move a flow, users need Move permission. You'll have that by default for flows you own, but you might need to add it for other users.
- **Rename:** You can rename a flow. To rename a flow, users need the Save permission. You'll have that by default for flows you own, but you might need to add it for other users.

## Tableau Server on Linux Administrator Guide

- **Delete:** You can delete a flow. To delete a flow, users need the Delete permission. You'll have that by default for flows you own, but you might need to add it for other users.

Who can do this

## Tableau Server Administrator

**Can do the following tasks across all the sites:**

- Create flows
- Edit published flows
- View a list of all draft flows
- Run flows
- Delete flows
- Download flows
- Change Owner
- Change Permissions
- Change Project
- Add/Remove Tags
- Change Description
- Change Name
- Update Flow Task
- Delete Flow Task

- Create a Flow Task\*
- Version Management\*

\*Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. Only Server Administrators can create a schedule.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:
  - Revision history must be enabled on the site.
  - User role is allowed to publish to the project.

## Tableau Site Administrator

**Can do the following tasks on flows published to the sites that they are site administrator for:**

- Create flows
- Edit published flows
- View a list of all draft flows
- Run flows
- Delete flows
- Download flows
- Change Owner
- Change Permissions

## Tableau Server on Linux Administrator Guide

- Change Project
- Add/Remove Tags
- Change Description
- Change Name
- Update Flow Task
- Delete Flow Task
- Create a Flow Task\*
- Version Management\*

Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. Only Server Administrators can create a schedule.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:
  - Revision history must be enabled on the site.
  - User role is allowed to publish to the project.

## Project Leader

**Can do the following tasks on flows published to the projects where they have project leader permissions:**

- Create flows
- Edit published flows
- Run Flows
- Delete
- Download
- Change Permissions
- Change Project
- Add/Remove Tags
- Change Description
- Change Name
- Update Flow Task
- Delete Flow Task
- Create a Flow Task\*
- Version Management\*

\*Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. Only Server Administrators can create a schedule.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:

- Revision history must be enabled on the site.
- User role is allowed to publish to the project.

## Project Owner

**Can do the following tasks on flows published to the projects that they own:**

- Create Flows
- Edit published flows
- Run Flows
- Delete
- Download
- Change Permissions
- Change Project
- Add/Remove Tags
- Change Description
- Change Name
- Update Flow Task
- Delete Flow Task
- Create a Flow Task\*
- Version Management\*

\* Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. Only Server Administrators can create a schedule.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:
  - Revision history must be enabled on the site.
  - User role is allowed to publish to the project.

## Flow Owner

### **Can do the following tasks on flows that they own:**

- Create Flows
- Edit Draft (flows they own) and Published Flows
- Run flows
- Delete flows
- Download flows
- Change Owner
- Change Permissions
- Change Project
- Add/Remove Tags
- Change Description
- Change Name

## Tableau Server on Linux Administrator Guide

- Update Flow Task
- Delete Flow Task
- Create a Flow Task\*
- Version Management\*

\*Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. Only Server Administrators can create a schedule.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:
  - Revision history must be enabled on the site.
  - User role is allowed to publish to the project.

## User with Creator License

**Can do the following tasks:**

- Create Flows
- Edit Draft (flows they own) and Published Flows
- Run Flows (with Run flow permissions)
- Delete (with delete permissions)
- Download (with download or Save as, and read permissions)
- Change Permissions (with Change Permissions)

- Change Project (with move permissions, and write permissions on the destination project)
- Add/Remove Tags (with read permissions)
- Change Description (with Save permissions)
- Change Name (with Save permissions)
- Update Flow task (with Execute permissions)
- Delete Flow Task (with Execute permissions)
- Create a Flow Task\* (with Execute permissions)
- Version Management\* (with view, read, save as, download permissions)

\* Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. Only Server Administrators can create a schedule.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:
  - Revision history must be enabled on the site.
  - User role is allowed to publish to the project.

## User with Explorer License

**Can do the following tasks:**

**Note:** Starting in version 2020.4, Explorer license users can no longer run flows on Tableau Server.

- Explorer license users (with Run flow permissions) can run flows on Tableau Cloud.
- Delete (with delete permissions)
- Download (with download or Save as, and read permissions)
- Change Permissions (with Change Permissions)
- Change Project (with move permissions and write permissions on the destination project)
- Add/Remove Tags (with read permissions)
- Change Description (with Save permissions)
- Change Name (with Save permissions)
- Update Flow task (with Execute permissions)
- Delete Flow Task (with Execute permissions)
- Create a Flow Task\* (with Execute permissions)
- Version Management\* (with view, read, save as, download permissions)

\*Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. Only Server Administrators can create a schedule.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:

- Revision history must be enabled on the site.
- User role is allowed to publish to the project.

## User with Viewer License

Viewers cannot manage flows, they can however view the flow and the different versions of the flow.

For more information about the full capabilities you can set on flows, see [Permission capabilities](#).

## Monitor Flow Health and Performance

After you publish flows and schedule them to run periodically, you want to know that they are running as expected and resolve any issues as they occur. You will also want to monitor and understand the performance of your flows.

This topic describes the various methods that Tableau Server provide to help you monitor your flows.

Detect issues as they occur and resolve them

You can set up Tableau Server to send email notifications when flows fail, or find and review errors on Tableau Server using the Alerts menu or by reviewing the flow pages for the flows that you are interested in. This type of monitoring allows you to detect problems as they occur.

Get notifications when a flow fails:

You can configure Tableau Server to send notifications about flow failure through email, on the Tableau site, or Slack. To set up notifications for your Tableau Server and sites, follow the instructions in [Step 2: Configure Flow Settings for your Tableau Server](#).

View and resolve errors

**Note:** Starting in version 2020.4.1, you can now create and edit flows directly in Tableau Server and Tableau Cloud. The content in this section applies to all platforms, unless specifically noted. For more information about authoring flows on the web, see Tableau Prep on the Web.

The following errors can happen when running a flow:

- **Connection errors:** Connection errors generally happen when Tableau Server is unable to connect to one or more data inputs or is unable to make a connection in one or more output steps.
  - For Input connection errors, use the **Edit connections** option on the **Connections** tab to make changes to connection details, then run the flow again.
  - For output connection errors, check the output location for the flow output steps. If the flow output is going to a network share, make sure the output steps are pointing to a safe listed location. After you make any changes republish the flow and try running it again.

**Note:** To fix output connection errors for flows that output to a file or network share, download the flow to Tableau Prep Builder, then republish the flow to your server. Flows that output to a published data source or database can be edited directly on the web.

- **Errors in the flow:** If there are errors in one or more steps in the flow, you will see an error message. You can edit the flow directly on the web and republish it. You can also download the flow to Tableau Prep Builder, resolve the errors, republish the flow to the server and then run the flow again.

- **Suspended flow tasks:** When a scheduled flow task fails to run after a configured number of attempts, the flow task is suspended. By default, a flow task is suspended after 5 consecutive flow tasks failures.

A flow can have multiple scheduled tasks assigned to it, but only the failed tasks are suspended. All other flow tasks will continue to run unless they have errors. To resolve a suspended task, review and resolve the errors then run the flow on-demand or let the flow run automatically based on the assigned schedule.

**Note:** Server administrators can configure the number of attempts before a flow run is suspended using the tsm configuration set option. For more details, see [Step 5: Optional Server Configurations](#).

You can view errors on the following pages:

## Flow Overview page

On this page you can see the status of the most recent flow run and any errors. Hover on the error text to review the error details. If a scheduled task is suspended, a warning icon shows next to the schedule. Hover on the icon to view the status.

After you resolve the error that caused the flow to fail or the task to be suspended, you can run the flow manually or let the flow run based on the assigned schedule. For suspended flow tasks, click the **Go to Scheduled Task** link on the tooltip for the suspended task to navigate to the **Scheduled Tasks** page and click the **Resume Scheduled Tasks** button to resume the suspended tasks.

## Tableau Server on Linux Administrator Guide

The screenshot shows the 'Tableau Prep Crane' interface. At the top, it displays the crane name 'Tableau Prep Crane', owner 'DataRockstar', and modification time 'Feb 26, 2020, 12:47 PM'. Below this is an 'Edit Flow' button and a navigation menu with 'Overview', 'Connections', 'Scheduled Tasks', 'Run History', and 'Lineage'. The 'Overview' tab is active, showing a description 'No description available.' and a table with columns: 'Run All', 'Output step', 'Output name', 'Status', 'Schedule', and 'Errors'. The table contains three rows for 'Output' and 'Output 2'. An error message is displayed over the table, stating: '1 error: Incremental refresh on step "Output" failed, the last processed filter value was blank or null. Try run the output again in full refresh setting. Download the flow'. Below the table is a flow diagram with steps: 'Aluminum\_Pla...', 'Grouping', 'Months', 'Crane Name', 'Name = Age', 'Change to date', and 'Output'. A 'Warning' icon is visible near the 'Age of Cranes' step.

### Connections page

The **Connections** page shows the most recent status and any related connectivity errors. To correct input errors, click the **More actions** ... menu for an input connection to edit the connection and change the server name, port, user name and password.

