Explain Data builds models of the data in a view to predict the value of a mark and then determines whether a mark is higher or lower than expected given the model. Next, it considers additional information, like adding additional columns from the data source to the view, or flagging record-level outliers, as potential explanations. For each potential explanation, Explain Data fits a new model, and evaluates how unexpected the mark is given the new information. Explanations are scored by trading off complexity (how much information is added from the data source) against the amount of variability that needs to be explained. Better explanations are simpler than the variation they explain.

| Explanation type      | Evaluation   |
|-----------------------|--|
| <b>Extreme values</b> | <p>Extreme values are aggregated marks that are outliers, based on a model of the visualized marks. The selected mark is considered to contain an extreme value if a record value is in the tails of the distribution of the expected values for the data.</p> <p>An extreme value is determined by comparing the aggregate mark with and without the extreme value. If the mark becomes less surprising by removing a value, then it receives a higher score.</p> <p>When a mark has extreme values, it doesn't automatically mean it has outliers, or that you should exclude those records from the view. That choice is up to you depending on your analysis. The explanation is simply pointing out an interesting extreme value in</p> |

| Explanation type                 | Evaluation   |
|----------------------------------|--|
| <b>Number of records</b>         | <p>the mark. For example, it could reveal a mistyped value in a record where a banana cost 10 dollars instead of 10 cents. Or, it could reveal that a particular sales person had a great quarter.</p> <p>The number of records explanation models the aggregate sum in terms of the aggregate count; average value of records models it in terms of the aggregate average. The better the model explains the sum, the higher the score.</p> <p>This explanation describes whether the sum is interesting because the count is high or low, or because the average is high or low.</p>   |
| <b>Average value of the mark</b> | <p>This type of explanation is used for aggregate marks that are sums. It explains whether the mark is consistent with the other marks because in terms of its aggregate count or average, noting the relation <math>SUM(X) = COUNT(X) * AVG(X)</math>.</p> <p>This explanation describes whether the sum is interesting because the count is high or low, or because the average is high or low.</p>  |
| <b>Contributing Dimensions</b>   | <p>This explanation models the target measure of the analyzed mark in terms of the breakdown among categories of the unvisualized dimension. The analysis balances the complexity of the model with how well the mark is explained.</p> <p><i>An unvisualized dimension</i> is a dimension that exists in the data source, but isn't currently being used in the view. This type of explanation is used for sums, counts and averages.</p> <p>The model for unvisualized dimensions is created by splitting out marks according to the categorical values of the explaining column, and then building a model with the value that includes all of the data points in the source visualization. For each row, the model</p> |

**Explanation type****Evaluation**

attempts to recover each of the individual components that made each mark. The analysis indicates whether the model predicts the mark better when components corresponding to the unvisualized dimension are modeled and then added up, versus using a model where the values of the unvisualized dimension are not known.

Aggregate dimension explanations explore how well mark values can be explained without any conditioning. Then, the model conditions on values for each column that is a potential explanation. Conditioning on the distribution of an explanatory column should result in a better prediction.

**Contributing Measures**

This explanation models the mark in terms of this unvisualized measure, aggregated to its mean across the visualized dimensions. An *unvisualized measure* is a measure that exists in the data source, but isn't currently being used in the view.

A Contributing Measures explanation can reveal a linear or quadratic relationship between the unvisualized measure and the target measure.

## Disable or Enable Explain Data for a Site

Explain Data is enabled for sites by default, but Tableau administrators may disable it.

1. Go to the **General** site settings.
2. (Tableau Server only) In the **Web Authoring** section, select **Let users edit workbooks in their browser**.
3. In the **Availability of Explain Data** section, select from these options:
  - **Enable** lets Creators and Explorers with the appropriate permissions run Explain Data in editing mode. Lets all users with appropriate permissions run

Explain Data when it is enabled for viewing mode.

- **Disable** prevents all users from running Explain Data or accessing Explain Data settings in workbooks.

4. In Tableau Cloud and Tableau Server 2023.3 or later, to use Explain Data:

- In the **Availability of Data Guide** section, select **Show**. For more information about Data Guide, see [Explore Dashboards with Data Guide](#).

## Use Dashboard Extensions

Extensions let you add unique features to dashboards or directly integrate them with applications outside Tableau. Adding extensions is easy; you incorporate them into dashboard layouts just like other dashboard objects.

Extensions expand dashboard functionality with the help of web applications created by third-party developers. If you're a developer and want to create your own extensions, see the [Tableau Extensions API documentation](#) on GitHub.

**Note:** Tableau administrators can turn off dashboard extensions for [Tableau Desktop](#), [Tableau Server](#), and [Tableau Cloud](#).

### Add an extension to a dashboard

1. In a Tableau workbook, open a dashboard sheet.
2. From the **Objects** section, drag **Extension** to the dashboard.

3. In the “Add an Extension” dialog box, do either of the following:
  - Search for and select an extension.
  - Click **Access Local Extensions**, and navigate to a .trex file you previously downloaded.
4. If prompted, allow or deny the dashboard extension access to data in the workbook. For more information, see [Data security, Network-enabled, and Sandboxed extensions](#).

If you allow access, follow any on screen instructions for configuring the extension.

**Note:** If you're using Tableau Server or Tableau Cloud, Extension objects will appear blank in prints, PDFs, and images of dashboards (including images in subscription emails).

### Configure a dashboard extension

Some dashboard extensions provide configuration options that let you customize features.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **Configure**.

2. Follow the on-screen instructions to configure the extension.

Reload a dashboard extension

If a dashboard extension becomes unresponsive, you might need to reload it, which is similar to refreshing a web page in a browser.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **Reload**.

The dashboard extension is refreshed and set to its original state.

2. If reloading the extension fails to return it to a useable state, try removing it from the dashboard and adding it again.

## Data security, Network-enabled, and Sandboxed extensions

Dashboard extensions are web applications that come in two forms:

- *Network-enabled extensions* run on web servers located outside of your local network.
- *Sandboxed extensions* run in a protected environment without access to any other resource or service on the web.

Before adding a Network-enabled extension or viewing a dashboard with one, be certain that you trust the website that hosts it. By default, dashboard extensions use the HTTPS protocol, which guarantees an encrypted channel for sending and receiving data, and ensures some privacy and security.

For more information about data security when using dashboard extensions, see [Extension Security - Best Practices for Deployment](#).

Allow or deny data access to a Network-enabled extension

Depending on how an extension is designed, it can access either visible data in a view, or full underlying data, table and field names from data sources, and information about data source connections. When you add an extension, or view a dashboard with one, you're given an opportunity to allow or deny the extension to run and access this data.

If you're viewing a dashboard with an extension that requires full data access, and that access has been denied, a message appears in place of the extension. If you trust the extension and want to use it, you can reset permissions and allow the extension to run.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **Reset Permissions**.

2. Click either **Allow** to let the extension run and access data, or **Deny** to prevent the extension from running.

Ensure that JavaScript is enabled in Tableau Desktop

Dashboard extensions interact with data using the Tableau Extensions API library, a JavaScript library. If you want to use extensions, be sure that JavaScript is enabled in the dashboard security settings:

Choose **Help > Settings and Performance > Set Dashboard Web View Security > Enable JavaScript**.

## Ensure that extensions run on Tableau Cloud or Tableau Server

You can add extensions to workbooks you publish from Tableau Desktop or directly in the web-authoring mode of Tableau Cloud and Tableau Server. A Tableau administrator must allow extensions to run on a site and add Network-enabled extensions to a safe list. Administrators should only allow extensions that you have tested and trust.

If you want to use a dashboard extension on Tableau Cloud or Tableau Server, direct your administrator to [Manage Dashboard Extensions in Tableau Cloud](#) or [Manage Dashboard Extensions in Tableau Server](#).

Supported web browsers for Sandboxed extensions

Sandboxed extensions run in all browsers supported [Tableau Server](#) and [Tableau Cloud](#) except Internet Explorer 11.

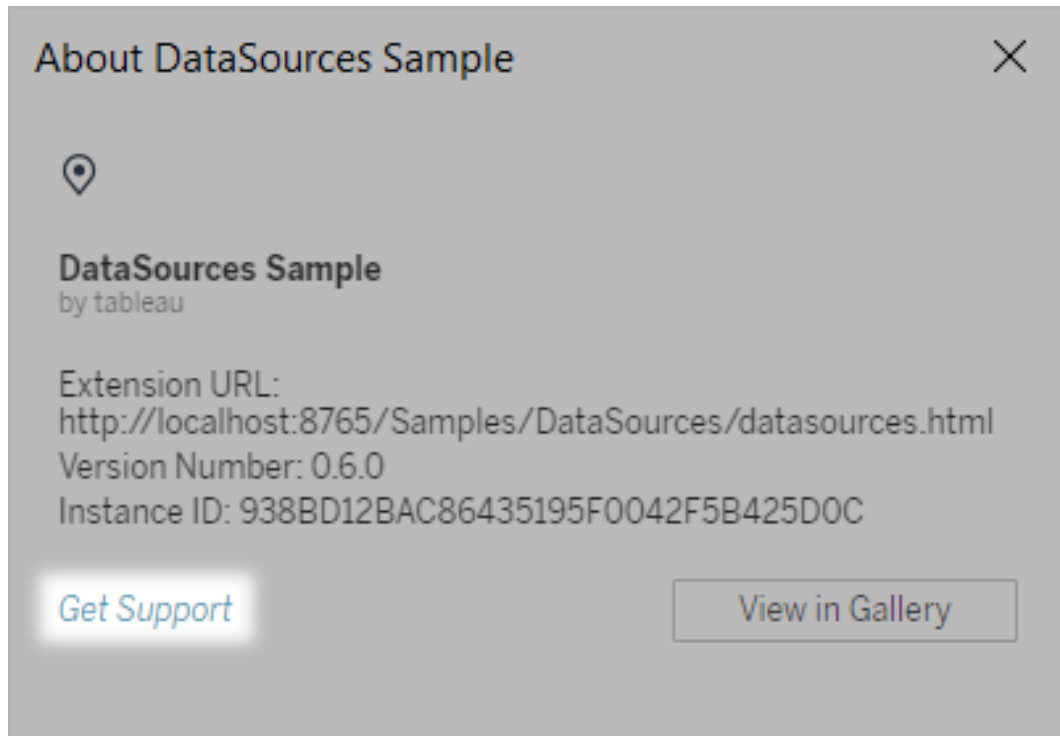

Supported versions of Tableau Server for Sandboxed extensions

You can use Sandboxed extensions in Tableau Server 2019.4 and later.

## Get support for dashboard extensions

To get help for an extension, you'll need to contact the developer or company who created it.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **About**.
2. Click **Get Support** to go to the support page of the extension developer.

**Note:** Tableau doesn't provide support for extensions or for other programs that interface with the Extensions API. However, you can submit questions and ask for help in the [Tableau developer community](#).

## Format Animations

Animate visualizations to better highlight changing patterns in your data, reveal spikes and outliers, and see how data points cluster and separate.

Animations visually transition between filter, sort, and zoom settings, different pages, and changes to filter, parameter, and set actions. As visualizations animate in response to these

changes, viewers can more clearly see how data differs, helping them make better informed decisions.

## Understanding simultaneous and sequential animations

When you author animations, you can choose between two different styles: simultaneous or sequential. Here are examples of each type.

### Simultaneous animations

The default simultaneous animations are faster and work well when showing value changes in simpler charts and dashboards.

Click the image above to replay the animation.

### Sequential animations

Sequential animations take more time but make complex changes clearer by presenting them step-by-step.

Click the image above to replay the animation.

## Animate visualizations in a workbook

When you create a new workbook, Tableau enables animations for your viz by default. You can turn animations on or off at the user and workbook level.

1. Choose **Format > Animations**.
2. If you want to animate every sheet, under **Workbook Default**, click **On**. Then do the following:
  - For **Duration**, choose a preset, or specify a custom duration of up to 10 seconds.
  - For **Style**, choose **Simultaneous** to play all animations at once or **Sequential** to fade out marks, move and sort them, and then fade them in.
3. To override workbook defaults for a particular sheet, change the settings under **Selected Sheet**.

**Note:** In the Selected Sheet section, “(Default)” indicates a setting that automatically reflects the related Workbook Default setting.

## Animations ×

### Workbook Default

On  Off

Duration  
1.00 seconds (Slow) ▼

Style  
Simultaneous ▼

**Reset All Sheets**

### Selected Sheet

#### Heat Map

Animation  
On (Default) ▼

Duration  
0.30 seconds (Fast) ▼

Style  
Sequential ▼

To replay an animation, click the **Replay** button in the toolbar. From the **Replay** button, you can also choose the speed at which the animation replays: actual speed, 2x speed, or 1/2 speed.

## Reset animation settings for a workbook

You can reset animations to return an entire workbook to the default animation settings. Be aware that this turns animations off by default.

1. Choose **Format > Animations**.
2. In the middle of the **Animations** pane, click **Reset All Sheets**.

## Completely disable all animations

When you create a new workbook, animations are enabled by default. If you find animations distracting while viewing vizs, you can completely disable them so they never play. (This isn't a system-wide setting; each user needs to apply it separately.)

- In Tableau Desktop, choose **Help > Settings and Performance**, and deselect **Enable Animations**.
- In Tableau Cloud or Tableau Server, click your profile image or initials in the top right corner of the browser, and choose **My Account Settings**. Then scroll down to the bottom of the page, deselect **Enable animations**, and click **Save Changes**.

**Note:** When animations are disabled, you can still choose **Format > Animations** in authoring mode and adjust settings—but they will have no effect.

## Format decimals for axes animations

If the number of decimal places for a measure is set to the default, then the number of decimals shown during the axis animation might fluctuate during the axes animation. To avoid this,

format the number of decimal places displayed for a measure. For more information, see [Format Numbers and Null Values](#).

## Why animations won't play

### Server rendering

Animations won't play if a viz is server-rendered. To ensure that vizzes render on a client computer or mobile device, use these techniques:

- If you're a viz author, [reduce viz complexity](#).
- If you're a Tableau Server administrator, [increase the complexity threshold for client-side rendering](#).

**Note:** On computers with lower processing power, animations may appear choppy, but users can continue to interact with vizzes without any delays in responsiveness.

### Unsupported browsers and features

Animations are supported by all web browsers except Internet Explorer.

The following Tableau features don't animate:

- Maps, polygons, and density marks in web browsers
- Pie and text marks
- Headers
- Forecasts, trends, and reference lines
- Page history trails (If a viz includes these, turn off animations to avoid unexpected behavior.)

## Format Numbers and Null Values

You can specify the format for numeric values that display in your viz, including measures, dimensions, parameters, calculated fields, and axis labels. When specifying a number format, you can select from a set of standard formats, such as number, currency, scientific, and per-

centage. You can also define a custom number format with the option to include special characters.

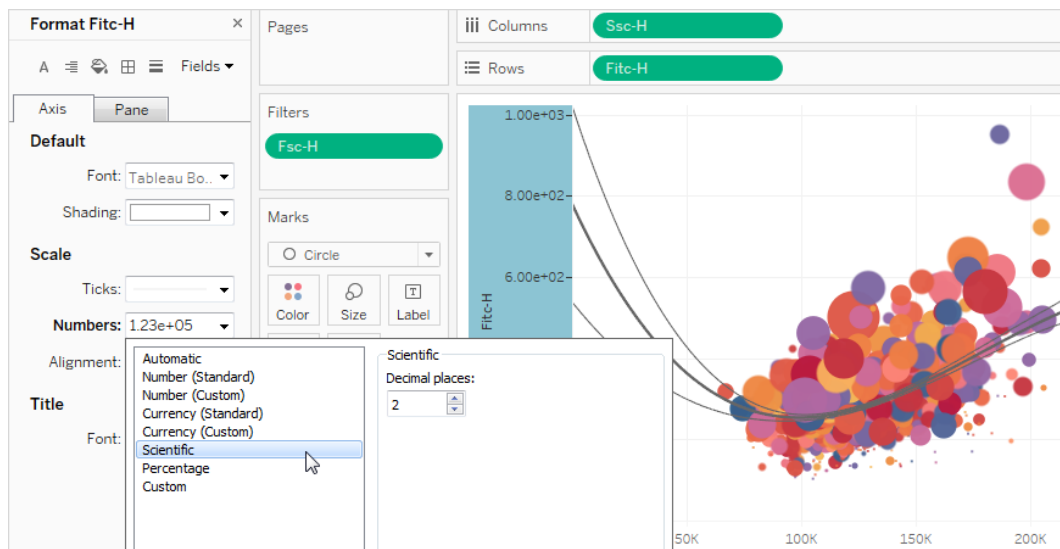

When a measure contains null values, you can use formatting to handle the null values in a different way, such as replacing nulls with zeros or hiding them.

## For Tableau Desktop

Specify a number format

1. Right-click (control-click on Mac) a number in the view and select **Format**.
2. In the **Format** pane, click the **Numbers** drop-down menu.
3. Select a number format.

Some formats require additional settings. For example, if you select **Scientific**, you must also specify the number of decimal places.

Here are the number formats and associated options available in Tableau.

### NUMBER FORMAT

### FORMAT OPTIONS

**Automatic:** format is automatically selected based on either the format spe- None.

cified by the data source or the data contained in the field.

**Number (Standard):** format is based on locale selected.

**Number (Custom):** format is customized to your choice.

**Locale:** number format changes based on the geographical location selected.

**Decimal Places:** the number of decimal places to display.

**Negative Values:** how negative values are displayed.

**Units:** the number is displayed using the specified units. For example, if the number is 20,000 and the units are thousands, the number will be displayed as 20K.

**Prefix/Suffix:** characters that precede and follow each displayed number.

**Include thousands separators:** whether the number shows separators every thousand (example: 100,000 vs. 100000).

**Currency (Standard):** format and currency symbol is based on locale selected.

**Currency (Custom):** format and currency symbol is customized to your choice.

**Locale:** currency format based on the geographical location selected.

**Decimal Places:** the number of decimal places to display.

**Negative Values:** how negative values are displayed.

**Units:** the number is displayed using the spe-

cified units. For example, if the number is 20,000 and the units are thousands, the number is displayed as 20K.

**Prefix/Suffix:** characters that precede and follow each displayed number.

**Include thousands separators:** whether the number shows separators every thousand (example: 100,000 vs. 100000).

**Scientific:** numbers are displayed in scientific notation.

**Decimal:** the number of decimal places to display.

**Percentage:** numbers are displayed as a percentage with the percent symbol. The value of 1 is interpreted as 100% and 0 as 0%

**Decimal:** the number of decimal places to display.

**Custom:** format is based entirely on what is specified in the format options.

**Custom:** type in the format you want to use, including special characters (optional). See "Define a custom number format" in this topic for details.

## Define a custom number format

To apply a custom number format in your viz:

1. Right-click (control-click on Mac) a number in the view and select **Format**.
2. In the **Format** pane, click the **Numbers** drop-down menu and select **Custom**.
3. In the **Format** field, define your formatting preferences using the following syntax: `Positive number format;Negative number format;Zero values.`

When defining your number format code, keep in mind that:

## Tableau Server on Linux Administrator Guide

- You can specify the formatting for up to three types of numbers in the following order: positive numbers, negative numbers, and zeros.
- Each number type must be separated by a semicolon (;).
- If you specify only one number type, the format for that type is used for all numbers.
- If you specify two number types, the format for the first type is applied to positive numbers and zeros, while the format for the second type is applied to negative numbers.
- If you skip types in your number format code, you must include a semicolon (;) for each of the missing types.

### Custom number format examples

Refer to the following table for examples of commonly used custom number format codes that you can use in your viz.

The syntax has three portions: <positive number format>;<negative number format>;<zero format> separated by semicolons.

| USE CASE                  | NUMBER CODE SYNTAX  | EXAMPLE OUTPUT   |
|---------------------------|---|--|
| Show only positive values | <code>#,###; ;</code><br><br>(note a blank space after the 2nd and 3rd semicolon) | Positive values: 1,234<br>Negative values: (only the blank space displays)<br>Zero values: (only the blank space displays) |
| Show only negative values | <code>;-#,###;</code>   | Positive values: (nothing displays)<br>Negative values: -1,234<br>Zero values: (nothing displays)                          |
| Show only zero values     | <code>::0;</code>   | Positive values: (nothing displays)<br>Negative values: (nothing displays)<br>Zero values: 0                               |

|                                     |  |  |
|-------------------------------------|--|--|
| Hide zero values                    | <code>#,###;-#,###;</code>                               | Positive values: 1,234<br>Negative values: -1,234<br>Zero values: (nothing displays)       |
| Show negative values in parentheses | <code>#,###;(#,###);</code>                              | Positive values: 1,234<br>Negative values: (1,234)<br>Zero values: (nothing displays)      |
| Add a character prefix to a value   | <code>\$/,###.##,-\$,###.##,\$0;</code>                  | Positive values: \$1,234.56<br>Negative values: -\$1,234.56<br>Zero values: \$0            |
| Add a character suffix to a value   | <code>#%;-#%;0%;</code>                                  | Positive values: 12%<br>Negative values: -34%<br>Zero values: 0%                           |
| Add text descriptors                | <code>"\$"#,#" Surplus";"\$"-##" Shortage";"\$"0;</code> | Positive values: \$1,234 Surplus<br>Negative values: \$-1,234 Shortage<br>Zero values: \$0 |

There are several ways to customize your number format to meet your needs. For more code guidance and examples, see [Review guidelines for customizing a number format](#) in the Microsoft Knowledge Base.

**Note:** There are slight deviations between the options described by Microsoft and those available in Tableau. For example, custom number formats that align text within columns aren't relevant in Tableau. Additionally, custom number formats to color code text aren't applicable because you can apply color to text using the Marks card. (For more information on applying color, see [Control the Appearance of Marks in the View](#).) Be sure to only use custom number formats that apply in Tableau.

## Tableau Server on Linux Administrator Guide

Include special characters in a custom number format

One of the benefits of custom number formatting is the ability to include special characters or symbols. Symbols can make it easier to quickly understand comparisons between measures and calculations in your viz.

For example, let's say you want to show a month-over-month comparison of profits for three of your company's top-selling products. Rather than using the standard label to show that the profit for these products changed +5%, -2%, and 0% label from last month, you can set the custom number format as follows to show these changes as ▲5%, ▼2%, and ►0.

Set the default number format for a field

Right-click (control-click on Mac) the field in the **Data** pane and select **Default Properties > Number Format**.

In the subsequent dialog box, specify a number format to be used whenever the field is added to the view. The default number format is saved with the workbook. It's also exported when you export the connection information.

**Note:** Formatting numbers using the **Format** pane overrides any number formatting applied elsewhere.

Format a measure as currency

The view in the following image shows profit over time. Notice that the profit figures on the vertical axis aren't formatted as currency.

To format the numbers as currency:

1. Right-click the **Profit** axis and choose **Format**.

2. On the **Axis** tab in the **Format** pane, under **Scale**, select the **Numbers** drop-down list, and then select one of the following:

**Currency (Standard)** to add a dollar sign and two decimal places to the figures.

**Currency (Custom)** to specify the number of decimal places, how to show negative values, the units, whether to include a prefix or suffix, and whether to include a separator character.

Use locale to specify number formats

By default, Tableau uses your computer's locale and language settings to format numbers. But you can explicitly set a different locale in the **Format** pane.

The following steps show how to set Swiss German currency, using the same view as in the previous section.

1. Right-click the **Profit** axis and select **Format**.
2. On the **Axis** tab, under **Scale**, select the **Numbers** drop-down list and then select **Currency (Standard)**.
3. In the **Locale** drop-down list, items appear in a **Language (Country)** format. For this example, select **German (Switzerland)**. The view updates to show the sales figures as Swiss Francs, formatted for the German language.

**Tip:** You can change the default currency setting so that every time you drag the **Profit** measure to a view it uses the settings you want. In the **Data** pane, right-click **Profit** (or other monetary measure), and select **Default Properties > Number Format**. Then format the field as shown above.

### Format null values

When a measure contains null values, they're usually plotted in a view as zero. However, sometimes that changes the view and you'd rather just suppress null values altogether. You can format each measure to handle null values in a unique way.

#### To format null values for a specific field:

1. Right-click the field in the view that has the null value (Control-click on a Mac) and choose **Format**.
2. Go to the **Pane** tab.
3. In the **Special Values** area, specify whether to show the null value using an indicator in the lower right corner of the view, plot it at a default value (such as zero for number fields), hide the value but connect the line, or hide and break the line to indicate that a null value exists.

- If you specify text in the **Text** field, it appears in the view for a null value when mark labels are turned on. See [Show and Hide Mark Labels](#).

**Note:** The Special Values area isn't available for dimensions or discrete measures.

## For Tableau Server or Tableau Cloud

### Specify a number format

When authoring a view on the web, you can specify the number format for a field used in the view.

1. In web editing mode, right-click a measure in the view and select **Format Number**.

2. In the dialog box that appears, select a number format.

Some formats provide additional settings. For example, if you select **Currency**, you can also specify the number of decimal places, as well as the units, and whether or not to include separators, such as commas.

In this example, Sales is formatted as a Currency with zero decimal places and thousand (k) units. Sales numbers in the view update with these settings. Labels and tooltips update as well.

Here are the number formats and associated options available in Tableau.

#### NUMBER FORMAT

#### FORMAT OPTIONS

**Automatic:** format is automatically selected based on either the format specified by the data source or the data contained in the field.

None.

**Number (Custom):** format is customized to your choice.

**Decimal Places:** the number of decimal places to display.

**Units:** the number is displayed using the specified units. For example, if the number is 20,000 and the units are thousands, the number is displayed as 20K.

**Include separators:** whether the number

shows separators every thousand (example: 100,000 vs. 100000).

**Currency (Custom):** format and currency symbol is customized to your choice.

**Decimal Places:** the number of decimal places to display.

**Units:** the number is displayed using the specified units. For example, if the number is 20,000 and the units are thousands, the number is displayed as 20K.

**Include separators:** whether the number shows separators every thousand (example: 100,000 vs. 100000).

**Percentage (Custom):** numbers are displayed as a percentage with the percent symbol. The value of 1 is interpreted as 100% and 0 as 0%

**Decimal Places:** the number of decimal places to display.

**Scientific (Custom):** numbers are displayed in scientific notation.

**Decimal Places:** the number of decimal places to display.

## Custom Date Formats

This article discusses using the custom date format field to format dates in a view. For an overview of how Tableau works with dates, see [Dates and Times](#), or [Changing Date Levels](#). For setting date properties for a **data source**, see [Date Properties for a Data Source](#).

## How to find the custom date format field

Format a date field in a view (Tableau Desktop)

To format a date field in the view in Tableau Desktop, right-click (Control-click on a Mac) the field and choose **Format**.

This opens the **Format** panel to the left of your view. Select the **Dates** field.

When you format dates, Tableau presents a list of available formats. Usually, the last item in the list is **Custom**. You can specify a custom date using format symbols listed in the Supported date format symbols table, either alone or in combination.

Format a date field in a view (Tableau Cloud and Tableau Server)

To format a date field in the view in Tableau Cloud and Tableau Server, right-click (Control-click on a Mac) the field and choose **Format Date**.

Format a date field in the Data pane (Tableau Desktop only)

To format a date field in the **Data** pane, right-click the field and choose **Default Properties > Date Format**.

The date formats in the table are supported when your workbook is connected to a Tableau extract or has a live connection to a data source that also supports the date format. (Refer to your data source's documentation to verify that the date format you want is supported.)

Tableau retrieves date formats from the data source. Tableau Server can also retrieve date formats from the Run As user account on the server that's running Tableau Server.

**Note:** The following date formats might not be the same as those used with the [Type Conversion](#) function. See [Convert Strings to Date Fields](#) for more information.

### Supported date format symbols

Use the following symbols to construct a custom date format.

| Symbol | Description   |
|--------|---|
| (:)    | Time separator. In some locales, a different character is used to represent the time separator. The time separator separates hours, minutes, and seconds when time values are formatted. The actual character used as the time sep- |

|        |  |
|--------|--|
|        | arator in formatted output is determined by your system settings.  |
| (/)    | Date separator. In some locales, a different character is used to represent the date separator. The date separator separates the day, month, and year when date values are formatted. The actual character used as the date separator in formatted output is determined by your system settings. |
| c      | Display the date as dddddd and display the time as tttttt, in that order. Display only date information if there's no fractional part to the date serial number; display only time information if there's no integer portion.  |
| d      | Display the day as a number without a leading zero (1-31).   |
| dd     | Display the day as a number with a leading zero (01-31).   |
| ddd    | Display the day as an abbreviation (Sun, Sat).   |
| dddd   | Display the day as a full name (Sunday, Saturday).   |
| ddddd  | Display the date as a complete date (including day, month, and year), formatted according to your system's short date format setting. The default short date format is m/d/yy.   |
| dddddd | Display a date serial number as a complete date (including day, month, and year) formatted according to the long date setting recognized by your system. The default long date format is mmmm dd, yyyy.  |
| aaaa   | The same as dddd, only it's the localized version of the string.   |
| w      | Display the day of the week as a number (1 for Sunday through 7 for Saturday).   |
| ww     | Display the week of the year as a number (1-54).   |
| M      | Display the month as a number without a leading zero (1-12). If m immediately follows h or hh, the minute rather than the month is displayed.  |
| MM     | Display the month as a number with a leading zero (01-12). If m immediately follows h or hh, the minute rather than the month is displayed.  |

|         |  |
|---------|--|
| MMM     | Display the month as an abbreviation (Jan-Dec).  |
| MMMM    | Display the month as a full month name (January-December).   |
| MMMMM   | Display the month as a single letter abbreviation (J-D)  |
| oooo    | The same as MMMM, but localized.   |
| q       | Display the quarter of the year as a number (1- 4).  |
| y       | Display the day of the year as a number (1-366).   |
| yy      | Display the year as a 2-digit number (00-99).  |
| yyyy    | Display the year as a 4-digit number (100-9999).   |
| h       | Display the hour as a number without leading zeros (0-23).   |
| Hh      | Display the hour as a number with leading zeros (00-23).   |
| N       | Display the minute as a number without leading zeros (0 59).   |
| Nn      | Display the minute as a number with leading zeros (00 59).   |
| S       | Display the second as a number without leading zeros (0 59).   |
| Ss      | Display the second as a number with leading zeros (00 59).   |
| 000     | Display milliseconds. Use a period character as a separator before specifying milliseconds.  |
| t t t t | Display a time as a complete time (including hour, minute, and second), formatted using the time separator defined by the time format recognized by your system. A leading zero is displayed if the leading zero option is selected and the time is before 10:00 A.M. or P.M. The default time format is h : mm : ss . |
| AM/PM   | Use the 12-hour clock and display an uppercase AM with any hour before noon; display an uppercase PM with any hour between noon and 11:59 P.M.   |
| am/pm   | Use the 12-hour clock and display a lowercase AM with any hour before noon; display a lowercase PM with any hour between noon and 11:59 P.M.   |
| A/P     | Use the 12-hour clock and display an uppercase A with any hour before noon; display an uppercase P with any hour between noon and 11:59 P.M.   |

|      |  |
|------|--|
| a/p  | Use the 12-hour clock and display a lowercase A with any hour before noon; display a lowercase P with any hour between noon and 11:59 P.M.   |
| AMPM | Use the 12-hour clock and display the AM string literal as defined by your system with any hour before noon; display the PM string literal as defined by your system with any hour between noon and 11:59 P.M. AMPM can be either uppercase or lowercase, but the case of the string displayed matches the string as defined by your system settings. The default format is AM/PM. |

## Custom date format examples

Any of the date format symbols in the table above can be used alone or in combination.

Specifying a custom format yyyy-MM-dd HH:mm:ss.000 would produce dates in the format 2015-05-10 11:22:16.543. Such a format might be appropriate for scientific data.

Specifying a custom format DDDD DD would produce dates that show the Weekday and the Day, as shown below.

Specifying a custom format `yy-mm-dd (dddd)` would produce dates in the format **18-01-04 (Thursday)**.

Specifying a custom format `"Q"1 YYYY` would produce dates that show **Q1 2018**.

## Support for Japanese era-based date formats

Tableau supports Japanese emperor-era-based date (Wareki) formats. Here's how to apply an era-based date format to a field in your view:

1. Set your workbook locale to Japanese.
2. Right-click the field in the view for which you want to set a date format.

3. Choose **Format**.
4. In the **Format** pane, from the **Dates** drop-down list, select a format.

If the format that you want isn't listed, you can construct your own date format. To do this, choose **Custom format** in the **Dates** box, then type your format using the Tableau date placeholders. The following era-based year placeholders are available:

| Symbol | Description  |
|--------|--|
| g      | Short era name (such as H for the Heisei era).   |
| gg     | Era name (such as 平成).   |
| ggg    | Long era name (for Japanese, this is the same as the regular era name).  |
| e      | Era-based year, such as 1 for the first year of an era.  |
| ee     | Era-based year, such as 01 for the first year of an era. If there's only one digit, then the era-based year will have a zero added to the front. |

If your workbook locale isn't Japanese, you can create a custom date format, then insert the language code !ja\_JP! in front of your format, so that it looks like this:

```
!ja_JP! gg ee"年"mm"月"dd"日"
```

The language code forces the date to be treated as if it's a Japanese date.

Era-based dates aren't fully supported by the Tableau Server browser view. In particular, if you publish a workbook that contains an interactive filter, the e and g placeholders won't be filled in:

**Order Date** gg ee年01月01日  gg ee年12月31日

To avoid this issue, don't show era-based dates in interactive filters if your workbook will be viewed in a browser.

## Using literal text in a date format

You may want your date format to include some words or phrases, such as **Fiscal Quarter q of yyyy**. However, if you type that text directly into the Tableau format box, it may treat the letters like date parts:

| Quarter of Order Date           |
|---------------------------------|
| Fi01/1/2010a1 quarter 1 of 2010 |
| Fi04/1/2010a2 quarter 2 of 2010 |
| Fi07/1/2010a3 quarter 3 of 2010 |
| Fi10/1/2010a4 quarter 4 of 2010 |

To prevent Tableau from doing this, put double quotes around the letters and words that shouldn't be treated as date parts: "Fiscal Quarter" q "of" yyyy.

If you want a literal quote inside of a quoted section, insert this code: "\"". For example, the format "Fiscal \" Quarter" would be formatted as **Fiscal " Quarter**.

## Format syntax in DATEPARSE function for extract data sources

If you're using the DATEPARSE function in an extract, use the syntax defined by the Unicode Consortium.

The following table lists the field types that can be represented in the format parameter of the DATEPARSE function. Click the field type to get information about the symbols, field patterns, examples, and descriptions from the Unicode Consortium website.

| Unit of time         | Notes   |
|----------------------|---|
| <a href="#">Era</a>  | n/a   |
| <a href="#">Year</a> | All symbols are supported in .hyper extracts except for "U".<br><br><b>Notes:</b> |

| Unit of time | Notes  |
|--------------|--|
|              | <ul style="list-style-type: none"> <li>• Negative values denote a year before Christ (BC).<br/>For example, <code>DATEPARSE ('y', '-10')</code> returns the first January of 11BC and <code>DATEPARSE ('y', '-0')</code> returns the first January of 1BC.</li> <li>• When working with the calendar year "y", the pattern "yy" requests the two low-order digits of the year. For numbers &lt; 70, the <code>DATEPARSE</code> function returns the year 2000+x. For numbers &gt;=70, the <code>DATEPARSE</code> function returns the year 1900+x.</li> <li>• When working with "Y" in "ISO week date" based calendars, the year transition occurs on a week boundary and may differ from the calendar year transition. The "Y" designation is used in conjunction with pattern character "w" in ISO year-week calendar. The ISO week date system is effectively a leap week calendar system that is part of the ISO 8601 date and time standard. Similar to "y", negative values for "Y" denote a year before Christ (BC).</li> </ul> |
| Month        | <p>All symbols are supported in .hyper extracts except for "l".</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>• The month designations are used in conjunction with "d" for the day number.</li> <li>• In contrast to ICU, .hyper extracts allow values 1–12. Other values cause an error.</li> </ul>  |
| Week         | <p>All symbols are supported in .hyper extracts except for "W".</p>  |

| Unit of time | Notes  |
|--------------|--|
|              | <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>• When working with "w", in contrast to ICU, .hyper extracts allow only valid weeks. A year has 52 or 53 weeks (ISO 8601). The DATEPARSE function validates the input. For example, an error occurs for the 53rd week of 2016 because the 53rd week doesn't exist for 2016.</li> <li>• When working with "W", ICU doesn't support this designation, but it's useful for dates like 1st Monday of September.</li> </ul> |
| Day          | <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>• When working with "d", in contrast to ICU, .hyper extracts only allow valid day numbers. For example, an error occurs for the 31st of February.</li> <li>• When working with "D", in contrast to ICU, .hyper extracts only allow valid day numbers. For example, an error occurs for the 366th day of 2017.</li> </ul>   |
| Hour         | <p>Only "h" and "H" symbols are supported in .hyper extracts.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>• When working with "h", .hyper extract don't allow negative values for this field. Negative values cause an error.</li> <li>• When working with "H", .hyper extracts don't allow negative values for this field. Negative values cause</li> </ul>   |

| Unit of time | Notes   |
|--------------|---|
|              | an error.   |
| Minute       | <b>Note:</b> In contrast to ICU, .hyper extracts don't allow negative values for this field. Negative values will cause an error.   |
| Second       | <b>Notes:</b> <ul style="list-style-type: none"> <li>In contrast to ICU, .hyper extracts don't allow negative values for this field. Negative values will cause an error.</li> <li>When working with "S", <code>DATEPARSE('ss.SSSS', '12.3456')</code> returns 1990-01-01 00:00:12:3456 AD.</li> </ul>                      |
| Quarter      | <b>Note:</b> In contrast to ICU, .hyper extracts only allow values 1–4. All other values cause an error.  |
| Weekday      | <b>Notes:</b> <ul style="list-style-type: none"> <li>When working with "e" and "ee", in contrast to ICU, .hyper extracts only allow values 1–7. All other values cause an error.</li> <li>When working with "c..cc", in contrast to ICU, .hyper extracts only allow values 1–7. All other values cause an error.</li> </ul> |
| Period       | n/a   |

## URL Actions

A URL action is a hyperlink that points to a web page, file, or other web-based resource outside of Tableau. You can use URL actions to create an email or link to additional information

about your data. To customize links based on your data, you can automatically enter field values as parameters in URLs.

**Tip:** URL actions can also open in a web page object in a dashboard. See [Actions and Dashboards](#) to learn more.

A URL action run from a tooltip menu. The link reflects the action name, not the target URL.

## Open a web page with a URL action

1. On a worksheet, select **Worksheet > Actions**. From a dashboard, select **Dashboard > Actions**.
2. In the Actions dialog box, click **Add Action** and then select **Go to URL**.
3. In the next dialog box, enter a name for the action. To enter field variables in the name, click the **Insert** menu to the right of the **Name** box.

**Note:** Give the action a descriptive name, because the link text in the tooltip is the name of the action, not the URL. For example, when linking to more product details, a good name could be "Show More Details".

4. Use the drop-down list to select a source sheet or data source. If you select a data source or dashboard you can select individual sheets within it.

5. Select how users will run the action.

**If you choose this option...**      **The action is run when the user...**

**Hover**      Mouses over a mark in the view. This option works best for highlight actions within a dashboard.

**Select**      Clicks a mark in the view. This option works well for all types of actions.

**Menu**      Right-clicks (control-clicks on Mac) a selected mark in the view, then clicks an option in a tooltip (menu). This option works particularly well for URL actions.

6. For URL Target, specify where the link will open:
- **New Tab if No Web Page Object Exists** — Ensures that the URL opens in a browser on sheets that lack web page objects. This is a good choice when Source Sheets is set to All or a data source.
  - **New Browser Tab** — Opens in the default browser.
  - **Web Page Object** — (Available only for dashboards with Web Page objects) Opens in the web page object you select.

**URL Target**

New Tab if No Web Page Object Exists  
 New Browser Tab  
 Web Page Object

## 7. Enter a URL

- The URL should start with one of the following prefixes: `http`, `https`, `ftp`, `mailto`, `news`, `gopher`, `tsc`, `tsl`, `sms`, or `tel`

**Note:** If no prefix is entered, `http://` is automatically appended to the beginning and the URL action will work in Tableau Desktop. However, if a URL action with no prefix is published to Tableau Server or Tableau Cloud, it will fail in the browser. Always provide a fully qualified URL for actions if the dashboard will be published.

**Note:** You can specify an ftp address only if the dashboard doesn't contain a web object. If a web object exists, the ftp address won't load.

- Tableau Desktop also supports local paths like `C:\Example folder-example.txt`, as well as file URL actions.
- To enter field and filter values as dynamic values in the URL, click the **Insert** menu to the right of the URL. Be aware that any referenced fields must be used in the view. For details, see [Using field and filter values in URLs](#).

▼ **Data Values**

[Learn more](#)

Encode data values that URLs do not support

Allow multiple values via URL parameters

Value Delimiter

Delimiter Escape Character

Below the URL you enter is a hyperlinked example you can click for testing.

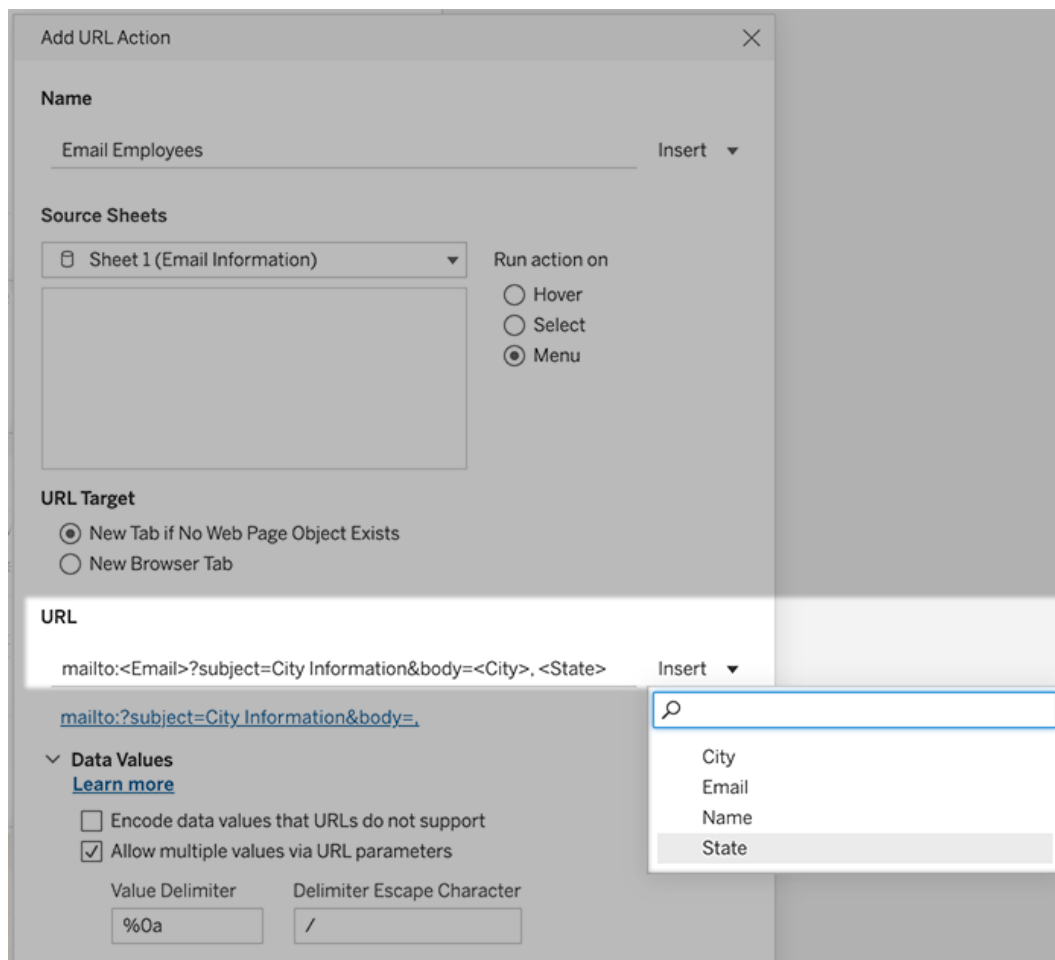

8. (Optional) In the Data Values section, select any of the following options:
  - **Encode Data Values that URLs Do Not Support** — Select this option if your data contains values with characters that browsers don't allow in URLs. For example, if one of your data values contains an ampersand, such as “Sales & Finance,” the ampersand must be translated into characters that your browser understands.
  - **Allow Multiple Values via URL Parameters** — Select this option if you are linking to a web page that can receive lists of values via parameters in the URL. For example, say you select several products in a view and you want to see each product's details hosted on a webpage. If the server can load multiple product details based on a list of identifiers (product ID or product name), you could use multi-select to send the list of identifiers as parameters.

When you allow multiple values, you must also define the delimiter escape character, which is the character that separates each item in the list (for example, a comma). You must also define the Delimiter Escape, which is used if the delimiter character is used in a data value.

## Create an email with a URL action

1. On a worksheet, select **Worksheet > Actions**. From a dashboard, select **Dashboard > Actions**.
2. In the Actions dialog box, click **Add Action**, and select **Go to URL**.
3. In the Source Sheets drop-down list, select the sheet that contains the field with the email addresses you want to send to.
4. In the URL box, do the following:
  - Type **mailto:**, and click the **Insert** menu at right to select the data field that contains email addresses.
  - Type **?subject=**, and enter text for the Subject line.
  - Type **&body=**, and click the **Insert** menu at right to select the fields of information that you want to include in the body of the email.

In the example below, the “Email” field contains the email addresses, the subject is “City Information”, and the body text of the email consists of the city and state data that is associated with the email address.

:

5. (Optional) Display data from your workbook in the body of your email as a vertical list instead of the default horizontal list. For example, suppose you have a horizontal list of cities, such as Chicago, Paris, Barcelona, which you would rather display vertically, like this:

Chicago

Paris

Barcelona

To make the list vertical, in the Data Values section, do the following:

- Deselect **Encode Data Values that URLs Do Not Support**
- Select **Allow Multiple Values via URL Parameters**.
- Type **%0a** in the **Value Delimiter** text box to add line breaks between each item in the list. (These are the URL-encoded characters for a line break.)

## Using field and filter values in URLs

When users trigger URL actions from selected marks, Tableau can send field, filter, and parameter values as variables in the URL. For example, if a URL action links to a mapping website, you could insert the address field to automatically open the currently selected address on the website.

1. In the Edit URL Action dialog box, begin typing the URL for the link.
2. Place the cursor where you want to insert a field, parameter, or filter value.
3. Click the **Insert** menu to the right of the text box and select the field, parameter, or filter you want to insert. The variable appears within angle brackets. You can continue adding as many variables as you need.

**Note:** Any referenced fields must be used in the view. Otherwise, the link won't display in the viz, even if it functions when you click Test Link.

### Including aggregated fields

The list of available fields includes only non-aggregated fields. To use aggregated field values as link parameters, first create a related calculated field, and add that field to the view. (If you don't need the calculated field in the visualization, drag it to Detail on the Marks card.)

### Inserting parameter values

When inserting parameter values, URL actions send the Display As value by default. To instead send the actual value, add the characters `~na` after the parameter name.

For example, say you have a parameter that includes IP addresses, with Actual Value strings such as `10.1.1.195` and Display As strings with more friendly values such as `Computer A (10.1.1.195)`. To send the actual value, you'd revise the parameter in the URL to look like this: `http://<IPAddress~na>/page.htm`.

## Create a Subscription to a View or Workbook

Subscriptions email you an image or PDF snapshot of a view or workbook at regular intervals—without requiring you to sign in to Tableau Server.

**Note:** Administrators determine whether subscriptions are turned on for a site.

If Tableau Catalog is turned on for a site, administrators can also determine whether subscription emails include relevant upstream data quality warnings. Tableau Catalog is available as part of the Data Management offering. For more information, see [About Tableau Catalog](#).

### Set up a subscription for yourself or others

When you open a view in Tableau Server, if you see a subscription icon (✉+) in the toolbar, you can subscribe to that view or to the entire workbook. You can subscribe other users who have permission to view the content if you own a workbook, if you are a project leader with an appropriate site role, or if you are an administrator.

1. From the Explore section of your site, select **All Workbooks** or **All Views**, or open the project that contains the view you want to subscribe to.

2. Open a view either directly, or after opening the containing workbook.
3. On the view toolbar, select **Watch > Subscriptions**.

4. Add the Tableau users or groups you want to receive the subscription. To receive a subscription, users must have the View and Download Image/PDF permissions and their accounts must also have email addresses.

If you own the workbook, select **Subscribe me**.

**Notes:**

- When you subscribe a group, each user is added individually at the time the subscription is created. If more users are added to the group later, you must re-subscribe the group for those new users to receive the subscription. Likewise, users later removed from the group will not have their subscriptions removed automatically unless their permissions to the subscribed view are removed.
  - You can't subscribe a group set.
5. Choose whether subscription emails include the current view or the entire workbook. If the view contains data only when high-priority information exists, select **Don't send if view is empty**.
  6. Choose the format for your snapshot: as a PNG image, a PDF attachment, or both.
    - If PDFs, choose the paper size and orientation you'd like to receive.

7. To clarify subscription emails, customize the subject line, and add a message.

**Note:** To update the subscription message, you must unsubscribe from the existing subscription and create a new subscription with a different message. For more information, see [Update or unsubscribe from a subscription](#).

8. When the workbook uses one data extract on a published connection, you can pick a frequency:

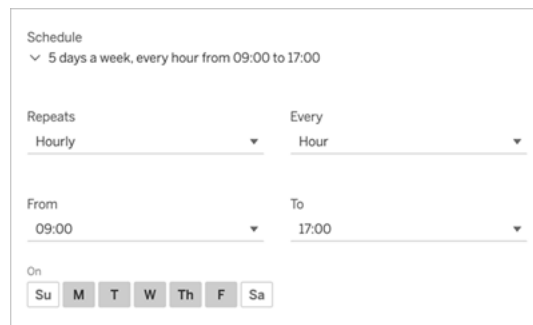

- **When Data Refreshes:** Sends only when data in the view or workbook is refreshed by running refresh schedules.
- **On Selected Schedule:** Pick a schedule for the subscription.

9. If frequency is not set to When Data Refreshes, pick a schedule:

- Choose from subscription schedules established by your administrator.
- For sites with **custom schedules enabled**, click the drop-down arrow to the left of the current settings.

Then specify a custom schedule that sends subscription emails whenever you wish. (The precise delivery time may vary if server load is high.)

To change the time zone, click the Time Zone link to go to your account settings page.

10. Click **Subscribe**.

When you receive a subscription email, you can select the image (or the link in the message body for PDF subscriptions) to be taken to the view or workbook in Tableau Server.

## Update or unsubscribe from a subscription

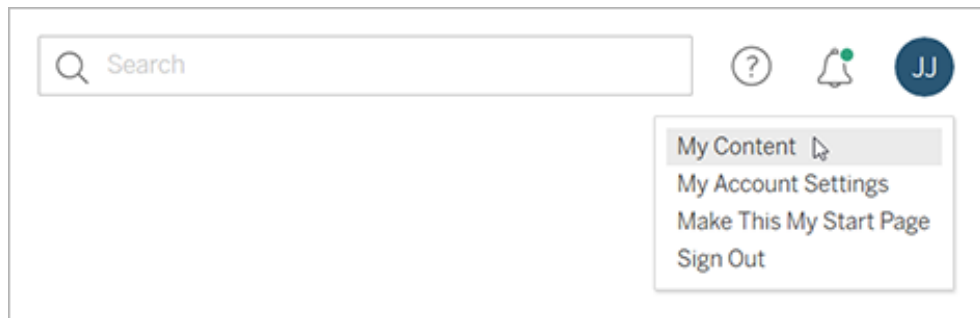

You can unsubscribe from an existing subscription, or make changes to a subscription's format, schedule, subject, or empty view mode.

1. Access your Tableau Server account settings by doing one of the following:
  - Click **Manage my subscriptions** at the bottom of a subscription email.

- Sign in to Tableau Server. At the top of the page, select your user icon, and then

select **My Content**.

2. Click **Subscriptions**.
3. Select the check box next to the view you want to unsubscribe from, click **Actions**, and then click **Unsubscribe**, or select the subscription option you'd like to change.

## Resume or delete suspended subscriptions

Sometimes, subscriptions fail because of an issue with the workbook or a problem loading the view. If a subscription fails more than five times, you'll receive a notification email that your subscription has been suspended. There are a few ways to resume a suspended subscription if you're a subscription owner or administrator:

- From the My Content area of Tableau web pages, an icon appears in the Last update column to indicate that the subscription is suspended. Select ... > **Resume Subscription** to resume.
- From the Subscriptions tab of the affected workbook, an icon appears in the last update column to indicate that the subscription is suspended. Select ... > **Resume Subscription** to resume.

You'll receive an email notification when the subscription is working again.

## See also

[Change subscription settings](#) in the Tableau Desktop and Web Authoring Help.

[Project-level administration](#) in the Tableau Cloud Help, to learn which site roles allow full Project Leader capabilities.

## Use Custom Views

A custom view is a shortcut to a specific state of interaction, such as filter selections and sorting, for a published viz. Custom views don't impact the underlying content. They're a good option if you find yourself adjusting the same filters or zooming into the same data every time you look at a viz.

Custom views aren't the same as web editing, which changes the underlying published content itself. See [Edit Tableau Views on the Web](#).

If the custom views are specifically for filter settings, consider using embedding filter parameters in a shared URL. See [Filter a published dashboard by editing the URL](#) from [The Data School](#).

### Notes on custom views

- A custom view doesn't modify the content it's built on.
- Deleting the original content deletes its custom views.
- If the original content is updated or republished, the custom view is also updated.

**Tip:** Some changes to the original content can break the custom view. See [Maintain Content with Custom Views](#) for best practices on modifying content with custom views.

- If a user is removed from the site, any shared custom views they owned are also lost.
- Subscriptions based on custom views may be more fragile than subscriptions based on the original content.

**Note:** As of the 2022.3 release, Tableau replaced user names in the custom view URL with IDs. Bookmarked URLs still work but are redirected to the new URL schema. This change is to add more company and user data protection.

## Create a custom view

Start by navigating to the individual view. Make whatever changes you want to capture in the custom view, such as selecting marks, filtering data, or changing sorts.

1. When you're ready to save the changes you've made as a custom view, select **Save Custom View** from the toolbar.

**Note:** The **Save Custom View** button appears in the toolbar after any changes are made to the current view.

2. In the **Save Custom View** dialog, enter a name for the custom view.
3. (Optional) Select **Make it my default**.
4. (Optional) Select **Make visible to others**. This makes the custom view available to everyone who can see the original content. However, there are several instances when this option isn't available:
  - The user is a Viewer site role.
  - The site's **User Visibility setting** is set to Limited.
  - The permission capability **Share Customized** is denied on the workbook.
5. Click **Save**.

## Find a custom view

### From a view

When you're looking at a viz, you can change to a different custom view by selecting the View icon in the toolbar. If there's room in the toolbar, the name of the custom view you're looking at is shown.

Any custom views you've made, and all visible custom views made by other users, appear in the list.

### From the workbook

When you're looking at content at the workbook level, use the **Custom Views** tab to see all the available custom views for that workbook.

## Set a default custom view

After you've found or made a custom view, you make it the default you see when you open that viz.

1. Select the **View** icon in the toolbar.
2. Check the **Set this view a your default** option.
3. Close the dialog to save.

The next time you open that viz, you'll land on that custom view.

## Share a custom view

By default, custom views are private and only appear for the user who created them.

**Note:** Users with a Viewer site role can't make custom views visible to others. However, they can share a custom view by copying and sharing the URL.

Users with a site role of Explorer or higher can set a custom view as visible to others. This setting allows anyone with access to the original content to see the custom view.

To change an existing private custom view to be visible to others (or to make a visible view private):

1. Select the **View** icon in the toolbar.
2. Toggle the eye icon to the view you want to share to the desired state.
3. Close the dialog to save.

The eye with a slash  indicates the view is private to you. The eye  indicates the view is visible to others.

## Delete a custom view

To delete a custom view:

1. Select the **View** icon in the toolbar.
2. Select the trash icon of the view you want to delete.
3. Confirm that you want to delete the view.

Take care when deleting

If you're the owner of a custom view that's visible to others, remember it's deleted for everyone if you delete it.

Deleting a custom view also deletes any subscriptions based on that custom view.

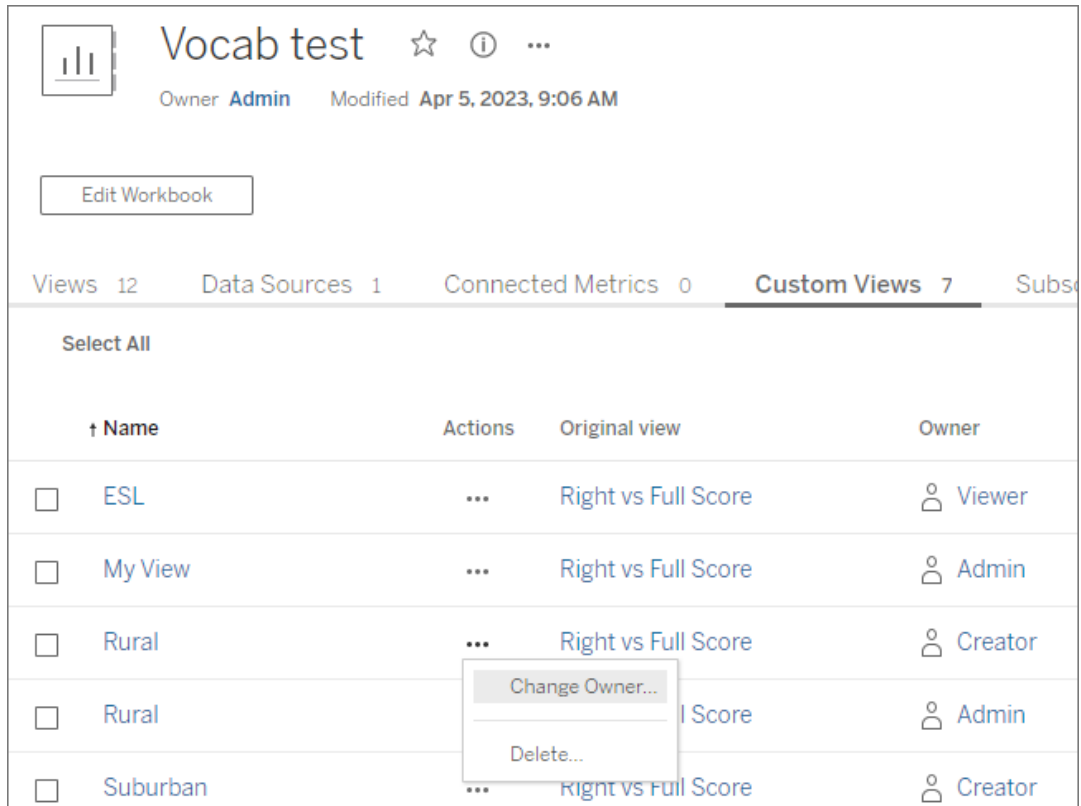

## Manage custom views

Administrators can change ownership for custom views and delete custom views created by other users.

Custom views can be managed for a piece of content or for a specific user.

## Tableau Server on Linux Administrator Guide

1. Go to the Custom Views tab for the workbook or user.
2. Use the action menu to change the owner or delete the custom view.

**Tip:** It's a best practice to change ownership of any custom views belonging to a user before removing them from the site. Deleting a user also deletes their custom views, including public views others may be using.

### Safely change content with custom views

If you need to modify a view that has custom views (or the data source the view is built on), be aware that certain changes can break custom views. For more information, see [Maintain Content with Custom Views](#).

## Publish Views to Salesforce

Bring your views from Tableau Cloud or Tableau Server right to your Salesforce ecosystem by publishing views to a CRM Analytics app or Salesforce Lightning page.

For more information, see [Publish Tableau Content to CRM Analytics](#) in Salesforce Help.

## Prerequisites

See a complete list of [prerequisites](#) in Salesforce Help, including required licenses, account setup, and permissions.

## Publish a view to Salesforce

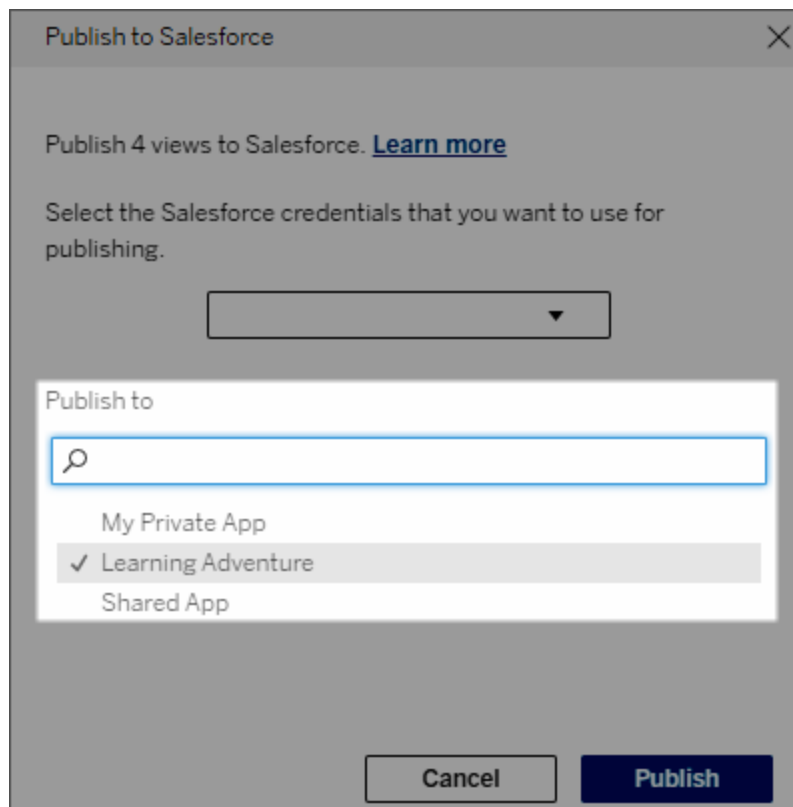

Select one or more views, including dashboards, sheets, and stories. Then, choose a destination from a list of CRM Analytics apps that you have access to edit or manage.

1. Select the view that you want to publish to Salesforce.

**Note:** You can select a maximum of 25 views at a time to publish to Salesforce.

2. For **Actions**, select **Publish to Salesforce**.
3. Select the Salesforce credentials that you want to use for publishing.
4. Select the destination app that you want to publish to. You can only see apps that you can edit or manage with the signed-in Salesforce user.

5. Click **Publish**.

## Who can see the published view in Salesforce?

When you publish a view to Salesforce, anyone with access to the selected CRM Analytics app or Lightning page can see that the content exists. However, only those signed in with existing Tableau permissions can see the view.

## Configuring Tableau Lightning Web Components and Seamless Authentication

Tableau Lightning web components (LWC) allow Salesforce customers to drag and drop Tableau views and Tableau Pulse metrics onto Salesforce Lightning pages.

- The Tableau View component allows you to add embedded views from Tableau Cloud or Tableau Server.

- The Tableau Pulse component allows you to add embedded Tableau Pulse metrics from Tableau Cloud.

Tableau LWC seamless authentication allows you to view Tableau content using connected app trusted tokens without signing in. Seamless authentication is optional for Tableau View LWC, and is required for Tableau Pulse LWC.

**Important:** [Salesforce Console](#) apps do not support the use of Tableau Lightning web components.

## Add Trusted URL

The Tableau view or Pulse URL that you want to add to your Lightning page must be added as a Trusted URL.

1. From your Salesforce app, select the gear in the top-right corner, and then select **Setup**.
2. On the left navigation pane, enter “Trusted URLs” in the **Quick Find** search bar.
3. Select the **Trusted URLs** settings page.
4. Select **New Trusted URL**.
5. Enter an **API Name** and **URL**, following the instructions on the settings page. **Note:** The URL must begin with `https://`
6. For CSP Context, select **All**.
7. For CSP Directives, check all boxes.
8. Select **Save**.

## Turn on Tableau LWCs and set up seamless authentication

Configure Salesforce settings

The following steps only need to be completed one time by a Salesforce admin:

1. From your Salesforce app, select the gear in the top-right corner, and then select **Setup**.
2. On the left navigation pane, enter “Tableau” in the **Quick Find** search bar.
3. Select the **Tableau Embedding** settings page.
4. Select the checkboxes for **Turn on Tableau Lightning Web Components** and **Turn on token-based single sign-on authentication**.

**Note:** Both of these boxes must be checked to configure the Tableau Pulse LWC. For the Tableau View LWC, you can choose not to set up token authentication and instead sign in manually when the component loads.

To use Tableau View LWC on Mobile, you must turn on token-based authentication and set up seamless authentication.

5. For **Select Tableau User Identity field**, set an org-level user field to authenticate the user in Tableau. You must select the Salesforce user field that corresponds with the Tableau username. The dropdown shows the field value for the current user, or null if no value is defined. If none of the user fields match the Tableau username, select an empty field (for example, Federation ID or a custom field). Then, populate the empty field with the Tableau username for your users.

**Note:** The Tableau User Identity field setting applies to all users and doesn't need to be set on an individual basis.

6. Save your changes.
7. If you're the Tableau admin, keep the Salesforce settings **Tableau Embedding** tab open while you configure Tableau settings in the next section. If you aren't the admin, share the **Issue URL** and **JWKS URI** with your Tableau admin.

### Configure Tableau settings

In one tab, open the Tableau Embedding settings page in your Salesforce org. In another tab, go to your Tableau site and follow these instructions to set up the Connected App.

For Tableau Server, follow these steps:

1. As a Tableau Server admin, sign in to the Tableau Services Manager (TSM) web interface.
2. Navigate to **User Identity & Access**, and then select the **Authorization Server** tab.
3. Select the checkbox for **Enable OAuth access for embedded content**.

4. Enter the **Issue URL** and **JWKS URI**, which you can find on the Salesforce org Tableau Embedding settings page. Use the **Copy** button on the Salesforce org settings page to copy the Issuer URL value, and then paste it into the TSM web interface. Repeat this process for the JWKS URI value.

**Note:** The JWKS URI field is marked as optional in the TSM web interface, however this value is required to use Tableau LWC seamless authentication.

5. Select **Save Pending Changes**.
6. Select **Pending Changes** in the upper-right corner of the page, and then select **Apply Changes and Restart** to stop and restart Tableau Server.

For more information, see [Register your EAS with Tableau Server](#).

For Tableau Cloud, follow these steps:

1. Open the Tableau **Settings** page, and then choose the **Connected Apps** tab.
2. From the New Connected App dropdown, select **OAuth 2.0 Trust**.
3. On the Create Connected App dialog, enter the **Issue URL** and **JWKS URI**, which you can find on the Salesforce org Tableau View Embedding settings page. Use the **Copy** button on the Salesforce org settings page to copy the Issuer URL value, and then paste it into the Tableau settings page. Repeat this process for the JWKS URI value.

**Important:** The Create Connected App dialog notes the JWKS URI field as optional, however this value is required to use Tableau LWC seamless authentication.

4. Select the checkbox for **Enable connected app**.
5. Select **Create**.

**Note:** The Connected App is named External Authorization Server.

For more information, see [Register your EAS with Tableau Cloud](#).

If you want to create a host mapping for this site, leave the Connected Apps tab open. You can use the URL for this page and the Copy Site ID button to populate the host mapping fields in the following section.

## Set up or edit host mapping

Follow these steps to create or edit a host mapping.

**Tip:** The Tableau User Identity field setting applies to all users and doesn't need to be set on an individual basis.

### Create a new host mapping

1. From your Salesforce app, select the gear in the top-right corner, and then select **Setup**.
2. On the left navigation pane, enter "Tableau" in the **Quick Find** search bar.
3. Select the **Tableau Embedding** settings page.
4. From the Tableau Host Mapping section, select **Create New**.
5. Fill in the host mapping details:
  - a. Tableau site URL: Enter a URL for the Tableau site that you want to map. The URL should contain the site name, unless it's an on-prem installation using the Default site. **Note:** If you want to create a host mapping for this site, leave the Connected Apps tab open. You can use the URL for this page and the Copy Site ID button to populate the host mapping fields in the following section.
  - b. Tableau site ID: Enter the site ID for the Tableau site that you want to map. You can use the Copy Site ID button on the Connected App settings page or on the Share dialog.
  - c. Tableau site host type: Select Tableau Cloud or Tableau Server.
6. Select **Save**. Or, if you want to return to the Tableau Embedding settings page without saving, select **Cancel**.

### Edit a host mapping

You can update the site ID and host type for an existing mapping. If you need to change the site URL, delete the existing mapping, and then create a new one with the correct URL.

1. From the Salesforce app Tableau Embeddings settings page, select Edit next to an existing host mapping.
2. Edit the **Tableau site ID** or **Tableau site host type** fields as needed.
3. Select **Save**. Or, if you want to return to the Tableau Embedding settings page without saving, select **Cancel**.

## Add Tableau LWCs to a Lightning page using Lightning App Builder

Tableau LWCs are available on App, Home, and Record Lightning pages only. For more information about Lightning page types and using the Lightning App Builder, see Lightning App Builder in Salesforce Help.

To add a Tableau View or Tableau Pulse LWC to an existing Lightning page, follow these steps:

1. Navigate to the Lightning page that you want to edit.
2. Select the gear icon in the top right.
3. Select Edit Page.
4. Proceed to the **Add a Tableau LWC to a Lightning page** section below.

To add a Tableau View or Tableau Pulse LWC to a new Lightning page, follow these steps:

1. From your Salesforce app, select the gear in the top-right corner, and then select **Setup**.
2. On the left navigation pane, enter “Lightning App Builder” in the **Quick Find** search bar.
3. Select the **Lightning App Builder** setup page.
4. Select **New**.
5. Select the page type that you want to create. Tableau LWCs are available on App, Home, and Record pages.
6. Select **Next**.
7. Enter a name and select a layout for the new page, and then select **Done**.

Add a Tableau LWC to a Lightning page

1. From the Components list on the left side of the page, drag and drop the Tableau View or Tableau Pulse component onto the page.
2. Configure the LWC:
  - [Configure a Tableau View Lightning Web Component](#)
  - [Configure a Tableau Pulse Lightning Web Component](#)

Save and activate the page

1. When you've finished adding and configuring a Tableau View or Tableau Pulse LWC, select **Save**.

## Tableau Server on Linux Administrator Guide

2. If you've created a new page, you are prompted to activate the page so that it's visible to users. Select **Activate**.
3. On the **Page Settings** tab of the Activation page, enter a name, choose an icon, and select your visibility preference.
4. (Optional) On the **Lightning Experience** tab of the Activation page, you can add the page to various Lightning Experience Apps.
5. (Optional): On the **Mobile Navigation** tab of the Activation page, you can add the page to the Mobile Navigation Menu.  
**Note:** Tableau Pulse LWC isn't available on Mobile.
6. Select **Save**.

## Embed multiple Tableau views

You can embed more than one Tableau view on a Salesforce Lightning page as long as all views come from the same site. Tableau only supports a single session, and that session is specific to the site. The most recently granted session will wipe out the previous one.

To embed Tableau views from multiple sites, you must create a separate Lightning page that is site-specific.

## Tableau View LWC seamless authentication on Mobile

**Note:** Tableau View LWC is available on iOS 17.2.1+. Tableau Pulse LWC isn't currently available on iOS or Android.

Consider the following best practices to prevent issues for mobile users:

- Lightning page type: Mobile users can access App Pages and Record Pages, but not Home Pages.

**Note:** Record Pages must be associated with a specific type of record.

- If you use the same page for both desktop and mobile users, select **Activation** to verify that the Lightning page is set as the Org Default for both desktop and phone form factors.

- Consider creating separate Lightning pages for desktop and mobile to provide a tailored visual experience. The height for the Tableau View component is fixed and won't dynamically adjust to different screen sizes.
- To add a scroll bar to a view, select **Show Toolbar** from the Tableau View component properties pane.
- For the App Page type, select **Activation**, and then select the **Lightning Experience** tab. Add your page to the LightningBolt list to make the page easier to find on mobile.
- On mobile, iOS blocks cross-site traffic by default. Open your mobile settings, select Salesforce settings, and then turn on **Allow Cross-Website Tracking**. For more information, see [Enable cross-website tracking](#).

## Troubleshooting Tableau View LWC seamless authentication

Verify the Salesforce and Tableau configuration

1. Verify that the **Issuer URL** and **JWKS URI** values match in both Salesforce and Tableau Settings and that JWKS URI ends with **id/keys**.
  - For Tableau Cloud, open the Salesforce Settings Tableau Embedding page in one tab. In another tab, open the Tableau Settings Connected Apps tab. On the Connected Apps tab, select **External Authorization Server**, and then select **Edit**. Verify that the **Issuer URL** and **JWKS URI** values match and that the JWKS URI ends with id/keys.
  - For Tableau Server, open the Salesforce Settings Tableau Embedding page in one tab. Then, sign in to the Tableau Services Manager (TSM) web interface, navigate to **User Identity & Access**, and then open the **Authorization Server** tab.
2. Verify Host Mapping: If you've saved a host mapping, verify that it has the correct site ID and host type.

Verify the JWT token

In the Tableau View Lightning web component property editor, select Debug Mode to verify that the JWT token is working as expected.

1. Open the console logs and copy the token.
2. Go to the [jwt.io](https://jwt.io) website and paste the token into the **Encoded** field.
3. Verify the following:

## Tableau Server on Linux Administrator Guide

- The subject (“sub”) matches the Tableau username.
- For Tableau Cloud, the audience (“aud”) is “tableau+SiteID”.  
For Tableau Server, the audience (“aud”) is “tableau”.
- The scope (“scp”) includes both “tableau:views:embed” and “tableau:insights:embed”.
- The issuer (“iss”) EAS server is accurate.

### Verify page activation

Sometimes, a user creates a Lightning page, but it hasn’t been activated or assigned anywhere, so users can’t find it. Select **Activation** to verify that the Lightning page is set as the Org Default for the intended form factors.

**Tip:**When debugging, it’s helpful to drag and drop a Rich Text component onto your page. Add a brief description of the page type and the view URL that you’re trying to embed. This allows you to be sure that the page being viewed by the end user is the page that the admin is editing.

Confirm that Tableau View LWC is working without seamless authentication (Tableau View LWC only)

1. From the Tableau View pane on your Lightning page, clear the checkbox for **Default Authentication Token**, and then save the changes.
2. If you’re signed in to Tableau in another tab, sign out. Ensure that navigating to the View URL redirects you to the Tableau sign-in page. Do not sign in.
3. Navigate to the Lightning page. The Tableau View LWC should display a **Sign in to Tableau** button.
4. Select **Sign in to Tableau**, and then enter your Tableau credentials to sign in.  
**Note:** If the view doesn’t load, this indicates a broader issue with authenticating to Tableau.

Error: LWC component version no longer supported (Tableau View LWC only)

To resolve this error, follow these steps:

1. In the Components list, search for “Tableau”, and then drag and drop a new **Tableau View** component onto the page.
2. Copy all properties from the Tableau View pane for the old component over to the new component.
3. Select the delete icon on the old component.

## Interact with Data in Tableau

This tutorial walks you through some of the basics of viewing and interacting with data visualizations, or views, in Tableau Server.

Tableau is a tool that lets you interact with published visualizations to explore insights, ask questions, and stay on top of your data. Here's how to get started.

### Go ahead. It's safe to click around

Tableau is built for interaction. What you do to a visualization changes how it looks for you, just for now.

Others will still see the visualization as it originally appeared. And the data used to build it stays the same, too.

### 1: What is a Tableau Site?

A Tableau Site is a place for your team to share data and data visualizations with each other. You can explore what they've published and made available to you.

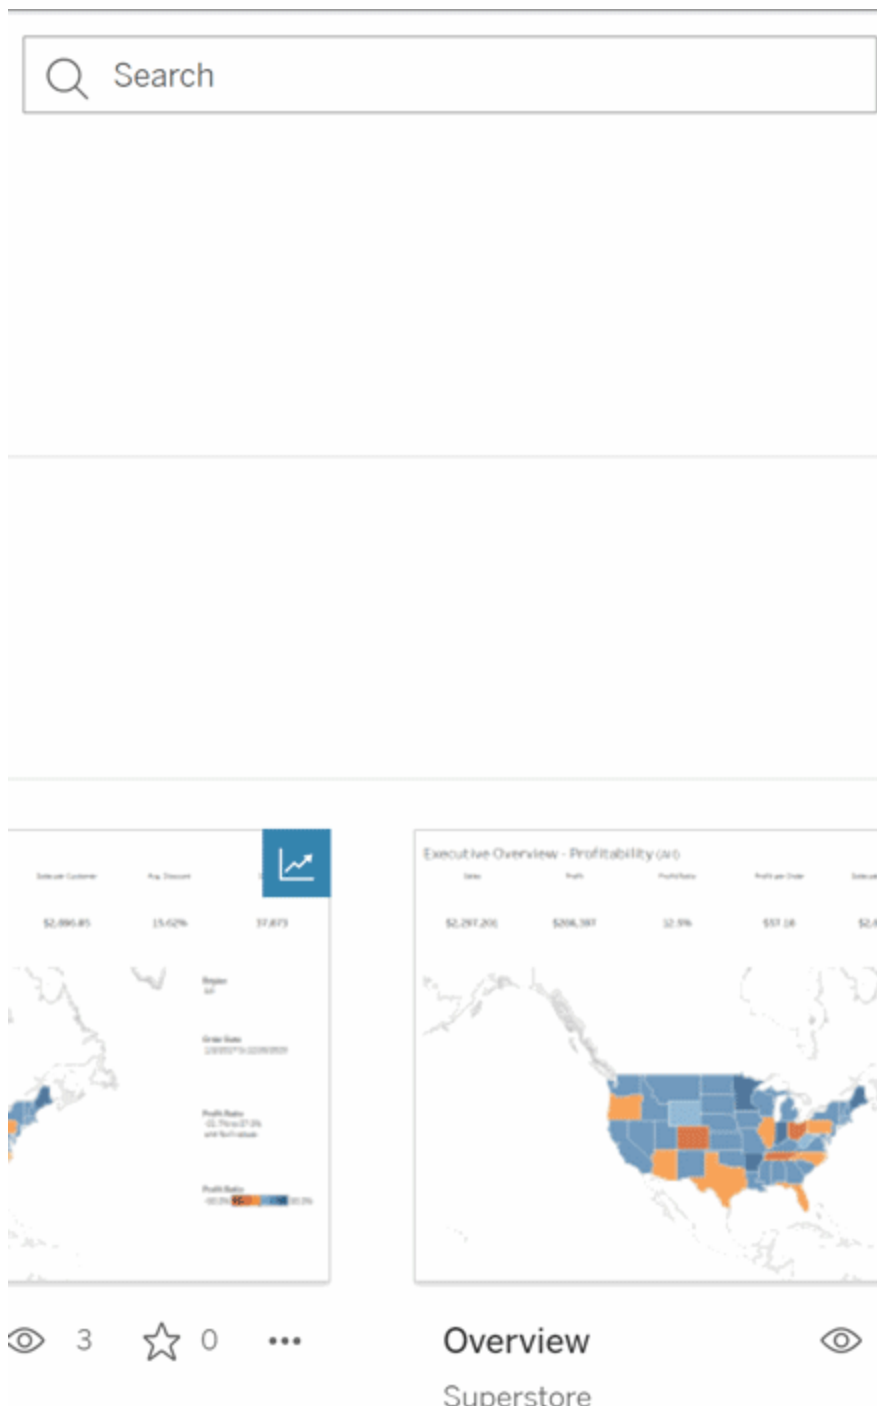

When you sign in to your Tableau site, you'll land on the home page.

## 2: Search for a viz

Tableau calls visualizations on a site Views. Use search to find views or workbooks (a package of views in a single file).

Search results will show all the different content types relevant to your query.

You can select See All for all search results if the views in the quick search aren't what you were looking for, or use the Explore page to browse. There you'll see all the different types of content a Tableau site can host.

### 3: Interact with Content

A published view is a canvas for you to interact and understand your data. Remember, you won't hurt or change the underlying data, or change what others see.

Here are some of the tools in your toolbox to find data insights.

See Details and Sort Data

Now that you know you can click on the data, let's check it out.

As you move the mouse across a view, you might see tooltips that reveal details about each data point, or mark. You can also select multiple marks.

Sort tables alphabetically or numerically by hovering over a column header and clicking the sort icon.

Filter Data

Trim or limit the visible data to a specific area, date, or category.

## Undo/Revert

Maybe you didn't mean to exclude everything but one area. Click Undo to remove the last change, or use Revert to undo all your selections.

## 4: Keep up

This view can automatically update with new data, so you don't need to go searching for new charts to get the latest information. Keep it handy by clicking the star icon to add it to your favorites.

All favorites are added to the Favorites page in the navigation panel. And any recent dashboard or view you explored also appears in the Home page, waiting for you next time.

There's a lot you can do in Tableau Server, and this just explored some of the basics. For more information, see [What Can I Do with a Tableau Web View?](#)

Happy exploring!

## Select Background Maps

Tableau comes installed with a set of background maps that you can access to create map views.

By default, Tableau maps appear with a **Light** background layer provided by Mapbox maps.