To fix output connection errors, edit the flow directly or download the flow in Tableau Prep Builder, correct the file path, then republish the flow to continue running it.

The screenshot shows the 'Connections' page for '2019.2Athena'. It displays the crane name, owner 'DataRockstar', and modification time 'May 30, 2019, 12:57 PM'. Below this is an 'Edit Flow' button and a navigation menu with 'Overview', 'Connections', 'Scheduled Tasks', 'Run History', and 'Lineage'. The 'Connections' tab is active, showing a table with columns: 'Connects to', 'Connection type', 'Authentication', 'Username', 'Input steps', 'Output Steps', and 'Errors'. The table contains two rows: 'athena.amazonaws.com' (Amazon Athena) and 'https://server' (Tableau Server Site). An error message is displayed over the table, stating: '1 error: Incorrect username or password. Edit the connection to provide a valid username and password.' A 'Warning' icon is visible at the top right of the page.

### Scheduled Tasks page

**Note:** The Data Management is required to see this tab.

View the scheduled tasks assigned to a flow. If a scheduled task is suspended, you can see the status of that tasks here and you can manually resume the flow tasks from this page.

Before resuming a suspended task, resolve any errors in the flow.

Error details are not shown on this page, but you can review them on the **Overview** or **Run History** pages. You can also click the links in the **Schedule type** column to view the details of what was scheduled and to edit the tasks.

A suspended scheduled task will automatically resume when the flow is republished, if you edit a connection for the flow or manually run the flow tasks. To manually resume a suspended tasks, on the **Scheduled Tasks** page, click **Resume Scheduled Tasks**. This resumes all suspended tasks for the flow.

To resume individual tasks, click the **More actions** **...** menu for a scheduled task and select **Resume**. You can also click **Run Now** to run all tasks for the flow immediately.

The screenshot shows the 'Scheduled Tasks' tab for a flow named 'My Super Test flow'. The page includes a navigation bar with 'Overview', 'Connections', 'Scheduled Tasks', 'Run History', and 'Lineage'. Below the navigation bar is a table with columns: Schedule type, Schedule, Actions, Output steps, Status, Last Run, and Next Scheduled Run. Two tasks are listed:

| Schedule type                                    | Schedule  | Actions | Output steps  | Status    | Last Run | Next Scheduled Run    |
|--|---|---------|---|-----------|----------|-----------------------|
| <input type="checkbox"/> Flow (1/2 linked tasks) | Run Flow - Every night - 11:00PM - All days of the week, at 11:00 PM (UTC-08:00) America/Los_Angeles                      | ...     | Create 'Annual Regional Performance hyper' (~~/My Tableau P... +1 | Failed    | Never    | Sep 2, 2021, 11:00 PM |
| <input type="checkbox"/> Flow (2 outputs)        | Run Flow - First of the month 1:00AM - Every 1 <sup>st</sup> day of the month, at 1:00 AM (UTC-08:00) America/Los_Angeles | ...     | Create 'Annual Regional Performance hyper' (~~/My Tableau P... +1 | Scheduled | Never    | Oct 1, 2021, 1:00 AM  |

## Run History page

**Note:** The Data Management is required to see this tab.

The **Run History** page shows the details of all the flow runs that have either completed or are in progress for each output. View any error details by hovering over the errors in the **Errors** column. The duration column shows you the run time of the flow.

**Note:** Starting in version 2020.2.1, the **Run Type** field shows the refresh type for the output. In prior releases this field showed whether the output was run on a schedule or on-

demand. For more information about setting up output refresh types, see [Refresh Flow Data Using Incremental Refresh](#).

The screenshot shows the Tableau Prep Crane interface for a flow named 'Tableau Prep Crane'. The 'Run History' tab is active, displaying a table of execution records. The table columns are: Output step, Run type, Run start, Run end, Duration, Status, Rows generated, and Errors. The table contains 11 rows of data, with some rows marked as 'Failed' and others as 'Succeeded'. An error tooltip is visible over one of the failed rows, providing details about the failure.

| Output step | Run type            | Run start             | Run end               | Duration | Status    | Rows generated | Errors                |
|-------------|---------------------|-----------------------|-----------------------|----------|-----------|----------------|-----------------------|
| Output 2    | Full refresh        | Jul 3, 2020, 2:29 AM  | Jul 3, 2020, 2:29 AM  | 00:00:06 | Succeeded | 7              |                       |
| Output      | Incremental refresh | Jul 2, 2020, 2:29 AM  | Jul 3, 2020, 2:29 AM  | 00:00:04 | Failed    | 0              | <a href="#">Error</a> |
| Output      | Incremental refresh | Jul 2, 2020, 2:28 AM  | Jul 2, 2020, 2:28 AM  | 00:00:04 | Failed    | 0              | <a href="#">Error</a> |
| Output 2    | Full refresh        | Jul 2, 2020, 2:28 AM  | Jul 2, 2020, 2:28 AM  | 00:00:06 | Succeeded | 7              |                       |
| Output 2    | Full refresh        | Jul 1, 2020, 2:29 AM  | Jul 1, 2020, 2:29 AM  | 00:00:06 | Succeeded | 7              |                       |
| Output      | Incremental refresh | Jul 1, 2020, 2:29 AM  | Jul 1, 2020, 2:29 AM  | 00:00:04 | Failed    | 0              | <a href="#">Error</a> |
| Output 2    | Full refresh        | Jun 30, 2020, 2:30 AM | Jun 30, 2020, 2:30 AM | 00:00:06 | Succeeded | 7              |                       |
| Output      | Incremental refresh | Jun 30, 2020, 2:30 AM | Jun 30, 2020, 2:30 AM | 00:00:04 | Failed    | 0              | <a href="#">Error</a> |
| Output      | Incremental refresh | Jun 29, 2020, 2:29 AM | Jun 29, 2020, 2:29 AM | 00:00:04 | Failed    | 0              | <a href="#">Error</a> |
| Output 2    | Full refresh        | Jun 29, 2020, 2:29 AM | Jun 29, 2020, 2:29 AM | 00:00:06 | Succeeded | 7              |                       |

**1 error**  
Incremental refresh on step "Output" failed, the last processed filter value was blank or null. Try run the output again in full refresh setting.  
[Download the flow](#)

## Alerts

When a flow fails, the alerts menu is populated with the error details with the option to re-run the flow, or download the flow to troubleshoot.

**Note:** Flow owners, Server or Site Administrators can see this menu.

Tableau Prep Conductor process status

- The Tableau Services Manager (TSM) status page is accessible in TSM and can be viewed by TSM administrators. You must be able to log into TSM to see this page.
- The Tableau Server status page appears in the Tableau Server web UI and is accessible by Tableau Server administrators. If you hover your mouse pointer over the status indicator for a process, a tooltip shows the node name and the port the process is running on. The Tableau Server status page does not show TSM processes.

The screenshot shows the Tableau Server Status page. The top navigation bar includes 'tableau', 'STATUS', 'MAINTENANCE', and 'CONFIGURATION'. The main content area is titled 'node1' and lists various processes with their status indicated by green checkmarks. A legend at the bottom identifies the status icons: Active (green checkmark), Busy (blue square), Degraded (red triangle), Error (red square), and Stopped (grey square).

| Process                            | Status |
|------------------------------------|--------|
| Gateway                            | Active |
| Application Server                 | Active |
| Interactive Microservice Container | Active |
| VizQL Server                       | Active |
| Cache Server                       | Active |
| Cluster Controller                 | Active |
| Search & Browse                    | Active |
| Backgrounder                       | Active |
| Background Microservice Container  | Active |
| Data Server                        | Active |
| Data Engine                        | Active |
| File Store                         | Active |
| Repository                         | Active |
| Tableau Prep Conductor             | Active |
| Ask Data                           | Active |
| Elastic Server                     | Active |
| TSM Controller                     | Active |
| License Server                     | Active |

When Tableau Server is functioning properly, Tableau Prep Conductor will show as Active or Busy:

- **Active**—The process is functioning as intended.
- **Busy**—The process is completing some task.
- **Down**—The process is down. The implications of this differ depending on the process.
- **Status unavailable**—Tableau Server is unable to determine the status of the process.

Who can do this

- **Tableau Server Administrators:**
  - Setup email notifications at the server level
  - Set up email notifications for a site
  - View errors
  - Resume suspended tasks
  - View alerts
  - view process status
- **Tableau Site Administrators:**
  - Set up email notifications at the site level
  - View errors
  - Resume suspended tasks
  - View alerts
- **Flow owners, project leaders and any user who is granted permissions to view the flow:**
  - View errors
  - Resume suspended tasks
  - View alerts (Flow owners)

Administrative Views for Flows

Administrative views can be used to monitor the activities related to flows, performance history, and the disk space used. The **Status** page contains an embedded Tableau workbook

with various administrative views that can be used to monitor different types of server or site activity.

For **Tableau Server** installations, you must install PostgreSQL drivers before you can see Administrative views. For more information, see [Database Drivers \(Linux\)](#), [Database Drivers \(Windows\)](#). Server administrators can use these views to see activity both at the server level (aggregated for all sites) or for a specific site. Only server administrators can filter by site.