The eight background maps that come installed with Tableau are described in this table.

| Background Map | Description  |
|----------------|--|
| <b>Light</b>   | A subtle map that puts the emphasis on the marks while providing geographic context. All areas without data appear in white or light gray. |
| <b>Normal</b>  | A general-purpose map similar to Light. Land areas without data appear in  |

| <b>Background Map</b> | <b>Description</b>   |
|-----------------------|--|
|                       | white or light gray, and bodies of water appear in light blue.   |
| <b>Dark</b>           | A subtle map that puts the emphasis on marks while providing geographic context. The inverse of the Light map; areas without data appear in black or dark gray.  |
| <b>Streets</b>        | A general-purpose map that includes major road and transit networks.   |
| <b>Outdoors</b>       | A general-purpose map that includes terrain and natural features, including bodies of water and parks.   |
| <b>Satellite</b>      | A stylized map with global satellite imagery.  |
| <b>Offline</b>        | A map that you can use while not connected to the internet. This background map stores the images that make up the map in a cache on your machine for improved performance and offline access. For more information, see the offline maps section. |
| <b>None</b>           | A visualization that displays data between latitude and longitude on a viz type other than a map.  |

## Change your background map:

In Tableau select **Map** > **Background Maps** and then select the background map you want to use.

## Change your default background map in Tableau Desktop (feature deprecated)

**Note:** Changing your default background map is a legacy feature that only works with WMS maps on Tableau Desktop. We don't recommend using this feature.

You can choose to set your default background map to a Web Map Service (WMS) or offline map. To learn more about using a WMS map, see [Use Web Map Services \(WMS\) Servers](#).

To specify a default background map:

1. In Tableau Desktop, select **Map > Background Maps > Add WMP Map...** or **Offline**.
2. Select **Map > Background Maps > Set as Default** to set the selected background map to the default.

The background map is automatically saved as a Tableau Map Source (.tmsd) file and placed in the Mapsources folder of your My Tableau

Repository. It's now the default background map for all new worksheets.

## Use the Offline background map

You can create and inspect data in a map view offline using the offline background map that comes with Tableau Desktop.

### To use the offline background map:

- In Tableau, select **Map > Background Maps > Offline**

**Note:** The offline background map uses map images stored on your machine. You can find these images in the following locations:

- **On Windows:** `C:\Program Files\Tableau\<Tableau Version>\Local\Maps`
- **On Mac:** `//Applications/<Tableau Version>.app/Contents/install/local/maps`

There are several actions, however, that require Tableau to retrieve a map image that may not be stored. If the new map image isn't stored on your machine, you won't be able to load the map until you reconnect to the online map that comes with Tableau.

You may need to reconnect to the online map if you would like to do one or more of the following:

- **Turn layers on or off** - if you decide to turn on a layer that isn't stored in the cache, Tableau needs to connect to retrieve the necessary information.

- **Zoom in or out** - zooming in or out on a map requires different map images. If the images at the specified zoom level don't exist in the cache, Tableau needs to retrieve the updated maps.
- **Pan** - panning sometimes requires new map images. If you're working offline and don't have the necessary map images and legends stored in the cache, the new images and legends won't load.

### To reconnect to the Tableau map:

- On Tableau Desktop, select **Map > Background Maps > Tableau**

**Note:** If you set a map to Offline and then publish the workbook, the published workbook will still use the Offline, stored maps, with all of the functionality and limitations of Offline maps noted earlier.

## Create and Troubleshoot Metrics (Retired)

### Retirement of legacy metrics

This article is about Tableau's legacy metrics feature, which was retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. In October 2023, Tableau retired the ability to embed legacy metrics in Tableau Cloud and in Tableau Server version 2023.3.

Tableau Pulse introduces a new way to track metrics. With Tableau Pulse, the metrics you create are used to generate insights about your data. These data insights are sent directly to users who follow the metrics, so they can learn about changes to their data in their flow of work. For more information, see [Create Metrics with Tableau Pulse](#).

If you have legacy metrics that you want to keep, note the data source, measure, and time dimension for those metrics and recreate them in Tableau Pulse. Legacy metrics won't be automatically migrated to Tableau Pulse.

Metrics provide a fast way to stay informed about your data. Because metrics update automatically and display their current value in the grid and list view of your content, you can check all the key numbers you care about in seconds.

At their most basic level, metrics show the value of an aggregate measure, like the sum of sales. More complex metrics can include timelines, comparisons, and statuses that provide an easy to understand indicator of how you're performing relative to a prior point in time or a value you have defined.

If you have a set of dashboards that you regularly check, create metrics for the numbers that you want to monitor, then track them in one place by adding them to your favorites or a collection, or by creating them in the same project. That way, you don't need to load and filter the dashboards unless you want to dig deeper into your data.

## Find metrics on your site

There are a few ways to find metrics on your Tableau site. To browse all the metrics that you have permission to view, navigate to the Explore page, then select **All Metrics** from the content type menu.

If you're looking for metrics related to a particular view or workbook, check the connected metrics for that content. To see connected metrics for a view, open the view, then click **Watch >**

**Metrics** in the view toolbar. The metrics displayed are ordered from the newest creation date to the oldest.

To see connected metrics for all the views in a workbook, navigate to the workbook, then click the **Connected Metrics** tab. You can sort these metrics using the Sort By menu.

## Components of a metric

The only data required to define a metric is an aggregate measure. Metrics are created from a mark in a view, and the measure associated with that mark defines the metric. The measure must be aggregated, because an unaggregated mark will not change over time. For information about dimensions and measures in Tableau, see [Dimensions and Measures, Blue and Green](#).

A metric can optionally be defined by a date dimension, and you can configure a comparison and a status for your metric. Each of these components will add context to the data presented on the metric card.

Metrics that have only a measure defining them will appear as a single number. This number will update when the data updates, but there will be no timeline on the card.

## Timeline

When you select a mark to define a metric, if the mark has a date dimension associated with it, that dimension becomes part of the metric definition. Metrics with a date dimension show a timeline, and you can configure the historical comparison for the metric. By default, the historical comparison is to the previous mark.

When you open a metric's details page, the timeline shows the value of the measure based on the granularity of the date dimension, for example, daily sales or monthly users. Hover over the points on the timeline to see historical values.

## Comparison

There are two types of comparisons that you can configure for metrics: historical comparisons and constant comparisons. You can configure a historical comparison only if a metric has a date dimension associated with it, but constant comparisons can be added for any type of metric.

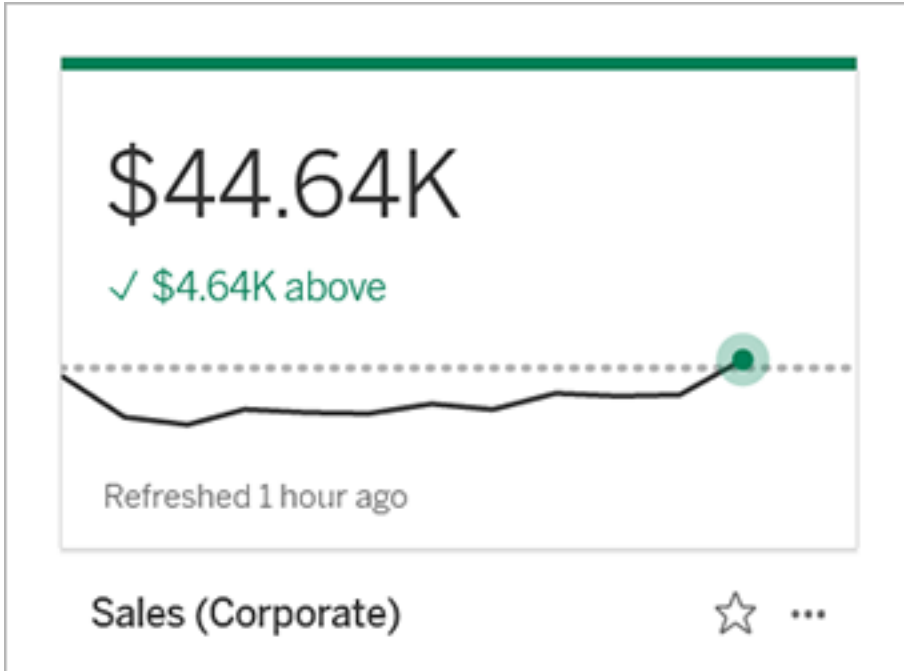

A historical comparison is a relative comparison between the current value and a specified number of hours, days, or other unit of time previous. For example, you could set a comparison between the current value for monthly sales and the value from 12 months ago. Every

time data is added to a metric, the historical comparison will adjust relative to the date or time of the new data.

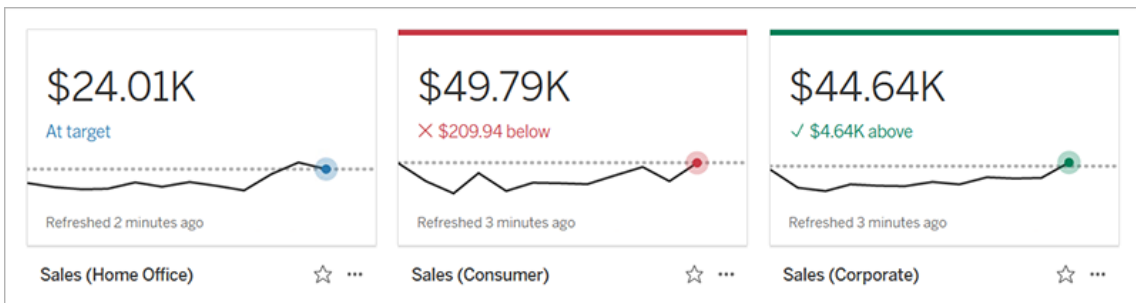

Constant comparisons are to a single value that doesn't change as new data is added. You might set a comparison to represent a threshold to stay above, for example, if you need to maintain a 90% on-time delivery rate. Or you might define a cumulative goal you are working toward, for example, a monthly sales target.

### Status

For metrics with a constant comparison, you can define whether being above, below, or at the comparison value is good, bad, or neutral. A metric with a “good” status will display a check mark next to the comparison value, and the metric card will have a green band at the top. A metric with a “bad” status will display an X next to the comparison value, and the metric card will have a red band at the top. Metrics with a “neutral” status appear the same as metrics without a status indicator; there is no icon or color applied to the card.

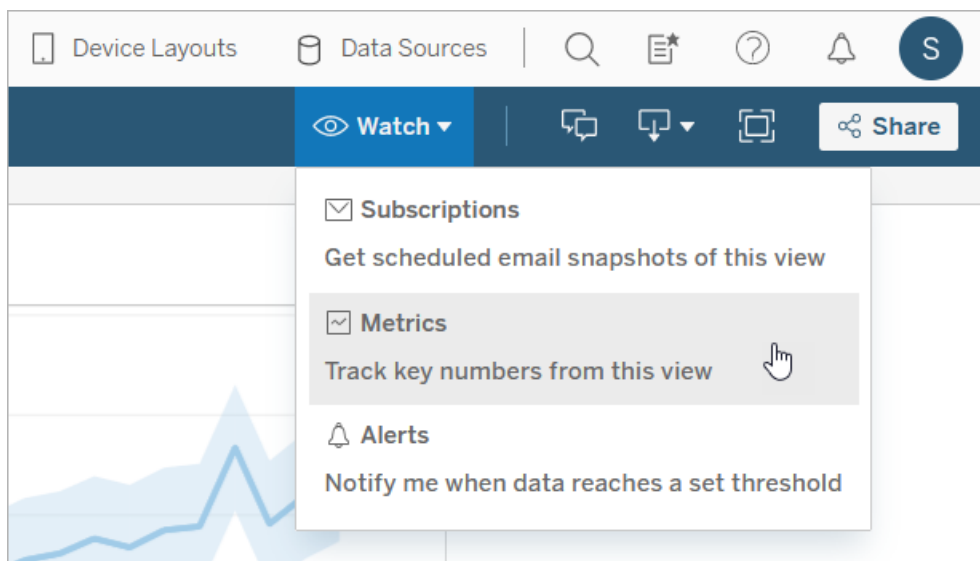

## Create a metric from a view

If you have a site role of Creator or Explorer (can publish), and you have the Create/Refresh Metric capability on the relevant workbook, you can create metrics on Tableau Cloud or Tableau Server.

Before you create a metric, check the connected metrics for the view to make sure that the metric you are planning to create doesn't already exist. Instead of creating a duplicate metric, open the existing metric and add it as a favorite.

Select the mark to define your metric

1. Navigate to the view that you want to create a metric from.
2. On the view toolbar, select **Watch > Metrics**.

The metrics pane opens.

3. If the pane shows connected metrics, select the **Create** button to enter authoring mode.
4. Select a mark. If you encounter an error, see [When you can't create a metric](#).

The measure associated with this mark defines your metric. Any filters you apply to the mark are applied to your metric. If this mark has a date dimension associated with it, that date dimension also defines your metric, and your metric will display a timeline.

The metrics pane shows a preview of your metric. The value in the preview is the most recent value for the metric, which may differ from the value of the mark you selected if it was not the most recent in the time series. The preview updates as you try different configurations.

Describe and configure your metric

The options available to configure your metric depend on the mark you select and on the type of comparison you choose.

1. The **Name** field is pre-populated based on the mark you select. You can give the metric a different name. A metric must have a unique name within the project it belongs to.
2. Under **Description**, enter an optional message to help others understand your metric. For example, describe filters applied to the metric or indicate the data source used by the metric.
3. For the **Date Range** (only for metrics with a date dimension), select one of the default options, or set a custom range. If your metric has a large number of marks, limiting the date range can make it easier to read the timeline.
4. Select the **Comparison Type** for the metric: historical or constant.
5. For **Historical** comparisons:
  - Enter how far prior you want to compare against. The unit of time for the comparison is the same as the granularity of your data, such as hours or months.
  - Select **Show Comparison Line** to include a second line for the comparison period on the timeline.
6. For **Constant** comparisons:
  - Enter the value to compare against. Don't include commas or symbols in this field. To enter a percentage, simply type the number without the percent sign, for example, enter 25 instead of 0.25 for a target of 25%. When you enter a valid target value, the preview updates to show how far above or below the target the current value is.
  - Set the **Status** for the comparison to indicate whether being above, at, or below the value is good, bad, or neutral. By default, the status is set to neutral. Check the metric preview to see how different statuses affect your metric.
7. Under **Definition > Measure**, select the measure to use for your definition from the drop-down. This option appears only if the mark you select has more than one measure associated with it.

Finalize your metric

1. Under **Project**, select **Change Location** to choose a different project for the metric. By default, your metric will be added to the same project that the view belongs to.

Every metric in a project must have a unique name. Because a metric's name and project are initially set based on the mark you select, you might run into a conflict when you try to save your metric, if another user has already created a metric from that mark.

Either choose a different project or name for your metric or, if you want to overwrite the existing metric, see [Overwrite a metric](#).

2. Click the **Create** button.

A message appears with a link to the metric in the project you added it to.

3. Verify that the permissions for your metric are correct, following the guidance in [Set permissions](#).

By default, a metric inherits the permissions of the project it is created in. Anyone with access to your metric will be able to see the metric's data, even if they don't have permission to access the connected view or data source.

Now that you've created a metric, you can manage the metric the same way you manage other independent pieces of content on your Tableau site. Though metrics are created from a view, they exist independently of that view, unlike data driven alerts or subscriptions. You can

move the metric to a different project without moving the connected view. For information about managing content on your Tableau site, see [Manage Web Content](#).

### Overwrite a metric

Once a metric is created, you can change the name, description, and configuration of the metric, but you can't change how the metric is defined. If you want to change the data that the metric uses, you must overwrite it. In order to overwrite a metric, you need to be the metric owner or be granted the correct permission capability.

1. To overwrite a metric, create a metric with the same name in the same project as the metric you want to overwrite.

The Overwrite Metric dialog appears.

2. Click the **Overwrite** button.

When you overwrite a metric, the metric continues to appear for those who have added it to their favorites, and any changes made to permissions for the previous metric will apply to the new metric.

### When you can't create a metric

If you select a mark on a chart that doesn't support metrics, you'll get an error message explaining why you can't create a metric. The table below summarizes these scenarios.

| Reason  | Scenarios   |
|---|---|
| You don't have the correct permissions.                                     | <ul style="list-style-type: none"><li>• The workbook owner or an administrator has denied the Create/Refresh Metric capability. For more information, see <a href="#">Permissions</a>.</li></ul>  |
| You can't access the complete data.   | <ul style="list-style-type: none"><li>• Row level security or user filters limit the data you can see. For more information, see <a href="#">Restrict Access at the Data Row Level</a>.</li></ul> |
| The password for the workbook's data source is not embedded or is no longer | <ul style="list-style-type: none"><li>• The workbook prompts for a password. For more information, see <a href="#">Set Credentials for Accessing Your Published Data</a>.</li></ul>               |

| Reason   | Scenarios  |
|--|--|
| <p>valid.</p> <p>The data isn't at the correct level of granularity.</p> | <ul style="list-style-type: none"> <li>• The data in the chart isn't aggregated. Metrics use aggregations, such as sum or average. For more information, see <a href="#">Data Aggregation in Tableau</a>.</li> <li>• There are multiple values per cell of data—a result of data blending. For more information, see <a href="#">Troubleshoot Data Blending</a>.</li> </ul>  |
| <p>The date dimension is not supported.</p>                              | <ul style="list-style-type: none"> <li>• The chart includes both date parts and date values. For more information, see <a href="#">Change Date Levels</a>.</li> <li>• The date dimension uses the ISO 8601 calendar rather than the standard Gregorian calendar. For more information, see <a href="#">ISO-8601 Week-Based Calendar</a>.</li> <li>• The date dimension is aggregated at the custom level of Month / Year or Month / Day / Year. For more information, see <a href="#">Custom Dates</a>.</li> </ul> |

## Edit a metric's configuration

Starting in 2022.2, you can change the configuration for a metric. A metric's configuration includes the comparison, date range, and status indicator. The configuration options available depend on the type of metric. Metrics with a timeline allow you to set a historical comparison or a constant comparison. Single number metric support only a constant comparison.

A metric's configuration does not include the metric definition (the measure and date dimension that generate the metric value). If you want to change the definition, overwrite the metric with a new metric.

To edit a metric's configuration, you must have the overwrite capability for the metric.

1. Open the metric details page for the metric you want to edit.
2. Mouse over the configuration section. Click anywhere on the section to enter editing mode.

Metric Details

**Owner**  
Jane Johnson

**Description**  
No description available.

**Configuration** 

|            |                |
|------------|----------------|
| Date Range | Last 12 months |
| Comparison | 1 month ago    |

3. For a timeline metric, set the date range to display on the metric card and details.
4. Select the comparison type. For a constant comparison, set a comparison value and status. For a historical comparison, set how far prior you want to compare against and choose whether to show a comparison line on the timeline.
5. Click **Save**. Your configuration changes will appear to anyone who views the metric.

## How metrics refresh

When a metric refreshes, it checks the connected view (the view the metric was created from) for new data. A refresh doesn't necessarily update the value of a metric, because there may be no changes to the data.

Metrics refresh at a frequency either based on an extract's refresh schedule or, for live data, every 60 minutes. The time of the last refresh is displayed on the metric.

## Fix failing refreshes

If a metric isn't able to access the connected view or its underlying data, the refresh will fail. If the refresh for your metric fails, you'll receive a notification, which notes the time of the failure and the affected metric.

Metric refreshes may fail for one of the following reasons.

- The connected view was deleted or modified.
- Permissions changed for the connected view.

- The password for the data source is no longer embedded or is no longer valid.
- The metric owner doesn't have the required site role to refresh the metric. A site role of Creator or Explorer (can publish) is required.
- There was a temporary connectivity issue, which will resolve itself.

To identify the cause of the failure, look at the metric details. Make sure that the metric owner has the required site role to refresh the metric. Then inspect the **Connected View**.

## Metric Details

**Owner**  
Jane Johnson

---

### Connected View

The metric has been created from this view:

Weekly Sales and Profit

**Definition**

|                |                  |
|----------------|------------------|
| Measure        | SUM(Profit)      |
| Date Dimension | WEEK(Order Date) |

If the connected view is still listed

Open the view to investigate the cause of the failure.

If the view loads, check that the measure and (optional) date dimension that define the metric are still present in the view.

## Tableau Server on Linux Administrator Guide

- If the view appears to be unchanged, you might no longer have permission to refresh metrics from it. The content owner or a Tableau administrator can change the Create/Refresh Metric permission capability. For more information, see [Permissions](#).
- If the measure is no longer present, the view has been modified so the metric can't connect to the data needed to refresh. The content owner or a Tableau administrator can check the revision history and restore previous versions. For more information, see [View Revision History](#).

If the view doesn't load, but instead prompts for a password or displays an error when connecting to the data source, the password for the data source is not embedded or is no longer valid. The content owner or a Tableau administrator can edit the data source connection to embed the password. For more information, see [Edit Connections](#).

If there is no connected view listed

The view was deleted or you no longer have permission to access the view. Contact your Tableau administrator for assistance.

## Resume suspended refreshes

If a refresh fails enough times, the refresh is suspended. You'll receive a notification if the refresh for your metric is suspended.

When a metric refresh is suspended, Tableau no longer attempts to get new data for the metric. Metrics with suspended refreshes continue to present historical data.

If the cause of the failure is fixed, you can resume the refresh.

1. Open the affected metric.
2. On the warning message, click **Resume refresh**.

Tableau attempts to perform the refresh. If this attempt succeeds, you'll receive a notification, and the refresh will resume on schedule. If the attempt doesn't succeed, your refresh remains suspended.

Try overwriting the metric if the connected view is still available. For more information, see [Overwrite a metric](#). Otherwise, you can keep the metric to reference past data or delete the metric.

**Note:** If the metric refresh is suspended because you don't have the required site role for it to refresh, you won't be able to resume the refresh or delete the metric.

## Metrics appear in Tableau Catalog

Starting in 2019.3, Tableau Catalog is available with Data Management in Tableau Cloud and Tableau Server. When the Tableau Catalog is enabled in your environment, you can see metrics in the Catalog lineage tool, and metrics affected by data quality warnings display those warnings. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

When you have metrics defined for the numbers you want to monitor, it's important to know if the data that the metrics rely on are impacted in any way. You can use Catalog in a couple of ways to know this. First, data quality warnings set on the data your metric is based on show on the metric. These warnings appear when you open a metric in Tableau Mobile, and in Tableau Server and Tableau Cloud when you hover over a metric in grid view and on the metric details page, as shown below:

For more information, see "Set a Data Quality Warning" in the [Tableau Server](#) or [Tableau Cloud Help](#).

You can also use the lineage tool in Tableau Catalog to see the upstream sources that your metric relies on. When doing an impact analysis, you can see which metrics are affected if a certain column or a table is changed or deprecated, or if certain workbooks are removed. Including metrics in the lineage means that Catalog gives a full picture of the impact changes can have on the assets in your environment.

## Set Credentials for Accessing Your Published Data

When you publish a workbook to Tableau Cloud or Tableau Server, you can publish the data source it connects to as part of the workbook (*embedded* into the workbook), or as a separate, standalone data source. In addition, if the data source you're publishing requires authentication, you can customize how credentials are obtained.

The type of authentication to your data source is independent of how people sign in to your Tableau Cloud or Tableau Server site. For example, to give people direct access to the data in a workbook, you would embed a database user's credentials into the data source's con-

nection. But anyone viewing the workbook would still need to be able to sign in to the site on Tableau Cloud or Tableau Server to open your workbook.

This topic describes how to set authentication on data connections as part of the publishing process.

**Note:** This topic doesn't apply to connections to that don't require authentication, such as text files or Excel files.

## Set the authentication type

For many types of connection you can embed a database user's name and password, or use single sign-on (SSO). Specific exceptions are described later in this topic.

The following steps describe how to set authentication as part of publishing a data source or workbook. You can do this for each connection in the data source.

1. In the Publish Workbook dialog box, go to the **Data Sources** area, which lists the workbook's connections, and select **Edit**.
2. In the **Manage Data Sources** popup, after you decide whether to publish the data source separately or as part of the workbook, select an authentication type for each connection in the data source. The available authentication types depend on the connection type, and they can include one or more of the following:
  - **Prompt user:** Users must enter their own database credentials to access the published data when the view or workbook loads.
  - **Embedded password:** The credentials you used to connect to the data will be saved with the connection and used by everyone who accesses the data source or workbook you publish.
  - **Server run as account:** A single Kerberos service account is used to authenticate the user. On Windows this is the account that Tableau Server runs as. On Linux it can be any Kerberos account.
  - **Viewer credentials:** The viewer's credentials are passed through to the database using SSO (usually Kerberos).
  - **Impersonate with embedded account or Impersonate with server Run As service account:** Impersonation using embedded credentials connects with the

embedded credentials and then switches to the viewer's identity (only for databases that support this). Impersonation using the Run As service account is similar but first, connects with the Kerberos service account before switching to the viewer's identity.

- **Refresh not enabled** or **Allow refresh access**: These options appear when you publish an extract of cloud data such as from Salesforce, and database credentials are needed to access the underlying data. **Allow refresh access** embeds the credentials in the connection, so that you can set up refreshes of that extract on a regular schedule.

**Important:** How you want to keep extracted data fresh is also a factor:

- If you want to set up an automatic refresh schedule, you must embed the password in the connection.
- If you're publishing a cloud data connection to Tableau Cloud, the publishing steps alert you if you must add Tableau Cloud to the data provider's authorized list.
- You can't publish an extract that's created from a Kerberos-delegated, row-level-secure data source.

#### Dropbox, OneDrive connections

For Dropbox and OneDrive, when you publish a data source or workbook and select **Embedded password**, Tableau creates a saved credential and embeds it in the data source or workbook.

#### Workbook connections to Tableau data sources

When you publish a workbook that connects to a Tableau Cloud or Tableau Server data source, rather than setting the credentials to access the underlying data, you set whether the workbook can access the published data source it connects to. Regardless of the original data type, the choice for server data sources is always **Embedded password** or **Prompt users**.

If you select to prompt users, a user who opens the workbook must have **View** and **Connect** permissions on the data source to see the data. If you select embed password, users can see the information in the workbook even if they don't have View or Connect permissions.

### Virtual connections

As of Tableau Cloud and Tableau Server 2022.3 and Tableau Desktop 2022.4, when you publish Tableau content like a data source or workbook that uses a virtual connection and select **Embed password** or **Embed credentials**, the viewer of the content will have your permissions to connect to and query the virtual connection. However, any data policies associated with the virtual connection are always evaluated using the viewer's identity—not yours.

For example, you publish a workbook that uses a virtual connection. To let viewers of the workbook connect to and query data by way of the virtual connection, you embed your permissions to connect to and query the virtual connection. Then, any data policies associated with the virtual connection prevent the viewers of the workbook from accessing any sensitive data.

When evaluating whether the tables in a virtual connection can be viewed and accessed, the identity of the content creator is used. However, when evaluating any data policies associated with the tables in a virtual connection, the viewer's identity is used. And the content creator can only ever embed connect permissions to the virtual connection—not edit permissions.

If you choose not to embed permissions, then only users with permissions to access the workbook or data source and with connect permissions to the virtual connection can access the workbook or data source.

The embed password and embed credentials options for virtual connections don't work in Tableau Cloud 2022.2, Tableau Server 2022.1, and Tableau Desktop 2022.3 and earlier. If you select these options before you upgrade to 2022.3 (for Tableau Cloud and Tableau Server) or 2022.4 (for Tableau Desktop), the options will work as expected after you upgrade. Then, you're able to embed your permissions for querying a virtual connection.

## Explore Dashboards with Data Guide

Have you ever discovered a new Tableau dashboard and wondered what data means or how to use it? Or, have you ever published a new dashboard and wished that you could include instructions about how to use your dashboard?

Data Guide provides helpful information about a dashboard and insights about the data behind it. Data Guide allows dashboard creators to provide more explanatory context for end users—like descriptions and links to resources—directly in the dashboard. And Data Guide automatically surfaces insights powered by [Explain Data](#) to help users find outliers and learn about explanations for a mark. Explain the Viz (powered by Explain Data) identifies outlier measures and potential key drivers behind them.

These contextually relevant details can help dashboard users navigate and use new dashboards more easily, allowing users to find insights faster, trust that they're looking at the right data, provide context for data, and establish confidence in their understanding of the viz.

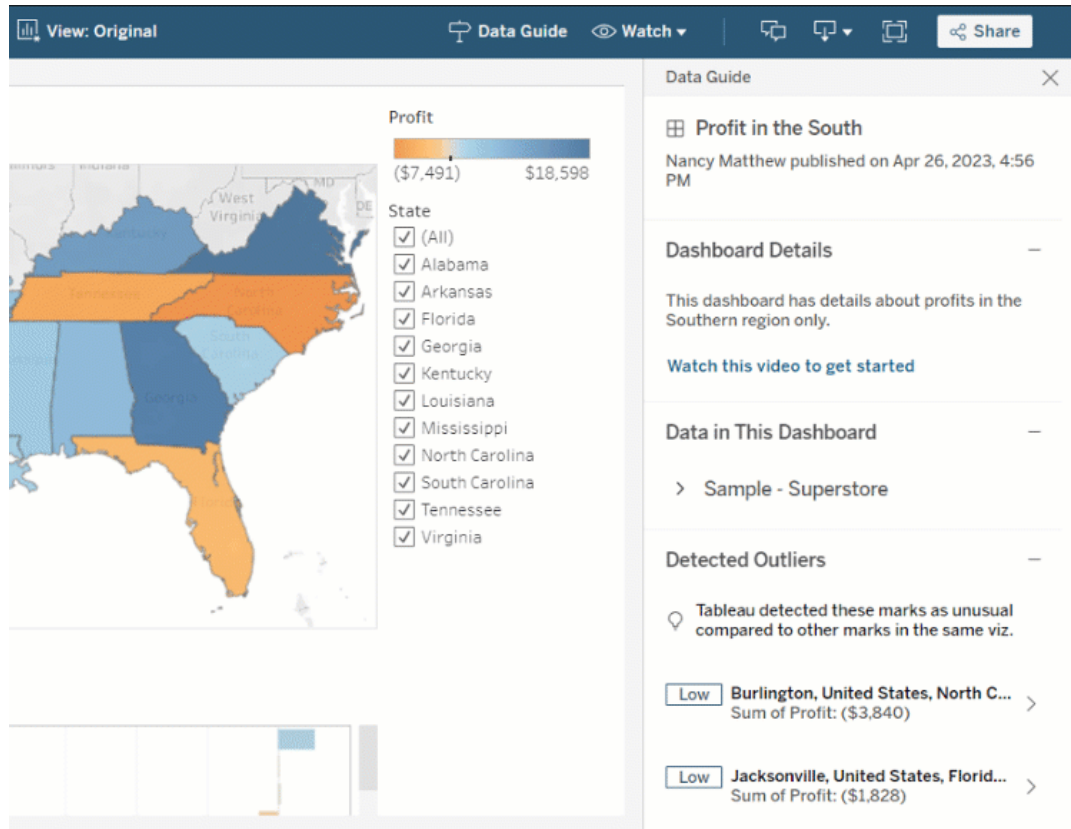

### Customize Data Guide as an author

1. From your dashboard, choose the **Edit** button.
2. Choose **Data Guide** in the toolbar.
3. In the Data Guide pane, type a description to help your end users understand the purpose of your dashboard.
4. Select **Add link**, and enter a descriptive label for your link text and the URL.
5. Choose **OK**.
6. Select a viz (a sheet in the dashboard). Data Guide updates automatically so you can add a description and resources that are relevant to each viz in your dashboard.
7. Type a description, and add links relevant to the viz.
8. Choose **OK**.

**Tip:** To use Data Guide to write custom alt text to improve the accessibility of your vizzes, see [Show more text and make it helpful](#).

## Explore Data Guide as a dashboard user

1. From the dashboard, choose **Data Guide** in the toolbar.
2. Read the description of the dashboard and explore resources provided by the dashboard author.
3. Expand **Data in This Dashboard** and **Detected Outliers** to learn more about the underlying data used in the dashboard.
4. Select a viz (an object in the dashboard).
5. Read the description of the viz and explore resources provided by the dashboard author.
6. Expand **Data Summary** and **Detected Outliers** to learn more about data in that viz.
7. Select a mark or multiple marks, such as a bar on a chart or a region on a map, to see information about **Data in This Mark** and **Applied Filters**. Select a single mark to see possible **Explanations** for its value.

## Explore Data Guide at different levels

By default, Data Guide is closed when you open a workbook. And you can open Data Guide in the toolbar. At the top of the Data Guide pane, you see the name of the dashboard or viz that you selected. As a dashboard author, you can write descriptions for both the dashboard and for individual vizzes that make up your dashboard.

### Understand dashboard-level details

At the dashboard level, Data Guide:

- Displays the dashboard's name, author, and last published date.
- Can include a description written by the dashboard author and links to related resources, such as videos or wiki pages.
- Lists the data sources used by the dashboard and details about the data, such as which dimensions and measures are used.
- Reveals detected outliers in the dashboard that are identified by Explain Data. For more information, see [Get Started with Explain Data](#).

Understand viz-level details

When a user selects a specific viz (dashboard object), Data Guide:

- Displays the viz's name.
- Can include a description written by the dashboard author and links to related resources, such as videos or wiki pages.

- Lists the data sources used by the dashboard, including the dimensions and measures used.
- Lists applied filters and data used in the viz, so you can identify how the data is being influenced by filters that users interact with. Only filters that a user can change are shown.
- Has a summary of the data used in the viz, including the number of data points and sorting details.
- Reveals detected outliers in the viz that are identified by Explain Data. For more information, see [Get Started with Explain Data](#).

Understand mark-level details

When a user selects a mark (or marks) such as region on a map, Data Guide:

- Displays the name of the mark.
- Lists applied filters and data used in the viz, so you know what's included and what's excluded.
- Reveals detected outliers in the viz that are identified by Explain Data. For more information, see Get Started with Explain Data.

The screenshot shows the Tableau Data Guide interface. On the left, a map highlights North Carolina in orange. The main panel, titled "Data Guide", contains the following sections:

- United States, North Carolina**
- Data in This Mark**
  - Sample - Superstore
    - Country: United States
    - State: North Carolina
    - Profit: (\$7,491)
- Applied Filters**
  - Filter 1 (generated)
    - State
- Explanations for This Mark**
  - Explore underlying values for United States, North Carolina
    - Low Sum of Profit (\$7,491)
  - Other things to explore
  - What is unique about United States, North Carolina?

## Control Data Guide visibility

By default, Data Guide is closed when you open a workbook. When you open or close Data Guide, it remains in this state for all workbooks on the site. In 2023.1 or later, a server administrator can hide Data Guide for all users. This removes the Data Guide button from the Tableau toolbar on all workbooks on the site. To hide Data Guide:

1. From the left pane, choose **Settings**.
2. From the **General** tab, scroll to **Availability of Data Guide**.
3. Choose **Hide**.
4. Choose **Save**.

## Set a Data Freshness Policy for Query Caches and View Acceleration

### Understand data freshness for Query Caches

You've built your workbook, and your team loves it. But sometimes people need to click the Refresh button for the most up-to-date data to appear in the viz. You built the workbook using a live connection, so why does the data need to be refreshed? The answer is performance.

To improve performance, Tableau caches the results of queries used to fetch data, so subsequent visits can reuse and return that cached data faster. You can click the Refresh button to retrieve updated data, but this can add to potential performance costs.

To balance data performance and freshness, set a data freshness policy for your workbook. When you set a data freshness policy, your data is refreshed at the time you specify. Tableau won't visualize cached data that doesn't meet the freshness policy you've set.

### Understand data freshness for View Acceleration

With the View Acceleration feature, Tableau precomputes selected workbooks to generate views, resulting in significantly reduced load times. A precomputation schedule is created based on the data freshness policy or extract schedule that you set for the selected workbooks to provide data that is both performant and fresh.

To minimize resource consumption, the number of precomputation jobs that you can run is limited to 12 per day. For example, if your data freshness policy is set to less than two hours, the performance benefits of View Acceleration are limited to the first 12 refreshes in a day.

## Choose what's best for your workbook

Some people might not want caching so that they always have the freshest data, while other people might want large caches to reduce overhead and improve workbook performance. The first step in setting a data freshness policy is to decide what's right for your business.

Tableau Cloud refreshes cached data every 12 hours by default, and workbook owners can set data freshness policies at the workbook level.

In Tableau Server, server administrators can [set a default caching policy for all sites on the server](#), and workbook owners can set data freshness policies at the workbook level.

**Note:** Data freshness policies aren't available in Tableau Desktop or for workbooks that use extract and file-based data sources.

## Edit a workbook data freshness policy

To edit a workbook data freshness policy, you must be the workbook owner, and the workbook must have a live connection to the data source.

1. Sign in to a site on Tableau Cloud or Tableau Server.
2. From the Home or Explore page, navigate to the workbook you want to set a policy for.
3. Click the details icon .
4. From the Workbook Details dialog, click **Edit Data Freshness Policy**.
5. Choose one of the following options:
  - Site default (12 hours)
  - Always live (Tableau will always get the latest data)
  - Ensure data is fresh every
  - Ensure data is fresh at
6. Click **OK**.

## Tableau Server on Linux Administrator Guide

Personal Space / Regional Sales

Search for views, metrics, workbooks, and more

Regional Sales

Owner [redacted] Modified Aug 5, 2021, 10:21 AM

Edit Workbook

Views 1 Data Sources 1 Connected Metrics 0 Custom Views 0 Subscriptions 0 Lineage

Select All Sort By: Sheet (first-last) ↑

| Type                       | Name           | Actions | Views (all-time) |
|----------------------------|----------------|---------|------------------|
| <input type="checkbox"/> ☆ | Regional Sales | ...     | 26               |

**Site default** refreshes your data every 12 hours, which is a great option if your audience regularly uses your dashboard, but doesn't need up-to-the-minute data freshness.

**Always live** provides the freshest data at all times, which can increase loading time.

**Ensure data is fresh every...** allows you to specify how often data is refreshed with the granularity of minutes, hours, days, or weeks.

**Ensure data is fresh at...** allows you to schedule the time and day for data refreshes. If you have an important meeting every Monday, Wednesday, and Friday at 09:00 AM Pacific time, then you can set your data refresh to occur at 08:45 AM every Monday, Wednesday, and Friday, so you have the freshest data when your meeting starts.

## Use Dynamic Axis Ranges

It's key that your users understand the range represented in a viz so that they can correctly analyze the data. Especially when analyzing multiple vizzes in a dashboard or multiple worksheets at the same time, it can be easy for users to misinterpret data when the range of the axes is different between vizzes. For example, when two bar charts appear next to each other, the bars in both charts might appear to be equivalent sizes. However, the axes might have very different ranges, making the charts misleading.

To help users understand the range of the axis, in 2023.3 and later, authors can use Dynamic Axis Ranges to set the minimum and maximum values of an axis range by using numeric parameters or date parameters. Then, as users navigate across vizzes, the axes update synchronously. This makes it easier for your users to analyze data across vizzes easily and accurately. And by limiting the range of the data, you can view a subset of data without filtering the underlying data or impacting the moving average of your data.

Dynamic Axis Ranges can also be used to extend or shorten the range of an axis without filtering out the underlying data. This is ideal for showing progress against a goal or showing a moving average.

### Supported field types

Dynamic Axis Ranges support any parameter that is compatible with the selected continuous axis, for example:

- Numeric parameters
- Temporal parameters (date or dateTime)

### Configure a dynamic axis range

1. From a Tableau sheet, [create a parameter](#) for your axis.
2. Right-click the axis, and choose **Edit Axis**.
3. For the Range, choose **Custom**. Then, select the parameter that you created for either the start or end axis extent.
4. Close the dialog box.

- If you're using multiple sheets on a dashboard, repeat these steps for the axes across the different sheets.

## Understand limitations and edge cases

Dynamic Axis Ranges aren't updated within **Stories**. If the parameter used for the axis is deleted, then the most recent parameter value remains as the axis extent. The next time you edit the axis, an error message will prompt you to choose a new parameter to be used.

## Use Dynamic Axis Titles

Tableau's flexibility empowers authors to quickly analyze different data sets and visualize data differently for deeper analysis. But with that flexibility, comes the responsibility to communicate accurately the data that is used in a viz. For example, it's critical to communicate the units of measure that change based on a parameter value. Imagine that you're looking at a viz of the weather that shows a forecast of 25 degrees. In Fahrenheit, that forecast might be a great ski trip. But in Celsius, that forecast might call for a trip to the beach.

As an author, you can use Dynamic Axis Titles to update the axis title based on the value of a parameter or a single-value field (for example, an LOD calculation). If you use **swap parameters**, the axis titles update to match the data being used.

## Supported field types

To be used as a Dynamic Axis Title, fields must be:

- A single-valued and a **fixed LOD calculation**
- A parameter
- A constant calculated field
- A top 1 set

## Configure a dynamic axis title

1. From a Tableau sheet, drag a continuous field onto a shelf.
2. Double-click the axis to open the **Edit Axis** dialog.
3. Under the **Axis Titles** section, choose the field you want to use for your axis title from the list.
4. Close the **Edit Axis** dialog.

For a more complex use case, first follow the steps in [Example: Swap Measures Using Parameters](#). Then, follow these steps:

1. Double-click the X axis to open the **Edit Axis** dialog.
2. Under the **Axis Titles** section, select **Parameter**, and then choose the Placeholder 2 selector.
3. Close the **Edit Axis** dialog.
4. Repeat these steps for the Y axis using Placeholder 1.

Now, when the parameters are changed, the axes titles update to reflect the data being displayed.

## Understand limitations and edge cases

Dynamic axis titles are cleared when the viz type is changed using Show Me. Also if you use subtitles, then the subtitle appears after the Dynamic Axis Title, just as it does for custom titles. Automatic subtitles are populated only when you have a continuous date value axis that is filtered to a single year with at least two time periods. The dynamic axis title functionality doesn't work when using the worksheet in a story (a sequence of visualizations that work together to convey information).

## Use Dynamic Zone Visibility

Dashboard space is valuable, especially when you want to progressively reveal insights about data. With Dynamic Zone Visibility, you can hide or reveal zones (tiled or floating dashboard elements) based on the value of a field or parameter. As you interact, zones on your dashboard appear or disappear. The result is a dynamic dashboard that doesn't compromise your desired layout.

While you can [show or hide objects by clicking a button on a dashboard](#), Dynamic Zone Visibility allows you to show and hide objects automatically. This is ideal for dashboards that are used by different user groups. For example, you might want to show different user groups different zones when they visit your dashboard.

And you can use Dynamic Zone Visibility with [Parameter Actions](#). For example, when a user clicks a mark on a viz, a previously hidden zone appears. This is ideal for complex dashboards because it allows you to choose when deeper levels of data are revealed.

### Supported field types

To be used for Dynamic Zone Visibility, a field or parameter must be:

- Boolean.
- Single value.
- Independent of the viz, meaning the field returns a constant value independent of the structure of the viz, such as a fixed level of detail (LOD) calculation.

### Configure a dynamic dashboard zone

The following example has two sheets that use [Superstore data](#): the first sheet has a bar chart with Sales by Category, and the second sheet has a bar chart with Sales by Sub-Category. By using Dynamic Zone Visibility, the second sheet is visible only after a mark is clicked in the Sales by Category zone. This example relies on a boolean calculated field, which is used as the source field for a parameter action. For the calculation to be used as the source field for the parameter action, the calculation must be added to the marks card.

1. From the Sales by Category sheet, [create a parameter](#). In this example, the parameter **Data type** must be set to **Boolean**.
2. From the Sales by Category sheet, [create a calculated field](#). This example uses the following calculation: `True`
3. On the Sales by Category sheet, drag the calculation that you created to **Details** on the marks card.
4. Create a dashboard.
5. Drag the sheet that you always want to be visible onto your dashboard. In our example, we want Sales by Category to be visible.
6. From your dashboard, click the Sales by Category zone (dashboard object). Then, from the Worksheet menu on your dashboard, [create a parameter action](#). This example uses the following **Change Parameter** action:  
The source sheet is set to use the dashboard you created and the Category Sales sheet.  
The **Target Parameter** is the parameter you created.

The **Source Field** is the calculation you created.

The screenshot shows the 'Add Parameter Action' dialog box. The 'Name' field is 'Dynamic zone action'. The 'Source Sheets' section includes a grid icon, a dropdown menu with 'Dynamic product sales dashboard', and a list of checkboxes for 'Category Sales' (checked) and 'Subcategory Sales'. The 'Target Parameter' dropdown is 'T|F Hide zone with parameter'. The 'Source Field' dropdown is 'T|F Calc for dy...' and the 'Aggregation' dropdown is 'None'. The 'Run action on' section has radio buttons for 'Hover', 'Select' (selected), and 'Menu'. The 'Clearing the selection will' section has radio buttons for 'Keep current value' and 'Set value to' (selected), followed by a dropdown menu showing 'False'. The 'Cancel' and 'OK' buttons are at the bottom right.

7. Drag the Sales by Sub-Category worksheet onto your dashboard.
8. Click the Sales by Category zone. From the upper right corner, click the dropdown arrow and select **Use as Filter**.
9. Click the Sales by Sub-Category zone, and then click the **Layout** tab.
10. Check the box for **Control visibility using value**.
11. From the dropdown, choose the parameter you created to control zone visibility.

**Note:** If the option to Control visibility using value doesn't contain the field you want to use, be sure that the field is a supported field type.

Now, when you click a category mark in the Sales by Category zone, the Sales by Sub-Category zone appears in your dashboard.

## Workbook Optimizer

The Workbook Optimizer is a tool that identifies if a workbook follows certain performance best practices. These guidelines are limited to what can be parsed from the workbook's

metadata and evaluated by a rules engine algorithm. Not all of its recommendations are applicable to or appropriate for every workbook. There are many aspects of performance that aren't captured by the Optimizer, some of which can offer easy wins. For more information, refer to [Streamline your workbook](#) and the whitepaper [Designing Efficient Production Workbooks](#).

### Run the Workbook Optimizer

The Workbook Optimizer is available from the publishing menu and publishing dialog in web authoring.

1. From the **File** menu, select **Publish** or **Publish As**. Alternatively, click the drop down next to Publish.
2. Click **Run Optimizer**. This opens a new dialog for the Workbook Optimizer.
3. The workbook is automatically evaluated against the guidelines and results display in one of three categories: Take action, Needs review, or Passed (or Passed and ignored).
  - You may see fewer than three categories. If no guidelines fall into a category, it doesn't display.
  - Expand each category to see the guidelines. You can also expand each guideline for more information about why it's a recommendation. Some have additional information specific to your workbook:
  - You can choose to address any or none of the guidelines. As running the Optimizer is a voluntary step in the publishing process, it doesn't prevent you from being able to publish.
4. To close the dialog and go back to the workbook, click Close.
5. To close the dialog and go back to (or open) the publishing dialog, click Publish.

The Workbook Optimizer is available from the publishing menu and publishing dialog in web authoring.

### Optimizer categories

The Optimizer breaks down its guidelines into three categories: take action, needs review, and passed.

**Take action** indicates that updating the workbook to follow these best practices have minimal to no impact on the functionality of the workbook. There's probably no reason to avoid making these changes.

**Needs review** indicates that following these best practices may involve modifying the workbook in more involved ways, such as restructuring a data source or simplifying a dashboard.

- For these guidelines, use your best judgment to determine what is possible or practical to address.
- Some recommendations may involve a lot of effort for minimal performance gain and aren't worth it.
- It may be useful to use the Performance Recorder to get a performance benchmark.
- Some may be deliberate choices you've made.

As the author, you're the final authority on what makes a workbook as efficient as possible. *Remember that some best practices should be broken to effectively deliver content.* Always weigh the goal of the workbook against changes to improve performance.

**Passed** indicates the guidelines are met and the workbook is already following best practices in that area. But remember, there are many aspects of performance that aren't captured by the Optimizer. This category is renamed **Passed and ignored** if any guidelines are ignored for the workbook.

## Ignore a guideline

Guidelines aren't always applicable to your situation. Perhaps you're publishing a template workbook for others to use and need to preserve unused fields and data sources. You don't want the optimizer to continue to notify you about those guidelines.

It's possible to ignore a guideline for a workbook.

1. From a specific guideline, click the **Ignore** button.
  - The guideline is muted and moves to the **Passed and ignored** section. Even if you run the optimizer again, that guideline won't appear in the Take action or Needs review section.
2. To resume evaluating the guideline, find its row in the **Passed and ignored** section and click the **Ignore** button again.
  - The optimizer runs again and the guideline is evaluated. It continues to be checked each time the optimizer runs.

## Autofix a guideline

Some suggestions from the workbook optimizer can be implemented without user input. For these guidelines, there's a button to autofix the rule. If the button doesn't appear you must manually address the issue.

From a specific guideline, click the Autofix button.

- The recommended action (such as closing an unused data source) is taken behind the scenes and the guideline moves to the Passed section.
- If the autofix fails for any reason, you'll be notified and prompted to resolve the issue manually.
- If the button isn't available, that guideline cannot be autofixed and must be addressed manually.

## The guidelines

Every guideline contains a "consider" statement that suggests a potential way to address the performance impact. These are necessarily general and may not apply in every situation. These suggestions are a starting point only; always frame your decisions in the context of your environment and the goals of your workbook.

**Note:** Not all suggestions are possible to perform in the browser and may require [editing in Tableau Desktop](#) instead.

---

Navigate to a guideline by letter: [A](#) . [B](#) . [C](#) . [D](#) . [E](#) . [F](#) . [G](#) . [H](#) . [I](#) . [J](#) . [K](#) . [L](#) . [M](#) . [N](#) . [O](#) . [P](#) . [Q](#) . [R](#) . [S](#) . [T](#) . [U](#) . [V](#) . [W](#) . [X](#) . [Y](#) . [Z](#)

---

Calculation length

From the Workbook Optimizer

*Sample output message:* The calculation **My calculation** is 600 characters long

Computing the results of complex calculations can impact performance.

Consider breaking the calculation apart and moving whatever is possible to the database, or using Tableau Prep to create the calculations prior to analysis.

#### Additional information

Complex and long calculations can either be written in a single calculation or nested (with some components written as standalone calculations that are used in the larger calculation). Building a calculation with nested components may make it easier to troubleshoot and maintain, but it can add complications and additional processing. If possible, pushing these components back to the data source may aid performance.

Comments in calculations count against the length, so this guideline may be triggered by a long comment rather than a long and complex calculation.

---

#### Calculation uses multiple data sources

##### From the Workbook Optimizer

*Sample output message:* The data source **Supply Chain** includes 17 calculations using fields from another data source.

When calculations use fields from multiple data sources, Tableau can't use any optimizations and must compute the calculation locally.

Consider using Tableau Prep to create the calculation and using an extract.

#### Additional information

By moving the cross-database calculation to the data layer, the processing can be performed before the user even requests the dashboard. See [Join your data \(Prep\)](#) and [Create level of detail and rank calculations](#) for more information.

Under some conditions a parameter may trigger this guideline. If a calculation is indicated that doesn't use multiple data sources, check to see if it has a parameter and if that parameter can be simplified.

---

### Dashboard size not fixed

From the Workbook Optimizer

*Sample output message:* The dashboard **Q3 analytics** isn't fixed size.

Fixed sized dashboards can be cached because they're a predictable size. Using automatic dashboard sizing means the results depend on the user's screen, and therefore the dashboard must be rendered every time. Rendering dashboards more often comes with a performance hit.

Consider using fixed dashboard sizing.

### Additional information

Although responsive elements are a best practice in web design, letting your dashboard resize can distort the layout of the content in addition to the performance impact of re-rendering. For Tableau visualizations, it's best to use a [fixed dashboard size](#) and use [device-specific dashboards](#) to support different devices and screen sizes.

---

### Filter uses conditional logic

From the Workbook Optimizer

*Sample output message:* The filter **Sample Type** uses conditional logic.

Dimension filtering can be done in various ways, such as on a list of values, by wildcard matching, or using conditional logic. Conditional logic can be slow.

Consider changing the filter to not use conditional logic. If necessary, make sure your logic tests for the most frequent outcome first and use ELSEIF or CASE when possible.

### Additional information

For more information on filtering, see [Filter Your Data](#).

---

Filter uses "Only Relevant Values"

From the Workbook Optimizer

*Sample output message:* The filter **Sample Type** uses "Only Relevant Values".

When a filter uses "Only Relevant Values", the interactive filter control only shows options that are applicable given the current state of the view. Every time a change is made to other filters, the list of values to be displayed must be requeryed, which has a performance impact.

Consider using dashboard filter actions instead. If the end-user benefit is valuable enough that this feature should be used, consider extracting the data and optimizing the extract.

Additional information

There are situations where using "Only Relevant Values" is necessary to avoid an unwieldy filter list. Instead of using interactive filters in that situation, try using [action filters](#). For example, consider a dashboard that has cascading filters for Category, Sub-Category, and Product ID, where Product ID is set to show "Only Relevant Values". Removing that restriction would expand the list of products significantly. Rather than using filters, you can build simple visualizations (such as a bar chart of Category and Sub-Category) and use it as a filter. The user clicks on a bar and the action filter is applied to the rest of the visualizations on the dashboard. For more information, see [Dashboard Actions](#).

---

Live data connections

From the Workbook Optimizer

*Sample output message:* The data source **Supply Chain** isn't an extract.

Tableau extracts are designed to be as efficient as possible for use with analytics. Using extracts is one of the easiest ways to improve performance due to the data source. Extracts also have many native features for optimization.

Consider extracting the data source.

## Tableau Server on Linux Administrator Guide

### Additional information

In some instances, taking an extract may put undesirable strain on the Tableau Server or Tableau Site's resources. Work with your Tableau administrator to determine the best course of action.

The whitepaper [Designing Efficient Workbooks](#) has extensive information about extracts and how to use them for performance. (You may need to sign in to access the whitepaper.)

### Multiple connections in a data source

From the Workbook Optimizer

*Sample output message:* The data source **Supply chain** uses multiple data connections.

Data sources that include multiple connections can't be computed locally.

Consider combining the data sources in Tableau Prep and using an extract for analysis.

### Additional information

See [Join your data \(Prep\)](#) for more information.

---

### Nested calculations

From the Workbook Optimizer

*Sample output message:* The calculation **My Calculation** references another calculation.

Nesting calculations can add complications and additional processing, especially with IF statements and other performance intensive functions.

Consider pushing the calculations to the data source or materialize them in an extract.

### Additional information

This rule may be triggered for a calculation that isn't in the viz itself but is referenced by a calculation in the viz. For example, imagine four fields:

1. **Points earned** (a field in the data source)
2. **Quiz score** = [Points earned]\*10
3. **Curved grade** = [Quiz score]\*1.05
4. **Letter grade** = IF [Curved grade] >= 90 THEN "A" ELSEIF [Curved grade] >= 80 THEN "B" ELSEIF [Curved grade] >=70 THEN "C" ELSEIF [Curved grade] >=60 THEN "D" ELSE "F" END

**Quiz score** is a non-nested calculation that only references a field. Both **Curved grade** and **Letter grade** are nested calculations because they contain references to other calculations. Even if only **Letter grade** is used in the viz, **Curved grade** also triggers the nested calculation rule because it's in use inside **Letter grade**.

For more information on materializing calculations in an extract (Compute Calculations Now), see [Materialize Calculations in Your Extracts](#).

For more information about building calculations in Tableau Prep, see [Calculations in Tableau Prep](#).

---

#### Non-materialized calculations

From the Workbook Optimizer

*Sample output message:* The data source **Supply Chain** hasn't been pre-computed.

Computing the results of a calculation can impact performance.

Consider pushing calculations to the data source when possible. If using an extract, materialize calculations to pre-compute their results.

#### Additional information

Pre-compute the data and calculations either in an extract or your back-end data source. By moving this additional processing to the data layer, the processing is completed before the user even requests the dashboard.

Taking an extract of your data often boosts performance, though there are tradeoffs in data freshness and some functionality. See [Extract Your Data](#) for more information about options

for extracts and [Materialize Calculations in Your Extracts](#) for more information on materializing calculations.

Extract your data: right click on the data source's name at the top of the Data pane and select **Extract Data**. In the configuration dialog, choose **Compute Calculations Now**.

---

Number of data sources

From the Workbook Optimizer

*Sample output message:* The workbook contains 17 data sources.

Each data source contributes to the amount of time Tableau spends loading and rendering a workbook.

Consider combining data sources if possible, especially when the level of granularity is the same or they support the same analysis.

Additional information

See [Relate Your Data](#) for more information on combining data sources, or consider using Tableau Prep.

However, be wary of over-combining data sources. Workbooks perform best when each type of analysis is built off a well-designed data source. If it's hard to combine your data sources, this could be a sign that the analysis should be split into multiple workbooks, each with a more targeted purpose.

**To split your analysis across multiple workbooks**, try one of these methods:

- Save a copy of the workbook and delete unnecessary sheets, dashboards, and data sources from each one. See [Streamline your workbook](#) for more information.
  - Copy specific sheets into a new workbook. This may be more efficient because copying a dashboard into a new workbook carries over only what is needed for that dashboard. However, not all formatting options are transferred. See [Copying Information Between Workbooks](#) for more information.
-

## Number of filters

From the Workbook Optimizer

*Sample output message:* The sheet **Classroom Distribution** contains 17 filters.

Excessive filters on a view create a more complex query.

Consider reducing the number of filters and using filter actions wherever possible. Not all types and formats of filters are created equal in terms of performance, so consider optimizing necessary filters.

## Additional information

The whitepaper [Designing Efficient Production Workbooks](#) has an entire section on filters that goes into much more detail. In brief:

- Reduce the overall number of filters
- Filters applied to multiple worksheets trigger multiple queries with every change
- Limit use of **Show only relevant values**. Using an extract helps optimize this feature if it's needed.
- Avoid high cardinality include/exclude filters
- Use the **Apply** button to prevent multiple refreshes as the user interacts with the filter
- Filter on fields that are present in the view
- Use continuous date filters rather than discrete date filters
- Context filters shouldn't be used purely to boost performance

Filter actions are an efficient way to guide the user through a dashboard. See [Filter Actions](#) for more information.

---

## Number of layout containers

From the Workbook Optimizer

*Sample output message:* The dashboard **Q3 analytics** contains 42 layout containers.

Layout containers can complicate dashboard rendering.

Consider removing unnecessary layout containers and simplifying the dashboard design.

### Additional information

For more information about layout containers and the Layout pane, see [Group items using layout containers](#).

---

### Number of LOD calculations

From the Workbook Optimizer

*Sample output message:* The workbook contains 42 LOD calculations.

Computing the results of complex calculations can impact performance. Often, LODs are used on the fly to address issues of granularity in the data source that could be handled prior to analysis.

Consider tailoring the data source to the analysis to avoid the need for as many LODs.

### Additional information

Level of Detail calculations are powerful tools, but they're expensive. Make sure you're only using them when necessary.

Production databases are designed to handle significant query loads and are a great option for moving processing out of Tableau. FIXED LOD calculations can sometimes be performed by the database. Tableau Prep also supports FIXED LOD calculations. See [Create level of detail and rank calculations](#) for more information.

---

### Number of views in a dashboard

From the Workbook Optimizer

*Sample output message:* Dashboard **Q3 analytics** contains 17 views

A dashboard must load all elements before it can be displayed. The more views a dashboard contains, the longer it takes to load. Although it often involves a redesign, reducing the number of views in a dashboard is often the best way to boost its efficiency.

Consider streamlining the dashboard to be as effective and simple as possible by reducing the number of views, filters, and other elements. Start with anything that can be removed immediately. See [Streamline your workbook](#) for other ways to reduce clutter in your dashboard.

#### Additional information

If a more substantial redesign is needed, remember that not all views have an equal impact on performance. Focus on sheets with the most marks, filters, or other complexity. A good strategy can be to limit the initial dashboard to summary information and only provide more details when the user requests them. There are many strategies for this sort of guided drill-down, including:

- Use action filters. See [Filter Actions](#) for more information.
- Hide detailed views in a container using a layout container with a show/hide button. See [Show and hide objects by clicking a button](#) for more information.
- Break the dashboard into multiple dashboards and use navigation buttons. See [Detailed options for Navigation and Download objects](#) for more information.

---

#### Number of workbook sheets

From the Workbook Optimizer

*Sample output message:* The workbook contains 42 visible sheets

The overall size of a workbook impacts how long it takes to be processed and displayed. All visible sheets must be loaded before Tableau can display a workbook or view. Reducing the number of sheets can help speed up load time.

Consider reducing the number of sheets in the workbook by closing unneeded sheets, hiding sheets that are used in a dashboard, or splitting the analysis into multiple workbooks.

#### Additional information

**Delete sheets that aren't necessary for the analysis:** right click on the sheet tab along the bottom of the workbook and select Delete.

**Hide sheets in use:** Worksheets used in a dashboard or story can't be deleted, but they can be hidden. See [Manage Sheets in Dashboards and Stories](#) for more information.

- Hide all of a dashboard's sheets: right-click the dashboard tab at the bottom of the workbook and select Hide All Sheets.
- Hide a specific sheet: right click the sheet tab at the bottom of the workbook and select Hide.

**If all sheets are needed,** decide if the analysis can be split into multiple workbooks, each with a more targeted purpose.

- Save a copy of the workbook and delete unnecessary sheets, dashboards, and data sources from each one. See [Streamline your workbook](#) for more information.
  - Copy specific sheets into a new workbook. This may be more efficient because copying a dashboard into a new workbook carries over only what is needed for that dashboard. However, not all formatting options are transferred. See [Copying Information Between Workbooks](#) for more information.
- 

### Unused data sources

From the Workbook Optimizer

*Sample output message:* The data source **Supply Chain** isn't used in the workbook.

Each data source contributes to the amount of time Tableau spends loading and rendering a workbook.

Consider closing data sources that aren't in use.

### Additional information

If any data sources aren't being used, close them: right click on the data source's name at the top of the Data pane and select **Close**.

---

## Unused fields

From the Workbook Optimizer

*Sample output message:* The data source **Supply Chain** contains 42 fields that aren't being used.

Hiding unused fields prevents them from being unnecessarily queried and reduce the size of extracts.

Consider hiding any fields that aren't being used, regardless of whether the data source is an extract.

Additional information

### Hide unused fields

- In Tableau Desktop: open the dropdown menu at the top of the Data pane and select **Hide All Unused Fields**.
  - In web authoring: right click on an unused field and select **Hide**. There's no way to bulk hide unused fields in web authoring. If hiding fields individually is prohibitive, consider [editing in Tableau Desktop](#) instead of working in the browser.
- 

## Uses data blending

From the Workbook Optimizer

*Sample output message:* The sheet **Classroom Distribution** uses data blending.

Data blending performance is driven by the number of unique members in the linking fields.

Consider using relationships when possible. If a blend is required, try to use low cardinality linking fields.

Additional information

There are [several ways to combine data](#) from multiple sources. [Data blending](#) sends two separate queries to two separate data sources and displays the results together in the viz. These

queries are at the level of the [linking fields](#) and the results are merged in memory in Tableau. Large query results require more processing to generate the final viz.

**Tip:** If you aren't using data blending but the Workbook Optimizer failed this rule, check if the workbook is using [cross data source filtering](#). Filtering across data sources suffers from similar performance issues around field cardinality.

---

Uses date calculations

From the Workbook Optimizer

*Sample output message:* The data source **Supply Chain** contains 17 date calculations.

Date logic can be complicated. Minimize the number of date calculations and conversion you have to do in Tableau.

Consider using DATEPARSE and MAKEDATE before other methods, and try to use built-in functions like DATEDIFF() when possible. If filtering on a date, use relative date filters or a continuous date filter instead of a discrete filter.

Additional information

Computing calculations in Tableau can have a significant performance impact, especially [date functions](#). Consider taking an extract and [materializing calculations](#), or pushing calculations to your data source. For more information about building calculations in Tableau Prep, see [Create Calculations in Tableau Prep](#).

**Note:** If a date calculation is nested in another calculation, the optimizer flags the nested date calculation, even if the parent calculation is the field used in the viz.

---

Uses grouping

From the Workbook Optimizer

*Sample output message:* The data source **Supply Chain** uses 17 grouped fields

Tableau's native grouping functionality loads the entire domain of the field, which can have a performance impact.

Consider using a calculated field with a CASE statement or sets instead of groups.

#### Additional information

In the testing performed for the [Designing Efficient Workbooks](#) whitepaper, grouping with CASE and sets performed better than the native group functionality.

The **CASE** function can be used to create groups. Imagine a scenario where the data involved a deck of cards. There's a field for the card value (2–10, J, Q, K, A) but the analysis should compare face cards to number cards. The case statement to make that grouping could be

```
CASE [Value]
  WHEN "J" THEN "Face card"
  WHEN "Q" THEN "Face card"
  WHEN "K" THEN "Face card"
  ELSE "Number card"
END
```

Sets have the added benefit of set actions, which make sets more powerful and flexible than traditional grouping. For more information, see [Create Sets](#) and [Set Actions](#).

# Manage Server

After installing Tableau Server, you can customize and manage your server. For example, you can manage security, licenses, sites, subscriptions and data-driven alerts, and more.

|  |             |

## Security

As a part of managing Tableau Server, you can configure authentication, data security, and network security.

### Authentication

Authentication verifies a user's identity. Everyone who needs to access Tableau Server—whether to manage the server, or to publish, browse, or administer content—must be represented as a user in the Tableau Server repository. The method of authentication may be performed by Tableau Server (“local authentication”), or authentication may be performed by an external process. In the latter case, you must configure Tableau Server for external authentication technologies such as Kerberos, SAML, or OpenID. In all cases, whether authentication takes place locally or is external, each user identity must be represented in the Tableau Server repository. The repository manages authorization meta data for user identities.

Looking for Tableau Server on Windows? See [Authentication](#).

Although all user identities are ultimately represented and stored in the Tableau Server repository, you must manage user accounts for Tableau Server in an identity store. There are two, mutually exclusive, identity store options: LDAP and local. Tableau Server supports arbitrary LDAP directories, but it's been optimized for Active Directory LDAP implementation. Alternatively, if you are not running an LDAP directory, you can use the Tableau Server local identity store. For more information see Identity Store.

As shown in the following table, the type of identity store you implement, in part, will determine your authentication options.

| Identity         | Authentication Mechanism |       |            |          |   |                |                |              |            |
|------------------|--------------------------|-------|------------|----------|---|----------------|----------------|--------------|------------|
|                  | Basic                    | SAM-L | Site SAM-L | Kerberos | (Windows only)<br>Automatic Logon<br>(Microsoft SSPI) | OpenID Connect | Connected Apps | Trusted Auth | Mutual SSL |
| Local            | X                        | X     | X          |          |   | X              | X              | X            | X          |
| Active Directory | X                        | X     |            | X        | X   |                | X              | X            | X          |
| LDAP             | X                        | X     |            |          |   |                | X              | X            | X          |

Access and management permissions are implemented through site roles. Site roles define which users are administrators, and which users are content consumers and publishers on the server. For more information about administrators, site roles, groups, Guest User, and user-related administrative tasks, see [Users](#) and [Site Roles for Users](#).

**Note:** In the context of authentication, it's important to understand that users are not authorized to access external data sources through Tableau Server by virtue of having an account on the server. In other words, in the default configuration, Tableau Server does not act as a proxy to external data sources. Such access requires additional configuration

of the data source on Tableau Server or authentication at the data source when the user connects from Tableau Desktop.

## Add-on authentication compatibility

Some authentication methods can be used together. The following table shows authentication methods that can be combined. Cells marked with an "X" indicate a compatible authentication set. Blank cells indicate incompatible authentication sets.

|                                | Con-<br>nected<br>Apps | Trusted<br>Authentic-<br>ation | Serve-<br>r-wide<br>SAML | Site<br>SAM-<br>L | Ker-<br>beros | (Win-<br>dows<br>only)<br><br>Auto-<br>matic<br>Logon<br>(Micro-<br>soft<br>SSPI) | Mutu-<br>al<br>SSL | Open-<br>ID Con-<br>nect |
|--------------------------------|------------------------|--------------------------------|--------------------------|-------------------|---------------|---|--------------------|--------------------------|

| Trusted<br>Authentic-<br>ation |                        | N/A                            | X                        | X                 | X             |   | X                  | X                        |
| Server-<br>wide<br>SAML        | X                      | X                              | N/A                      | X                 |               |   |                    |                          |
| Site SAML                      | X                      | X                              | X                        | N/A               |               |   |                    |                          |

Tableau Server on Linux Administrator Guide

|                                  |   |   |   |   |     |     |     |     |
|----------------------------------|---|---|---|---|-----|-----|-----|-----|
| Kerberos                         | X | X |   |   | N/A |     |     |     |
| Automatic Logon (Microsoft SSPI) |   |   |   |   |     | N/A |     |     |
| Mutual SSL                       | X | X |   |   |     |     | N/A |     |
| OpenID Connect                   | X | X |   |   |     |     |     | N/A |
| Personal Access Token (PAT)      | * | * | * | * | *   | *   | *   | *   |

\* PATs, by design, do not work directly with the authentication mechanism listed in these columns to authenticate to the REST API. Instead, PATs use Tableau Server user account credentials to authenticate to the REST API.

## Client authentication compatibility

Authentication handled through a user interface (UI)

| Clients                 | Authentication Mechanism |       |            |                   |  |                 |                 |               |             |                               |
|-------------------------|--------------------------|-------|------------|-------------------|--|-----------------|-----------------|---------------|-------------|-------------------------------|
|                         | Bas-ic                   | SA-ML | Site SA-ML | Ker-beros         | (Win-dows only)<br>Auto-matic Logon<br>(Micro-soft SSPI) | Open-ID Connect | Con-nected Apps | Trus-ted Auth | Mut-ual SSL | Per-sonal Acces-s Token (PAT) |
| Table-au Desk-t-op      | X                        | X     | X          | X                 | X  | X               |                 |               | X           |                               |
| Table-au Prep Bui-lde-r | X                        | X     | X          | X                 | X  | X               |                 |               | X           |                               |
| Table-au Mobile         | X                        | X     | X          | X<br>(iOS only *) | X<br>**  | X               |                 |               | X           |                               |
| Web                     | X                        | X     | X          | X                 | X  | X               | X               | X             | X           |                               |

Tableau Server on Linux Administrator Guide

|          |  |  |  |  |  |  |     |  |  |  |
|----------|--|--|--|--|--|--|-----|--|--|--|
| Browsers |  |  |  |  |  |  | *** |  |  |  |
|----------|--|--|--|--|--|--|-----|--|--|--|

\* Kerberos SSO isn't supported for Android, but a fall back to user name and password is possible. For more information, see Note 5: Android platform.

\*\* SSPI is not compatible with the Workspace ONE version of the Tableau Mobile app.

\*\*\* In embedding workflows only.

Authentication handled programmatically

| Clients    | Authentication Mechanism |       |            |          |   |                |                |              |            |                             |
|------------|--------------------------|-------|------------|----------|---|----------------|----------------|--------------|------------|-----------------------------|
|            | Basic                    | SA-ML | Site SA-ML | Kerberos | (Windows only)<br>Automatic Logon<br>(Microsoft SSPI) | OpenID Connect | Connected Apps | Trusted Auth | Mutual SSL | Personal Access Token (PAT) |
| REST API   | X                        |       |            |          |   |                | X              |              |            | X                           |
| tabcmd 2.0 | X                        |       |            |          |   |                |                |              |            | X                           |
| tabcmd     | X                        |       |            |          |   |                |                |              |            |                             |

## Local authentication

If the server is configured to use local authentication, then Tableau Server authenticates users. When users sign-in and enter their credentials, either through Tableau Desktop, `tabcmd`, API, or web client, Tableau Server verifies the credentials.

To enable this scenario, you must first create an identity for each user. To create an identity, you specify a username and a password. To access or interact with content on the server, users must also be assigned a site role. User identities can be added to Tableau Server in the server UI, using [tabcmd Commands](#), or using the [REST API](#).

You can also create groups in Tableau Server to help manage and assign roles to large sets of related user groups (e.g., “Marketing”).

When you configure Tableau Server for local authentication, you can set password policies and account lockout on failed password attempts. See [Local Authentication](#).

**Note:** Tableau with multi-factor (MFA) authentication is available for Tableau Cloud only.

## External authentication solutions

Tableau Server can be configured to work with a number of external authentication solutions.

### Kerberos

You can configure Tableau Server to use Kerberos for Active Directory. See [Kerberos](#).

### SAML

You can configure Tableau Server to use SAML (security assertion markup language) authentication. With SAML, an external identity provider (IdP) authenticates the user's credentials, and then sends a security assertion to Tableau Server that provides information about the user's identity.

For more information, see [SAML](#).

### OpenID Connect

OpenID Connect (OIDC) is a standard authentication protocol that lets users sign in to an identity provider (IdP) such as Google. After they've successfully signed in to their IdP, they are automatically signed in to Tableau Server. To use OIDC on Tableau Server, the server must be configured to use the local identity store. Active Directory or LDAP identity stores are not supported with OIDC. For more information, see [OpenID Connect](#).

### Mutual SSL

Using mutual SSL, you can provide users of Tableau Desktop, Tableau Mobile, and other approved Tableau clients a secure, direct-access experience to Tableau Server. With mutual SSL, when a client with a valid SSL certificate connects to Tableau Server, Tableau Server confirms the existence of the client certificate and authenticates the user, based on the user name in the client certificate. If the client does not have a valid SSL certificate, Tableau Server can refuse the connection. For more information, see [Configure Mutual SSL Authentication](#).

### Connected apps

#### Direct trust

Tableau connected apps enable a seamless and secure authentication experience by facilitating an explicit trust relationship between your Tableau Server site and external applications where Tableau content is embedded. Using connected apps also enables a programmatic way to authorize access to the Tableau REST API using JSON Web Tokens (JWTs). For more information, see [Use Tableau Connected Apps for Application Integration](#).

#### EAS or OAuth 2.0 trust

You can register an external authorization server (EAS) with Tableau Server to establish a trust relationship between your Tableau Server and an EAS using the OAuth 2.0 standard protocol. The trust relationship provides your users with single sign-on experience, through your IdP, to embedded Tableau content. In addition, registering an EAS enables a programmatic way to authorize access to the Tableau REST API using JSON Web Tokens (JWTs). For more information, see [Configure Connected Apps with OAuth 2.0 Trust](#).

## Trusted authentication

Trusted authentication (also referred to as "Trusted tickets") lets you set up a trusted relationship between Tableau Server and one or more web servers. When Tableau Server receives requests from a trusted web server, it assumes that the web server has already handled whatever authentication is necessary. Tableau Server receives the request with a redeemable token or ticket and presents the user with a personalized view which takes into consideration the user's role and permissions. For more information, see [Trusted Authentication](#).

## LDAP

You can also configure Tableau Server to use LDAP for user authentication. Users are authenticated by submitting their credentials to Tableau Server, which will then attempt to bind to the LDAP instance using the user credentials. If the bind works then the credentials are valid and Tableau Server grants the user a session.

"Binding" is the handshake/authentication step that happens when a client tries to access an LDAP server. Tableau Server does this for itself when it makes various non-authentication related queries (such as importing users and groups).

You can configure the type of bind you want Tableau Server to use when verifying user credentials. Tableau Server supports GSSAPI and simple bind. Simple bind passes credentials directly to the LDAP instance. We recommend that you configure SSL to encrypt the bind communication. Authentication in this scenario maybe be provided by the native LDAP solution, or with an external process, like SAML.

For more information about planning for and configuring LDAP, see [Identity Store and External Identity Store Configuration Reference](#).

## Other authentication scenarios

- REST API: [Signing In and Out \(Authentication\)](#)

**Note:** REST API does not support SAML single-sign (SSO).

- Mobile device authentication: [Single sign-on for Tableau Mobile](#)
- Certificate trust for TSM clients: [Connecting TSM clients](#)
- PAM integration for TSM administration: [TSM Authentication](#)

### Data access and source authentication

You can configure Tableau Server to support a number of different authentication protocols to various different data sources. Data connection authentication may be independent of Tableau Server authentication.

For example, you may configure user authentication to Tableau Server with local authentication, while configuring OAuth or SAML authentication to specific data sources. See [Data Connection Authentication](#).

### Local Authentication

If the server is configured to use local identity store, then Tableau Server authenticates users. When users sign-in and enter their credentials, either through Tableau Desktop, `tabcmd`, API, or web client, Tableau Server verifies the credentials. Tableau user names stored in the identity store are associated with rights and permissions for Tableau Server. After authentication is verified, Tableau Server manages user access (authorization) for Tableau resources.

To use local authentication, you must configure Tableau Server with a local identity store during Setup. You cannot use local authentication if your Tableau Server has been configured with an external identity store (LDAP, Active Directory, etc).

**Note:** Identity pools, which is a tool designed to complement and support additional user provisioning and authentication options you might need in your organization, supports OpenID Connect (OIDC) authentication only. For more information, see [Provision and Authenticate Users Using Identity Pools](#).

## Password storage

When local authentication is used, the user's salted and hashed password is stored in the repository. Passwords are never stored directly, rather, the result of salting and hashing the password is stored. Server uses the PBKDF2 derivation function with the HMAC SHA512 hashing function.

## Configure password settings

After you install Tableau Server with local authentication, you can use Tableau Server Manager (TSM) to configure a number of password-related settings:

- Password policies: these policies define the requirement for password structure, such as length, character types, and other requirements.
- Password expiration: enable and specify password expiry.
- Login rate limit: Tableau Server throttles the time between sign-in attempts after users enter 5 incorrect passwords. Users will need to wait a few seconds before attempting another sign-in. If users continue to enter incorrect passwords, then they must wait for exponentially longer periods of time in between sign-in attempts. By default, the maximum time between sign-in attempts is 60 minutes.

Lock out account access after too many failed attempts. You can specify how many failed attempts users are allowed to enter before they are locked out. For information on how to unlock access to a locked account, see [View and manage users on a site](#) .

- User password reset: Enable users to reset passwords. Enabling password reset will configure Tableau Server to display a link on the sign-in page. Users who forget passwords or want to reset a password can click the link to initiate a reset-password workflow. Password reset must be configured using TSM CLI, as described below.

## Use the TSM web interface

## Tableau Server on Linux Administrator Guide

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click on **User Identity & Access** on the **Configuration** tab and then click **Authentication Method**.
3. Select Local authentication from the drop-down menu to display the password settings.
4. Configure the password settings and then click **Save Pending Changes**.
5. Click **Pending Changes** at the top of the page:

6. Click **Apply Changes and Restart**.

### Use the TSM CLI

For the initial configuration of password policies, we recommend that you use the configuration file template below to create a json file. You can also set any single configuration key listed below with the syntax described in [tsm configuration set](#).

1. Copy the following json template to a file. Fill in the key values with your password policy configuration. See the reference section that follows for more information about key options.

```
{  
  
  "configKeys": {  
  
    "wgserver.localauth.policies.mustcontainletters.enabled":  
    false,  
  
    "wgserver.localauth.policies.mustcontainuppercase.enabled":  
    false,  
  
  }  
}
```

```

    "wgserver.localauth.policies.mustcontainnumbers.enabled":
false,

    "wgserver.localauth.policies.mustcontainsymbols.enabled":
false,

    "wgserver.localauth.policies.minimumpasswordlength.enabled":
false,

    "wgserver.localauth.policies.minimumpasswordlength.value": 8,

    "wgserver.localauth.policies.maximumpasswordlength.enabled":
false,

    "wgserver.localauth.policies.maximumpasswordlength.value":
255,

    "wgserver.localauth.passwordexpiration.enabled": false,

    "wgserver.localauth.passwordexpiration.days": 90,

    "wgserver.localauth.ratelimiting.maxbackoff.minutes": 60,

    "wgserver.localauth.ratelimiting.maxattempts.enabled": false,

    "wgserver.localauth.ratelimiting.maxattempts.value": 5,

    "features.PasswordReset": false

    }
}

```

2. Run the `tsm settings import -f file.json` to pass the json file with the appropriate values to Tableau Services Manager to configure Tableau Server.
3. Run the `tsm pending-changes apply` command to apply the changes. See `tsm pending-changes apply`.

#### Configuration file reference

This section lists all of the options that can be used to configure password polices.

## Tableau Server on Linux Administrator Guide

`wgserver.localauth.policies.mustcontainletters.enabled`

Default value: `false`

Require at least one letter in passwords.

`wgserver.localauth.policies.mustcontainuppercase.enabled`

Default value: `false`

Require at least one upper-case letter in passwords.

`wgserver.localauth.policies.mustcontainnumbers.enabled`

Default value: `false`

Require at least one number letter in passwords.

`wgserver.localauth.policies.mustcontainsymbols.enabled`

Default value: `false`

Require at least one special character in passwords.

`wgserver.localauth.policies.minimumpasswordlength.enabled`

Default value: `false`

Enforce minimum-length passwords.

`wgserver.localauth.policies.minimumpasswordlength.value`

Default value: 8

The minimum number of characters passwords must have. Enter a value between 4 and 255, inclusive. You must set `wgserver.localauth.policies.minimumpasswordlength.enabled` to `true` to enforce this value.

`wgserver.localauth.policies.maximumpasswordlength.enabled`

Default value: `false`

Enforce maximum-length passwords.

`wgserver.localauth.policies.maximumpasswordlength.value`

Default value: `255`

The maximum number of characters passwords may have. Enter a value between 8 and 225, inclusive. You must set `wgserver.localauth.policies.maximumpasswordlength.enabled` to `true` to enforce this value.

`wgserver.localauth.passwordexpiration.enabled`

Default value: `false`

Enforce password expiry.

`wgserver.localauth.passwordexpiration.days`

Default value: `90`

The number of days before a password expires. Enter a value between 1 and 365, inclusive. You must set `wgserver.localauth.passwordexpiration.enabled` to `true` to enforce this value.

`wgserver.localauth.ratelimiting.maxbackoff.minutes`

Default value: `60`

Maximum time between sign-in attempts after a user enters multiple incorrect passwords. Enter a value between 5 and 1440, inclusive.

`wgserver.localauth.ratelimiting.maxattempts.enabled`

Default value: `false`

Enforce account lock out after 5 incorrect passwords are entered. To change the number of incorrect passwords that will trigger account lock out, you set `wgserver.localauth.ratelimiting.maxattempts.value`.

`wgserver.localauth.ratelimiting.maxattempts.value`

Default value: 5

The number of incorrect passwords that a user may enter to trigger account lock out. Enter a value between 5 and 100, inclusive. You must set `wgserver.localauth.ratelimiting.maxattempts.enabled` to `true` to enforce this value.

`features.PasswordReset`

Default value: `false`

Enable users to reset passwords. Tableau Server must be configured to send email for this feature to operate. See [Configure SMTP Setup](#).

## SAML

SAML (Security Assertion Markup Language) is an XML standard that allows secure web domains to exchange user authentication and authorization data. You can configure Tableau Server to use an external identity provider (IdP) to authenticate users over SAML 2.0. No user credentials are stored with Tableau Server, and using SAML enables you to add Tableau to your organization's single sign-on environment.

You can use SAML server wide, or you can configure sites individually. Here's an overview of those options:

- **Server-wide SAML authentication.** A single SAML IdP application handles authentication for all Tableau Server users. Use this option if your server has only the Default site, as it is unnecessary to configure site specific SAML in this case. You may also use

Server-wide SAML in multisite environments, but users are limited to a single IdP to across all sites.

- **Server-wide local authentication and site-specific SAML authentication.** In a multi-site environment, users who are not enabled for SAML authentication at the site level can sign in using local authentication.
- **Server-wide SAML authentication and site-specific SAML authentication.** In a multi-site environment, all users authenticate through a SAML IdP configured at the site level, and you specify a server-wide default SAML IdP for users that belong to multiple sites.

If you want to use site-specific SAML, you must configure server-wide SAML before you configure individual sites. Server-side SAML does not need to be enabled for site-specific SAML to function, but it must be configured.

User authentication through SAML does not apply to permissions and authorization for Tableau Server content, such as data sources and workbooks. It also does not control access to underlying data that workbooks and data sources connect to.

**Notes:**

- Tableau Server supports both service provider initiated and IdP initiated SAML in browsers and in the Tableau Mobile app. SAML connections from Tableau Desktop must be service provider initiated.
- Identity pools, which is a tool designed to complement and support additional user provisioning and authentication options you might need in your organization, supports OpenID Connect (OIDC) authentication only. For more information, see Provision and Authenticate Users Using Identity Pools.

**Authentication overview**

The following image shows the steps to authenticate a user with single sign-on in a typical service provider initiated flow:

1. User navigates to the Tableau Server sign-in page or clicks a published workbook URL.
2. Tableau Server starts the authentication process by redirecting the client to the configured IdP.
3. The IdP requests the user's username and password from the user. After the user submits valid credentials, the IdP authenticates the user.
4. The IdP returns the successful authentication in the form of a SAML Response to the client. The client passes the SAML Response to Tableau Server.
5. Tableau Server verifies that the username in the SAML Response matches a licensed user stored in the Tableau Server Repository. If a match is verified, then Tableau Server responds to the client with the requested content.

### SAML Requirements

Before you configure SAML on Tableau Server, make sure your environment meets the requirements.

**Important:** SAML configurations, both with the IdP and on Tableau Server, are case sensitive. For example, URLs configured with the IdP and on Tableau Server must match exactly.

### Certificate and identity provider (IdP) requirements

To configure Tableau Server for SAML, you need the following:

- **Certificate file.** A PEM-encoded x509 certificate file with a **.crt** extension. This file is used by Tableau Server, not the IdP. If you have an SSL certificate, it is possible in some circumstances to use the same certificate with SAML. For more information, see [Using SSL certificate and key files for SAML](#) later in this article.

Tableau Server requires a certificate-key pair to sign the request that is sent to the IdP. This reduces the threat of a man-in-the-middle attack given the difficulty of spoofing a signed request. Additionally, Tableau Server verifies that the AuthNResponse it receives from the trusted IdP. Tableau Server verifies the AuthNResponse by using the signature produced by the IdP. The IdP certificate metadata is provided to Tableau Server as part of the initial SAML configuration process.

Signed requests are not always necessary for all IdPs. By default, Tableau Server requires signed requests. We recommend this configuration to ensure a more secure communication transmission with the IdP. Work with your IdP team to understand if disabling signed requests is necessary. To disable signed requests see [samlSettings Entity](#).

- **Signature algorithm.** The certificate must use a secure signature algorithm, for example SHA-256. If you attempt to configure Tableau Server for SAML with a certificate that uses SHA-1 signature hash, Tableau Server will reject the certificate. You can configure Tableau Server to accept the less-secure SHA-1 hash by setting the `tsm.wgserver.saml.blocklisted_digest_algorithms` configuration key.
- **RSA key and ECDSA curve sizes.** The Tableau Server certificate must have an RSA key strength of 2048, and the IdP certificate must have either an RSA key strength of 2048 or ECDSA curve size of 256.

You can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys, `wgserver.saml.min_allowed.rsa_key_size` and `wgserver.saml.min_allowed.elliptic_curve_size`.

- **Certificate key file.** An RSA or DSA private key file that has the `.key` extension. RSA keys must be in in PKCS#1 or PKCS#8 format.

Password protection requirements are as follows:

- The PKCS#1 RSA key file cannot be password protected.
- To use a password-protected key file, you must configure SAML with a RSA PKCS#8 file. **Note:** A PKCS#8 file with a null password is not supported.
- Password-protected key files are not supported in site-specific SAML deployments.

**Summary of support**

| Key file format           | Server-Wide SAML Support | Site-Level SAML Support |
|---------------------------|--------------------------|-------------------------|
| PKCS#8 RSA                | Yes                      | No                      |
| PKCS#8 (no/null password) | No                       | No                      |
| PKCS#1 RSA                | Yes                      | Yes                     |
| PKCS#1 RSA (password)     | No                       | No                      |
| PKCS#1 DSA (password)     | No                       | No                      |

- **IdP must sign SAML assertions with a secure signature algorithm.** By default, Tableau Server will reject SAML assertions signed with the SHA-1 algorithm. You can configure Tableau Server to accept assertions signed with the less-secure SHA-1 hash

by setting the `tsm wgserver.saml.blocklisted_digest_algorithms` configuration key.

- **IdP account that supports SAML 2.0 or later.** You need an account with an external identity provider. Some examples are PingFederate, SiteMinder, and Open AM.
- **IdP provider that supports import and export of XML metadata.** Although a manually created metadata file might work, Tableau Technical Support cannot assist with generating the file or troubleshooting it.
- **Username:** Required. The IdP configuration must include the "username" attribute or claim and the corresponding SAML configuration attribute on Tableau Server must be set to "username" as well.

## SSL off-loading

If your organization terminates SSL connections from the IdP at a proxy server before sending the authentication request to Tableau Server, then you may need to make a proxy configuration. In this scenario, SSL is "off-loaded" at the proxy server, which means the https request is terminated at the proxy server and then forwarded to Tableau Server over http.

Tableau Server validates the SAML response message returned from the IdP. Since SSL is off-loaded at the proxy, Tableau Server will validate with the protocol that it receives (http), but the IdP response is formatted with https, so validation will fail unless your proxy server includes the X-Forwarded-Proto header set to `https`. See [Configure Tableau Server to work with a reverse proxy server and/or load balancer](#).

## Using SSL certificate and key files for SAML

If you are using a PEM-encoded x509 certificate file for SSL, you can use the same file for SAML. For SSL, the certificate file is used to encrypt traffic. For SAML, the certificate is used for authentication.

In addition to the requirements listed in [Certificate and identity provider \(IdP\) requirements](#) above, to use the same certificate for both SSL and SAML, the certificate must also meet the following condition to work for SAML:

## Tableau Server on Linux Administrator Guide

- Confirm that the certificate includes only the certificate that applies to Tableau Server and not any other certificates or keys.

To do this, you can create a backup copy of the certificate file, and then open the copy in a text editor to review its contents.

### User management requirements

When you enable SAML, user authentication is performed outside of Tableau, by the IdP. However, user management is performed by an identity store: either an external identity store (Active Directory or LDAP) or by Tableau Server in a local identity store. For more information about planning for user management with Tableau Server, see [Identity Store](#).

When you configure the identity store during Setup, you must select the option that reflects how you want to use SAML. Note, if you want to use site-specific SAML, you must configure server-wide SAML before you configure individual sites.

- **For site-specific SAML:** If you have multiple sites on Tableau Server and want to set up each site for a particular IdP or IdP application (or configure some sites not to use SAML), configure Tableau Server to manage user with a local identity store. For site-specific SAML, Tableau Server relies on the IdP for authentication and does not use passwords.
- **For server-wide SAML:** If you configure server-wide SAML with a single IdP, you can configure Tableau Server to use the local identity store or an external identity store.
- **For both server-wide SAML authentication and site-specific SAML authentication:**
  - **When using a local identity store**, it is important that you use a username that has email address formatting. Using a complete email address helps to guarantee the uniqueness of the username in Tableau Server, even when two users have the same email prefix but have different email domains. To ensure uniqueness in identities, leverage full email address formatting across both systems or upgrade Tableau Server to version 2022.1.x or later and run the [identity migration](#)

background job.

- **In a multi-site environment**, all users authenticate through a SAML IdP configured at the site level. In this scenario, you specify a server-wide default SAML IdP for users who belong to multiple sites. To configure this scenario, Tableau Server must be configured with a local identity store.
- **Ignore domain when matching SAML username attribute.** Beginning in Tableau Server versions 2021.4.21, 2022.1.17, 2022.3.9, and 2023.1.5, you can configure Tableau Server to ignore the domain portion of the username attribute when matching the identity provider (IdP) user name to a user account on Tableau Server. For example, the username attribute in the IdP might be `alice@example.com` to match a user named `alice` in Tableau Server. Ignoring the domain portion of the username attribute might be useful if you already have users defined in Tableau Server that match the prefix portion of the username attribute but not the domain portion of the username attribute.

**Important:** We do not recommend ignoring the domain name without taking precautions. Specifically, verify that user names are unique across the configured domains that you've created in your IdP. Configuring Tableau Server to ignore the domain name has the potential to result in unintended user sign-in. Consider the case where your IdP has been configured for multiple domains (e.g., `example.com` and `tableau.com`). If two users with the same first name, but different user accounts (e.g., `alice@tableau.com` and `alice@example.com`) are in your organization, then you could have a mapping mismatch.

To configure Tableau Server to ignore domain names in the username attribute from the IdP, set `wgserver.ignore_domain_in_username_for_matching` to `true`. For more information, see `wgserver.ignore_domain_in_username_for_matching`.

**Notes:**

- This command only works in Tableau Server deployments that are in `legacy-identity-mode` or deployments that have not been updated through the [identity migration](#) to use the Identity Service.
- When you change the `tsm` command to ignore the domain name in the `username` attribute, all user names in Tableau Server must have a domain name.

**Note:** The [REST API](#) and `tabcmd` do not support SAML single-sign (SSO). To sign in, you must specify the name and password of a user who has been created on the server. The user may be managed by the local identity store or an external identity store, depending on how you have configured Tableau Server. REST API or `tabcmd` calls will have the permissions of the user you sign in as.

### SAML compatibility notes and requirements

- **Matching usernames:** The user name stored in Tableau Server must match the configured user name attribute sent by the IdP in the SAML assertion. By default, Tableau Server expects the incoming assertion to contain an attribute called "username" with that user's information. For example, if the user name for Jane Smith is stored in PingFederate as `jsmith`, it must also be stored in Tableau Server as `jsmith`.

#### When configuring SAML during authentication

If you are configuring SAML as part of the initial Tableau Server setup, make sure the account you plan to use exists in your IdP before you run setup. During Tableau Server setup you create the server administrator account.

#### When running multiple domains

If you use an Active Directory or LDAP external identity store and you are running in multiple domains (that is, users belong to multiple domains, or your Tableau Server installation includes multiple domains), the IdP must send both the user name *and* domain attributes for a user in the SAML assertion. Both these user name and domain attributes

must match exactly the user name and domain stored in Tableau Server. Do *one* of the following:

- Set `domain\username` in the username field
- Set domain in the domain field and set user name in the username field

When setting the domain attribute, you can use the fully qualified domain name (FQDN) or the shortname.

Where the domain isn't specified, it will be considered the default domain.

For more information, see Support for multiple domains and the "Match Assertions" section in the **Use TSM CLI** tab of Configure Server-Wide SAML.

- **Signature algorithm:** Tableau Server uses SHA256 signature algorithm.
- **Single Log Out (SLO):** Tableau Server supports both service provider (SP)-initiated SLO and identity provider (IdP)-initiated SLO for both server-wide SAML and site-specific SAML.
- **External authentication types:** Tableau Server supports using one external authentication type at a time.
- **Mutual SSL:** Tableau Server does not support mutual SSL (two-way SSL) and SAML together. If you want to use mutual SSL, you can configure it on the IdP.
- **Assertions encoding:** Assertions must be UTF-8 encoded.
- **Encryption and SAML assertions:**
  - **Server-wide SAML:** When Tableau Server is configured for server-wide SAML, Tableau Server supports encrypted assertions from the IdP. Encryption assertions are enabled by the certificate that you upload as part of the initial configuration for server-wide SAML. SAML requests and responses can be sent over HTTP or HTTPS.

- **Site-specific SAML:** When Tableau Server is configured for site-specific SAML, Tableau Server does not support encrypted assertions from the IdP. However, all SAML requests and responses are sent over HTTPS to secure communication with the IdP. HTTP requests and responses are not supported.
- **User identity in Tableau Server for tabcmd users:** As described in User management requirements section above, to use tabcmd, you must sign in as a user defined on the server. You cannot use SAML accounts with **tabcmd**.
- **Using SAML SSO with Tableau Desktop:** By default, Tableau Desktop allows SP-initiated SAML authentication.

If your IdP does not support this functionality, you can disable SAML sign-in for Tableau Desktop using the following command:

```
tsm authentication saml configure --desktop-access disable
```

For more information, see `tsm authentication saml <commands>`.

- **Distributed installations:** TSM versions of Tableau Server (2018.2 and newer) use the Client File Service to share files in a multi node cluster. After you have configured SAML on the initial node in your cluster, the Client File Service will distribute certificate and key files to the other nodes.
- **Login URL:** For users to be able to sign in, your IdP must be configured with SAML Login endpoint that sends a POST request to the following URL:

```
https://<tableauserver>/wg/saml/SSO/index.html.
```

- **Logout URL:** To enable users to sign out after signing in with SAML (single logout, or SLO), your IdP must be configured with a SAML Logout endpoint that sends a POST request to the following URL:

```
https://<tableauserver>/wg/saml/SingleLogout/index.html.
```

**Note:** Tableau Server supports both service provider (SP)-initiated SLO and identity provider (IdP)-initiated SLO for both server-wide SAML and site-specific SAML.

- **Post-logout redirect URL:** By default, when a user signs out of Tableau Server, the sign-in page is displayed.

To display a different page after sign-out, use the `tsm authentication saml configure` command with the `-su` or `--signout-url` option.

- To specify an absolute URL, use a fully-qualified URL starting with `http://` or `https://`, as in this example:

```
tsm authentication saml configure -su https://example.com
```

- To specify a URL relative to the Tableau Server host, use a page starting with a `/` (slash):

```
tsm authentication saml configure -su /ourlogoutpage.html
```

- **Active Directory Federation Service (AD FS):** You must configure AD FS to return additional attributes for Tableau authentication with SAML. The **Name ID** and **username** attributes can be mapped to the same AD attribute: **SAM-Account-Name**.
- **AuthNContextClassRef :** AuthNContextClassRef is an optional SAML attribute that enforces validation of certain authentication "contexts" in IdP initiated flows. You can set comma-separated values for this attribute with TSM. When this attribute is set, Tableau Server validates that the SAML response contains at least one of the values listed. If the SAML response does not contain one of the configured values, authentication will be rejected, even if the user has successfully authenticated with the IdP.

Leaving this optional attribute blank will result in default behavior: any successfully authenticated SAML response will result in a user being granted a session within Tableau Server.

## Tableau Server on Linux Administrator Guide

This value is only evaluated for server-wide SAML. If site-SAML is configured, the `AuthNContextClassRef` attribute will be ignored.

To set this value with TSM web interface, see [Configure Server-Wide SAML](#).

To set this value with tsm configuration set, use the key, `wgserver.saml.authcontexts`, to set a comma-separated list of values.

To set this value with a JSON configuration file, see [samlSettings Entity](#).

### Using SAML SSO with Tableau client applications

Tableau Server users with SAML credentials can sign in to the server from Tableau Desktop or the Tableau Mobile app. For full compatibility, we recommend that the Tableau client application version matches that of the server. To connect using site-specific SAML, users must run version 10.0 or later of the Tableau client application.

Connecting to Tableau Server from Tableau Desktop or Tableau Mobile uses a service provider (SP) initiated connection.

## Redirecting authenticated users back to Tableau clients

When a user signs in to Tableau Server, Tableau Server sends a SAML request (`AuthnRequest`) to the IdP, which includes the Tableau application's **RelayState** value. If the user has signed in to Tableau Server from a Tableau client such as Tableau Desktop or Tableau Mobile, it's important that the RelayState value is returned within the IdP's SAML response back to Tableau.

When the RelayState value is not returned properly in this scenario, the user is taken to their Tableau Server home page in the web browser, rather than being redirected back to the application they signed in from.

Work with your Identity Provider and internal IT team to confirm that this value will be included as part of the IdP's SAML response, and then preserved by any network appliance (such as a proxy or load balancer) that resides between your IdP and Tableau Server.

## XML data requirements

As part of SAML configuration, you exchange XML metadata between Tableau Server and the IdP. This XML metadata is used to verify a user's authentication information when the user initiates the Tableau Server sign-in process.

Tableau Server and the IdP each generates its own metadata. Each set of metadata must contain the information described in the following list. If either set is missing information, errors can occur when you configure SAML or when users try to sign in.

- **HTTP POST and HTTP REDIRECT:** Tableau Server supports HTTP POST and HTTP REDIRECT requests for SAML communications. In the SAML metadata XML document that is exported by the IdP, the `Binding` attribute can be set to HTTP-POST or HTTP-REDIRECT.
- When the `Binding` attribute set to HTTP-POST, the SAML metadata that Tableau Server and the IdP each export must contain the following elements.
  - The element that specifies the URL that the IdP redirects to after successful authentication. This is required in the Service Provider metadata, not the Identity Provider metadata.

```
<md:AssertionConsumerService Bind-
ing="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Loca-
tion="https://<tableau-server>/wg/saml/SSO/index.html
index="0" isDefault="true"/>
```

For Site SAML, the `Location` endpoint is `/samlser-  
vice/public/sp/metadata?alias=<site alias>`.

- The logout endpoint element appears in Tableau Server metadata and specifies the URL that the IdP will use for Tableau Server's logout endpoint. If this element is not in the IdP metadata, Tableau Server cannot negotiate a logout endpoint with the IdP and the SAML Logout feature will not be available within Tableau

### Server:

```
<md:SingleLogoutService Bind-  
ing="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Loca-  
tion="https://SERVER-NAME:9031/idp/slo"
```

- Verify that the metadata XML from the IdP includes a **SingleSignOnService** element, in which the binding is set to HTTP-POST, as in the following example:

```
<md:SingleSignOnService Bind-  
ing="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Loca-  
tion="https://SERVER-NAME:9031/idp/SSO.saml2"/>
```

- This element should appear in IdP metadata and specifies the URL that Tableau Server will use for the IdP's logout endpoint.

```
<md:SingleLogoutService Bind-  
ing="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Loca-  
tion="https://SERVER-NAME:9031/idp/slo"/>
```

- **Attribute named *username*:** You must configure the IdP to return an assertion that includes the `username` attribute in the `saml:AttributeStatement` element. The assertion's attribute type must be `xs:string` (it should *not* be typed as `xs:any`).

The following example shows what this might look like.

```
<saml:Assertion assertion-element-attributes>  
  <saml:Issuer>issuer-information</saml:Issuer>  
  <Signature xmlns="http://www.w3.org/2000/09/xmldsig#">  
    ...  
  </Signature>  
  <saml:Subject>  
    ...
```

```

</saml:Subject>
<saml:Conditions condition-attributes >
  ...
</saml:Conditions>
<saml:AuthnStatement authn-statement-attributes >
  ...
</saml:AuthnStatement>

<saml:AttributeStatement>
  <saml:Attribute Name="username" NameFormat-
t="urn:oasis:names:tc:SAML:2.0:attrname-format:basic">
    <saml:AttributeValue xmlns:x-
s="http://www.w3.org/2001/XMLSchema" xmlns:x-
si="http://www.w3.org/2001/XMLSchema-instance"
xsi:type="xs:string">
      user-name
    </saml:AttributeValue>
  </saml:Attribute>
</saml:AttributeStatement>
</saml:Assertion>

```

By default, Tableau Server will read the `username` attribute in the `AuthNResponse` returned from the Idp. However, some IdPs may return a different attribute that is intended to identify the user.

To change the SAML attribute that passes the `username` value, run the following TSM command:

```
tsm authentication saml map-assertions --user-name <USER-NAME>.
```

See `tsm authentication`.

- **Dynamic group membership using SAML assertions:**

Beginning in Tableau Server 2024.2, if SAML (or site SAML) is configured and the capability's setting enabled (server-wide or site-level), you can dynamically control group membership through custom claims included in the SAML XML response sent by the identity provider (IdP).

When configured, during user authentication, the IdP sends the SAML assertion that contains two custom group membership claims: `group` (`https://tableau.com/groups`) and group names (for example, "Group1" and "Group2") to assert the user into. Tableau validates the assertion and then enables access to the groups and the content whose permissions are dependent on those groups.

For more information, see [Dynamic group membership using assertions](#).

### Example SAML XML response

```
<saml2p:Response
  xmlns:saml2p="urn:oasis:names:tc:SAML:2.0:protocol"
  . . . . .
  . . . . .
  <saml2:Assertion
    . . . . .
    . . . . .
    xmlns:saml2="urn:oasis:names:tc:SAML:2.0:assertion"
    <saml2:AttributeStatement
      xmlns:saml2="urn:oasis:names:tc:SAML:2.0:assertion">
        <saml2:Attribute
          Name="https://tableau.com/groups"
          NameFormat="urn:oasis:names:tc:SAML:2.0:attrname-format:unspecified">

```

## Configure Server-Wide SAML

Configure server-wide SAML when you want all single sign-on (SSO) users on Tableau Server to authenticate through a single SAML identity provider (IdP), or as the first step to configuring site-specific SAML in a multi-site environment.

If you have configured server-wide SAML and are ready to configure a site, see [Configure Site-Specific SAML](#).

The SAML configuration steps we provide make the following assumptions:

- You are familiar with the options for configuring SAML authentication on Tableau Server, as described in the [SAML](#) topic.
- You have verified that your environment meets the [SAML Requirements](#), and obtained the SAML certificate files described in those requirements.

### Before you begin

As part of your disaster recovery plan, we recommend keeping a backup of certificate and IdP files in a safe location off of the Tableau Server. The SAML asset files that you upload to Tableau Server will be stored and distributed to other nodes by the Client File Service. However, these files are not stored in a recoverable format. See [Tableau Server Client File Service](#).

**Note:** If you use the same certificate files for SSL, you could alternatively use the existing certificate location for configuring SAML, and add the IdP metadata file to that directory

when you download it later in this procedure. For more information, see Using SSL certificate and key files for SAML in the SAML requirements.

If you are running Tableau Server in a cluster, then the SAML certificates, keys, and metadata file will be automatically distributed across the nodes when you enable SAML.

Use the TSM web interface

This procedure requires that you upload the SAML certificates to TSM so that they are properly stored and distributed in the server configuration. The SAML files must be available to the browser on the local computer where you are running the TSM web interface in this procedure.

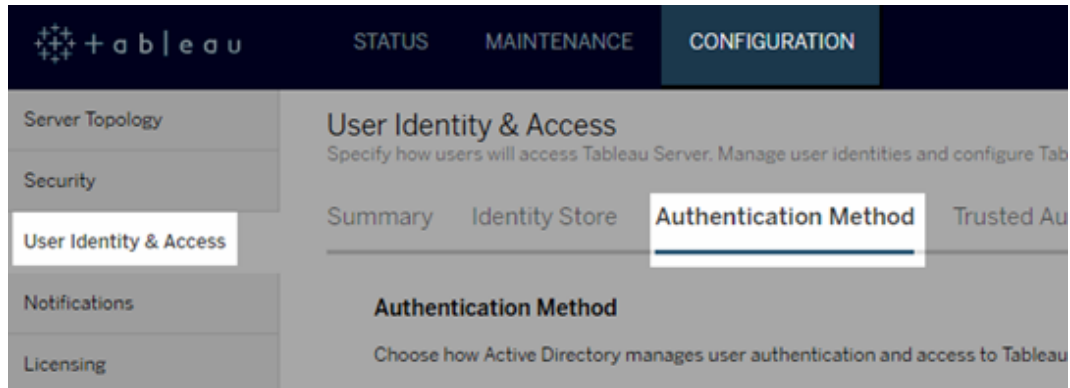

If you have gathered and saved the SAML files to the Tableau Server as recommended in the previous section, then run the TSM web interface from the Tableau Server computer where you copied the files.

If you are running the TSM web interface from a different computer, then you will need to copy all SAML files locally before proceeding. As you follow the procedure below, browse to the files on the local computer to upload them to TSM.

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see Sign in to Tableau Services Manager Web UI.

2. On the **Configuration** tab, select **User Identity & Access**, and then select the **Authentication Method** tab.

3. For **Authentication Method**, select **SAML**.
4. In the SAML section that appears, complete Step 1 in the GUI, entering the following settings (do not yet select the check box to enable SAML for the server):

- **Tableau Server return URL**—The URL that Tableau Server users will access, such as `https://tableau-server`.

Using `https://localhost` or a URL with a trailing slash (for example, `http://tableau_server/`) is not supported.

- **SAML entity ID**—The entity ID uniquely identifies your Tableau Server installation to the IdP.

You can enter your Tableau Server URL again here. If you plan to enable site-specific SAML later, this URL also serves as the base for each site's unique ID.

- **SAML certificate and key files**— Click **Select File** to upload each of these files.

If you are using a PKCS#8 passphrase-protected key file, you must enter the passphrase with TSM CLI:

```
tsm configuration set -k wgserver.saml.key.passphrase -v
<passphrase>
```

After you provide the information required in Step 1 in the GUI, the **Download XML Metadata File** button in Step 2 in the GUI becomes available.

5. Now select the **Enable SAML authentication for the server** check box above Step 1 in the GUI.
6. Complete the remaining SAML settings.
  - a. For Steps 2 and 3 in the GUI, exchange metadata between Tableau Server and the IdP. (Here's where you might need to check in with the IdP's documentation.)

Select **Download XML Metadata File**, and specify the file location.

For other IdPs, go to your IdP account to add Tableau Server to its applications (as a service provider), providing the Tableau metadata as appropriate.

Follow the instructions in the IdP's website or documentation to download the IdP's metadata. Save the .xml file to the same location that holds your SAML certificate and key files. For example:

```
/var/opt/tableau/tableau_server/data/saml/idp-metadata.xml
```

- b. Return to the TSM web UI. For Step 4 in the GUI, enter the path to the IdP metadata file, and then click **Select File**.

- c. For Step 5 in the GUI: In some cases, you may need to change the assertion values in the Tableau Server configuration to match the assertion names that are passed by your IdP.

You can find assertion names in the IdP's SAML configuration. If different assertion names are passed from your IdP, then you must update Tableau Server to use the same assertion value.

**Tip:** “Assertions” are a key SAML component, and the concept of mapping assertions can be tricky at first. It might help to put this in a tabular-data context, in which the assertion (attribute) name is equivalent to a column heading in the table. You enter that “heading” name, rather than an example of a value that might appear in that column.

- d. For Step 6 in the GUI, select the Tableau applications in which you want to give users a single sign-on experience.

**Note:** The option to disable mobile access is ignored by devices running Tableau Mobile app version 19.225.1731 and higher. To disable SAML for devices running these versions you must disable SAML as a client login option on Tableau Server.

- e. For the SAML sign-out redirect, if your IdP supports single logout (SLO), enter the page you want to redirect users to after they sign out, relative to the path you entered for the Tableau Server return URL.
- f. (Optional) For Step 7 in the GUI, do the following:
  - Add a comma-separated value for the `AuthNContextClassRef` attribute. For more information about how this attribute is used, see SAML compatibility notes and requirements.
  - Specify a domain attribute if not sending the domain as part of the username (i.e., `domain\username`). For more information, see When running multiple domains.

7. Click **Save Pending Changes** after you've entered your configuration information.

8. Click **Pending Changes** at the top of the page:

9. Click **Apply Changes and Restart**.

Use the TSM CLI

## Before you begin

Before you begin, do the following:

- Go to your IdP's website or application, and export the IdP's metadata XML file.

Confirm that the metadata XML from the IdP includes a **SingleSignOnService** element, in which the binding is set to `HTTP-POST`, as in the following example:

```
<md:SingleSignOnService Bind-  
ing="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Loca-  
tion="https://SERVER-NAME:9031/idp/SSO.saml2"/>
```

- Gather the certificate files and place them on Tableau Server.

In the Tableau Server folder, create a new folder named `SAML`, and place copies of the SAML certificate files in that folder. For example:

```
/var/opt/tableau/tableau_server/data/saml
```

## Step 1: Configure return URL, SAML entity ID, and specify certificate and key files

1. Open the command prompt shell and configure the SAML settings for the server (replacing placeholder values with your environment path and file names).

```
tsm authentication saml configure --idp-entity-id https://t-
ableau-server --idp-metadata /var/opt/tableau/tableau_server-
/data/saml/<metadata-file.xml> --idp-return-url
https://tableau-server --cert-file /var/opt/tableau/tableau_
server/data/saml/<file.crt> --key-file /var/-
opt/tableau/tableau_server/data/saml/<file.key>
```

For more information, see `tsm authentication saml configure`.

2. If you are using a PKCS#8 key that is protected with a passphrase, enter the passphrase as follows:

```
tsm configuration set -k wgserver.saml.key.passphrase -v <pass-
phrase>
```

3. If SAML is not already enabled on Tableau Server; for example, you're configuring it for the first time, or you have disabled it, enable it now:

```
tsm authentication saml enable
```

4. Apply the changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt.

For more information, see `tsm pending-changes apply`.

## Step 2: Generate Tableau Server metadata and configure the IdP

1. Run the following command to generate the required XML metadata file for Tableau server.

```
tsm authentication saml export-metadata -f <file-name.xml>
```

You can specify a file name, or omit the `-f` parameter to create a default file named `samlmetadata.xml`.

2. On your IdP's website or in its application:

- Add Tableau Server as a Service Provider.

Refer to your IdP's documentation for information about how to do this. As part of the process of configuring Tableau Server as a Service Provider, you will import the Tableau Server metadata file you generated from the `export-metadata` command.

- Confirm that your IdP uses **username** as the attribute to verify users.

## Step 3: Match assertions

In some cases, you may need to change the assertion values in the Tableau Server configuration to match the assertion names that are passed by your IdP.

You can find assertion names in the IdP's SAML configuration. If different assertion names are passed from your IdP, then you must update Tableau Server to use the same assertion value.

**Tip:** "Assertions" are a key SAML component, and the concept of mapping assertions can be tricky at first. It might help to put this in a tabular-data context, in which the assertion (attribute) name is equivalent to a column heading in the table. You enter that "heading" name, rather than an example of a value that might appear in that column.

The following table shows the default assertion values and the configuration key that stores the value.

| Assertion    | Default value           | Key   |
|--------------|-------------------------|---|
| Username     | username                | wgserver.saml.idpattribute.username           |
| Display name | displayName             | Tableau does not support this attribute type. |
| Email        | email                   | Tableau does not support this attribute type. |
| Domain       | (not mapped by default) | wgserver.saml.idpattribute.domain             |

To change a given value, run the `tsm configuration set` command with the appropriate key:value pair.

For example, to change the `username` assertion to the value, `name`, run the following commands:

```
tsm configuration set -k wgserver.saml.idpattribute.username -v
name
```

```
tsm pending-changes apply
```

Alternatively, you can use the `tsm authentication saml map-assertions` command to change a given value.

For example, to set the domain assertion to a value called `domain` and specify its value as "example.myco.com," run the following commands:

```
tsm authentication saml map-assertions --domain example.myco.com
```

```
tsm pending-changes apply
```

## Optional: Disable client types from using SAML

By default, both Tableau Desktop and the Tableau Mobile app allow SAML authentication.

## Tableau Server on Linux Administrator Guide

If your IdP does not support this functionality, you can disable SAML sign-in for Tableau clients using the following commands:

```
tsm authentication saml configure --desktop-access disable
```

```
tsm authentication saml configure --mobile-access disable
```

**Note:** The `--mobile-access disable` option is ignored by devices running Tableau Mobile app version 19.225.1731 and higher. To disable SAML for devices running these versions you must disable SAML as a client login option on Tableau Server.

```
tsm pending-changes apply
```

### Optional: Add AuthNContextClassRef value

Add a comma-separated value for the `AuthNContextClassRef` attribute. For more information about how this attribute is used, see SAML compatibility notes and requirements.

To set this attribute run the following commands:

```
tsm configuration set -k wgserver.saml.authcontexts -v <value>
```

```
tsm pending-changes apply
```

Test the configuration

1. In your web browser, open a new page or tab, and enter the Tableau Server URL.

The browser redirects you to the IdP's sign-in form.

2. Enter your single sign-on user name and password.

A screenshot of a web-based sign-in form. At the top, there is a green checkmark icon followed by the text "Please sign on first and we'll send you right along." Below this, there are two input fields: "Username" with the text "jsmith" and "Password" with ten black dots. At the bottom, there are two buttons: a teal "Sign On" button and a dark teal "Cancel" button.

The IdP verifies your credentials and redirects you back to your Tableau Server start page.

### Configure SAML with Salesforce IdP on Tableau Server

This topic provides road-map steps that describe how to configure SAML on Tableau Server with the Salesforce IdP.

This topic also explains how to enable Lightning Web Component (LWC). The LWC allows Salesforce administrators to embed a Tableau visualization within a Lightning page. When SSO is configured for Tableau Viz LWC on Tableau Server, the user experience is seamless: after the user signs into Salesforce, embedded Tableau views will work without further authentication to Tableau Server.

### Enable Salesforce as a SAML Identity Provider

If you have not yet configured Salesforce as an IdP, then follow the procedure, [Enable Salesforce as a SAML Identity Provider](#), on the Salesforce Help site.

During the process to enable Salesforce as a SAML IdP, you will either specify a certificate or Salesforce will generate a self-signed certificate for use with SAML. Download this certificate

## Tableau Server on Linux Administrator Guide

(.crt file) and the associated provider metadata file (.xml). You will need these assets in the next step.

### Configure SAML on Tableau Server

Using the certificate and metadata files that you downloaded in the previous step, follow the procedure in [Configure Server-Wide SAML](#).

As part of the configuration process, you will generate a SAML Entity ID and a login URL for Tableau Server. You will need these assets for the next step.

(Optional) After you have configured server-wide SAML, you can configure site-specific SAML on Tableau Server. See [Configure Site-Specific SAML](#).

### Add Tableau Server as a Connected App in Salesforce

Follow the procedure, [Integrate Service Providers as Connected Apps with SAML 2.0](#), on the Salesforce Help site.

In this process, you will create a new connected app (Tableau Server). Some important details follow:

- Select "Enable SAML"
- Enter the Entity ID and the login URL that you generated when configuring Tableau in the previous section. By default, login URL is `https://<tableauserver>/wg/saml/SSO/index.html`.
- For the IdP certificate, be sure to select the same certificate that you specified or generated when you enabled Salesforce as a SAML provider.
- To allow users to sign in to Tableau Server from your org, manage access to your connected app by assigning the appropriate profiles or permission sets.

### Enable Lightning Web Component

To enable LWC for SAML SSO on Tableau Server, you must enable in-frame authentication. Before you enable LWC, upgrade to the latest maintenance release of Tableau Server. Two additional version details are important:

- If you are not running the latest maintenance release, and your users are running Chrome browsers to access Salesforce Lightning, then review the Tableau KB article,

### Embedded Views Fail to Load After Updating to Chrome 80.

- If you are using LWC with site-specific SAML on Tableau Server, then you must be running the Tableau Server 2020.4 or later.

After you have configured SAML on Tableau Server, run the following TSM commands to enable in-frame authentication:

```
tsm configuration set -k wgserver.saml.iframe_idp.enabled -v true  
  
tsm pending-changes apply
```

### Embed Tableau Views into Salesforce

After you have configured Tableau Server for SSO, you can then install the LWC in your Salesforce org and embed Tableau views. See [Embed Tableau Views into Salesforce](#).

### Configure SAML for Tableau Viz Lightning Web Component

Tableau provides a Lightning Web Component (LWC) for embedding a Tableau visualization within a Salesforce Lightning page.

This topic describes how to enable a SSO experience for embedded Tableau visualizations in a Salesforce Lightning page. SSO for the Tableau Viz LWC scenario requires SAML configuration. The SAML IdP used for Tableau authentication must be either the Salesforce IdP or same IdP that is used for your Salesforce instance.

In this scenario, Salesforce administrators can drag-and-drop Tableau Viz LWC into the Lightning page to embed a visualization. Any view that is available to them on Tableau Server can be displayed in the dashboard by entering the embedded URL to the view.

When single sign-on (SSO) is configured for Tableau Viz LWC on Tableau Server, the user experience is seamless: after the user signs into Salesforce, embedded Tableau views will work without further authentication to Tableau Server.

When SSO is not configured, then users will need to reauthenticate with Tableau Server to view embedded visualizations from Tableau Server.

### Requirements

- The SAML IdP used for Tableau authentication must be either the Salesforce IdP or same IdP that is used for your Salesforce instance. See [Configure SAML with Salesforce IdP on Tableau Server](#).
- SAML must be configured on Tableau Server. See [Configure Server-Wide SAML](#), or [Configure Site-Specific SAML](#).
- SAML must be configured for Salesforce.
- Install the Tableau Viz Lightning Web Component. See [Embed Tableau Views into Salesforce](#).

### Configuring the authentication workflow

You may need to make additional configurations to optimize the sign-in experience for users who access Lightning with embedded Tableau views.

If a seamless authentication user experience is important, then you will need to make some additional configurations. In this context, “seamless” means that users who access the Salesforce Lightning page where Tableau Viz LWC SSO has been enabled, will not be required to perform any action to view the embedded Tableau view. In the seamless scenario, if the user is logged into Salesforce, then embedded Tableau views will be displayed with no additional user action. This scenario is enabled by *in-frame authentication*.

For a seamless user experience you will need to enable in-frame authentication on Tableau Server and at your IdP. The sections below describe how to configure in-frame authentication.

On the other hand, there are scenarios where users are interacting with the Lightning page that will require them to click a “Sign in” button to view the embedded Tableau view. This scenario, where a user must take another action to view the embedded Tableau view, is called pop-up authentication.

Pop-up authentication is the default user experience if you do not enable in-frame authentication.

## Enable in-frame authentication on Tableau Server

Before you enable in-frame authentication on Tableau Server, you must have already configured and enabled SAML on Tableau Server.

Run the following TSM commands to enable in-frame authentication:

```
tsm configuration set -k wgserver.saml.iframe_idp.enabled -v true  
  
tsm pending-changes apply
```

**Note:** Clickjack protection is enabled by default on Tableau Server. When you enable in-frame authentication, clickjack protection is temporarily disabled for the in-frame authentication session. You should evaluate the risk of disabling clickjack protection. See [Clickjack Protection](#).

## Tableau Server Versioning

For the best user experience, run the latest maintenance release of Tableau Server.

If you are not running the latest maintenance release, and your users are running Chrome browsers to access Salesforce Lightning, then review the Tableau KB article, [Embedded Views Fail to Load After Updating to Chrome 80](#).

### Enable in-frame authentication with your SAML IdP

As described above, a seamless authentication user experience with Salesforce Mobile requires IdP support for in-frame authentication. This functionality may also be referred to as “iframe embedding” or “framing protection” at IdPs.

## Salesforce safelist domains

In some cases, IdPs only allow enabling in-frame authentication by domain. In those cases, set the following Salesforce wildcard domains when you enable in-frame authentication:

```
*.force
```

```
*.visualforce
```

## Salesforce IdP

Salesforce IdP supports in-frame authentication by default. You do not need to enable or configure in-frame authentication in the Salesforce configuration. However, you must run the TSM command on Tableau Server as described above.

## Okta IdP

See *Embed Okta in an iframe*, in the Okta Help Center topic, [General customization options](#).

## Ping IdP

See the Ping support topic, [How to Disable the "X-Frame-Options=SAMEORIGIN" Header in PingFederate](#).

## OneLogin IdP

See *Framing protection*, in the OneLogin Knowledge Base article, [Account Settings for Account Owners](#).

## ADFS and EntraID IdP

Microsoft has blocked all in-frame authentication and it cannot be enabled. Instead, Microsoft only supports pop-up authentication in a second window. As a result, pop up behavior can be blocked by some browsers, which will require users to accept pop ups for the `force.com` and `visualforce.com` sites.

### Salesforce Mobile App

If your users primarily interact with Lightning on the Salesforce Mobile App, then you should be aware of the following scenarios:

- The Salesforce Mobile App requires that you configure SSO/SAML to view embedded Tableau.

- The Salesforce Mobile App requires in-frame authentication. Pop-up authentication does not work. Instead, users on the Salesforce Mobile App will see the Tableau sign-in button but will not be able to sign to Tableau.
- Mobile App will not work on ADFS and Azure AD IdP.
- The Mobile App uses OAuth tokens to enable SSO. There are scenarios where the OAuth token refreshes and logs users out, requiring users to log back in. To learn more, see the Tableau KB article, [Tableau Viz Lightning Web Component On Salesforce Mobile App Prompts for Sign-in](#).
- The SSO behavior differs according to the version of Salesforce Mobile App (iOS vs Android) and the the IdP:

| IdP            | Mobile OS | SSO behavior   |
|----------------|-----------|--|
| Salesforce IdP | Android   | SSO works initially, but users will need to sign-in after some time.   |
|                | iOS       |  |
| External IdP   | Android   | SSO does not work. Users will need to manually sign-in. (SSO must still be configured to enable users access to embedded Tableau views). |
|                | iOS       | SSO works initially, but users will need to sign-in after some time.   |

### Configure SAML with Azure AD IdP on Tableau Server

You can configure Azure AD as a SAML identity provider (IdP), and add Tableau Server to your supported single sign-on (SSO) applications. When you integrate Azure AD with SAML and Tableau Server, your users can sign in to Tableau Server using their standard network credentials.

#### Before you begin: Prerequisites

Before you can configure Tableau Server and SAML with Azure AD, your environment must have the following:

## Tableau Server on Linux Administrator Guide

- SSL certificate encrypted using SHA-2 (256 or 512 bit) encryption, and that meets the additional requirements listed in the following sections:
  - SSL certificate requirements
  - SAML Certificate and identity provider (IdP) requirements
- If your users are signing in from a domain that's not the default domain, review SAML Requirements and User Management in Deployments with External Identity Stores to ensure the domain attribute value is set and defined to avoid any sign in issues later on.

### Step 1: Verify SSL connection to Azure AD

Azure AD requires an SSL connection. If you haven't done so yet, complete the steps in Configure SSL for External HTTP Traffic to and from Tableau Server, using a certificate that meets the requirements as specified above.

Alternatively, if Tableau Server is configured to work with a reverse proxy or load balancer where SSL is being terminated (commonly referred to as SSL off-loading), then you don't need to configure external SSL.

If your organization uses Azure AD App proxy, see the section below, [Azure AD App Proxy](#).

### Step 2: Configure SAML on Tableau Server

Complete the steps in Configure Server-Wide SAML through downloading the Tableau Server metadata to an XML file. At that point, return here and continue to the next section.

### Step 3: Configure Azure AD claim rules

The mapping is case sensitive and requires exact spelling, so double-check your entries. The table here shows common attributes and claim mappings. You should verify the attributes with your specific Azure AD configuration.

| LDAP Attribute          | Outgoing Claim Type |
|-------------------------|---------------------|
| onpremisesamaccountname | username            |

|             |  |
|-------------|--|
| Given-Name  | firstName<br><br><b>Note:</b> This is optional.  |
| Surname     | lastName<br><br><b>Note:</b> This is optional.   |
| netbiosname | domain<br><br><b>Note:</b> This is only required if you have users signing in from a domain that's not the default domain. |

In some organizations, Azure AD as a SAML IdP is used in with Active Directory as the identity store for Tableau Server. In this case, `username` is usually the `sAMAccountName` name. See Microsoft's documentation for identifying the `sAMAccountName` attribute within Azure AD to map to the `username` attribute.

#### Step 4: Provide Azure AD metadata to Tableau Server

1. Return to the TSM web UI, and navigate to **Configuration > User Identity & Access > Authentication Method** tab.
2. In Step 4 of the SAML configuration pane, enter the location of the XML file you exported from Azure AD, and select **Upload**.

3. Complete the remaining steps (matching assertions and specifying client type access) as specified in Configure Server-Wide SAML. Save and apply changes.
4. Perform the following steps if this isn't the first time configuring SAML:

## Tableau Server on Linux Administrator Guide

- a. Stop Tableau Server, open TSM CLI, and run the following commands.

```
tsm configuration set -k wgserver.saml.sha256 -v true  
  
tsm authentication saml configure -a -1
```

- b. Apply the changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### Azure AD App Proxy

If you're running Azure AD App Proxy in front of Tableau Server and SAML is enabled, then you'll need to make an additional configuration to Azure AD App Proxy.

Tableau Server can only accept traffic from one URL when SAML is enabled. However, by default, Azure AD App Proxy sets an external URL and an internal URL.

You must set both of these values to the same URL in your custom domain. For more information, see the Microsoft documentation, [Configure custom domains with Azure AD Application Proxy](#).

### Troubleshooting

#### Azure AD App Proxy

In some cases, links to views render internally but fail externally when traffic is crossing an Azure AD App Proxy. The issue arises when there's a pound sign (#) in the URL and users are

accessing the link with a browser. The Tableau Mobile app is able to access URLs with a pound sign.

### User session timeouts appear to be ignored

When Tableau Server is configured for SAML, users might experience sign in errors because the IdP maximum authentication age setting is set to a value greater than Tableau's maximum authentication age setting. To resolve this issue, you can use the tsm configuration set option `wgserver.saml.forceauthn` to require the IdP to reauthenticate the user each time Tableau redirects the authentication request, even if the IdP session for the user is still active.

For example, when the Azure AD setting `maxInactiveTime` is greater than Tableau Server's setting `maxAuthenticationAge`, Tableau redirects the authentication request to the IdP who subsequently sends Tableau an assertion that the user is already authenticated. However, because the user was authenticated outside of Tableau Server's `maxAuthenticationAge`, Tableau rejects the user authentication. In cases like this, you can do one or both of the following:

- Enable the `wgserver.saml.forceauthn` option to require the IdP to reauthenticate the user every time Tableau redirects the authentication request. For more information, see `wgserver.saml.forceauthn`.
- Increase Tableau Server's `maxAuthenticationAge` setting. For more information, see "a, --max-auth-age <max-auth-age>" in the tsm authentication topic.

### AppID mismatch

When reviewing the `vizportal.log` file, you might see "*The intended audience doesn't match the recipient*" error.

To resolve this issue, ensure the appID matches what is sent. Azure will automatically append "SPN" to the appID when using the application ID with the app that is being used. You can change the value in the Tableau SAML settings by adding "SPN:" prefix to the application ID.

For example: SPN:myazureappid1234

## Tableau Server on Linux Administrator Guide

### Configure SAML with AD FS on Tableau Server

You can configure Active Directory Federation Services (AD FS) as a SAML identity provider, and add Tableau Server to your supported single sign-on applications. When you integrate AD FS with SAML and Tableau Server, your users can sign in to Tableau Server using their standard network credentials.

#### Prerequisites

Before you can configure Tableau Server and SAML with AD FS, your environment must have the following:

- A server running Microsoft Windows Server 2008 R2 (or later) with AD FS 2.0 (or later) and IIS installed.
- We recommend that you secure your AD FS server (for example, using a reverse proxy). When your AD FS server is accessible from outside your firewall, Tableau Server can redirect users to the sign in page hosted by AD FS.
- SSL certificate encrypted using SHA-2 (256 or 512 bit) encryption, and that meets the additional requirements listed in the following sections:
  - SSL certificate requirements
  - SAML Certificate and identity provider (IdP) requirements

#### Step 1: Verify SSL connection to AD FS

AD FS requires an SSL connection. If you haven't done so yet, complete the steps in [Configure SSL for External HTTP Traffic to and from Tableau Server](#), using a certificate that meets the requirements as specified above.

Alternatively, if Tableau Server is configured to work with a reverse proxy or load balancer where SSL is being terminated (commonly referred to as SSL off-loading), then you do not need to configure external SSL.

## Step 2: Configure SAML on Tableau Server

Complete the steps in **Configure Server-Wide SAML** through downloading the Tableau Server metadata to an XML file. At that point, return here and continue to the next section.

## Step 3: Configure AD FS to accept sign-in requests from Tableau Server

**Note:** These steps reflect a third-party application and are subject to change without our knowledge.

Configuring AD FS to accept Tableau Server sign-in requests is a multi-step process, starting with importing the Tableau Server XML metadata file to AD FS.

1. Do one of the following to open the **Add Relying Party Trust Wizard**:

### Windows Server 2008 R2:

- a. Select **Start menu > Administrative Tools > AD FS 2.0**.
- b. In **AD FS 2.0**, under **Trust Relationships**, right-click the **Relying Party Trusts** folder, and then click **Add Relying Party Trust**.

### Windows Server 2012 R2:

- a. Open **Server Manager**, and then on the **Tools** menu, click **AD FS Management**.
- b. In **AD FS Management**, on the **Action** menu, click **Add Relying Party Trust**.

2. In the **Add Relying Party Trust Wizard**, click **Start**.
3. On the **Select Data Source** page, select **Import data about the relying party from a file**, and then click **Browse** to locate your Tableau Server XML metadata file. By default, this file is named **samlspmetadata.xml**.

4. Click **Next**, and on the **Specify Display Name** page, type a name and description for the relying party trust in the **Display name** and **Notes** boxes.
5. Click **Next** to skip the **Configure Multi-factor Authentication Now** page.
6. Click **Next** to skip the **Choose Issuance Authorization Rules** page.
7. Click **Next** to skip the **Ready to Add Trust** page.
8. On the **Finish** page, select the **Open the Edit Claim Rules dialog for this relying party trust when the wizard closes** check box, and then click **Close**.

Next, you'll work in the **Edit Claim Rules** dialog, to add a rule that makes sure the assertions sent by AD FS match the assertions Tableau Server expects. At a minimum, Tableau Server needs an email address. However, including first and last names in addition to email will ensure the user names displayed in Tableau Server are the same as those in your AD account.

1. In the **Edit Claim Rules** dialog box, click **Add Rule**.
2. On the **Choose Rule Type** page, for **Claim rule template**, select **Send LDAP Attributes as Claims**, and then click **Next**.
3. On the **Configure Claim Rule** page, for **Claim rule name**, enter a name for the rule that makes sense to you.
4. For **Attribute store**, select **Active Directory**, complete the mapping as shown below, and then click **Finish**.

The mapping is case sensitive and requires exact spelling, so double-check your entries. The table here shows common attributes and claim mappings. Verify attributes with your specific Active Directory configuration.

| LDAP Attribute   | Outgoing Claim Type |
|------------------|---------------------|
| SAM-Account-Name | Name ID             |

|                  |           |
|------------------|-----------|
| SAM-Account-Name | username  |
| Given-Name       | firstName |
| Surname          | lastName  |

If you are running AD FS 2016 or later, then you must add a rule to pass through all claim values. If you are running an older version of AD FS, skip to the next procedure to export AD FS metadata.

1. Click **Add Rule**.
2. Under **Claim rule template**, choose **Pass Through or Filter an Incoming Claim**.
3. Under **Claim rule name**, enter Windows.
4. On the **Edit Rule - Windows** pop-up:
  - Under **Incoming claim type**, select **Windows account name**.
  - Select **Pass through all claim values**.
  - Click **OK**.

Now you will export AD FS metadata that you'll import to Tableau Server later. You will also make sure the metadata is configured and encoded properly for Tableau Server, and verify other AD FS requirements for your SAML configuration.

1. Export AD FS Federation metadata to an XML file, and then download the file from **`https://<adfs server name>/federationmetadata/2007-06/FederationMetadata.xml`**.
2. Open the metadata file in a text editor like Sublime Text or Notepad++, and verify that it is correctly encoded as UTF-8 without BOM.

If the file shows some other encoding type, save it from the text editor with the correct encoding.

3. Verify that AD FS uses forms-based authentication. Sign-ins are performed in a browser window, so you need AD FS to default to this type of authentication.

Edit `c:\inetpub\adfs\ls\web.config`, search for the tag , and move the line so it appears first in the list. Save the file so that IIS can automatically reload it.

**Note:** If you don't see the `c:\inetpub\adfs\ls\web.config` file, IIS is not installed and configured on your AD FS server.

4. (Optional) This step is required only if AD FS is configured as an IDP for site-specific SAML. This step is not required if AD FS is configured as the IDP for server-wide SAML.

Configure an additional AD FS relying party identifier. This allows your system to work around any AD FS issues with SAML logout.

Do one of the following:

**Windows Server 2008 R2:**

- a. In **AD FS 2.0**, right-click on the relying party you created for Tableau Server earlier, and click **Properties**.
- b. On the **Identifiers** tab, in the **Relying party identifier** box, enter `https://<tableauservername>/public/sp/metadata` and then click **Add**.

**Windows Server 2012 R2:**

- a. In **AD FS Management**, in the **Relying Party Trusts** list, right-click on the relying party you created for Tableau Server earlier, and click **Properties**.
- b. On the **Identifiers** tab, in the **Relying party identifier** box, enter `https://<tableauservername>/public/sp/metadata` and then click **Add**.

**Note:** AD FS can be used with Tableau Server for a single relying party to the same instance. AD FS cannot be used for multiple relying parties to the same instance,

for example, multiple site-SAML sites or server-wide and site SAML configurations.

#### Step 4: Provide AD FS metadata to Tableau Server

1. Return to the TSM web UI, and navigate to **Configuration > User Identity & Access > Authentication Method** tab.
2. In Step 4 of the SAML configuration window, enter the location of the XML file you exported from AD FS, and select **Upload**.

3. Complete the remaining steps (matching assertions and specifying client type access) as specified in Configure Server-Wide SAML.
4. Save and apply changes.
5. Perform the following steps if this is not the first time configuring SAML:
  - a. Stop Tableau Server, open TSM CLI, and run the following commands:
 

```
tsm configuration set -k wgserver.saml.sha256 -v true
```

```
tsm authentication saml configure -a -1
```
  - b. Apply the changes:
 

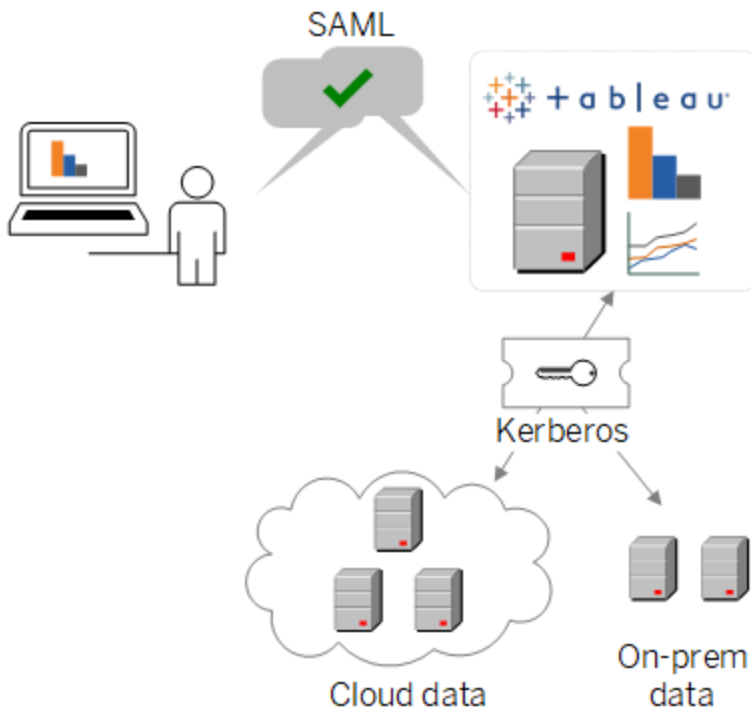

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### Use SAML SSO with Kerberos Database Delegation

In a Windows Active Directory (AD) environment, you can enable SAML single sign-on (SSO) to Tableau Server, along with Kerberos database delegation. This provides authorized users direct access to Tableau Server, as well as to the underlying data defined in their published workbooks and data sources.

#### Overview of the process

In a typical scenario:

1. One of your Tableau analysts publishes a dashboard to Tableau Server. That dashboard contains a connection to a Hadoop cluster, for example, that is configured to accept Kerberos credentials.

Then the workbook publisher sends a link to colleagues for review.

2. When a colleague clicks the link, Tableau Server authenticates the user through the SAML SSO process. Then it looks at the user's authorization scheme, and if allowed, uses the Tableau Server keytab to access the underlying database on behalf of the user. This populates the dashboard with the Hadoop data that the user is authorized to see.

### Configure Tableau Server for SAML with Kerberos

Using SAML with Kerberos works inherently when you complete the processes to enable each separately:

1. Configure Tableau Server for SAML, as described in [Configure Server-Wide SAML](#).
2. Configure Tableau Server and your underlying databases to accept Kerberos credentials, as described in [Enable Kerberos Delegation](#) and related articles.

### Configure Site-Specific SAML

Use site-specific SAML in a multi-site environment when you want to enable single sign-on, and you also use multiple SAML identity providers (IdPs) or IdP applications. When you enable site SAML, you can specify the IdP or IdP application for each site, or configure some sites to use SAML and the others to use the default server-wide authentication method.

If you want all server users to use SAML and sign in through the same IdP application, see [Configure Server-Wide SAML](#).

### Prerequisites for enabling site-specific SAML

Before you can enable SAML single sign-on at the site level, complete the following requirements:

- The Tableau Server identity store must be configured for local identity store.

You cannot configure site-specific SAML if Tableau Server is configured with an external identity store such as Active Directory or OpenLDAP.

- Make sure your environment and your IdP meet the general SAML Requirements.

Some features are supported only in server-wide SAML deployments, including but not limited to:

- Password-protected key files, which are not supported in site-specific SAML deployments.
- You must configure server-wide SAML before you configure site-specific SAML. You do not need to enable server-wide SAML, but site-specific SAML requires the server-wide configuration. See [Configure Server-Wide SAML](#).
- Note the location of the SAML certificate files. You will provide this when you Configure the server to support site-specific SAML.

For more information, see [Put metadata and certificate files in place](#) in the topic on configuring server-wide SAML.

- Add Tableau Server as a service provider to your IdP. You can find this information in the documentation the IdP provides.
- Confirm that the system clocks of the computer hosting the site-SAML IdP and the computer hosting Tableau Server are within 59 seconds of each other. Tableau Server does not have a configuration option to adjust the response skew (time difference) between the Tableau Server computer and the IdP.

## Server-wide settings related to site-specific SAML

**Return URL and entity ID:** In the settings for configuring site-specific SAML, Tableau provides a site-specific return URL and entity ID based on these settings. The site-specific return URL and entity ID cannot be modified. These configurations are set by TSM as described in [Configure Server-Wide SAML](#).

**Authentication age and response skew:** Server-wide settings, maximum authentication age and response skew, do not apply to site-specific SAML. These configurations are hard-coded:

- The maximum authentication age refers to how long an authentication token from the IdP is valid after it is issued. The hard-coded maximum authentication age site-specific SAML is 24 days.
- The response skew is the maximum number of seconds difference between Tableau Server time and the time of the assertion creation (based on the IdP server time) that still allows the message to be processed. The hard-coded site-specific value for this is 59 seconds.

**Username:** Required. In addition to the server-wide SAML configuration attribute, the site-specific SAML configuration attribute must be set to "username."

**Note:** For site-specific SAML to operate successfully with a server-wide SAML default, the username attribute configured for server-wide SAML with the `wgserver.saml.idpattribute.username` configuration key must be "username". The IdP used for server-wide SAML must deliver the username in an attribute named "username."

5 Match attributes

Match the attribute names (assertions) in the IdP's SAML configuration to the corresponding attribute names on Tableau Server. Click Test Connection to fetch available attributes.

| Tableau Server Attribute   | Identity Provider (IdP) Assertion Name   |
|--|--|
| Username or Email<br>Enter the username or email address attribute that the IdP sends during the authentication process. This must match the attribute name in Tableau   | <input type="text" value="username"/>  |
| Display Name<br>Enter an assertion name for either the first name and last name, or for the full name, depending on how the IdP stores this information. Tableau Server uses these attributes to set the display name. | <input type="radio"/> First name <input type="text" value="firstName"/><br><input checked="" type="radio"/> Last name <input type="text" value="lastName"/><br><input type="radio"/> Full name <input type="text" value="FullName"/> |

**HTTP POST and HTTP REDIRECT:** For site-specific SAML, Tableau Server supports HTTP-POST, HTTP-REDIRECT, and HTTP-POST-SimpleSign.

### Configure the server to support site-specific SAML

After you complete the prerequisites listed above, you can run the following commands to configure the server to support site-specific SAML.

1. **Configure Server-Wide SAML.** At a minimum, you must run the following TSM command (if you have already configured server-wide SAML, skip to Step 2):

```
tsm authentication saml configure --idp-entity-id <tableau-server-entity-id> --idp-return-url <tableau-server-return-url> --cert-file <path-to-saml-certificate.crt> --key-file <path-to-saml-keyfile.key>
```

2. **Enable site SAML.** Run the following commands:

```
tsm authentication sitesaml enable

tsm pending-changes apply
```

## About the commands

The `sitesaml enable` command exposes the **Authentication** tab on each site's **Settings** page in the Tableau Server web UI. After you configure the server to support site SAML, you can continue to Configure SAML for a site to work through the settings on the **Authentication** tab.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

If you want to review the commands and settings that will be carried out when you run `pending-changes apply`, you can run the following command first:

```
tsm pending-changes list --config-only
```

## Configure SAML for a site

This section takes you through the configuration steps that appear on the **Authentication** tab in the Tableau Server Settings page. In a self-hosted Tableau Server installation, this page appears only when support for site-specific SAML is enabled at the server level.

**Note:** To complete this process, you will also need the documentation your IdP provides. Look for topics that refer to configuring or defining a service provider for a SAML connection, or adding an application.

## Step 1: Export metadata from Tableau

To create the SAML connection between Tableau Server and your IdP, you need to exchange required metadata between the two services. To get metadata from Tableau Server, choose one of the following methods. See the IdP's SAML configuration documentation to confirm the correct option.

- Select **Export metadata** button to download an XML file that contains the Tableau Server SAML entity ID, Assertion Consumer Service (ACS) URL, and X.509 certificate.

The entity ID is site-specific, and based on the server-wide entity ID that you specified when you enabled site SAML on the server. For example, if you specified `https://tableau_server`, you might see the following entity ID for the site:

```
https://tableau_server-  
/samlservice/public/sp/metadata?alias=48957410-9396-430a-967c-  
75bdb6e002a0
```

You cannot modify the site-specific entity ID or ACS URL that Tableau generates.

- Select **Download certificate** if your IdP expects the required information in a different way. For example, if it wants you to enter the Tableau Server entity ID, ACS URL, and

X.509 certificate in separate locations.

The following image has been edited to show that these settings are the same in Tableau Cloud and Tableau Server.

1 Export metadata from Tableau Online | Server

Select an option for obtaining metadata required by the Identity Provider (IdP):

- Export an XML file that contains the metadata.

or

- Copy the Tableau Online entity ID and ACS URL individually, and download the X.509 certificate and save it as a CER file.

Tableau Online entity ID

Assertion Consumer Service URL (ACS)

## Step 2 and Step 3: External steps

For step 2, to import the metadata you exported in step 1, sign in to your IdP account, and use the instructions provided by the IdP's documentation to submit the Tableau Server metadata.

For step 3, the IdP's documentation will guide you also in how to provide metadata to a service provider. It will instruct you to download a metadata file, or it will display XML code. If it displays XML code, copy and paste the code into a new text file, and save the file with a .xml extension.

## Step 4: Import IdP metadata to the Tableau site

On the **Authentication** page in Tableau Server, import the metadata file that you downloaded from the IdP or configured manually from XML it provided.

**Note:** If editing the configuration, you will need to upload the metadata file so Tableau knows to use the correct IdP entity ID and SSO service URL.

## Step 5: Match attributes

Attributes contain authentication, authorization, and other information about a user. In the **Identity Provider (IdP) Assertion Name** column, provide the attributes that contain the information Tableau Server requires.

- **Username or Email:** (Required) Enter the name of the attribute that stores user names or email addresses.
- **Display name:** (Optional) Some IdPs use separate attributes for first and last names, and others store the full name in one attribute. If you're using SAML with local authentication, the display name attribute isn't synchronized with the SAML IdP.

Select the button that corresponds to the way your IdP stores the names. For example, if the IdP combines first and last name in one attribute, select **Display name**, and then enter the attribute name.

### 5 Match attributes

Match the attribute names (assertions) in the IdP's SAML configuration to the corresponding attribute names on Tableau Server. Click Test Connection to fetch available attributes.

| Tableau Server Attribute   | Identity Provider (IdP) Assertion Name                      |
|--|---|
| <p><b>Username or Email</b></p> <p>Enter the username or email address attribute that the IdP sends during the authentication process. This must match the attribute name in Tableau</p>   | <input style="width: 100%;" type="text" value="NameID"/>    |
| <p><b>Display Name</b></p> <p>Enter an assertion name for either the first name and last name, or for the full name, depending on how the IdP stores this information. Tableau Server uses these attributes to set the display name.</p> |   |
| <input checked="" type="radio"/> <b>First name</b>   | <input style="width: 100%;" type="text" value="firstName"/> |
| <input type="radio"/> <b>Last name</b>   | <input style="width: 100%;" type="text" value="lastName"/>  |
| <input type="radio"/> <b>Full name</b>   | <input style="width: 100%;" type="text" value="FullName"/>  |

## Step 6: Manage users

Select existing Tableau Server users, or add new users you want to approve for single sign-on.

When you add or import users, you also specify their authentication type. On the Users page, you can change users' authentication type any time after adding them.

For more information, see [Add Users to a Site or Import Users and Set the User Authentication Type for SAML](#).

**Important:** Users that authenticate with site-specific SAML can belong only to one site. If a user needs to access multiple sites, set their authentication type to the server default. Depending on how site-specific SAML was configured by the server administrator, the server default is either local authentication or server-wide SAML.

## Step 7: Troubleshooting

Start with the troubleshooting steps suggested on the [Authentication](#) page. If those steps do not resolve the issue, see [Troubleshoot SAML](#).

### Update SAML Certificate

After you have configured SAML authentication, you may need to periodically update the certificate. In some cases, you may need to change the certificate for operational changes in your IT environment. In either case, you must use TSM or the [Site Authentication](#) page to update the SAML certificate that has already been configured.

Below are the steps to update the certificate and key files for server-wide and site-specific SAML implementations.

### Update certificate for server-wide SAML

To change or update the certificate (and the corresponding key file if required) for server-wide SAML, follow the steps below:

1. Open TSM in a browser:

<https://<tsm-computer-name>:8850>. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Stop Tableau Server.

You can do this either from the TSM web UI, by clicking **Tableau Server is running**, and selecting **Stop Tableau Server**, or from the command line, using the `tsm stop` command.

3. On the **Configuration** tab, select **User Identity & Access**, and then select the **Authentication Method** tab.

4. For **Authentication Method**, select **SAML**.
5. Complete Step 1 - Step 4 in the GUI to update the SAML certificate file and exchange metadata between Tableau Server and your IdP.

## Tableau Server on Linux Administrator Guide

The screenshot shows a configuration page for SAML authentication. It is divided into four steps:

- Step 1:** Provide the location for the following SAML attributes and files.
  - Tableau Server return URL: Required (text input)
  - SAML entity ID: Required (text input)
  - SAML certificate file: Select File (button)
  - SAML key file: Select File (button)
- Step 2:** Download XML metadata file, and register it with your IdP.
  - Download XML Metadata File (button)
- Step 3:** Go to your IdP's website or application and add Tableau Server as a Service Provider. Then export your IdP's metadata XML file.
- Step 4:** Upload your IdP's metadata XML file.
  - SAML IdP metadata file: Select File (button)

6. Click **Save Pending Changes** after you've entered your configuration information.
7. Click **Pending Changes** at the top of the page:

8. Click **Apply Changes and Restart**.

After you change the certificate, you must run `tsm pending-changes apply` to restart Tableau Server services. We also recommend restarting any other services on the computer that use the SAML certificate. If you are changing a root certificate on the operating system, you must reboot the computer.

### Update certificate for site-specific SAML

The certificate used for Tableau site metadata is provided by Tableau and not configurable. To update the certificate for site-specific SAML, you must upload a new certificate to your IdP and re-exchange the metadata with Tableau Server.

1. Sign in to the site as a server or site administrator, and select **Settings > Authentication**.
2. Under Authentication types, select **Edit connection** to expand the UI.
3. Open a new tab or window, and sign in to your IdP account.

4. Use the instructions provided by the IdP's documentation to upload a new SAML certificate.
5. Download the new XML metadata file to provide to Tableau Server.
6. Return to the **Authentication** page in Tableau Server, and in Step 4 of the UI, import the metadata file that you downloaded from the IdP.
7. Click the **Apply** button.

### Troubleshoot SAML

This topic provides information about resolving issues that can occur when you configure SAML authentication.

### SAML and Enable Automatic Logon

If you are using SAML and if Tableau Server is also configured to use Active Directory, do not also select **Enable automatic logon**. **Enable automatic logon** and SAML cannot both be used on the same server installation.

### HTTP status 500 error when configuring SAML

Under some circumstances you might get an HTTP status 500 error and see the following error after enabling SAML and navigating to the Tableau Server URL in a browser:

```
org.opensaml.saml2.metadata.provider.MetadataProviderException:  
User specified binding is not supported by the Identity Provider  
using profile urn:oasis:names:tc:SAML:2.0:profiles:SSO:browser
```

To help resolve this error, make sure of the following:

- The IdP URL for the SSO profile specified in the SAML tab is correct.
- The IdP URL for the SSO profile provided while creating the service provider in the IdP is correct.

## Tableau Server on Linux Administrator Guide

- The IdP is configured to use `HTTP-POST` requests. (Redirect and SOAP are not supported.)

If any of these settings were not correct, make appropriate updates and then perform the SAML configuration steps again, starting with generating and exporting the XML metadata document from Tableau Server.

If these settings are correct, but you still see the error, examine the metadata XML that is produced by Tableau Server and by the IdP, as described in SAML Requirements.

### Signing in from the command line

SAML is not used for authentication when you sign in to Tableau Server using `tabcmd` or the [Tableau Data Extract command line utility](#) (provided with Tableau Desktop), even if Tableau Server is configured to use SAML. These tools require the authentication configured when Tableau Server was originally installed (either local authentication or AD).

### Login fails: Failed to find the user

Login fails with the following message:

```
>Login failure: Identity Provider authentication successful for user
<username from IdP>. Failed to find the user in Tableau Server.
```

This error typically means that there is a mismatch between the usernames stored in Tableau Server and provided by the IdP. To fix this, make sure that they match. For example, if Jane Smith's username is stored in the IdP as `jsmith` it must be stored in Tableau Server as `jsmith`.

### Login fails: SSL offloading

Logon fails with the following message:

```
Unable to Sign In - Invalid username or password.
```

Additionally, the `vizportal` logs (set to `debug` mode) contain the following message:

```
DEBUG com.tableau.core.util.RemoteIP - Found header null in X-  
FORWARDED-PROTO
```

**Note:** To log SAML-related events, `vizportal.log.level` must be set to `debug`. For more information, see [Change Logging Levels](#).

This combination of messages indicates a misconfiguration of an external proxy server that is offloading SSL for the connection to Tableau Server. To resolve this issue, see the KB article, ["Unable to Sign In" and "Invalid username or password" Error With SAML After Upgrading](#).

#### SAML error log

SAML authentication takes place outside Tableau Server, so troubleshooting authentication issues can be difficult. However, login attempts are logged by Tableau Server. You can create a snapshot of log files and use them to troubleshoot problems. For more information, see [Log File Snapshots \(Archive Logs\)](#).

**Note:** To log SAML-related events, `vizportal.log.level` must be set to `debug`. For more information, see [Change Logging Levels](#).

Check for SAML errors in the following files in the unzipped log file snapshot:

```
\vizportal\vizportal-<n>.log
```

The application process (`vizportal.exe`) handles authentication, so SAML responses are logged by that process.

#### Trailing slash

On the SAML tab, confirm that the **Tableau Server return URL** does not end with a trailing slash

Correct: **`http://tableau_server`**

Incorrect: `http://tableau_server/`

## Tableau Server on Linux Administrator Guide

### Confirm connectivity

Confirm that the Tableau Server you are configuring has either a route-able IP address or a NAT at the firewall that allows two-way traffic directly to the server.

You can test your connectivity by running telnet on Tableau Server and attempting to connect with the SAML IdP. For example: `C:\telnet 12.360.325.10 80`

The above test should connect you to the HTTP port (80) on the IdP and you should receive an HTTP header.

### Multiple domains

On the SAML tab, confirm that the Tableau Server **Domain** attribute will detect the domain in the `domain\username` format in the SAML assertion by leaving it blank.

Correct: `<empty>`

Incorrect: `yourdomain.com`

## Kerberos

Kerberos is a three-way authentication protocol that relies on the use of a trusted third-party network service called the Key Distribution Center (KDC) to verify the identity of computers and provide for secure connections between the computers through the exchange of *tickets*. These tickets provide mutual authentication between computers or services, verifying that one has permission to access the other.

Tableau Server supports Kerberos authentication in an Active Directory Kerberos environment, with authentication to Tableau Server being handled by Kerberos.

### Notes:

- The Kerberos support in Tableau Server is for user authentication. It does not handle internal permissions and authorization related to Tableau Server content, such as workbooks.
- Identity pools, which is a tool designed to complement and support additional user provisioning and authentication options you might need in your organization, supports

OpenID Connect (OIDC) authentication only. For more information, see [Provision and Authenticate Users Using Identity Pools](#).

### How Kerberos works

When you configure Tableau Server for Kerberos in an Active Directory (AD) environment, the AD domain controller also serves as the Kerberos Key Distribution Center (KDC) and issues Ticket Granting Tickets to the other nodes in the domain. Users authenticated by the KDC do not have to authenticate further when connecting to Tableau Server.

The following is a diagram of the authentication workflow.

- 1** User logs into their Active Directory domain.
- 2** The Kerberos KDC authenticates the user and sends a Ticket Granting Ticket (TGT) to the user's computer.
- 3** The user connects to Tableau Server in Tableau Desktop or in a web browser.
- 4** Tableau Server authenticates the user.

### Kerberos Requirements

You can configure Kerberos authentication for Tableau Server running in Active Directory environments.

#### General requirements

- **External Load Balancer/Proxy Server:** If you are going to use Tableau Server with Kerberos in an environment that has external load balancers (ELBs) or proxy server, you need to set these up before you configure Kerberos in the Tableau Server Configuration utility. See [Configuring Proxies and Load Balancers for Tableau Server](#).
- **iOS Browser Support:** An iOS user can use Kerberos authentication with mobile Safari if a Configuration Profile specifying the user's Kerberos identity is installed. See [Configuring an iOS Device for Kerberos Support](#) in the Tableau Mobile Help. For more information about browser support for Kerberos SSO, see [Tableau Client Support for Kerberos SSO](#).
- Tableau Server supports constrained delegation for authentication to data sources. In this scenario, the Tableau data access account is specifically granted rights to the target database SPNs. Unconstrained delegation is not supported.
- The supported data sources (SQL Server, MSAS, PostgreSQL, Hive/Impala, and Teradata) must be configured for Kerberos authentication.
- A keytab file that is configured with the service provider name for the Tableau Server for user authentication. For more information, see [Understanding Keytab Requirements](#).
- Beginning in Tableau Server 2021.2.25, 2021.3.24, 2021.4.19, 2022.1.15, 2022.3.7, and 2023.1.3 (or later), ensure keytab files are created with AES-128 or AES-256 ciphers. RC4 and 3DES ciphers are no longer supported. For more information, see ["Tableau Server could not authenticate you automatically"](#) in the Tableau Knowledge Base.

## Active Directory requirements

You must meet the following requirements to run Tableau Server with Kerberos in an Active Directory environment:

- Tableau Server must use Active Directory (AD) for authentication.
- The domain must be an AD 2003 or later domain for Kerberos connections to Tableau Server.
- Smart Card Support: Smart cards are supported when users sign into their workstations with a smartcard and this results in a Kerberos TGT being granted to the user from Active Directory.
- Single-Sign On (SSO): Users must be granted a Kerberos Ticket Granting Ticket (TGT) from Active Directory when they sign into their computers. This is standard behavior for domain-joined Windows computers and standard for Mac computers that use AD as their network account server. For more information on using Mac computers and Active Directory, see [Join your Mac to a network account server](#) in the Apple Knowledge Base.

## Kerberos delegation

For Kerberos delegation scenarios the following are required:

- If the domain is AD 2003 or later, single domain Kerberos delegation is supported. The users, Tableau Server, and backend database must be on the same domain.
- If the domain is AD 2008, there is limited cross domain support. Users from other domains can be delegated if the following conditions are met. Tableau Server and the backend database must be on the same domain, and a two way trust is required between the domain where Tableau Server resides and the user's domain.
- If the domain is 2012 or later, full cross-domain delegation is supported. AD 2012 R2 is

preferred because it has a dialog for configuring constrained delegation, while 2012 non-R2 requires manual configuration.

### Understanding Keytab Requirements

Kerberos authentication relies on credentials that are stored in specially formatted files called keytab files. You may need to generate keytab files for your Tableau Server deployment. This topic describes the keytab files that Tableau Server uses to access various services in a typical organization. You may need to generate keytabs for Tableau Server to integrate into the following services:

- User authentication (SSO) in Windows Active Directory
- Data source delegation
- Operating system
- Directory service

**Important:** Beginning in Tableau Server 2021.2.25, 2021.3.24, 2021.4.19, 2022.1.15, 2022.3.7, and 2023.1.3 (or later), ensure keytab files are created with AES-128 or AES-256 ciphers. RC4 and 3DES ciphers are no longer supported. For more information, see "[Tableau Server could not authenticate you automatically](#)" in the Tableau Knowledge Base.

If your organization includes IT professionals who handle identity, authentication, and/or security, then you should work with them to create a plan for generating appropriate keytabs for your Tableau Server deployment.

#### User authentication (SSO) in Windows Active Directory

If you will be using Active Directory as the identity store for Tableau Server, and you want users to authenticate with Kerberos SSO, then you will need to generate a keytab file for Tableau Server.

| Tableau is running on...           | Need to manually generate a keytab? |
|------------------------------------|-------------------------------------|
| Windows in Active Directory domain | Yes                                 |
| Linux in Active Directory domain   | Yes                                 |

|  |   |
|--|---|
| Windows or Linux in non-Active Directory environment | Kerberos SSO is not a supported scenario. |
|--|---|

Follow these recommendations (for Windows and Linux versions of Tableau Server):

- Create a service account in your directory for Tableau Server.
- Create a keytab specifically for the Tableau Server service account. Do not reuse the keytab file that the computer account/OS uses to authenticate. You may use the same keytab for Kerberos SSO as you use for the directory authentication in the scenario above.
- You must create service principal names (SPN) in Active Directory for the Tableau Server service.
- Use the batch file in the next section to create the SPNs and the keytab file.
- After you have created the SPNs, upload the keytab file as described in Configure Kerberos.

## Batch file: Set SPN and create keytab in Active Directory

You can use a batch file to set the service principal names (SPN) and create a keytab file. These operations are a part of the process to enable Kerberos SSO for Tableau Server (on Windows or Linux) running in Active Directory.

In previous versions of Tableau Server (before 2018.2), the configuration script was generated from the Tableau Server Configuration utility.

To generate a configuration script, copy and paste the following batch file contents into a text file. The batch file creates service principal names (SPN) for Tableau Server and will create a keytab file for the user you specify in the file.

Follow the directions in the file contents. After you have finished customizing the file, save it as a .bat file.

## Tableau Server on Linux Administrator Guide

This file must be run in an Active Directory domain by a Domain admin, who will be prompted for the service account password of the account you specify in the file.

The batch file uses the Windows `set`, `setspn`, and `ktpass` commands.

**Note:** The batch file below is self-documented. However, if you do not have experience with Kerberos and generating keytab files, we recommend that you read the Microsoft blog post, [All you need to know about Keytab files](#), before proceeding. Environmental details in your organization may require additional configuration of the `ktpass` command. For example, you must determine what to set for the `/crypto` parameter. We recommend specifying a single `/crypto` value that is required by your KDC. See the Microsoft article, [ktpass](#) for the full list of supported values for the `/crypto` parameter.

Creating a keytab file for user authentication in Active Directory must be performed on a Windows computer as specified here. Creating this keytab file on a Linux computer is not supported.