Who can do this?

Tableau Server administrators and Tableau Site administrators can both view and work with Administrative Views. Only Server administrators can filter by site.

### Action by all users

Use this view to gather insight into how flows are being used. This includes actions like publish, download, and flow runs. You can filter the view by actions, by site, and by time range. The Total Users count shows the number of users who have performed an action. This value is not affected by any filtering. The Active user count shows the number of users who have been active during the selected time period and performed one of the selected actions.

# Tableau Server on Linux Administrator Guide

## Action by Specific User

Use this view to gather insights about how an individual user is working with flows. You can filter the view by user name, the type of action, time range, and by site.

## Action by Recent Users

This view shows you which users have been active on Tableau Server over the past 24 hours.

This can be useful if you need to do some maintenance activity on the server and want to know which users and how many this will affect, and what they're doing.

The view shows **Active**, **Recently Active**, and **Idle** users that are currently signed in to Tableau Server.

For this view, an active user is one who took an action in the last 5 minutes, a recently active user is one who last took an action within 30 minutes, and an idle user is one who last took an action more than 30 minutes ago.

Select a user to see only the actions that user performed recently. Hover over an action to see details of the action.

### Backgrounder Task Delays

This view shows the delay for extract refresh tasks, subscription, and flow tasks—that is, the amount of time between when they are scheduled to run and when they actually run. You can use the view to help identify places you can improve server performance by distributing your task schedules and optimizing tasks.

Possible reasons for the delays and ways to reduce the delays include the following:

## Tableau Server on Linux Administrator Guide

- Many tasks are scheduled for the same time.

In the example view, tasks that show long delays are clustered at the same time every day, which creates spikes in the wait time. You can set the Timeline filter to a single day to view task delays by hour and identify the hours of the day when many tasks are scheduled at the same time. One solution is to distribute the tasks to off-peak hours to reduce load on the server.

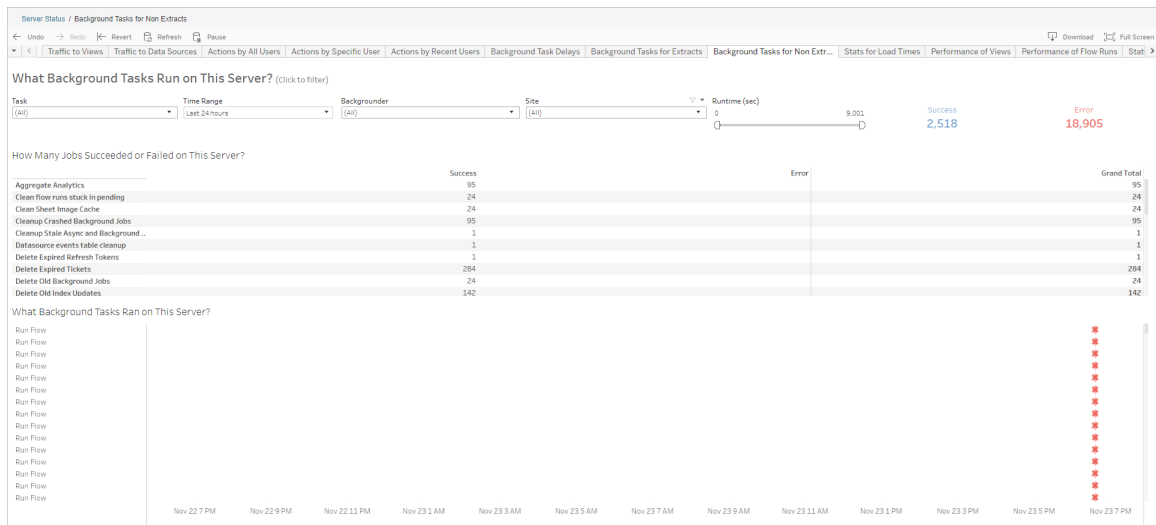

- Other server processes running at the same time are consuming server resources and slowing down performance.

Monitor the CPU and memory usage of server processes to identify processes that consume the most resources, then adjust the configuration of processes on your server.

For more information on monitoring processes, see [Collect Data with Windows Performance Monitor](#).

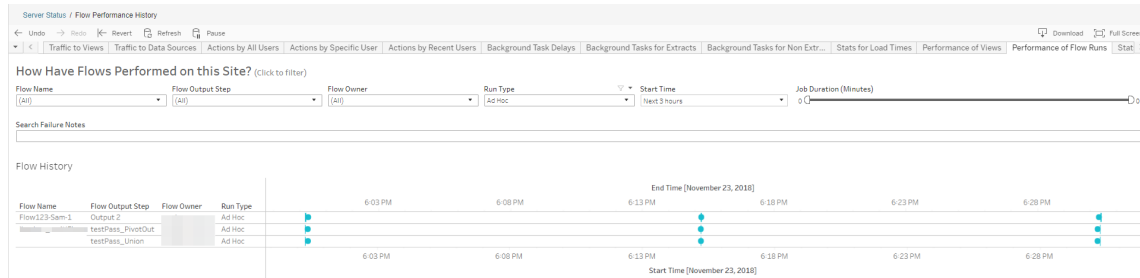

### Background Tasks for Non Extracts

Background Tasks are created to run flows (scheduled and ad hoc). You can use this view to see how many flow tasks succeeded or failed on this site. For details on a task, hover over its icon.

## Performance of Flow Runs

Use this view to see the performance history for all the flows on a site. You can filter by Flow Name, Output Step Name, Flow Owner, Run Type (Scheduled or Ad Hoc), and the time the flow runs were started.

Questions you can answer using this view include:

- **What flow tasks are currently scheduled?** – To do this, use the Start Time filter and select the time frame you want to look at. For example, to see flow tasks that are scheduled in the next 3 hours, select **Hours** -> **Next** -> and enter **3**.
- **What is the duration of flow tasks?** - To answer this, click on a mark in the view to see details, including the task duration.
- **How many flows were run ad hoc, and how many were scheduled runs?** - To answer this, use the **Run Type** filter and select **Ad hoc** or **Scheduled**.

This view can also show you the following information:

- Flows with the highest run frequency have the most marks.
- To see flows that are currently running at the same time, hover over a mark that shows **“In Progress”** or **“Pending and select “Keep Only”** to filter all flow runs that are currently running.
- To see flows that are running at the same time during a specific time range, select a

range for the **Start Time** filter. For example, select **“Next three hours”** to see which flows will be running in the next three hours.

### Stats for Space Usage

Use this view to identify which flow outputs are taking up the most disk space on the server. Disk space usage is displayed by user, project, and by the size of flow output and is rounded down to the nearest number.

Use the Min Size filter to control which flow outputs are displayed, based on the amount of space they take up. Use the object type filter for flows.

- **What Users Use the Most Space** – This section shows the users who own flows (when filtered for flows) that are taking up the most space. Click a user name to filter the next two graphs for that user.
- **What Projects Use the Most Space** – This section shows the projects with flows (when filtered for flows) that are using the most space.
- **What Workbooks, Data Source and Flows Use the Most Space** – This section shows the flows (when filtered for flows) that take up the most space.

Who can do this

- **Tableau Server Administrators:**
  - Setup email notifications at the server level
  - Set up email notifications for a site
  - View errors
  - Resume suspended tasks
  - View alerts
  - view process status
- **Tableau Site Administrators:**
  - Set up email notifications at the site level
  - View errors
  - Resume suspended tasks
  - View alerts
- **Flow owners, project leaders and any user who is granted permissions to view the flow:**
  - View errors
  - Resume suspended tasks
  - View alerts (Flow owners)

## Developer Resources - REST APIs

Use Tableau Server REST APIs to automate and seamlessly integrate Tableau into your existing workflows. Tableau Server REST API gives you programmatic access to work with your content, users, sites, and now flows. Manage provisioning, permissions, and publishing on Tableau Server or Tableau Cloud via HTTP. The REST API gives you access to the functionality behind the data sources, projects, workbooks, site users, sites, and flows. You can use this access to create custom applications or to script interactions with server resources.

Tableau REST API supports the following flow functionality:

New flow endpoints have been added to support publishing flows, scheduling flows, running flows on demand, managing permissions, downloading flows and such. For a full list of all the new REST API endpoints for flows, see [Flow Methods](#).

In addition, **existing endpoints** have been updated to support flow functionality such as Creating New Schedules for Flows, Creating new sites, updating existing sites, and managing default permissions.

**Note:** The Data Management license is required when using REST API to run flows.

## About Tableau Catalog

Data is increasing in volume, formats, and importance leading to more complex environments. With the rapid pace that data changes, it can be hard to keep track of that data and how it's being used in such complex environments. At the same time, more users need to access more of that data in more places, and it's difficult for users to find the right data. Ultimately, this causes a lack of trust in the data because people question whether they're using the right source or if the source is up to date.