## SPN and keytab batch file contents

**Beginning in Tableau Server 2022.3, 2022.1.8, 2021.4.12, 2021.3.17, 2021.2.18, 2021.1.20, and 2020.4.23**

/ptype KRB5_NT_PRINCIPAL /crypto DES-CBC-CRC /out key-
tabs\kerberos.keytab
```

### Operating system

If your organization uses Kerberos for authentication, then the computer where Tableau Server is running must be authenticated with the Kerberos realm in which it's running.

| <b>Tableau is running on...</b>                      | <b>Need to manually generate a keytab?</b> |
|--|--|
| Windows in Active Directory domain                   | No   |
| Linux in Active Directory domain                     | Yes  |
| Windows or Linux in non-Active Directory environment | Yes  |

If you are running Tableau Server on Windows, and the computer is joined to the Active Directory, then you do not need to manage or generate a keytab file for the operating system.

If you are running Tableau Server on Linux in a Kerberos realm (MIT KDC or Active Directory), then you will need to generate a keytab file specifically for the computer operating system. The keytab you create for the computer should be specifically for OS authentication. Do not use the same keytab file for OS authentication that you will be using for the other services described later in this topic.

#### Directory service

If your organization uses a directory service, such as LDAP or Active Directory, to manage user identity, then Tableau Server requires read-only access to the directory.

Alternatively, you can configure Tableau Server to manage all accounts by installing with a local identity store. In this case, you do not need a keytab.

The following table summarizes keytab requirements:

| <b>Tableau is running on...</b> | <b>Directory service</b> | <b>Need to manually generate a keytab?</b> |
|---------------------------------|--------------------------|--|
| Windows in AD domain            | Active Directory         | No   |
| Windows                         | LDAP (GSSAPI bind)       | Yes  |
| Linux                           | Active Directory or LDAP | Yes  |

|                  |  |                     |
|------------------|--|---------------------|
|                  | (GSSAPI bind)                          |                     |
| Windows or Linux | Active Directory or LDAP (Simple bind) | No                  |
| Windows or Linux | Local identity store                   | No keytab required. |

If you need to manually generate a keytab for this scenario, then you will use it for GSSAPI bind to the directory. Follow these recommendations:

- Create a service account in your directory for Tableau Server.
- Create a keytab specifically for the Tableau Server service account. Do not reuse the keytab file that the computer account/OS uses to authenticate.
- Upload the keytab file as part of the json configuration of the Tableau Server identity store. See identityStore Entity.

As part of your disaster recovery plan, we recommend keeping a backup of the keytab and conf files in a safe location off of the Tableau Server. The keytab and conf files that you add to Tableau Server will be stored and distributed to other nodes by the Client File Service. However, the files are not stored in a recoverable format. See Tableau Server Client File Service.

#### Datasource delegation

You can also use Kerberos delegation to access data sources in an Active Directory. In this scenario, users can be authenticated to Tableau Server with any supported authentication mechanism (SAML, local authentication, Kerberos, etc), but can access datasources that are enabled by Kerberos.

Follow these recommendations:

- The computer account for Tableau Server (Windows or Linux) must be in Active Directory domain.

- The keytab file that you use for Kerberos delegation can be the same keytab that you use for Kerberos user authentication (SSO).
- The keytab must be mapped to the service principal for Kerberos delegation in Active Directory.
- You may use the same keytab for multiple data sources.

For more information, see the following configuration topics:

- Tableau Server on Linux: [Enable Kerberos Delegation](#)
- Tableau Server on Windows: [Enabling Kerberos Delegation](#)

### Configure Kerberos

You can configure Tableau Server to use Kerberos. This allows you to provide a single sign-on (SSO) experience across all the applications in your organization. Before you configure Tableau Server for Kerberos make sure your environment meets the Kerberos Requirements.

**Note:** Kerberos constrained delegation for SSO to Tableau Server is not supported. (Constrained delegation for data sources is supported.) For more information, see Single-Sign On (SSO) in Kerberos Requirements.

To configure Kerberos, you must first enable Kerberos, and then specify a keytab file for user authentication. The keytab file you specify must be configured with the service provider name for the Tableau Server for user authentication. If you are using Kerberos authentication for data sources, those credentials should be included in the single keytab file that you will specify during Kerberos configuration on Tableau Server.

As part of your disaster recovery plan, we recommend keeping a backup of the keytab file in a safe location off of the Tableau Server. The keytab file that you add to Tableau Server will be stored and distributed to other nodes by the Client File Service. However, the file is not stored in a recoverable format. See Tableau Server Client File Service.

Use the TSM web interface

## Tableau Server on Linux Administrator Guide

1. Open TSM in a browser:  
  
https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.
2. Click **User Identity & Access** on the **Configuration** tab and then click **Authentication Method**.
3. Under **Authentication Method**, select **Kerberos** in the drop-down menu.
4. Under Kerberos, select **Enable Kerberos for single sign-on (SSO)**.
5. To copy the keytab file to the server, click **Select File**, and then browse to the file on your computer.

**Authentication Method**

Specify how Active Directory manages user authentication and access to Tableau Server.

Kerberos

**Kerberos**

Use Kerberos to provide a single sign-on experience across all applications in your organization. Enable Kerberos on Tableau Server and upload the keytab file. [Learn more](#)

Enable Kerberos for single sign-on (SSO)

Copy the .keytab file to Tableau Server.

Keytab file

6. Click **Save Pending Changes** after you've entered your configuration information.
7. Click **Pending Changes** at the top of the page:

8. Click **Apply Changes and Restart**.

## Use the TSM CLI

1. Copy the keytab file to the computer running Tableau Server and run the following command to set permissions on the file:

```
chmod 644 "/path/keytab_file"
```

If you are running Tableau Server on in a distributed cluster deployment, then you will need to manually distribute the keytab file to each node and then set the permissions. Copy the keytab file to the same directory on each node in the cluster. After you have copied the keytab file to each node and set permissions on the file, then run the following TSM commands on one node. The configuration will propagate to each node.

2. Type the following command to specify the location and name of the keytab file:

```
tsm authentication kerberos configure --keytab-file <path-to-keytab_file>
```

3. Type the following command to enable Kerberos:

```
tsm authentication kerberos enable
```

4. Run `tsm pending-changes apply` to apply changes.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Confirm your SSO configuration

Once Tableau Server has restarted, test your Kerberos configuration from a web browser on a different computer by typing the Tableau Server name in the URL window:

You should be automatically authenticated to Tableau Server.

### Tableau Client Support for Kerberos SSO

This article describes some requirements for and nuances with using Kerberos single sign-on (SSO) with Tableau Server, depending on the particular Tableau client and operating system. Tableau clients covered in this article include common web browsers, Tableau Desktop, and the Tableau Mobile app.

#### General browser client support

To use browser-based Kerberos Single Sign-on (SSO), the following must be true:

- Kerberos must be enabled on Tableau Server.
- The user must have a user name and password to sign in to Tableau Server.

**Note:** When Kerberos SSO fails, users can fall back on their user name and password credentials, if a fall back is set up.

- The user must be authenticated to Active Directory through Kerberos on the client computer or mobile device. Specifically, this means that they have a Kerberos Ticket Granting Ticket (TGT).

#### Tableau Desktop and browser clients

On Windows or the Mac, you can use Kerberos SSO to sign in to Tableau Server from the following versions of Tableau Desktop or browser. Where noted, additional configuration is required.

## Windows

- Tableau Desktop 10.3 or later supported.
- Internet Explorer - supported, may require configuration - see [Note 1](#)
- Chrome - supported, may require configuration - see [Note 1](#)
- Firefox - requires configuration - see [Note 2](#)
- Safari - not supported

## Mac OS X

- Tableau Desktop 10.3 or newer
- Safari - supported
- Chrome - see [Note 3](#)
- Firefox - see [Note 2](#)
- Internet Explorer - not supported

## Tableau Mobile app clients

On a iOS or Android device, you can use the following Tableau Mobile or mobile browser versions to use Kerberos authentication to Tableau Server:

### iOS

- Tableau Mobile app- see [Note 4](#)
- Safari - see [Note 4](#)
- Chrome - not supported

### Android - see [Note 5](#)

- Tableau Mobile app
- Chrome

## Operating system and browser-specific notes

The following notes describe configuration requirements or issues with specific operating system and client combinations.

## Note 1: Internet Explorer or Chrome on Windows desktop

Kerberos SSO is supported in both Internet Explorer and Chrome, but it requires configuration in **Windows Internet Options**:

1. Enable **Integrated Windows Authentication**.
2. Verify that Tableau Server URL is in the local intranet zone.

Internet Explorer can sometimes detect intranet zones and configure this setting. If it has not detected and configured the Tableau Server URL, you must manually add the URL to the local intranet zone.

To enable Integrated Windows Authentication:

1. In Windows Control Panel, open **Internet Options**.
2. On the **Advanced** tab scroll down to the **Security** section.
3. Select **Enable Integrated Windows Authentication**.
4. Click **Apply**.

To verify or add the Tableau Server URL to the local intranet zone:

1. In Windows Control Panel, open **Internet Options**.
2. On the **Security** tab, select **Local intranet**, and then click **Sites**.
3. On the **Local intranet** dialog box, click **Advanced**.

In the **Websites** field, look for the internal Tableau Server URL.

In some organizations, IT administrators will use a wildcard (\*) to specify internal URLs. For example, the following URL includes all servers in the internal `example.lan` namespace in the local intranet zone:

```
https://*.example.lan
```

The following image shows a specific URL of `https://tableau.example.lan`.

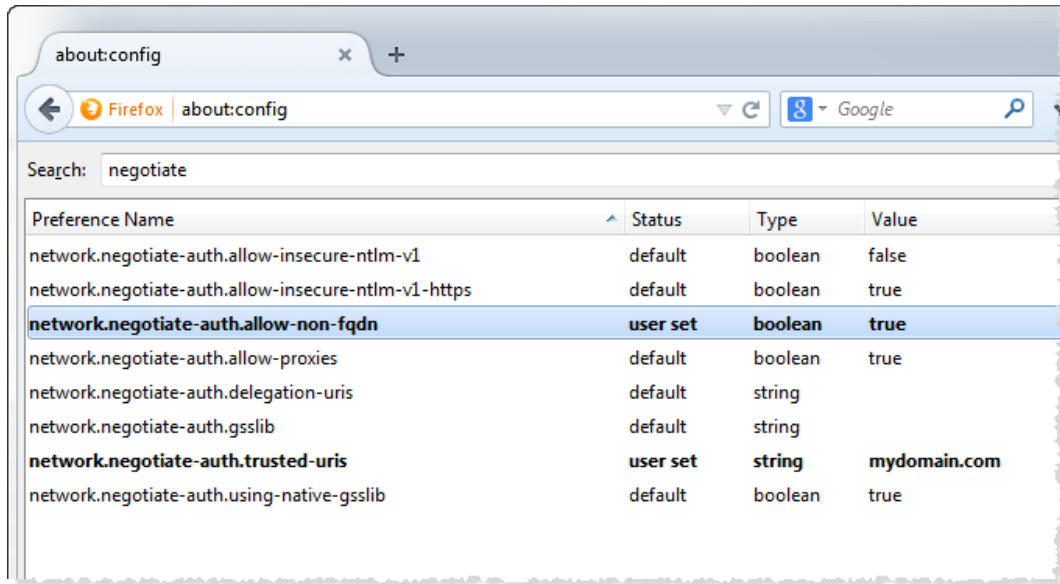

4. If the Tableau Server URL or a wildcard URL is not specified in the **Websites** field, enter the Tableau Server URL in the **Add the website to the zone** field, click **Add**, and then click **OK**.

If the Tableau Server URL is already listed in **Websites**, you can simply close the dialog.

## Note 2: Firefox on Windows or Mac OS X desktop

You can use Firefox with Kerberos SSO on either Windows or Mac to sign in to Tableau Server. To do this, you must complete the following steps to configure Firefox to support Kerberos:

1. In Firefox, enter `about:config` in the address bar.
2. Click **I'll be careful, I promise** when warned about changing advanced settings.
3. Enter `negotiate` in the **Search** box.

4. Double-click **network.negotiate-auth.allow-non-fqdn**, and then set the value to **true**.
5. Double-click **network.negotiate-auth.trusted-uris** and enter the Tableau Server fully qualified domain name (FQDN). For example, `tableau.example.com`.

### Note 3: Chrome on Mac OS X desktop

According to Chrome documentation, Kerberos SSO works on a Mac when you launch Chrome from a terminal window with the following command:

```
open -a "Google Chrome.app" --args --auth-server-whitel-
ist="tableauserver.example.com"
```

where `tableauserver.example.com` is the URL for Tableau Server in your environment.

However, we have found inconsistent results in our testing. Therefore, if you want to use Kerberos SSO on a Mac, we recommend that you use Safari or Firefox. For more information, see the *Integrated Authentication* section at [HTTP authentication](#) on The Chromium Projects site.

**Note:** Users can still use Chrome on Mac OS X to sign in to Tableau Server, but they might be prompted to enter their user name and password (single sign-on may not work).

## Note 4: Mobile Safari or Tableau Mobile on iOS

Kerberos SSO is supported if iOS is configured for Kerberos. The iOS device must have a Kerberos authentication configuration profile installed. This is usually done by an enterprise IT group. Tableau Support cannot assist with configuring iOS devices for Kerberos. See the [authentication topic](#) in the *Tableau Mobile Deployment Guide*.

## Note 5: Android platform

Kerberos SSO is not supported on the Tableau Mobile app on the Android operating system. You can still use your Android device and the Tableau Mobile app or a supported mobile browser to connect to Tableau Server if Kerberos has a fall back set up for when SSO fails to accept user name and password authentication. In this scenario, rather than authenticating with Kerberos, users will be prompted to enter their credentials when accessing Tableau Server.

## More information

- *Tableau Mobile Deployment Guide*: [Control authentication and access for Tableau Mobile](#)
- See *Web Browsers* under [Tableau Server Tech Specs](#)

### Troubleshoot Kerberos

The troubleshooting suggestions in this topic are divided into issues related to single sign-on (SSO) on the server and issues with the delegated data sources.

Also see the Tableau Community wiki page, [Testing Database Kerberos Configuration On Linux](#).

### Single sign-on to Tableau Server

In a Kerberos SSO environment, a user signing in to Tableau Server from a web browser or Tableau Desktop might see a message indicating that Tableau Server can't sign them in automatically (using single sign-on). It suggests that they provide a Tableau Server user name and password instead.

## Troubleshooting sign-in errors on the client computer

- **Enter the user name and password**—To check the user's general access to Tableau Server, sign in by entering the user's name and password.

If these credentials fail, the user might not be a user on Tableau Server. For Kerberos SSO to work, the user must be able to access Tableau Server, and they must be granted a Ticket Granting Ticket (TGT) by Active Directory (as described in the **TGT** item later in this list).

- **Check other users' SSO credentials**—Try to connect with SSO to Tableau Server using other user accounts. If all users are affected, the problem might be in the Kerberos

configuration.

- **Use a computer other than the server computer**—Kerberos SSO does not work when you sign in to Tableau Server on localhost. Clients must connect from a computer other than the Tableau Server computer.
- **Use a server name, not IP address**—Kerberos SSO does not work if you enter an IP address as the Tableau Server name. In addition, the server name you use to access Tableau Server must match the name used in the Kerberos configuration (see [Key table entry](#), below).
- **Confirm that the client has TGT**—The client computer must have a TGT (Ticket Granting Ticket) from the Active Directory domain. Constrained delegation, with the proxy granting a ticket, is not supported.

To confirm the client computer has a TGT, do the following:

- On Windows, open a command prompt and type the following: `klist tgt`
- On the Mac, open a terminal window and type the following: `klist`

The output should show a TGT for the user/domain trying to authenticate to Tableau Server.

The client computer might not have a TGT in the following circumstances:

- The client computer is using a VPN connection.
- The client computer is not joined to the domain (for example, it is a non-work computer being used at work).
- The user signed in to the computer with a local (non-domain) account.
- The computer is a Mac that is not using Active Directory as a network account server.

- **Confirm browser version and settings**—For web browser sign-in, make sure the browser is supported for Kerberos and, if necessary, is configured correctly.
  - Internet Explorer (IE) and Chrome work “out of the box” on Windows.
  - Safari works “out of the box” on the Mac.
  - Firefox requires additional configuration.

For more information, see Tableau Client Support for Kerberos SSO.

## Troubleshooting sign-in errors on the server

If you cannot solve the problem from the client computer, your next steps are to troubleshoot on the computer running Tableau Server. The administrator can use the request ID to locate the sign-in attempt in the Apache logs on Tableau Server.

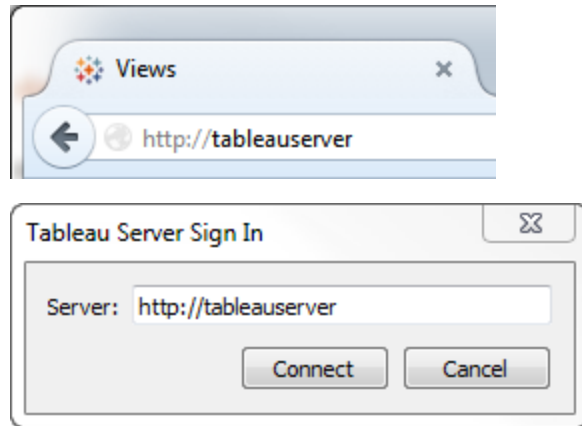

- **Log files**—Check the Apache error.log for an error with the exact time/date of the failed sign-in attempt.
- **Key table entry**—If the error.log entry includes the message, “No key table entry matching HTTP/<servername>.<domain>.<org>@”, for example:

```
[Fri Oct 24 10:58:46.087683 2014] [[:error] [pid 2104:tid 4776]
[client 10.10.1.62:56789] gss_acquire_cred() failed: Unspecified GSS failure. Minor code may provide more information (,
No key table entry found matching HTTP/servername.domain.com@)
```

This error is a result of a mismatch of any of the following:

- **Tableau Server URL** - The URL used by the client computer to access the server.

This is the name that you type into Tableau Desktop or a browser address bar. It could be a shortname (`http://servername`) or a fully-qualified domain name (`http://servername.domain.com`)

- **DNS reverse lookup** for the server IP address.

This looks up a DNS name using an IP address.

At a command prompt type:

```
ping servername
```

with the IP address returned by pinging the server, do a reverse DNS lookup type:

```
nslookup <ip address>
```

The nslookup command will return network information for the IP address. In the *Non-authoritative answer* portion of the response, verify that the fully qualified domain name (FQDN) matches the following configured values:

- The Kerberos .keytab file
- Service Principal Name (SPN) for the server

For more information about configuring these values, see [Understanding Keytab Requirements](#).

## Verify Kerberos configuration script

You may need to modify the `ktpass` command that you used to generate the keytab file for environmental variables. Review the troubleshooting steps in the Knowledge Base article, [Unable to Generate Kerberos Script Configuration for Tableau Server](#).

Data source SSO

## Delegated data source access failures

Check the `vizqlserver` log files for "workgroup-auth-mode."

Look for "workgroup-auth-mode" in the log files. It should say "kerberos-impersonate" not "as-is".

## Kerberos delegation multi-domain configuration

Tableau Server can delegate users from other Active Directory domains. If your database uses MIT Kerberos, you may need to adjust your Kerberos principal to database user mapping. Specifically, you will need to update `krb5.conf` with rules for each Kerberos realm that users will connect from. Use the `auth_to_local` tag in the `[realms]` section to map principal names to local user names.

For example, consider a user, `EXAMPLE\jsmith`, whose Kerberos Principal is `jsmith@EXAMPLE.LAN`. In this case, Tableau Server will specify a delegated user, `jsmith@EXAMPLE`. Tableau Server will use the Active Directory legacy domain alias as the Kerberos Realm.

The target database may already have a rule such as the following to map the user, `jsmith@EXAMPLE.LAN` to the database user, `jsmith`.

```
EXAMPLE.LAN = {  
    RULE: [1:$1@$0] (. *@EXAMPLE.LAN) s/@.*//  
    DEFAULT  
}
```

To support delegation, you must add another rule to map `jsmith@EXAMPLE` to a database user:

```
EXAMPLE.LAN = {
    RULE: [1:$1@$0] (. *@EXAMPLE.LAN) s/@.*//
    RULE: [1:$1@$0] (. *@EXAMPLE) s/@.*//
    DEFAULT
}
```

See the MIT Kerberos Documentation topic, [krb5.conf](#), for more information.

## Cross-domain constrained delegation

In some cross-domain scenarios where the KDC is running on a Windows Server prior to Windows 2012, delegation may fail. Errors you may see include:

- SQL Server Network Interfaces: The system cannot contact a domain controller to service the authentication request. Please try again later.
- SQL Server Native Client: Cannot generate SSPI context.
- The Domain Controller returns: `KRB-ERR-POLICY error with a status STATUS_CROSSREALM_DELEGATION_FAILURE (0xc000040b)`.

Cross-domain refers to a scenario where Tableau Server is running in a different domain than the data source with different service accounts. For example:

- Tableau Server runs on DomainA with DomainA service account.
- SQL Server runs on DomainB with DomainB service account.

Traditional constrained delegation only works if both servers are in the same domain. The user can come from other domains.

If you are seeing the errors noted above, then to enable this scenario, your Active Directory administrator should remove any traditional constrained delegation which is configured on the delegating account. Removing delegation can be achieved with Active Directory management tools or by removing the values associated with the Active Directory property, `msDS-AllowedToDelegateTo`.

If you want to preserve an existing single domain delegation alongside cross-domain delegation, you must configure both using resource-based constrained delegation.

For more information about Kerberos and constrained delegation, see the Microsoft topic, [Kerberos Constrained Delegation Overview](#).

## Web authoring

There are two web authoring scenarios that do not support Kerberos delegation: "Connect to data on the web" and "Create datasource on the web." feature does not support delegation yet. Specifically, if you create a datasource that uses Kerberos on the with web authoring, the data source will use Run As service account authentication. If you want to use Kerberos delegation to create a datasource, then you must publish with Tableau Desktop. For more information on Run As service account, see [Enable Kerberos Service Account Access](#).

## Configure Mutual SSL Authentication

Using mutual SSL, you can provide users of Tableau Desktop, Tableau Mobile, and other approved Tableau clients a secure, direct-access experience to Tableau Server. With mutual SSL, when a client with a valid SSL certificate connects to Tableau Server, Tableau Server confirms the existence of the client certificate and authenticates the user, based on the user name in the client certificate. If the client does not have a valid SSL certificate, Tableau Server can refuse the connection.

You can also configure Tableau Server to fall back to username/password authentication if mutual SSL fails. Additionally, a user can log in using the REST API with a username and password (if one exists) whether or not fallback authentication is configured.

### User authentication session time limits

When users log in with mutual SSL, the authentication session is governed by the same method that governs the Tableau Server global authentication session configuration.

For clients that connect to Tableau Server using a web browser, configuration of the global authentication session is described in the *Security Hardening Checklist*, see 9. Verify session lifetime configuration.

Sessions for connected clients (Tableau Desktop, Tableau Mobile, Tableau Prep Builder, and Bridge) use OAuth tokens to keep users logged in by re-establishing a session. By default, OAuth client tokens reset after a year. If a client token has not been used in 14 days, then it will expire. You can change these values by setting the `refresh_token.absolute_expiry_in_seconds` and `refresh_token.idle_expiry_in_seconds` options. See `tsm configuration set Options`.

### Certificate usage

Before you enable and configure mutual SSL, you must configure external SSL. External SSL authenticates Tableau Server to the client and encrypts the session using the certificate and key that is required when you configure external SSL.

For mutual SSL, an additional certificate file is required. The file is a concatenation of CA certificate files. The file type must be `.cert`. A "CA" is a *certificate authority* that issues certificates to the client computers that will connect to Tableau Server. The action of uploading the CA certificate file establishes a trust, which enables Tableau Server to authenticate the individual certificates that are presented by the client computers.

As part of your disaster recovery plan, we recommend keeping a backup of the certificate and revocation (if applicable) files in a safe location off of the Tableau Server. The certificate and revocation files that you add to Tableau Server will be stored and distributed to other nodes by the Client File Service. However, the files are not stored in a recoverable format. See `Tableau Server Client File Service`.

### **RSA key and ECDSA curve sizes**

The CA certificate used for mutual SSL must either have an RSA key strength of 2048, or ECDSA curve size of 256.

.You can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys:

- `ssl.client_certificate_login.min_allowed.rsa_key_size`
- `ssl.client_certificate_login.min_allowed.elliptic_curve_size`

See tsm configuration set Options.

### Client certificate requirements

Users authenticating to Tableau Server with mutual SSL must present a client certificate that meets minimum security requirements.

### Signing algorithm

Client certificates must use a SHA-256 or greater signing algorithm.

Tableau Server configured for mutual SSL authentication will block authentication of users with client certificates that use the SHA-1 signing algorithm.

Users who attempt to log in with SHA-1 client certificates encounter an "Unable to sign in" error, and the following error will be visible in the VizPortal logs:

```
Unsupported client certificate signature detected: [certificate Signature Algorithm name]
```

You can configure Tableau Server to accept the less secure SHA-1 signing algorithm by setting the `ssl.client_certificate_login.blocklisted_signature_algorithms` tsm configuration option.

### RSA key and ECDSA curve sizes

The client certificate used for mutual SSL must either have an RSA key strength of 2048, or ECDSA curve size of 256.

Tableau Server will fail mutual authentication requests from client certificates that do not meet these requirements. You can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys:

- `ssl.client_certificate_login.min_allowed.rsa_key_size`
- `ssl.client_certificate_login.min_allowed.elliptic_curve_size`

See tsm configuration set Options.

Use the TSM web interface

1. Configure SSL for External HTTP Traffic to and from Tableau Server.
2. Open TSM in a browser:  
  
`https://<tsm-computer-name>:8850`. For more information, see Sign in to Tableau Services Manager Web UI.
3. On the **Configuration** tab, select **User Identity & Access > Authentication Method**.
4. Under **Authentication Method**, select **Mutual SSL** in the drop-down menu.
5. Under Mutual SSL, select **Use mutual SSL and automatic sign in with client certificates**.
6. Click **Select File** and upload your certificate authority (CA) certificate file to the server.

The file (.crt) is an all-in-one file that includes certificates of CAs that are used for client authentication. The file you upload must be a concatenation of the various PEM-encoded certificate files, in order of preference.

7. Enter remaining SSL configuration information for your organization.

**Username format:** When Tableau Server is configured for mutual SSL, the server gets the user name from the client certificate, so it can establish a direct sign-in for the client user. The name that Tableau Server uses depends on how Tableau Server is configured for user authentication:

- Local Authentication—Tableau Server uses the UPN (User Principal Name) from the certificate.
- Active Directory (AD)—Tableau Server uses LDAP (Lightweight Directory Access Protocol) to get the user name.

Alternatively, you can set Tableau Server to use the CN (Common Name) from the client certificate.

The screenshot shows the 'Authentication Method' configuration dialog box. It has a title bar 'Authentication Method' and a subtitle 'Specify how Active Directory manages user authentication and access to Tableau Server.' Below the subtitle is a dropdown menu currently set to 'Mutual SSL'. Under the 'Mutual SSL' section, there is a checkbox for 'Use mutual SSL and automatic sign in with client certificates' which is unchecked. Below this is a label 'SSL CA certificate file' followed by a 'Select File' button. Another checkbox 'Use username and password if SSL authentication fails' is also unchecked. Below this is a label 'Username retrieval method' followed by three radio button options: 'LDAP (Lightweight Directory Access Protocol)', 'UPN (User Principal Name)' (which is selected), and 'CN (Common Name)'. At the bottom of the dialog are two buttons: 'Cancel' and 'Save Pending Changes'.

8. Click **Save Pending Changes** after you've entered your configuration information.
9. Click **Pending Changes** at the top of the page:

10. Click **Apply Changes and Restart**.

Use the TSM CLI

Step 1: Require SSL for external server communication

To configure Tableau Server to use SSL for external communication between Tableau Server and web clients, run the `external-ssl enable` command as follows, providing the names for the server certificate's `.crt` and `.key` files:

```
tsm security external-ssl enable --cert-file <file.crt> --key-file <file.key>
```

- For `--cert-file` and `--key-file`, specify the location and file name where you saved the server's CA-issued SSL certificate (.crt) and key (.key) files.
- The above command assumes the you are signed in as a user that has the **Server Administrator** site role on Tableau Server. You can instead use the `-u` and `-p` parameters to specify an administrator user and password.
- If the certificate key file requires a passphrase, include the `--passphrase` parameter and value.

## Step 2: Configure and enable mutual SSL

Add mutual authentication between the server and each client, and allow for Tableau client users to be authenticated directly after the first time they provide their credentials.

1. Run the following command:

```
tsm authentication mutual-ssl configure --ca-cert <certificate-
file.crt>
```

For `--ca-cert`, specify the location and file name of the certificate authority (CA) certificate file.

The file (.crt) is an all-in-one file that includes certificates of CAs that are used for client authentication. The file you upload must be a concatenation of the various PEM-encoded certificate files, in order of preference.

2. Run the following commands to enable mutal SSL and apply the changes:

```
tsm authentication mutual-ssl enable
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart

behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### Additional options for mutual SSL

You can use `mutual-ssl configure` to configure Tableau Server to support the following options.

For more information, see [tsm authentication mutual-ssl <commands>](#).

## Fallback authentication

When Tableau Server is configured for mutual SSL, authentication is automatic and clients must have a valid certificate. You can configure Tableau Server to allow a fallback option, to accept user name and password authentication.

```
tsm authentication mutual-ssl configure -fb true
```

Tableau Server accepts username and password authentication from REST API clients, even if the above option is set to `false`.

## User name mapping

When Tableau Server is configured for mutual SSL, the server authenticates the user directly by getting the user name from their client certificate. The name that Tableau Server uses depends on how the server is configured for user authentication:

- **Local Authentication**—uses the UPN (User Principal Name) from the certificate.
- **Active Directory (AD)**—uses LDAP (Lightweight Directory Access Protocol) to get the user name.

You can override either of these defaults to set Tableau Server to use the common name.

```
tsm authentication mutual-ssl configure -m cn
```

For more information, see [Mapping a Client Certificate to a User During Mutual Authentication](#)

## Certificate Revocation List (CRL)

You might need to specify a CRL if you suspect that a private key has been compromised, or if a certificate authority (CA) did not issue a certificate properly.

```
tsm authentication mutual-ssl configure -rf <revoke-file.pem>
```

### How Mutual SSL Authentication Works

Mutual (or two-way) SSL authentication provides a combination of an encrypted data stream, mutual authentication of both server and client, and direct access convenience. To use mutual SSL with Tableau Server, you need the following:

- External SSL configured on Tableau Server.
- A trusted CA-issued SSL certificate for Tableau Server. The file is a concatenation of CA certificate files. A "CA" is a *certificate authority* that issues certificates to the client computers that will connect to Tableau Server. The action of uploading the CA certificate file establishes a trust, which enables Tableau Server to authenticate the individual certificates that are presented by the client computers.
- A certificate on each client that will connect to Tableau Server.
- A Tableau Server configured to use mutual SSL.

Tableau Server and the client verify that each other has a valid certificate, and Tableau Server authenticates the user, based on the user name in the client certificate.

The following image shows a little more detail about the sequence of events that occurs with mutual SSL.

1. The user navigates to Tableau Server.
2. Tableau Server sends its SSL certificate to the client computer.
3. The client computer verifies the Tableau Server certificate.
4. The client computer sends its certificate to Tableau Server.
5. Tableau Server verifies the client certificate.
6. Tableau Server references the user name in the client certificate to authenticate the user.

### Mapping a Client Certificate to a User During Mutual Authentication

When you use mutual (two-way) SSL authentication, the client presents its certificate to Tableau Server as part of the authentication process. Tableau Server then maps user information in the client certificate to a known user identity. The strategy that Tableau Server uses to perform client mapping depends on the content of your organization's client certificates.

This topic discusses the ways information in a client certificate can map to a user identity and how to change the way Tableau Server performs that mapping. To understand how the mapping happens and whether you need to change it, you must know how client certificates are structured in your organization.

- [User-name mapping options](#)
- [Change the certificate mapping](#)
- [Address user-name ambiguity in multi-domain organizations](#)

### User-name mapping options

Tableau Server uses one of the following approaches to map a client certificate to a user identity:

- **Active Directory.** If Tableau Server is configured to use Active Directory for user authentication, when Tableau Server receives a client certificate, it passes the certificate to Active Directory, which maps the certificate to an Active Directory identity. Any explicit user name information in the certificate is ignored.

**Note:** This approach requires client certificates to be published for the user accounts in Active Directory.

- **User principal name (UPN).** A client certificate can be configured to store the user name in the user principal name field. Tableau Server reads the UPN value and maps it to a user in Active Directory or to a local user.
- **Common name (CN).** A client certificate can be configured to store the user name in the common name field of the certificate. Tableau Server reads the CN value and maps it to a user in Active Directory or to a local user.

If you configure the server for Active Directory authentication and UPN or CN user-name mapping, put the user name in one of the following formats:

`username, domain/username, or username@domain.`

**For example:** `jsmith, example.org/jsmith, or jsmith@example.org.`

If the server uses local authentication, the format of the name in the UPN or CN fields is not predetermined, but the name in the field must match a user name on the server.

## Tableau Server on Linux Administrator Guide

### Change the certificate mapping

You use the `tsm authentication mutual-ssl <commands>` commands to map a client certificate to a user identity in Tableau Server:

```
tsm authentication mutual-ssl configure -m <value>
```

Possible values are `ldap` for Active Directory mapping, `upn` for UPN mapping, or `cn` for CN mapping.

When you first install and configure Tableau Server, the server sets the default user-name mapping to match the server's authentication type:

- If the server is configured to use Active Directory, it also uses Active Directory for mapping the certificate to the user identity.
- If the server is configured to use local authentication, the server gets the user-name value from the UPN field in the certificate.

If the default behavior for how Tableau Server maps a user name to an identity is not correct for your server configuration, run the following set of commands to change the mapping to use the CN value:

```
tsm authentication mutual-ssl configure -m cn
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Address user-name mapping ambiguity in multi-domain organizations

Under some circumstances, the user name in a certificate's UPN or CN field can be ambiguous. This ambiguity can lead to unexpected results when the user name is mapped to a user identity on the server.

For example, if Tableau Server is presented with a user name that does not include a domain, the server maps the user name to an identity using the default domain. This can cause an incorrect user-name mapping, potentially assigning a user a different user's identity and permissions.

This can occur particularly in environments where the following conditions apply:

- Your organization supports multiple Active Directory domains.
- The server is configured to use Active Directory authentication.
- The server is configured to use UPN or CN mapping.
- Some users have the same user name but different domains. For example, `jsmith@example.org` and `jsmith@example.com`.
- The user name in the certificate's UPN or CN fields does not include the domain as part of the user name—for example, it shows `jsmith`.

To avoid incorrect user-name mapping, make sure the client certificates include fully qualified user names with the domain, using the format `jsmith@example.org` or `example.org/jsmith`.

## OpenID Connect

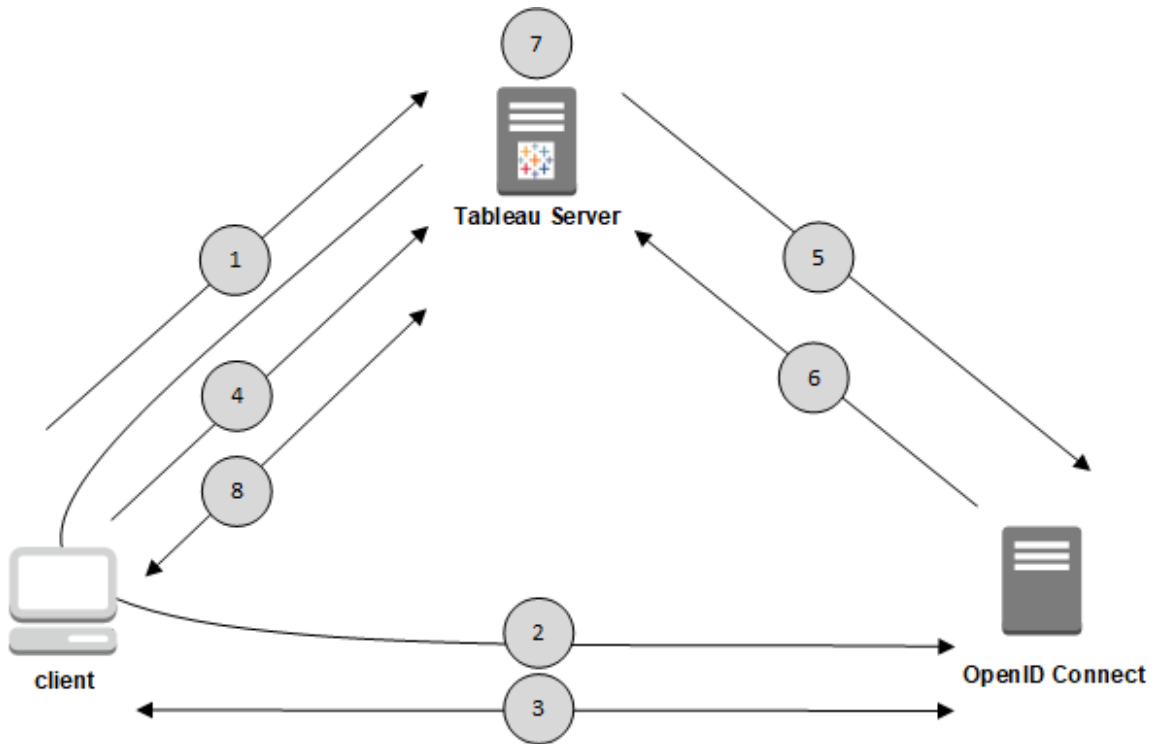

You can configure Tableau Server to support OpenID Connect (OIDC) for single sign-in (SSO). OIDC is a standard authentication protocol that lets users sign in to an identity provider (IdP) such as Google or Salesforce. After they've successfully signed in to their IdP, they are automatically signed in to Tableau Server.

Configuring OIDC involves several steps. The topics in this section provide general information about using Tableau Server with OIDC, and provide a sequence for configuring the IdP and Tableau Server.

**Note:** Unless otherwise noted, information about OIDC authentication applies to both OIDC authentication configured in TSM during Tableau Server setup or OIDC authentication configured with **identity pools**.

### Authentication overview

This section describes the OpenID Connect (OIDC) authentication process with Tableau Server.

1. A user attempts to log in to Tableau Server from a client computer.
2. Tableau Server redirects the request for authentication to the IdP gateway.

3. The user is prompted for credentials and successfully authenticates to the IdP. The IdP responds with a redirect URL back to Tableau Server. The redirect URL includes an authorization code for the user.
4. The client is redirected to Tableau Server and presents the authorization code.
5. Tableau Server presents the client's authorization code to the IdP along with its own client credentials. Tableau Server is also a client of the IdP. This step is intended to prevent spoofing or man-in-the-middle attacks.
6. The IdP returns an access token and an ID token to Tableau Server.
  - JSON Web Token (JWT) validation: By default Tableau Server performs a validation of the IdP JWT. During discovery, Tableau Server retrieves the public keys specified by the `jwtks_uri` in the IdP configuration discovery document. Tableau Server validates the ID token for expiry and then verifies the JSON web signature (JWS), the issuer (IdP), and the client ID. You can learn more about the JWT process in the OpenID documentation, [10. Signatures and Encryption](#), and the IETF proposed standard, [JSON Web Token](#). We recommend leaving JWT validation enabled, unless your Idp does not support it.
  - The ID token is a set of attribute key-pairs for the user. The key-pairs are called *claims*. Here is an example IdP claim for a user:

```

"sub"                :
"7gYhRR3HiRRCaRcgvY50ubrtjGQBMJW4rXbpPFp-
g2cptHP62m2sqowM7G1LwjN5"
"email"              : "alice@example.com",
"email_verified"     : true,
"name"                : "Alice Adams",
"given_name"         : "Alice",
"family_name"        : "Adams",
"phone_number"       : "+359 (99) 100200305",
"profile"            : "https://tableau.com/users/alice"

```

7. Tableau Server identifies the user from the IdP claims and completes the authentication request from step 1. Tableau Server searches for the user's account record stored in the repository by matching the "sub" (subject identifier) to identify the correct user account. If no user account is stored with the sub claim value, then Tableau Server searches for a username in the repository that matches the "email" claim from the IdP. When a username match succeeds, Tableau Server will store the corresponding sub claim to the user's record in the repository. Tableau Server can be configured to use different claims for this process. See [Requirements for Using OpenID Connect](#).

8. Tableau Server authorizes the user.

### How Tableau Server works with OpenID Connect

OpenID Connect (OIDC) is a flexible protocol that supports many options for the information that's exchanged between a service provider (here, Tableau Server) and an IdP. The following list provides details about the Tableau Server implementation of OIDC. These details can help you understand what types of information Tableau Server sends and expects, and how to configure an IdP.

- Tableau Server supports only the OpenID Authorization Code Flow as described in the [OpenID Connect final specification](#) in the OpenID Connect documentation.
- Tableau Server relies on using discovery or a provider URL to retrieve the OpenID provider metadata. Alternatively, you can host a static discovery document on Tableau Server. For more information see [Configure Tableau Server for OpenID Connect](#).
- Tableau Server supports the `client_secret_basic` and `client_secret_post` client authentication.
- Tableau Server expects a `kid` value in the `id_token` attribute's JOSE Header. This value is matched with one of the keys found in the JWK Set document, whose URI is specified by the `jwks_uri` value in the OpenID discovery document. A `kid` value must be present even if there is only one key in the JWK Set document.

- Tableau Server does include OpenID support for the JWK `x5c` parameter or for using X.509 certificates.
- By default, Tableau Server ignores proxy settings and sends all OpenID requests directly to the IdP.

If Tableau Server is configured to use a forward proxy to connect to the internet, then you must make additional changes as described in [Configure Tableau Server for OpenID Connect](#).

### Requirements for Using OpenID Connect

This topic describes the requirements to use OpenID Connect with Tableau Server.

**Note:** The TSM authentication configuration commands apply only to OIDC authentication configured in TSM during Tableau Server setup. To make OIDC authentication configuration changes for identity pools, you can use the [Update Authentication Configuration](#) endpoint using Tableau REST OpenAPI.

### Summary of requirements

- IdP account
- Local identity store
- IdP claims - mapping users
- Authentication context

#### IdP account

You must have access to an identity provider (IdP) that supports the OpenID Connect (OIDC) protocol. You must also have an account with the IdP. OpenID Connect is supported by many identity providers. The OIDC protocol is an open and flexible standard, and as such, not all implementations of the standard are identical. As you configure Tableau Server for OIDC, work with your IdP.

The Google IdP implementation has been extensively tested with Tableau Server and is the model IdP for the configuration documented in these topics.

### Local identity store

To use OpenID Connect on Tableau Server, one of the following must be true:

- **If configuring OIDC in TSM during Tableau Server setup**, Tableau Server must be configured to use a local identity store. The server must be configured so that you explicitly create users on the Tableau Server, rather than importing them from an external directory such as Active Directory. Managing users with an external identity store is not supported with OpenID.
- **If configuring OIDC using [identity pools](#)**, OIDC can be configured with 1) a local identity store or 2) AD or LDAP is the identity store configured in TSM during Tableau Server setup.

### IdP claims - mapping users

To sign in successfully to Tableau Server, a given user must be provisioned in OpenID and then mapped to a user account on Tableau Server. OpenID uses a method that relies on *claims* to share user account attributes with other applications. Claims include user account attributes such as email, phone number, given name, etc. To understand how Tableau Server maps IdP claims to user accounts, see OpenID Connect.

Tableau Server relies on the IdP claims to map user accounts from the IdP to those hosted on Tableau Server. By default, Tableau Server expects the IdP to pass the email claim. Depending on your IdP, you may need to configure Tableau Server to use a different IdP claim.

If you are using Google as an IdP, then use the default, `email` claim to map IdP identities to Tableau Server user accounts. If you are not using Google as an IdP, then work with your IdP to determine the claim for which you should configure Tableau Server.

## Default: using email claim to map users

By default, the user's user name in Tableau Server must match the `email` claim in the IdP ID token. Therefore, in the default configuration, you must use email addresses (also referred to

as UPN) as the username in Tableau Server. If you use Google as the IdP, the user name in Tableau Server must be the user's Gmail address (`alice@gmail.com`). Using a complete email address helps to guarantee the uniqueness of the user name in Tableau Server, even when two users have the same email but are on different email hosts.

**Note:** When you create a user identity in Tableau Server, you specify a user name, password, and optionally an email address. For using OpenID Connect in the default configuration, the user name (expressed as an email address) is the value that must match the user's name in the IdP. The optional email address in the Tableau Server user identity is not used for OpenID authentication.

## Ignoring the domain name

You can configure Tableau to ignore the domain portion of an email address when matching the IdP `email` claim to a user account on Tableau Server. In this scenario, the `email` claim in the IdP might be `alice@example.com`, but this will match a user named `alice` in Tableau Server. Ignoring the domain name might be useful if you already have users defined in Tableau Server that match the user names portion of the `email` claim, but not the domain portions.

**Important:** We do not recommend ignoring the user domain name without taking precautions. Specifically, verify that user names are unique across the configured domains that you've created in your IdP.

Setting Tableau Server to ignore the user domain name has the potential to result in unintended user log on. Consider the case where your IdP has been configured for multiple domains (`example.com` and `tableau.com`). If two users with the same first name, but different user accounts (`alice@tableau.com` and `alice@example.com`) are in your organization, then the first one to complete the OpenID provisioning sequence will claim the `sub` mapping in the IdP. If the wrong user is mapped, then the other user will be unable to log on until the associated `sub` value is reset.

To configure Tableau Server to ignore domain names in user names from the IdP, set `tsm authentication openid configure --ignore-domain` to `true`. For more information, see `tsm authentication openid <commands>`.

When you change the `tsm authentication openid configure --ignore-domain` option to ignore the domain in user names, all user names in Tableau Server must have a domain name.

## Using custom claims to map users

As referenced in OpenID Connect, the `sub` claim is often included in IdP claims. Typically, the `sub` claim is a unique string that identifies a given user account. The benefit of using a `sub` claim is that it will not change, even if you or another admin updates other user attributes or IdP claims (email, phone number, etc) associated with that account. By default, Tableau Server identifies and verifies OpenID users according to the `sub` claim in the IdP ID token.

The OpenID `sub` claim value must be mapped to the corresponding user in Tableau Server. Since the `sub` claim is an arbitrary string, a different claim is used to associate accounts during the first sign-in session. The first time a user signs in to Tableau Server with OpenID, Tableau will match the OpenID user account to a corresponding user account in Tableau Server. By default, Tableau will use the IdP claim, `email`, to identify the Tableau user. Tableau will then update that user's record with the `sub` claim from OpenID. Since the ID token always includes the `sub` claim along with other claims, on subsequent sessions, Tableau will identify that user with the `sub` claim only.

For some organizations, mapping user names with the email address is not reliable or not supported by the IdP. Beginning with Tableau Server 10.2, you can map user accounts from any arbitrary IdP claim to the Tableau Server username.

The IdP claim you are using must map exactly to a corresponding Tableau Server username. In the example below, the username is `kwilliams`.

The screenshot shows the Tableau Server interface with the 'New User' dialog box open. The dialog contains the following fields and options:

- Username:** kwilliams (with a green message 'Username available')
- Display name:** Kirk Williams
- Password:** [masked]
- Confirm password:** [masked]
- Email (optional):** [empty]
- Site:** All sites (dropdown menu)
- Search sites:** [input field]
- Site role table:**

| Site   | Site role  |
|--|------------|
| <input checked="" type="checkbox"/> Customer Support | Interactor |
| <input checked="" type="checkbox"/> Default          | Publisher  |
| <input type="checkbox"/> Development                 |            |
- Selected users are Server Administrators
- Buttons:** Cancel, Create

To change the IdP claim that is used to map identity on Tableau Server, use the `tsm authentication openid map-claims --user-name` command. For more information, see `tsm authentication openid <commands>`.

## Changing the `sub` claim

As described above, the `sub` claim is the identifier that Tableau Server uses to identify users after the initial mapping session. The `sub` claim is written to the corresponding user account in Tableau Server. If your IdP does not provide a `sub` claim, then you can specify an arbitrary claim to use instead. Like `sub`, the claim value you specify must be unique and should not change when other user claims are updated.

## Tableau Server on Linux Administrator Guide

To specify a different IdP claim for default sub claim, use the use the `tsm authentication openid map-claims --id` command. For more information, see `tsm authentication openid <commands>`.

Where `arbitraryClaim` is the name of the IdP claim that you want to use as the replacement for the `sub` claim.

### Authentication context

If your OpenID Connect IdP requires a specific authentication context, you can specify a list of essential and voluntary ACR values using the `vizportal.openid.essential_acr_values` and `vizportal.openid.voluntary_acr_values` configuration keys. For more information, see `tsm configuration set Options`.

### Configure the Identity Provider for OpenID Connect

This topic provides information about configuring an identity provider (IdP) to use OpenID Connect (OIDC) with Tableau Server. This is one step in a multi-step process. The following topics provide information about configuring and using OIDC with Tableau Server.

1. OpenID Connect Overview
2. Configure the Identity Provider for OpenID Connect (you are here)
3. Configure Tableau Server for OpenID Connect
4. Signing In to Tableau Server Using OpenID Connect

### Configure the IdP

Before you can use OpenID Connect with Tableau Server, you must have an account with an identity provider (IdP) and a project or application with the IdP. When you configure Tableau Server, you will need to be able to provide the following information:

- Client ID. This is the identifier that the IdP assigned to your application.
- Client secret. This is a token that is used by Tableau to verify the authenticity of the response from the IdP. This value is a secret and should be kept securely.
- Configuration URL. This is the URL at the provider's site that Tableau Server should send authentication requests to.

## Redirect URL

Some IdPs will require a redirect URL for your Tableau Server.

You can manually construct your URL for the IdP using the following syntax:

```
<protocol>://<host>/vizportal/api/web/v1/auth/openIdLogin
```

For example, `https://tableau.example.com/vizportal/api/web/v1/auth/openIdLogin`.

## Example IdP process

The following procedure provides an outline of the steps that you follow with the provider. As an example, the procedure discusses using Google as a provider. However, each provider has a somewhat different flow, so the specifics of the steps (and their order) might vary depending on your provider.

1. Register at the provider's developer site and sign in. For example, for Google, you can go to the Developers Console at this URL: <https://console.developers.google.com>
2. Create a new project, application, or relying party account.
3. In the developer dashboard, follow the steps for getting an OAuth 2.0 client ID and client secret. Record these values for later.

**Note:** Keep the client secret in a secure place.

## Tableau Server on Linux Administrator Guide

4. On the developer site, find the URL of the endpoint that the IdP uses for OpenID Connect discovery. For example, Google uses the URL <https://accounts.google.com/.well-known/openid-configuration>. Record this URL for later.

Alternatively, if your IdP has provided you with a static discovery document, copy that file to a local directory on the Tableau Server for later.

### Configure Tableau Server for OpenID Connect

This topic describes how to configure Tableau Server to use OpenID Connect (OIDC) for single-sign on (SSO). This is one step in a multi-step process. The following topics provide information about configuring and using OIDC with Tableau Server.

1. OpenID Connect Overview
2. Configure the Identity Provider for OpenID Connect
3. Configure Tableau Server for OpenID Connect (you are here)
4. Signing In to Tableau Server Using OpenID Connect

#### Notes:

- Before you perform the steps described here, you must configure the OpenID identity provider (IdP) as described in [Configure the Identity Provider for OpenID Connect](#).
- The procedures described in this topic apply to OIDC authentication configured in TSM during Tableau Server setup and not OIDC authentication configured with identity pools. For more information about identity pools, see [Provision and Authenticate Users Using Identity Pools](#).

#### Use the TSM web interface

1. Open TSM in a browser:

<https://<tsm-computer-name>:8850>. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click **User Identity & Access** on the **Configuration** tab and then click **Authentication Method**.
3. Under **Authentication Method**, select **OpenID Connect** in the drop-down menu.
4. Under OpenID Connect, select **Enable OpenID authentication for the server**.
5. Enter the OpenID configuration information for your organization:

**Authentication Method**

Specify how the identity store manages user authentication and access to Tableau Server.

OpenID Connect ▼

**OpenID Connect**

Use OpenID when you want users on Tableau Server to authenticate with an external OpenID Connect Identity Provider. Follow the steps below to configure OpenID.

Enable OpenID authentication for the server

**Step 1:** Create the OpenID configuration by providing the client id, secret, and discovery URL provided by your OpenID Connect Identity Provider.

Provider client ID

Provider client secret

Provider configuration URL

**Step 2:** Provide the hostname and protocol of the return URL your OpenID Connect Identity Provider will use to redirect users back to Tableau Server.

Tableau Server external URL

**Step 3:** Copy the URL below and configure your OpenID Connect Identity Provider to redirect users to this endpoint after authenticating.

**Note:** If your provider relies on a configuration file hosted on the local computer (rather than a file hosted at a public URL), you can specify the file with the tsm authentication `openid <commands>`. Use the `--metadata-file <file_path>` option to specify a local IdP configuration file.

6. Click **Save Pending Changes** after you've entered your configuration information.
7. Click **Pending Changes** at the top of the page:

8. Click **Apply Changes and Restart**.

Use the TSM CLI

The procedure in this section describes how to use TSM command line interface to configure OpenID Connect. You can also use a configuration file for the initial configuration of OpenID Connect. See `openIDSettings` Entity.

1. Use the `configure` command of `tsm authentication openid <commands>` to set the following required options:

`--client-id <id>`: Specifies the provider client ID that your IdP has assigned to your application. For example, `"laakjwdlnaoiloadjkwha"`.

`--client-secret <secret>`: Specifies the provider client secret. This is a token that is used by Tableau to verify the authenticity of the response from the IdP. This value is a secret and should be kept securely. For example, `"fwahfkjaw72123="`.

`--config-url <url>` or `--metadata-file <file_path>`: Specifies location of provider configuration json file. If the provider hosts a public json discovery file, then use `--config-url`. Otherwise, specify a path on the local computer and file name for `--metadata-file` instead.

`--return-url <url>`: The URL of your server. This is typically is the public name of your server, such as `"http://example.tableau.com"`.

For example, run the command:

```
tsm authentication openid configure --client-id "laakjwdlnaoiloadjkwha" --client-secret "fwahfkjaw72123=" --config-url "https://example.com/openid-configuration" --return-url "http://tableau.example.com"
```

There are additional, optional configurations that you can set for Open ID Connect using either `openIDSettings` Entity or `tsm authentication openid <commands>`. In addition, if you need to configure IdP claim mapping, see [Options for openid map-claims](#).

2. Type the following command to enable Open ID Connect:

```
tsm authentication openid enable
```

3. Run `tsm pending-changes apply` to apply changes.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see [tsm pending-changes apply](#).

### Signing In to Tableau Server Using OpenID Connect

This topic provides information about signing in to Tableau Server using OpenID Connect. The following topics provide information about configuring and using OpenID Connect with Tableau Server.

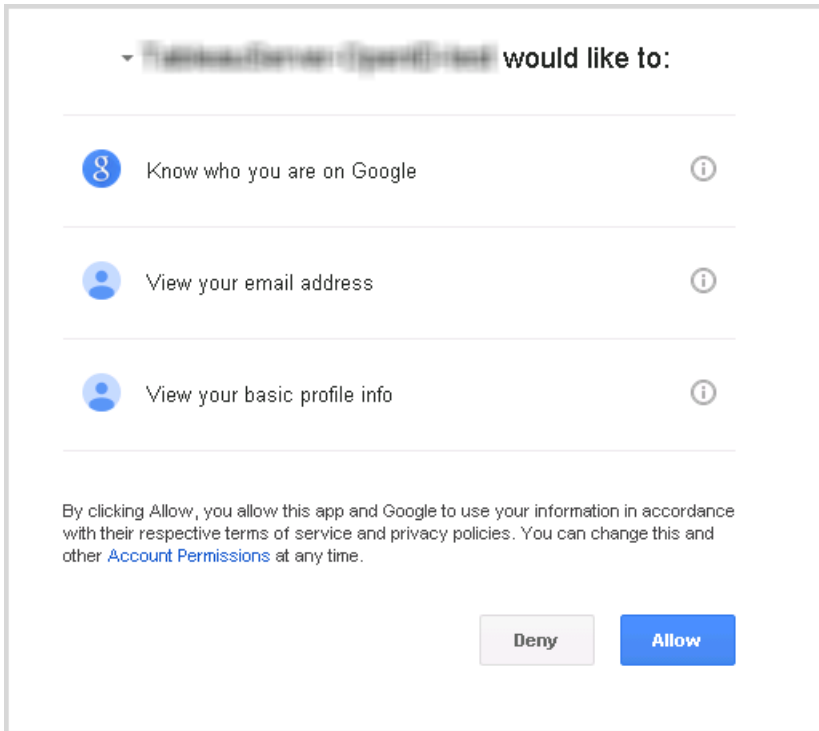

- [OpenID Connect](#)
- [Configure the Identity Provider for OpenID Connect](#)
- [Configure Tableau Server for OpenID Connect](#)
- [Signing In to Tableau Server Using OpenID Connect \(you are here\)](#)

### Signing in using OpenID Connect

After Tableau Server has been configured to use OpenID Connect, users who access the server and aren't already signed in are redirected to the IdP site, where they are prompted to sign in. Users enter the credentials that they have with the IdP. In many cases, the user is also

asked to authorize the IdP to share information with Tableau Server, as in the following example:

When a user signs in using OpenID Connect, the IdP sends a unique user identifier (known in OpenID as the sub value) as part of the information that's redirected to Tableau Server. This sub value is associated with the user's Tableau user identity.

#### Restricting sign-in to server administrators for command-line tools

Command-line tools for working with Tableau Server (`tabcmd`, TSM, and `tableau.com`) do not support sign-in using OpenID Connect. When OpenID Connect is enabled for the server, these tools still require sign-in using a Tableau Server username and password.

Even if users normally authenticate using OpenID Connect, each user has a Tableau Server username and password. This means that users could use command-line tools like `tabcmd`. As a security measure, you can make sure that *only* server administrators can use command-line tools. To do this, use `tsm configuration set` to set `wgserv-er.authentication.restricted` to `true`. When this setting is `true`, only server

administrators can sign in to Tableau Server using a username and password; all other users *must* sign in to the server using a single sign-on (SSO) option like OpenID Connect. The effect is that users who are not administrators also cannot then use command-line tools. To make this change, run the following sequence of TSM commands:

```
tsm configuration set -k wgserver.authentication.restricted -v true
tsm pending-changes apply
```

### OpenID Connect Authentication Request Parameters

The OpenID authentication request sent from Tableau Server passes information using a limited set of parameters, as listed in this topic. If your OpenID IdP requires parameters that are not in the following list, it is not compatible for use with Tableau Server.

- `scope`. This value specifies a profile that tells the IdP what user information claims to return. This value can be configured by a Tableau Server administrator. The default value is "openid email profile". For more information, see [Configure the scope value](#) later in this document.
- `response_type`. OpenID Connect supports multiple flows. This value tells the IdP which flow Tableau Server expects. Tableau supports only the authorization code flow, and the value is always set to "code".
- `client_id`. This value specifies the server's ID (**Provider client ID** in the Tableau Server Configuration dialog box), which lets the IdP know where the request came from. It is provided by the IdP when the service is registered. The value is configurable by a Tableau Server administrator.
- `redirect_uri`. This value specifies the URL that the IdP redirects to after the user has authenticated using OpenID Connect. The URL must include the host and protocol (for example, `http://example.tableau.com`), but Tableau provides the URL endpoint.
- `nonce`. Tableau Server generates a nonce value to verify that the client that it redirected to matches the entity that comes back from the IdP.

## Tableau Server on Linux Administrator Guide

### Configure the scope value

The `scope` value indicates to the IdP the information that Tableau Server requests about the user. By default, Tableau Server sends the value "openid profile email". This indicates that Tableau uses OpenID to authenticate (this part of the `scope` attribute value must always be included ) and that Tableau Server is requesting the user profile and email information during the exchange of the user authorization code.

If this default scope is not appropriate for your scenario, you can have Tableau Server request custom information about the user. To do so, you configure the IdP with a custom profile (for example, something like "tableau-scope"). You can then configure Tableau Server to send the scope request using the name of the custom profile.

To change the scope value that Tableau Server requests, use the following TSM CLI command:

```
tsm authentication openid configure --custom-scope-name custom-  
scope-name
```

### Notes:

- Tableau Server always includes "openid" as part of the scope value (even if you don't include it in the `custom_scope` setting).
- The TSM authentication configuration commands apply only to OIDC authentication configured in TSM during Tableau Server setup. To make OIDC authentication configuration changes for identity pools, you can use the [Update Authentication Configuration](#) endpoint using Tableau REST OpenAPI.

### Changing IdPs in Tableau Server for OpenID Connect

This topic provides information about changing an identity provider (IdP) if you have configured Tableau Server to use OpenID Connect.

#### Change providers

You might decide to change the IdP that Tableau Server is configured to use. To do so, you follow the procedure that you used to configure the first IdP: establish an account, get a customer

ID and secret, configure Tableau Server with that information, and provide the IdP with the redirect URL for Tableau Server. For more information, see [Configure Tableau Server for OpenID Connect](#).

## Reset user identifiers

However, you also need to perform an additional step: you must clear any user identifiers (`sub` values or claims) that have already been associated with Tableau Server users. The new IdP will have different `sub` values for each user, and you must clear the existing ones so that Tableau Server can store a new `sub` value when the user signs in using the new IdP.

To clear `sub` values for users, use the `tabcmd reset_openid_sub` command. You can reset (that is, clear) `sub` values for an individual user, as in the following example:

```
tabcmd reset_openid_sub --target-username jsmith
```

You can also clear the `sub` value for all users using this command:

```
tabcmd reset_openid_sub --all
```

**Note:** Clearing user identifiers for members of an [identity pool](#) is not supported.

### Troubleshoot OpenID Connect

Use the following topics to troubleshoot OpenID Connect (OIDC) issues in Tableau Server.

OIDC protocol is supported by many identity providers. The OIDC protocol is an open and flexible standard, and as such, not all implementations of the standard are identical. Most issues that administrators encounter when configuring Tableau Server for OIDC are the result of how different identity providers implement OIDC. If you encounter errors as you set up OIDC with Tableau Server, we recommend that you work with your IdP to resolve them.

### Enabling enhanced OpenID logging

To efficiently troubleshoot OpenID Connect issues in Tableau Server, enable enhanced logging by setting the logging level to debug, and full logging for OpenID using the

## Tableau Server on Linux Administrator Guide

`vizportal.openid.full_server_request_logging_enabled` configuration key to `true` using these TSM commands:

```
tsm configuration set -k vizportal.log.level -v debug
```

```
tsm configuration set -k vizportal.openid.full_server_request_logging_enabled -v true
```

```
tsm pending-changes apply
```

After completing your troubleshooting, we recommend setting the values of both configuration keys back to their defaults to limit the information collected in logs and to reduce log file sizes. For details on resetting configuration keys to defaults, see [Resetting a configuration key to default](#).

**Note:** Enhanced logging for [identity pools](#) isn't supported. However, `vizportal.log.level debug` logging is supported.

### Signing in from the command line

Even if Tableau Server is configured to use OIDC, it isn't used if you sign in to Tableau Server using `tabcmd`, the [Tableau REST API](#), or the [Tableau Data Extract command line utility](#) (provided with Tableau Desktop).

### Login failed

Login can fail with the following message:

```
Login failure: Identity Provider authentication unsuccessful for user <username from IdP>. Failed to find the user in Tableau Cloud.
```

This error typically means that there's a mismatch between a username stored in Tableau Server and the username provided by the IdP. To fix this, make sure that they match. For example, if Jane Smith's username is stored in the IdP as `jsmith` it must be stored in Tableau Server as `jsmith` as well.

## Error 69: "Unable to Sign In"

An error 69 might be returned when you attempt to sign in to Tableau Server with a web browser and receive an error, "Unable to Sign In. Sign in failed. Contact your Tableau Server administrator." The URL that returns this message is `https://example.com/#/error/signin/69?redirectPath=%2`.

If you receive this error, check with your IDP provider to verify if the IdP is expecting `client_secret_post` instead of `client_secret_basic` (the Tableau default).

If the IdP is expecting `client_secret_post`, then you must set the `vizportal.openid.client_authentication` parameter to `client_secret_post`.

For example, if you receive this error and you have configured OIDC for the Salesforce IdP, then you must set the `vizportal.openid.client_authentication` parameter.

See `tsm configuration set Options` for more information.

### OpenID error log

OpenID authentication takes place outside Tableau Server, so troubleshooting authentication issues can be difficult. However, sign-in attempts are logged by Tableau Server. You can create a snapshot of log files and use them to troubleshoot problems. For more information, see [Tableau Server Logs and Log File Locations](#).

**Note:** To log OpenID-related events, `vizportal.log.level` must be set to `debug` with `tsm configuration set Options`.

Check for OpenID errors in the following files in the unzipped log file snapshot:

```
\vizportal\vizportal-<n>.log
```

### User not found

An error "user not found" might be returned if the "sub" claims have changed after initial login of users. You can verify this issue if you see the following in the vizportal logs: `Possible conflicting or stale account: <username> A different user already owns this account.`

If you continue to see this issue, reset the "sub" claims for that user or for all users on Tableau Server. For more information, see [Reset user identifiers](#).

## Trusted Authentication

When you embed Tableau Server views into web pages, everyone who visits the page must be a licensed user on Tableau Server. When users visit the page they are prompted to sign in to Tableau Server before they can see the view. If you already have a way of authenticating users on the webpage or within your web application, you can avoid this prompt and save your users from having to sign in twice by setting up trusted authentication.

Trusted authentication simply means that you have set up a trusted relationship between Tableau Server and one or more web servers. When Tableau Server receives requests from these trusted web servers it assumes that your web server has handled whatever authentication is necessary.

**Note:** Client browsers must be configured to [allow third-party cookies](#) if you want to use trusted authentication with embedded views.

### How Trusted Authentication Works

The diagram below describes how trusted authentication works between the client's web browser, your web server(s) and Tableau Server.

**1 User visits the webpage:** When a user visits the webpage with the embedded Tableau Server view, the webpage sends a GET request to your web server for the HTML for that page.

**2 Web server POSTS to Tableau Server:** The web server sends a POST request to the trusted Tableau Server (for example, `https://<server_name>/trusted`, not `https://<server_name>`). That POST request must have a `username` parameter. The `username` value must be the username for a licensed Tableau Server user. If Tableau Server is hosting multiple sites and the view is on a site other than the Default site, then the POST request must also include a `target_site` parameter.

**3 Tableau Server creates a ticket:** Tableau Server checks the IP address or host name of the web server (192.168.1.XXX in the above diagram) that sent the POST request. If the web server is listed as a trusted host then Tableau Server creates a ticket in the form of a unique string. Tickets must be redeemed within three minutes after they are issued. Tableau

Server responds to the POST request with that ticket. Or if there is an error and the ticket cannot be created, then Tableau Server responds with a value of `-1`. The server must have an IPv4 address. IPv6 addresses are not supported. For more information, see [Ticket Value of -1 Returned from Tableau Server](#).

**4 Web server passes the URL to the browser:** The web server constructs the URL for the view and inserts it into the HTML for the page. The ticket is included (for example, `https://<server_name>/trusted/<unique_ticket>/views/<view_name>`). The web server passes the HTML back to the client's web browser.

**5 Browser requests view from Tableau Server:** The client web browser sends a GET request to Tableau Server that includes the URL with the ticket.

**6 Tableau Server redeems the ticket:** Tableau Server redeems the ticket, creates a session, logs the user in, removes the ticket from the URL, and then sends the final URL for the embedded view to the client.

The session allows the user to access any of the views that the user would have if they logged onto the server. In the default configuration, users authenticated with trusted tickets have restricted access such that only views are available. They cannot access workbooks, project pages, or other content hosted on the server.

To change this behavior, see the `wgserver.unrestricted_ticket` option at [tsm configuration set Options](#).

How is a trusted ticket stored?

Tableau Server stores trusted tickets in the Tableau Server repository using the following process:

1. Tableau Server generates a two-part ticket: the first part is a Base64-encoded unique ID (UUID) and the second part is a 24-character random secret string.
2. Tableau Server hashes the secret string and stores it with the unique ID in the repository. Hashing takes the secret string as input, and uses an algorithm to compute a

unique string. This unique string protects the security of the secret string from unauthorized users.

3. Tableau Server sends the Base64 UUID and the original 24-character random string to the client.
4. The client returns the Base64 UUID and the original 24-character secret string to Tableau Server as part of the request for a view.
5. Tableau Server locates the string pair with the Base64 UUID, and then hashes the secret string to verify that it matches the hash stored in the repository.

This process ensures that any trusted ticket content stored on Tableau Server cannot be used to impersonate users or access content protected by authentication. However, because the full trusted ticket is sent over HTTP between Tableau Server and the client, the process relies on secure and encrypted transmission of HTTP data. Therefore, we recommend that you only deploy trusted tickets over SSL/TLS or another layer of network encryption.

#### Add Trusted IP Addresses or Host Names to Tableau Server

The first step in setting up trusted authentication is to configure Tableau Server to recognize and trust requests from one or more web servers:

Use the TSM web interface

1. Open TSM in a browser:  
  
https://<server\_name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.
2. Click User **Identity & Access** on the **Configuration** tab and then click **Trusted Authentication**.
3. Under **Trusted Authentication**, for each trusted host, enter the name or IP address and then click **Add**:

## Tableau Server on Linux Administrator Guide

**Trusted Authentication**

Use trusted authentication to allow single sign-on to view Tableau Server content embedded in webpages. Establish a trusted relationship between Tableau Server and one or more web server by adding trusted hosts and specifying token length for each trusted ticket. Do not set up trusted authentication if your web server uses SSPI. [Learn more](#)

|               |  |                                       |
|---------------|--|---------------------------------------|
| Trusted hosts | <input type="text" value="10.32.139.6"/> | <input type="button" value="Delete"/> |
|               | <input type="text" value="webservice1"/> | <input type="button" value="Delete"/> |
|               | <input type="text" value="webservice2"/> | <input type="button" value="Add"/>    |
| Token Length  | <input type="text" value="24"/>          | <input type="button" value="x"/>      |

### Notes:

The values you specify completely overwrite any previous setting. Therefore, you must include the full list of hosts if you want to amend an existing list.

Static IP addresses are required: The web servers you specify must use static IP addresses, even if you use host names.

If you have one or more proxy servers between the computer that is requesting the trusted ticket (one of those configured in Step 2 as shown at Trusted Authentication) and Tableau Server, you also need to add them as trusted gateways using the `tsm configuration set gateway.trusted` option. See [Configuring Proxies and Load Balancers for Tableau Server](#) for steps.

4. Enter a value in **Token Length** (Optional).

The token length determines the number of characters in each trusted ticket. The default setting of 24 characters provides 144 bits of randomness. The value can be set to any integer between 9 and 255, inclusive.

5. Click **Save Pending Changes** after you've entered your configuration information.
6. Click **Pending Changes** at the top of the page:

## 7. Click **Apply Changes and Restart**.

### Use the TSM CLI

#### 1. Enter the following command:

```
tsm authentication trusted configure -th <trusted IP address or
host name>
```

In the command above, <trusted IP address> should be a comma-separated list of the IPv4 addresses or host names of your web server(s), with each host name or IP address in quotes.

**Note:** The values you specify completely overwrite any previous setting. Therefore, you must include the full list of hosts in the `tsm authentication trusted configure -th` command. (You cannot amend the list of hosts by running the `tsm authentication trusted configure -th` command repeatedly.)

For example:

```
tsm authentication trusted configure -th "192.168.1.101",
"192.168.1.102", "192.168.1.103"
```

or

```
tsm authentication trusted configure -th "webserv1", "web-
serv2", "webserv3"
```

**Notes:**

Each host name or IP address in the list must be in double-quotes, followed by a

comma and one space after each comma.

The web servers you specify must use static IP addresses, even if you use host names.

2. If you have one or more proxy servers between the computer that is requesting the trusted ticket (one of those configured in Step 2 as shown at Trusted Authentication) and Tableau Server, you also need to add them as trusted gateways using the `tsm configuration set gateway.trusted` option. See [Configuring Proxies and Load Balancers for Tableau Server](#) for steps.
3. Type the following command to save the changes to all the server configuration files:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

There are other optional trusted authentication configurations (legacy support, logging, and timeout settings) that you can make by passing a json file to Tableau Server. See `trustedAuthenticationSettings Entity`.

Next, you need to [configure your web server to receive tickets from Tableau Server](#).

#### Get a Ticket from Tableau Server

After you've [added trusted IP addresses](#) to Tableau Server, you're ready to configure your web server to get tickets from Tableau Server via POST requests ([Step 2 in the diagram](#)). The POST request must be sent to `http://<server_name>/trusted`. For example, the POST request must be sent to `http://tabserv/trusted` not `http://tabserv`.

**Note:** If SSL is enabled you must use https instead of http. For example: `https://tabserv/trusted`.

Here's the data you can use in a POST request to Tableau Server:

- **username=<username>** (required): The username for a licensed Tableau Server user. If you are using Local Authentication the username can be a simple string (for example, `username=jsmith`). If you are using Active Directory with multiple domains you must include the domain name with the user name (for example, `username=MyCo\jsmith`).
- **target\_site=<site id>** (required if view not on Default site): Specifies the site containing the view if Tableau Server is running **multiple sites** and the view is on a site other than the Default site (for example, `target_site=Sales`). The value you use for `<site id>` should be the **Site ID** that was provided when the site was created. This value is case sensitive. If the **Site ID** is `SAles`, then the `target_site=SAles`.
- **client\_ip=<IP address>** (optional): Used to specify the IP address of the computer whose web browser is accessing the view (for example, `client_ip=123.45.67.891`). It is not the IP address of the web server making the POST request of Tableau Server. If you decide to use this parameter, see [Optional: Configure Client IP Matching](#) for more information.

Tableau Server's response to the POST request will be a unique string (the ticket). If Tableau Server isn't able to process the request, the return will be `-1`. See [Ticket Value of -1 Returned from Tableau Server](#) for tips on how to correct this. Also, in order for users to successfully authenticate when they click an embedded view, their browsers must be configured to [allow third-party cookies](#).

The ticket format changed in Tableau Server 10.2. The ticket format is now a string composed of two parts. Each part is a 128 bit string that is encoded before it is returned to the client. The first part is a universally unique ID (UUID v4) that is Base64-encoded. The second part is a 24-character secure random string. The concatenation of these parts can be expressed as

## Tableau Server on Linux Administrator Guide

Base64(UUIDv4):SecureRandomString. An example of a ticket might look like this:

```
9D1ObyqDQmSIOyQpKdy4Sw== : dg62gCsSE0QRArXNTOp6mlJ5.
```

Next, you need to add code that allows the web server to **construct an URL** for the view that includes the view's location and the ticket.

### Display the View with the Ticket

After you **create the POST request**, you need to write code that provides the web server with the view's location and the ticket from Tableau Server. It will use this information to display the view. How you specify it depends on whether the view is embedded, and if Tableau Server is running multiple sites.

### Tableau Server View Examples

Here's an example of how to specify a view that users only access via Tableau Server (the view is not embedded):

```
http://<server_name>/trusted/<unique_ticket>/views/<workbook_
name>/<view_name>
```

If Tableau Server is running **multiple sites** and the view is on a site other than the Default site, you need to add `t/<site_id>` to the path. For example:

```
http://<server_name>/trusted/<unique_ticket>/t/Sales/views/<workbook_
name>/<view_name>
```

Use the same capitalization that you see in the Tableau Server URL.

### Embedded View Examples

Here are some examples of how to specify embedded views. Because there are two approaches you can take with embed code, both ways are provided below. Regardless of which you use, there is some information unique to trusted authentication that you must provide. For more information, search for "Writing Embed Code" in the Tableau Server Help.

**Note:** The examples below use embed code parameters. For more information, see [Embed Code Parameters](#) in the Tableau Help.

## Script Tag Examples

This example uses the `ticket` object parameter:

```
<script type="text/javascript" src-
c="http://myserver/javascripts/api/viz_v1.js"></script>
<object class="tableauViz" width="800" height="600" style-
e="display:none;">
  <param name="name" value="MyCoSales/SalesScoreCard" />
  <param name="ticket" value-
e="9D10byqDQmSIOyQpKdy4Sw==:dg62gCsSE0QRARXNTOp6m1J5" />
</object>
```

Here's what the above example looks like for a multi-site Tableau Server, where the view is published on the `Sales` site:

```
<script type="text/javascript" src-
c="http://myserver/javascripts/api/viz_v1.js"></script>
<object class="tableauViz" width="800" height="600" style-
e="display:none;">
  <param name="site_root" value="/t/Sales" />
  <param name="name" value="MyCoSales/SalesScoreCard" />
  <param name="ticket" value-
e="9D10byqDQmSIOyQpKdy4Sw==:dg62gCsSE0QRARXNTOp6m1J5" />
</object>
```

Instead of using `ticket`, you can use the `path` parameter to state the full path of the view explicitly. When `path` is used, you do not also need the `name` parameter, which is usually a required parameter in Tableau JavaScript embed code:

```
<script type="text/javascript" src-
c="http://myserver/javascripts/api/viz_v1.js"></script>
```

## Tableau Server on Linux Administrator Guide

```
<object class="tableauViz" width="900" height="700" style-  
e="display:none;">  
  <param name="path" value-  
="tru-  
sted/9D10byqDQmSIOyQpKdy4Sw-  
w==:dg62gCsSE0QRArXNTOp6mlJ5/views/MyCoSales/SalesScoreCard" />  
</object>
```

Here's the same example, but for a multi-site server. Note that `/t/<site_id>` is used here:

```
<script type="text/javascript" src-  
c="http://myserver/javascripts/api/viz_v1.js"></script>  
<object class="tableauViz" width="900" height="700" style-  
e="display:none;">  
  <param name="path" value-  
="tru-  
sted/9D10byqDQmSIOyQpKdy4Sw-  
w==:dg62gCsSE0QRArXNTOp6mlJ5/t/Sales/views/MyCoSales/SalesScoreCard"  
/>  
</object>
```

### Iframe Tag Example

```
<iframe src-  
="h-  
ttp://t-  
abserver-  
/trus-  
ted/9D10byqDQmSIOyQpKdy4Sw-  
w==:dg62gCsSE0QRArXNTOp6mlJ5/views/workbookQ4/SalesQ4?:embed=yes"  
width="800" height="600"></iframe>
```

### Optional: Configure Client IP Matching

By default, Tableau Server does not consider the client web browser IP address when it creates or redeems tickets. To change this, you need to do two things: specify an IP address using the `client_ip` parameter in the POST request that obtains the ticket, and follow the steps below to configure Tableau Server to enforce client IP address matching.

1. Open TSM CLI and type the following command:

```
tsm configuration set -k wgserver.extended_trusted_ip_checking  
-v true
```

2. Then type the following command:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### Test Trusted Authentication

The steps below provide a method you can use to test retrieving a trusted ticket from your web server. This simple test can help evaluate connectivity between the web server and Tableau Server, and whether or not trusted authentication has been configured correctly.

**Important:** The test code provided in this topic runs client-side in the browser to provide a quick, visual validation that trusted authentication is configured correctly on Tableau Server. If the client browser loading the html page is not on the trusted web server, you may have to temporarily trust the client IP. In practice, you should never trust client IP addresses as part of your trusted authentication configuration. All trusted IP addresses are able to request tickets as any user including your administrator. In a production environment, all trusted authentication flows should run server-side, between Tableau Server and the trusted web server(s) only.

Because the test is run on a client browser, the test isn't an exact replica of the communication path in a production environment. After successfully running the test, we recom-

mend that you then test requesting tickets for your users with a server-side post request for final verification.

An alternative testing method is to run a trusted ticket generator to test your configuration. The following URL references a trusted ticket generator that is not supported by Tableau. However the generator has been used by many customers to test their trusted ticket configuration:

<https://github.com/mkannan-tsi/Trusted-Ticket-Generator>.

### Step 1: Add a test user

Create a user on the Tableau Server that you can use to test trusted ticket functionality. See [Add Users to Tableau Server](#). Add that user to a site on the server, and set the user's site role to **Explorer**.

### Step 2: Create a test HTML page

Paste the following code into a new .html file that you save on the Tableau Server machine where you're performing the test from. You can change the labels and style attributes as you prefer.