Tableau Catalog integrates features like lineage, impact analysis, data dictionary, data quality warnings, and search into your Tableau applications, helping solve these problems differently from a stand-alone catalog. It focuses on both IT and the end user so that everyone using Tableau Server or Tableau Cloud has more trust in and visibility into the data, while also enabling more discoverability. Tableau Catalog builds a catalog out of the Tableau content being used by your organization, enabling comprehensive functionality like the following:

- **Impact analysis and lineage.**
  - You can see the workbooks and other Tableau content that depend on particular columns or fields from tables or data sources you manage. When you need to make changes to your data, you can notify the impacted Tableau authors using email.
  - As a workbook author, you can use lineage to trace the fields that your workbook depends on.
  - As a user, when you use a Tableau visualization, you can see where the data came from that was used to create the view.
- **Curation and trust.** As a data steward, you can add helpful metadata, like descriptions and certification, so that users find the right data. You can set data quality warnings,

view data details on the Data Details pane, certify assets, and remove assets from the catalog.

- **Data discovery.** In Tableau Desktop or Tableau web authoring, you can use Tableau Catalog to search for databases, tables, data sources, and virtual connections to analyze in Tableau and connect to them from the search results.

Starting in 2019.3, Tableau Catalog is available as part of the Data Management offering for Tableau Server and Tableau Cloud. When the product key is active and enabled, the catalog features described above are integrated into the product you're using, so you can work with the data where you find it.

## How Tableau Catalog works

Tableau Catalog discovers and indexes all the content on your site—workbooks, data sources, sheets, virtual connections, and flows—to gather metadata about the content. From the metadata, external assets (databases, tables, and other objects) are identified. Knowing the relationships between the content and the external assets enables Tableau to display the lineage of the content and external assets. Tableau Catalog also enables users to connect to external assets using Tableau Server or Tableau Cloud.

Users on your site can publish or delete content, can attach data quality warnings or certifications, or do anything else that changes the content or its metadata on the site, and Tableau Catalog will update its information accordingly.

For information about how you can use Tableau Catalog to support data governance in your organization, see [Governance in Tableau](#) in the Tableau Blueprint Help.

## Key Tableau Catalog terms

- **Metadata.** Information about the data.
- **Tableau content.** Content created in Tableau such as workbooks, data sources, virtual connections, and flows.
- **External assets.** The metadata about the databases and tables used by Tableau content that's published to Tableau Server or Tableau Cloud.

## License Tableau Catalog

Tableau Catalog is licensed through Data Management. For information about how Data Management licensing works, see License Data Management.

## Enable Tableau Catalog

After Tableau Server or Tableau Cloud is licensed with the Data Management, you can enable Tableau Catalog by doing one of the following tasks:

- **For Tableau Cloud**, no action is necessary. Tableau Catalog is on by default, configured to use derived permissions, and ready to use. For more information about derived permissions, see the Permissions on metadata topic.
- **For Tableau Server**, the Server admin must first enable the Tableau Metadata API using the `tsm maintenance metadata-services` command. For more information, see Enable Tableau Catalog.

After the Metadata API is enabled, Tableau Catalog is on by default, configured to use derived permissions, and ready to use. For more information about derived permissions, see the Permissions on metadata topic.

## Features and functionality

To learn more about the features you can use with Tableau Catalog, see the following Help articles:

### Data discovery

- In the **Connect** pane on Tableau Desktop, under **Search for Data** select **Tableau Server** to [connect to data using Tableau Server or Tableau Cloud](#). When Tableau Catalog is enabled, in addition to searching for published data sources to connect to, you can now search for and connect to the specific databases, tables, and objects used by published data sources and workbooks on your Tableau Server or your Tableau Cloud site.
- **Search** is expanded to include results based on columns, databases, tables, and other objects when Tableau Catalog is enabled.
- If you author in the web, in addition to published data sources, you can also [connect to databases and tables](#).

- If you use Tableau Prep on the web, you can [create new flows based on external assets](#), such as databases and tables.
- If you [connect to Salesforce Data Cloud](#), you'll see support for native Data Cloud objects built into Tableau Catalog. Data Lake Objects (DLOs), Data Model Objects (DMOs), and calculated insights appear distinct in search, connect, and lineage pages, which makes discovering, connecting to, and reusing them simpler.

### Curation and trust

- [Certify your data assets](#) to help users find trusted and recommended data.
- Set [data quality warnings](#) to alert users to data quality issues, such as stale or deprecated data.
- Add [sensitivity labels](#) to warn users about data that needs to be handled with care.
- Add [custom labels](#) to classify data in ways that suit the needs of your organization
- [Manage data labels](#) to extend the label names and categories available to users.
- Categorize items on Tableau Server and Tableau Cloud using [tags](#) to help users filter external assets.
- Better understand published visualizations by using the [Data Details](#) tab to see information about the data used.
- [Add descriptions](#) to databases, tables, and columns to help users find the data they're looking for.

### Lineage and impact analysis

- Use [lineage](#) to trace the source of your data and to analyze the impact of changes to your data and identify which users might be impacted.
- [Email owners](#) of a workbook, data source, or flow about data-related updates. Do the same with database, table, or object contacts.

### Developer resources

You can use metadata methods in the Tableau REST API to programmatically update certain metadata. For more information about the metadata methods, see [Metadata Methods](#) in the Tableau Server REST API.

In addition to the REST API, you can use the [Tableau Metadata API](#) to programmatically query metadata from the content published to Tableau Server or Tableau Cloud. The Metadata API is fast and flexible and is best when you are looking to find out specific inform-

ation about the relationship between metadata and its structures. Explore and test queries against the Metadata API using an interactive in-browser tool called [GraphiQL](#).

**Note:** Data Management is not required to use the Metadata API or GraphiQL.

## About Virtual Connections and Data Policies

Virtual connections are a Tableau content type, along with data sources, workbooks, and flows, to help you see and understand your data. Virtual connections provide a central access point to data. Another key feature introduced with virtual connections is data policies, which support row-level security at the connection level, rather than the workbook or data source level. Row-level security data policies are applied to any workbook, data source, or flow that uses the virtual connection.

A virtual connection can access multiple tables across several databases. Virtual connections let you manage extracting the data and the security in one place, at the connection level.

For information about row-level security options, see an [Overview of Row-Level Security Options in Tableau](#).

Not every virtual connection has an associated data policy. You can also use a virtual connection simply as a central place to manage connection credentials.

## Key terms

- **Virtual connection.** A sharable resource that provides a central access point to data.
- **Connection.** The server name, database, and credentials you use to access data. A virtual connection has one or more connections. Each connection accesses one database or file.
- **Virtual connection table.** A table in a virtual connection.
- **Data policy.** A policy that's applied to one or more tables in a virtual connection to filter data for users. For example, use a data policy to apply row-level security to tables in a virtual connection.
- **Policy table.** A fact or data table in a data policy that is filtered.
- **Policy column.** A column that's used to filter the data in the policy tables. A policy column can be in a policy table or in an entitlement table.
- **Entitlement table.** A table that includes both a policy column you can use to filter policy tables and another column you can relate (map) to a column in a policy table.
- **Policy condition.** An expression or calculation that is evaluated for every row at query time. If the policy condition is TRUE, then the row is shown in the query.

## License virtual connections and data policies

Virtual connections and data policies are licensed through Data Management. For information about how Data Management licensing works, see [License Data Management](#).

## Enable virtual connections and data policies

Virtual connections and data policies are automatically enabled on Tableau Server and Tableau Cloud with Data Management.

## Permissions

Permissions for virtual connections work much like the permissions for other Tableau content. After you publish a virtual connection, anyone can view the connection. However, only the connection creator and administrators can access data using the connection, until the connection creator explicitly grants more permissions.

When you create a virtual connection, you must set the permissions for the Connect capability to enable other users to connect to data using the virtual connection. The Connect capability

allows you to share a virtual connection and allows users to query it. With connect permissions, a user can view the tables in a virtual connection and create content using the tables. For more information, see [Set permissions on a virtual connection](#).

### Permissions vs. data policies

Permissions define what a person can or can't do with a piece of content in Tableau. Permissions are made up of capabilities—the ability to do things like view content, web edit, download data sources, or delete content. Permission rules define which capabilities are allowed or denied for a user or group on a piece of content. The interplay between license level, site role, and potentially multiple permission rules factor into the final determination of what a person can or can't do—their effective permissions. See [Permissions](#) for details.

Data policies filter the data in a virtual connection, making sure that people see only the data they're supposed to see. A data policy is applied and filters the data when it's viewed in the Tableau content (for example, a workbook or flow). The policy condition in a data policy is a calculation or expression that defines access to the data. User functions are often used to limit access to users or groups. Access can be based on the user name, the group a user belongs to, or a region value. See [Create a Data Policy for Row-Level Security](#) for details.

Both permissions and data policies govern access. Simply put, permissions determine which *content* you can see, access, use, or create; data policies determine which *data* you can see.

### How permissions and data policies work together

Tableau permissions are applied to Tableau content first. People can only do the things they have the capabilities to do with Tableau content—data policies don't override Tableau permissions. After permissions are evaluated, the data policy is applied to determine which data in the virtual connection the person can see based on the policy condition.

The following example describes the effects of permissions and data policies on a virtual connection that contains salary data:

- The virtual connection is in the HR project, which is restricted to Tableau users in the HR group. Anyone outside the HR group can't see content in the HR project, which means they can't browse to, connect to, or view the virtual connection.