```
<html>
<head>
<title>Trusted Ticket Requester</title>
<script type="text/javascript">
    function submitForm(){
        document.getElementById('form1').action =
            document.getElementById('server').value + "/trusted";
    }
</script>
<style type="text/css">
    .style1 {width: 100%;}
    .style2 {width: 429px;}
    #server {width: 254px;}
</style>
```

```

</head>
<body>
<h3>Trusted Ticketer</h3>
<form method="POST" id="form1" onSubmit="submitForm()">
  <table class="style1">
    <tr>
      <td class="style2">Username</td>
      <td><input type="text" name="username" value="" /></td>
    </tr>
    <tr>
      <td class="style2">Server</td>
      <td><input type="text" id="server" name="server" value="https://" /></td>
    </tr>
    <tr>
      <td class="style2">Client IP (optional)</td>
      <td><input type="text" id="client_ip" name="client_ip" value="" /></td>
    </tr>
    <tr>
      <td class="style2">Site (leave blank for Default site; otherwise enter the site name)</td>
      <td><input type="text" id="target_site" name="target_site" value="" /></td>
    </tr>
    <tr>
      <td class="style2"><input type="submit" name="submittable" value="Get Ticket" /></td>
      <td>&#160;</td>
    </tr>
  </table>

```

## Tableau Server on Linux Administrator Guide

```
</form>
```

```
<h4>Be sure to add your IP as a Trusted IP address to the server-
```

```
</h4>
```

```
</body>
```

```
</html>
```

### Step 3: Retrieve a trusted ticket from Tableau Server

The following procedure will return a trusted ticket from Tableau Server.

1. Open the web page that you created in the previous step.

**Trusted Ticketer**

Username

Server

Client IP (optional)

Site (leave blank for Default site; otherwise enter the site name)

**Be sure to add your IP as a Trusted IP address to the server**

This operation requires JavaScript, so the web browser might prompt you to allow scripts to run.

2. In the text boxes, enter the following:
  - **Username:** The test user that was created in Step 1.
  - **Server:** the address of your Tableau Server, e.g., `https://<server_name>`.
  - **Client IP (optional):** The IP address of the user's computer, if it's configured for client trusted IP matching.
  - **Site:** The name of the Tableau Server site that the test user is a member of.
3. Click **Get Ticket**. One of the following will be returned:
  - **A unique ticket:** A trusted ticket is a string composed of a base64-encoded UUID and a 24-character random string, for example,  
9D101xmDQmSIOyQpKdy4Sw== : dg62gCsSE0QRARXNTOp6m1J5.

- **-1:** If the value, `-1` is returned, the configuration contains an error. See [Ticket Value of -1 Returned from Tableau Server](#).

#### Step 4: Test access with trusted ticket

Now that you have a ticket, you can use it to access content on Tableau Server.

Construct a URL with the unique ticket that you generated in the previous step to verify access with the trusted ticket. The URL syntax is different if you are accessing a Tableau Server with a single site vs a server that hosts multiple sites.

#### Default site server url

```
https://<server_name>/trusted/<unique_ticket>/views/<workbook_name>/<view_name>
```

#### Non-default site server url

```
https://<server_name>/trusted/<unique_ticket>/t/<site_name>/views/<workbook_name>/<view_name>
```

Variables in the URLs are indicated by angle brackets (< and >). All other syntax is literal.

#### Troubleshoot Trusted Authentication

This section includes some common issues and errors you might encounter when you're configuring trusted authentication.

A common source for trusted authentication errors are misconfiguration with a proxy server or load balancer. If your Tableau Server operates behind a reverse proxy server or a load balancer, see [Configure Tableau Server to work with a reverse proxy server and/or load balancer](#) and [Add a Load Balancer](#).

Trusted authentication information is written to `/var/opt/tableau/tableau_server-/data/tabsvc/logs/vizqlserver/vizql-*.log`.

To increase the logging level from `info` to `debug`, run the following commands:

## Tableau Server on Linux Administrator Guide

```
tsm configuration set -k vizqlserver.trustedticket.log_level -v
debug
tsm pending-changes apply
```

To test your trusted authentication deployment, see [Test Trusted Authentication](#).

## See also

For more troubleshooting information for specific errors, see the following topics accessible from the **Other articles in this section** below:

### Request for ticket by web server

- Ticket Value of -1 Returned from Tableau Server
- HTTP 401 - Not Authorized
- HTTP 404 - File Not Found
- Invalid User (SharePoint or C#)

### Viewer redeeming ticket

- Attempting to Redeem the Ticket from the Wrong IP Address
- Cookie Restriction Error

### Navigating between several embedded views

- An error occurred communicating with the server (403)

Ticket Value of -1 Returned from Tableau Server

Tableau Server returns -1 for the ticket value if it cannot issue the ticket as part of the trusted authentication process. Before troubleshooting this scenario, be sure to set the log level for trusted authentication to `debug` as specified in [Troubleshoot Trusted Authentication](#).

The exact reason for this message is written to the `vizqlserver_node*-* .log.*` files in the following folder:

```
/var/opt/tableau/tableau_server/data/tabsvc/logs/vizqlserver
```

Here are some things to confirm:

- **All web server host names or IP addresses are added to trusted hosts**

The log error, "Invalid request host: <ip\_address>" may indicate that the IP address or host name for the computer sending the POST request is not in the list of trusted hosts on Tableau Server. See [Add Trusted IP Addresses or Host Names to Tableau Server](#) to learn how to add IP addresses or host names to this list.

- **IP addresses are IPv4**

If you are using IP addresses to specify trusted hosts, they must be in Internet Protocol version 4 (IPv4) format. An IPv4 address looks like this: 123.456.7.890. IPv6 addresses (for example, fe12::3c4a:5eab:6789:01c%34) are not supported as a way of inputting trusted hosts.

- **Username in POST request is a valid Tableau Server user**

The username you send in the POST request must be a licensed Tableau Server user. You can see a list of users by signing in to Tableau Server as an administrator.

The following log errors indicate a user POST issue:

- "Missing username and/or client\_ip"
- "Invalid user: <username>"
- "Unlicensed user is not allowed: <username>"

#### **Username in POST request includes domain**

If Tableau Server is configured to use Local Authentication, the username that you send in the POST can be a simple string. However, if the server is configured for Active Directory you must include the domain name with the user name (domain\username). For example, the username parameter might be: `username=dev\jsmith`. A common error log for this scenario is "Invalid user: <username>".

- **Content-Type is specified**

## Tableau Server on Linux Administrator Guide

If you are designing an ASP.NET or C# application, you need to declare the content type in your HTTP request. For example:

```
http.setRequestHeader("Content-Type", "application/x-www-form-urlencoded; charset=UTF-8")
```

If you do not specify content type and Tableau Server returns a -1, the log files contain the error: "missing username and/or client\_ip".

### HTTP 401 - Not Authorized

If you receive a **401- Not Authorized error**, it could be for one of the following reasons:

- You may have configured Tableau Server to use Active Directory with SSPI. If your web server uses SSPI, you do not need to set up trusted authentication. You can embed views and your users will have access to them as long as they are licensed Tableau server users and members of your Active Directory. For more information, see `tsm authentication sspi <commands>`.

**Note:** SSPI can only be configured on Tableau Server for Windows.

- Or a **302- Redirect error** after you have deployed Tableau Server, then it's likely the trusted ticket code you have written to construct the URL for the client has not been updated to account for the two-part ticket URL format. For more information, see [Get a Ticket from Tableau Server](#).

### HTTP 404 - File Not Found

You may receive this error if your program code references a Tableau Server URL that does not exist. For example, your web server may construct an invalid URL that cannot be found when the webpage tries to retrieve it.

Another cause for this error is if you did not enter the trusted web servers as specified in [Add Trusted IP Addresses or Host Names to Tableau Server](#). If you have already entered the trusted web servers, verify that the IP addresses or host names are correct.

### Invalid User (SharePoint or C#)

You may encounter this error if you've configured Tableau Server for trusted authentication.

The example code for the SharePoint .dll references the following GET request:

```
SPContext.Current.Web.CurrentUser.Name
```

The above request will return the display name of the current Windows Active Directory user.

If you want to use the login ID, then you will need to change the code to:

```
SPContext.Current.Web.CurrentUser.LoginName
```

After you make the change, recompile the SharePoint .dll.

### Attempting to Redeem the Ticket from the Wrong IP Address

When you've configured Tableau Server for trusted authentication, you may encounter issues with redeeming the ticket.

This issue can occur when Tableau Server is configured to enforce client IP address matching. Because the client web browser IP address is not considered by default when redeeming the ticket, make sure that the client's web browser IP address that is sent in the POST request to Tableau Server is the same as when the browser tries to retrieve the embedded view.

For example, in the Trusted Authentication diagram, if the **POST request in step 3** sends the parameter `client_ip=74.125.19.147`, then the **GET request in step 5** must come from that same IP address.

For more information, see [Optional: Configure Client IP Matching](#) to learn how to configure Tableau Server to enforce client IP address matching.

### Cookie Restriction Error

When a user signs in to Tableau Server, a session cookie is stored in their local browser. The stored cookie is how Tableau Server maintains that the signed in user has been authenticated and can access the server. Because the cookie is set with the same domain or sub-domain as

the browser's address bar, it is considered a first-party cookie. If a user's browser is configured to block first-party cookies, they will be unable to sign in to Tableau Server.

When a user signs in to Tableau Server via an embedded view, or in an environment where trusted authentication has been configured, the same thing happens: a cookie is stored. In this case, however, the browser treats the cookie as a third-party cookie. This is because the cookie is set with a domain that's different from the one shown in the browser's address bar. If a user's web browser is set to block third-party cookies, authentication to Tableau Server will fail. To prevent this from occurring, web browsers must be configured to allow third-party cookies.

## Personal Access Tokens

Personal access tokens (PATs) provide you and your Tableau Server users the ability to create long-lived authentication tokens. PATs enable you and your users to sign in to Tableau REST API without requiring hard-coded credentials (username and password) or interactive sign-in. For more information about using PATs with Tableau REST API, see [Signing In and Out \(Authentication\)](#) in the Tableau REST API Help.

We recommend creating PATs for automated scripts and tasks that are created with the Tableau REST API:

- **Improve security:** Personal access tokens reduce risk in the event credentials are compromised. In the case where Tableau Server uses Active Directory or LDAP as an identity store, you can reduce the impact of credential compromise by using a personal access token for automated tasks. If a token gets compromised or is used in automation that is failing or posing a risk, you can just revoke the token. You do not need to rotate or revoke the user's credentials.
- **Audit and track:** As an administrator, you can review Tableau Server logs to track when a token is used, what sessions are created from that token, and the actions that are performed in those sessions. You can also determine if a session and the related tasks were performed from a session that was generated from a token or from an

interactive signin.

- **Manage automation:** A token can be created for each script or task that is run. This allows you to silo and review automation tasks across your organization. Additionally, by using tokens then password resets or metadata changes (username, email, etc.) on user accounts will not disrupt automation as it would when credentials are hard-coded into the scripts.

#### Notes:

- To use PATs with tabcmd, install the compatible version of tabcmd from <https://tableau.github.io/tabcmd/>.
- PATs are not used for generic client access to the Tableau Server web UI or TSM.
- Configuring PATs expiration and disabling or limiting users access to PATs creation from the UI is available in Tableau Cloud only.
- PATs are automatically revoked when a **user's authentication method** is changed.

#### Understand personal access tokens

When a personal access token (PAT) is created, it is hashed then stored in the repository. After the PAT is hashed and stored, the PAT secret is shown once to the user and then no longer accessible after the users dismisses the dialog. Therefore, users are instructed to copy the PAT to a safe place and to handle it as they would a password. When the PAT is used at run-time, Tableau Server compares the PAT presented by the user to the hashed value stored in the repository. If a match is made, then an authenticated session is started.

In the context of authorization, the Tableau Server session that is authenticated with a PAT has the same access and privileges as the PAT owner.

**Note:** Users can't request concurrent Tableau Server sessions with a PAT. Signing in again with the same PAT, whether at the same site or a different site, will terminate the previous session and result in an authentication error.

#### Server administrator impersonation

Beginning with version 2021.1, you can enable Tableau Server PAT impersonation. In this scenario, PATs that are created by server administrators can be used for **user impersonation**

## Tableau Server on Linux Administrator Guide

when using the Tableau REST API. Impersonation is useful in scenarios where you are embedding end-user-specific Tableau content within your application. Specifically, impersonation PATs allow you to build applications that query as a given user and retrieve content that the user is authorized for within Tableau Server, without hard-coding any credentials.

For more information, see [Impersonating a User](#) Tableau REST API Help.

### Enable Tableau Server to accept personal access tokens during impersonation sign-in requests

By default, Tableau Server does not allow impersonation for server administrator PATs. You must enable the server-wide setting by running the following commands.

```
tsm authentication pat-impersonation enable [global options]
```

```
tsm pending-changes apply
```

**Important:** After you have run the commands, all PATs created by server administrators (including preexisting PATs) can be used for impersonation. To bulk-revoke all existing server administrator PATs, you can post the `DELETE /api/{api-version}/auth/serverAdminAccessTokens` URI. For more information, see [Impersonating a User](#) in the Tableau REST API Help.

### Create personal access tokens

Users must create their own PATs. Administrators cannot create PATs for users.

Users with accounts on Tableau Server can create, manage, and revoke personal access tokens (PATs) on the **My Account Settings** page. See [Manage Your Account Settings](#) in the Tableau User Help for more information.

**Note:** A user can have up to 10 PATs.

### Change personal access tokens expiry

Personal access tokens (PATs) expire if they are not used after 15 consecutive days. If they are used more frequently than every 15 days, PATs expire after one year. After a year, new

PATs must be created. Expired PATs will not display on the **My Account Settings** page.

You can change PATs expiration period by using the `refresh_token.absolute_expiry_in_seconds` option with the `tsm configuration set` command.

#### Revoke a personal access token

As an administrator, you can also revoke a user's PAT. A user can also revoke their own personal access tokens (PATs) on the **My Account Settings** page using the procedure described in the [Manage Your Account](#) topic in the Tableau User Help.

1. Sign in to Tableau Server as a server or site administrator.
2. Locate the user whose PAT you want to revoke. For more information about navigating Server Admin pages and locating users, see [View, Manage, or Remove Users](#).
3. Click the user's name to open their profile page.
4. On the user's profile page, click the **Settings** tab.
5. In the **Personal Access Tokens** section, identify the PAT that you want to revoke and then click **Revoke**.
6. In the dialog box, click **Delete**.

#### Track and monitor personal access token usage

All personal access token (PAT)-related actions are logged in the Tableau Server Application Server (vizportal) service. To locate PAT-related activities, filter log entries containing the string, `RefreshTokenService`.

A PAT is stored in this format: `Token Guid: <TokenID(Guid)>`, where the `TokenID` is a base64 encoded string. The secret value is not included in the logs.

For example:

```
Token Guid: 49P+CxmARY6A2GHxyvHHAA== (e3d3fe0b-1980-458e-80d8-61f1-
caf1c700).
```

## Tableau Server on Linux Administrator Guide

The following is an example snippet of two log entries. The first entry shows how a user is mapped to a PAT. The second entry shows a refresh event for the same PAT:

```
RefreshTokenService - Issued refresh token to the following user:  
jsmith. Token Guid: 49P+CxmARY6A2GHxyvHHAA== (e3d3fe0b-1980-458e-  
80d8-61f1caf1c700)  
RefreshTokenService - Redeemed refresh token. Token Guid:  
49P+CxmARY6A2GHxyvHHAA== (e3d3fe0b-1980-458e-80d8-61f1caf1c700)
```

To locate key operations, filter log entries containing the string, `OAuthController`.

## Use Tableau Connected Apps for Application Integration

Beginning with Tableau Server 2022.1, Tableau connected apps enable a seamless and secure authentication experience by facilitating an explicit trust relationship between your Tableau Server site and external applications where Tableau content is embedded. , Tableau connected apps extended its capabilities to support REST API authorization. And as of October 2023, REST API authorization using connected apps is respected by the Tableau Metadata API.

**Note:** Tableau connected apps and Salesforce connected apps are different and offer different functionality. Today, Tableau connected apps are optimized for embedding Tableau views and metrics in external applications and used to authorize access to the Tableau REST API. (In October 2023, Tableau retired the ability to embed metrics in Tableau Cloud and Tableau Server version 2023.3.).

There are two types of connected apps you can configure: direct trust or OAuth 2.0 trust.

Direct trust

Using *direct trust*, you can:

- Restrict access to which content can be embedded and where that content can be embedded

- Provide users the ability to access embedded content using single sign-on (SSO) without having to integrate with an identity provider (IdP)
- Provide users the ability to authenticate directly from your external application
- Programmatically authorize access to the Tableau REST API and Tableau Metadata API (starting in Tableau Server October 2023) on users' behalf using JSON Web Token (JWT)
- Scope Tableau REST API capabilities users or applications can perform
- Enable additional features like:
  - Group assertions (beginning in Tableau Server 2024.2)

For more information about this connected app type, see [Configure Connected Apps with Direct Trust](#).

#### OAuth 2.0 trust

Using *OAuth 2.0 trust*, you can:

- Restrict access to which content can be embedded and where that content can be embedded
- Provide users the ability to access embedded content using single sign-on (SSO) through your identity provider (IdP)
- Provide access using standard OAuth 2.0 standard protocol
- Programmatically authorize access to Tableau REST API (and the Metadata API starting in Tableau Server 2023) on users' behalf
- Scope Tableau REST API capabilities users or applications can perform
- Enable additional features like:
  - Group assertions (beginning in Tableau Server 2024.2)

For more information about this connected app type, see [Configure Connected Apps with OAuth 2.0 Trust](#).

### Configure Connected Apps with Direct Trust

Beginning with Tableau Server version 2022.1, Tableau connected apps enable a seamless and secure authentication experience by facilitating an explicit trust relationship between your Tableau Server site and external applications.

#### Notes:

- Connected apps functionality, without UI, for Tableau Server became available in Tableau Server version 2021.4 through the [Connected App methods](#) in the Tableau REST API.
- To enable embedding through connected apps, Tableau Server must be configured to use SSL for HTTP traffic.
- In order for the session token to be valid, the clocks of the external application and the server that hosts the external application must be set to Coordinated Universal Time (UTC). If either clock uses a different standard, the connected app will not be trusted.

#### How connected apps work

The trust relationship between your Tableau Server site and external application is established and verified through an authentication token in the JSON Web Token (JWT) standard, which uses a shared secret provided by the Tableau connected app and signed by your external application.

## Key components of a connected app

The following components of the connected work together with the JWT in your external application to authenticate users and display embedded content.

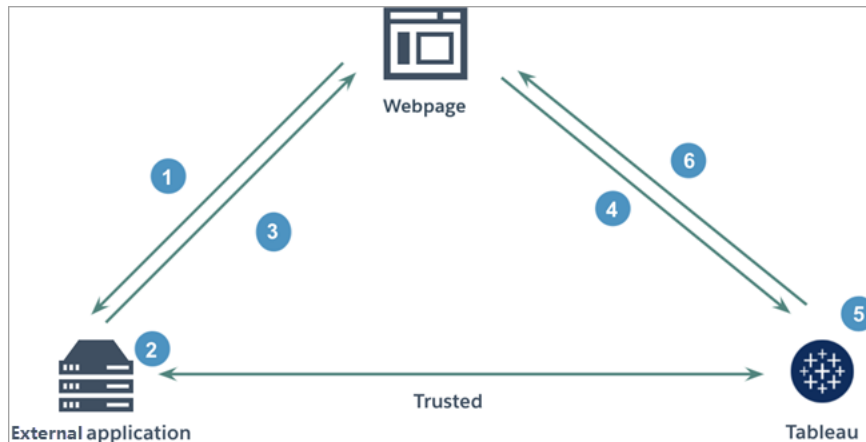

- **Secrets:** Secrets are keys shared by Tableau and your external application. They are used in signatures that form the JWT. A secret is required when using connected apps for embedding authentication or REST API authorization. Secrets can be created in a connected app, do not expire, and remain valid until deleted.

- **Domain allowlist (embedding workflows only):** You can specify a list of allowed domains in each connected app. Tableau content embedded through a connected app is only allowed under the specified domains. This helps ensure that content is exposed under the domains that are secured and approved by your business.
- **Access level (embedding workflows only):** You can specify what content can be embedded through a connected app by associating a connected app with one project or all projects. If you specify one project, only the content in the selected project can be embedded through the connected app. If you want to specify multiple projects, you must use the Tableau REST API.

## Connected app workflow

### Embedding workflows

The diagram below illustrates how authentication works between your external application (web server and webpage) and connected app.

1. **User visits the webpage:** When a user visits the embedded content on a webpage, webpage sends a GET request to your external application to retrieve the HTML on that webpage.
2. **External application constructs an authentication token:** The external application constructs a JWT, which contains a secret from the connected app (see Step 3 below for additional JWT requirements) and the scope of user access for the embedded content. The secret is signed by the external application and is used for verification of the trust relationship in a later step.

3. **External application responds with authentication token:** The external application responds to the page with the JWT in the embedded content's URL called by the webpage.
4. **Webpage requests content from Tableau:** With the attempt to load the embedded content, the webpage calls the embedded content's URL, which sends a GET request to Tableau.
5. **Tableau validates the token:** Tableau receives the JWT and verifies the trust relationship with the external application by identifying the connected app and shared secret used in the JWT. Then Tableau creates a session for the user. The session not only respects the embedding scopes defined in the JWT, but also the restrictions specified in the connected app, including the allowed domains and allowed projects.
6. **Tableau returns the content based on the restricted embedding context:** The embedded content only loads when the page is under an allowed domain and the content is published to an allowed project (if applicable). The authenticated user can only interact with the embedded content by the scope defined in the JWT.

Create a connected app

## Step 1: Create a connected app

Create a connected app from Tableau Server's Settings page.

1. As a server admin, sign in to Tableau Server.
2. From the left pane, select **Settings > Connected Apps**.
3. Click the New Connected App button drop-down arrow and select **Direct Trust**.

**Note:** If you're using Tableau Server 2023.3 or earlier, click **New Connected App** button.

4. In the Create Connected App dialog box, do *one* of following:
  - For *REST API authorization workflows (including Metadata API workflows that use the REST API for authentication)*, in the Connected app name text box, enter a name for the connected app and click the **Create** button.

**Note:** You can ignore **Access level** and **Domain allowlist** when configuring a connected app for REST API and Metadata API authorization.

- For *embedding workflows*, do the following:
  - i. In the Connected app name text box, enter a name for the connected app.
  - ii. From the Applies to drop-down menu, select **All project** or **Only one project** to control which views or metrics can be embedded. If you select the "Only one project" option, select the specific project to scope to. For more information about these two options, see Access level (embedding workflows only).

**Notes:**

- In Tableau Server 2023.3, Tableau retired the ability to embed metrics.
  - Beginning with Tableau Server 2024.2, you can specify multiple projects using the Tableau REST API. For more information, see [Create Connected App](#) and [Update Connected App](#) methods in the REST API Help.
- iii. In the Domain allowlist, specify the domains using the rules described in Domain formatting below to control where views or metrics can be embedded.

**Important:** We recommend using the domain allowlist as a security best practice to ensure Tableau content is only embedded in locations that you allow.

- iv. When finished, click the **Create** button.

**Create Connected App**

Connected app name: MyCo

Access level: Applies to: Only one project; Project name: MyCo

Domain allowlist:  All domains;  Only specified domains: \*.myco.com

Buttons: Cancel, Create

- 5. Next to the connected app's name, click the actions menu and select **Enable**. For security purposes, a connected app is set to disabled by default when created.

- 6. Make note of the connected app's ID, also known as the client ID, to use in Step 3 below.

## Step 2: Generate a secret

You can generate a total of two secrets for each connected app. The second secret can be used for secret rotation purposes to help protect against issues if a secret is compromised.

1. On the detail page of the connected app you created in Step 1, click the **Generate New Secret** button.
2. Make note of the secret ID and secret value to use in Step 3 below.

## Step 3: Configure the JWT

After you've generated a secret, you want to enable your external application to send a valid JWT. JWT is a standard used to securely transfer information between two parties. The JWT is signed by your external application to securely send information to Tableau Server. The JWT references the connected app, the user that the session is being generated for, and the level of access the user should have.

A valid JWT includes the following information:

- Connected app ID, also known as the client ID, from Step 1
- Secret ID and secret value generated in Step 2
- Registered claims and header:

| Claim | Name      | Description or required value                              |
|-------|-----------|--|
| "kid" | Secret ID | Required (in header). The connected app's secret key iden- |

|  |                 |   |
|--|-----------------|---|
|  |                 | tifier.   |
| "iss"  | Issuer          | Required (in header). Unique issuer URI that identifies the trusted connect app and its signing key.  |
| "alg"  | Algorithm       | Required (in header). JWT signing algorithm. Only HS256 is supported.   |
| "sub"  | Subject         | User name of the authenticated Tableau Server user.   |
| "aud"  | Audience        | Value must be: "tableau".   |
| "exp"  | Expiration Time | A valid JWT must not be expired. The expiration time (in UTC) of the JWT must be within the configured maximum validity period. The maximum validity period can be configured using the tsm viz-portal.oauth.connected_apps.max_expiration_period_in_minutes command. |
| "jti"  | JWT ID          | Required as a claim. The JWT ID claim provides a unique identifier for the JWT and is case sensitive.   |
| "scp"<br><br><b>Important:</b> Do not use "scope". | Scope           | For <i>embedding workflows</i> , supported values include:<br><br>"tableau:views:embed"<br>"tableau:views:embed_authoring"<br>Added in  |

|  |   |
|--|---|
|  | <p>Tableau Server 2022.3</p> <p>"</p> <p><code>tableau:metrics:embed</code>"</p> <p>(Retired in Tableau Server 2023.3)</p> <p><code>"tableau:ask_data:embed"</code> (Added in Tableau Server 2023.1)</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>• Values must be passed as a list type.</li> <li>• For <code>tableau-views:embed</code> and <code>tableau-views:embed_authoring</code>, the scope respects users' permissions already configured in Tableau Server and allows users to interact with the tools in the embedded view if available in the original view.</li> <li>• We recommend the embed code exclude the toolbar parameter. For more information see Known issues (embedding workflows only) below.</li> </ul> <p><i>For REST API authorization</i></p> |
|--|---|

|  |   |
|--|---|
|  | <p><i>workflows</i>, see REST API methods that support JWT authorization.</p> <p>For <i>Metadata API workflows that use the REST API for authentication</i>, the only supported scope is <code>tableau-content:read</code>.</p> |
| <p><code>https://tableau.com/groups</code></p> | <p>For <i>embedding workflows</i> only.</p> <p>Value must match the name of one or more groups in Tableau Server. For more information, see the Dynamic group membership (embedding workflows only) section below.</p>          |

### Example JWTs

Here are example JWTs in both Java and Python languages. The Java and Python examples use the `nimbus-jose-jwt` library and the `PyJWT` library, respectively.

#### Java

```
import com.nimbusds.jose.*;
import com.nimbusds.jose.crypto.*;
import com.nimbusds.jwt.*;

import java.util.*;

...
```

```

String secret = "secretvalue";
String kid = "connectedAppSecretId";
String clientId = "connectedAppClientId";
List<String> scopes = new
ArrayList<>(Arrays.asList("tableau:views:embed"));
String username = "username";
JWSSigner signer = new MACSigner(secret);
JWSHeader header = new
JWSHeader.Builder(JWSAlgorithm.HS256).keyID(kid).customParam("iss",
clientId).build();
JWTClaimsSet claimsSet = new JWTClaimsSet.Builder()
    .issuer(clientId)
    .expirationTime(new Date(new Date().getTime() + 60 * 1000)) //ex-
pires in 1 minute
    .jwtID(UUID.randomUUID().toString())
    .audience("tableau")
    .subject("username")
    .claim("scp", scopes)

    .build();
SignedJWT signedJWT = new SignedJWT(header, claimsSet);
signedJWT.sign(signer);
model.addAttribute("token", signedJWT.serialize());

```

## Python

```

import jwt

token = jwt.encode(
    {
        "iss": connectedAppClientId,
        "exp": datetime.datetime.utcnow() + datetime.timedelta
(minutes=5),
        "jti": str(uuid.uuid4()),
        "aud": "tableau",
        "sub": user,

```

```
        "scp": ["tableau:views:embed", "tableau:metrics:embed"]
    },
    connectedAppSecretKey,
    algorithm = "HS256",
    headers = {
        'kid': connectedAppSecretId,
        'iss': connectedAppClientId
    }
)
```

After you've configured the JWT, when the code is run by your external application, it will generate a token.

## Step 4: Next steps

### For embedding workflows

After the JWT has been configured, you must add embed code to your external application. Ensure that you include the valid JWT you configured in Step 3 above in the web component that your external application calls.

For more information about embedding Tableau content, see one or both of the following:

- Embed metrics, see [Embed Metrics into Webpages](#) topic in the Tableau Help. (In Tableau Server 2023.3, Tableau retired the ability to embed metrics.)
- Embed Tableau views and metrics using the [Tableau Embedding API v3](#).

**Note:** For users to successfully authenticate when they access embedded content, browsers must be configured to allow third-party cookies.

### For REST API authorization workflows

After the JWT has been configured, you must add the valid JWT to the REST API Sign In request for authorized access. For more information, see [Access Scopes for Connected Apps](#).

## For Metadata API workflows

After the JWT has been configured, you must add the valid JWT to the REST API Sign In request. For more information, see [Access Scopes for Connected Apps](#).

### Manage a connected app

The Connected Apps page is where you can manage all the connected apps for your site. You can perform tasks such creating, deleting, and disabling connected apps; and revoking or generating new secrets if existing secrets have been compromised.

1. As a server admin, sign in to Tableau Server.
2. From the left pane, select **Settings > Connected Apps**.
3. Select the check box next to the connected app you want to manage and do one or more of the following:
  - **Generate a new secret** according to the rotation timeline specified by your organization's security policies. To generate an additional secret, click on the name of the connected app and then click the **Generate New Secret** button. A connected app can have a maximum of two secrets. Both secrets can be active at the same time, do not expire, and remain valid until deleted.
  - **Review the connected app details** by clicking the name of the connected app to see when the connected app was created, its ID, project and domain scopes, and its secrets.
  - **Change the project scope or domain**, in the Actions menu, select **Edit**. Make your changes and click **Update**.

**Note:** If you change the project or domain scopes and the embedded content doesn't exist in either the new project or new domain, the embedded view or metric is unable to display and users will see an error when accessing the embedded content.

- **Delete a secret** by clicking the connected app's name. On the connected app's page, click **Actions** next to the secret and select **Delete**. In the confirmation dialog box, select **Delete** again.

**Note:** If the connected app's secret is being used by an external application, the embedded view or metric is unable to display after the secret is deleted. For more information, see [Effects of disabling or deleting a connected app, or deleting a secret below](#).

- **Disable a connected app**, in the Actions menu, select **Disable**. If the connected app is being used by an external application, the embedded view or metric is unable to display after the connected app is disabled. For more information, see [Effects of disabling or deleting a connected app, or deleting a secret below](#).

**MyCo ...**  
 Status **Enabled** Created **Dec 1, 2021**

|   |   |                     |
|---|---|---------------------|
| Secret<br>(Maximum of 2)  | Generated on December 01, 2021          | Actions ▾           |
|   | ID 9ada8675-97ad-4af3-95c8-7f2edfc3dfe3 | Value *****         |
|   | Generated on December 01, 2021          | Actions ▾           |
|   | ID 5f95545c-feb1-47de-aaf5-c328f6160823 | Value *****         |
| <input type="checkbox"/> Delete a secret before generating a new one. |   | Generate New Secret |
| Client ID   | c1e941a9-9246-4759-bd8c-94e814711fb2    | Copy Client Id      |
| Access level  | MyCo                                    |                     |
| Domain allowlist  | *.myco.com                              |                     |

## Effects of disabling or deleting a connected app, or deleting a secret

To display embedded content to your user or enable REST API access through a connected app, the connected app must be enabled and its secret generated. If the connect app is being used in your external application and is either disabled or deleted, or its secret deleted or replaced, users will get a 403 error.

To avoid this issue, ensure the connect app is enabled and the JWT is using the correct secret ID and value.

## Access level (embedding workflows only)

You can select one of two project types when configuring a connected app's access level. The access level controls which content can be embedded.

- **All projects:** This option enables the content in all projects to be embedded
- **Only one project:** This option enables only the content in the specified project to be embedded. If the specified project contains nested projects, embedding content in those nested projects is not enabled.

### About multiple projects

Starting in Tableau Server 2024.2, you can enable the content in multiple projects for a connected app using the Tableau REST API only. To specify which projects, use the "project IDs" in either the [Create a Connected App](#) or [Update a Connected App](#) methods.

**Note:** When multiple projects are configured for your connected app, Tableau displays **Multiple projects** for the connected app's access level. If you select either **Only one project** or **All projects** and update the connected app, the "Multiple projects" option will no longer be visible. If you need to configure the connected app for multiple projects again, you must use the REST API.

## Domain allowlist rules (embedding workflows only)

The connected app's domain allowlist enables you to restrict access to embedded Tableau content to all domains or some domains; or exclude some domains or block all domains.

**Important:** We recommend using the domain allowlist as a security best practice to ensure Tableau content is only embedded in locations that you allow.

### Domain options

You can select one of two options when configuring a connected app's domain allowlist:

- **All domains:** As the default option, this option enables unrestricted access to embedded content.

- **Only specific domains:** This option gives you the ability to scope down access to embedded content. If you use this option, follow the formatting rules specified in the following section, Domain formatting.

## Domain formatting

In the domain allowlist text box, you can enter one or more domains using the formatting examples below.

**Note:** Domain formatting rules also apply when using the [Connect App methods](#) in the Tableau REST API.

Here are some formatting examples based on common scenarios:

| To specify...                   | Example                                     | Embedding access  |
|---------------------------------|---|---|
| Range of domains                | *.myco.com                                  | Embedded content is accessible from all subdomains under myco.com.  |
| All ports                       | myco.com:*                                  | Embedded content is access from all ports in myco.com.  |
| Specific port                   | myco.com:8080                               | Embedded content is accessible from port 8080 in myco.com only.   |
| Multiple discrete domains       | myco.com<br>events.myco.com<br>ops.myco.com | Embedded content is accessible from all three domains.<br><br><b>Note:</b> When specifying multiple domains, type each domain on a new line or separate domains with a space. For the REST API, domains must be separated by a space. |
| Secure traffic only             | https:                                      | Embedded content is securely accessible regardless of domain.   |
| Secure traffic to all ports for | https:*myco.com:*                           | Embedded content is securely accessible from all ports on all subdomains under  |

|                    |              |  |
|--------------------|--------------|--|
| a range of domains |              | myco.com.                              |
| No domains         | [no domains] | Access to embedded content is blocked. |

## Dynamic group membership (embedding workflows only)

Beginning in Tableau Server 2024.2, if connected apps are configured and the capability's setting is enabled, you can dynamically control group membership through custom claims included in the JWT sent by the external application.

When configured, during user authentication, the external application sends the JWT that contains two custom claims for group membership: `group` (`https://tableau.com/groups`) and `group names` (for example, "Group1" and "Group2") to assert the user into. Tableau validates the JWT and then enables access to the groups and the content whose permissions are dependent on those groups.

For more information, see [Dynamic group membership using assertions](#).

## Known issues (embedding workflows only)

There are a couple of known issues when using connected apps that will be addressed in a future release.

- **Toolbar features:** When embedded content has the toolbar parameter defined, not all toolbar features will work. To work around this issue, we recommend you hide the toolbar parameter like in the example below.

```
<tableau-viz id='tab-viz' src='https://<your_server>/t/<your_
site>/...'
      toolbar='hidden'>
</tableau-viz>
```

- **Published data sources:** Published data sources set to **Prompt User** for database credentials will not display. To work around this issue, if possible, we recommend data source owners embed their database credentials instead.
- **Embedded views on multiple sites:** In Tableau Server 2023.1 and earlier, switching between views on different sites in the same browser causes error **1008: Could not fetch secret for connect app**. To work around this issue, upgrade to Tableau Server 2023.3 or later.
- **Ask Data objects in embedded dashboards:** Ask Data objects in embedded dashboards will not load. (In Tableau Server 2024.2 will retire Ask Data.)
- **Metrics and domain allowlists:** Embedded metrics views will display despite access restrictions that might be specified in the connected apps' domain allowlists. **Note:** Metrics data accessed from toolbars of embedded views will work as expected. (In Tableau Server 2023.3, Tableau retired the ability to embed metrics.)

## Troubleshoot

You can refer to Troubleshoot Connected Apps - Direct Trust for errors that might be associated with the connected app and suggested troubleshooting steps.

## Configure Connected Apps with OAuth 2.0 Trust

As a Tableau Server admin, you can register one or more external authorization servers (EASs) to establish a trust relationship between your Tableau Server and the EAS using the OAuth 2.0 standard protocol.

When embedded Tableau content is loaded in your external application, a standard OAuth flow is used. After users successfully sign in to the IdP, they are then automatically signed in to Tableau Server. Follow the steps described below to register your EAS with Tableau Server.

### **Important:**

- Some of the procedures in this topic require configuration with third party software and services. We've made a best effort to verify the procedures to enable the EAS feature

on Tableau Server. However, third-party software and services might change or your organization might differ. If you encounter issues, refer to your third-party documentation for authoritative configuration details and support.

- To enable embedding through EAS, Tableau Server must be configured to use SSL for HTTP traffic.
- In order for the session token to be valid, the clocks of the external application and the server that hosts the external application must be set to Coordinated Universal Time (UTC). If either clock uses a different standard, the connected app will not be trusted.

## Step 1: Before you begin

To register an EAS with Tableau Server, you must have an EAS already configured. In addition, the EAS must send a valid JSON Web Token (JWT) that contains the registered claims and header listed in the table below.

| Claim | Name      | Description or required value  |
|-------|-----------|--|
| "kid" | Key ID    | Required (in header). A unique key identifier from the identity provider.  |
| "iss" | Issuer    | Required (in header or as a claim). Unique issuer URI that identifies the trusted connect app and its signing key.   |
| "alg" | Algorithm | Required (in header). JWT signing algorithm. Supported algorithm names are listed in the <a href="#">Class JWSSAlgorithm</a> page in the javadoc.io documentation. The signing algorithm can be configured using the <code>viz-portal.oauth.external_authorization_server.blocklisted_jws_algorithms</code> command. |

|       |                 |   |
|-------|-----------------|---|
| "sub" | Subject         | User name of the authenticated Tableau Server user.   |
| "aud" | Audience        | Value must be: "tableau"  |
| "exp" | Expiration Time | A valid JWT must not be expired. The expiration time (in UTC) of the JWT must be within the configured maximum validity period. Maximum validity period can be configured using vizportal.oauth.external_authorization_server.max_expiration_period_in_minutes command.   |
| "jti" | JWT ID          | The JWT ID claim provides a unique identifier for the JWT and is case sensitive.  |
| "scp" | Scope           | <p>For <i>embedding workflows</i>, supported values include:</p> <p>"tableau:views:embed"</p> <p>"tableau:views:embed_authoring" (Added in Tableau Server 2022.3)</p> <p>"tableau:metrics:embed" (Retired in Tableau Server 2023.3)</p> <p>"tableau:ask_data:embed"(Added in Tableau Server 2023.1. Will be retired in Tableau Server 2024.2)</p> |

|  |                                 |   |
|--|---------------------------------|---|
|  |                                 | <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>• Values must be passed as a list type.</li> <li>• For <code>tableau-views:embed</code>, the scope respects users' permissions already configured in Tableau Server and allows users to interact with the tools in the embedded view if available in the original view.</li> <li>• We recommend the embed code exclude the toolbar parameter. For more information see Known issues (embedding workflows only) below.</li> </ul> <p>For <i>REST API authorization workflows</i>, see REST API methods that support JWT authorization.</p> <p>For <i>Metadata API workflows that use the REST API for authentication</i>, the only supported scope is <code>tableau-content:read</code>.</p> |
| <p><code>https://tableau.com/groups</code></p> | <p>Dynamic group membership</p> | <p>For <i>embedding workflows</i> only.</p>   |

|  |  |   |
|--|--|---|
|  |  | Value must match the name of one or more groups in Tableau Server. For more information, see Dynamic group membership (embedding workflows only) section below. |
|--|--|---|

**Note:** The JWT claims above are documented in the [Registered Claim Names](#) section in the documentation distributed by the Internet Engineering Task Force (IETF) organization.

## Step 2: Register your EAS with Tableau Server

By registering your EAS with Tableau Server, you establish a trust relationship between the EAS and Tableau Server. This means when users access Tableau content embedded in your external application, they are redirected to authenticate with the IdP. The EAS generates the authentication token, which is passed to Tableau Server for verification. After the trust relationship is verified, access to the embedded content is granted users.

**Note:** Some EAS support the option to display a consent dialog that asks for users' approval for the application to access Tableau content. To ensure the best experience for your users, we recommend you configure your EAS to automatically consent to the external application's request on users' behalf.

### About site-level EAS

Beginning in Tableau Server 2024.2, you can configure site-level EAS. To register an EAS at the site-level, connected apps must be enabled in Tableau Server Manager (TSM).

#### Server-wide EAS

There are two ways you can register server-wide EAS: using the TSM web UI or using TSM CLI.

After registering the EAS, the established trust relationship applies to all sites on Tableau Server.

## Option 1: Using TSM web UI

1. As a Tableau Server admin, sign in to the Tableau Services Manager (TSM) web UI. For more information, see [Sign in to Tableau Services Manager Web UI](#).
2. Do *one* of the following:
  - In Tableau Server 2024.2 and later, navigate to User Identity & Access page > **Connected Apps** tab.
  - In Tableau Server 2023.3 and earlier, navigate to User Identity & Access page > **Authorization Server** tab.
3. Do *one* of the following:
  - In Tableau Server 2024.2 and later:
    - a. Select the **Enable connected apps** check box.
    - b. Select the second radio button, **Allow connected apps (configure at site level) and server-wide OAuth 2.0 trust (configure below)**.
    - c. In the **Issuer URL** text box, paste the issuer URL of the EAS.
    - d. Click the **Save Pending Changes** button.

The screenshot shows the 'User Identity & Access' configuration page in the Tableau web UI. The page title is 'User Identity & Access' with a subtitle 'Configure user access to Tableau Server and manage user identities. Learn more'. There are four tabs: 'Identity Store', 'Authentication Method', 'Trusted Authentication', and 'Connected Apps', with 'Connected Apps' being the active tab. Below the tabs, the section is titled 'Enable Connected Apps' with a subtitle 'Allow trusted relationships between Tableau Server and external applications using connected apps. Connected apps support both direct trust and OAuth 2.0 trust. Learn more'. There are two main options: a checked checkbox for 'Enable connected apps' and a radio button selected for 'Allow connected apps (configure at site level) and server-wide OAuth 2.0 trust (configure below)'. Below this, there is a text prompt: 'Enter information about the external authorization server that will generate the access token.' There are two input fields: 'Issuer URL' with the value 'https://dev-12345678.okta.com/oauth2/ausd0' and 'JWKS URI' with the value 'Optional'. At the bottom, there are two buttons: 'Cancel' and 'Save Pending Changes'.

- In Tableau Server 2023.3 and earlier:

- a. Select the **Enable OAuth access for embedded content** check box.
- b. In the **Issuer URL** text box, paste the issuer URL of the EAS.
- c. Click the **Save Pending Changes** button.

**User Identity & Access**  
Configure user access to Tableau Server and manage user identities. [Learn more](#)

Identity Store   Authentication Method   Trusted Authentication   **Authorization Server**

**Register External Authorization Server**  
Establish trusted relationship with an external authorization server. [Learn more](#)

Enable OAuth access for embedded content

Server-wide trust

Enter information about the external authorization server that will generate the access token.

Issuer URL  

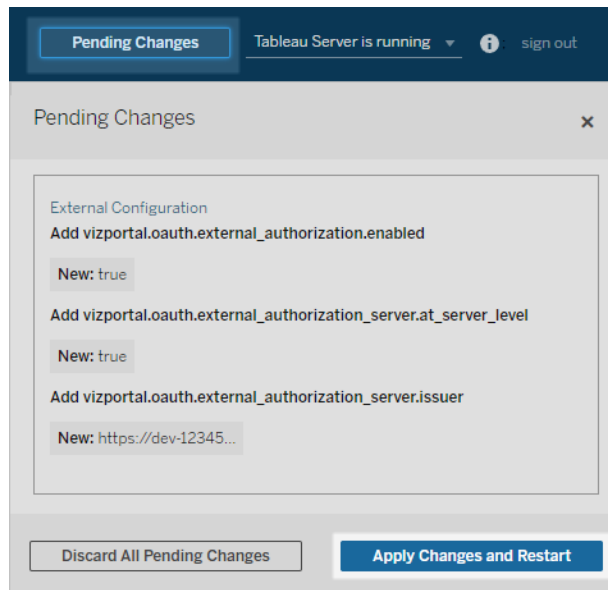

JWKS URI  

4. When finished, do the following:
  - a. In the upper-right corner of the page, click the **Pending Changes** button.
  - b. In the bottom-right corner of the page, click the **Apply Changes and Restart**

button to stop and restart Tableau Server.

## Option 2: Using TSM CLI

1. Open a command prompt as an admin on the initial node (where TSM is installed) in the cluster.
2. Run the following commands:

```
tsm configuration set -k vizportal.oauth.external_authorized_apps.enabled -v true
tsm configuration set -k vizportal.oauth.external_authorized_apps.issuer -v "<issuer_url_of_EAS>"
tsm restart
```

### Site-level EAS

Beginning in Tableau Server 2024.2, you can register one or more EASs for a site. After registering the EAS at the site level, the established trust relationship applies to the site only.

**Note:** A prerequisite to configuring site-level EAS is that connected apps is enabled in TSM.

## Step 1: Enable connected apps

1. As a Tableau Server admin, sign in to the Tableau Services Manager (TSM) web UI.  
For more information, see [Sign in to Tableau Services Manager Web UI](#).
2. Navigate to User Identity & Access page > **Connected Apps** tab.
3. Select the **Enable connected apps** check box.
4. Do *one* of the following:
  - Select the first radio button, **Allow connected apps (configure at site level)** to enable registering EASs at the site-level only.

- (Default) Select the second radio button, **Allow connected apps (configure at site level) and server-wide OAuth 2.0 trust (configure below)** to enable registering EASs at both the site-level and server-wide. If you choose this option, ensure the issuer URL specified at the site-level is different from the server-wide

issuer URL.

The screenshot shows the 'User Identity & Access' configuration page in Tableau Server. The 'CONFIGURATION' tab is active, and the 'Connected Apps' sub-tab is selected. The page title is 'User Identity & Access' with a subtitle 'Configure user access to Tableau Server and manage user identities. Learn more'. Below the title are four tabs: 'Identity Store', 'Authentication Method', 'Trusted Authentication', and 'Connected Apps'. The 'Connected Apps' tab is active. The main content area is titled 'Enable Connected Apps' and includes a description: 'Allow trusted relationships between Tableau Server and external applications using connected apps. Connected apps support both direct trust and OAuth 2.0 trust. Depending on the trust type, connected apps are configurable at the server (in TSM) or site (in site settings) level. Learn more'. There are three radio buttons: 'Enable connected apps' (checked), 'Allow site-level connected apps', and 'Allow site-level connected apps and server-wide connected apps with OAuth 2.0 trust (configure below)'. Below the radio buttons is a text prompt: 'Enter information about the external authorization server that will generate the access token.' There are two text input fields: 'Issuer URL' (marked as 'Required') and 'JWKS URI' (marked as 'Optional'). At the bottom of the form are two buttons: 'Cancel' and 'Save Pending Changes'.

5. Click the **Save Pending Changes** button.
6. When finished, do the following:
  - a. In the upper-right corner of the page, click the **Pending Changes** button.
  - b. In the bottom-right corner of the page, click the **Apply Changes and Restart** button to stop and restart Tableau Server.

## Step 2: Register the EAS

1. As a Tableau Server admin, sign in to Tableau Server.
2. From the left pane, select **Settings > Connected Apps**.
3. Click the New Connected App button drop-down arrow and select **OAuth 2.0 Trust**.
4. In the Create Connected App dialog box, do the following:
  - a. In the **Name** text box, enter a name for the connected app.
  - b. In the **Issuer URL** text box, paste the issuer URL of the EAS.

- c. Select the **Enable connected app**. For security purposes, a connected app is set to disabled by default when created.
- d. When finished, click the **Create** button.

**Create Connected App**

Establish a trusted relationship with an external authorization server. Enter information about the external authorization server that will generate the JSON web token (JWT). [Learn more](#)

Connected app name:

Issuer URL:

JWKS URI:

Enable connected app

5. After the connected app is created, copy the connected app's site ID. The site ID is used for the JWT's "aud" (Audience) claim described in Step 1 above.

## Step 3: Next steps

### For embedding workflows

After configuring Tableau Server to use your EAS, you must add embed code to your external application. Ensure that you include the valid JWT generated by your EAS, as described in Step 1, in the web component that your external application calls.

For more information about embedding Tableau content, see one or both of the following:

- Embed metrics, see [Embed Metrics into Webpages](#) topic in the Tableau Help. (In Tableau Server 2023.3, Tableau retired the ability to embed metrics.)

- Embed Tableau views and metrics using the [Tableau Embedding API v3](#).

**Note:** For users to successfully authenticate when they access embedded content, browsers must be configured to allow third-party cookies.

Control where content can be embedded using domain allowlist for embedding

Starting in Tableau Server 2023.3, you and your users can control whether Tableau content can be embedded without restriction or restricted to certain domains using the Update Embedding Settings for Site method in Tableau REST API.

By default, the `unrestrictedEmbedding` site setting for embedding is set to `true` to allow unrestricted embedding. Alternatively, you and your users can set the setting to `false` and specify the domains where Tableau content in external applications can be embedded using the `allowList` parameter.

For more information, see one or both of the following:

- [Update Embedding Settings for Site](#) in the Tableau REST API Help
- [Tableau Site Setting for Embedding](#) in the Tableau Embedding API v3 Help.

### For REST API authorization workflows

After the JWT has been configured, you must add the valid JWT to the REST API Sign In request for authorized access. For more information, see [Access Scopes for Connected Apps](#).

### For Metadata API workflows

After the JWT has been configured, you must add the valid JWT to the REST API Sign In request. For more information, see [Access Scopes for Connected Apps](#).

### Dynamic group membership (embedding workflows only)

Beginning in Tableau Server 2024.2, if connected apps are configured and the capability's setting is enabled, you can dynamically control group membership through custom claims included in the JWT sent by the external application.

When configured, during user authentication, the external application sends the JWT that contains two custom claims for group membership: `group` (<https://tableau.com/groups>) and group names (for example, "Group1" and "Group2") to assert the user into. Tableau validates the JWT and then enables access to the groups and the content whose permissions are dependent on those groups.

For more information, see [Dynamic group membership using assertions](#).

## Known issues (embedding workflows only)

There are a couple of known issues when using connected apps that will be addressed in a future release.

- **Toolbar features:** When embedded content has the toolbar parameter defined, not all toolbar features will work. To work around this issue, we recommend you hide the toolbar parameter like in the example below.

```
<tableau-viz id='tab-viz' src='https://<your_server>/t/<your_
site>/...'
      toolbar='hidden'>
</tableau-viz>
```

- **Published data sources:** Published data sources set to **Prompt User** for database credentials will not display. To work around this issue, if possible, we recommend data source owners embed their database credentials instead.
- **Embedded views on multiple sites:** In Tableau Server 2023.1 and earlier, switching between views on different sites in the same browser causes error **1008: Could not fetch secret for connect app**. To work around this issue, upgrade to Tableau Server 2023.3 or later.

## Troubleshoot

When embedded content fails to display in your external application or Tableau REST API authorization fails, you can use a browser's developer tools to inspect and identify error codes that might be associated with the EAS feature enabled on Tableau Server .

Refer to the table below to review the description of the error code and potential resolution.

| Error code | Summary               | Description                     | Potential resolution or explanation   |
|------------|-----------------------|---------------------------------|---|
| 5          | SYSTEM_USER_NOT_FOUND | Tableau user could not be found | To resolve this issue, verify the 'sub' (Subject) claim value in the JWT is "username" for the authenticated Tableau Server. This value is case sensitive.  |
| 16         | LOGIN_FAILED          | Login failed                    | <p>This error is typically caused by one of the following claim issues in the JWT:</p> <ul style="list-style-type: none"> <li>• The 'exp' (Expiration Time) exceeds the default maximum validity period. To resolve this issue, review <b>registered claims</b> required for a valid JWT and ensure the correct value is used. To change the maximum validity period, you can use the viz-portal.oauth.external_authorization_server.max_expiration_period_in_minutes command.</li> <li>• The 'sub' (Subject) is calling an unknown user. To resolve this issue, verify the 'sub' claim is "username". This value is case sensitive.</li> </ul> |

|       |   |                                   |  |
|-------|---|-----------------------------------|--|
| 67    | FEATURE_NOT_ENABLED                       | On-demand access is not supported | On-demand access is available through licensed Tableau Cloud sites only.   |
| 10081 | COULD_NOT_RETRIEVE_IDP_METADATA           | Missing EAS metadata endpoint     | To resolve this issue, verify the EAS is configured correctly and the correct issuer is being called.  |
| 10082 | AUTHORIZATION_SERVER_ISSUER_NOT_SPECIFIED | Missing issuer                    | To resolve this issue, verify the correct issuer is being called. To change the issuer URL, you can use the viz-portal.oauth.external_authorization_server.issuer command.   |
| 10083 | BAD_JWT                                   | JWT header contains issues        | The 'kid' (Secret ID) or 'clientId' (Issuer) claims are missing from the JWT header. To resolve this issue, ensure this information is included.   |
| 10084 | JWT_PARSE_ERROR                           | JWT contains issues               | To resolve this issue, verify the following: <ul style="list-style-type: none"> <li>• The 'aud' (Audience) value referenced in the JWT uses the "tableau" value. This value is case sensitive.</li> <li>• The 'aud' (Audience) and 'sub' (Subject) are included in the JWT.</li> </ul> |
| 10085 | COULD_NOT_FETCH_JWT_KEYS                  | JWT could not find keys           | Could not find the secret.<br>To resolve this issue, verify the  |

|       |  |   |   |
|-------|--|---|---|
|       |  |   | <p>correct issuer is being called.</p> <p>To change the issuer URL, you can use the viz-portal.oauth.external_authorization_server.issuer command.</p>  |
| 10087 | BLOCKLISTED_JWS_ALGORITHM_USED_TO_SIGN | Issue with the JWT signing algorithm            | <p>To resolve the issue, you can remove the signing algorithm. For more information, see viz-portal.oauth.external_authorization_server.blocklisted_jws_algorithms.</p>   |
| 10088 | RSA_KEY_SIZE_INVALID                   | Issue with JWT signing requirements             | <p>To resolve this issue, verify with the EAS or IdP the JWT is being signed with an RSA key size of 2048.</p>  |
| 10091 | JTI_ALREADY_USED                       | Unique JWT required                             | <p>The JWT has already been used in the authentication process. To resolve this issue, the EAS or IdP must generate a new JWT.</p>  |
| 10092 | NOT_IN_DOMAIN_ALLOW_LIST               | Domain of the embedded content is not specified | <p>To resolve this issue, ensure the <code>unrestrictedEmbedding</code> setting is set to <code>true</code> or <code>domainAllowlist</code> parameter includes the domains where Tableau content is embedded using the <a href="#">Update Embedding Settings for Site</a> method in the Tableau REST API.</p> |
| 10094 | MISSING_                               | Missing JWT ID                                  | <p>To resolve this issue, verify the</p>  |

|       |   |                              |   |
|-------|---|------------------------------|---|
|       | REQUIRED_JTI  |                              | 'jti' (JWT ID) is included in the JWT.  |
| 10096 | JWT_EXPIRATION_EXCEEDS_CONFIGURED_EXPIRATION_PERIOD |                              | The 'exp' (Expiration Time) exceeds the default maximum validity period. To resolve this issue, review <a href="#">registered claims</a> required for a valid JWT and ensure the correct value is used. To change the maximum validity period, you can use the <code>vizportal.oauth.external_authorization_server.max_expiration_period_in_minutes</code> command. |
| 10097 | SCOPES_MALFORMED                                    | Issues with scopes claim     | This error can occur when the 'scp' (Scope) claim is either missing from the JWT or not passed as a list type. To resolve this issue, verify 'scp' is included in the JWT and passed as a list type. For troubleshooting help with a JWT, see <a href="#">Debugger</a> on the auth0 site.   |
| 10098 | JWT_UNSIGNED_OR_ENCRYPTED                           | JWT is unsigned or encrypted | Tableau does not support an unsigned or encrypted JWT.  |
| 10099 | SCOPES_MISSING_IN_JWT                               | Missing scopes claim         | The JWT is missing the required 'scp' (Scope) claim. To resolve this issue, verify 'scp' is included in the JWT. For troubleshooting help with a JWT, see <a href="#">Debugger</a> on the auth0 site.   |

|       |                        |                          |  |
|-------|------------------------|--------------------------|--|
| 10100 | JTI_PERSISTENCE_FAILED | Unexpected JWT ID error  | There was an unexpected error with the 'jti' (JWT ID). To resolve this issue, a new JWT with a new 'jti' must be generated.                                |
| 10103 | JWT_MAX_SIZE_EXCEEDED  | JWT exceeds maximum size | This error can occur when JWT size exceeds 8000 bytes. To resolve this issue, make sure that only the necessary claims are being passed to Tableau Server. |

### Access Scopes for Connected Apps

Starting with Tableau Server version 2022.3, using Tableau connected apps, you can programmatically call and access the Tableau REST API through your custom application on behalf of Tableau Server users. Access to the REST API is enabled by a JSON Web Token (JWT) defined as part of the initial Sign In request. The JWT must contain scopes that define the REST API methods that are available to your custom application and its users through the connected app.

Authorize access to the REST API using connected apps to:

- Enhance security—using a JWT as a bearer token is inherently more secure than storing and managing admin user passwords through .env files in vaults
- Enhance efficiency—using a JWT as a bearer token enables a simplified impersonation with one request to the Sign In endpoint instead of two requests
- Extend and automate complex Tableau integrations and backend queries—such as dynamic content retrieval and advanced filtering

### Scope actions

Connected apps use scopes that grant access to content or administrative actions through the REST API methods that support JWT authorization (below). A scope is a colon-separated string that starts with the namespace `tableau`, followed by the Tableau resource that access

is being granted to, such as `datasources`, and ends with the action that is allowed on the resource, such as `update`.

The action a scope can take include:

- `create`
- `read`
- `run`
- `update`
- `download`
- `delete`

For example, a scope that allows your custom application to call the [Update Data Source](#) method looks like:

```
tableau:datasources:update
```

### Scope types

The type of scope you use depends on the content or administrative action that you want to enable. Scopes generally fall into one of the following types: content read, individual, wild-card, and cross-category.

- **Content read scope:** The content read scope, `tableau:content:read`, enables supported GET methods for Tableau content. When you use this scope, you enable actions across REST API categories. More specifically, using this scope you enable GET methods for data sources, metrics, views, workbooks, projects, and sites. Starting in Tableau Server 2023.3, you also specify this scope in a JWT that will be used to create a credentials token for use with the [Metadata API](#).

**Note:** To enable GET methods for administrative actions, like users and groups, you can use their individual scopes.

- **Individual scopes:** To enable supported content and administrative actions, you can use their individual scopes. An individual scope is generally associated with a single method and REST API category.

### Examples:

- To enable publish or update a data source action, you can use the individual `tableau:datasources:create` or `tableau:datasources:update` scope, respectively.
- For administrative actions like add or remove users, you can use the individual `tableau:users:create` or `tableau:users:delete` scope, respectively.

**Note:** There are some individual scopes that can enable actions across REST API categories. For example, `tableau:views:download` enables actions in the view data and workbooks REST API categories.

- **Wildcard (\*) scopes:** For certain scopes, you can replace the action with the wildcard character (\*) to enable supported actions within a specific REST API category.

### Examples:

- You can use the `tableau:projects:*` wildcard scope to enable the create, delete, update actions in the projects REST API category.
- You can use the `tableau:users:*` wildcard scope to enable the get/list, add, delete, update actions in the users REST API category.
- You can use the `tableau:tasks:*` wildcard scope to enable the get/list, add, delete, update and run actions of extract and subscriptions REST API categories. In addition, this scope enables update data source (if an extract) and update workbook.
- **Cross-category scopes:** In addition to the content read scope, there are a few additional scopes that, if used, enable supported actions across different REST API categories.

### Examples:

- If using the `tableau:tasks:run` scope, you enable actions in the data sources and workbooks REST API categories.
- Again, if using the `tableau:views:download` scope, you enable actions in the view data and workbook REST API categories.
- If using permissions scopes like `tableau:permissions:update` or `tableau:permissions:delete`, you enable actions in the data sources, workbooks, and projects REST API categories.

Summary of how to authorize REST API access

The following list summarizes the steps to request access to the REST API through a JWT:

1. **Create a connected app** using one of the following methods:
  - Configure Connected Apps with Direct Trust
  - Configure Connected Apps with OAuth 2.0 Trust
2. **Generate a valid JWT**—at runtime your custom application will generate a valid JWT, configured with the scopes you have included
3. **Make a Sign In request**—your custom application will make a Sign In request using the JWT to return a Tableau credentials token and site ID (LUID)
4. **Use the Tableau access token in subsequent requests**—in subsequent REST API calls, use 1) the Tableau credentials token as the `X-Tableau-Auth` header value and 2) the site ID (LUID) in the request URI

## Example

For example, suppose you create a connected app using direct trust. Using direct trust, your custom application that calls the REST API generates a valid JWT using the client ID and client secret generated by the connected app.

### Scopes in the JWT

To successfully authorize access to the REST API, the JWT must also contain the scopes that define the REST API capabilities. For example, to enable various data source-related methods, you might include the following scopes in the JWT:

```
"tableau-
:con-
tent:read", "t-
ableau-
:data-
sources:cre-
ate", "t-
ableau-
```

## Tableau Server on Linux Administrator Guide

```
:data-  
sources:update","tableau:datasources:download","tableau:tasks:run"
```

Or

```
"tableau:content:read","tableau:datasources:*","tableau:tasks:run"
```

**Note:** Scope values must be passed as a list type.

### Sign In Request URI

To make a call to the REST API, your custom application must first make a Sign In request to generate a Tableau credentials token.

```
POST https://myco/api/3.17/auth/signin
```

### Request body

To authorize REST API access using a JWT, the Sign In request body must contain the valid JWT like the example below.

```
<tsRequest>  
  <credentials jwt-  
="eyJ-  
pc3MiOiI4ZTFiNzE3Mi0zOWMzLTRhMzItODg3ZS1mYzJiNDExOWY1NmQiLCJh-  
bGciOiJIUzI1NiIsImt-  
pZCI6ImIwMTE1YmY5LTNhNGItNGM5MS1iMDA5LWNmMGxNzBimWE1NiJ9.eyJh-  
dWQiOiJ0YWJsZWFlIi-  
wic3ViI-  
joicmlvaGFuQHRhYmxlYXUuY29tIi-  
wic2NwIjp-  
bInRhYmxlYXU6c2l0ZXM6cmVhZCJdLCJp-  
c3MiOiI4ZTFiNzE3Mi0zOWMzLTRhMzItODg3ZS1mYzJiNDExOWY1NmQiLCJleHAiOjE2-  
NDg2Njg0Mzk-  
sIm-  
p0aSI6IjY1ZWZmMmYxLTNmZTgtNDc5Ny1hZmRiLTMyODMzZDVmZGJkYSJ9.mUv2o4gtB-  
TrMVLEXY5XTpzDQTGvfE2LGi-3O2vdGfT8">  
  <site contentUrl="mycodotcom"/>
```

```

    </credentials>
</tsRequest>

```

## Response body

The Sign In request produces the following response body, which includes the Tableau credentials token.

```

<tsResponse>
  <credentials token="12ab34cd56ef78ab90cd12ef34ab56cd">
    <site id="9a8b7c6d5-e4f3-a2b1-c0d9-e8f7a6b5c4d" contentUrl="" />
    <user id="9f9e9d9c-8b8a-8f8e-7d7c-7b7a6f6d6e6d" />
  </credentials>
</tsResponse>

```

After the Tableau access token is generated, add the Tableau credentials token to the header of all subsequent REST API requests.

## Header

```
X-Tableau-Auth:12ab34cd56ef78ab90cd12ef34ab56cd
```

All subsequent REST API requests using the Tableau access token are then bounded by the scopes in the JWT.

REST API methods that support JWT authorization

The following scopes can be associated with the connected app to define access and methods your custom application can have to the [REST API](#) on users' behalf.

## Notes:

- For other REST API capabilities not listed in the table below, you can use other authorization mechanisms to access the methods. For more information, see [Authentication Methods](#) in the Tableau REST API Help.
- Both the [Sign In](#) and [Sign Out](#) methods are supported by JWT authorization but do not require scopes to use beginning in Tableau Server 2023.3.

- For scopes supported by the Embedding API v3, see one of the following:
  - Configure Connected Apps with Direct Trust
  - Configure Connected Apps with OAuth 2.0 Trust

## Wildcard (\*) scopes

Wildcard scopes use the wildcard character (\*) instead of a specific action, to enable multiple supported actions within a specific REST API category. These include:

| Scope   | Methods enabled  |
|---|--|
| tableau:datasources:*                           | Enables create, update, and update connection data source methods.                         |
| tableau:metrics:*                               | Enables query, update, and delete metrics actions.   |
| tableau:workbooks:*                             | Enables publish, update, download, and preview image workbook actions.                     |
| tableau:groups:*                                | Enables create, query, update, and delete groups actions.                                  |
| tableau:projects:*                              | Enables create, delete, and update projects methods.                                       |
| tableau:users:*                                 | Enables get/list, add, delete, and update users methods.                                   |
| tableau:tasks:*                                 | Enables get/list, add, delete, update and run methods for extracts and subscription tasks. |
| <b>Note:</b> This scope is also cross-category. | Enables update methods for data sources for workbooks.                                     |

## Cross-category scopes

Cross-category scopes enable multiple supported actions across multiple REST API categories. These include:

| Scope   | Methods enabled  |
|---|--|
| <code>tableau:content:read</code>   | Enables read/list methods for Tableau content, including data sources, metrics, views, workbooks, projects, and sites.                                   |
| <code>tableau:tasks:run</code>  | Enables run methods for data sources, workbooks, and extracts.   |
| <code>tableau:views:download</code>                                       | Enables download methods for view data and workbooks.  |
| <code>tableau:tasks:*</code><br><b>Note:</b> This scope is also wildcard. | Enables get/list, add, delete, update and run methods for extracts and subscription tasks.<br><br>Enables update methods for data sources for workbooks. |

## Individual scopes

| Method                   | Scope             | Description  |
|--------------------------|-------------------|--|
| (Methods without scopes) | (None)            | When no scopes are defined in the JWT, access to the REST API is denied. |
| Sign in                  | (No scope needed) | Signs you in as a user on the specified site on Tableau Server.          |
| Sign out                 | (No scope needed) | Signs you out of the current session.                                    |

| Method               | Scope                              | Description   |
|----------------------|------------------------------------|---|
| (Content read scope) | <code>tableau:content:read</code>  | Enables read/list actions for Tableau content: data sources, metrics, views, workbooks, and projects. |
| <b>Labels</b>        |                                    |   |
| Delete Label         | <code>tableau:labels:delete</code> | Deletes a data label by its LUID.   |
| Delete Labels        | <code>tableau:labels:delete</code> | Deletes the data labels on one or more assets.  |
| Get Label            | <code>tableau:labels:read</code>   | Gets a data label by its LUID.  |
| Get Labels           | <code>tableau:labels:read</code>   | Displays information about the data labels on one or more assets.                                     |
| Update Label         | <code>tableau:labels:update</code> | Updates a label by its LUID.  |

| Method   | Scope                                   | Description  |
|--|---|--|
| Update Labels                                    | <code>tableau:labels:update</code>      | Creates or updates labels on one or more assets.   |
| <b>Data sources</b>                              |   |  |
| (All <code>tableau-datasources: methods</code> ) | <code>tableau:datasources:*</code>      | Enables create data source, update data source, and update data source connection methods. |
| Publish data source                              | <code>tableau:datasources:create</code> | Publish a data source to a site or append data to an existing published data source.       |
| Query data source                                | <code>tableau:content:read</code>       | Get information about a published data source.   |
| Query data sources                               | <code>tableau:content:read</code>       | Get information about all published data source on a site.                                 |

| Method                                    | Scope                                   | Description   |
|---|---|---|
| Query data source connections             | <code>tableau:content:read</code>       | Get server address, port, user name, or password information about a published data source. |
| Update data source                        | <code>tableau:datasources:update</code> | Update owner, project or certification status of the data source.                           |
| Update data source connection             | <code>tableau:datasources:update</code> | Update server address, port, user name, or password of the data source connection.          |
| Update data source now                    | <code>tableau:tasks:run</code>          | Run extract refresh.  |
| <b>Extracts</b>                           |   |   |
| (All <code>tableau:tasks:</code> methods) | <code>tableau:tasks:*</code>            | Enables create, delete, get, list, run, and update refresh actions for extracts, sub-       |

| Method   | Scope                             | Description   |
|--|-----------------------------------|---|
|  |                                   | scriptions, update data source (for data sources with extracts), and update workbook methods. |
| List extract refresh tasks in site   | <code>tableau:tasks:read</code>   | List the extract refreshes tasks configured for in a site.                                    |
| Run extract refresh task   | <code>tableau:tasks:run</code>    | Runs an extract refresh task.   |
| <b>Flows</b>   |                                   |   |
| Publish flow   | <code>tableau:flows:create</code> | Publish a flow.   |
| <h2>Metrics</h2> <h3>Retirement of the legacy metrics feature</h3> <p>Tableau's legacy metrics feature was retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. In October 2023, Tableau retired the ability to embed legacy metrics in Tableau Cloud and in Tableau Server version 2023.3. With Tableau Pulse, we've developed an improved experience to track metrics and ask questions of your data. For more information, see <a href="#">Create Metrics with Tableau Pulse</a> to learn about the new experience and <a href="#">Create and Troubleshoot</a></p> |                                   |   |

| Method  | Scope                                 | Description   |
|---|---------------------------------------|---|
| <b>Metrics (Retired)</b> for the retired feature. |                                       |   |
| (All <code>tableau:metrics:</code> methods)       | <code>tableau:metrics:*</code>        | Enables query, update, and delete metrics actions.                      |
| (All <code>tableau:metrics:</code> methods)       | <code>tableau:metrics:*</code>        | Enables query, update, and delete metrics actions.                      |
| Get metric  | <code>tableau:content:read</code>     | Get a metric.   |
| Delete metric                                     | <code>tableau:metrics:delete</code>   | Delete a metric.  |
| List metrics                                      | <code>tableau:content:read</code>     | Get list of metrics for a site.   |
| Query metrics data                                | <code>tableau:metrics:download</code> | Get underlying data of a metric in comma-separated value (.csv) format. |
| Update metric                                     | <code>tableau:metrics:update</code>   | Update owner, project, suspend status, and name of the metric.          |

| Method                                    | Scope                             | Description   |
|---|-----------------------------------|---|
| <b>Subscriptions</b>                      |                                   |   |
| (All <code>tableau:tasks:</code> methods) | <code>tableau:tasks:*</code>      | Enables create, delete, get, list, run, and update refresh actions for extracts, subscriptions, update data source (for data sources with extracts), and update workbook methods. |
| Create subscription                       | <code>tableau:tasks:create</code> | Create a subscription.  |
| Delete subscription                       | <code>tableau:tasks:delete</code> | Delete a subscription.  |
| Get subscription                          | <code>tableau:tasks:read</code>   | Gets the details of a subscription.   |
| List subscriptions                        | <code>tableau:tasks:read</code>   | Lists subscriptions in a site.  |
| Update subscription                       | <code>tableau:tasks:update</code> | Updates a subscription.   |
| <b>Views</b>                              |                                   |   |

| Method                | Scope                               | Description   |
|-----------------------|-------------------------------------|---|
| Delete custom view    | <code>tableau:views:update</code>   | Delete the specified custom view.                             |
| Get custom view       | <code>tableau:content:read</code>   | Get the details of a specified custom view.                   |
| Get custom view image | <code>tableau:views:download</code> | Download a .png format image file of a specified custom view. |
| Get view              | <code>tableau:content:read</code>   | Get details about a view.                                     |
| Get view by path      | <code>tableau:content:read</code>   | Get details for all views on a site using the specified name. |
| List custom views     | <code>tableau:content:read</code>   | Get a list of custom views on a site.                         |
| Query view data       | <code>tableau:views:download</code> | Get a view rendered in comma-separated value (.csv) format.   |
| Query view PDF        | <code>tableau:views:download</code> | Get a view as a PDF (.pdf) file.                              |

| Method  | Scope                                 | Description  |
|---|---------------------------------------|--|
| Query view image                              | <code>tableau:views:download</code>   | Get a view as an image (.png) file.                                    |
| Query views for site                          | <code>tableau:content:read</code>     | Get all views for a site.  |
| Query views for workbook                      | <code>tableau:content:read</code>     | Get all views for the specified workbook.                              |
| Query view preview image                      | <code>tableau:views:download</code>   | Get the thumbnail image (.png) of the view.                            |
| Update custom view                            | <code>tableau:views:update</code>     | Change the owner or name of an existing custom view.                   |
| <b>Workbooks</b>                              |                                       |  |
| (All <code>tableau-workbooks:methods</code> ) | <code>tableau:workbooks:*</code>      | Enables publish, update, download, and preview image workbook actions. |
| Publish workbook                              | <code>tableau:workbooks:create</code> | Publish a workbook (.twb or .twbx).                                    |

| Method                       | Scope                                    | Description  |
|------------------------------|--|--|
| Query workbook               | <code>tableau:content:read</code>        | Get a specified workbook and its details.                        |
| Query workbook for site      | <code>tableau:content:read</code>        | Get a list of workbooks published to a site.                     |
| Query workbook preview image | <code>tableau:workbooks:download</code>  | Get the thumbnail image (.png) of the workbook.                  |
| Update workbook              | <code>tableau:workbooks:update</code>    | Modify an existing workbook.                                     |
| Update workbook connection   | <code>tableau:workbooks:update</code>    | Update the connection information.                               |
| Update workbook now          | <code>tableau:tasks:run</code>           | Initiate a workbook refresh outside of a scheduled task.         |
| <b>Publish</b>               |  |  |
| Append to file upload        | <code>tableau:file_uploads:create</code> | Upload a block of data and append it to the data that is already |

| Method                          | Scope   | Description   |
|---------------------------------|---|---|
|                                 |   | uploaded - to be used after an upload has been initiated using the "initiate file upload" method. |
| Initiate file upload            | <code>tableau:file_upload-<br/>s:create</code>  | Initiate the upload process of a file.  |
| <b>Download</b>                 |   |   |
| Download data source            | <code>tableau-<br/>:datasources:download</code> | Download the data source (.tdsx).   |
| Download view crosstab<br>Excel | <code>tableau:views:download</code>             | Download an Excel (.xlsx) file containing crosstab data from the view.                            |
| Download workbook               | <code>tableau:workbooks:download</code>         | Download a workbook (.twb or .twbx).  |
| Download workbook revision      | <code>tableau:workbooks:download</code>         | Download a specific version of the workbook (.twb or .twbx).                                      |

| Method                                   | Scope                               | Description   |
|--|-------------------------------------|---|
| Download workbook PDF                    | <code>tableau:views:download</code> | Download a PDF (.pdf) file containing images of the sheets in the workbook.         |
| Download workbook PowerPoint             | <code>tableau:views:download</code> | Download a PowerPoint (.pptx) file containing slides of the sheets in the workbook. |
| <b>Users</b>                             |                                     |   |
| (All <code>tableau:users</code> methods) | <code>tableau:users:*</code>        | Enables add, query, update, and remove users actions.                               |
| Add user to group                        | <code>tableau:groups:update</code>  | Add a user to a group.  |
| Add user to site                         | <code>tableau:users:create</code>   | Add a user and assign the user to a site.   |
| Get users in group                       | <code>tableau:groups:read</code>    | Get a list of users in a group.   |
| Get users on site                        | <code>tableau:users:read</code>     | Get all users   |

| Method                                     | Scope                              | Description   |
|--|------------------------------------|---|
|  |                                    | on a site.  |
| Query user on site                         | <code>tableau:users:read</code>    | Get a user on a site.                                     |
| Remove users from group                    | <code>tableau:groups:update</code> | Remove a user from a group.                               |
| Remove user from site                      | <code>tableau:users:delete</code>  | Remove the user from a site.                              |
| <b>Groups</b>                              |                                    |   |
| (All <code>tableau:groups:</code> methods) | <code>tableau:groups:*</code>      | Enables create, query, update, and delete groups actions. |
| Create group                               | <code>tableau:groups:create</code> | Create a group.   |
| Delete group                               | <code>tableau:groups:delete</code> | Delete a group.   |
| Get groups for user                        | <code>tableau:users:read</code>    | Get a list of groups that a user belongs to.              |
| Query groups                               | <code>tableau:groups:read</code>   | Get a list of groups on a site.                           |
| Update group                               | <code>tableau:groups:update</code> | Update a group.   |

| Method                                  | Scope                      | Description  |
|---|----------------------------|--|
| <b>Projects</b>                         |                            |  |
| (All tableau-<br>:projects: methods)    | tableau:projects:*         | Enables create, update, and delete projects actions.               |
| Create project                          | tableau:projects:create    | Create a project.  |
| Delete project                          | tableau:projects:delete    | Delete a project.  |
| Query project                           | tableau:content:read       | Get a list of projects.  |
| Update project                          | tableau:projects:update    | Update the name, description, or project hierarchy of the project. |
| <b>Permissions</b>                      |                            |  |
| (All tableau-<br>:permissions: methods) | tableau:permissions:*      | Enables add, query, update, delete permissions actions.            |
| Add data source permissions             | tableau:permissions:update | Add permissions to a data source for a Tableau Server user or      |

| Method                         | Scope                      | Description   |
|--------------------------------|----------------------------|---|
|                                |                            | group.  |
| Add default permissions        | tableau:permissions:update | Add default permission capabilities to a user or group, for metric, flow, workbook, data source, data role, or lens resources in a project. |
| Add project permissions        | tableau:permissions:update | Add permissions to a project for a user or group  |
| Add view permissions           | tableau:permissions:update | Add permissions to a view for a user or group.  |
| Add workbook permissions       | tableau:permissions:update | Add permissions to a specified workbook for a user or group.  |
| Delete data source permissions | tableau:permissions:delete | Delete default permission capabilities of a user or group, for met-   |

| Method                        | Scope                                   | Description  |
|-------------------------------|---|--|
|                               |   | ric, flow, workbook, data source, data role, or lens resources in a project.   |
| Delete default permissions    | <code>tableau:permissions:delete</code> | Delete default permission capabilities of a user or group, for metric, flow, workbook, data source, data role, or lens resources in a project. |
| Delete project permissions    | <code>tableau:permissions:delete</code> | Delete the project permission for a user or group.   |
| Delete view permissions       | <code>tableau:permissions:delete</code> | Delete the view permission for a user or group.  |
| Delete workbook permissions   | <code>tableau:permissions:delete</code> | Delete the workbook permission for a user or group.  |
| Query data source permissions | <code>tableau:permissions:read</code>   | Get a list of permissions  |

| Method                                    | Scope                                 | Description   |
|---|---------------------------------------|---|
|   |                                       | for the data source.  |
| Query default permissions                 | <code>tableau:permissions:read</code> | Get default permission capabilities of users and groups for metrics, workbooks, and data sources. |
| Query project permissions                 | <code>tableau:permissions:read</code> | Get a list of permissions for the project.  |
| Query view permissions                    | <code>tableau:permissions:read</code> | Get a list of permissions for the view.   |
| Query workbook permissions                | <code>tableau:permissions:read</code> | Get a list of permissions for the workbook.   |
| <b>Site</b>                               |                                       |   |
| (All <code>tableau:sites:</code> methods) | <code>tableau:sites:*</code>          | Enables create, query, update, and delete sites actions.  |
| Create site                               | <code>tableau:sites:create</code>     | Create a site on Tableau Server.  |

| Method                   | Scope                | Description   |
|--------------------------|----------------------|---|
| Get recently viewed site | tableau:content:read | Get views and workbooks details on the most recently created, updated, or accessed by the signed in user. |
| Query sites              | tableau:sites:read   | List all sites on Tableau Server.   |
| Query views for site     | tableau:content:read | List all views on a site.   |
| Update site              | tableau:sites:update | Update a site.  |

Troubleshoot scopes

## 401001 - signin error

If you encounter error 401001, the **Sign In** response body is appended with one of the following additional connected apps-specific error codes: 16, 10084, or 10085.

For example, in the following response body, "10084" is the connected apps error code you can use to help troubleshoot issues with signing in to Tableau Server using a JWT for REST API authorization.