- The virtual connection has Connect permissions granted only to members of the HR Business Partners group. All others in the HR group can see that the virtual connection exists, but they can't view the data it contains. When they view a workbook that uses that virtual connection, they can't see any data.
- The virtual connection also contains a data policy that filters the salary data based on the individual user, so HR Business Partners can see only rows that pertain to employees in their business unit. When they view a workbook that uses that virtual connection, they see data only for their business unit.

## Features and functionality

For the manager of data, virtual connections provide:

- **Securely managed service accounts.** If you use a 'service account' model, now instead of having to share that service account information with any user who wants to access that data, you can give the service account credentials to the few analysts who are empowered to create virtual connections.
- **Agile physical database management.** You must make database changes (for example, a field is added or table name is changed) only one time in the virtual connection, rather than in every piece of content where the data is used.
- **Reduced data proliferation.** By centrally managing extract refresh schedules, refreshes are scheduled once, ensuring that anyone who accesses the data from that virtual connection is seeing fresh data.
- **Centralized row-level security.** You can create data policies that apply row-level security to both Tableau extracts and live queries at the connection level. The data policies are applied to any workbook, data source, or flow that uses the virtual connection.

**Note:** Data policies are valid for flow input data, but not for flow output data. Users with access to flow output data will see all of the data, and not only a subset of it that pertains only to them.

As the user of data, you benefit from virtual connections knowing that you have:

- **Appropriate access** to only the data you should see, because row-level security is already applied to the data.

- **Flexibility** to use data that's been curated and secured. The virtual connection stores and shares the connection information. All you have to do is create a data source with a data model specific to your needs.
- **Trust** that data is fresh because the extract refresh schedule has already been set.
- The ability to **share** content freely, assured that you won't put security at risk because data policies are always enforced.

### Virtual connection editor workflow

The virtual connection editor enables you to create:

- Virtual connections, which are a Tableau content type that provides a sharable central access point to data.
- Data policies that support row-level security at the connection level.

After you create a virtual connection and its associated data policies, you can publish it and set the permissions to share with other users. You can also schedule extract refreshes so that all content that uses the virtual connection is accessing fresh data.

The following diagram shows the workflow to create a virtual connection. At any time during the process, you can publish or save a draft of your connection, but the connection must be published before you can schedule extract refreshes or use (or edit) a virtual connection. You must also set permissions before others can use the connection.

Click a step in the process to go to that help topic.

## Next step

The first step is to Create a Virtual Connection.

## Create a Virtual Connection

A virtual connection is a Tableau content type that provides a sharable central access point to data, and supports row-level security at the connection level. Creating a virtual connection is a multi-step process. This topic covers connecting to the data you want to share and working in the Tables tab of the virtual connection editor.

### Connect to data

To create a virtual connection in Tableau Cloud or Tableau Server:

## Tableau Server on Linux Administrator Guide

1. From the Home or Explore page, click **New > Virtual Connection**.
2. In the Connect to Data dialog box, select the connector for your data. For a list of supported connectors for virtual connections, see [Creators: Connect to Data](#) in the Tableau Desktop and Web Authoring help.
3. Enter the information you're prompted for. The credentials you enter are saved in the virtual connection, so connection users don't have to enter credentials to connect to the data.
4. Click **Sign In** if prompted. To add another connection, click  and select a connector, enter credentials, and sign in.

A virtual connection can have multiple connections. Each connection accesses one database or file.

**Note:** For Tableau Cloud, virtual connections that connect to private network data use Tableau Bridge to keep data fresh. For information about configuring Tableau Bridge, see [Configure and Manage the Bridge Client Pool](#). For information about supported connections, see [Connectivity with Bridge](#).

### Add another connection

As needed, add another connection to a virtual connection and connect to more than one database by clicking  next to **Connections**. You can add a connection to a different server or database, or to the same server or database.

With multiple connections, you can:

- Use a table from any connection or database as an entitlement table in a data policy that secures tables from other connections and databases.
- Add or replace tables in a virtual connection with tables from a different database. For example, say you migrate data from one database to another. In the virtual connection editor, you can add a connection to the second database and replace the existing tables from the first database with tables from the second one.
- Add multiple connections to the same server or database. This can be helpful when you need to for example access data from the same database but with different credentials.

- Share a group of tables that are related or meant to be used together, no matter where they're physically located. For example, from multiple databases you can group tables related to employee information.

When you open a virtual connection to edit it, if prompted you must authenticate connections in sequence. If any connections fail to authenticate, you can't edit the virtual connection.

Select tables to include in the connection

If necessary, select a database to view the tables in it.

1. On the left, under **Tables**, select the tables and click or drag them to the Tables tab on the right. You can include tables from different connections. Include an entitlement table, if you're using one.
2. (Optional) Click **New Custom SQL** to create a custom table schema.

**Note:** Virtual connections don't support tables with a spatial data type.

Select live or extract mode for tables

You can set individual tables—whether they're from multiple connections or not—to either live or extract mode in the same virtual connection.

- **Live-** Tables are queried directly from the database. (Live is the default.)
- **Extracts-** Tables are extracted and saved to Tableau.

As an example, you can set some tables to extract mode so that they're not impacted by report generation or heavy customer traffic.

Under Tables, select the table or tables you want to change the mode for and select **Actions**, and **Change to Live** or **Change to Extract**. Alternatively, select the Actions Menu (...) in the table's row and select **Live** or **Extract**.

Incremental Extracts

Starting in Tableau Cloud June 2024 and Tableau Server 2024.2, you can configure table extracts for incremental refresh.

## Tableau Server on Linux Administrator Guide

When configuring an incremental extract, you specify a key column that is used to identify new rows. When the incremental extract is refreshed, only the rows where the key column has increased will be added to the extract. Fewer rows processed means a faster extract refresh job and less load on the database.

For example, suppose we have an extract for the **Batters** table, and the data in the extract is:

| <b>Year</b> | <b>Team</b> |
|-------------|-------------|
| 1978        | Lions       |
| 1979        | Tigers      |

The **Batters** table is configured for incremental extract refresh, and the key column is **Year**.

The live table is updated with a new row for **1980**:

| <b>Year</b> | <b>Team</b> |
|-------------|-------------|
| 1978        | Lions       |
| 1979        | Tigers      |
| 1980        | Bears       |

When the **Batters** table's extract is refreshed incrementally, only rows that exceed the greatest value in the extract's key column are added. In this case, that means that the **1980** row is added to the extract. Instead of refreshing the entire extract file, only 1 row is processed and appended.

You can still do a full refresh on an extract configured for incremental refresh if you want to refresh the entire extract.

To configure incremental refresh for a table extract:

1. Change the table from **Live** to **Extract**.
2. Select the Actions Menu (...) in the table's row and select **Extract Settings...**
3. Check **Enable incremental refresh**.

4. Select an incrementing column to use when determining which rows to add.
5. Select **Save Settings**.

### Convert to Custom SQL

Starting in Tableau Cloud June 2024 and Tableau Server 2024.2, you can approximate the SQL used to connect to a table and use that as a starting point for your own custom SQL. Custom SQL allows you to filter or make other query changes that can modify the result set. Creating custom SQL this way instead of using **New Custom SQL** in the data pane is less impactful to existing virtual connections. Downstream assets see the table as the same table instead of a new one.

To convert a table to custom SQL:

1. Select the Actions menu (...) in the row for the table.
2. Select **Convert to Custom SQL**.
3. In the **Edit Custom SQL** dialog, edit the SQL as needed.
4. Select **Generate Table**.

Note: The SQL that first appears in the dialog should be considered a starting point, and may not work without modification. The virtual connection editor lacks nuanced

information about the specific SQL syntax used in the connection. If you encounter errors when selecting the Generate Table button, try removing or changing single quotes, double quotes, back quotes, and square brackets to make the SQL compliant with the database you're using.

To edit the custom SQL:

1. Select the Actions menu (...) in the row for the table.
2. Select **Edit Custom SQL**.
3. In the **Edit Custom SQL** dialog, edit the SQL.
4. Select **Generate Table**.

To return the table to its default state, without custom SQL:

1. Select the Actions menu (...) in the row for the table.
2. Select **Replace**.
3. In the replace table dialog, select the original table name.
4. Select **OK**.

Extract table data

After a table or tables are changed from live to extract but haven't been extracted yet, click **Create Pending Extracts** (or **Run Pending Extracts** in Tableau Server 2023.3 and earlier) to run the pending extracts. After all pending extracts are run, click **Refresh All Extracts** (or **Run All Extracts** in Tableau Server 2023.3 and earlier) to extract all table data at that time.

Alternatively, in Tableau Cloud June 2024 or Tableau Server 2024.2 and later, select the Actions Menu (...) in the table's row and select **Refresh Extract...** If incremental refresh is not configured for the table, you can only select **Refresh (Full)**. If incremental refresh is configured, you can choose either **Refresh (Full)** to refresh the extract completely, or **Refresh (Incremental)** to incrementally refresh the extract.

You must run any pending extracts before you publish the virtual connection. You can't edit the connection while extracts are generated.

Schedule extract refreshes of the tables in your virtual connection on the virtual connection page after you publish the connection. See [Schedule Extract Refreshes for a Virtual Connection](#).

### Set the table visibility state

Use the Visibility toggle on the Tables tab to show or hide tables and their data from users.

 Users can see table data. You can create a data policy to govern which data users can see. (Visible is the default.)

 Users can't see table data. You can use hidden tables in a data policy and as an entitlement table.

### See table details

Click a table at the top of the Tables tab to see its details. You can make simple edits in the Table Details section, such as change a table name, hide or rename a column, or change a data type.

Switch the table information you see using these icons:

-  A list of columns in the table and each column's data type.
-  Sample data for each column and linked keys, if available. Linked keys show which columns link to other tables. They're visible only when databases have primary and foreign key information.
-  The range of values in a histogram for each column selected.

#### Refresh data from the database

Click the refresh icon  in the toolbar to get the latest data from the database for all the connections in a virtual connection, including:

- The lists of databases, tables, and columns. Both the tables included in a virtual connection and not included are refreshed.
- Table and histogram data.

For tables in live mode, refreshing retrieves the latest list of databases, tables, and columns and the most recent table and histogram data. For tables in extract mode, refreshing retrieves the updated list of tables and columns. But to see the most recent table and histogram data, you must start a new extract. For example, when there's a new column in a database table and you click the refresh icon, the new column appears in the editor but its data does not. To see the most current data, you must start a new extract.

Refreshing data invalidates any currently cached data. Closing and reopening the editor, switching tables from extract to live mode, and changing a connection credential like user-name or password also refreshes data.

Who can do this

To create a virtual connection, you must

- have credentials to the database that the virtual connection connects to, and
- be a server or site administrator, or a Creator.

Next steps

After tables have been added and configured on the Tables tab, you can choose to Create a Data Policy for Row-Level Security or Publish a Virtual Connection and Set Permissions.

See also

[Use a .properties file to customize a JDBC connection](#) — If you're customizing a JDBC-based connection, you can also make customizations in a .properties file

## Create a Data Policy for Row-Level Security

Use a data policy to apply row-level security to one or more tables in a virtual connection. A data policy filters the data, ensuring that users see only the data they're supposed to see. Data policies apply to both live and extract connections.

About data policies

A data policy has three main components:

## Tableau Server on Linux Administrator Guide

1. The tables it applies to, called policy tables. These are the tables that are filtered.
2. The mapped columns that define the relationships between tables (for example, between entitlement and fact tables) and between table columns and policy columns. A policy column is the column used to filter data.
3. The policy condition, which is an expression or calculation that is evaluated for every row at query time. If the policy condition is TRUE, then the row is shown in the query.

When you create a data policy, you need a column you can use to filter the data. This column is called a policy column. Data is filtered by the policy condition, usually using a user function, such as USERNAME() or FULLNAME().

If your policy table includes a column that you can filter on, then use that column as your policy column.

When a policy table doesn't include such a column, use an entitlement table with a column you can use to filter the data. An entitlement table is a table that includes both a policy column you can use to filter policy tables and another column you can relate (map) to a column in a policy table (as shown in the data policy example image above).

### Filter with a policy column from a policy table

The most common way to filter data is to use a column in the table that has the data that you want to filter on. Use that column as a policy column and then map the appropriate table columns to the policy column.

To use a policy column to filter your data, first, add tables to the policy from the left pane. To add a table, do one of the following:

- Double-click the table name.
- Click the drop-down arrow near the table name and select **Manage table with policy**.
- Or, drag the table to the right and drop it on **Add as Policy Table**.

After a table is added to a policy, a shield icon  appears to the right of the table name in the left pane indicating that it's a policy table.

Next, map columns to create a relationship between the column name in the table and the policy column name. Use the policy column name in the data policy condition to control row-level data access for users:

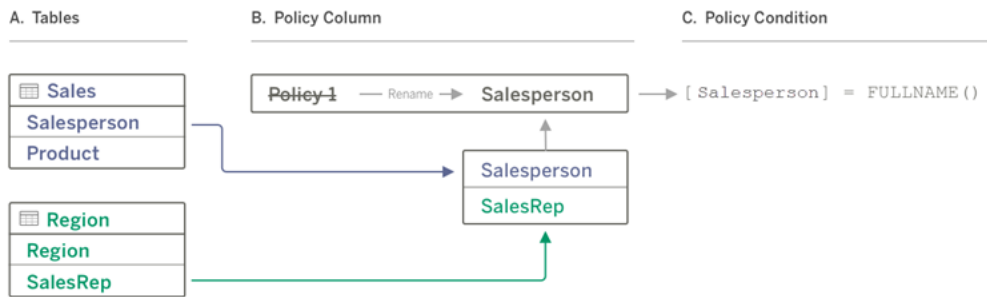

1. Click **+Add Column to Map** to add one or more columns you'll use to filter data.
2. Name the policy column. You'll use this name in the policy condition.
3. For each table the policy applies to, use the drop-down menu to select the table column that maps to the policy column.
4. Repeat this process for as many policy columns as you want to use in the policy condition.

**Tip:** Instead of using the +Add Column to Map button, you can start typing the calculation in the policy condition area and use auto-complete to choose the column name, which will then populate the policy column information under Step 1.

An example using a policy column from a policy table

- A. The Sales table has a [Salesperson] column, and the Region table has a [SalesRep] column. The Salesperson and SalesRep data matches the full name of Tableau users on your site.
- B. You want to filter the Sales and Region data by Salesperson, so you name the policy column "Salesperson" and then map the Salesperson column from Sales and the SalesRep column from Region to the Salesperson policy column.
- C. Then write the policy condition to filter both tables. Use the [Salesperson] policy column and the FULLNAME() user function so that each user can see only their own data.

Filter with policy column from an entitlement table

Entitlement tables are used when your policy table doesn't contain a column you can filter on. You can use the entitlement table to map a column in the data table to a column in the entitlement table. Note the following:

- Be sure to include the entitlement table as a table in the virtual connection. You can use a table from any connection or database as a central entitlement table that secures tables across many other databases. In some cases, an entitlement table that's in the same database as the tables you're securing can be a potential security risk because of the potential for exposing employee data. And having an entitlement table in a different database can make it easier to control permissions, for example, to grant someone access to a database.
- If you don't want virtual connection users to see the entitlement table, you can toggle the setting in the Visibility column on the Tables tab to hide it. Once hidden, the entitlement table is still available for policy filtering but can't be used in vizs or workbook data sources.

**Note:** Connecting directly to a flow output (.hyper file) is not supported for the entitlement table. The flow output must write directly to the database.

To use an entitlement table to filter your data:

1. Add the data tables that you want the data policy to apply to. Do one of the following:
  - Double-click the table name.
  - Click the drop-down arrow near the table name and select **Manage table with policy**.
  - Or, drag the table to the right and drop it on **Add as Policy Table**.
2. After a table is added to a policy, a shield icon  appears to the right of the table name in the left pane indicating that it's a policy table.
3. Select the entitlement table, then either:
  - Click the drop-down arrow and select **Use as entitlement table**.
  - Or, drag the table to the right and drop it on **Add as Entitlement Table**.
4. For each table that the policy applies to, click the drop-down menu and select the

column to map the policy table to the entitlement table.

An example using a policy column from an entitlement table

- The data you want to filter has an `EMP_ID` column, but not an employee name column. However, you have a second table that includes columns for both `EMP_ID` and the employee's `FULL NAME`. And, the values in the employee `FULL NAME` column match the full name of Tableau users on your site.
- You can add `Employees` table to the policy as an entitlement table, and then map the policy table column name `EMP_ID` to the entitlement column name `EMP_ID` for each table.
- Then use the `FULLNAME()` function in your policy condition to match the Tableau Server user's full name with the entitlement table's `[FULL NAME]` column (which is the policy column) so that each user can see only their own data.

Write a policy condition

The last step in creating a data policy is to write a policy condition, which is a calculation or expression used to define row-level access. Policy conditions are often used to limit access to users or groups through user functions.

A policy condition:

- Is required in a data policy.
- Must evaluate to true or false.
- Shows rows when the policy condition is true.

When you close a policy tab, it doesn't discard your work.

## Tableau Server on Linux Administrator Guide

### Policy condition examples

Shows only rows where the Region column value is North:

```
[Region] = "North"
```

Enables a signed-in user to see the rows where the user's name matches the value in EmployeeName:

```
FULLNAME() = [EmployeeName]
```

Enables members of the Managers group to see all rows, while users can see only the rows where their username matches the value in the employee\_name column:

```
ISMEMBEROF('Managers') OR USERNAME() = [employee_name]
```

### Supported Tableau functions in policy conditions

Policy conditions support a subset of Tableau functions:

- Logical (except null-related)
- String
- User
- Date
- Number: MIN, MID, MAX

To see which specific functions are supported, in the virtual connection editor, on the Data Policies tab, see the **Reference** panel on the right.