```
<error code="401001">
  "summary": "Signin Error",
  "detail": "Error signing in to Tableau Cloud (10084)"
</error>
```

To help resolve the issue, refer to the description of the applicable error code and its potential causes.

- **16: Could not find user**—this error can occur because the incorrect "sub" (user name) was specified
- **10084: Could not parse access token**—this error can occur for the following reasons:
  - JWT is invalid or there was an unexpected problem
  - Incorrect "aud" (audience) was specified
  - For direct trust, there was a problem with signing the secret
- **10085: Could not fetch secret to verify signature for client ID**—this error can occur for the following reasons:
  - Incorrect client ID in "iss" specified
  - For direct trust, incorrect "kid" (secret ID) was specified
  - For EAS, unable to fetch keys from the JWKSsource

## 401002 - unauthorized access error

If you encounter error 401002 and have confirmed that you have the appropriate permissions to make the request, ensure the scope included in the JWT is correct and matches the request you're trying to make. For a list of endpoints and supported scopes, see the REST API methods that support JWT authorization section above.

### Troubleshoot Connected Apps - Direct Trust

When embedded content fails to display in your custom application or Tableau REST API authorization fails, you can use a browser's developer tools to inspect and identify error codes that might be associated with the Tableau connected app that's used to display the embedded content.

**Note:** In order for the session token to be valid, the clocks of the external application and the server that hosts the external application must be set to Coordinated Universal Time (UTC). If either clock uses a different standard, the connected app will not be trusted.

Refer to the table below to review the description of the error code and potential resolution.

| Error code | Summary               | Description                       | Potential resolution or explanation  |
|------------|-----------------------|-----------------------------------|--|
| 5          | SYSTEM_USER_NOT_FOUND | Tableau user could not be found   | To resolve this issue, verify the 'sub' (Subject) claim value in the JWT is "username" for Tableau Server. This value is case sensitive.   |
| 16         | LOGIN_FAILED          | Login failed                      | <p>This error is typically caused by one of the following claim issues in the JWT:</p> <ul style="list-style-type: none"> <li>• The 'exp' (Expiration Time) exceeds the default maximum validity period. To resolve this issue, review <b>registered claims</b> required for a valid JWT and ensure the correct value is used. To change the maximum validity period, you can use the viz-portal.oauth.connected_apps.max_expiration_period_in_minutes command.</li> <li>• The 'sub' (Subject) is calling an unknown user. |       | MISSING_IN_JWT                | scopes claim             | 'scp' (scope) claim. To resolve this issue, verify 'scp' is included in the JWT. For troubleshooting help with a JWT, see <a href="#">Debugger</a> on the auth0 site. |
| 10100 | JTI_PERSISTENCE_FAILED        | Unexpected JWT ID error  | There was an unexpected 'jti' (JWT ID) error. To resolve this issue, a new JWT with a new 'jti' must be generated.  |
| 10103 | JWT_MAX_SIZE_EXCEEDED         | JWT exceeds maximum size | This error can occur when JWT size exceeds 8000 bytes. To resolve this issue, make sure that only the necessary claims are being passed to Tableau Server.            |
| 10105 | ORIGIN_HEADER_NOT_A_VALID_URI | Invalid Origin header    | This error can occur because 1) a URL is specified in the domain allowlist and 2) the Origin header does not contain a valid URL.                                     |

## Data Connection Authentication

You can configure data connection authentication using Kerberos, OAuth, and single sign-on.

More information

- [Tableau Server on Linux - Connecting to a Windows Shared Directory](#) (Tableau Community)
- [Setting an Oracle Connection to Use TNSNames.ora or LDAP.ora](#) (Tableau Support)

### Enable Kerberos Delegation

Kerberos delegation enables Tableau Server to use the Kerberos credentials of the viewer of a workbook or view to execute a query on behalf of the viewer. This is useful in the following situations:

- You need to know who is accessing the data (the viewer's name will appear in the access logs for the data source).
- Your data source has row-level security, where different users have access to different rows.

### Supported data sources

Tableau supports Kerberos delegation with the following data sources:

- Cloudera: Hive/Impala
- Denodo
- Hortonworks
- Oracle
- PostgreSQL
- Spark
- SQL Server
- Teradata
- Vertica

MSAS is not supported on Linux platforms.

### Requirements

Kerberos delegation requires Active Directory.

- The Tableau Server **identity store** must be configured to use Active Directory.
- The computer where Tableau Server is installed must be joined to the Active Directory domain.
- MIT Kerberos KDC is not supported.

### Web authoring and user Kerberos authentication

When configuring Connect to Data for a given target, you may select Integrated or Windows authentication as the preferred authentication method. However, for web authoring scenarios, the default behavior will be to use the Kerberos service account (“Run As” account) instead.

To enable user credentials in web authoring scenarios with Kerberos delegation, you must make an additional configuration using TSM. Run the following commands:

## Tableau Server on Linux Administrator Guide

```
tsm configuration set -k native_api.WebAuthoringAuthModeKerberosDelegation -v true

tsm pending-changes apply
```

After making this configuration, Kerberos Delegation becomes the default operation when selecting integrated authentication with web authoring. However, this setting will not prevent content creators from accessing the service account. Creators can still publish content that connects with the Run As service account, using Tableau Desktop or other methods.

For more information on Run As service account, see [Enable Kerberos Service Account Access](#).

### Configuration process

This section provides an example of the process to enable Kerberos delegation. The scenario also includes example names to help describe the relationships between the configuration elements.

1. Tableau Server will need a Kerberos service ticket to delegate on behalf of the user that is initiating the call to the database. You must create a domain account that will be used to delegate to the given database. This account is referred to as the Run As service account. In this topic, the example user configured as the delegation/Run As account is `tabsrv@example.com`.

The account must be configured with Active Directory User and Computers on a Windows Server that is connected to the user domain:

- Open the **Properties** page for the Run As service account, click the **Delegation** tab and select **Trust this user for delegation to specified services only** and **Use any authentication protocol**.
2. Create a keytab file for the Run As service account.

For example, the following commands create a keytab (`tabsrv-runas.keytab`) using the `ktutil` tool:

```
sudo ktutil
```

```
ktutil: addent -password -p tabsrv@EXAMPLE.COM -k 2 -e <encryption scheme>
```

Encryption schemes for this command include RC4-HMAC, aes128-cts-hmac-sha1-96, and aes256-cts-hmac-sha1-96. Consult your IT team for the correct encryption scheme for your environment and data source.

```
ktutil: wkt tabsrv-runas.keytab
```

Tableau Server will use the Run As service account and the associated keytab to authenticate and make a direct connection to the database.

3. Copy the keytab into the Tableau Server data directory and set proper ownership and permissions. If you are running a multi-node deployment, then you must run the following commands on each node in the cluster.

```
mkdir /var/opt/keytab
sudo cp -p tabsrv-runas.keytab /var/opt/keytab
sudo chown $USER /var/opt/keytab/tabsrv-runas.keytab

chgrp tableau /var/opt/keytab/tabsrv-runas.keytab

chmod g+r /var/opt/keytab/tabsrv-runas.keytab
```

4. Run the following TSM commands to enable Kerberos delegation, set the delegation service account, and associate the keytab file with the service account:

```
tsm configuration set -k wgserver.delegation.enabled -v true
tsm configuration set -k native_api.datasources_impersonation_runas_principal -v tabsrv@EXAMPLE.COM
tsm configuration set -k native_api.datasources_impersonation_runas_keytab_path -v /var/opt/keytab/tabsrv-runas.keytab
tsm configuration set -k native_api.protocol_transition_and_short_domain -v false
```

## Tableau Server on Linux Administrator Guide

```
tsm configuration set -k native_api.protocol_transition_upper-  
case_realm -v true
```

In some cases, TSM may return an error mentioning `--force-keys`. If you get this error, run the command again with the `--force-keys` parameter appended to the argument.

5. Run the following TSM command apply the changes to Tableau Server:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

6. Enable delegation for data connections:
  - **SQL Server**—See [Enabling Kerberos Delegation for SQL Server](#) in the Tableau Community.
  - **PostgreSQL**—See [Enabling Kerberos Delegation for PostgreSQL](#) in the Tableau Community.
  - **Teradata**—See [Enabling Kerberos Delegation for Teradata](#) in the Tableau Community.
  - **Denodo**—See [Enabling Kerberos Delegation for Denodo on Linux](#) in the Tableau Community.
  - **Oracle**—See [Enable Kerberos Delegation for Oracle](#) in the Tableau Community.

- **Cloudera**—See [Enable Kerberos Delegation for Hive/Impala](#) in the Tableau Community.
- **Vertica**—See [Enabling Kerberos Delegation for Vertica](#) in the Tableau Community.

Troubleshoot Kerberos

### Enable Kerberos Delegation for JDBC Connectors

As of version 2020.2, Tableau Server supports Kerberos delegation for JDBC connectors.

Kerberos delegation enables Tableau Server to use the Kerberos credentials of the viewer of a workbook or view to execute a query on behalf of the viewer. This is useful in the following situations:

- You need to know who is accessing the data (the viewer's name will appear in the access logs for the data source).
- Your data source has row-level security, where different users have access to different rows.

## Supported data sources

Tableau supports JDBC Kerberos RunAs authentication with the following data sources:

- Oracle
- PostgreSQL

Both native and JDBC-based connectors use the same configuration on Tableau Server on Linux. See [Enable Kerberos Delegation](#).

### Enable Kerberos Run As Authentication for JDBC Connectors

As of version 2020.2, Tableau Server supports Kerberos authentication for JDBC connectors.

## Tableau Server on Linux Administrator Guide

You can configure Tableau Server to use a Kerberos service account to access a database. In this scenario, Tableau Server connects to databases with a service account, also referred to as a "Run As service account". This scenario is referred to as "Run As authentication"

To use Run As authentication on Tableau Server you must first create a workbook or data-source in Tableau Desktop that uses integrated authentication. When you publish to Tableau Server you will get the option to use Run As authentication. When creating a datasource with Web Authoring, Run As authentication is the default operation if you select integrated authentication.

### Supported data sources

Tableau supports JDBC Kerberos delegation with the following data sources:

- Oracle
- PostgreSQL

Both native and JDBC-based connectors use the same configuration on Tableau Server on Linux. To configure Run As authentication see [Enable Kerberos Service Account Access](#).

### OAuth Connections

Tableau Server supports OAuth for a number of different connectors. In many cases, OAuth functionality doesn't require additional configuration on Tableau Server.

From Tableau, when users sign in to data with a connector that uses OAuth, users are redirected to the authentication provider's sign in page. After users provide their credentials and authorize Tableau to access their data, the authentication provider sends Tableau an **access token** that uniquely identifies Tableau and the users. This access token is used to access data on users' behalf. For more information, see [Overview of the OAuth process](#) below.

Using OAuth-based connections provides the following benefits:

- **Security:** Your database credentials are never known to or stored in Tableau Server, and the access token can be used only by Tableau on behalf of users.

- **Convenience:** Instead of having to embed your data source ID and password in multiple places, you can use the token provided for a particular data provider for all published workbooks and data sources that access that data provider.

**Note:** For live connections to Google BigQuery data, each workbook viewer can have a unique access token that identifies the user, rather than sharing a single username and password credential.

### Overview of the OAuth process

The following steps describe a workflow in the Tableau environment that calls the OAuth process.

1. A user takes an action that requires access to a cloud-based data source.  
  
For example, you open a workbook that's published to Tableau Server.
2. Tableau directs the user to the cloud data provider's sign in page. The information that is sent to the data provider identifies Tableau as the requesting site.
3. When the user signs in to the data, the provider prompts the user to confirm their authorization for Tableau Server to access the data.
4. Upon the user's confirmation, the data provider sends an access token back to Tableau Server.
5. Tableau Server presents the workbook and data to the user.

The following user workflows can use the OAuth process:

## Tableau Server on Linux Administrator Guide

- Creating a workbook and connecting to the data source from Tableau Desktop or from Tableau Server.
- Publishing a data source from Tableau Desktop.
- Signing in to Tableau Server from an approved *client*, such as Tableau Mobile or Tableau Desktop.

### Default saved credential connectors

*Saved credentials* refers to the functionality where Tableau Server stores user tokens for OAuth connections. This allows users to save their OAuth credentials to their user profile on Tableau Server. After they've saved the credentials, they won't be prompted when they subsequently publish, edit, or refresh when accessing the connector.

**Note:** When editing Tableau Prep flows on the web, you may still be prompted to reauthenticate.

The following connectors use saved credentials by default and don't require additional configuration on Tableau Server.

- Anaplan
- Box
- Dropbox
- Esri ArcGIS Server
- Google Ads, Google Drive
- LinkedIn Sales Navigator
- Marketo
- OneDrive (Additional configuration is required starting with 2022.3)
- Oracle Eloqua
- ServiceNow ITSM
- Snowflake - To use "private link" requires additional configuration. For more information, see [Configure Snowflake OAuth for Partner Applications](#) on the Snowflake website and [Configure OAuth for Snowflake Connections](#).

The following connectors can use saved credentials with additional configuration by the server administrator.

- Azure Data Lake Storage Gen2, Azure Synapse, Azure SQL Database, Databricks

For more information, see [Configure Azure AD for OAuth and Modern Authentication](#).

- Dremio

For more information, see [Set Up OAuth for Dremio](#).

- Google Analytics, Google BigQuery, Google Sheets (deprecated in Tableau version 2022.1)

For more information, see [Set up OAuth for Google](#).

**Note:** If Tableau Server isn't listed in the Accessed Apps list in the Google admin console, you can manually add a new app to the list using its client ID. To create a client ID, see [Change Google OAuth to Saved Credentials](#).

- Intuit QuickBooks Online

For more information, see [Set Up OAuth for Intuit QuickBooks Online](#).

OneDrive (Starting with 2022.3)

For more information, see [Configure Custom OAuth for a site](#)

- Salesforce

For more information, see [Change Salesforce.com OAuth to Saved Credentials](#).

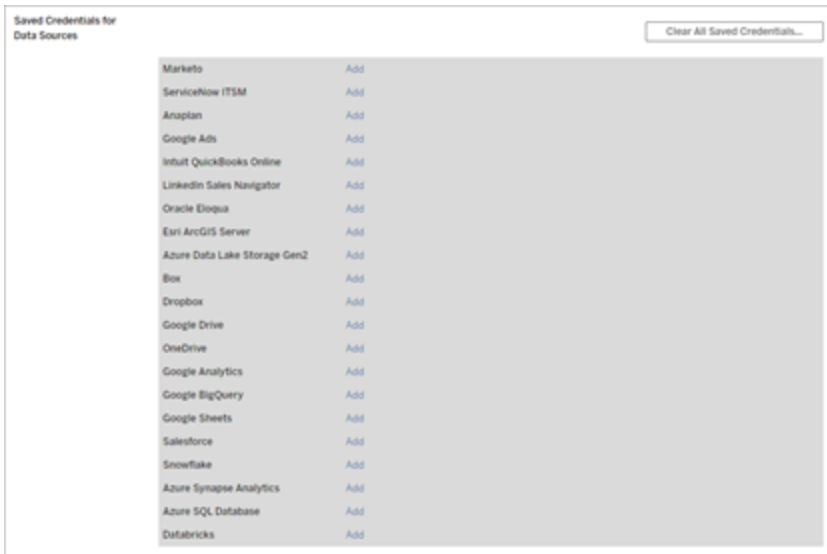

- Salesforce CDP

For more information, see [Connect Tableau Server to the Salesforce Data Cloud](#).

- Snowflake

Starting with version 2024.2. For more information, see [Change Snowflake OAuth to Saved Credentials](#).

All supported connectors are listed under **Saved Credentials for Data Sources** on users' **My Account Settings** page on Tableau Server. Users manage their saved credentials for each connector.

## Access tokens for data connections

You can embed credentials based on access tokens with data connections, to enable direct access after the initial authentication process. An access token is valid until a Tableau Server user deletes it, or the data provider revokes it.

It's possible to exceed the number of access tokens your data source provider allows. If that's the case, when a user creates a token, the data provider uses the length of time since last access to decide which token to invalidate to make room for the new one.

## Access tokens for authentication from approved clients

By default, Tableau Server sites allow users to access their sites directly from approved Tableau clients, after users provide their credentials the first time they sign in. This type of

authentication also uses OAuth access tokens to store the users' credentials securely.

For more information, see [Disable Automatic Client Authentication](#).

### Default-managed keychain connectors

*Managed keychain* refers to the functionality where OAuth tokens are generated for Tableau Server by the provider and shared by all users in the same site. When a user first publishes a data source, Tableau Server prompts the user for the data source credentials. Tableau Server submits the credentials to the data source provider, which returns OAuth tokens for Tableau Server to use on behalf of the user. On subsequent publishing operations, the OAuth token stored by Tableau Server for the same class and username is used so that the user isn't prompted for the OAuth credentials. Should the data source password change, then the preceding process is repeated and the old token is replaced by a new token on Tableau Server.

Additional OAuth configuration on Tableau Server isn't required for the default-managed keychain connectors:

- Google Analytics, Google BigQuery, and Google Sheets (deprecated in Tableau version 2022.1)
- Salesforce

## Token limits and storage

Google has a 50 token limit per user per client application (in this scenario, Tableau Server is the client application). Because the OAuth token is stored on Tableau Server and reused by the user, the user is unlikely to exceed the token limit.

All user tokens are encrypted at rest when stored on Tableau Server. See [Manage Server Secrets](#) for more information.

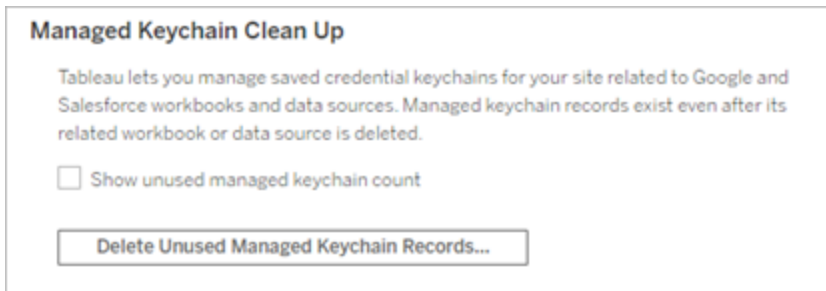

## Removing unused keychain records

A managed keychain record contains connection attributes like dbClass, username, and OAuth secret attributes. All managed keychain records for a given site are merged,

encrypted, and stored in PostgreSQL.

Records are persisted even for workbooks and data sources that have been removed. Over time, these records can grow to large sizes, which may cause issues.

We recommend purging the unused keychain records periodically as a regular maintenance task. You can view the number of records and unused records stored on each site. You can also delete unused records.

To access **Managed Keychain Clean Up**, sign in to the Tableau Server admin pages, navigate to the site where you want to delete unused records, and click **Settings**.

## Scenario limitations with managed keychain

Three scenarios aren't supported when using managed keychain OAuth with Tableau Server:

- Prompting for OAuth credentials on live connections. Users must embed credentials on live connections with managed-keychain OAuth
- Editing the OAuth data source connection on Tableau Server
- Web authoring

## Convert managed keychain to saved credentials

You can convert the connectors that use managed keychain to use saved credentials by configuring Tableau Server with an OAuth client ID and secret for each connector. By converting these connectors to saved credentials, users are able to manage their credentials for each

connector type on the **My Account Settings** page on Tableau Server. Additionally, live connection prompts, editing connections, and web authoring are also supported.

Configure a custom OAuth for a site

For a subset of connectors, you can configure site-level OAuth by configuring custom OAuth clients. For more information, see one of the following topics:

- For Azure Data Lake Storage Gen2, Azure SQL Database, Azure Synapse, and Databricks, see [Configure custom OAuth for a site](#).
- For Dremio, see [Set Up OAuth for Dremio](#).
- For Google Analytics, Google BigQuery, Google Sheets (deprecated in Tableau version 2022.1), see [Configure custom OAuth for a site](#).
- For Salesforce, see [Configure custom OAuth for a site](#).
- For Salesforce CDP, see [Connect Tableau Server to the Salesforce Data Cloud](#).
- For Snowflake, see [Option 2: Configure OAuth for Snowflake Connections by Site](#).

Change Salesforce.com OAuth to Saved Credentials

By default, the Salesforce.com connector uses a managed keychain for OAuth tokens that are generated for Tableau Server by the data provider and shared by all users in the same site. You can configure Tableau Server with saved client ID and client secret. There are three scenarios where you might want to do this:

- **Salesforce connector**—If you're using the Salesforce connector, you can configure Tableau Server with an OAuth client ID and secret, so the connector can use saved credentials.
- **Write to CRM Analytics**—If you're writing Tableau Prep flow data to Salesforce CRM Analytics (version 2022.3 and later), configure Tableau Server with an OAuth client ID and secret, so the flow can run in Tableau Server using saved credentials.
- **Einstein Discovery**—If you are integrating Einstein Discovery extensions with Tableau Server, you need to do this OAuth client ID and secret configuration. The abil-

ity to integrate Einstein Discovery and Tableau Server was added in version 2021.1.0. For more information, see [Configure Einstein Discovery Integration](#).

This topic describes how to set up your Salesforce.com data sources and Einstein Discovery extensions for OAuth saved credentials. Complete these steps for each Tableau Server instance.

For more information about managed keychain and saved credentials, see [OAuth Connections](#)

**Notes:**

- The Salesforce connector requires managed keychain (default), server-wide OAuth, or site-specific OAuth.
- To use saved credentials for a site, server-wide OAuth must be configured first.
- Server-wide OAuth can be used whether site-wide OAuth is configured.
- If using site-specific OAuth, each site must be configured individually.
- To support live connection prompts, editing connections, and web authoring, convert managed keychain to saved credentials to avoid errors.

## Summary of steps

Set up OAuth by following these general steps:

1. Create a Connected App in Salesforce.
2. Use the information you obtained in step 1 to configure Tableau Server.
3. (Optional) Configure site-specific OAuth.

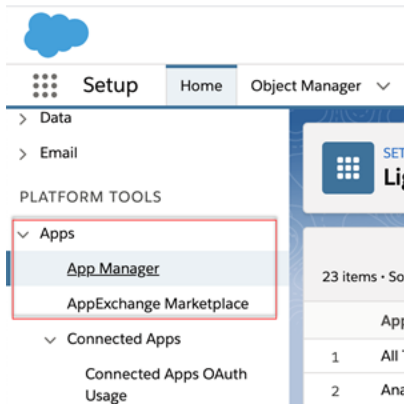

## Step 1: Create a Salesforce connected app

**Note:** This procedure documents the process in Salesforce Lightning. If you are using the traditional interface, the navigation may be different but the configuration is the same.

1. Sign in to your Salesforce.com developer account, click your user name in the upper-right, and then select **Setup**.

2. In the left navigation column, under **Apps**, select **App Manager**.

3. In the Connected Apps section, click **New Connected App**.

4. In **Basic Information**, give the app a name, tab through the api field so it will self-populate in the correct format, and enter a contact email for the app.
5. In the **API [Enable OAuth Settings]** section, select **Enable OAuth Settings**.
6. In the new OAuth settings that appear, for **Callback URL**, type the fully qualified domain name of your server, using the `https` protocol, and append the following text to the URL: `auth/add_oauth_token`.

For example:

`https://www.your_tableau_server.com/auth/add_oauth_token`

7. Move the following items from **Available OAuth Scopes** to **Selected OAuth Scopes**:
  - **Access the identity URL service (id, profile, email, address, phone)**
  - **Manage user data via APIs (api)**
  - **Perform requests any time (refresh\_token, offline access)**
8. Click **Save**.

After you save the app, Salesforce populates the API section with the following IDs that you will use to configure Tableau Server:

- **Consumer Key**
- **Consumer Secret**
- **Callback URL**

## Step 2: Configure Tableau Server for Salesforce.com OAuth

Once your connected app is created in Salesforce and you have the Customer Key, Customer Secret, and the Callback URL, you can configure Tableau Server for Salesforce data connections and outputs, and Einstein Discovery.

1. On the Tableau Server computer, at a command prompt, run the following commands:

```
tsm configuration set -k oauth.salesforce.client_id -v <your_customer_key>
```

```
tsm configuration set -k oauth.salesforce.client_secret -v <your_customer_secret>
```

```
tsm configuration set -k oauth.salesforce.redirect_uri -v  
<your_redirect_URL>
```

2. (Optional) To change the default login server, type the following command:

```
tsm configuration set -k oauth.salesforce.server_base_url -v  
<URL>
```

3. Enter the following command to apply changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Configure custom OAuth for a site

You can configure a custom Salesforce OAuth client for a site.

Consider configuring a custom OAuth client to 1) override an OAuth client if configured for the server or 2) enable support for securely connecting to data that requires unique OAuth clients.

When a custom OAuth client is configured, the site-level configuration takes precedence over any server-side configuration and all new OAuth credentials created use the site-level OAuth client by default. No Tableau Server restart is required for the configurations to take effect.

**Important:** Existing OAuth credentials established before the custom OAuth client is configured are temporarily usable but both server administrators and users must update their saved credentials to help ensure uninterrupted data access.

## 1: Prepare the OAuth client ID, client secret, and redirect URL

Before you can configure the custom OAuth client, you need the information listed below. After you have this information prepared, you can register the custom OAuth client for the site. For more information, see the section **Register OAuth Client With Snowflake**, above.

- **OAuth client ID and client secret:** First register the OAuth client with the data provider (connector) to retrieve the client ID and secret generated for Tableau Server.
- **Redirect URL:** Note the correct redirect URL. You will need this during the registration process in **Step 2** below.

`https://<your_server_name>.com/auth/add_oauth_token`

For example, `https://example.com/auth/add_oauth_token`

## 2: Register the OAuth client ID and client secret

Follow the procedure described below to register the custom OAuth client to the site.

1. (Versions 2024.1 and earlier) On the Tableau Server computer, run the following command to enable the Snowflake OAuth service:

```
tsm configuration set -k native_api.enable_snowflake_
privatelink_on_server -v true
```

**Note:** For versions 2024.2 and newer, skip step 1 regardless of whether a Snowflake private connection is being used or not.

2. Sign in to your Tableau Server site using your admin credentials and navigate to the **Settings** page.
3. Under OAuth Clients Registry, click the **Add OAuth Client** button.
4. Enter the required information, including the information from **Step 1** above:

- a. For **Connection Type**, select the connector whose custom OAuth client you want to configure.
- b. **OAuth Instance URL** is required if multiple OAuth clients are being registered. Otherwise, it is optional.
- c. For **Client ID**, **Client Secret**, and **Redirect URL**, enter the information you prepared in **Step 1** above.
- d. Click the **Add OAuth Client** button to complete the registration process.

5. (Optional) Repeat step 3 for all supported connectors.
6. Click the **Save** button at the bottom or top of the Settings page to save changes.

### 3: Validate and update saved credentials

To help ensure uninterrupted data access, you (and your site users) must delete the previous saved credentials and add it again to use the custom OAuth client for the site.

1. Navigate to your **My Account Settings** page.
2. Under **Saved Credentials for Data Sources**, do the following:
  - a. Click **Delete** next to the existing saved credentials for the connector whose custom OAuth client you configured in **Step 2** above.
  - b. Next to connector name, click **Add** and follow the prompts to 1) connect to the

custom OAuth client configured in **Step 2** above and 2) save the latest credentials.

## 4: Notify users to update their saved credentials

Make sure you notify your site users to update their saved credentials for the connector whose custom OAuth client you configured in **Step 2** above. Site users can use the procedure described in Update saved credentials to update their saved credentials.

# Manage access tokens

After you configure the server for OAuth, you can allow users to manage their own access tokens in their profile settings, or you can manage the tokens centrally. For more information, see Allow Saved Access Tokens.

Connect Tableau Server to the Salesforce Data Cloud

Note: Data Cloud was previously called Customer Data Platform.

## Tableau Server (version 2023.3 and later)

The Salesforce Data Cloud connector was released for Tableau Desktop and Tableau Prep in 2023.2, for Tableau Cloud in June 2023, and for Tableau Server in 2023.3. This connector seamlessly connects Tableau to Data Cloud, and is available for Tableau Desktop, Tableau Cloud, Tableau Server, and Tableau Prep. Compared to the earlier Customer Data Platform connector, the Salesforce Data Cloud connector is simpler to set up, recognizes Data Spaces, presents clearer object labels, and is powered by accelerated queries. See the steps below.

Note: The Customer Data Platform connector was deprecated in Tableau Server 2023.3 and can't be used for new connections starting in Tableau Server 2024.2. Existing

4. In **Basic Information**, give the app a name, tab through the API field so it will auto-populate in the correct format, and enter a contact email for the app.
5. In the **API [Enable OAuth Settings]** section, select **Enable OAuth Settings**.
6. In the new OAuth settings that appear, for **Callback URL**, type the fully qualified domain name of your server, using the `https` protocol, and append the following text to the URL: `auth/add_oauth_token`.  
For example:  
`https://www.your_tableau_server.com/auth/add_oauth_token`
7. Move the following items from **Available OAuth Scopes** to **Selected OAuth Scopes**:
  - **Access the identity URL service (id, profile, email, address, phone)**
  - **Manage user data via APIs (api)**
  - **Perform requests any time (refresh\_token, offline access)**
  - **Perform ANSI SQL queries on Customer Data Platform data (cdp\_query\_api)**
  - **Manage Customer Data Platform profile data (cdp\_profile\_api)**
  - **Manage Customer Data Platform Ingestion API data (cdp\_ingest\_api)**
8. Click **Save**.

After you save the app, Salesforce populates the API section with the following IDs that you will use to configure Tableau Server:

- **Consumer Key**
- **Consumer Secret**
- **Callback URL**

## Step 2: Configure Tableau Server for Salesforce.com OAuth

Once your connected app is created in Salesforce and you have the Customer Key, Customer Secret, and the Callback URL, you can configure Tableau Server for Salesforce data connections and outputs, and Einstein Discovery.

1. On the Tableau Server computer, at a command prompt, run the following commands:

```
tsm configuration set -k oauth.salesforce.client_id -v <your_customer_key>
tsm configuration set -k oauth.salesforce.client_secret -v
```

```
<your_customer_secret>
```

```
tsm configuration set -k oauth.salesforce.redirect_uri -v
```

```
<your_redirect_URL>
```

2. (Optional) To change the default login server, type the following command:

```
tsm configuration set -k oauth.salesforce.server_base_url -v
```

```
<URL>
```

3. Enter the following command to apply changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the **pending-changes apply** command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Configure custom OAuth for a site

For setup instructions, see the OAuth Connections topic.

## Tableau Server (version 2023.1 and earlier)

**Warning:** The Customer Data Platform was deprecated in October 2023 and is unavailable in Tableau Server 2024.2 and later. To ensure that assets continue to function, Tableau recommends that customers modify existing assets to use the Salesforce Data Cloud connector.

This section describes how to connect from Tableau Server to the Salesforce Customer Data Platform through OAuth authentication.

The steps described in this section are required to use Salesforce Customer Data Platform data in Tableau Server.

### Step 1: Set up the connector

1. Download the latest Salesforce Customer Data Platform connector (Salesforce\_CDP.taco file) from the [Tableau Exchange Connectors](#) site.

## Tableau Server on Linux Administrator Guide

2. Move the .taco file to the Tableau connector folder:
  - **Windows:** `C:\Users[Windows User]\Documents\My Tableau Repository\Connectors`
  - **Linux:** `/opt/tableau/connectors` OR `/var/opt/tableau_server-/data/tabsvc/vizqlserver/Connectors/`
3. Restart Tableau Server.

## Step 2: Install the Customer Data Platform JDBC driver

**Note:** Tableau version 2023.1 for Server is only compatible with JDBC driver version 18 and above.

1. Download the latest JDBC driver (Salesforce-CDP-jdbc-[*version*].jar file) from the Salesforce CDP GitHub site: <https://github.com/forcedotcom/Salesforce-CDP-jdbc/releases>
2. Move the downloaded Salesforce-CDP-jdbc-[*version*].jar file to the following location:
  - **Windows:** `C:\Program Files\Tableau\Drivers`
  - **Linux:** `/opt/tableau/tableau_driver/jdbc`

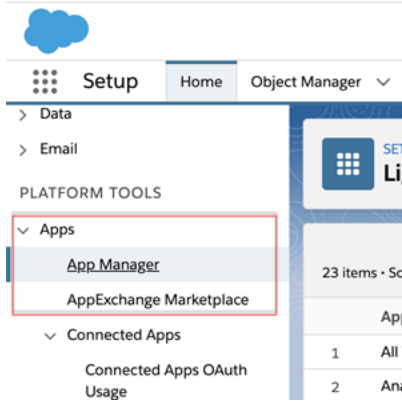

## Step 3: Create a Salesforce connected app

After creating the API scopes, use the following procedure to create a Salesforce connected app to handle OAuth delegation from Tableau Server.

1. Sign in to your Salesforce Customer Data Platform account as an admin, click your username in the upper-right, and then select **Setup**.

2. In the left pane, under Apps, select **App Manager**.

3. In the Connected Apps section, click **New Connected App**.

4. In **Basic Information**, give your connected app a name (for example, Example.com), tab through the API field so it self-populates in the correct format, and enter a contact email address for the app.
5. In the **API [Enable OAuth Settings]** section, select **Enable OAuth Settings**, and then do the following:
  - a. In the new OAuth settings that appear, for **Callback URL**, type the fully qualified domain name (FQDN) of your Tableau Server, using the `https` protocol, and append the following text to the URL: `/auth/add_oauth_token`.

For example: `https://example.com/auth/add_oauth_token`

- b. Move the following items from **Available OAuth Scopes** to **Selected OAuth Scopes**:

- **Manage user data via APIs (api)**
- **Perform requests on your behalf at any time (refresh\_token, offline\_access)**
- **Manage Customer Data Cloud profile data (cdp\_profile\_api)**
- **Perform ANSI SQL queries on Customer Data Platform data (cdp\_query\_api)**

6. When finished, click **Save**.
7. Go to your **App Manager** list, navigate to your connected app, click the dropdown arrow, and then select **Manage**.

After you save the app, the **API (Enable OAuth Settings)** section is populated with the following IDs that you'll use to configure Tableau Server:

- **Consumer Key**
- **Consumer Secret**
- **Callback URL**

**Note:** Save your Consumer Key, Secret, and Callback URL for use later.

## Use OAuth with the Customer Data Platform

Consider configuring a custom OAuth client to 1) override an OAuth client if configured for the server or 2) enable support for securely connecting to data that requires unique OAuth clients.

After the connected app is created in Salesforce and you have the Consumer Key, Consumer Secret, and the Callback URL, you can configure Tableau Server for the Customer Data Platform OAuth connections. To get started gather the following information.

- **Consumer Key:** The Consumer Key, also known as the client ID in Tableau, is generated from the procedure at the end of Step 4. Use this value for `[your_consumer_key]` in the following `tsm` command.
- **Consumer Secret:** The Consumer Secret, also known as the client secret in Tableau, is generated from the procedure at the end of Step 4. Use this value for `[your_consumer_secret]` in the following `tsm` command.
- **Callback URL:** The Callback URL, also known as the redirect URL in Tableau, is your Tableau Server URL `https://example.com` and `"/auth/add_oauth_token"` appended to it. Use this value for `[your_callback_url]` in the following `tsm` command.
- **Configuration ID:** The value for the `oauth.config.id` parameter you use in the following `tsm: customer_360_audience`

### Use TSM Commands for OAuth Setup

Run the following `tsm` commands to configure OAuth.

```
tsm configuration set -k oauth.config.clients -v "[{"oauth.config.id": "customer_360_audience", "oauth.config.client_
```

## Tableau Server on Linux Administrator Guide

```
id\":"[your_consumer_key]\"," \\"oauth.config.client_secret\":"\["  
[your_consumer_secret]\"," \\"oauth.config.redirect_uri\":"\["[your_call-  
back_url]\"}]" --force-keys
```

```
tsm pending-changes apply
```

### Setting multiple connectors

If you have multiple connectors to set, you must include all of them in a single command. For example:

```
tsm configuration set -k oauth.config.clients -v "[{\\"oau-  
th.config.id\":"custom_360_audience\"," \\"oauth.config.client_  
id\":"[your_consumer_key]\"," \\"oauth.config.client_secret\":"\["  
[your_consumer_secret]\"," \\"oauth.config.redirect_uri\":"\["[your_call-  
back_url]\"}, {\\"oauth.config.id\":"dremio\"," \\"oau-  
th.config.client_id\":"[your_client_id]\"," \\"oauth.config.client_  
secret\":"[your_client_secret]\"," \\"oauth.config.redirect_uri\":"\["  
[your_server_url]/auth/add_oauth_token\"}, {\\"oau-  
th.config.id\":"azure_sql_dw\"," \\"oauth.config.client_id\":"[your_  
client_id]\"," \\"oauth.config.client_secret\":"[your_client_  
secret]\"," \\"oauth.config.redirect_uri\":"\["[your_server_url]/au-  
th/add_oauth_token\"}, {\\"oauth.config.id\":"azure_sqldb\"," \\"oau-  
th.config.client_id\":"[your_client_id]\"," \\"oauth.config.client_  
secret\":"[your_client_secret]\"," \\"oauth.config.redirect_uri\":"\["  
[your_server_url]/auth/add_oauth_token\"}]" --force-keys
```

```
tsm pending-changes apply
```

## Step 1: Register OAuth client ID and client secret

Complete the following procedure to register the custom OAuth client to your site.

1. Sign into Tableau Server using your site admin credentials and navigate to the **Settings** page.

2. Under **OAuth Clients Registry**, select the **Add OAuth Client** button.
3. For **Connection Type**, select Customer Data Platform.
4. For OAuth Provider, select **Custom IDP**.
5. Enter the **Client ID**.
6. Enter the **Client Secret**.
7. Enter the **Redirect URL**.
8. For Choose OAuth Config File, select the **Choose a file** button to upload the config file.
9. Select the **Add OAuth Client** button to complete the registration process.
10. Select the Save button at the bottom or top of the Settings page to save changes.

## Step 2: Validate and update saved credentials

To help ensure uninterrupted data access, you (and your site users) must delete any previous saved credentials and add them again.

1. Navigate to your My Account Settings page.
2. Under **Saved Credentials for Data Sources**, select **Delete** next to the existing saved credentials.
3. Next to the same connector, select **Add**.
4. Follow the prompts to connect to the Customer Data Platform connector.
5. Select **Save**.

## Step 3: Notify users to update their saved credentials

Make sure you notify your site users to update their saved credentials for the Customer Data Platform connector. Site users can use the procedure described in Manage Saved Credentials for Data Connections to update their saved credentials.

## Hyper Query Processing (Beta)

**Note:** Since Hyper Query Processing is a Beta release the name can change before general release.

The Customer Data Platform (CDP) connector is now powered with the Hyper Query Processing Engine. It supports interactive analytics with fast data query processing and simplifies the connect-to- data experience for faster data exploration. The Hyper query processing engine speeds up query time when querying Customer Data Platform data from Tableau with live connections and Tableau data extracts.

**Beta Feature:** Hyper Query Processing beta feature offers extra functionality at no cost. You can opt to try this service with your sole discretion. Any use of the Beta Service is subject to the applicable Beta Services Terms provided at [Agreements and Terms](#).

# Enable Hyper Query Processing in Tableau Server

Complete the following steps to enable Hyper Query Processing.

1. Connect to Salesforce CDP.
2. Follow the directions on the screen to install the hyper jdbc driver.

-Salesforce-cdp-hyper-beta-1.15.0.jar or download the .jar file from [here](#).

3. Move the downloaded file to any of the following directory paths depending on your system.

Windows - C:\Program Files\Tableau\Drivers

macOS - /Users/[user]/Library/Tableau/Drivers

4. After you've moved the driver to the correct path, connect again. Your Customer Data Platform connector is ready to use in Tableau Server.

**Note:** The Hyper Query Processing support is a beta release. It's available for Tableau Server. Tableau Desktop and Tableau Online will be supported from December 2022. These dates are subject to change.

### Set up OAuth for Google

By default, the Google Analytics, Google BigQuery, and Google Sheets (deprecated in Tableau version 2022.1) connectors use a managed keychain for OAuth tokens that are generated for Tableau Server by the provider and shared by all users on the same site.

You can convert the connectors that use managed keychain to use saved credentials by configuring Tableau Server with an OAuth client ID and secret for each connector.

This topic describes how to set up your Google Analytics, Google BigQuery, and Google Sheets connections for OAuth with saved credentials. Complete these steps for each Tableau Server instance.

**Note:** Google Drive connections use saved credentials by default and, starting in Tableau 2022.3, require Tableau Server to be set up with an OAuth client ID and secret for Google.

For more information about managed keychain and saved credentials, see [OAuth Connections](#)

### Notes:

- All Google-based connectors require managed keychain (default), server-wide OAuth, or site-specific OAuth.
- To use saved credentials for a site, server-wide OAuth must be configured first.
- Server-wide OAuth can be used whether site-wide OAuth is configured.
- If using site-specific OAuth, each site must be configured individually.
- To support live connection prompts, editing connections, and web authoring, convert managed keychain to saved credentials to avoid errors.

## Summary of steps

Set up OAuth by following these general steps:

1. Enable API access and create an access token from Google.
2. Use the information you obtained in step 1 to configure Tableau Server.
3. (Optional) Configure site-specific OAuth.
4. Create and edit a Google data source.

## Obtain a client ID and enable Google APIs

**Note** These steps reflect the settings in the Google Cloud Platform console at the time of this writing. For more information, see [Using OAuth 2.0 for Web Server Applications](#) in the Google Developers Console Help.

1. Sign in to [Google Cloud Platform](#), and then click **Go to my console**.
2. On the dropdown menu, **Select a Project**, select **Create project**.
3. In the new project form that appears, complete the following:
  - Give the project a meaningful name that reflects the Tableau Server instance for which you'll use this project.
  - Determine whether you want to change the project ID.

**Note** After you create the project, you won't be able to change the project ID. For more information, click the question mark icons.

The screenshot shows a 'New Project' dialog box with two input fields. The first field, labeled 'Project name', contains the text 'Tableau Server OAuth'. The second field, labeled 'Project ID', contains the text 'tableau-server-oauth'. Below the fields are two buttons: a blue 'Create' button and a grey 'Cancel' button. A mouse cursor is pointing at the 'Create' button.

4. Open the new project, navigate to **APIs & Services > OAuth consent screen**, and select the User Type.
5. Click the **OAuth consent screen** tab and then enter a meaningful name for the **Product name** shown to users.
6. Click **Credentials** and click the **Create Credentials** tab, then click **OAuth client ID**.
7. On the **Create OAuth client ID** screen, fill out the required fields. Follow the steps to authorize your OAuth tokens:
  - Select **Web Application**.
  - Enter a client **Name**.
  - For **Authorized JavaScript Origins**, click **ADD URI** and enter the Tableau Server domain name using HTTP or HTTPs.
  - For **Authorized redirect URIs**, click **ADD URI** and replace the example text with the Internet address for your Tableau Server, and add the following text to

the end of it: **auth/add\_oauth\_token**. For example:

```
https://your_server_url.com/auth/add_oauth_token
```

8. Copy the Authorized Redirect URI, and paste it in a location that you can access from your Tableau Server computer.
9. Click **Create** .
10. Copy the following values that Google returns, and paste them in a location that you can access from your Tableau Server computer:
  - Client ID
  - Client secret
11. In **APIs & services**, verify that **BigQuery API**, **Google Drive API** (to enable Google Sheets), or **Analytics API** is enabled. To enable APIs, click **ENABLE API** at the top of the page.

**Note:** To establish a connection between Tableau Server and Google Analytics 4, you must enable both the Google Analytics Admin API and the Google Analytics Data API in the Google console. By adding these APIs, you can prevent any potential permissions errors that may arise during the process.

## Configure Tableau Server for Google OAuth

Using the information you obtained by completing the steps in Obtain a client ID and enable Google APIs, configure your Tableau Server:

- On the Tableau Server computer, open the shell and run the following commands to specify the access token and URI:

```
tsm configuration set -k oauth.google.client_id -v <your_client_ID>
```

```
tsm configuration set -k oauth.google.client_secret -v <your_
client_secret>
```

```
tsm configuration set -k oauth.google.redirect_uri -v <your_
authorized_redirect_URI>
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Configure custom OAuth for a site

You can configure a custom Google OAuth client for a site.

Consider configuring a custom OAuth client to 1) override an OAuth client if configured for the server or 2) enable support for securely connecting to data that requires unique OAuth clients.

When a custom OAuth client is configured, the site-level configuration takes precedence over any server-side configuration and all new OAuth credentials created use the site-level OAuth client by default. No Tableau Server restart is required for the configurations to take effect.

**Important:** Existing OAuth credentials established before the custom OAuth client is configured are temporarily usable but both server administrators and users must update their saved credentials to help ensure uninterrupted data access.

### 1: Prepare the OAuth client ID, client secret, and redirect URL

Before you can configure the custom OAuth client, you need the information listed below.

After you have this information prepared, you can register the custom OAuth client for the site.

For more information, see the section **Register OAuth Client With Snowflake**, above.

- **OAuth client ID and client secret:** First register the OAuth client with the data provider (connector) to retrieve the client ID and secret generated for Tableau Server.
- **Redirect URL:** Note the correct redirect URL. You will need this during the registration process in **Step 2** below.

`https://<your_server_name>.com/auth/add_oauth_token`

For example, `https://example.com/auth/add_oauth_token`

## 2: Register the OAuth client ID and client secret

Follow the procedure described below to register the custom OAuth client to the site.

1. (Versions 2024.1 and earlier) On the Tableau Server computer, run the following command to enable the Snowflake OAuth service:

```
tсм configuration set -k native_api.enable_snowflake_
privatelink_on_server -v true
```

**Note:** For versions 2024.2 and newer, skip step 1 regardless of whether a Snowflake private connection is being used or not.

2. Sign in to your Tableau Server site using your admin credentials and navigate to the **Settings** page.
3. Under OAuth Clients Registry, click the **Add OAuth Client** button.
4. Enter the required information, including the information from **Step 1** above:
  - a. For **Connection Type**, select the connector whose custom OAuth client you want to configure.

- b. **OAuth Instance URL** is required if multiple OAuth clients are being registered. Otherwise, it is optional.
- c. For **Client ID**, **Client Secret**, and **Redirect URL**, enter the information you prepared in **Step 1** above.
- d. Click the **Add OAuth Client** button to complete the registration process.

5. (Optional) Repeat step 3 for all supported connectors.
6. Click the **Save** button at the bottom or top of the Settings page to save changes.

### 3: Validate and update saved credentials

To help ensure uninterrupted data access, you (and your site users) must delete the previous saved credentials and add it again to use the custom OAuth client for the site.

1. Navigate to your **My Account Settings** page.
2. Under **Saved Credentials for Data Sources**, do the following:
  - a. Click **Delete** next to the existing saved credentials for the connector whose custom OAuth client you configured in **Step 2** above.
  - b. Next to connector name, click **Add** and follow the prompts to 1) connect to the custom OAuth client configured in **Step 2** above and 2) save the latest credentials.

## 4: Notify users to update their saved credentials

Make sure you notify your site users to update their saved credentials for the connector whose custom OAuth client you configured in **Step 2** above. Site users can use the procedure described in [Update saved credentials](#) to update their saved credentials.

## Create and edit Google data source

Next, you must publish the Google data sources to the server. For example, see the Tableau Desktop topic, [Google BigQuery](#).

After you've published the data sources, the final step is to edit the data source connection to use the embedded access token that you configured earlier. See [Edit Connections on Tableau Server](#).

## Managing access tokens

After you configure the server for OAuth, you can allow users to manage their own access tokens in their profile settings, or you can manage the tokens centrally. For more information, see [Allow Saved Access Tokens](#).

### Configure Azure AD for OAuth and Modern Authentication

The Azure Synapse, Azure SQL Database, Azure Databricks, Azure Data Lake Gen2, OneDrive and SharePoint Online, and SharePoint Lists (JDBC) connectors support authentication through Azure AD by configuring an OAuth client for Tableau Server.

**Note:** OAuth support for Azure AD is only supported with [Microsoft SQL Server driver 17.3](#) and later.

# Step 1: Register OAuth client for Azure

Follow the steps below to register and configure an OAuth application for Azure under a specific Azure tenant.

1. Sign in to the [Azure portal](#).
2. If you have access to multiple tenants, select the tenant in which you want to register an application.
3. Search for and select **Azure Active Directory**.
4. Under **Manage**, select **App registrations**, and then select **New registration**.
5. Enter "Tableau Server OAuth", or similar value as the **Name**.
6. Under the **Supported account types** field in the app registration page, select who can use this application.

**Note:** If you want to use the Client ID & Client Secret of your application for accounts under a different tenant, choose the second option (Multitenant).

7. Under **Redirect Uri** (optional) field, choose **Web**, and then enter the internet address of your server appended by the string, `/auth/add_oauth_token`.

For example: `https://your_server_url.com/auth/add_oauth_token`

8. Select **Register**. After the registration completes, the Azure portal displays the app registration's Overview pane, which includes its Application (client) ID. Also referred to as *Client ID*, this value uniquely identifies your application in the Microsoft identity platform.
9. Copy the value, it will be used as the `[your_client_id]` field in the following steps.
10. Select **Certificates & secrets** on the left bar, and then choose **New client secret**.
11. Add a description of the secret.
12. Select **Client secret lifetime**.
13. Choose **Add** and then copy the secret. The secret will be used as `[your_client_secret]` in the following steps.
14. Select **API permissions** on the left bar.
15. Choose **Add permissions**.
16. Select **Microsoft Graph**.
17. Choose **Delegated permissions**.

18. Under **Select permissions**, select all OpenId permissions (email, offline\_access, openid, and profile).
19. Choose **Add permissions**.
20. Add additional permissions. Follow the steps below for the connector(s) that you are enabling:
  - Azure SQL database
    - a. Click **Add a permission**.
    - b. Select **My APIs**.
    - c. Click **Azure SQL Database**, and then **Delegated permissions**.
    - d. Select **user\_impersonation**, and then click **Add permissions**.
  - OneDrive and SharePoint Online
    - a. Click **Add a permission**.
    - b. Select **Microsoft Graph**.
    - c. Click **Delegated permissions**.
    - d. Under **Select permissions**, in the filter search box, enter and then add the following permissions:
      - Files.Read.All
      - Sites.Read.All
      - User.Read
  - SharePoint lists (JDBC)
    - a. Click **Add a permission**.
    - b. Select **Microsoft Graph**.
    - c. Click **Delegated permissions**.
    - d. Under **Select permissions**, in the filter search box, enter and then add User.Read permission.
    - e. Click **Add a permission** again.
    - f. Select **SharePoint**.
    - g. Click **Delegated permissions**.
    - h. Expand the **AllSites** section, and then select and add the AllSites.Manage permission.

## Step 2: Configure Tableau Server for Azure

Configuring Tableau Server requires running a Tableau Server Manager (TSM) command. Azure Data Lake Storage Gen2 requires a different set of commands than the common command that is run for Azure Synapse, Azure SQL Database, or Databricks.

## Configure default OAuth client for Azure Data Lake Storage Gen2

To configure Tableau Server for Data Lake Storage Gen2, you must have the following configuration parameters:

- **Azure OAuth client ID:** The client ID is generated from the procedure in Step 1. Copy this value for `[your_client_id]` in the first tsm command.
- **Azure OAuth client secret:** The client secret is generated from the procedure in Step 1. Copy this value for `[your_client_secret]` in the second tsm command.
- **Tableau Server URL:** Enter your Tableau Server URL, such as `https://myco.com`. Copy this value for `[your_server_url]` in the third tsm command.

Run the following tsm commands to configure Tableau Server OAuth for Azure Data Lake Storage Gen2:

- `tsm configuration set -k oauth.azuredatalake_storage_gen2.client_id -v [your_client_id] --force-keys`
- `tsm configuration set -k oauth.azuredatalake_storage_gen2.client_secret -v [your_client_secret] --force-keys`
- `tsm configuration set -k oauth.azuredatalake_storage_gen2.redirect_uri -v http://[your_server_url]/auth/add_oauth_token --force-keys`
- `tsm pending-changes apply`

## Configure default client for Azure Synapse, Azure SQL Database, or Databricks

To configure Tableau Server, you must have the following configuration parameters:

- **Azure OAuth client ID:** Generated from the procedure in Step 1. Copy this value for `[your_client_id]` in the tsm command.
- **Azure OAuthClient secret:** Generated from the procedure in Step 1. Copy this value for `[your_client_secret]` in the second tsm command.
- **Tableau Server URL:** This is your Tableau Server URL, such as `https://myserver.com`. Copy this value for `[your_server_url]` in the third tsm command.

## Tableau Server on Linux Administrator Guide

- **Configuration ID:** The value for the `oauth.config.id` parameter in the following `tsm` command. Valid values:
  - **Azure Synapse:** `azure_sql_dw`
  - **Azure SQL Database:** `azure_sqldb`
  - **Databricks:** `databricks`

Run the following `tsm` commands to configure Azure AD for Azure Synapse, Azure SQL Database, or Databricks. For example, to set up Azure Synapse:

```
tsm configuration set -k oauth.config.clients -v "[{"oauth.config.id": "azure_sql_dw", "oauth.config.client_id": "[your_client_id]", "oauth.config.client_secret": "[your_client_secret]", "oauth.config.redirect_uri": "[your_server_url]/auth/add_oauth_token"}]" --force-keys
```

```
tsm pending-changes apply
```

## Configure a default OAuth client for OneDrive and SharePoint Online

To configure Tableau Server for OneDrive and SharePoint Online, you must have the following configuration parameters:

- **Azure OAuth client ID:** The client ID is generated from the procedure in Step 1. Copy this value for `[your_client_id]` in the first `tsm` command.
- **Azure OAuth client secret:** The client secret is generated from the procedure in Step 1. Copy this value for `[your_client_secret]` in the second `tsm` command.
- **Tableau Server URL:** This is your Tableau Server URL, such as `https://myco.com`. Copy this value for `[your_server_url]` in the third `tsm` command.

Run the following `tsm` commands to configure Tableau Server OAuth for OneDrive and SharePoint Online:

- `tsm configuration set -k oauth.onedrive_and_sharepoint_online.client_id -v [your_client_id] --force-keys`

- `tsm configuration set -k oauth.onedrive_and_sharepoint_online.client_secret -v [your_client_secret] --force-keys`
- `tsm configuration set -k oauth.onedrive_and_sharepoint_online.redirect_uri -v http://[your_server_url]/auth/add_oauth_token --force-keys`
- `tsm pending-changes apply`

## Configure a default OAuth client for SharePoint Lists (JDBC)

To configure Tableau Server for SharePoint Lists (JDBC), you must have the following configuration parameters:

- **Azure OAuth client ID:** The client ID is generated from the procedure in Step 1. Copy this value for [your\_client\_id] in the first tsm command.
- **Azure OAuth client secret:** The client secret is generated from the procedure in Step 1. Copy this value for [your\_client\_secret] in the first tsm command.
- **Tableau Server URL:** This is your Tableau Server URL, such as <https://myco.com>. Copy this value for [your\_server\_url] in the first tsm command.

Run the following tsm commands to configure Tableau Server OAuth SharePoint Lists (JDBC):

- `tsm configuration set -k oauth.config.clients -v "[{\\"oauth.config.id\\":\\"cdata_sharepoint\\", \\"oauth.config.client_id\\":\\"[your_client_id]\\", \\"oauth.config.client_secret\\":\\"[your_client_secret]\\", \\"oauth.config.redirect_uri\\":\\"[your_server_url]/auth/add_oauth_token\\"}]" --force-keys`
- `tsm pending-changes apply`

## Configure a default OAuth client for OneDrive (deprecated)

To configure Tableau Server for OneDrive (deprecated), you must have the following configuration parameters:

- **Azure OAuth client ID:** The client ID is generated from the procedure in Step 1. Copy this value for [your\_client\_id] in the first tsm command.
- **Azure OAuth client secret:** The client secret is generated from the procedure in Step 1. Copy this value for [your\_client\_secret] in the second tsm command.

- **Tableau Server URL:** This is your Tableau Server URL, such as `https://myco.com`. Copy this value for `[your_server_url]` in the third `tsm` command.

To continue run the following `tsm` commands to configure Tableau Server OAuth for OneDrive (deprecated):

- `tsm configuration set -k oauth.onedrive.client_id -v [your_client_id] --force-keys`
- `tsm configuration set -k oauth.onedrive.client_secret -v [your_client_secret] --force-keys`
- `tsm configuration set -k oauth.onedrive.redirect_uri -v http://[your_server_url]/auth/add_oauth_token --force-keys`
- `tsm pending-changes apply`

## Server Restart Scenarios

After you configure a default OAuth client, the following scenarios can occur.

- A restart prompt appears if the pending changes require a server restart.
- You can suppress the prompt using the `--ignore-prompt` option, but this doesn't stop the restart.
- If the changes don't require a restart, the changes are applied without a prompt. For more information, see [tsm pending-changes apply](#).

## Setting multiple connectors

If you have multiple connectors to set, you must include all of them in a single command. For example:

```
tsm configuration set -k oauth.config.clients -v "[{"oauth.config.id":"azure_sql_dw", "oauth.config.client_id":"[your_client_id]", "oauth.config.client_secret":"[your_client_secret]", "oauth.config.redirect_uri":"[your_server_url]/auth/add_oauth_token"}, {"oauth.config.id":"azure_sqldb", "oauth.config.client_id":"[your_client_id]", "oauth.config.client_secret":"[your_client_secret]", "oauth.config.redirect_uri":"[your_server_url]/auth/add_oauth_token"}]
```

```
{\"oauth.config.id\": \"databricks\", \"oauth.config.client_id\": \"
[your_client_id]\", \"oauth.config.client_secret\": \"[your_client_
secret]\", \"oauth.config.redirect_uri\": \"[your_server_url]/au-
th/add_oauth_token\"}]\" --force-keys
```

```
tsm pending-changes apply
```

## Configure custom OAuth for a site

You can configure custom Azure Data Lake Storage Gen2, Azure Synapse, Azure SQL Database, and Databricks OAuth clients for a site.

Consider configuring a custom OAuth client to 1) override an OAuth client if configured for the server or 2) enable support for securely connecting to data that requires unique OAuth clients.

When a custom OAuth client is configured, the site-level configuration takes precedence over any server-side configuration and all new OAuth credentials created use the site-level OAuth client by default. No Tableau Server restart is required for the configurations to take effect.

**Important:** Existing OAuth credentials established before the custom OAuth client is configured are temporarily usable but both server administrators and users must update their saved credentials to help ensure uninterrupted data access.

### 1: Prepare the OAuth client ID, client secret, and redirect URL

Before you can configure the custom OAuth client, you need the information listed below.

After you have this information prepared, you can register the custom OAuth client for the site.

For more information, see the section **Register OAuth Client With Snowflake**, above.

- **OAuth client ID and client secret:** First register the OAuth client with the data provider (connector) to retrieve the client ID and secret generated for Tableau Server.
- **Redirect URL:** Note the correct redirect URL. You will need this during the registration process in **Step 2** below.

`https://<your_server_name>.com/auth/add_oauth_token`

For example, `https://example.com/auth/add_oauth_token`

## 2: Register the OAuth client ID and client secret

Follow the procedure described below to register the custom OAuth client to the site.

1. (Versions 2024.1 and earlier) On the Tableau Server computer, run the following command to enable the Snowflake OAuth service:

```
tsm configuration set -k native_api.enable_snowflake_
privatelink_on_server -v true
```

**Note:** For versions 2024.2 and newer, skip step 1 regardless of whether a Snowflake private connection is being used or not.

2. Sign in to your Tableau Server site using your admin credentials and navigate to the **Settings** page.
3. Under OAuth Clients Registry, click the **Add OAuth Client** button.
4. Enter the required information, including the information from **Step 1** above:
  - a. For **Connection Type**, select the connector whose custom OAuth client you want to configure.
  - b. **OAuth Instance URL** is required if multiple OAuth clients are being registered. Otherwise, it is optional.
  - c. For **Client ID**, **Client Secret**, and **Redirect URL**, enter the information you prepared in **Step 1** above.
  - d. Click the **Add OAuth Client** button to complete the registration process.

5. (Optional) Repeat step 3 for all supported connectors.
6. Click the **Save** button at the bottom or top of the Settings page to save changes.

### 3: Validate and update saved credentials

To help ensure uninterrupted data access, you (and your site users) must delete the previous saved credentials and add it again to use the custom OAuth client for the site.

1. Navigate to your **My Account Settings** page.
2. Under **Saved Credentials for Data Sources**, do the following:
  - a. Click **Delete** next to the existing saved credentials for the connector whose custom OAuth client you configured in **Step 2** above.
  - b. Next to connector name, click **Add** and follow the prompts to 1) connect to the custom OAuth client configured in **Step 2** above and 2) save the latest credentials.

### 4: Notify users to update their saved credentials

Make sure you notify your site users to update their saved credentials for the connector whose custom OAuth client you configured in **Step 2** above. Site users can use the procedure described in Update saved credentials to update their saved credentials.

#### Configure OAuth for Snowflake Connections

There are multiple ways you can configure OAuth for Snowflake connections, depending on which version of Tableau you are using and how many sites you are updating. This topic

covers configuration for each available option.

For all versions of Tableau up to and including version 2024.1, the Tableau Snowflake connector by default uses an OAuth proxy hosted in AWS (GALOP), which uses a common client ID and secret. Starting with Tableau 2020.4, you can optionally configure Tableau Server to use a new OAuth service that runs in the same location as that instance of Tableau. This requires providing your own client ID and secret, which is referred to as custom OAuth. Starting in 2024.2, the GALOP proxy will be deprecated and the instructions below for setting up custom OAuth will be **required**, as it will now use the local OAuth service for authentication.

The benefits provided by Custom OAuth include:

- Improved security
- You can use OAuth in isolated environments that cannot connect to the OAuth Proxy (GALOP).
- You don't have to safe-list the GALOP IP addresses to run the OAuth flow in AWS PrivateLink or Azure Private Link VPCs.

## Register OAuth Client With Snowflake

To use a custom OAuth setup in Tableau Server, you must first register your OAuth client and obtain a Client ID and Client Secret to complete the configuration. For Tableau Server versions 2024.2 and later, this step is required, regardless of which configuration option you are using. To register a custom OAuth client with Snowflake, follow the steps described in [Configure Snowflake OAuth for Custom Clients](#).

After you register, you'll use the following Snowflake parameters to configure Tableau Server:

- Account instance URL
- Client ID
- Client secret
- Redirect URL

**Note:** The Redirect URL is the same when entered both on the Snowflake and Tableau sides. The format is:

`https://your_server_url.com/auth/add_oauth_token`

For example, `https://example.com/auth/add_oauth_token`

## Option 1: Configure OAuth for Snowflake Connections using TSM

We recommend using this option when you need to update several sites at once.

**Note:** This configuration option is not available for use on Tableau Cloud.

1. (Versions 2024.1 and earlier) On the Tableau Server computer, run the following command to enable the Snowflake OAuth service:

```
tsm configuration set -k native_api.enable_snowflake_
privatelink_on_server -v true
```

**Note:** For versions 2024.2 and newer, skip step 1 regardless of whether a Snowflake private connection is being used or not.

2. Copy, paste, and customize the following command in a text editor:

**Note:** If you're making these configuration changes in Tableau Server 2021.1 and later, note that the format of `oauth.snowflake.clients` value has changed.

## Tableau Server on Linux Administrator Guide

```
tsm configuration set -k oauth.snowflake.clients -v " [{\"oauth.snowflake.instance_url\": \"https://account.snowflakecomputing.com\", \"oauth.snowflake.client_id\": \"client_id_string\", \"oauth.snowflake.client_secret\": \"client_secret_string\", \"oauth.snowflake.redirect_uri\": \"http://your_server_url.com/auth/add_oauth_token\" }]"
```

The `oauth.snowflake.clients` key takes an array of key pairs. Each element in the key pair must be encapsulated by double quotes. Double quotes must be escaped as `\`.

To specify multiple account instance URLs, separate each additional OAuth client wrapped in braces (`{}`) with a comma (`,`), as in this example:

```
tsm configuration set -k oauth.snowflake.clients -v " [{\"oauth.snowflake.instance_url\": \"https://account.snowflakecomputing.com\", \"oauth.snowflake.client_id\": \"client_id_string1\", \"oauth.snowflake.client_secret\": \"client_secret_string1\", \"oauth.snowflake.redirect_uri\": \"http://your_server_url.com/auth/add_oauth_token\" }, {\"oauth.snowflake.instance_url\": \"https://account2.snowflakecomputing.com\", \"oauth.snowflake.client_id\": \"client_id_string2\", \"oauth.snowflake.client_secret\": \"client_secret_string2\", \"oauth.snowflake.redirect_uri\": \"http://your_server_url.com/auth/add_oauth_token\" }]"
```

Replace the values for each key:

- Account instance URL: `oauth.snowflake.instance_url`
- Client ID: `oauth.snowflake.client_id`

- Client secret: `oauth.snowflake.client_secret`
- Redirect URL: `oauth.snowflake.redirect_uri`

**Note:** Before running the command, verify the syntax carefully. TSM won't validate this input.

Copy the command into TSM CLI and run the command.

3. Enter the following command to apply the changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt.

For more information, see `tsm pending-changes apply`.

## Option 2: Configure OAuth for Snowflake Connections by Site

**Note:** This option is also available for Tableau Cloud starting with version 2024.2.

You can configure a custom Snowflake OAuth client at the site level by using the Tableau Server UI.

Consider configuring a custom OAuth client to 1) override an OAuth client if configured for the server or 2) enable support for securely connecting to data that requires unique OAuth clients.

When a custom OAuth client is configured, the site-level configuration takes precedence over any server-side configuration and all new OAuth credentials created use the site-level OAuth client by default. No Tableau Server restart is required for the configurations to take effect.

**Important:** Existing OAuth credentials established before the custom OAuth client is configured are temporarily usable but both server administrators and users must update their saved credentials to help ensure uninterrupted data access.

### 1: Prepare the OAuth client ID, client secret, and redirect URL

Before you can configure the custom OAuth client, you need the information listed below. After you have this information prepared, you can register the custom OAuth client for the site. For more information, see the section **Register OAuth Client With Snowflake**, above.

- **OAuth client ID and client secret:** First register the OAuth client with the data provider (connector) to retrieve the client ID and secret generated for Tableau Server.
- **Redirect URL:** Note the correct redirect URL. You will need this during the registration process in **Step 2** below.

`https://<your_server_name>.com/auth/add_oauth_token`

For example, `https://example.com/auth/add_oauth_token`

### 2: Register the OAuth client ID and client secret

Follow the procedure described below to register the custom OAuth client to the site.

1. (Versions 2024.1 and earlier) On the Tableau Server computer, run the following command to enable the Snowflake OAuth service:

```
tsm configuration set -k native_api.enable_snowflake_
privatelink_on_server -v true
```

**Note:** For versions 2024.2 and newer, skip step 1 regardless of whether a Snowflake private connection is being used or not.

2. Sign in to your Tableau Server site using your admin credentials and navigate to the **Settings** page.
3. Under OAuth Clients Registry, click the **Add OAuth Client** button.
4. Enter the required information, including the information from **Step 1** above:
  - a. For **Connection Type**, select the connector whose custom OAuth client you want to configure.
  - b. **OAuth Instance URL** is required if multiple OAuth clients are being registered. Otherwise, it is optional.
  - c. For **Client ID**, **Client Secret**, and **Redirect URL**, enter the information you prepared in **Step 1** above.
  - d. Click the **Add OAuth Client** button to complete the registration process.

5. (Optional) Repeat step 3 for all supported connectors.
6. Click the **Save** button at the bottom or top of the Settings page to save changes.

### 3: Validate and update saved credentials

To help ensure uninterrupted data access, you (and your site users) must delete the previous saved credentials and add it again to use the custom OAuth client for the site.

1. Navigate to your **My Account Settings** page.
2. Under **Saved Credentials for Data Sources**, do the following:
  - a. Click **Delete** next to the existing saved credentials for the connector whose custom OAuth client you configured in **Step 2** above.
  - b. Next to connector name, click **Add** and follow the prompts to 1) connect to the custom OAuth client configured in **Step 2** above and 2) save the latest credentials.

## 4: Notify users to update their saved credentials

Make sure you notify your site users to update their saved credentials for the connector whose custom OAuth client you configured in **Step 2** above. Site users can use the procedure described in Update saved credentials to update their saved credentials.

### Set Up OAuth for Intuit QuickBooks Online

This topic describes how to set up your Intuit QuickBooks Online data sources for OAuth authentication. Complete these steps for each Tableau Server instance.

Setting up OAuth for QuickBooks Online consists of the following tasks:

1. Create a Connected App on the Intuit developer platform.
2. Use the information you get as part of the Connected App to configure your server.
3. (Optional) Configure site-specific OAuth.

## Step 1: Create an Intuit app

1. Sign in to your Intuit developer account, and then click **My Apps**.
2. In the **Just start coding** section, click **Select APIs**.
3. Select **Accounting** and click **Create App**.

4. In the **Get your app ready for submission** section, click the link to get your production keys.

**Important:** You must use production keys rather than development keys.

5. Copy the app token, OAuth consumer key, and OAuth consumer secret.

## Step 2: Configure Tableau Server for Intuit QuickBooks Online

- On the Tableau Server computer, open the bash shell and run the following commands:

```
tsm configuration set -k oauth.quickbooks.oauth_callback_uri -v  
http://YOUR-SERVER/auth/add_oauth_token
```

```
tsm configuration set -k oauth.quickbooks.consumer_key -v  
<your_consumer_key>
```

```
tsm configuration set -k oauth.quickbooks.consumer_secret -v  
<your_consumer_secret>
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

# Managing access tokens

If you run an extract refresh job for your QuickBooks Online data source, Tableau Server attempts to renew access tokens for you. To help ensure that your access tokens do not expire, run your extract refresh jobs more than once a month. Otherwise, the access tokens from QuickBooks Online expire and your extract refresh jobs fail. If your access tokens do expire, you can edit your saved credentials from the **Settings** page.

The saved credentials can be managed centrally or by your users. For more information, see [Allow Saved Access Tokens](#).

## Set Up OAuth for Dremio

This topic describes how to set up Dremio data sources for OAuth authentication. Complete these steps for each Tableau Server instance.

Setting up OAuth for Dremio consists of the following tasks:

1. Register an OAuth client with Dremio.
2. Use the information you obtained in Step 1 to configure Tableau Server for Dremio OAuth.
3. (Optional) Configure site-specific OAuth.

## Step 1: Register OAuth client in Dremio

Use the [Identity Providers](#) topic in the Dremio documentation to configure a Dremio-supported IdP to get the OAuth client ID and secret configuration parameters needed to configure Tableau Server for Dremio OAuth.

## Step 2: Configure Tableau Server for Dremio OAuth

To configure Tableau Server for Dremio OAuth, you will use the parameters listed below in the `tsm` command that follows.

- **Dremio client ID:** The client ID is generated from the registration process in Step 1. Copy this value for `[your_client_id]` in the `tsm` command.
- **Dremio client secret:** The client secret is generated from the procedure in Step 1. Copy this value for `[your_client_secret]` in the `tsm` command.
- **Tableau Server URL:** This is your Tableau Server URL, such as `https://-myco.com`. Copy this value for `[your_server_url]` in the `tsm` command.
- **Configuration ID:** This is the value for the `oauth.config.id` parameter you will use in the `tsm` command: `dremio`

Run the following `tsm` commands to configure OAuth for Dremio:

```
tsm configuration set -k oauth.config.clients -v "[{"oauth.config.id":"dremio", "oauth.config.client_id":"[your_client_id]", "oauth.config.client_secret":"[your_client_secret]", "oauth.config.redirect_uri":"[your_server_url]/auth/add_oauth_token"}]" --force-keys
```

```
tsm pending-changes apply
```

## Setting multiple connectors

If you have multiple connectors to set, you must include all of them in a single command. For example:

```
tsm configuration set -k oauth.config.clients -v "[{"oauth.config.id":"dremio", "oauth.config.client_id":"[your_client_id]", "oauth.config.client_secret":"[your_client_secret]", "oauth.config.redirect_uri":"[your_server_url]/auth/add_oauth_token"}, {"oauth.config.id":"customer_360_audience", "oauth.config.client_id":"[your_client_id]", "oauth.config.client_secret":"[your_client_secret]", "oauth.config.redirect_uri":"[your_server_url]/auth/add_oauth_token"}, {"oauth.config.id":"azure_sql_dw", "oauth.config.client_id":"[your_client_id]", "oauth.config.client_secret":"[your_client_secret]", "oauth.config.redirect_uri":"[your_server_
```

```
url]/auth/add_oauth_token\"}, {\"oauth.config.id\": \"azure_sqldb\",  
\"oauth.config.client_id\": \"[your_client_id]\", \"oau-  
th.config.client_secret\": \"[your_client_secret]\", \"oau-  
th.config.redirect_uri\": \"[your_server_url]/auth/add_oauth_  
token\"}]\" --force-keys
```

```
tsm pending-changes apply
```

# Configure custom OAuth for a site

You can configure custom Dremio OAuth for a site.

Consider configuring a custom OAuth client to 1) override an OAuth client if configured for the server or 2) enable support for securely connecting to data that requires unique OAuth clients.

When a custom OAuth client is configured, the site-level configuration takes precedence over any server-side configuration and all new OAuth credentials created use the site-level OAuth client by default. No Tableau Server restart is required for the configurations to take effect.

**Important:** Existing OAuth credentials established before the custom OAuth client is configured are temporarily usable but both server administrators and users must update their saved credentials to help ensure uninterrupted data access.

## 1: Prepare the OAuth client ID, client secret, and redirect URL

Before you can configure the custom OAuth client, you need the information listed below. After you have this information prepared, you can register the custom OAuth client for the site. For more information, see the section **Register OAuth Client With Snowflake**, above.

- **OAuth client ID and client secret:** First register the OAuth client with the data provider (connector) to retrieve the client ID and secret generated for Tableau Server.
- **Redirect URL:** Note the correct redirect URL. You will need this during the registration process in **Step 2** below.

`https://<your_server_name>.com/auth/add_oauth_token`

For example, `https://example.com/auth/add_oauth_token`

## 2: Register the OAuth client ID and client secret

Follow the procedure described below to register the custom OAuth client to the site.

1. (Versions 2024.1 and earlier) On the Tableau Server computer, run the following command to enable the Snowflake OAuth service:

```
tsm configuration set -k native_api.enable_snowflake_
privatelink_on_server -v true
```

**Note:** For versions 2024.2 and newer, skip step 1 regardless of whether a Snowflake private connection is being used or not.

2. Sign in to your Tableau Server site using your admin credentials and navigate to the **Settings** page.
3. Under OAuth Clients Registry, click the **Add OAuth Client** button.
4. Enter the required information, including the information from **Step 1** above:
  - a. For **Connection Type**, select the connector whose custom OAuth client you want to configure.
  - b. **OAuth Instance URL** is required if multiple OAuth clients are being registered. Otherwise, it is optional.
  - c. For **Client ID**, **Client Secret**, and **Redirect URL**, enter the information you prepared in **Step 1** above.
  - d. Click the **Add OAuth Client** button to complete the registration process.

Create OAuth Client

Connection Type: Snowflake

OAuth Instance URL: Optional

Client ID:

Client Secret:

Redirect URL:

Close Add OAuth Client

5. (Optional) Repeat step 3 for all supported connectors.
6. Click the **Save** button at the bottom or top of the Settings page to save changes.

### 3: Validate and update saved credentials

To help ensure uninterrupted data access, you (and your site users) must delete the previous saved credentials and add it again to use the custom OAuth client for the site.

1. Navigate to your **My Account Settings** page.
2. Under **Saved Credentials for Data Sources**, do the following:
  - a. Click **Delete** next to the existing saved credentials for the connector whose custom OAuth client you configured in **Step 2** above.
  - b. Next to connector name, click **Add** and follow the prompts to 1) connect to the custom OAuth client configured in **Step 2** above and 2) save the latest credentials.

### 4: Notify users to update their saved credentials

Make sure you notify your site users to update their saved credentials for the connector whose custom OAuth client you configured in **Step 2** above. Site users can use the procedure described in Update saved credentials to update their saved credentials.

#### Set Up OAuth for Dropbox

This topic describes how to set up your Dropbox data sources for OAuth authentication. Complete the steps for each Tableau Server instance.

Setting up OAuth for Dropbox consists of the following tasks:

1. Create a new app in your Dropbox developer portal App console.
2. Use the information you get as part of creating the new app to configure your server.
3. (Optional) Configure site-specific OAuth.

## Step 1: Create a new app

1. Sign in to your Dropbox developer console, and then choose **App console**.
2. Click the **Create app** button.
3. Configure and name your app and choose the **Create app** button.
4. After the app is created, navigate to its Permissions tab and ensure that the files.-content.read permission is selected.
5. Navigate to the **Settings** tab and add a Redirect URI using the internet address for your Tableau Server.
6. Add the following text to the end of the URI: auth/add\_oauth\_token. For example:
7. https://your\_server\_url.com/auth/add\_oauth\_token
8. Copy the app key, app secret, and redirect URI from the **Settings** tab.

## Step 2: Configure Tableau Server for Dropbox

On the Tableau Server computer, open the bash shell, and run the following tsm commands:

```
tsm configuration set -k oauth.dropbox.redirect_uri -v <your_authorized_redirect_uri>
```

```
tsm configuration set -k oauth.dropbox.client_id -v <your_app_key>
```

```
tsm configuration set -k oauth.dropbox.client_secret -v <your_app_secret>
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command displays a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--`

`ignore-prompt` option, but this doesn't change the restart behavior. If the changes don't require a restart, the changes are applied without a prompt. For more information, see [tsm pending-changes apply](#).

## Configure custom OAuth for a site

You can configure custom Dropbox OAuth for a site.

Consider configuring a custom OAuth client to 1) override an OAuth client if configured for the server or 2) enable support for securely connecting to data that requires unique OAuth clients.

When a custom OAuth client is configured, the site-level configuration takes precedence over any server-side configuration and all new OAuth credentials created use the site-level OAuth client by default. No Tableau Server restart is required for the configurations to take effect.

**Important:** Existing OAuth credentials established before the custom OAuth client is configured are temporarily usable but both server administrators and users must update their saved credentials to help ensure uninterrupted data access.

### 1: Prepare the OAuth client ID, client secret, and redirect URL

Before you can configure the custom OAuth client, you need the information listed below. After you have this information prepared, you can register the custom OAuth client for the site. For more information, see the section **Register OAuth Client With Snowflake**, above.

- **OAuth client ID and client secret:** First register the OAuth client with the data provider (connector) to retrieve the client ID and secret generated for Tableau Server.
- **Redirect URL:** Note the correct redirect URL. You will need this during the registration process in **Step 2** below.

`https://<your_server_name>.com/auth/add_oauth_token`

For example, `https://example.com/auth/add_oauth_token`

## 2: Register the OAuth client ID and client secret

Follow the procedure described below to register the custom OAuth client to the site.

1. (Versions 2024.1 and earlier) On the Tableau Server computer, run the following command to enable the Snowflake OAuth service:

```
tsm configuration set -k native_api.enable_snowflake_
privatelink_on_server -v true
```

**Note:** For versions 2024.2 and newer, skip step 1 regardless of whether a Snowflake private connection is being used or not.

2. Sign in to your Tableau Server site using your admin credentials and navigate to the **Settings** page.
3. Under OAuth Clients Registry, click the **Add OAuth Client** button.
4. Enter the required information, including the information from **Step 1** above:
  - a. For **Connection Type**, select the connector whose custom OAuth client you want to configure.
  - b. **OAuth Instance URL** is required if multiple OAuth clients are being registered. Otherwise, it is optional.
  - c. For **Client ID**, **Client Secret**, and **Redirect URL**, enter the information you prepared in **Step 1** above.
  - d. Click the **Add OAuth Client** button to complete the registration process.

5. (Optional) Repeat step 3 for all supported connectors.
6. Click the **Save** button at the bottom or top of the Settings page to save changes.

### 3: Validate and update saved credentials

To help ensure uninterrupted data access, you (and your site users) must delete the previous saved credentials and add it again to use the custom OAuth client for the site.

1. Navigate to your **My Account Settings** page.
2. Under **Saved Credentials for Data Sources**, do the following:
  - a. Click **Delete** next to the existing saved credentials for the connector whose custom OAuth client you configured in **Step 2** above.
  - b. Next to connector name, click **Add** and follow the prompts to 1) connect to the custom OAuth client configured in **Step 2** above and 2) save the latest credentials.

### 4: Notify users to update their saved credentials

Make sure you notify your site users to update their saved credentials for the connector whose custom OAuth client you configured in **Step 2** above. Site users can use the procedure described in Update saved credentials to update their saved credentials.

#### Set Up Amazon Redshift IAM OAuth

Starting in Tableau 2023.3.2 for on premise (Tableau Desktop, Tableau Server, and Tableau Prep), you can use OAuth 2.0/OIDC to federate identity from an external identity provider to

Amazon Redshift.

These instructions are for the older AWS IAM service. For IAM IDC integration see [Set Up Amazon Redshift IAM Identity Center OAuth](#).

Depending on the identity provider, there are different steps needed to configure the integration. This is a high level overview. Tableau cannot provide detailed instructions for how to configure AWS or the IDP, but the general approach is described below.

## Step 1: Configure the IDP

1. Create OAuth clients on the IDP for Tableau Desktop, and Tableau Server or Tableau Cloud. The Desktop client should enable `PKCE` and use `http://localhost` redirects.
2. Add custom claims to use for authorization to roles. In particular, if you are using original IAM, you may want to add claims for `DbUser` and `DbGroups`. These can be used in your IAM policies later.
3. Create the Tableau OAuth config files. See documentation on [GitHub](#), and examples [here](#). We welcome examples for other IDPs.
  - a. Be sure to prefix the Tableau OAuth config IDs with `"custom_"`.
  - b. If your IDP supports dynamic localhost port then disable `OAuthCapFixedPortInCallbackUrl`. If your IDP does not support this, make sure to add several localhost callback URLs to the allowlist in the config file and on the IDP.
4. Install the new Tableau OAuth configuration files in the `OAuthConfigs` folder associated with each application on desktop hosts (Tableau Desktop, Tableau Prep Builder, Tableau Bridge), and on each Tableau Server and Tableau Cloud site that will be using OAuth.

# Configure IDP on AWS

1. Create the IDP model on the AWS. See Amazon docs [Web Identity Federation](#) and [Create OIDC Identity Provider](#).
2. Create roles and policies specifically for the IDP. See [Create Role for OIDC](#) in the AWS docs.

## Configure Roles for Redshift Users

Attach the policies needed for Redshift. You may use custom claims from the token to authorize to roles. There are several examples with SAML in [the AWS documentation](#). These can be easily adapted to OAuth. In the case of OAuth, the claims are just “DbUser”, “DbGroups”, etc.