**Note:** If the virtual connection has a data policy that contains **user functions** (for example, `USERNAME()`) and you connect to it from a workbook or data source and create an extract there, the extract will contain only the rows that match the virtual connection data policy at the time the extract is created. To take advantage of a virtual connection with user functions in the data policy, use a live connection from the workbook or data source to the virtual connection instead of an extract.

Who can do this

To create a data policy, you must

- have credentials to the database that the virtual connection connects to, and
- be a server or site administrator, or a Creator.

Next steps

After you create a data policy, the next step is to verify that it works as you expect it to. See [Test Row-Level Security with Preview as User](#). Or, if you're ready to share the virtual connection and its data policies with others, see [Publish a Virtual Connection and Set Permissions](#).

Resources

For detailed information about calculations, see [Understanding Calculations in Tableau](#) in the Tableau Desktop and Web Authoring help.

For information about user functions, see [User Functions](#) in the Tableau Desktop and Web Authoring help.

For information about other row-level security options in Tableau, see [Overview of Row-Level Security Options in Tableau](#) in the Tableau Server help.

## Test Row-Level Security with Preview as User

Use **Preview as user** to test your data policy. You can see the data as the user sees it and ensure that row-level security is working as expected. This helps when the data policy keeps you from seeing the rows in the table (for example, if only salespeople can see rows, and you're not a salesperson).

To preview the data when the data policy is applied:

1. Select a table.
2. In the Table Details section, select the **With policy applied** check box.
3. Click **Preview as user**, select a **Group** (optional) and a **User**.
4. Verify that the policy shows the correct data for that user in the table details.
5. Repeat for other users as needed.

**Tip:** In Table Details, click  to show the range of values for a column, including which values show and which are filtered out by the data policy. Select one or two columns that are good indicators that the policy is correctly filtering the data.

Who can do this

To test a virtual connection, you must

- have credentials to the database that the virtual connection connects to, and
- be a server or site administrator, or a Creator.

Next step

After you test your data policy, when you're ready to share the virtual connection with others, see [Publish a Virtual Connection and Set Permissions](#).

## Publish a Virtual Connection and Set Permissions

When you work in the virtual connection editor, your changes are automatically saved as a draft while you work. To share a new virtual connection with other users, you need to publish it.

Save a draft

You can manually save a draft of the connection by clicking the save icon  in the toolbar or by selecting **File > Save Draft** from the menu.

When editing a published virtual connection, the connection stays available to users in its current published state. You can save your updates as a draft while you work on the connection in the editor. To share the updates to the virtual connection with other users, you need to publish it.

Draft in progress

If you close the editor while updating a published virtual connection, the next time you open the connection in the editor within seven days, you have the option of continuing to make edits to the existing draft, starting a new draft, or opening the connection in its current published state by clicking **Cancel**.

To return to a draft version of an unpublished virtual connection, you need to manually save the URL of the draft **before** you close the editor. You can use the URL to open the draft in the editor the next time you want to work on the connection within seven days. For example:

```
https://yourserver.test.com/published-connection-editor/?draft=d1789edc-5d9f-40ae-988d-9fc879f37a98
```

### Publish the connection

To publish a new connection:

1. Click the **Publish** button in the upper right corner of the editor or select **File > Publish** from the menu.
2. In the Publish dialog box:
  - a. Type a name in the **Name** field.
  - b. Select a project to save the connection to.
3. Click **Publish**.

To publish an updated connection, click the **Publish** button in the upper right corner of the editor or select **File > Publish** from the menu.

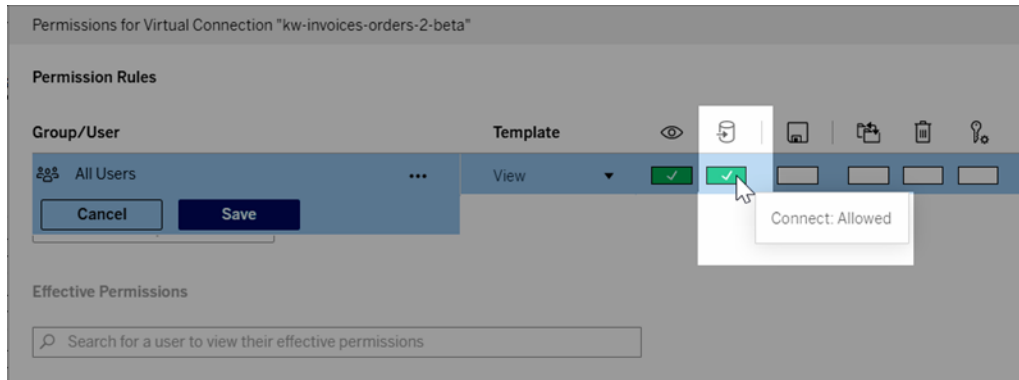

### Set permissions on a virtual connection

After you publish a virtual connection, you need to set the permissions so that others can use it. By default, all users can **View** the connection, in other words, see it listed under Virtual Connections in Tableau, but unless you set the **Connect** capability to Allowed, only you and administrators can use the virtual connection. For more information on the Connect capability, see Permissions.

To set permissions:

## Tableau Server on Linux Administrator Guide

1. Navigate to the virtual connection.
2. Open the Actions menu (...) and click **Permissions**.
3. Check the box under the Connect icon so that connect is allowed for all users.

**Tip:** You can add additional rules if you want to grant the permission only to certain users or groups.

4. Click **Save**.

For more information about permissions on Tableau content, see [Permissions](#). For information on embedding passwords when you publish Tableau content such as a data source or workbook that uses a virtual connection, see [Virtual connections](#) in the Tableau Server help.

Who can do this

To publish a virtual connection or set permissions, you must

- have credentials to the database that the virtual connection connects to, and
- be a server or site administrator, or a Creator.

Next step

After you publish a virtual connection and set its permissions, you can [Use a Virtual Connection](#).

## Schedule Extract Refreshes for a Virtual Connection

One of the benefits of virtual connections is that you can reuse the same extract multiple times, reducing data proliferation and removing redundant extract refresh jobs. To ensure that extract

data is fresh for any content that uses a virtual connection, you can create an extract refresh schedule for the tables in your connection after you publish the connection.

You can also schedule extract refreshes of data sources and workbooks that use virtual connections. See [Schedule Refreshes on Tableau Cloud](#) and [Refresh Data on a Schedule](#) (Tableau Server).

Extract tables

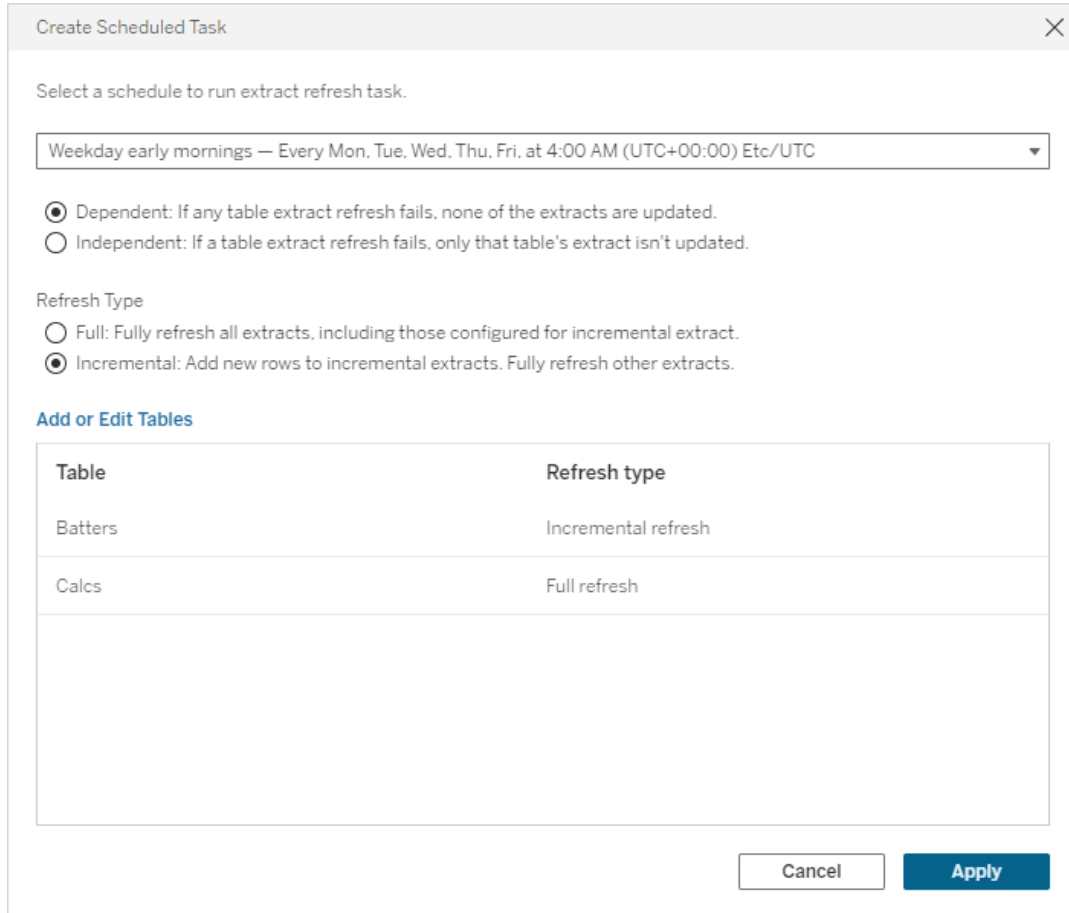

See [Extract table data](#).

Schedule extract refreshes on Tableau Server

1. Navigate to the virtual connection page. (From the **Home** or **Explore** page, click **Virtual Connections** from the dropdown menu, then select your virtual connection.)
2. At the top of the page, a heading should say **Data is Extract**. If it says **Data is Live**, refresh your browser.
3. Select the **Scheduled Tasks** tab and click **+New Task**.
4. The **Create Scheduled Task** dialog box opens. The **Create Scheduled Task** dialog box looks different in Tableau Server and Tableau Cloud. If you're using Tableau Cloud, see [Schedule Extract Refreshes for a Virtual Connection](#) in the Tableau Cloud Product Help.
5. Select a schedule from the dropdown menu.
6. For cases when multiple tables use extracts, select **Dependent** or **Independent**. (In Tableau Server 2023.3 and earlier, these options were "Keep tables in sync" and "Refresh tables independently", but the underlying meaning is the same.)
  - **Dependent** means that none of the extracts will be updated if one or more tables' extract refresh jobs fails.
  - **Independent** means that the success or failure of a table's extract job doesn't affect whether or not other tables' extracts are updated.
7. Select **Refresh Type**. You can configure the type of extract in the virtual connection editor. For more information, see the Incremental Extracts section of the [Create a Virtual Connection page](#). (In Tableau Server 2023.3 and earlier, virtual connections don't support incremental extracts, so you won't see these options.)
  - **Full** means that full extract refresh jobs will be run on all extracts in the virtual connection, regardless of whether they are configured for full extract refresh or incremental extract refresh.

- **Incremental** means that incremental extract refresh jobs will be run on all incremental extracts in the virtual connection. For all other extracts in the virtual connection, full extract refresh jobs will be run.
8. Select **Add or Edit Tables** and select the tables you want to refresh.
  9. Select **OK**.
  10. Select **Apply**.

### Time limit for extract refreshes

To ensure that long running refresh tasks don't take up all system resources and don't prevent refreshes of other extracts on your site, extract refreshes for a virtual connection are subject to a two-hour time limit. For more information about the timeout limit for refresh tasks and suggestions for resolving these errors, see [Time limit for extract refreshes](#). However note that virtual connections support only full and not incremental refreshes.

Who can do this

To publish a virtual connection or set permissions, you must

- have credentials to the database that the virtual connection connects to, and
- be a server or site administrator, or a Creator.

Next step

After you schedule extract refreshes for a virtual connection, you can [Use a Virtual Connection](#)

## Use a Virtual Connection

After a virtual connection is published and permissions are set, it's available to users to connect to data in the same ways that users access all data in Tableau. When you must edit a virtual connection or the data policy in the connection—for example, when the underlying schema changes—simply open the connection in the virtual connection editor, make your changes, and either save or publish the updates. You can also replace an existing data source in a workbook with a virtual connection.

Connect to a virtual connection

For web authoring in Tableau Cloud or Tableau Server:

1. On the Home or Explore page, click **New**.
2. Select the type of content you want to create: workbook, flow, or published data source.
3. In **Connect to Data > On This Site > Content Type** dropdown menu, select **Virtual Connections**.
4. Select the name of the connection and click **Connect**.

For Tableau Desktop and Tableau Prep:

1. On the Connect pane, under Search for Data, click **Tableau Server**.
2. Enter the server name and click **Connect**, or click **Tableau Cloud**.
3. Enter the information prompted for.
4. On the Search for Data dialog box, from the Content Type dropdown menu, select **Vir-**

### tual Connections.

5. Select the name of the connection and click **Connect**.

**Note:** There's no need to enter credentials when you connect using a virtual connection. The credentials to access the data are embedded in the connection.

#### Edit a virtual connection or data policy

When editing a published virtual connection, the connection stays available to users in its current published state. For more information, see [Publish a Virtual Connection and Set Permissions](#).

To edit a connection, navigate to it from the Explore page. Note that even though database credentials are embedded in the connection, only those with the database credentials can make any changes to a virtual connection.

1. From the dropdown menu, select **All Virtual Connections**, then select the connection you want to edit.
2. Click **Edit Virtual Connection**.
3. Enter the information prompted for to connect. To edit a connection, you must enter the credentials required to access the data.
4. Click **Sign In**.
5. In the virtual connection editor, make your changes and then either save a draft or publish the connection.

#### Respond to underlying schema changes

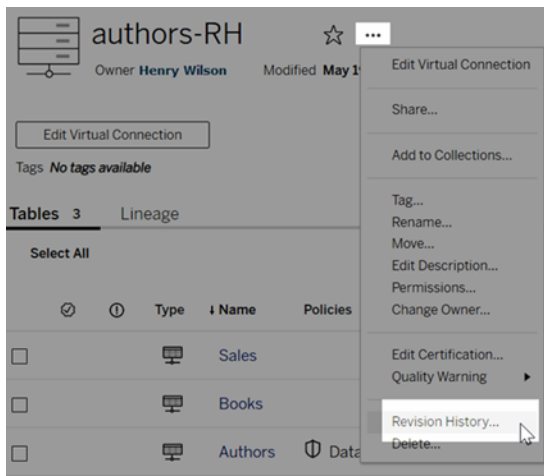

When the underlying schema in a virtual connection changes—for example, a table is added or deleted, or a column is added or renamed—you must edit the virtual connection to reflect the schema changes and then republish the connection. (If the connection has extracts, remember to refresh the extracts.) This way, you can add or edit the tables, columns, and policies in the connection before new data is exposed to everyone.

## Work with virtual connection revision history

When you publish a virtual connection, a version is saved in the revision history for Tableau Cloud or Tableau Server. You can revert to a previous version at any time.

To access revision history, you must have a **Creator** site role and the **View** and **Overwrite** permissions.

To see the virtual connection revision history, click the actions menu (. . .) for the virtual connection, then click **Revision History**.

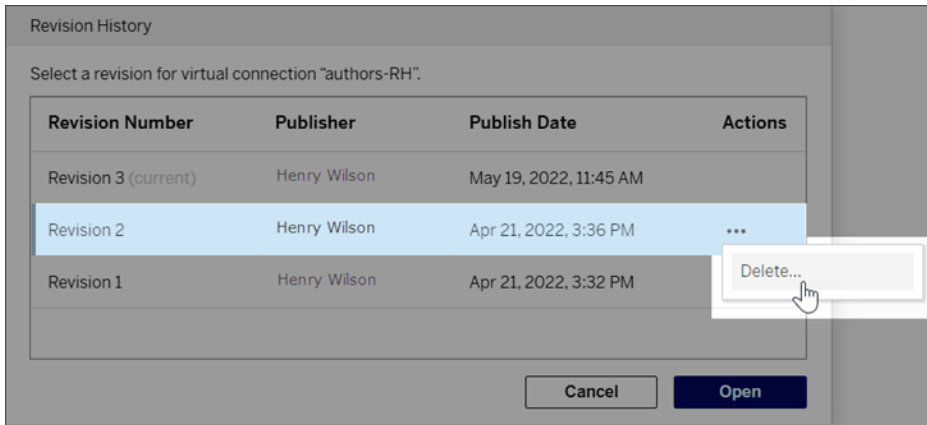

## Restore or delete a virtual connection revision

To restore a virtual connection revision, select a revision, and then click **Open**. You are then prompted to discard the existing version of the connection. When you click **Discard and Continue**, the revision you selected becomes the current version of the connection.

## Tableau Server on Linux Administrator Guide

To delete a revision, from the revision's actions menu ( . . . ), click **Delete**.

Replace an existing data source in a workbook with a virtual connection

For web authoring in Tableau Cloud or Tableau Server:

1. Download the workbook. For more information, see [Download Views and Workbooks](#) in Tableau Desktop Help.
2. In Tableau Desktop, open the workbook and replace its existing data source with a virtual connection. For more information, see [Replace Data Sources](#) in Tableau Desktop Help.
3. In Tableau Desktop, upload the workbook to your Tableau Cloud or Tableau Server site. For more information, see [Upload Workbooks to a Tableau Site](#) in Tableau Desktop Help.
4. In Tableau Cloud or Tableau Server, click **Publish** to save your changes to the server.

For Tableau Desktop:

1. Open the workbook and replace its existing data source with a virtual connection. For more information, see [Replace Data Sources](#) in Tableau Desktop Help.
2. Republish the workbook. For more information, see [Simple Steps to Publish a Workbook](#) in Tableau Desktop Help.

Who can do this

To use a virtual connection, you must be a server or site administrator, or Creator.

To edit a virtual connection or data policy, you must

- have credentials to the database that the virtual connection connects to, and
- be a server or site administrator, or a Creator.

To migrate existing content to use a virtual connection, you must

- be a server or site administrator, or
- be a Creator who is also the data source owner.