Here is an example of the policy from the AWS documentation:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "redshift:GetClusterCredentials",
      "Resource": [
        "arn:aws:redshift:us-west-1:123456789012:dbname:cluster-
        identifier/dev",
        "arn:aws:redshift:us-west-1:123456789012:dbuser:cluster-
        identifier/${redshift:DbUser}",
        "arn:aws:redshift:us-west-1:123456789012:cluster-
        :cluster-identifier"
      ],
      "Condition": {
        "StringEquals": {
          "aws:userid": "AROAJ2UCCR6DPCEXAMPLE:${red-
          shift:DbUser}@example.com"
        }
      }
    }
  ]
}
```

```

    },
    {
      "Effect": "Allow"
      "Action": "redshift:CreateClusterUser",
      "Resource": "arn:aws:redshift:us-west-1:12345:d-
buser:cluster-identifier/${redshift:DbUser}"
    },
    {
      "Effect": "Allow",
      "Action": "redshift:JoinGroup",
      "Resource": "arn:aws:redshift:us-west-1:12345:d-
bgroup:cluster-identifier/my_dbgroup"
    },
    {
      "Effect": "Allow",
      "Action": [
        "redshift:DescribeClusters",
        "iam:ListRoles"
      ],
      "Resource": "*"
    }
  ]
}

```

## Connect to Redshift

The user must specify the **role ARN** to assume, and select the OAuth config installed earlier.

Amazon Redshift

General Initial SQL Advanced

Server  
myredshift.cluster

Port  
5439

Database  
TestV1

Authentication  
OAuth

Federation Type  
IAM Role

AWS Role ARN  
arn:aws:iam::1234:role/fed-redshift

OAuth Provider  
custom\_my\_okta

Require SSL

Sign In

When properly configured, the user will be redirected to the IDP to authenticate and authorize tokens for Tableau. Tableau will receive openid and refresh tokens. AWS is able to validate the token and signature from the IDP, extract the claims from the token, look up the mapping of

claims to IAM role, and either permit or block Tableau from assuming the role on the user's behalf. (in other words, [AssumeRoleWithWebIdentity](#)).

## Tokens

By default Redshift OAuth IAM passes the ID token to the driver. For on-premise customers, including those using Tableau Bridge, you may use a TDC file to pass the access token instead.

```
<connection-customization class='redshift' enabled='true' version='10.0'>
  <vendor name='redshift' />
  <driver name='redshift' />
  <customizations>
    <customization name='CAP_OAUTH_FEDERATE_ACCESS_TOKEN' value='yes' />
  </customizations>
</connection-customization>
```

For more information about configuring and installing .tdc files, see [Customize and Tune a Connection](#) and [Using a .tdc File with Tableau Server](#).

## Okta

If using Okta it's better to use a “custom authorization server” rather than the “org authorization server.” The custom authorization servers are more flexible. There is a custom authorization server created by default, which is called “default”. The authorization URL should look like this:

```
https://${yourOktaDomain}/oauth2/{authServerName}/v1/authorize
```

## Update Driver

For Redshift OAuth using the original IAM service, you may use either:

- Redshift ODBC v1 driver starting with version 1.59, which can be downloaded from <https://docs.aws.amazon.com/redshift/latest/mgmt/configure-odbc-connection.html>.
- Redshift ODBC v2 driver starting with version 2.0.1.0, which can be downloaded from <https://github.com/aws/amazon-redshift-odbc-driver/tags>. Note there is no v2 driver for OSX.

## Troubleshooting

The best way to diagnose errors is to remove Tableau from the picture. You can instead test using the driver manager or a similar tool. This is just for troubleshooting - you shouldn't use a DSN or the "Other ODBC" connector for regular usage of this feature. To help ensure a valid test, the parameters should be the same as shown below, except for the cluster information, database, token, and namespace.

If you see an error message about invalid/expired token coming from the driver on the first connection (it will have a SQLState error code like [28000] or [08001] in the error message), then Tableau successfully completed the OAuth flow, and failed in the driver. This means there is a

misconfiguration on either the AWS side or the IDP side. There may also be permissions or authorization errors returned from the driver, which is also out of Tableau's control.

Before you begin testing, you first need to get an access token (the default for IAM IDC) or refresh token (if customized) to send to the driver.

Here is an example with Okta. Almost all IDPs have a way to do this which is quite similar. Note that to use this flow you need to have enabled resource owner password grant type. Substitute the IDP URL, client secret, client ID, username, and password.

```
curl -X POST "https://OKTA_URL/v1/token" \  
-H 'accept: application/json' \  
-H "Authorization: Basic $(echo -n 'CLIENTID:CLIENTSECRET' | \  
base64)" \  
-H "Content-Type: application/x-www-form-urlencoded" \  
-d "grant_type=  
e=password&username=USER&password=PASSWORD&scope=openid"
```

Once you have the token, you can use a DSN to test. For Windows, you can use the ODBC driver manager. On Mac you can use the iODBC driver manager UI. On Linux you can use the isql command line tool that is included with Tableau Server in the customer-bin folder.

Tableau recommends you do not use other plugins to test, because they may not work in a server environment. They either use a fixed AWS profile, or require direct access to a browser.

Below is an example of using the ODBC driver manager on Windows.

## Set Up Amazon Redshift IAM Identity Center OAuth

Starting in Tableau 2023.3.2 for on premise (Tableau Desktop, Tableau Server, and Tableau Prep), you can use OAuth 2.0/OIDC to federate identity from an external identity provider to Amazon Redshift.

These instructions are for the newer AWS IAM IDC service. For original IAM integration see [Set Up Amazon Redshift IAM OAuth](#).

Depending on the identity provider, there are different steps needed to configure the integration. This is a high level overview. Tableau cannot provide detailed instructions for how to configure AWS or the IDP, but this is the general approach.

For some detailed examples of implementing authentication with Redshift, see "[Integrate Tableau and Okta with Amazon Redshift using AWS IAM Identity Center](#)" and "[Integrate Tableau and Microsoft Entra ID with Amazon Redshift using AWS IAM Identity Center](#)".

## Step 1: Configure the IDP

1. Create OAuth clients on the IDP for Tableau Desktop and Tableau Server or Tableau Cloud. The Desktop client should enable `PKCE` and use `http://localhost` redirects.
2. Add any required custom claims to use for authorization to roles.
3. Create the Tableau OAuth config files. See documentation on [GitHub](#), and [examples](#). We welcome examples for other IDPs.
  - a. Be sure to prefix the Tableau OAuth config IDs with `"custom_"`.
  - b. If your IDP supports dynamic localhost port then disable `OAuth_CAP_FIXED_PORT_IN_CALLBACK_URL`. If it does not, make sure to add several localhost callback URLs to the allowlist in the config file and on the IDP.

4. Install the new Tableau OAuth configuration files in the `OAuthConfigs` folder associated with each application on desktop hosts (Tableau Desktop, Tableau Prep Builder, Tableau Bridge), and on each Tableau Server and Tableau Cloud site that will be using OAuth.

## Step 2: Configure IDP and Roles on AWS

See your AWS documentation for information on doing this.

## Step 3: Connect to Redshift

1. Connect to Redshift.
2. Select OAuth for **Authentication**.
3. Select Identity Center for **Federation Type**.
4. (Optional) Specify the **Identity Center Namespace** if necessary.

Amazon Redshift

General Initial SQL Advanced

Server  
redshift.acme.com

Port  
5439

Database  
dev

Authentication  
OAuth

Federation Type  
Identity Center

Identity Center Namespace  
Optional

OAuth Provider  
custom\_my\_okta

Require SSL

Sign In

When correctly configured, you will be redirected to the IDP to authenticate and authorize tokens for Tableau. Tableau will receive an access token and refresh tokens. It will send the access token to the driver for authentication.

# Tokens

By default Redshift OAuth to IAM IDC passes the access token to the driver. For on-premise customers, including those using Tableau Bridge, you may use a TDC file to pass the ID token instead.

```
<connection-customization class='redshift' enabled='true' version='10.0'>
  <vendor name='redshift' />
  <driver name='redshift' />
  <customizations>
    <customization name='CAP_OAUTH_FEDERATE_ID_TOKEN' value='yes' />
  </customizations>
</connection-customization>
```

For more information about configuring and installing .tdc files, see [Customize and Tune a Connection](#) and [Using a .tdc File with Tableau Server](#).

# Okta

If you are using Okta, it's better to use a "custom authorization server" instead of the "org authorization server." The custom authorization servers are more flexible. A custom authorization server is created by default and called "default". The authorization URL should look like this:

```
https://${yourOktaDomain}/oauth2/{authServerName}/v1/authorize
```

| Summary  |                                 |
|--|---------------------------------|
| Provider<br>dev-██████████.okta.com/oauth2/default | Provider Type<br>OpenID Connect |

| Audiences (1)  |  | Actions ▼ |
|--|--|-----------|
| Also known as client ID, audience is a value that identifies the application that is registered with an OpenID Connect provider. |  |           |
|  |  | < 1 >     |
| Audience   |  |           |
| <input type="radio"/> ██████████   |  |           |

## Update the driver

For Redshift OAuth using the IAM IDC service, you need to use at least version 2.x of the ODBC driver. Download the latest version of the Redshift ODBC driver found on <https://github.com/aws/amazon-redshift-odbc-driver/tags>. Note that there is no v2 driver yet for OSX.

## Troubleshooting Redshift IAM IDC OAuth

The best way to diagnose errors is to remove Tableau from the picture. You can instead test using the driver manager or a similar tool. This is just for troubleshooting - you shouldn't use a DSN or the "Other ODBC" connector for regular usage of this feature. To help ensure a valid test, the parameters should be the same as shown below, except for the cluster information, database, token, and namespace.

If you see an error message about invalid/expired token coming from the driver on the first connection (it will have a SQLState error code like [28000] or [08001] in the error message), then Tableau successfully completed the OAuth flow, and failed in the driver. This means there is a misconfiguration on either the AWS side or the IDP side. There may also be permissions or authorization errors returned from the driver, which is also out of Tableau's control.

## Tableau Server on Linux Administrator Guide

Before you begin testing, you first need to get an access token (the default for IAM IDC) or refresh token (if customized) to send to the driver.

Here is an example with Okta. Almost all IDPs have a way to do this which is quite similar. Note that to use this flow you need to have enabled resource owner password grant type. Substitute the IDP URL, client secret, client ID, username, and password.

```
curl -X POST "https://OKTA_URL/v1/token" \  
-H 'accept: application/json' \  
-H "Authorization: Basic $(echo -n 'CLIENTID:CLIENTSECRET' | \  
base64)" \  
-H "Content-Type: application/x-www-form-urlencoded" \  
-d "grant_type= \  
e=password&username=USER&password=PASSWORD&scope=openid"
```

Once you have the token, you can use a DSN to test. For Windows, you can use the ODBC driver manager. On Linux you can use the isql command line tool that is included with Tableau Server in the customer-bin folder.

Tableau recommends you do not use other plugins to test, because they may not work in a server environment. They either use a fixed AWS profile, or require direct access to a browser.

Below is an example of using the ODBC driver manager on Windows.

## Allow Saved Access Tokens

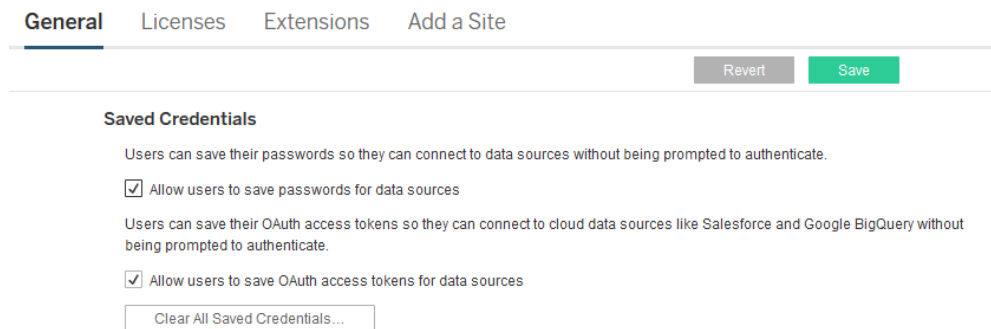

After you configure Tableau Server for OAuth, you can decide to allow users to manage their own OAuth credentials, or you want to manage them centrally. If you want users to manage their own, you need to enable user profile settings from the server.

**Note:** If you have not yet configured your server to enable OAuth data connections, see the related topics listed below.

1. Sign in to Tableau Server as a server administrator.
2. **Single-site:** Click **Settings > General**.  
**Multisite:** In the site menu, click **Manage All Sites** and then click **Settings > General**.
3. In the **Saved Credentials** section, select the following:

- **Allow users to save passwords for data sources** (allows users to save their individual credentials with data sources).
- **Allow users to save OAuth access tokens for data sources**

4. Click **Save**.

After you select these check boxes, users will see a **Manage Credentials** section in their profile settings, where they can add access tokens for OAuth data connections.

## Managing credentials centrally

Server administrators alternatively can manage OAuth credentials centrally. This can work well, for example, if multiple users work from the same data, and you have a dedicated user account for your data provider.

To manage credentials centrally, you do the following:

- Clear the check boxes described in the preceding procedure.
- Edit connection information as data sources are published.

When you edit the connection, you embed credentials that use an OAuth access token instead of an individual's user name and password.

When the settings for saving passwords and access tokens are not enabled, the Manage Credentials section is excluded from users' profile settings.

## See also

[Set up OAuth for Google](#)

[Change Salesforce.com OAuth to Saved Credentials](#)

[Configure OAuth for Snowflake Connections](#)

[Set Up OAuth for Intuit QuickBooks Online](#)

[Troubleshoot OAuth Connections](#)

This topic provides information about resolving issues that can occur when you configure OAuth data connections.

## Conflict error

In some cases, users may receive an error when attempting to connect with OAuth. The first sentence of the error message is:

*The server encountered an internal error or misconfiguration and was unable to complete your request.*

This error indicates that the fully qualified domain name (FQDN) of the Tableau Server needs to be added to the allowlist redirect key on Tableau Server.

## Tableau Server on Linux Administrator Guide

When users are accessing a Tableau Server by the local host name (`https://tableau`) and the OAuth data provider is responding to the public DNS name (`https://data.example.com`), Tableau Server must associate the external FQDN with the local server name. The local host name is the server name in the URL that users enter when accessing Tableau Server from the internal network.

To fix this error, run `tsm configuration set` with the `oauth.whitelisted.redirect_to_origin_host` key option. This key takes a value pair, "`internal_host,FQDN1,FQDN2`". For example, the following commands set the local host name to *tableau* and the FQDN to *tableau.example.com*:

```
tsm configuration set -k oauth.whitelisted.redirect_to_origin_host -v "tableau,tableau.example.com"
```

```
tsm pending-changes apply
```

In the case where multiple public URLs are used to access the internal Tableau Server, add additional FQDNs to the command, separated by commas, for example:

```
tsm configuration set -k oauth.whitelisted.redirect_to_origin_host -v "tableau,tableau.example.com,tableau2.example.com"
```

If you need to edit an existing allowlist redirect configuration, you must enter the full mapping set. You cannot truncate or append existing configuration keys.

### Configure SAP HANA SSO

You can configure Tableau Server to use SAML delegation to provide a single sign-on (SSO) experience for SAP HANA. This scenario is not dependent on SAML authentication to Tableau Server. You do not need to use SAML sign on with Tableau Server in order to use HANA SAML delegation. You can sign in to Tableau Server using whatever method you choose.

With SAML delegation for SAP HANA, Tableau Server functions as an identity provider (IdP).

Before you begin

Configuring SAML delegation with SAP HANA requires configuration on both Tableau Server and on SAP HANA. This topic provides configuration information about configuring Tableau Server. Before you configure Tableau Server, you must complete the following:

- Acquire a SAML certificate and key file for Tableau Server.
  - The certificate file must be a PEM-encoded x509 certificate with the file extension `.cert` or `.pem`. This file is used by Tableau Server and must also be installed on HANA.
  - The private key must be a DER-encoded private key file, in PKCS#8 format, that is not password protected and has the file extension `.der`. This file is only used by Tableau Server.
- Install the certificate in HANA. To avoid `libxmlsec` errors in HANA, we recommend configuring in-memory certificate store on SAP HANA. For more information, see this [SAP support topic](#).
- Install the latest version of SAP HANA driver (minimum version is 1.00.9) on Tableau Server.
- Configure network encryption from Tableau Server to SAP HANA (recommended).

For more information about generating the certificate/key pair, encrypting the SAML connection, and configuring SAP HANA, see [How to Configure SAP HANA for SAML SSO with Tableau Server](#) in the Tableau Community.

### Configure Tableau Server SAML for SAP HANA

The following procedure describes how to configure SAML for SAP HANA on Tableau Server using `tsm data-access`. You can also configure SAML for SAP HANA using the `sapHanaSettings` Entity.

If you are running Tableau Server in a distributed deployment, run the following procedure on the initial node.

## Tableau Server on Linux Administrator Guide

1. Place certificate files in a folder named `saml`. For example:

```
/var/opt/saml
```

2. Run the following commands to specify the location of the certificate and key files:

```
tsm data-access set-saml-delegation configure --cert-key <cert-key> --cert-file <cert-file>
```

Where `<cert-key>` and `<cert-file>` are file paths to the private key and certificate file, respectively.

For example,

```
tsm data-access set-saml-delegation configure --cert-key /var/opt/saml/hana_pkey_pkcs8.der --cert-file /var/opt/saml/hana_certificate.pem
```

You can specify other options. For example, you can specify user name format and how credentials are normalized. See `tsm data-access`.

3. Run the following commands to enable delegation:

```
tsm data-access set-saml-delegation enable

tsm configuration set -k wgserver.sap_hana_sso.enabled -v true

tsm configuration set -k wgserver.delegation.enabled -v true
```

4. When you have finished, run `tsm pending-changes apply`.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart beha-

rior. If the changes do not require a restart, the changes are applied without a prompt.  
For more information, see `tsm pending-changes apply`.

### Enable Kerberos Service Account Access

You can configure Tableau Server to use a Kerberos service account to access a database. In this scenario, Tableau Server connects to databases with a service account, also referred to as a "RunAs account".

To use RunAs authentication on Tableau Server you must first create a workbook or data-source that uses integrated authentication. When users publish to Tableau Server they will get the option for RunAs authentication. If you create a datasources with Tableau Server web authoring that uses integrated authentication, the datasources will use RunAs authentication by default.

**Note:** *Integrated authentication* is also referred to as *Windows Authentication* on some connectors. In both cases, Tableau Server uses Kerberos authentication.

### Data Access with the RunAs Service Account

To use RunAs authentication, the RunAs account requires read and query permissions to external databases. As designed, Tableau Server users with the *Creator* role or the *Explorer (Can Publish)* role have full access to the RunAs account for queries to external databases.

For example, a user with the Creator role can view all databases that have been granted access to the RunAs service account. They can also list tables and run Custom SQL.

If the Creator-user specifies the database host name and selects Integrated Authentication when creating a new data source with web authoring, then databases that have been granted RunAs access will be displayed to the user.

View access to database assets are not restricted to users who connect to Tableau Server with web authoring. Sophisticated users, who have the same roles noted above and who

have knowledge of database server names, could create workbooks with Tableau Desktop that display databases that have been granted RunAs access.

## Recommendations

Whether user access to databases in these scenarios is acceptable must be assessed by your organization. Generally, reducing the usage and scope of the RunAs service account will reduce the likelihood of inadvertent user access to database content. However, reducing the usage and scope of the RunAs service account may also impose more credential management to you and your users.

Evaluate the following recommendations in context of your business needs and data access policies.

- Firstly, be sure that you trust all users who have Creator roles or Explorer (Can Publish) roles. You will rely on these users to perform actions in Tableau with integrity.
- If you cannot trust all of your users who have publishing rights on data sources that are accessed by the RunAs service account, then you should consider embedding credentials for those data sources.
- If a data source is not set up for automated extract refreshes, that is, the data source is primarily accessed as a live connection, then you may be able to use Kerberos Delegation. For requirements, see Enable Kerberos Delegation.

### Requirements

- MIT Kerberos is not supported.
- The RunAs service account must have read access to the target database.

### Configuration process

This section provides an example of the process to enable Kerberos service account access.

1. Create a domain user account to act as the RunAs service account. This account must have read access to the target database.

In the example here, the RunAs service account is User principal named `tab-srv@example.com`.

2. Create a keytab file for the RunAs service account.

For example, the following commands create a keytab (`tabsrv-runas.keytab`) using the `ktutil` tool:

```
ktutil
```

```
ktutil: addent -password -p tabsrv@EXAMPLE.COM -k 2 -e <encryption scheme>
```

Encryption schemes for this command include `RC4-HMAC`, `aes128-cts-hmac-sha1-96`, and `aes256-cts-hmac-sha1-96`. Consult your IT team for the correct encryption scheme for your environment and data source.

```
ktutil: wkt tabsrv-runas.keytab
```

Tableau Server will use the RunAs service account and the associated keytab to authenticate and make a direct connection to the database.

3. Copy the keytab into the Tableau Server data directory and set proper ownership and permissions. The keytab should be readable by the unprivileged user. The default unprivileged user created by Tableau Setup is `tableau`.

If you are running a multi-node deployment, then you must run the following commands on each node in the cluster:

```
mkdir /var/opt/tableau/tableau_server/keytab
sudo cp -p tabsrv-runas.keytab /var/opt/tableau/tableau_server/
keytab
sudo chown $USER /var/opt/tableau/tableau_server/keytab/tabsrv-
runas.keytab
chgrp tableau /var/opt/tableau/tableau_server/keytab/tabsrv-
runas.keytab
chmod g+r /var/opt/tableau/tableau_server/keytab/tabsrv-
runas.keytab
```

4. Run the following TSM commands to enable RunAs access, set the RunAs service account, and associate the keytab file with the service account.

```
tsm configuration set -k features.RunAsAuthLinux -v true --force-keys
tsm configuration set -k native_api.datasources_runas_principal -v tabsrv@EXAMPLE.COM --force-keys
tsm configuration set -k native_api.datasources_runas_keytab_path -v /var/opt/tableau/tableau_server/keytab/tabsrv-runas.keytab --force-keys
```

5. Run the following TSM command apply the changes to Tableau Server deployment:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### Enable Kerberos Run As Authentication for JDBC Connectors

As of version 2020.2, Tableau Server supports Kerberos authentication for JDBC connectors.

You can configure Tableau Server to use a Kerberos service account to access a database. In this scenario, Tableau Server connects to databases with a service account, also referred to as a "Run As service account". This scenario is referred to as "Run As authentication"

To use Run As authentication on Tableau Server you must first create a workbook or data source in Tableau Desktop that uses integrated authentication. When you publish to Tableau Server you will get the option to use Run As authentication. When creating a data source with Web Authoring, Run As authentication is the default operation if you select integrated authentication.

# Supported data sources

Tableau supports JDBC Kerberos delegation with the following data sources:

- Oracle
- PostgreSQL

Both native and JDBC-based connectors use the same configuration on Tableau Server on Linux. To configure Run As authentication see [Enable Kerberos Service Account Access](#).

## SQL Server Impersonation

Impersonation in the context of Tableau Server means allowing one user account to act on behalf of another user account. You can configure Tableau and Microsoft SQL Server to perform database user impersonation, so that the SQL Server database account used by Tableau Server queries on behalf of SQL Server database users, who are also Tableau users.

The main benefit of this feature is it allows administrators to implement and control their data security policy in one place: their databases. When Tableau users access a view with a live connection to a SQL Server database, the view only displays what the users' database permissions authorize them to see. An additional benefit is that the users don't have to respond to a database sign-in prompt when they open the view. Also, workbook publishers don't have to rely on user-specific filters to restrict what's seen in views.

## Impersonation Requirements

Here's what you need to use feature:

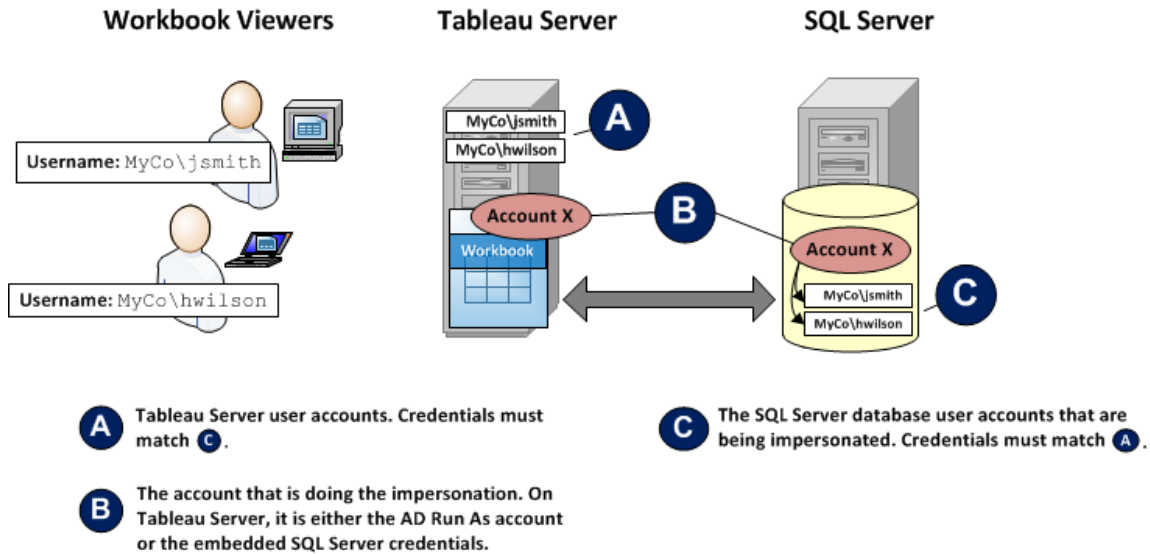

- **Live connections to SQL Server only:** Impersonation can only be used for views that have a live connection to a SQL Server database, version 2005 or newer.
- **Individual database accounts:** Each person who'll be accessing the view must have an explicit, individual account in the SQL Server database to which the view connects. Members of an Active Directory (AD) group cannot be impersonated. For example, if

Jane Smith is a member of the AD group Sales, and her database administrator adds the Sales AD group to the SQL Server database, Jane cannot be impersonated.

- **Matching credentials and authentication type:** The credentials of each Tableau user's account and their Tableau user authentication type must match their credentials and authentication type in the SQL Server database. For example, if Jane Smith's Tableau Server user account is `MyCo\j.smith`, the username on the SQL Server database must also be `MyCo\j.smith`. SQL Server must be using Windows Integrated Authentication.
- **SQL Server prerequisites:** In SQL Server you should have a data security table, a view that enforces data security, and you should require that your database users use the view.
- **SQL IMPERSONATE account:** You need a SQL Server database account that has IMPERSONATE permission for the above database users. This is either an account with the sysadmin role or one that has been granted IMPERSONATE permission for each individual user account (see the [MSDN article on EXECUTE AS](#)). The SQL Server account must be one of the following:
  - The Tableau Server Run As service account. See [Enable Kerberos Service Account Access](#).
  - The workbook publisher's account. See [Impersonate with Embedded SQL Credentials](#).

### How Impersonation Works

Here's an illustration of how database user impersonation works:

In the above illustration, Jane Smith (MyCo\jsmith) is a West Coast sales representative and Henry Wilson (MyCo\hwilson) covers the East. In the SQL Server database, the account permissions for Jane's account, MyCo\jsmith, only give her access to West Coast data. Henry's account, MyCo\hwilson, can only access data for the East Coast.

A view has been created that displays data for the entire country. It has a live connection to a SQL Server database. Both users sign in to Tableau Server and click the view. Tableau Server connects to SQL Server using a database account with IMPERSONATE permission for each user's database account. This account acts on behalf of each user's database account.

When the view displays, it is restricted by each user's individual database permissions: Jane sees only the West Coast sales data, Henry sees only the East Coast data.

#### Impersonate with a Run As Service Account

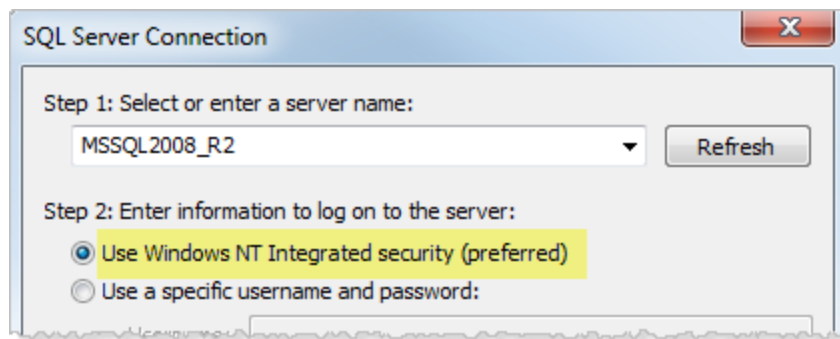

Impersonating via a Run As service account is the recommended way to perform impersonation. The Run As service account is an Active Directory user account the Tableau Server service can run under on the machine hosting Tableau Server. This same account must have IMPERSONATE permission for the database user accounts in SQL Server. From a data

## Tableau Server on Linux Administrator Guide

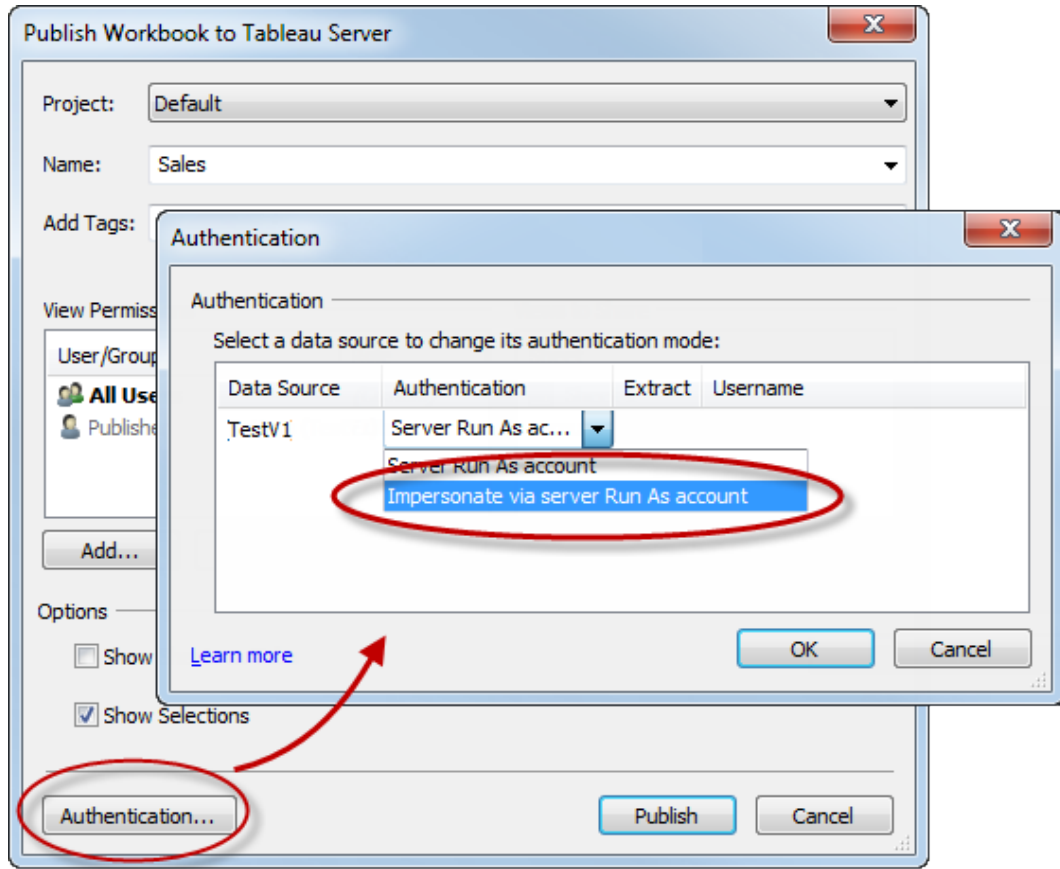

security standpoint, using the Tableau Server Run As service account for impersonation gives the administrator the most control.

To set up impersonation with a Run As User account:

1. Enable Kerberos Service Account Access.
2. Create a workbook in Tableau Desktop. When you create the data connection, select **Use Windows NT Integrated security** for the workbook's live connection to a SQL Server database:

3. In Tableau Desktop, publish the workbook to Tableau Server (**Server > Publish Workbook**).
4. In the Publish dialog box, click Authentication, then in the Authentication dialog box, select **Impersonate via server Run As account** from the drop-down list:

5. Click **OK**.
6. Test the connection by signing into Tableau Server as a user. When you click a view, you should not be prompted for database credentials and you should only see the data the user is authorized to see.

#### Impersonate with Embedded SQL Credentials

You can also perform impersonation by having the person who publishes a view embed their SQL Server account credentials in the view. Tableau Server can be running under any type of account, but it will use these credentials, supplied by the publisher, to connect to the database.

This may be the right choice for your site if the account that handles the impersonation cannot be an Active Directory (AD) account and if you're comfortable giving workbook publishers an account with a potentially high permission level on SQL Server.

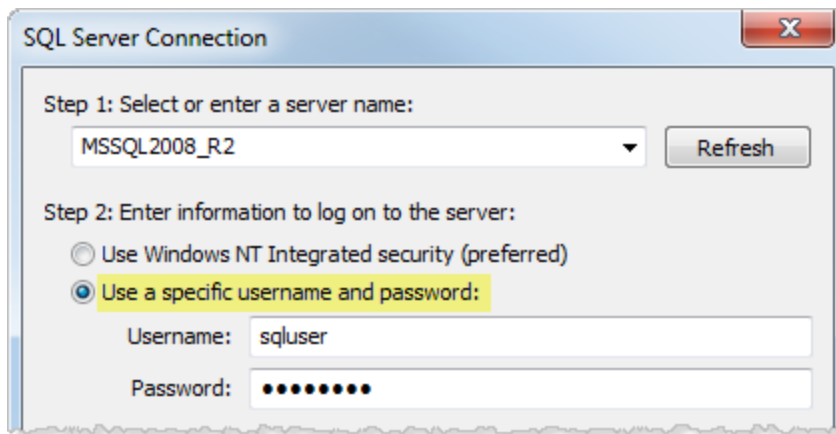

**Note:**

To use this approach, **Embedded Credentials** must be enabled on the server Settings page in Tableau Server:

To impersonate with the workbook publisher's SQL account:

1. In Tableau Desktop, create a workbook. When you create the data connection, select Use a specific username and password for the workbook's live connection to a SQL Server database:

2. Publish the workbook to Tableau Server (**Server > Publish Workbook**).

3. In the Publish dialog box, click Authentication, then in the Authentication dialog box, select **Impersonate via embedded password** from the drop-down list:

4. Click **OK**.
5. Test the connection by signing in to Tableau Server as a user. When you click a view, you should not be prompted for database credentials and you should only see the data the user is authorized to see.

## Configure a Custom TSM Administration Group

This topic describes how to configure a custom TSM administration group.

## Tableau Server on Linux Administrator Guide

By default, the Tableau Server installation process creates a group called `tmsadmin`. Users in this group are authorized as administrators of TSM. You can change this default group during installation. See Help Output for `initialize-tsm` Script.

If you have already installed Tableau Server and wish to change the group used for TSM administration, follow the procedure in this topic.

You can configure Tableau Server to use an arbitrary group as a custom TSM administration group. Once configured, any user that is a member of the custom group will be able to administer TSM.

### Step 1: Create the new group

Create a new group on your computer. Do not change the permissions on the default group as created by Linux.

### Step 2: Configure Tableau Server

The custom TSM administration group name is stored in the `tms.authorized.groups` configuration key. If you want to specify a group name (other than `tmsadmin`) then you will need to update the `tms.authorized.groups` configuration key and then restart Tableau Server.

Use the `tms configuration set` command to set the group name value. For example, to change the TSM administrative group name to `myadmingroup`, run the following commands:

```
tms configuration set -k tms.authorized.groups -v myadmingroup
tms pending-changes apply
```

### Notes

- Setting the `tms.authorized.groups` configuration key overwrites any existing value stored on that key.
- If you have users in the existing `tmsadmin` group, and you overwrite the `tms.authorized.groups` configuration key with a new value, then the users in the existing `tmsadmin` group will no longer be authorized for TSM.
- You can specify multiple groups by entering a comma-separated list of group names as the value.

### Step 3: Add users to the new group

After you finished setting `tsm.authorized.groups`, any user in the new group(s) that you have specified will have full TSM administrative rights on Tableau Server.

## Authorization

*Authorization* refers to how and what users can access on Tableau Server after authentication has been verified. Authorization includes:

- What users are allowed to do with content hosted on Tableau Server, including projects, sites, workbooks, and views.
- What users are allowed to do with the data sources that are managed by Tableau Server.
- What tasks users are allowed to perform to administer Tableau Server, such as configuring server settings, running command line tools, creating sites, and other tasks.

Authorization for these actions is managed by Tableau Server and determined by a combination of the user's site role and permissions associated with specific entities such as workbooks and data sources.

## Site roles

Site roles define who is an administrator. Administrators can be assigned at the site or server level. For non-admins, site roles indicate the maximum level of access a user can have on a given site, subject to permissions set on content assets. For example, if one user is assigned the Viewer site role, and another the CreatorCreator

For more information about site roles, see [Set Users' Site Roles](#).

## Permissions

Permissions determine whether a given user is allowed or denied to perform a specific action on a specific content asset.

As an administrator setting up Tableau Server, it's important that you understand how permissions are evaluated. Understanding the Tableau permissions process will enable you to

set up and configure permissions on sites, projects, and other assets so that you can control how content and data is shared, published, viewed, extracted, and imported.

Four important concepts to understand about permissions in Tableau are:

- **Permissions are asset-based.** Permissions are assigned to individual content assets (projects, data sources, workbooks) and are granted to users or groups.
- **Permissions are implicitly denied, and non-admin users must explicitly be allowed to access content.** The process by which Tableau Server determines the “allow” or “deny” permission is explained in detail in Permissions.
- **Permissions inheritance exists only in locked projects and in workbooks with tabbed views.** When content permissions are locked to the top-level project, workbooks, views, and data sources in the entire project hierarchy will use the default permissions set at the top-level project. In workbooks saved with the option **Show sheets as tabs**, views inside those workbooks use the workbook permissions. For more information, see Permissions.
- **In a project that is not locked, initial permissions are a one-time copy of the container item's permissions.** A data source or workbook starts with the default permissions, but authorized users can subsequently edit permissions on those assets. For more information on default permissions and projects, see Permissions.

Tableau Server provides a flexible permissions infrastructure that allows you to manage access to all content for countless scenarios. For more detailed information, see Permissions.

## Data access and external authorization

There are scenarios where Tableau Server and Desktop rely on external authorization to enable access to data. For example:

- Users connecting to external data sources might require authorization that is outside the scope of Tableau Server’s authority. If users publish an external data source, Tableau Server will manage access and capabilities of that data source. But if users embed an external data source in a workbook, it’s up to the user who publishes the workbook to determine how other users who open the workbook will authenticate with the underlying data that the workbook connects to.
- Running Tableau Server in an organization with Active Directory, where Tableau has been configured with a Run As user account, results in a dependency on Active Directory and NTFS for authorization. For example, if you configure Tableau Server to use

the Run As account to impersonate users connecting to SQL, then object-level authorization is reliant on NTFS and Active Directory.

- How users authenticate and are authorized by specific database solutions can differ. As noted, Tableau Server can be configured to provide access authorization when a data source is configured, but some databases will authorize access according to their own authentication scheme.

## Data Security

Tableau provides several ways for you to control which users can see which data. For data sources that connect to live databases, you can also control whether users are prompted to provide database credentials when they click a published view. The following three options work together to achieve different results:

- **Database login account:** When you create a data source that connects to a live database, you choose between authenticating to the database through Windows NT or through the database's built-in security mechanism.
- **Authentication mode:** When you publish a data source or a workbook with a live database connection, you can choose an **Authentication mode**. Which modes are available depends on what you choose above.
- **User filters:** You can set filters in a workbook or data source that control which data a person sees in a published view, based on their Tableau Server login account.

The table below outlines some dependencies with the above options:

| <b>Database Connection Options</b>                    |  | <b>Data Security Questions</b>                                |   |   |
|---|--|---|---|---|
| <b>Database login account uses...</b>                 | <b>Authentication mode</b>   | <b>Is database security possible per Tableau Server user?</b> | <b>Are user filters the only way to restrict which data each user sees?</b> | <b>Are web caches shared among users?</b> |
| Active Directory credentials (Windows Authentication) | Kerberos service account   | No  | Yes   | Yes                                       |
|   | Impersonate via server Kerberos service account  | Yes   | No*   | No  |
|   | Viewer enters their credentials  | Yes   | No*   | No  |
| User name and password                                | Prompt user: Viewers are prompted for their database credentials when they click a view. Credentials can be saved. | Yes   | No  | No  |
|   | Embedded credentials: The workbook or data source publisher can embed their database credentials.                  | No  | Yes   | Yes                                       |
|   | Impersonate via embedded password: Database cre-   | Yes   | No*   | No  |

| <i>Database Connection Options</i>    |  | <i>Data Security Questions</i>                                |   |   |
|---------------------------------------|--|---|---|---|
| <b>Database login account uses...</b> | <b>Authentication mode</b>                         | <b>Is database security possible per Tableau Server user?</b> | <b>Are user filters the only way to restrict which data each user sees?</b> | <b>Are web caches shared among users?</b> |
|                                       | dentials with impersonate permission are embedded. |   |   |   |

\* Because it can create unexpected results, Tableau recommends that you not use this authentication mode with user filters.

User filters, the embedded credentials option and the impersonation modes have similar effects—when users click a view, they are not prompted for database credentials and they see only the data that pertains to them. However, user filters are applied in the workbook by authors, and the impersonation authentication modes rely on security policies defined by administrators in the database itself.

## Overview of Row-Level Security Options in Tableau

Sometimes you want to filter data based on the user that is requesting it. For example:

- You want regional salespeople to see sales figures only for their region.
- You want sales managers to see statistics only for salespeople that report to them.
- You want students to see visualizations based only on their own test scores.

An approach to filtering data this way is called row-level security (RLS). There are multiple methods to accomplish row-level security both inside and outside of Tableau, each with its own pros and cons.

## Tableau Server on Linux Administrator Guide

### Create a user filter and map users to values manually

The simplest way to achieve row-level security in Tableau is through a user filter where you manually map users to values. For example, you could manually map a user named “Alice” to the value “East” so that she only sees rows in the data source where the “Region” column is “East”.

This method is convenient but high maintenance, and attention must be paid to security. It must be done per-workbook, and you must update the filter and republish the data source as your user base changes. When you publish an asset with this type of user filter, you need to set permissions so that users cannot save or download it and remove the filter, thereby gaining access to all of the data.

For more information, see [Create a user filter and map users to values manually](#) in the Tableau Desktop and Web Authoring help.

### Create a dynamic user filter using a security field in the data

Using this method, you create a calculated field that automates the process of mapping users to data values. This method requires that the underlying data include the security information you want to use for filtering. For example, using a calculated field, the USERNAME() function, and a “Manager” column in the data source, you could determine if the user requesting the view is a manager and adjust the data in the view accordingly.

Because filtering is defined at the data level and automated by the calculated field, this method is less error prone than mapping users to data values manually. When you publish an asset with this type of user filter, you need to set permissions so that users cannot save or download it and remove the filter, thereby gaining access to all of the data.

For more information, see [Create a dynamic filter using a security field in the data](#) in the Tableau Desktop and Web Authoring help.

### Use a data policy

Starting in Tableau 2021.4, when Data Management is enabled in Tableau Server or Tableau Cloud, users with a Creator license can implement row-level security through data policies on

virtual connections. Because virtual connections are centralized and reusable, you can manage row-level security for each connection in one place, safely and securely, across all content that uses that connection.

Unlike the above solutions for row-level security in Tableau, this method doesn't carry the same risk of exposing information if an author neglects to properly secure permissions on the workbook or data source, because the policy is enforced on the server for every query.

Row-level security through virtual connection data policies was developed to address shortcomings of other row-level security solutions. We recommend this solution in most situations where it's an option.

For more information on row-level security using data policies on virtual connections, see [About Virtual Connections and Data Policies](#).

#### Use existing RLS in the database

Many data sources have mechanisms for RLS built in. If your organization has already put effort into building row-level security in a data source, you may be able to take advantage of your existing RLS.

It is not necessarily easier or better to implement a built-in RLS model vs. building it with Tableau in mind; these techniques are generally leveraged when an organization has already invested in these technologies and they want to take advantage of that investment, or when they need to apply the same security policies to other database clients in addition to Tableau.

The main benefit of using built-in RLS is that administrators can implement and control their data security policy in one place: their databases.

For more information, see [Row-Level Security in the Database](#).

#### Row-level security option comparison

| RLS option         | Useful when  | Pros   | Cons   |
|--------------------|--|--|--|
| Manual user filter | <ul style="list-style-type: none"> <li>You are doing a proof of concept</li> </ul> | <ul style="list-style-type: none"> <li>Simple at small scales</li> </ul> | <ul style="list-style-type: none"> <li>High-maintenance</li> </ul> |

|                     |   |  |  |
|---------------------|---|--|--|
|                     | <p>or testing user filtering functionality</p> <ul style="list-style-type: none"> <li>You are creating a static workbook to use with an unchanging group of users</li> <li>You understand the data security risk of having the permissions set incorrectly</li> </ul> | <ul style="list-style-type: none"> <li>Easy to understand mapping</li> <li>Good for testing</li> </ul>   | <ul style="list-style-type: none"> <li>Need to update filter and republish as user base changes</li> <li>Permissions must be secured to prevent users from seeing unfiltered data</li> <li>Must be replicated in every workbook</li> </ul> |
| Dynamic user filter | <ul style="list-style-type: none"> <li>You don't have a Data Management license</li> <li>The data contains information you can use to filter it</li> <li>You understand the data security risk of having the permissions set incorrectly</li> </ul>                   | <ul style="list-style-type: none"> <li>Relatively easy to set up</li> </ul>  | <ul style="list-style-type: none"> <li>Permissions must be secured to prevent users from seeing unfiltered data</li> <li>Must be replicated in every workbook or data source</li> </ul>  |
| Data policy         | <ul style="list-style-type: none"> <li>You have a Data Management license</li> <li>The data contains information you can use to filter it</li> <li>Ease of data security is a significant concern</li> </ul>  | <ul style="list-style-type: none"> <li>Centralized</li> <li>Secure</li> <li>Low-maintenance</li> <li>Responsibilities for security and analytics can be separated</li> </ul> | <ul style="list-style-type: none"> <li>Data Management license required</li> </ul>   |

|                     |   |  |   |

## RLS Best Practices for Data Sources and Workbooks

Row-level security (RLS) in Tableau restricts the rows of data a certain user can see in a workbook. This differs from Tableau permissions, which control access to content and feature functionality. For example, permissions control whether a user can comment on or edit a

workbook, while row-level security enables two users viewing the same dashboard to see only the data each user is allowed to see.

There are several ways to implement RLS in Tableau. For example, you can set RLS at the data source or workbook level, or you can set RLS at the connection level using a virtual connection with a data policy (requires Data Management). See the [Overview of Row-Level Security Options in Tableau](#) for details about alternatives.

**Note:** This topic focuses on RLS best practices for data sources and workbooks. For more in-depth examples of the concepts outlined in this topic, refer to the whitepaper [Best Practices for Row Level Security with Entitlement Tables](#) or [How to Set Up Your Database for Row Level Security in Tableau](#) on the blog *Tableau and Behold*.

### RLS workflow

For live connections and multi-table extracts, the basic RLS workflow is:

1. The user is identified by logging into Tableau Server or Tableau Cloud
  - This requires a distinct username per user and secure single sign-on (SSO)
  - Active Directory, LDAP, or the Tableau REST API can be used to synchronize user names and establish permissions
2. The set of data entitlements for the user is retrieved from all possible data entitlements
  - This requires a data structure that can link entitlements to the Tableau username
3. The data is filtered by the entitlements for that user
  - This often requires using user functions in a calculated field
4. The published, filtered data is used to build content
  - Using a published (rather than embedded) data source with a data source filter ensures the RLS cannot be modified by downloading or web editing the workbook

How the joins, calculated fields, and filters are set up depends on the structure of the data and how users are managed.

## Entitlement tables

Any unique combination of attributes that the data can be filtered on is an entitlement. Most commonly, there are separate tables for specifying the entitlements themselves and mapping those entitlements to users or user roles. Denormalizing is recommended from a performance standpoint because joins are expensive operations.

The entitlements view, consisting of the entitlements mapped to users or roles, is joined with the data. A user-based data source filter is then applied, acting as a WHERE clause that brings in only the entitlements—and therefore the appropriate data rows—for the relevant user. (Query optimization should ensure the filtering occurs before joining when the query is processed to minimize data duplication. For more information, see Performance and processing order of operations.)

## Entitlement table models

Generally, there are two models for representing entitlements:

### **Full mapping to the deepest level of granularity**

- Entitlements are defined fully for every column.
- There is one row in the mapping table for every possible entitlement the user has.
- This model requires fewer join clauses.

### **Sparse entitlements**

- Entitlements are defined for every level of hierarchy, with NULL used to represent an “all” state.
- There is a single row in the mapping table for a particular level in the entitlement hierarchy, which vastly reduces the number of entitlement rows for users at high levels in a hierarchy.
- This model requires more complex joins and filters.

## Users and roles

Combinations of entitlements are commonly represented as *roles*, which are then linked to users in a many-to-many mapping table. This allows for easily changing or removing a user from the role, while still maintaining a record of the role and its entitlements.

Alternatively, a many-to-many mapping table can be created that instead assigns users directly to entitlements as opposed to going through joining a role table. It will require managing the values more directly in the table but does eliminate a join.

**Note:** The user values associated with a role or entitlement need to match the username or full name on the Tableau site in order to take advantage of the user functions in Tableau Desktop.

### Joins

Regardless of the model used to represent the entitlements, it is advisable to join all entitlements and mapping tables together into a single denormalized entitlements view. While at first this will cause a “blowup” (highly duplicative) version of the entitlements, the data source filter on the user will reduce it back down. You will also want this view if you plan on using an extract.

The deepest granularity method can have a performance benefit when everything is hierarchical—you only need to do a single join on the deepest level of the hierarchy. This only works if all of the attributes at the lowest level are distinct. If there is a chance for duplication (for example, a Central sub-region in more than one region), then you’ll need to join on all the columns to achieve the effect of a distinct key value.

The actual details and their performance characteristics depend on the data system and require testing. For example, using a single key could potentially improve the performance because the join is then only executing on one column, but correctly indexing all of the columns may give equal performance when other factors are taken into consideration.

### Implement row-level security

#### Deepest granularity

After the denormalized view of mapped entitlements is created, an inner join is set up between the view and the data in the Tableau data connection dialog. The data can remain in a traditional star schema. Alternatively, the dimension and fact tables can be materialized together

into two views. Multi-table extracts will build extract tables to match the joins, so creating the two views will simplify the resulting extract. The SQL will follow this basic pattern:

```
SELECT *
FROM data d INNER JOIN entitlements e ON
d.attribute_a = e.attribute_a AND
d.attribute_b = e.attribute_b AND ...
WHERE e.username = USERNAME()
```

### Sparse entitlements

If your entitlements more closely resemble the sparse entitlements model, then the custom SQL to join the data to the entitlements would be a little more complex because of the NULL values. Conceptually, it would look like the following:

```
SELECT *
FROM data d
INNER JOIN entitlements e ON
(e.region_id = d.region_id OR ISNULL(e.region_id) AND
(e.sub_region_id = d.sub_region_id OR ISNULL(e.sub_region_id) AND
(e.country_id = d.country_id OR ISNULL(e.country_id)
```

Without using custom SQL, this can be done with a cross join and additional filters in Tableau Desktop. Create a join calculation on both sides of the join dialog that simply consists of the integer 1 and set them equal. This joins every row from the data table with every row in the entitlements table.

Then you need a calculation (or individual calculations) to account for the levels in the hierarchy. For example, you could have several calculations that follow this format: `[region_id] = [region_id (Entitlements View)] OR ISNULL([region_id (Entitlements View)])`

Or you could have a combined calculation for all levels in one:

```
([region_id] = [region_id (Entitlements View)] OR ISNULL([region_id
(Entitlements View)])
AND
```

## Tableau Server on Linux Administrator Guide

```
([sub_region_id] = [sub_region_id (Entitlements View)] OR ISNULL  
([sub_region_id (Entitlements View)])  
AND  
([country_id] = [country_id (Entitlements View)] OR ISNULL([country_  
id (Entitlements View)])
```

The ISNULL function matches any entitlement column to all items in the other column. As always with RLS, these calculations should be added as data source filters.

### Data source filter

For both approaches, once the entitlements are correctly joined with the data, a filter needs to be set up to limit the data for a specific user. A calculated field should be created with a user function. For example, a simple Boolean comparison of whether the user listed in the Username field is the same as the username of the person logged into the Tableau site: `[Username] = USERNAME()`

This calculation should be used as a data source filter (with TRUE selected).

If the data source is embedded and a user has permissions to web edit or download the workbook, then the RLS is nonexistent since the filters enforcing it can be easily removed. The Tableau data source should be published separately as opposed to being left embedded in the workbook.

### All access with deepest granularity

There is also a common scenario in which there are two access levels within the organization: people who can see everything (“all access”) or people with some reasonably definable subset of entitlements. This is most commonly seen for embedded applications—the organization hosting the data can see everything, but each client can only see their own data. In this case, you need a way to return the full data for the “all access” users, while maintaining the deepest granularity joins for all other users.

For this technique, you will use Tableau groups to create an override using a calculation in the join condition.

1. Create a group for users who should see all the data (here called All Access)
2. From the fact view, create a left join with two join conditions
  - The first join condition should be on the column that represents the deepest level of granularity
  - The second join condition should be two calculations:
    - On the left side (the fact view), for the calculation, enter `True`
    - On the right side (the entitlements view), the calculation should be: `IF ISMEMBEROF('All Access') THEN False ELSE True END`
3. On a sheet, create a calculation structured as: `[Username] = USERNAME() OR ISMEMBEROF(['All Access'] ([Entitlements View]))`
4. Create a data source filter on the username calculation

If a user is a member of the All Access group, then the join becomes a left join on `True = False`. This means there are no matches at all in the entitlements view, so the entire fact view is returned with NULLs for the columns from the entitlements view (zero duplication). In the case where the user is not part of the All Access group, the `True = True` join condition doesn't change anything and the join will function as expected.

The user calculation used as a data source filter is true for all rows when the group override is working, or it will filter down to only the user's deepest granularity in the hierarchy.

### Performance and processing order of operations

When a visualization is viewed in Tableau Desktop, Tableau Server, or Tableau Cloud, Tableau sends an optimized query to the RDBMS which then processes the query and sends results back to Tableau to render the visualization with the resulting data. The order of operations for when joins, calculations, and filters are carried out depends on the query optimizer and how the query is executed.

### Live connections

When using a live connection to a data source in Tableau, the performance of the query execution is dependent on the query optimizer which translates the incoming SQL into an efficient plan for retrieving the data.

There are two ways the query can be processed:

1. Filter the entitlement rows to the user then join to the fact table
2. Join the entitlements to the fact table then filter to the user's rows

In an ideal situation, the query optimizer will ensure the database processes the query by *filtering then joining*. If a user is entitled to everything, this means the maximum number of rows processed will be the number of rows in the data table.

If the database processes the query by *joining then filtering*, there may be duplication of data. The maximum number of rows processed will be the number of users entitled to see that particular row times each row in the data table.

It will be clear if this second scenario happens: your queries take a long time to finish, you get errors, or there is an indication of performance issues in the database. Your total data volume will expand exponentially, which could cause inordinate system strain on the backend.

## Extracts

When the data source in Tableau is a live connection, Tableau sends every query that is necessary to render a particular viz or dashboard to the RDBMS. When the data source is an extract, the process of querying data from the underlying data source only happens at extract creation and refresh. All of the individual queries for visualizations are answered by the extract engine from the extract file.

The same order of operations issue is present when building single table extracts. However, the “blowup” will happen both on the underlying data source and within the resulting extract itself.

### Considerations with extracts

Starting in Tableau 2018.3, the data engine can create a multi-table extract and RLS can be implemented as described above. Using multiple table extracts reduces the time it takes to generate an extract with many-to-many relationships by not materializing the join.

The extract should be built with a *data object* and an *entitlements object*. This is the simplest storage in the extract and results in the best performance.

- The *data object* is the table, view or custom SQL query that represents the denormalized combination of the fact and necessary dimension tables
- The *entitlements object* is a denormalized table, view or custom SQL query of whatever entitlements are necessary to filter the data at the most granular level, which requires:
  - A column for username matching the exact usernames in Tableau Server or Tableau Cloud
  - A row for each of the most granular entitlements to the data object

This format is laid out in the deepest granularity method above. Multi-table extracts use the same method, with the caveat that only two data objects are being joined and any field-specific filtering is already applied within the object.

Because multiple table extracts have extract filters disabled, you can filter either in the views or tables you connect to in the data source, or define the filters in custom SQL objects in the Tableau data connection dialog.

**Note:** As with live connections, if the data source is embedded and a user has permissions to web edit or download the workbook, then the RLS is nonexistent since the filters enforcing it can be easily removed. The extract should be published separately as opposed to being left embedded in the workbook.

### Single table extracts

The following method is only recommended when using a version of Tableau prior to 2018.3—multiple table extracts are preferable if available.

Single table extracts materialize any joins you build when constructing the Tableau data source and stores everything as a single table through one query, the results of which are transformed in a single table in the extract file. This denormalization carries the risk of causing massive data duplication, as every row that was allocated to more than one entitlement or user would be duplicated as a result of the many-to-many relationship.

To prevent this duplication:

## Tableau Server on Linux Administrator Guide

1. Create a Security Users Field that contains the usernames for that entitlement
  - for example, a value may be “bhowell|mosterheld|rdugger”
2. Use the CONTAINS() function within Tableau to correctly identify individual users
  - For example, `CONTAINS([Security Users Field], USERNAME())`

This method obviously has some caveats. It requires that you go from your entitlements in rows to a single column separated correctly using SQL, and that column can only contain so many characters. Partial matches can be trouble, and you need to use separators that will never be valid in the IDs themselves. Although it is performant within the Tableau Data Engine, as a string calculation it will be very slow for most databases. This limits your ability to switch back to a live connection.

Alternatively, you can take different extracts per “role” or entitlement level, so that only the data appropriate to that person or level is contained within the extract, but this will require processes to appropriately permission and leverage template publication within Tableau Server, generally via the APIs.

### Use built-in row-level security in a database

Many databases have mechanisms for RLS built in. If your organization has already put effort into building row-level security in a database, you might be able to take advantage of your existing RLS. It's not necessarily easier or better to implement a built-in RLS model vs. building it with Tableau in mind; these techniques are generally leveraged when an organization has already invested in these technologies and they want to take advantage of the investment. The main benefit of using built-in RLS is that administrators can implement and control their data security policy in one place: their databases. For more information, see [Row-Level Security in the Database](#).

## Row-Level Security in the Database

If your organization has already put effort into building out row-level security (RLS) in a database, you might be able to use one of the following techniques to take advantage of your existing RLS. In order to leverage the database's security models, live connections are required. Additionally, these techniques are likely not available in Tableau Cloud; the Tableau username

for Tableau Cloud is a unique email address that is not typically the user identity on the database side.

It is not necessarily easier or better to implement a built-in RLS model vs. building it with Tableau in mind; these techniques are generally leveraged when an organization has already invested in these technologies and they want to take advantage of the investment.

**Note:** For information on the alternatives you can use to implement row-level security in Tableau, see an [Overview of Row-Level Security Options in Tableau](#).

### Impersonation (Microsoft SQL Server)

Microsoft SQL Server (and a few related systems) can be configured so that users of the database only have access to views with RLS filters built in, either using Security Junction Tables or views built by the DBA. Tableau can take advantage of this using a concept called “impersonation.”

When publishing a Tableau data source containing an MS SQL Server connection to Tableau Server, there are two authentication options available to take advantage of impersonation. The menu you see will depend on whether you logged into the SQL Server using network authentication or by entering username/password credentials.

To enable RLS filtering for any user who can access the published data source in Tableau Server, either the AD Run-As Account or the embedded SQL server credentials must have permission to EXECUTE AS for all of the Tableau users in the database that will be accessing the dashboard or data source. All Tableau users must exist in the database server as users, with SELECT rights for the Views you are trying to connect to (and have RLS applied to). See [Impersonation Requirements](#) for the comprehensive list of requirements.

### Kerberos and constrained delegation

Constrained delegation within Tableau Server using Kerberos operates similarly to impersonation in that it allows Tableau Server to use the Kerberos credentials of the view of a work-

## Tableau Server on Linux Administrator Guide

book or view to execute a query on behalf of the viewer, so if RLS is set up on the database, the viewer of the workbook will see only their data.

To see the comprehensive list of databases where Kerberos delegation is supported, see [Enable Kerberos Delegation](#). Active Directory is required; the computer where Tableau Server is installed must be joined to the Active Directory domain. The **authentication method** specified when publishing the data source must be **viewer credentials**.

Note that Kerberos can be leveraged for RLS when using Microsoft Analysis Services.

### OLAP Cubes

OLAP Cube connections in Tableau do not have the equivalent of a data source filter, which is required for the entitlements table-based RLS method in Tableau, or access to the `USERNAME()` function. For these reasons, Kerberos and constrained delegation is a recommended approach to RLS with OLAP databases, which allows Tableau to leverage user filtering that has already been implemented on the OLAP Server side.

If the users viewing the dashboard will not be part of the domain, then the manual approach to creating user filters is possible. However, because the User Filter Set generated cannot be added as a data source filter, and will instead exist on the filters shelf, it is important that Web Editing and Download Workbook functionality is not permissible for any published views using this method.

### SAML delegation and SAP HANA

If Tableau Server is configured to use [Configure SAP HANA SSO](#) to provide a single sign-on experience, the viewer credentials are used to execute the query as that user, which will operate within whatever security is applied on the user level. The **authentication method** specified when publishing the data source must be **viewer credentials**.

### Initial SQL to force a user-specific session (Oracle VPD)

Initial SQL enables you to specify a SQL command that is run when the connection is made to the database for the purpose of setting up temporary tables to use during the session or to set up a custom data environment.

For Oracle VPD, you can set up a session specific to a user by running a particular stored procedure or function to set the context of the database connection to match the Tableau user's username:

```
begin
DBMS_SESSION.SET_IDENTIFIER([TableauServerUser]);
end;
```

The same high-level requirements hold true for using this for RLS as with impersonation; the DBA must set up VPD and all of the associated users to exist on the database.

On MS SQL Server, you could force an EXECUTE as command (however, this is similar to what Tableau does with impersonation already) :

```
EXECUTE AS USER = [TableauServerUser] WITH NO REVERT;
```

**Note:** If the data source is embedded and a user has permissions to web edit or download the workbook, then the RLS is nonexistent since the initial SQL enforcing it can be easily removed. The data source should be published separately instead of being embedded in the workbook.

#### Comparison matrix for row-level security methods

| Method                              | Useful when  | Pros   | Cons  |
|-------------------------------------|--|--|---|
| Entitlements table<br>(Recommended) | <ul style="list-style-type: none"> <li>• There is an existing concept of entitlements in the database</li> <li>• The organization is setting up Row Level Security for the first time</li> </ul> | <ul style="list-style-type: none"> <li>• Easy to test, update, maintain, and scale</li> <li>• Works for both live connections and extracts in version 2018.3+</li> </ul> | <ul style="list-style-type: none"> <li>• Requires creating and maintaining entitlements table</li> <li>• Could require selecting and creating appropriate keys to optimize for performance</li> </ul> |

## Tableau Server on Linux Administrator Guide

### CONTAINS() with extracts

- Implementing RLS in extracts prior to version 2018.3
- Allows you to take advantage of extract efficiencies
- Requires mapping all users to a single column
- Difficult to switch back to live connections because of string calculation

### Impersonation

- Every user accessing the data will exist as a user in your SQL server (Usually, internal deployments)
- Security is handled and maintained in one place—the database
- Requires every person accessing the view to exist as a user within your SQL Server
- Only works for Microsoft SQL Server

### Kerberos

- All necessary databases are set up for Kerberos delegation and RLS is set up on the database (usually internal deployments)
- The viewer's name appears on the access logs for the database
- Security is handled and maintained in the database
- Tableau must be configured to use LDAP-Active Directory
- Tableau Server must be joined to the AD domain
- Every user must exist within your AD

|             |  |  |   |
|-------------|--|--|---|
| Initial SQL | <ul style="list-style-type: none"> <li>• The database supports initial SQL and RLS is set up on the database side</li> </ul> | <ul style="list-style-type: none"> <li>• Allows the passing of Tableau parameters at load time</li> <li>• Dedicated connection that can't be shared with other users</li> <li>• Users must exist within database to execute query as user</li> </ul> | <ul style="list-style-type: none"> <li>• Not all databases support initial SQL</li> <li>• Potential performance implications because of restricted cache sharing</li> </ul> |
|-------------|--|--|---|

## Manage Server Secrets

Tableau Server needs to store a number of secrets it uses to perform various functions, typically securing internal communication, communicating with other applications or the operating system, or providing secure communication with clients. In this context, the term *secret* may refer to a password, a token, or other string that is used to authenticate one entity to another.

There are two categories of secrets that are required to run Tableau Server. They differ according to how the secrets are generated:

- **Secrets that are generated by administrators.** These include credentials and associated secrets for the Run As User account and the SMTP credentials used by Tableau Server.
- **Secrets that are automatically generated by various processes in the system.** For example, a secret is required to protect communication between the Cluster Con-

troller and ZooKeeper processes. And a number of different passwords are required for each service and programmatic user that communicates with Postgres.

Most secrets are encrypted while at rest. When a secret is needed, it is decrypted at run time.

This topic describes how secrets storage works and what you need to do to properly manage storage of secrets on Tableau Server.

### Understanding how secrets storage works

During installation Tableau Server generates and stores a master key in a Java keystore. The master key is used to encrypt a configuration encryption key that is used across the system.

Whenever a new secret is created or updated, the secret is encrypted with the configuration encryption key. The encrypted value is then stored with its corresponding configuration parameter in a YAML file on the server. Parameters that hold an encrypted value use the format, `ENC(<encrypted string>)`, where `<encrypted string>` is a Base64-encoded encrypted string.

At run time, when a given secret needs to be accessed, the encrypted values are read into memory and decrypted with the configuration encryption key.

In the case of pending changes, where secrets are entered during a configuration change, the entire transaction is encrypted. In this scenario, after you enter a secret and then save the pending change, the secret is transmitted to the Coordination Service (over encrypted SSL). The Coordination Service encrypts the secret and stores it until the pending changes are applied. When changes are applied, the secret (still encrypted) is promoted to the current configuration version.

Tableau Server encrypts secrets using 256-bit AES in GCM mode. The keys used for secure storage are different than the asset keys that are used to encrypt embedded database credentials before they are stored in the repository.

### Who has access to the master key?

In a default installation, the Java keystore for Tableau Server will be replicated into the `/tabs-vc/keystores` folder for each service on that node under `/var/opt/tableau/tableau_`

```
server/data/tabsvc/config.
```

For example,

```
/var/opt/tableau/tableau_server/data/tabsvc/config/tabadminagent_  
<version_number>/tabsvc/keystores/tableauserver.jks.
```

If you use a custom install directory, then the keystore files will be found under

```
<install_directory>/tableau_server/data/tabsvc/config/<service  
name_#.version_number>/tabsvc/keystores
```

By default, the following users and groups have access to this directory:

- root
- tableau (user)
- members of the 'tableau' group

#### Import and export configuration information

Tableau Services Manager introduces the capability to import and export configuration information using tsm settings export.

**Note:** This version of Tableau Server does not support restoring configuration information from a backup. Instead, we recommend using the export and import configuration commands to backup and restore configuration information.

While configuration secrets are encrypted when stored on disk internally, when the configuration is exported to a file, secrets are written into the file in plain text. It is up to the administrator to take measures to protect this file. There are a variety of options available:

- Write the file to an encrypted file system.
- Write the file to a directory that is restricted to specific users or groups by file system permissions.
- Encrypt the output file.

### Securing secrets for import and export operations

This section describes how to PGP encrypt the backup output. With this method, you will create a named pipe and provide it as the file argument, then use that as input to gpg encrypt it. The advantage is the secrets are never written to disk in plain text. gpg must be available and a private key available. An example of this method is shown in the following section.

The example in this section describes one way of handing secrets to store them on a separate computer.

See the following external references for more information:

- [File encryption on the command line](#)
- [mkfifo\(1\) - Linux man page](#)

### Example: encrypt and export

The following is an example of how to secure the file when exporting the configuration.

```
mkfifo -m 600 /tmp/secure1 && (gpg --symmetric --batch --yes --pass-  
phrase-file ~/.secrets/pgppassphrase.txt --cipher-algo AES256 --out-  
put encrypted.enc < /tmp/secure1 &) && tsm settings export -f  
/tmp/secure1 && rm /tmp/secure1
```

The details of this operation are:

- Create a named pipe with access limited by file permissions to rw for current user.

```
mkfifo -m 600 /tmp/secure1
```

- Call gpg to encrypt the data sent to the named pipe, backgrounding it to a separate process. It will block waiting for data. The result will be a file containing the encrypted data.

```
gpg --symmetric --batch --yes --passphrase-file ~/.secret-  
s/pgppassphrase.txt --cipher-algo AES256 --output encrypted.enc  
< /tmp/secure1 &
```

- Call tsm to export the configuration, providing the named pipe as the file argument.

```
tsm settings export -f /tmp/secure1
```

- Delete the named pipe.

```
rm /tmp/secure1
```

The encrypted data is in the file "encrypted.enc."

### Example: decrypt and import

The following is an example of how to decrypt and import the configuration.

```
mkfifo -m 600 /tmp/secret2 && (gpg --decrypt --batch --yes --pass-  
phrase-file ~/.secrets/pgppassphrase.txt encrypted.enc > /tm-  
p/secret2 &) && tsm settings import -f /tmp/secret2 && rm  
/tmp/secret2
```

The details of this operation are:

- Create a named pipe with access limited by file permissions to rw for current user.

```
mkfifo -m 600 /tmp/secure2
```

- Decrypt the configuration and send it to the named pipe. Background this to a separate process, it will block waiting to be read.

```
gpg --decrypt --batch --yes --passphrase-file ~/.secret-  
s/pgppassphrase.txt encrypted.enc > /tmp/secret2 &
```

- Execute the tsm configuration import command, logging in as needed.

```
tsm settings import -f /tmp/secret2
```

- Delete the named pipe.

```
rm /tmp/secure1
```

The pending configuration contains the imported configuration.

## Tableau Server on Linux Administrator Guide

Run `tsm pending-changes apply` to commit changes. If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### Cluster nodes

When adding a new node to your Tableau Server cluster, you will first need to generate the node configuration file (tsm topology). The node configuration file contains a copy of the master keystore file used for encrypting the configuration secrets.

**Important:** We strongly recommend that you take additional measures to secure the node configuration file when exporting a configuration file with secrets.

When [installing and configuring Tableau Server on the new node](#), you will need to provide the node configuration file to the `initialize-tsm` command. You can use a similar technique as described above to decrypt the contents of the file that was previously encrypted and send it via a named pipe to the `initialize-tsm` command.

### Secrets storage event logging

The following events related to secrets storage are logged:

- Generating new encryption keys
- Encryption key is rolled or changed
- Encrypting a new value in the configuration file

For more information about log files and where they are stored, see [Work with Log Files](#).

### Managing secrets

As a Tableau Server administrator the most important task related to secrets storage is to periodically update secrets. In some cases (server troubleshooting or auditing), you may need to retrieve a password.

For other operations, such as upgrading versions, backing up and restoring, or adding new nodes to a cluster—as noted above—Tableau Server manages secrets storage and related processes automatically.

### Updating secrets

You should update secrets periodically, according to your company's security policy.

To update the master key and automatically generated secrets, run `tsm security regenerate-internal-tokens`.

### Retrieving passwords

In some cases, you may need to retrieve a password for troubleshooting or other operations. For example, you may need the Postgres readonly user credentials that are generated and encrypted by Tableau Server. In these cases, you can run a `tsm` command that will retrieve and decrypt the password for you.

To retrieve a password, open Command Prompt and issue a `tsm configuration get` command for one of the parameters listed in the table below.

For example, to retrieve a password for the readonly Postgres user, type the following command:

```
tsm configuration get -k postgres.readonly_password
```

The command will return the password in clear text:

```
$ tsm configuration get -k postgres.readonly_password
```

```
password
```

| Configuration Parameter                           | Description  |
|---|--|
| <code>clustercontroller.zookeeper.password</code> | Password for cluster controller to connect to zookeeper. |
| <code>indexandsearchserver.client.password</code> | Password for logging into Index and Search Server.       |

|  |   |
|--|---|
| <code>indexandsearchserver.ssl.admin.cert.bytes</code>     | Admin certificate that is used for administrative access to the Index and Search Server. The admin certificate is used to generate the node certificate.              |
| <code>indexandsearchserver.ssl.admin.key.file_bytes</code> | Certificate key for administrative access to the Index and Search Server.   |
| <code>indexandsearchserver.ssl.node.cert.bytes</code>      | Certificate that is used for Index and Search Server node-to-node communication.  |
| <code>indexandsearchserver.ssl.node.key.file_bytes</code>  | Certificate key that is used for Index and Search Server node-to-node communication.  |
| <code>indexandsearchserver.ssl.root.cert.bytes</code>      | Certificate that is used to sign the admin and node certificates . This certificate is used by TSM for health check and by NLP to connect to Index and Search Server. |
| <code>indexandsearchserver.ssl.root.key.file_bytes</code>  | Certificate key for root certificate.   |
| <code>filestore.zookeeper.password</code>                  | Password for filestore to connect to zookeeper.   |
| <code>hyper.connection.init_password</code>                | Password used to initialize the Hyper database for user <code>tableau_internal_user</code> and is then used for connecting to Hyper.                                  |
| <code>jdbc.password</code>                                 | Password for the rails Postgres user.   |
| <code>kms.persistent_store</code>                          | A collection of master encryption keys (MEKs) used by the Key Management System.  |

|                                  |   |
|----------------------------------|---|
| maestro.rserve.password          | Password for connecting to an external Rserve instance used by Tableau Prep Conductor for running flows that have nodes with R scripts.   |
| maestro.tabpy.password           | Password for connecting to an external TabPy (Python server) instance used by Tableau Prep Conductor for running flows that have nodes with Python scripts.   |
| oauth.google.client_secret       | Client secret of the Google Cloud Platform account.   |
| oauth.quickbooks.consumer_secret | Consumer secret of the Intuit developer account.  |
| oauth.salesforce.client_secret   | Client secret of the Salesforce developer account.  |
| pgsql.adminpassword              | <p>Password for the tblwgadmin Postgres user.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>Note:</b> Although the configuration parameter is encrypted in Tableau's configuration files (tabsvc.yml, workgroup.yml), this password is stored in plain text in files used by SAML.</p> </div> |
| pgsql.readonly_password          | Password for the readonly Postgres user.  |
| pgsql.remote_password            | Password for the tableau Postgres user.   |
| redis.password                   | Password for Redis.   |

|   |   |
|---|---|
|   | <p><b>Note:</b> Although the configuration parameter is encrypted in Tableau's configuration files (tabsvc.yml, workgroup.yml), the configuration will still be in plain text in the redis.conf file that is consumed by the Redis application. Redis does not support encrypted/secured passwords.</p> |
| servercrashupload.proxy_server_password | Password for custom proxy server used to upload crash reports.  |
| service.runas.password                  | Password of the Run As users. Stored temporarily.   |
| ssl.cert.file_bytes                     | The content of one of the three SSL certificate files uploaded by the administrator. The certificate files are required to enable secure external connections to Tableau Server.  |
| ssl.chain.file_bytes                    | The chain file(s) for the certificates uploaded by the administrator for external SSL.  |
| ssl.key.file_bytes                      | Key file(s) for the certificates uploaded by the administrator for external SSL.  |
| ssl.key.passphrase                      | Optional passphrase used to protect the external SSL key.   |
| svcmonitor.notification.smtp.password   | SMTP Server password supplied by the administrator through TabConfig.exe.   |
| tabadminservice.password                | Password for the service that allows  |

|                                     |  |
|-------------------------------------|--|
|                                     | server admins to download log files through the web interface.               |
| vizportal.openid.client_secret      | This is the password ("provider client secret") used for OpenID Connect SSO. |
| vizqlserver.external_proxy_password | Password used to authenticate to an external proxy.                          |
| wgserver.domain.password            | Password used to bind to Active Directory.                                   |
| wgserver.saml.key.passphrase        | Passphrase used to access the PKCS#8 SAML key file.                          |
| zookeeper.tsm.password              | Password that TSM uses to connect to Zookeeper coordination service          |

## Extension Security - Best Practices for Deployment

The following information is for IT officers and administrators, Tableau server and site administrators, and anyone who is interested in managing dashboard and viz extensions and the security of their data and business. The suggestions for deployment are intended for companies that have a mix of users who are on Tableau Desktop and Tableau Server or Tableau Cloud.

### Security for extensions in Tableau

Extensions are web applications that could be hosted inside your network, or outside on a third-party server, or in a secure *sandboxed* environment hosted by Tableau. Extensions can interact with other components in the dashboard and potentially have access to the visible and underlying data in the workbook (through a well-defined API). Tableau supports two types of extensions:

### Network-enabled extensions

Network-enabled extensions are hosted on web servers that are located inside or outside of your local network and have full access to the web. Network-enabled extensions can connect with other applications and services. Network-enabled extensions offer new capabilities to Tableau, such as new types of data visualizations, natural language generation, and support for write-back scenarios. Network-enabled extensions have full access to the web, which means that while they can offer rich features and experiences by being able to connect to outside resources, they should be evaluated before deploying or adopting.

### Sandboxed extensions

Sandboxed extensions run in a protected environment without access to any other resource or service on the web. Sandboxed extensions are hosted by Tableau and provide the most security and eliminate the risk of data exfiltration. To safeguard against cyber-attacks, the Sandboxed extensions environment and hosting service has undergone extensive penetration testing by a 3rd-party consultant.

You can use Sandboxed and Network-enabled extensions in Tableau Desktop, Tableau Server, and Tableau Cloud. Tableau Server and Tableau Cloud provide the most control over the extensions your users can run.

### Potential security risks with Network-enabled extensions

Because extensions are web applications there's the potential that a Network-enabled extension could be vulnerable to certain types of malicious attacks, which in turn could present a risk to your computer or data. The [Open Web Application Security Project \(OWASP\)](#) annually identifies the most critical web application security risks. These risks include the following:

- SQL injection
- Cross-site scripting (XSS)
- Sensitive data exposure

These risks could compromise the extension if the developers of the extension don't properly validate and handle user inputs, or if they generate dynamic queries to access sensitive databases. As you evaluate the extensions that you want to allow in Tableau, be sure to consider how they manage authentication, data access, or user input, and how they mitigate security risks.

### Mitigating the security threats with Network-enabled extensions

Understanding what an extension does is a first step to identifying the risks for your enterprise. Often, a dashboard or viz extension doesn't access underlying data in the workbook and all the JavaScript code runs in the context of the browser running on the user's computer. In these cases, no data leaves the computer even though the extension might be hosted on a third-party site outside of your domain. Some extensions allow you to connect Tableau with other applications you have already deployed in your domain.

Tableau provides security measures and security requirements for extensions. These requirements are enabled for Tableau Desktop, Tableau Server, and Tableau Cloud.

- All extensions must use the HTTP Secure (HTTPS) protocol.
- By default, anyone using a dashboard with a Network-enabled extension will be prompted and asked to allow the extension permission to run. The extension must request permission if it accesses underlying data.

## Tableau Server on Linux Administrator Guide

- To run on Tableau Server or Tableau Cloud, the URL of the Network-enabled extension must be added to a safe list. The server administrator manages this list for Tableau Server; the site administrator manages this list for Tableau Cloud.
- On Tableau Server and Tableau Cloud, the server or site administrator (respectively) can control whether the prompt appears for each Network-enabled extension.

For more information, see [Manage Dashboard and Viz Extensions in Tableau Server](#).

### Manage extensions using Tableau

Extensions provide a way to add unique features to dashboards and new visualizations to worksheets. You can use extensions to directly integrate the dashboard with applications outside of Tableau. While extensions open up a world of possibilities, there are instances where you need or want to maintain control of how extensions are deployed in your company or enterprise. In this respect, extensions are no different from any other software that you intend to use. Before you deploy software applications in your company you should thoroughly test and verify that the software works as expected and is secure. The same is true for extensions.

First, determine what level of access your users should have, and identify the extensions you want to use (or conversely, the extensions you don't want to use). Then use the controls and features within Tableau to restrict and curate the dashboard and viz extensions users have access to.

- Do you need to restrict who can add or use extensions in Tableau Desktop? See [Recommendations for Tableau Desktop](#)
- Do you need to restrict or control the extensions your users have access to? See [Recommendations for Tableau Server and Tableau Cloud](#).

### Recommendations for Tableau Desktop

You have a range of options for deploying Tableau Desktop in your company. You can allow unrestricted access to Sandboxed and Network-enabled extensions, or you can put limits and restrictions on who has access to extensions and under what circumstances.

By default, Tableau Desktop users have unrestricted access to Sandboxed and Network-enabled extensions. You can use two options during installation to change the default settings.

- Turn off all extensions (`DISABLEEXTENSIONS`)
- Turn off Network-enabled extensions (`DISABLENETWORKEXTENSIONS`).

**Note:** You can change these settings after Tableau Desktop installation by editing the Registry (Windows) or running a script (Mac) on each Desktop. See [Turn off dashboard extensions](#).

## Deployment scenarios

Using the installation settings, you can deploy Tableau Desktop in several ways.

- **Allow all extensions** - In this deployment scenario, you choose to trust Tableau authors to select the Sandboxed and Network-enabled extensions they want to use. If you want to empower your Tableau Desktop users with the greatest flexibility, use the default installation settings. Using the default settings, Tableau Desktop users have unrestricted access to Sandboxed and Network-enabled extensions. The default settings are: `DISABLEEXTENSIONS=0` and `DISABLENETWORKEXTENSIONS=0`. See [Install Tableau Desktop from the Command Line](#).
- **Only allow Sandboxed extensions** - In this scenario, you know that Sandboxed extensions are safe and you want to allow them, but you aren't sure about Network-enabled extensions and want to prevent their use. To turn off support for Network-enabled extensions, set the `DISABLENETWORKEXTENSIONS` property (`DISABLENETWORKEXTENSIONS=1`). Keep the default setting for enabling extensions (`DISABLEEXTENSIONS=0`). See [Install Tableau Desktop from the Command Line](#).
- **No extensions allowed** - In this scenario, you don't want to allow users to use extensions of either type, Network-enabled or Sandboxed. In this case, turn support for all extensions off by using the `DISABLEEXTENSIONS` property (`DISABLEEXTENSIONS=1`). See [Install Tableau Desktop from the Command Line](#).

**Use a combination of settings** You might have some users who need and should have unrestricted access to all extensions, and others for whom access to Sandboxed extensions is sufficient, and then finally a set of users who need no access to extensions at all. Because the extension options are set per desktop, you can configure your deployment for specific users and their use cases.

**Web authoring** - If Tableau Server or Tableau Cloud are available for your users, they can use web authoring to access extensions. In web authoring, the server or site settings for extensions apply. In this scenario, the server and site administrators can determine which extensions to allow users access to. Administrators can use the server and site settings to restrict access to Sandboxed extensions only, or to restrict access to Sandboxed extensions and the Network-enabled extensions that have been added to a safe list.

If extensions are enabled on Tableau Desktop, users have unrestricted access to extensions.

You can turn off extensions on Tableau Desktop to restrict access per desktop. And restrict access to Sandboxed extensions only.

### Recommendations for Tableau Server and Tableau Cloud

If your users have access to Tableau Server or Tableau Cloud, you can use the built-in security controls to put limits and restrictions on the extensions that can be used and under what circumstances. If you've turned off extensions on Tableau Desktop, you can still allow users to

add extensions in web authoring, but you can limit the number of extensions that can be used to just ones you approve of.

Use Tableau Server/Online settings to control access to Sandboxed extensions per site.

Use Tableau Server/Online settings to control access to Network-enabled extensions that you approve.

Creators can use web authoring to add Sandboxed extensions and approved Network-enabled extensions. All users can view and use Sandboxed and approved Network-enabled extensions.

Trust Sandboxed extensions and the Network-enabled extensions on the safe list

Starting with Tableau 2019.4, only Sandboxed extensions are allowed to run by default. Network-enabled extensions aren't allowed unless they've been added to the safe list. Administrators can add Network-enabled extensions to the settings page for the site (**Settings > Extensions > Enable specific Extensions**).

**Note** To make the safe list the default behavior for extensions in Tableau 2018.2 and Tableau 2018.3, you must change the settings for the site. On the Extensions settings page, under **Default behavior for Extensions**, clear the **Enable unknown**

**extensions...** option. In Tableau Server 2019.1, Tableau 2019.2, and Tableau 2019.3, by default, no extensions are allowed to run unless they've been added to the safe list.

### Checklist for the safe list:

- Does the extension come from a source that you know and trust?
- Check the URL of the extension. Does the URL look suspicious or contain dubious domain names?
- Does the extension require access to full (underlying data) or summary data? See [Understand data access](#).
- Test the extensions before allowing broad use. See [Test extensions for security](#). See [Test Network-enabled extensions for security](#).

### Add extensions to the safe list:

- See [Add extensions to the safe list and configure user prompts](#).

### Block specific extensions from running on Tableau Server

On Tableau Server, you can block specific extensions by adding their URL to the block list. This is useful if you have multiple sites that are configured differently for extensions. For example, if you have a test site where you want to be able to test internal or third-party extensions, you might have enabled the default behavior for extensions, where unlisted extensions are allowed to run provided they do not access the underlying data in the workbook. Adding an extension to the block list prevents it from inadvertently being used on the test site.

- Add the URL of the extensions that you don't want to allow to the blocked list. This option is only available on Tableau Server. See [Block specific extensions](#).

### Turn off extensions for a site

By default, extensions are enabled on Tableau Server and Tableau Cloud. On Tableau Server, the server administrator can turn off extensions for a site. On Tableau Cloud, the site administrator can turn off extensions for the site. On Tableau Server, the server administrator can turn off extensions completely, which overrides the site settings. You should not have to change this setting on the server or for the site, as you can control the Network-enabled

extensions that you want to allow on the safe list. You can also control the settings for Sandboxed extensions, which are allowed by default.

- To disable extensions on a site (Tableau Server, Tableau Cloud), change the site settings that enables users to run extensions on the site. See [Control extensions and access to data](#).

#### Show or hide user prompts to run Network-enabled extensions

When you add a Network-enabled extension to the safe list, you can configure whether users see prompts by default when they are adding the extension to a dashboard, or when they are interacting with a view that has the extension. The prompt tells users details about the Network-enabled extension and whether the extension has access to full data. The prompt gives users the ability to allow or deny the extension from running. You can hide this prompt from users, allowing the extension to run immediately. When enabled for a site, Sandboxed extensions are allowed by default and do not prompt users.

#### Turn off Sandboxed extensions

Starting in Tableau 2019.4, Sandboxed extensions are enabled for Tableau Server and Tableau Cloud by default. Sandboxed extensions run in a protected environment and are hosted by Tableau. Administrators can control whether to let users run Sandboxed extensions on a site. Sandboxed extensions don't need to be added to the safe list. When Sandboxed extensions are allowed, users are able to freely add Sandboxed extensions to dashboards and are able to open and use dashboards that contain Sandboxed-extensions. If you need to block a Sandboxed extension, a server administrator can add the Sandboxed extension to a global block list. If you need to turn off Sandboxed extensions completely, you can change the default setting for the site. If you change the default setting for Sandboxed extensions, only the extensions (including Sandboxed extensions) that are on the safe list are allowed to run.

## Tableau Server Key Management System

Tableau Server has three Key Management System (KMS) options that allow you to enable encryption at rest. One is a local option that is available with all installations of Tableau

## Tableau Server on Linux Administrator Guide

Server. Two additional options require Advanced Management (formerly Server Management add-on), but allow you to use a different KMS.

Beginning in version 2019.3, Tableau Server added these KMS options:

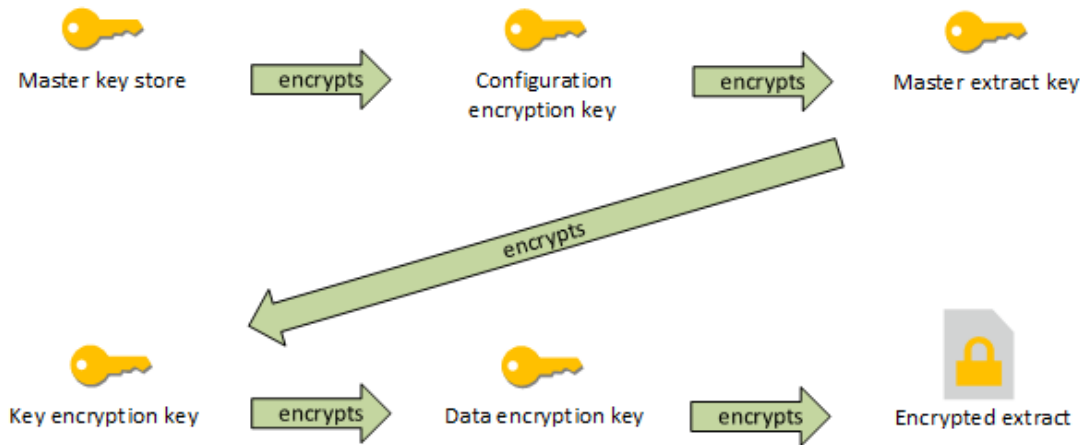

- A local KMS that is available with all installations. This is described below.
- An AWS-based KMS that comes as part of Advanced Management. For details, see [AWS Key Management System](#).

Beginning in version 2021.1, Tableau Server added another KMS option:

- An Azure-based KMS that comes as part of Advanced Management. For details, see [Azure Key Vault](#).

### Tableau Server local KMS

The Tableau Server local KMS uses the secret storage capability described in [Manage Server Secrets](#) to encrypt and store the master extract key. In this scenario, the Java keystore serves as the root of the key hierarchy. The Java keystore is installed with Tableau Server. Access to the master key is managed by native file system authorization mechanisms by the operating system. In the default configuration, the Tableau Server local KMS is used for encrypted extracts. The key hierarchy for local KMS and encrypted extracts is illustrated here:

## Troubleshoot configuration

### Multi-node misconfiguration

In a multi-node setup for AWS KMS, the `tsm security kms status` command may report healthy (OK) status, even if another node in the cluster is misconfigured. The KMS status check only reports on the node where the Tableau Server Administration Controller process is running and does not report on the other nodes in the cluster. By default the Tableau Server Administration Controller process runs on the initial node in the cluster.

Therefore, if another node is misconfigured such that Tableau Server is unable to access the AWS CMK, those nodes may report Error states for various services, which will fail to start.

If some services fail to start after you have set KMS to the AWS mode, then run the following command to revert to local mode: `tsm security kms set-mode local`.

### Regenerate RMK and MEK on Tableau Server

To regenerate the root master key and the master encryption keys on Tableau Server, run the `tsm security regenerate-internal-tokens` command.

## Extract Encryption at Rest

Extract encryption at rest is a data security feature that allows you to encrypt .hyper extracts while they are stored on Tableau Server.

Tableau Server administrators can enforce encryption of all extracts on their site or allow users to specify to encrypt all extracts associated with particular published workbooks or data sources.

### Limitations

Before they can be encrypted, older .tde file extracts must be upgraded to .hyper file extracts. This happens automatically as a part of the encryption job. For more information about the impacts of extract upgrade, see [Extract Upgrade to .hyper Format](#).

Temporary files and cache files are not encrypted at rest with this feature.

## Tableau Server on Linux Administrator Guide

Workbooks (.twb) and data source files (.tds) are not encrypted with this feature. These files will contain metadata such as database table column names and formatting instructions. In certain cases, they may contain some row-level data if it is included in filters.

Other data files, such as Excel or JSON files, are not encrypted with this feature unless they are converted to extracts before being published.

When extracts are downloaded from the server they are decrypted.

### Performance Overview

#### Increase in Backgrounder Load

You may see a slight to moderate increase in backgrounder load when you turn on encryption at rest. Encryption and decryption are computationally intensive operations. Encryption at rest alters existing backgrounder jobs and introduces new jobs to run on backgrounder. The overall increase in backgrounder load depends on the number and size of affected extracts and how often the scenarios below apply.

- **Initial publishing:** When publishing workbooks or data sources using extracts that should be encrypted, the encryption happens on the server's backgrounders.
- **Extract refreshes from Tableau Server:** Full and incremental refreshes of encrypted extracts on Tableau Server will consume slightly more CPU.
- **Extract refreshes from Tableau Bridge and third-party applications (e.g., Informatica, Alteryx):** These flows will require new encryption jobs, scheduled on the backgrounders for any refreshed extract, resulting in a slight to moderate increase in backgrounder load.
- **Encrypting and decrypting extracts in already published workbooks and data sources:** If the site setting for encryption at rest is set to **Enable**, users might choose to encrypt or decrypt extracts in already published workbooks and data sources on Tableau server. Depending on the number and size of extracts, this will add slight to moderate load on the backgrounders.
- **Changing a site's encryption mode:** When switching a site's setting for encryption at rest to **Disable** or **Enforce**, the backgrounder will, respectively, decrypt or encrypt all

existing extracts on the site. Depending on the number and size of extracts, this may significantly increase the load on backgrounders until all extracts are unencrypted or encrypted.

- **Rotating encryption keys:** Rotating encryption keys results in the backgrounders re-encrypting all existing extracts published on that site, using fresh encryption keys. Depending on the number and size of extracts, this may significantly increase the load on backgrounders until all extracts are re-encrypted.

If running at or over capacity, consider:

- Adding additional backgrounder processes and resources.
- Letting users encrypt individual workbooks and data sources instead of enforcing encryption for the whole site or disable encryption at rest for sites where it isn't necessary. Note that scheduled and ad hoc extract refreshes will take precedence over encryption and decryption jobs.

#### Increase in Viz Load Time and Worker Load

Query performance, for example, when loading or interacting with a viz or dashboard, will require the data being decrypted once, when loaded from disk to memory. This will result in a slight increase in viz load time and CPU consumption on worker nodes for the first user loading a workbook. This will not affect other users accessing those workbooks at the same time because the data will already be decrypted in memory.

#### Impact on Backup and Restore

Encrypted extracts in backups remain encrypted. The size of backup files (.tbks) may increase up to 50-100% due to the ineffectiveness of compression on encrypted extracts. The size increase depends, among other factors, on the number of extracts that are encrypted. The time to restore a backup that contains encrypted extracts might increase slightly due to the time to exchange encryption keys.

If your Tableau Server installation has mostly or only encrypted extracts, consider disabling compression during backups to significantly improve the time backups take. To learn more about TSM backup, see [tsm maintenance backup](#).

## Tableau Server on Linux Administrator Guide

### Enforce Encryption at Rest on a Site

Tableau Server administrators can enforce encryption of all extracts on their site.

1. In a web browser, sign in to Tableau Server as a server administrator.
2. Go to the site you want to configure.
3. Click **Settings**.
4. Scroll down to the Extract Encryption at Rest section.  
Click **Enforce** to encrypt all extracts that are published and stored on the site.  
Encrypting all existing extracts stored on the site may take a while.
5. Click **Save**

### Enable Encryption at Rest on a Site

Tableau Server administrators can allow users to specify to encrypt all extracts associated with particular published workbooks or data sources.

1. In a web browser, sign in to Tableau Server as a server administrator.
2. Go to the site you want to configure.
3. Click **Settings**.
4. Scroll down to the Extract Encryption at Rest section.
5. Click **Enable** to allow users to optionally encrypt extracts on the site.  
Changing to Enable will cancel pending decryption jobs and pending encryption jobs.  
No encryption jobs are created.
6. Click **Save**

### Disable Encryption at Rest on a Site

1. In a web browser, sign in to Tableau Server as a server administrator.
2. Go to the site you want to configure.
3. Click **Settings**.
4. Scroll down to the Extract Encryption at Rest section.
5. Click **Disable** to not allow encrypted extracts on the site.  
Changing to Disable will decrypt all existing encrypted extracts. Decrypting all extracts stored on the site may take a while.

6. Click **Save**

#### View Extract Encryption Mode for All Sites

1. On a multi-site server, click **Manage all sites** on the site menu.

**Note:** The **Manage all sites** option only displays when you are signed in as a server administrator.

2. Click **Sites**.
3. The encryption mode of each site is displayed in the **Extract encryption at rest** column.

#### Encrypt or Decrypt Extracts for a Published Workbook or Data Source

**Note:** The option to encrypt or decrypt the extracts associated with particular published workbook or data source is only available when the site setting for encryption at rest is set to **Enable**. When a site is set to **Disable**, all content is not encrypted. When a site is set to **Enforce**, all content is encrypted.

**Note:** You must be the owner or administrator.

1. Go to the published workbook or published data source page.
2. Click the dropdown menu that says **Encrypted Extract** or **Unencrypted Extract**.
3. Select **Unencrypted**.

You will see a message that says, "Decrypting extract."

-or-

Select **Encrypted**.

An encryption job is started.

Alternatively, you can encrypt or decrypt extracts on the card view action menu, list view action menu, and action menu in the header section.

#### Encrypt or Decrypt Multiple Items

1. Go to the Data Sources page.
2. Select the check box beside one or more data sources.

## Tableau Server on Linux Administrator Guide

3. In the upper-left of the Data Sources page, click **Actions**.
4. Click **Encrypt** or **Decrypt**.

### View Encryption Status for a Single Item

1. Sign in to the site.
2. Go to a single data source page.  
-or-  
Go to a single workbook page for a workbook containing embedded data sources.
3. The encryption status is displayed on the page.

### Filter Data Sources by Encryption Status

1. In the site, click **Explore**.
2. At the top-right, click the Explore: Top-level Projects dropdown menu and select **All Data Sources**.
3. Click the filter icon.
4. Scroll down to the “Live or extract” section and select a filtering option: All, Live, Extracts, Unencrypted Extracts, Encrypted Extracts, Currently Encrypting, or Currently Decrypting.
5. Select the checkbox beside “Include .tde and .hyper files” if you want to include “Live to .tde file” and “Live to .hyper file” connections in your filter results.

### Filter Workbooks by Encryption Status

1. In the site, click **Explore**.
2. At the top-right, click the Explore: Top-level Projects dropdown menu and select **All Workbooks**.
3. Click the filter icon.
4. Scroll down to the “Live or extract” section and select a filtering option: All, Live, Extracts, Published, Unencrypted Extracts, Encrypted Extracts, Currently Encrypting, or Currently Decrypting.
5. Select the checkbox beside “Include .tde and .hyper files” if you want to include “Live to .tde file” and “Live to .hyper file” connections in your filter results.  
Any workbooks that have at least one connection that matches the filter selection will be displayed.

## View Status of Encrypt or Decrypt Extracts Background Tasks

1. In the site, click **Site Status**.
2. Click **Background Tasks for Non Extracts** to see completed and pending background task details.  
Note: **Background Tasks for Non Extracts** includes all tasks not related to extract refreshes, so it includes encryption jobs.
3. In the Task menu, select **Encrypt Extracts** or **Decrypt Extracts** and click **Apply**.
4. In the Time Range menu, select a range.  
You see "Encrypt Extracts" or "Decrypt Extracts" background tasks for all of your extract-based published data sources and workbooks.

## The tabcmd Utility

The tabcmd command-line utility has commands and options to control extract encryption. For more information, see the tabcmd documentation.

## Specify the extract encryption mode when you create a site

```
tabcmd createsite <site-name> --extract-encryption-mode [enforced |
enabled | disabled]
```

## Specify the extract encryption mode when you edit a site

```
tabcmd editsite <site-name> --extract-encryption-mode [enforced |
enabled | disabled]
```

## Get the extract encryption mode when you list sites

```
tabcmd listsites --get-extract-encryption-mode
```

## Encrypt extracts when you publish a workbook, data source, or extract to the server

```
tabcmd publish "filename.hyper" --encrypt-extracts
```

## Tableau Server on Linux Administrator Guide

### Decrypt all extracts on a site

**Note:** Depending on the number and size of extracts, this operation may consume significant server resources. Consider running this command outside of normal business hours.

```
tabcmd decryptextracts <site-name>
```

### Encrypt all extracts on a site

**Note:** Depending on the number and size of extracts, this operation may consume significant server resources. Consider running this command outside of normal business hours.

```
tabcmd encryptextracts <site-name>
```

### Reencrypt all extracts on a site with new encryption keys

You must specify a site.

**Note:** Depending on the number and size of extracts, this operation may consume significant server resources. Consider running this command outside of normal business hours.

```
tabcmd reencryptextracts <site-name>
```

For more information, see `reencryptextracts`.

### Tableau Server Rest API

With the Tableau Server REST API you can manage Tableau Server resources programmatically. You can use this access to create your own custom applications or to script interactions with Tableau Server resources.

To learn more, see [Extract Encryption Methods](#).

## Network Security

There are three main network interfaces in Tableau Server:

- **Client to Tableau Server:** The client can be a web browser, Tableau Mobile, Tableau Desktop, or the tabcmd utility.
- **Tableau Server to your database(s):** To refresh data extracts or handle live database connections, Tableau Server needs to communicate with your database(s).
- **Server component communication:** This applies to distributed deployments only.

In most organization, Tableau Server is also configured to communicate with the internet and with a SMTP server.

### Client to Tableau Server

A Tableau Server client can be a web browser, a device running Tableau Mobile, Tableau Desktop, or tabcmd commands. Communications between Tableau Server and its clients use standard HTTP requests and responses. We recommend configuring Tableau Server for HTTPS for all communications. When Tableau Server is configured for SSL, all content and communications between clients are encrypted using SSL, and the HTTPS protocol is used for requests and responses.

By default, passwords are communicated from browsers and tabcmd to Tableau Server using 1024-bit public/private key encryption. This level of encryption is not considered robust enough for secure communications. Additionally, this method, where a public key is sent to the recipient in the clear and without network layer authentication is susceptible to man-in-the-middle attacks.

To adequately secure network traffic from clients to Tableau Server, you must configure SSL with a certificate from a trusted certificate authority.

See [Configure SSL for External HTTP Traffic to and from Tableau Server](#).

## Tableau Server on Linux Administrator Guide

### Client access from the Internet

We recommend a gateway proxy server to enable secure client access from the internet to your Tableau Server. We do not recommend running Tableau Server in a DMZ or otherwise outside your protected, internal network.

Configure a reverse proxy server, with SSL enabled, to handle all inbound traffic from the internet. In this scenario, the reverse proxy is the only external IP address (or range of addresses if multiple reverse proxies are load-balancing inbound requests) that Tableau Server will communicate with. Reverse proxies are transparent to requesting clients, thereby obfuscating Tableau Server network information and simplifying client configuration.

For configuration information, see [Configuring Proxies and Load Balancers for Tableau Server](#).

### Clickjack Protection

By default, Tableau Server has *clickjack protection* enabled. This helps prevent certain types of attacks in which the attacker overlays a transparent version of a page on top of an innocuous-looking page in order to lure a user into clicking links or entering information. With clickjack protection enabled, Tableau Server imposes certain restrictions on embedding views. For more information, see [Clickjack Protection](#).

## Tableau Server to your database

Tableau Server makes dynamic connections to databases to process result sets and refresh extracts. It uses native drivers to connect to databases whenever possible and relies on a generic ODBC adapter when native drivers are unavailable. All communications to the database are routed through these drivers. As such, configuring the driver to communicate on non-standard ports or provide transport encryption is part of the native driver installation. This type of configuration is transparent to Tableau.

When a user stores credentials for external data sources on Tableau Server, they are stored encrypted in Tableau Server's internal database. When a process uses those credentials to

query the external data source, the process retrieves the encrypted credentials from the internal database and decrypts them in process.

## Tableau Server to the internet

In some cases, where users connect to external data sources, such as the Tableau map servers, then Tableau Server will need to connect to the internet. We recommend that you run all components of Tableau inside your protected network. Therefore, connections to the internet may require that you configure Tableau Server to use a forward proxy.

## Tableau Server to a SMTP server

You can configure Tableau Server to send event notifications to administrators and users. As of version 2019.4, Tableau Server supports TLS for the SMTP connection. See [Configure SMTP Setup](#).

## Communication with the repository

You can configure Tableau Server to use Secure Sockets Layer (SSL) for encrypted communications on all traffic that is exchange with the Postgres repository to and from other server components. By default, SSL is disabled for communications between server components and the repository.

For more information, see `tsm security repository-ssl enable`

## Server component communication in a cluster

There are two aspects to communication between Tableau Server components in a distributed server installation: trust and transmission. Each server in a Tableau cluster uses a stringent trust model to ensure that it is receiving valid requests from other servers in the cluster. Computers in the cluster running a gateway process accept requests from third parties (clients), unless they are fronted by a load balancer, in which case the load balancer receives the requests. Servers not running a gateway process only accept requests from other trusted members of the cluster. Trust is established by an allowlist of IP address, port,

and protocol. If any of these are invalid, the request is ignored. All members of the cluster can communicate with each other.

When a user stores credentials for external data sources on Tableau Server, they are stored encrypted in Tableau Server's internal database. When a process uses those credentials to query the external data source, the process retrieves the encrypted credentials from the internal database and decrypts them in process.

### Clickjack Protection

Tableau Server includes protection against clickjack attacks. *Clickjacking* is a type of attack against web pages in which the attacker tries to lure users into clicking or entering content by displaying the page to attack in a transparent layer over an unrelated page. In the context of Tableau Server, an attacker might try to use a clickjack attack to capture user credentials or to get an authenticated user to change settings on your server. For more information about clickjack attacks, see [Clickjacking](#) on the Open Web Application Security Project website.

**Note:** Clickjack protection was available in previous versions of Tableau Server, but was disabled by default. New installations of Tableau Server 9.1 and later will always have clickjack protection on unless you explicitly disable it.

#### Effects of clickjack protection

When clickjack protection is enabled on Tableau Server, the behavior of pages loaded from Tableau Server changes in the following ways:

- Tableau Server adds the `X-Frame-Options: SAMEORIGIN` header to certain responses from the server. In the current versions of most browsers, this header prevents the content from being loaded into an `<iframe>` element, which helps prevent clickjacking attacks.
- The top-level page from Tableau Server cannot be loaded in `<iframe>` elements. This includes the sign-in page. One consequence is that you cannot host Tableau Server

pages in an application that you create.

- Only views can be embedded.
- If an embedded view requires data source credentials, a message is displayed in the **<iframe>** element with a link to open the view in a secure window where the user can safely enter credentials. Users should always verify the address of the opened window before entering credentials.
- Views can be loaded only if they include the `:embed=y` parameter in the query string, as in this example:

```
http://<server>/views/Sales/CommissionModel?:embed=y
```

**Note:** When clickjack protection is enabled, embedded views that use the URL copied from the browser address bar might not load. These view URLs usually contain the hash symbol (#) after the server name (for example, `http://myserver-#/views/Sales/CommissionModel?:embed=y`) are blocked when clickjack protection is enabled on Tableau Server.

### Disabling clickjack protection

You should leave clickjack protection enabled unless it is affecting how your users work with Tableau Server. If you want to disable clickjack protection, use the following `tsm` commands:

1. `tsm configuration set -k wgserver.clickjack_defense.enabled -v false`
2. `tsm pending-changes apply`

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart beha-

rior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## HTTP Response Headers

Tableau Server supports some of the response headers specified in the [OWASP Secure Headers Project](#).

This topic describes how to configure the following response headers for Tableau Server:

- HTTP Strict Transport Security (HSTS)
- Referrer-Policy
- X-Content-Type-Options
- X-XSS-Protection

Tableau Server also supports the Content Security Policy (CSP) standard. CSP configuration is not covered in this topic. See [Content Security Policy](#).

### Configuring response headers

All response headers are configured with the `tsm configuration set` command.

When you are finished configuring response headers, run `tsm pending-changes apply`.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### HTTP Strict Transport Security (HSTS)

HSTS forces clients connecting to Tableau Server to connect with HTTPS. For more information see the OWASP entry, [HTTP Strict Transport Security \(HSTS\)](#).

### Options

`gateway.http.hsts`

Default value: `false`

The HTTP Strict Transport Security (HSTS) header forces browsers to use HTTPS on the domain where it is enabled.

`gateway.http.hsts_options`

Default value: `"max-age=31536000"`

By default, HSTS policy is set for one year (31536000 seconds). This time period specifies the amount of time in which the browser will access the server over HTTPS.

Referrer-Policy

Beginning in 2019.2, Tableau Server includes the ability to configure Referrer-Policy HTTP header behavior. This policy is enabled with a default behavior that will include the origin URL for all "secure as" connections (policy `no-referrer-when-downgrade`). In previous versions, the Referrer-Policy header was not included in responses sent by Tableau Server. For more information about the various policy options that Referrer-Policy supports, see the OWASP entry, [Referrer-Policy](#).

Options

`gateway.http.referrer_policy_enabled`

Default value: `true`

To exclude the Referrer-Policy header from responses sent by Tableau Server, set this value to `false`.

`gateway.http.referrer_policy`

Default value: `no-referrer-when-downgrade`

This option defines the referrer policy for Tableau Server. You may specify any of the policy value strings listed in the [Referrer-Policy](#) table on the OWASP page.

### X-Content-Type-Options

The X-Content-Type-Options response HTTP header specifies that the MIME type in the Content-Type header should not be changed by the browser. In some cases, where MIME type is not specified, a browser may attempt to determine the MIME type by evaluating the characteristics of the payload. The browser will then display the content accordingly. This process is referred to as "sniffing." Misinterpreting the MIME type can lead to security vulnerabilities.

For more information see the OWASP entry, [X-Content-Type-Options](#).

#### Option

gateway.http.x\_content\_type\_nosniff

Default value: `true`

The X-Content-Type-Options HTTP header is set to 'nosniff' by default with this option.

### X-XSS-Protection

The HTTP X-XSS-Protection response header is sent to the browser to enable cross-site scripting (XSS) protection. The X-XSS-Protection response header overrides configurations in cases where users have disabled XSS protection in the browser.

For more information see the OWASP entry, [X-XSS-Protection](#).

#### Option

gateway.http.x\_xss\_protection

Default value: `true`

The X-XSS-Protection response header is enabled by default with this option.

### Content Security Policy

Tableau Server supports the Content Security Policy (CSP) standard. CSP is intended to be an additional layer of security against cross-site scripting and other malicious web-based

attacks. CSP is implemented as a HTTP response header that allows you to specify where external resources, such as scripts and images, can be safely loaded from.

See the [Mozilla website](#) for more information about CSP.

### Configure and enable CSP

CSP is configured and enabled using the `tsm configuration set Options` command. If you are running Tableau Server in a distributed deployment, run these commands on the initial node in the cluster. The configuration will be applied across the cluster after you run `tsm pending-changes apply`.

## Step 1: Set default directives

Tableau Server includes the set of default directives in the table below.

To set a directive, use the following `tsm` syntax:

```
tsm configuration set -k content_security_policy.-
directive.<directive_name> -v "<value>"
```

For example, to set the `connect_src` directive, run the following command:

```
tsm configuration set -k content_security_policy.directive.connect_
src -v "* unsafe-inline"
```

| Option  | Default value | Description   |
|---|---------------|---|
| <code>content_security_policy.-directive.default_src</code> | 'none'        | Serves as a fallback for the other fetch directives.<br><br>Valid values for <code>default_src</code> . |
| <code>content_security_policy.-directive.connect_src</code> | *             | Restricts the URLs which can be loaded using script interfaces.   |

|   |                   |   |
|---|-------------------|---|
|   |                   | Valid values for <code>connect_src</code> .   |
| <code>content_security_policy.directive.script_src</code> | *                 | Specifies valid sources for JavaScript.<br><br>Valid values for <code>script_src</code> .   |
| <code>content_security_policy.directive.style_src</code>  | * 'unsafe-inline' | Specifies valid sources for stylesheets.<br><br>Valid values for <code>style_src</code> .   |
| <code>content_security_policy.directive.img_src</code>    | * data:           | Specifies valid sources of images and favicons.<br><br>Valid values for <code>img_src</code> .  |
| <code>content_security_policy.directive.font_src</code>   | * data:           | Specifies valid sources for fonts loaded using <code>@font-face</code> .<br><br>Valid values for <code>font_src</code> .  |
| <code>content_security_policy.directive.frame_src</code>  | * data:           | Specifies valid sources for nested browsing contexts loading using elements such as <code>&lt;frame&gt;</code> and <code>&lt;iframe&gt;</code> .<br><br>Valid values for <code>frame_src</code> . |

|   |                   |   |
|---|-------------------|---|
| content_security_policy.-<br>directive.object_src | data:             | Specifies valid sources for the <object>, <embed>, and <applet> elements.<br><br>Valid values for <code>object_src</code> .   |
| content_security_policy.-<br>directive.report_uri | /vizql/csp-report | Instructs the user agent to report attempts to violate the CSP. These violation reports consist of JSON documents sent via an HTTP POST request to the specified URI.<br><br>Valid values for <code>report_uri</code> . |

## Step 2: Add additional directives (optional)

The default directives included with Tableau Server are a subset of directives that are supported by CSP.

For a full list of supported CSP directives, go to <https://developer.mozilla.org/en-US/docs/Web/HTTP/Headers/Content-Security-Policy>.

You can add directives to the existing default set, by using adding the new directive in the `content_security_policy.directive` namespace. You must include the `--force-keys` parameter when adding new directives. The syntax is as follows:

```
tsm configuration set -k content_security_policy.directive.<new_directive_name> -v "<value>" --force-keys
```

For example, to add the `worker-src` directive, run the following command:

```
tsm configuration set -k content_security_policy.directive.worker-
src -v "none" --force-keys
```

### Step 3: Specify report-only directives (optional)

You can configure CPS to report some directives and to enforce others. When you set `content_security_policy.enforce_enabled` to true, then all directives are enforced (even if `content_security_policy.report_only_enable` is also set to true).

To specify directives as "report-only" and not enforced, add the directives to the `report_only_` directive namespace. You must include the `--force-keys` parameter when adding new directives. The syntax is as follows:

```
tsm configuration set -k content_security_policy.report_only_dir-
ective.<directive_name> -v "<value>" --force-keys
```

For example, to report only on the `script_src` directive, run the following command:

```
tsm configuration set -k content_security_policy.report_only_dir-
ective.script_src -v " http://*.example.com" --force-keys
```

### Step 4: Enable CSP on Tableau Server

After you have configured directives, enable CSP on Tableau Server.

The following options are used to enable enforcement or report only mode for the directives you have set.

| Option   | Default value | Description  |
|--|---------------|--|
| <code>content_security_policy.enforce_enabled</code> | false         | Adds a CSP header to all requests so that any violation will be enforced by the browser. |
| <code>content_security_policy.report_only_</code>    | true          | Adds a CSP header to all   |

|         |  |  |
|---------|--|--|
| enabled |  | requests so that any violation will be recorded in our vizql-client logs, but will not be enforced by the browser. |
|---------|--|--|

To enable enforcement of the CSP directives that you've specified, run the following command

```
tsm configuration set -k content_security_policy.enforce_enabled -v true
```

## Step 5: Run tsm pending-changes apply

When you are finished configuring CSP, run `tsm pending-changes apply`.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### View CSP report

To view CSP violations for a given viz, load the viz in a browser that includes developer tools. This example uses the Chrome browser.

1. Load a test viz with violations that is hosted on the Tableau Server deployment where you configured CSP.
2. Enter `CTRL+Shift+I` to open the developer tools in Chrome.
3. Click the **Network** tab.
4. In the **Filter** field, enter `csp-report`, and then click **Find All**.

- If there are no violations then the search will not return any CSP reports.
- If there are violations, click the Headers tab in the results pane and scroll to the bottom to view **Request Payload**.

## SSL

SSL (Secure Sockets Layer) is a standard security technology that establishes an encrypted link between a web server and clients. To use SSL, you need to install an SSL certificate on Tableau Server.

You can configure Tableau Server to use SSL in the following ways:

- Use SSL for external HTTP traffic.
- Use mutual (two-way) SSL between clients (Tableau Desktop, web browsers, and `tabcmd.exe`) and Tableau Server.
- Use SSL for all HTTP traffic between internal server components and the repository.

If you are using mutual SSL, each client also needs a certificate.

**Note:** Tableau Server uses SSL for user authentication. SSL is not used to handle permissions and authorization to content (data sources and workbooks) hosted on Tableau Server.

### Configure SSL for External HTTP Traffic to and from Tableau Server

You can configure Tableau Server to use Secure Sockets Layer (SSL) encrypted communications on all external HTTP traffic. Setting up SSL ensures that access to Tableau Server is secure and that sensitive information passed between the server and Tableau clients—such as Tableau Desktop, the REST API, analytics extensions, and so on—is protected. Steps on how to configure the server for SSL are described this topic; however, you must first acquire a certificate from a trusted authority, and then import the certificate files into Tableau Server.

Mutual SSL authentication is not supported on Tableau Mobile.

### SSL certificate requirements

Acquire an Apache SSL certificate from a trusted authority (for example, Verisign, Thawte, Comodo, GoDaddy). You can also use an internal certificate issued by your company. Wild-card certificates, which allow you to use SSL with many host names within the same domain, are also supported.

When you acquire an SSL certificate for external communication to and from Tableau Server, follow these guidelines and requirements:

- All certificate files must be valid PEM-encoded X509 certificates with the extension `.crt`.
- Use a SHA-2 (256 or 512 bit) SSL certificate. Most browsers no longer connect to a server that presents an SHA-1 certificate.
- In addition to the certificate file, you must also acquire a corresponding SSL certificate key file. The key file must be a valid RSA or DSA private key file (with the extension `.key` by convention).

You can choose to passphrase-protect the key file. The passphrase you enter during configuration will be encrypted while at rest. However, if you want to use the same certificate for SSL and SAML, you must use a key file that is *not* passphrase protected.

**Important:** If your key file is passphrase protected, you must verify that the related cryptographic algorithm is supported by the version of Tableau Server you are running. Tableau Server uses OpenSSL to open password protected key files. As of August 2023, the latest releases of Tableau Server (2021.3.26, 2021.4.21, 2022.1.17, 2022.3.9, 2023.1.5, and newer) run OpenSSL 3.1. Previous versions of Tableau Server ran OpenSSL 1.1. A number of cryptographic algorithms have been retired and are no longer supported in OpenSSL 3.1. If you are using a passphrase protected key file on an older version of Tableau Server that is still running OpenSSL 1.1, review the

following Knowledge Base article before you upgrade to the latest version of Tableau Server: [Gateway and Prep Conductor failed to start when using External SSL with passphrase to protect the key file after upgrade to Tableau Server 2022.1.17](#).

- **SSL certificate chain file:** A certificate chain file is required for Tableau Desktop on the Mac and for Tableau Prep Builder on the Mac and Tableau Prep Builder on Windows. The chain file is also required for the Tableau Mobile app if the certificate chain for Tableau Server is not trusted by the iOS or Android operating system on the mobile device.

The chain file is a concatenation of all of the certificates that form the certificate chain for the server certificate. All certificates in the file must be x509 PEM-encoded and the file must have a `.crt` extension (not `.pem`).

- For multiple sub-domains, Tableau Server supports wildcard certificates.
- Verify that the domain, host name, or IP address that clients use to connect to Tableau Server is included in the Subject Alternative Names (SAN) field. Many clients (Tableau Prep, Chrome and Firefox browsers, etc) require valid entry in the SAN field to establish a secure connection.

**Note:** If you plan to configure Tableau Server for single-sign on using SAML, see [Using SSL certificate and key files for SAML](#) in the SAML requirements to help determine whether to use the same certificate files for both SSL and SAML.

### Configuring SSL for a Cluster

You can configure a Tableau Server cluster to use SSL. If the initial node is the only one running the gateway process (which it does by default), you need to configure SSL only on that node, using the steps described in this topic.

## SSL with multiple gateways

A highly available Tableau Server cluster can include multiple gateways, fronted by a load balancer. If you are configuring this type of cluster for SSL, you have the following choices:

- **Configure the load balancer for SSL:** Traffic is encrypted from the client web browsers to the load balancer. Traffic from the load balancer to the Tableau Server gateway processes is not encrypted. No SSL configuration in Tableau Server is required by you. It's all handled by the load balancer.
- **Configure Tableau Server for SSL:** Traffic is encrypted from the client web browsers to the load balancer, and from the load balancer to the Tableau Server gateway processes. For more information, continue to the following section.

## Additional configuration information for Tableau Server cluster environments

When you want to use SSL on all Tableau Server nodes that run a gateway process, you complete the following steps.

1. Configure the external load balancer for SSL passthrough.

Or if you want to use a port other than 443, you can configure the external load balancer to terminate the non-standard port from the client. In this scenario, you would then configure the load balancer to connect to Tableau Server over port 443. For assistance, refer to the documentation provided for the load balancer.

2. Make sure the SSL certificate is issued for the load balancer's host name.
3. Configure the initial Tableau Server node for SSL.
4. If you are using mutual SSL, upload the SSL CA certificate file. See `tsm authentication mutual-ssl <commands>`.

SSL certificate and key files will be distributed to each node as part of the configuration process.

## Tableau Server on Linux Administrator Guide

### Prepare the environment

When you get the certificate files from the CA, save them to a location accessible by Tableau Server, and note the names of the certificate .crt and .key files and the location where you save them. You will need to provide this information to Tableau Server when you enable SSL.

### Configure SSL on Tableau Server

Use the method you're most comfortable with.

#### Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. On the **Configuration** tab, select **Security > External SSL**.

**Note:** If you are updating or changing an existing configuration, click **Reset** to clear the existing settings before proceeding.

3. Under **External web server SSL**, select **Enable SSL for server communication**.
4. Upload the certificate and key files, and if required for your environment, upload the chain file and enter the passphrase key:

**External web server SSL**  
 Configure SSL for secure communication between Tableau Server and web clients. [Learn more about external web server SSL.](#)

Enable SSL for server communication

SSL certificate file (Required)

SSL certificate key file (Required)

SSL certificate key passphrase

SSL certificate chain file

If you are using SSL for server communication and want to configure SSL communication between Tableau Server and clients using certificates on both the server and clients, you must first enable mutual SSL. [Click here to configure the mutual SSL authentication method.](#)

If you are running Tableau Server in a distributed deployment, then these files will be automatically distributed to each appropriate node in the cluster.

5. Click **Save Pending Changes**.
6. Click **Pending Changes** at the top of the page:

7. Click **Apply Changes and Restart**.

#### Use the TSM CLI

After you have copied the certificate files to the local computer, run the following commands:

```
tsm security external-ssl enable --cert-file <path-to-file.crt> --
key-file <path-to-file.key>
```

```
tsm pending-changes apply
```

See the command reference at `tsm security external-ssl enable` to determine whether you want to include additional options for `external-ssl enable`. Tableau has specific recommendations for the `--protocols` option.

The `external-ssl enable` command imports the information from the `.crt` and `.key` files. If you run this command on a node in a Tableau Server cluster, it also distributes the information to any other gateway node.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### Port redirection and logging

After the server has been configured for SSL, it accepts requests to the non-SSL port (default is port 80) and automatically redirects to the SSL port 443.

**Note:** Tableau Server supports only port 443 as the secure port. It cannot run on a computer where another application is using port 443.

SSL errors are logged in the at the following location. Use this log to troubleshoot validation and encryption issues:

```
/var/opt/tableau/tableau_server/data/tabsvc/logs/httpd/error.log
```

## Add SSL port to the local firewall

If you are running a local firewall, you must add the SSL port to the firewall on Tableau Server. The example below describes how to configure the firewall running on RHEL/CentOS distributions. The example uses **Firewalld**, which is the default firewall on CentOS.

1. Start firewalld:

```
sudo systemctl start firewalld
```

2. Add port 443 for SSL:

```
sudo firewall-cmd --permanent --add-port=443/tcp
```

3. Reload the firewall and verify the settings:

```
sudo firewall-cmd --reload
```

```
sudo firewall-cmd --list-all
```

### Change or update SSL certificate

After you have configured SSL, you may need to periodically update the certificate. In some cases, you may need change the certificate for operational changes in your IT environment. In either case, you must use TSM to replace the SSL certificate that has already been configured for external SSL.

Do not copy a new certificate to the file directory on the operating system. Rather, when you add the certificate with either the TSM web UI or the `tsm security external-ssl enable` command, the certificate file is copied to the appropriate certificate store. In a distributed deployment, the certificate is also copied across the nodes in the cluster.

To change or update the SSL certificate (and the corresponding key file if required), follow the steps in the previous section of this topic, [Configure SSL on Tableau Server](#).

After you change the certificate, you must run `tsm pending-changes apply` to restart Tableau Server services. We also recommend restarting any other services on the computer that use the SSL certificate. If you are changing a root certificate on the operating system, you must reboot the computer.

### Example: SSL Certificate - Generate a Key and CSR

**Important:** This example is intended to provide general guidance to IT professionals who are experienced with SSL requirements and configuration. The procedure described in this article is just one of many available methods you can use to generate the required files. The process described here should be treated as an example and not as a recommendation.

---

When you configure Tableau Server to use Secure Sockets Layer (SSL) encryption, this helps ensure that access to the server is secure and that data sent between Tableau Server and Tableau Desktop is protected.

Looking for Tableau Server on Windows? See [Example: SSL Certificate - Generate a Key and CSR](#).

Tableau Server uses Apache, which includes [OpenSSL](#). You can use the OpenSSL toolkit to generate a key file and Certificate Signing Request (CSR) which can then be used to obtain a signed SSL certificate.

**Note:** Beginning in Tableau Server versions 2021.3.26, 2021.4.21, 2022.1.17, 2022.3.9, 2023.1.5, and later, Tableau Server runs OpenSSL 3.1.

Steps to generate a key and CSR

To configure Tableau Server to use SSL, you must have an SSL certificate. To obtain the SSL certificate, complete the steps:

1. [Generate a key file](#).
2. [Create a Certificate Signing Request \(CSR\)](#).
3. [Send the CSR to a certificate authority \(CA\) to obtain an SSL certificate](#).
4. [Use the key and certificate to configure Tableau Server to use SSL](#).

You can find additional information on the [SSL FAQ page](#) on the Apache Software Foundation website.

## Configure a certificate for multiple domain names

Tableau Server allows SSL for multiple domains. To set up this environment, you need to modify the OpenSSL configuration file, `openssl.conf`, and configure a Subject Alternative Name (SAN) certificate on Tableau Server. See [For SAN certificates: modify the OpenSSL configuration file](#) below.

## Generate a key

Generate a key file that you will use to generate a certificate signing request.

1. Run the following command to create the key file:

```
openssl genrsa -out <yourcertname>.key 4096
```

**Notes:**

- This command uses a 4096-bit length for the key. You should choose a bit length that is at least 2048 bits because communication encrypted with a shorter bit length is less secure. If a value is not provided, 512 bits is used.
- To create PKCS#1 RSA keys with Tableau Server versions 2021.3.26, 2021.4.21, 2022.1.17, 2022.3.9, 2023.1.5, and later, you must use the additional option `-traditional` when running `openssl genrsa` command based on the OpenSSL 3.1. For more information about the option, see <https://www.openssl.org/docs/man3.1/man1/openssl-rsa.html>.

## Create a certificate signing request to send to a certificate authority

Use the key file you created in the procedure above to generate the certificate signing request (CSR). You send the CSR to a certificate authority (CA) to obtain a signed certificate.

**Important:** If you want to configure a SAN certificate to use SSL for multiple domains, first complete the steps in [For SAN certificates: modify the OpenSSL configuration file](#) below, and then return to here to generate a CSR.

1. Run the following command to create a certificate signing request (CSR) file:

```
openssl req -new -key yourcertname.key -out yourcertname.csr -  
config /opt/tableau/tableau_server-  
/packages/apache.<version>/conf/openssl.cnf
```

2. When prompted, enter the required information.

**Note:** For **Common Name**, type the Tableau Server name. The Tableau Server name is the URL that will be used to reach the Tableau Server. For example, if you reach Tableau Server by typing `tableau.example.com` in the address bar of your browser, then `tableau.example.com` is the common name. If the common name does not resolve to the server name, errors will occur when a browser or Tableau Desktop tries to connect to Tableau Server.

## Send the CSR to a certificate authority to obtain an SSL certificate

Send the CSR to a commercial certificate authority (CA) to request the digital certificate. For information, see the Wikipedia article [Certificate authority](#) and any related articles that help you decide which CA to use.

## Use the key and certificate to configure Tableau Server

When you have both the key and the certificate from the CA, you can configure Tableau Server to use SSL. For the steps, see [Configure External SSL](#).

For SAN certificates: modify the OpenSSL configuration file

In a standard installation of OpenSSL, some features are not enabled by default. To use SSL with multiple domain names, before you generate the CSR, complete these steps to modify the **openssl.cnf** file.

1. Navigate to the Apache **conf** folder for Tableau Server.

For example: `/opt/tableau/tableau_server/packages/apache.<version_code>/conf`

2. Open **openssl.cnf** in a text editor, and find the following line: `req_extensions = v3_req`

This line might be commented out with a hash sign (#) at the beginning of the line.

```
UTF8Strings
# so use this option with caution!
string_mask = nombstr

# req_extensions = v3_req # The extensions to add to a
certificate request

[ req_distinguished_name ]
countryName = Country Name (2 letter code)
```

If the line is commented out, uncomment it by removing the # and **space** characters from the beginning of the line.

3. Move to the [ **v3\_req** ] section of the file. The first few lines contain the following text:

```
# Extensions to add to a certificate request
basicConstraints = CA:FALSE
keyUsage = nonRepudiation, digitalSignature, keyEncipherment
```

After the **keyUsage** line, insert the following line:

```
subjectAltName = @alt_names
```

If you're creating a self-signed SAN certificate, do the following to give the certificate permission to sign the certificate:

- a. Add the `cRLSign` and `keyCertSign` to the **keyUsage** line so it looks like the following: `keyUsage = nonRepudiation, digitalSignature, keyEncipherment, cRLSign, keyCertSign`
  - b. After the **keyUsage** line, add the following line: `subjectAltName = @alt_names`
4. In the [ **alt\_names** ] section, provide the domain names you want to use with SSL.

## Tableau Server on Linux Administrator Guide

```
DNS.1 = [domain1]
DNS.2 = [domain2]
DNS.3 = [etc]
```

The following image shows the results highlighted, with placeholder text that you would replace with your domain names.

A screenshot of a text file containing certificate request configuration. The text is as follows:

```
[ v3_req ]

# Extensions to add to a certificate request

basicConstraints = CA:FALSE
keyUsage = nonRepudiation, digitalSignature, keyEncipherment
subjectAltName = @alt_names

[alt_names]
DNS.1 = domain1
DNS.2 = domain2
DNS.3 = etc
```

The values 'domain1', 'domain2', and 'etc' are highlighted in yellow. The line 'subjectAltName = @alt\_names' is also highlighted in yellow.

5. Save and close the file.
6. Complete the steps in [Create a certificate signing request to send to a certificate authority](#) section, above.

### Configure SSL for Internal Postgres Communication

You can configure Tableau Server to use SSL (TLS) for encrypted communication between the Postgres repository and other server components. By default, communication that is internal to Tableau Server components is not encrypted.

While you enable support for internal SSL, you can also configure support for direct connections to the repository from Tableau clients, such as Tableau Desktop, Tableau Mobile, REST API, web browsers.

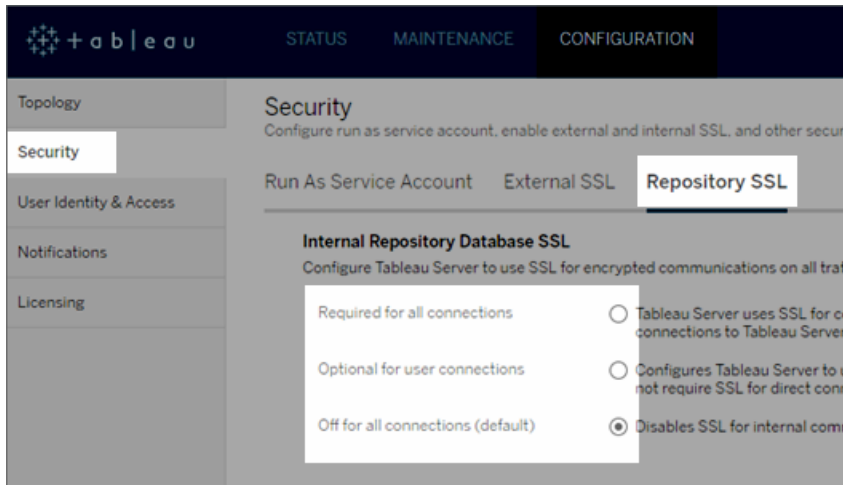

Use the TSM web interface

1. As a server administrator, open TSM in a browser:

`https://<tsm-computer-name>:8850`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. On the **Configuration** tab, select **Security > Repository SSL**.

3. Select one of the options for using repository SSL.

- **Required for all connections**—uses SSL for internal Tableau Server communication, and requires SSL for Tableau clients and any external (non-Tableau) clients that connect directly to the postgres repository, including those using the **tableau** or **readonly** user.

**Important:** Unless you complete the steps in [Configure Postgres SSL to Allow Direct Connections from Clients](#), to place the certificate files in the correct location on the client computers, Tableau clients and external postgres clients will not be able to validate the identity of the Tableau repository by comparing certificates on the client computers with the SSL certificate from the repository computer.

- **Optional for user connections**—When enabled, Tableau uses SSL for internal Tableau Server communication, and supports but does not require SSL for direct connections to the server from Tableau clients and external clients.
- **Off for all connections (default)**—Internal server communication is not encrypted, and SSL is not required for direct connections from clients.

4. Click **OK**.

The first two options generate the server's certificate files, **server.crt** and **server.key**, and place them in the following location.

```
/var/opt/tableau/tableau_server/data/tabsvc/config/pgsql_<version>/security
```

Use this .crt file if you need to configure clients for direct connections.

#### Use the TSM CLI

To enable SSL for internal traffic among the server components, run the following commands:

```
tsm security repository-ssl enable  
  
tsm pending-changes apply
```

## What the command does

`repository-ssl enable` generates the server's certificate files, which it places in the following location:

```
/var/opt/tableau/tableau_server/data/tabsvc/config/pgsql_<version>/security
```

By default, this command sets Tableau Server to require SSL for traffic between the repository and other server components, as well as for direct connections from Tableau clients (including for connections through the **tableau** or **readonly** users).

To complete the configuration, you must also do the steps described in [Configure Postgres SSL to Allow Direct Connections from Clients](#), to place the certificate files in the correct location on the client computers.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Option for repository-ssl enable

If you want to require SSL only for internal Tableau Server communication, and not for direct connections from client apps, use the following option with the `repository-ssl enable` command:

```
--internal-only
```

## Cluster environments

If you run `repository-ssl enable` on a node in a cluster, it copies the required certificate file to the same location on each other node.

For more information about downloading the public certificate for direct connections, see [Configure Postgres SSL to Allow Direct Connections from Clients](#).

### Configure Custom SSL Certificate for TSM Controller

The Tableau Server Administration Controller (aka, Controller) is the management component for administration changes to the Tableau Server cluster. By default the Controller runs on the initial (first) node of a Tableau Server cluster. Although it is technically possible to run multiple Controllers in a single Tableau cluster deployment, this is not a recommended practice.

The Controller includes an API that can be managed by various clients: TSM CLI, TSM Web Client, REST clients (curl, postman), etc. Using these clients, Tableau Server administrators can make configuration changes to the server cluster. The Controller, along with Zookeeper, manages and performs the configuration changes across the nodes.

### Default TSM SSL functionality

**Note** As is convention, the term “SSL” is used here when referring to using TLS to secure HTTPS traffic.

By default, the client connection is encrypted with SSL by means of a self-signed certificate that is created by Tableau Server during setup and renewed by the Controller. In addition to encryption, the identity (hostname or IP) of the Controller host machine is validated against the subject name presented in the certificate during the SSL handshake. However, because the certificate is self-signed, the trustworthiness of the certificate is not absolute .

In the case of CLI connection to the Controller, the inability to absolutely trust the certificate is not a huge security risk, since a man in the middle attack would generally require a malicious user access to the Tableau Server cluster in a private network. If a malicious user can spoof the certificate for the controller in CLI scenario then the malicious user already has “the keys to the kingdom.”

However, in the scenario where administrators are connecting to the Controller over TSM Web UI from outside the internal network, the lack of host validation via trusted certificate authority presents more of a security risk.

Until recently, customers running TSM Web UI on a Windows machine could place the Tableau Server CA certificate in a Windows trusted root store. Most browsers would validate the trust of the certificate by virtue of this configuration. Today, Chrome no longer validates (trusts) self-signed certificates that are placed in the OS trust store. Now, Chrome (and most major browsers) will only trust certificates that chain back to a trusted third-party root CA.

## Tableau Server v2023.1 SSL custom certificate

The custom SSL TSM certificate feature closes the trust gap by allowing administrators to configure the TSM Controller with an identity certificate that chains back to a trusted third-party root CA.

There are a number of important details to understand:

- Trust for the TSM custom SSL certificate is validated when connecting with TSM Web UI.
- Trust validation is not attempted for TSM CLI scenario. As described previously, a “man-in-the-middle” attack on the CLI scenario does not present a credible risk.
- Certificate chain may be included in the configuration. The chain may present all certificates signed by intermediate CAs. The chain can end at any point, and any certificates missing from the chain are presumed to be installed in the operating system trust store.

## Configuration

You must use TSM CLI, to configure (or update) SSL custom certificate for TSM.

See `tsm security custom-tsm-ssl enable`.

## Configure Postgres SSL to Allow Direct Connections from Clients

When Tableau Server is configured to use SSL for internal communication with the postgres repository, you can also require Tableau clients and external postgres clients that connect directly to the repository to verify the identity of the Tableau postgres repository by comparing the SSL certificate presented by the internal postgres instance with the certificate distributed to the Tableau or external postgres client.

Direct connections include those using the **tableau** user or the **readonly** user. Examples of Tableau clients include Tableau Desktop, Tableau Mobile, REST API, web browsers.

1. Enable internal SSL for the repository by running the following commands:

```
tsm security repository-ssl enable
```

```
tsm pending-changes apply
```

This enables internal SSL support and generates new server certificate and key files, and requires all Tableau clients to use SSL to connect to the repository. For additional repository-ssl commands and options, see `tsm security`.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

2. (Optional) If you have configured your client computer to validate Postgres SSL connections, then you must import the certificate that is generated by Tableau Server onto the computers running Tableau Desktop. For each client computer that will connect directly to the repository, do the following:

- Copy the **server.crt** file to the client computer. You can find this file in the following directory:

```
/var/opt/tableau/tableau_server/data/tabsvc/config/pgsql_  
<version_code>/security
```

**Note:** Do not copy **server.key** to the client computer. This file should reside only on the server.

- Import the certificate into the computer's certificate store.

For information, use the documentation from the operating system manufacturer.

3. (Optional) Configure any external (non-Tableau) postgres clients (PgAdmin or Dbeaver for example) to verify the identity of the Tableau Server postgres repository. Do this in the postgresql JDBC driver the client is using to connect by setting the "sslmode" directive to "verify-ca" or "verify-full". The options available may be different

depending on the version of the postgres driver being used. For more information, see the drive documentation about SSL support.

### Configure Mutual SSL Authentication

Using mutual SSL, you can provide users of Tableau Desktop, Tableau Mobile, and other approved Tableau clients a secure, direct-access experience to Tableau Server. With mutual SSL, when a client with a valid SSL certificate connects to Tableau Server, Tableau Server confirms the existence of the client certificate and authenticates the user, based on the user name in the client certificate. If the client does not have a valid SSL certificate, Tableau Server can refuse the connection.

You can also configure Tableau Server to fall back to username/password authentication if mutual SSL fails. Additionally, a user can log in using the REST API with a username and password (if one exists) whether or not fallback authentication is configured.

### User authentication session time limits

When users log in with mutual SSL, the authentication session is governed by the same method that governs the Tableau Server global authentication session configuration.

For clients that connect to Tableau Server using a web browser, configuration of the global authentication session is described in the *Security Hardening Checklist*, see 9. Verify session lifetime configuration.

Sessions for connected clients (Tableau Desktop, Tableau Mobile, Tableau Prep Builder, and Bridge) use OAuth tokens to keep users logged in by re-establishing a session. By default, OAuth client tokens reset after a year. If a client token has not been used in 14 days, then it will expire. You can change these values by setting the `refresh_token.absolute_expiry_in_seconds` and `refresh_token.idle_expiry_in_seconds` options. See `tsm configuration set Options`.

### Certificate usage

Before you enable and configure mutual SSL, you must configure external SSL. External SSL authenticates Tableau Server to the client and encrypts the session using the certificate and

key that is required when you configure external SSL.

For mutual SSL, an additional certificate file is required. The file is a concatenation of CA certificate files. The file type must be `.crt`. A "CA" is a *certificate authority* that issues certificates to the client computers that will connect to Tableau Server. The action of uploading the CA certificate file establishes a trust, which enables Tableau Server to authenticate the individual certificates that are presented by the client computers.

As part of your disaster recovery plan, we recommend keeping a backup of the certificate and revocation (if applicable) files in a safe location off of the Tableau Server. The certificate and revocation files that you add to Tableau Server will be stored and distributed to other nodes by the Client File Service. However, the files are not stored in a recoverable format. See Tableau Server Client File Service.

### **RSA key and ECDSA curve sizes**

The CA certificate used for mutual SSL must either have an RSA key strength of 2048, or ECDSA curve size of 256.

You can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys:

- `ssl.client_certificate_login.min_allowed.rsa_key_size`
- `ssl.client_certificate_login.min_allowed.elliptic_curve_size`

See `tsm configuration set Options`.

## **Client certificate requirements**

Users authenticating to Tableau Server with mutual SSL must present a client certificate that meets minimum security requirements.

### **Signing algorithm**

Client certificates must use a SHA-256 or greater signing algorithm.

Tableau Server configured for mutual SSL authentication will block authentication of users with client certificates that use the SHA-1 signing algorithm.

Users who attempt to log in with SHA-1 client certificates encounter an "Unable to sign in" error, and the following error will be visible in the VizPortal logs:

```
Unsupported client certificate signature detected: [certificate Signature Algorithm name]
```

You can configure Tableau Server to accept the less secure SHA-1 signing algorithm by setting the `ssl.client_certificate_login.blocklisted_signature_algorithms` tsm configuration option.

### **RSA key and ECDSA curve sizes**

The client certificate used for mutual SSL must either have an RSA key strength of 2048, or ECDSA curve size of 256.

Tableau Server will fail mutual authentication requests from client certificates that do not meet these requirements. You can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys:

- `ssl.client_certificate_login.min_allowed.rsa_key_size`
- `ssl.client_certificate_login.min_allowed.elliptic_curve_size`

See tsm configuration set Options.

Use the TSM web interface

1. Configure SSL for External HTTP Traffic to and from Tableau Server.
2. Open TSM in a browser:
 

`https://<tsm-computer-name>:8850`. For more information, see Sign in to Tableau Services Manager Web UI.
3. On the **Configuration** tab, select **User Identity & Access > Authentication Method**.
4. Under **Authentication Method**, select **Mutual SSL** in the drop-down menu.

5. Under Mutual SSL, select **Use mutual SSL and automatic sign in with client certificates**.
6. Click **Select File** and upload your certificate authority (CA) certificate file to the server.

The file (.crt) is an all-in-one file that includes certificates of CAs that are used for client authentication. The file you upload must be a concatenation of the various PEM-encoded certificate files, in order of preference.

7. Enter remaining SSL configuration information for your organization.

**Username format:** When Tableau Server is configured for mutual SSL, the server gets the user name from the client certificate, so it can establish a direct sign-in for the client user. The name that Tableau Server uses depends on how Tableau Server is configured for user authentication:

- Local Authentication—Tableau Server uses the UPN (User Principal Name) from the certificate.
- Active Directory (AD)—Tableau Server uses LDAP (Lightweight Directory Access Protocol) to get the user name.

Alternatively, you can set Tableau Server to use the CN (Common Name) from the client certificate.

The screenshot shows a configuration window titled "Authentication Method". It contains the following elements:

- A dropdown menu set to "Mutual SSL".
- A section titled "Mutual SSL" with a description: "Use mutual SSL for secure communication between Tableau Server and web clients and for automatic sign-in across all Tableau Server components. [Learn more](#)".
- A checkbox labeled "Use mutual SSL and automatic sign in with client certificates", which is checked.
- A label "SSL CA certificate file" next to a "Select File" button.
- A checkbox labeled "Use username and password if SSL authentication fails", which is unchecked.
- A section titled "Username retrieval method" with a description: "Specify a method for retrieving the username from the certificate." It contains three radio button options: "LDAP (Lightweight Directory Access Protocol)", "UPN (User Principal Name)" (which is selected), and "CN (Common Name)".
- At the bottom, there are two buttons: "Cancel" and "Save Pending Changes".

8. Click **Save Pending Changes** after you've entered your configuration information.
9. Click **Pending Changes** at the top of the page:

10. Click **Apply Changes and Restart**.

Use the TSM CLI

## Step 1: Require SSL for external server communication

To configure Tableau Server to use SSL for external communication between Tableau Server and web clients, run the `external-ssl enable` command as follows, providing the names for the server certificate's `.cert` and `.key` files:

```
tsm security external-ssl enable --cert-file <file.cert> --key-file <file.key>
```

- For `--cert-file` and `--key-file`, specify the location and file name where you saved the server's CA-issued SSL certificate (`.cert`) and key (`.key`) files.
- The above command assumes the you are signed in as a user that has the **Server Administrator** site role on Tableau Server. You can instead use the `-u` and `-p` parameters to specify an administrator user and password.
- If the certificate key file requires a passphrase, include the `--passphrase` parameter and value.

## Step 2: Configure and enable mutual SSL

Add mutual authentication between the server and each client, and allow for Tableau client users to be authenticated directly after the first time they provide their credentials.

1. Run the following command:

```
tsm authentication mutual-ssl configure --ca-cert <certificate-  
file.crt>
```

For `--ca-cert`, specify the location and file name of the certificate authority (CA) certificate file.

The file (`.crt`) is an all-in-one file that includes certificates of CAs that are used for client authentication. The file you upload must be a concatenation of the various PEM-encoded certificate files, in order of preference.

2. Run the following commands to enable mutual SSL and apply the changes:

```
tsm authentication mutual-ssl enable  
  
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Additional options for mutual SSL

You can use `mutual-ssl configure` to configure Tableau Server to support the following options.

For more information, see [tsm authentication mutual-ssl <commands>](#).

## Fallback authentication

When Tableau Server is configured for mutual SSL, authentication is automatic and clients must have a valid certificate. You can configure Tableau Server to allow a fallback option, to

accept user name and password authentication.

```
tsm authentication mutual-ssl configure -fb true
```

Tableau Server accepts username and password authentication from REST API clients, even if the above option is set to `false`.

## User name mapping

When Tableau Server is configured for mutual SSL, the server authenticates the user directly by getting the user name from their client certificate. The name that Tableau Server uses depends on how the server is configured for user authentication:

- **Local Authentication**—uses the UPN (User Principal Name) from the certificate.
- **Active Directory (AD)**—uses LDAP (Lightweight Directory Access Protocol) to get the user name.

You can override either of these defaults to set Tableau Server to use the common name.

```
tsm authentication mutual-ssl configure -m cn
```

For more information, see [Mapping a Client Certificate to a User During Mutual Authentication](#)

## Certificate Revocation List (CRL)

You might need to specify a CRL if you suspect that a private key has been compromised, or if a certificate authority (CA) did not issue a certificate properly.

```
tsm authentication mutual-ssl configure -rf <revoke-file.pem>
```

### Mapping a Client Certificate to a User During Mutual Authentication

When you use mutual (two-way) SSL authentication, the client presents its certificate to Tableau Server as part of the authentication process. Tableau Server then maps user information in the client certificate to a known user identity. The strategy that Tableau Server uses to perform client mapping depends on the content of your organization's client certificates.

This topic discusses the ways information in a client certificate can map to a user identity and how to change the way Tableau Server performs that mapping. To understand how the mapping happens and whether you need to change it, you must know how client certificates are structured in your organization.

- [User-name mapping options](#)
- [Change the certificate mapping](#)
- [Address user-name ambiguity in multi-domain organizations](#)

### User-name mapping options

Tableau Server uses one of the following approaches to map a client certificate to a user identity:

- **Active Directory.** If Tableau Server is configured to use Active Directory for user authentication, when Tableau Server receives a client certificate, it passes the certificate to Active Directory, which maps the certificate to an Active Directory identity. Any explicit user name information in the certificate is ignored.

**Note:** This approach requires client certificates to be published for the user accounts in Active Directory.

- **User principal name (UPN).** A client certificate can be configured to store the user name in the user principal name field. Tableau Server reads the UPN value and maps it to a user in Active Directory or to a local user.
- **Common name (CN).** A client certificate can be configured to store the user name in the common name field of the certificate. Tableau Server reads the CN value and maps it to a user in Active Directory or to a local user.

If you configure the server for Active Directory authentication and UPN or CN user-name mapping, put the user name in one of the following formats:

username, domain/username, or username@domain.

For example: jsmith, example.org/jsmith, or jsmith@example.org.

If the server uses local authentication, the format of the name in the UPN or CN fields is not predetermined, but the name in the field must match a user name on the server.

### Change the certificate mapping

You use the `tsm authentication mutual-ssl <commands>` commands to map a client certificate to a user identity in Tableau Server:

```
tsm authentication mutual-ssl configure -m <value>
```

Possible values are `ldap` for Active Directory mapping, `upn` for UPN mapping, or `cn` for CN mapping.

When you first install and configure Tableau Server, the server sets the default user-name mapping to match the server's authentication type:

- If the server is configured to use Active Directory, it also uses Active Directory for mapping the certificate to the user identity.
- If the server is configured to use local authentication, the server gets the user-name value from the UPN field in the certificate.

If the default behavior for how Tableau Server maps a user name to an identity is not correct for your server configuration, run the following set of commands to change the mapping to use the CN value:

```
tsm authentication mutual-ssl configure -m cn
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do

not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### Address user-name mapping ambiguity in multi-domain organizations

Under some circumstances, the user name in a certificate's UPN or CN field can be ambiguous. This ambiguity can lead to unexpected results when the user name is mapped to a user identity on the server.

For example, if Tableau Server is presented with a user name that does not include a domain, the server maps the user name to an identity using the default domain. This can cause an incorrect user-name mapping, potentially assigning a user a different user's identity and permissions.

This can occur particularly in environments where the following conditions apply:

- Your organization supports multiple Active Directory domains.
- The server is configured to use Active Directory authentication.
- The server is configured to use UPN or CN mapping.
- Some users have the same user name but different domains. For example, `jsmith@example.org` and `jsmith@example.com`.
- The user name in the certificate's UPN or CN fields does not include the domain as part of the user name—for example, it shows `jsmith`.

To avoid incorrect user-name mapping, make sure the client certificates include fully qualified user names with the domain, using the format `jsmith@example.org` or `example.org/jsmith`.

## Configure Encrypted Channel to LDAP External Identity Store

Tableau Server that is configured to connect to an external LDAP identity store must query the LDAP directory and establish a session. The process of establishing a session is called *binding*. There are multiple ways to bind. Tableau Server supports two methods of binding to an

LDAP directory:

- **Simple bind:** Establishes a session by authenticating with a username and password. By default, Tableau Server will attempt StartTLS to encrypt sessions when connecting to Windows Active Directory. If Tableau Server has a valid TLS certificate, then the session will be encrypted. Otherwise, LDAP with simple bind is not encrypted. If you are configuring LDAP with simple bind, we strongly recommend that you enable LDAP over SSL/TLS.
- **GSSAPI bind:** GSSAPI uses Kerberos to authenticate. When configured with a keytab file, authentication is secure during GSSAPI bind. However, subsequent traffic to the LDAP server is not encrypted. We recommend configuring LDAP over SSL/TLS .  
**Important:** StartTLS is not supported for GSSAPI bind with Active Directory.

If you are running Tableau Server on Linux on a computer that is joined to an Active Directory domain, you can configure GSSAPI. See LDAP with GSSAPI (Kerberos) bind.

This topic describes how to encrypt the channel for **simple LDAP bind** for communications between Tableau Server and LDAP directory servers.

Certificate requirements

- You must have a valid PEM-encoded x509 SSL/TLS certificate that can be used for encryption. The certificate file must have an extension `.crt`.
- Self-signed certificates are not supported.
- The certificate you install must include `Key Encipherment` in the key usage field to be used for SSL/TLS. Tableau Server will only use this certificate for encrypting the channel to the LDAP server. The expiry, trust, and CRL and other attributes are not validated.
- If you are running Tableau Server in a distributed deployment, then you must manually copy the SSL certificate to each node in the cluster. Copy the certificate only to those

## Tableau Server on Linux Administrator Guide

nodes where the Tableau Server Application Server process is configured. Unlike other shared files in a cluster environment, the SSL certificate used for LDAP will not be automatically distributed by the Client File Service.

- If you are using a PKI or non-3rd party certificate, upload the CA root certificate to the Java trust store.

### Import certificate into the Tableau keystore

If you do not have certificates already in place on your computer that are configured for the LDAP server then you must obtain a SSL certificate for the LDAP server and import it into the Tableau system keystore.

Use the "keytool" Java tool to import certificates. In a default installation, this tool is installed with Tableau Server in the following location:

```
/opt/tableau/tableau_server/packages/repository.<installer version>/jre/bin/keytool.
```

The following command imports the certificate:

```
sudo "<installation_directory>/packages/repository*/jre/bin/keytool  
-importcert -file "<cert_directory/<cert_name.crt>" -alias "<cert_  
alias>" -keystore /etc/opt/tableau/tableau_server-  
/tableauservicesmanagerca.jks -storepass changeit -noprompt
```

The password for the Java keystore is `changeit`. (Do not change the password for the Java keystore).

### Encryption methods

Tableau Server 2021.1 and newer supports two methods for encrypting the LDAP channel for simple bind: StartTLS and LDAPS.

- **StartTLS:** This is the default configuration for communicating with Active Directory in Tableau Server 2021.2. Beginning with Tableau Server 2021.2, TLS is enforced for simple bind LDAP connections to Active Directory. This default TLS configuration is enforced for both new installations and for upgrade scenarios.

**Note:** StartTLS is only supported on Tableau Server on Linux when communicating with Active Directory and simple bind. StartTLS is not supported for communication with other LDAP server types or with GSSAPI.

The StartTLS method works by establishing an insecure connection with the Active Directory server. After a client-server negotiation, the connection is upgraded to a TLS encrypted connection. As the default configuration, this scenario only requires a valid TLS certificate on Tableau Server. No other configuration is required.

- **LDAPS:** Secure LDAP, or LDAPS, is a standard encrypted channel that requires more configuration. Specifically, in addition to a TLS certificate on Tableau Server, you must set the host name and the secure LDAP port for the target LDAP server.

LDAPS is supported on any LDAP server, including Active Directory servers.

### Configure encrypted channel for simple bind

This section describes how to configure Tableau Server to use an encrypted channel for LDAP simple bind.

#### When to configure

You must configure Tableau Server to use an encrypted channel for LDAP simple bind before Tableau Server is initialized or as part of configuring the initial node as mentioned in the “Use the TSM CLI” tab in Configure Initial Node Settings.

## Tableau Server on Linux Administrator Guide

For new installations of Tableau Server

If your organization uses an LDAP directory other than Active Directory, then you cannot use the TSM GUI Setup to configure the identity store as part of Tableau Server installation. Instead, you must use JSON entity files to configure the LDAP identity store. See [identityStore Entity](#).

Before you configure the identityStore entity, import a valid SSL/TLS certificate into the Tableau key store as documented earlier in this topic.

Configuring LDAPS requires setting the hostname and sslPort options in the identityStore JSON file.

For new installations in an Active Directory environment

If you are using Active Directory as an external identity store, you must run the GUI version of Tableau Server Setup. Unlike the CLI process for installing Tableau Server, the GUI version of Setup includes logic to simplify and validate Active Directory configuration.

The Tableau Server Setup GUI where you configure Active Directory is shown here.

**Identity Store**

You cannot change the identity store after initializing.

Local  
 Active Directory

|  |                                      |
|--|--------------------------------------|
| Domain                                   | NetBIOS (Nickname)                   |
| <input type="text" value="example.lan"/> | <input type="text" value="example"/> |

|                                       |                                   |
|---------------------------------------|-----------------------------------|
| Hostname                              | Port                              |
| <input type="text" value="Hostname"/> | <input type="text" value="Port"/> |

Specify and configure the encryption method Tableau Server will use to communicate with Active Directory. Encrypted communication (TLS/SSL) requires a valid certificate in the Tableau certificate store.

To use LDAPS, you must specify a hostname and port.

LDAP over StartTLS (encrypted channel)  
 LDAPS (encrypted channel)  
 LDAP (unencrypted channel)

Tableau Server requires read access to Active Directory. Specify how Tableau Server will authenticate with Active Directory.

LDAP simple bind  
 LDAP GSSAPI bind

|                                       |                                       |
|---------------------------------------|---------------------------------------|
| Username                              | Password                              |
| <input type="text" value="Username"/> | <input type="text" value="Password"/> |

If you are installing a new instance of Tableau Server on Linux and you have a valid SSL/TLS certificate installed in the Tableau keystore, we recommend that you leave the default option set to StartTLS.

If you want to configure for LDAPS, then enter the hostname and secure port (typically 636) for the LDAP server, before selecting the LDAPS option.

## Tableau Server on Linux Administrator Guide

You can make changes to these configurations after you install by signing into TSM Web UI, clicking the **Configuration** tab, **User Identity & Access**, and then **Identity Store**.

### Upgrade scenarios

If you are upgrading to a 2021.2 (or newer) version of Tableau Server and using Active Directory as your external identity store, then the encrypted channel is enforced for LDAP simple bind connections. If you do not have an encrypted channel configured, then upgrade will fail.

To successfully upgrade to version 2021.2 or newer, one of the following must be true:

- The existing Tableau Server installation has already been configured for LDAPS and includes a certificate in the Tableau key store.
- A valid SSL/TLS certificate is present in the Tableau key store prior to upgrading. In this scenario, the default StartTLS configuration will enable an encrypted channel.
- The encrypted LDAP channel has been disabled as described in the following section.

### Disable default encrypted LDAP channel

If you are running Tableau Server on Linux and connecting to Active Directory, you can disable the encrypted channel requirement.

When disabled, user credentials that are used to establish the bind session with Active Directory are communicated in plaintext between Tableau Server and the Active Directory server.

### Disable new installation

If you will be using Active Directory as your identity store, then you must use the TSM GUI to configure the Active Directory connection. See [Configure Initial Node Settings](#).

**Identity Store**

You cannot change the identity store after initializing.

Local  
 Active Directory

|  |                                      |
|--|--------------------------------------|
| Domain                                   | NetBIOS (Nickname)                   |
| <input type="text" value="example.lan"/> | <input type="text" value="example"/> |

|                                       |                                   |
|---------------------------------------|-----------------------------------|
| Hostname                              | Port                              |
| <input type="text" value="Hostname"/> | <input type="text" value="Port"/> |

Specify and configure the encryption method Tableau Server will use to communicate with Active Directory. Encrypted communication (TLS/SSL) requires a valid certificate in the Tableau certificate store.

To use LDAPS, you must specify a hostname and port.

LDAP over StartTLS (encrypted channel)  
 LDAPS (encrypted channel)  
 LDAP (unencrypted channel)

Tableau Server requires read access to Active Directory. Specify how Tableau Server will authenticate with Active Directory.

LDAP simple bind  
 LDAP GSSAPI bind

|                                       |                                       |
|---------------------------------------|---------------------------------------|
| Username                              | Password                              |
| <input type="text" value="Username"/> | <input type="text" value="Password"/> |

Select **LDAP (unencrypted channel)** when running Setup.

Disable before upgrading

If you are upgrading to Tableau Server 2021.2 (or newer) from an earlier version, run the following commands on earlier version of Tableau Server before you upgrade:

## Tableau Server on Linux Administrator Guide

```
tsm configuration set -k wgserver.domain.ldap.starttls.enabled -v  
false --force-keys
```

```
tsm pending-changes apply
```

To verify that the key has been set, run the following command:

```
tsm configuration get -k wgserver.domain.ldap.starttls.enabled
```

The command should return `false`.

### Error messages

The following error messages may be displayed or logged. If you see these errors, do the following:

- Verify that your certificate is valid and imported to the Tableau key store as described earlier in this topic.
- (LDAPS only) - Verify that the host and port name is correct.

### In the Setup GUI

The following error will be displayed if you have misconfigured LDAPS or StartTLS when running the Setup or Upgrade GUI.

```
TLS handshake failed. Tableau Server and the Active Directory server  
could not negotiate a compatible level of security.
```

### Vizportal logs

If you are configuring LDAPS or StartTLS using CLI, the following error message will not be displayed. Rather, the error will be logged in the vizportal logs at `/var/opt/tableau/tableau_server/data/tabsvc/logs/vizportal`.

```
Authentication with LDAP server failed. The provided credentials or  
configuration are either incorrect or do not have the necessary per-  
missions to bind.
```

## System User, sudo Privileges, and systemd

This topic describes system user, systemd user service, and sudo privilege in the context of Tableau Server.

### Privilege separation

Following standard security best practices, Tableau Server for Linux runs processes with the least privilege possible. During installation, the unprivileged user, *tableau*, is created in a server authorized group (*tableau*).

An example user entry in the `/etc/passwd` file is as follows:

- `tableau:x:993:991:Tableau Server:/var/opt/tableau/tableau_server:/bin/bash`

All processes run as the unprivileged *tableau* user. This means that if one of the Tableau Server processes (such as a process displaying vizzes to users) were compromised in some fashion, it would only be able to impact Tableau Server, not the rest of the Linux system. For this reason, you should not add the *tableau* unprivileged user to the *tmsadmin* group. The *tmsadmin* group should only contain accounts that require authorization to access OS-related Tableau configurations.

The *tableau* user and *tmsadmin* group are created by the Tableau Server initialization process. You can specify a different unprivileged user or TSM authorization group during installation. For more information about system users and groups, in the context of installation and LDAP configuration, see Identity Store.

### *sudo* privileges

The first version (10.5) of Tableau Server on Linux relied on sudo privileges by updating the sudoers file. Updating the sudoers file conflicts with some system management configuration best practices and security policies. Therefore, the 2018.1 version (and later) of Tableau Server no longer creates or uses a privileged user (*tsmagent*). Nor does the current version of Tableau Server update or include a Tableau-specific sudoers file.

All privileged operations now occur during package and software installation.

### systemd user service

In the 10.5 version of Tableau Server on Linux, sudo privileges were required to modify or restart the TSM services, which required systemctl commands. All TSM services were run from the normal system-wide systemd process (`process ID 1`, which runs all processes on the operating system). In this scheme, systemd process runs as root. Therefore, the 10.5 version of Tableau Server required sudo privileges.

With the current 2018.1 (and later) releases, we have removed the need for sudo privileges by making use of the systemd capability to run as a user service. The systemd user service runs as a normal user, so it does not need any special privileges once it has been enabled.

In normal use cases, you will not need to issue commands to systemd because TSM takes care of that. However, for troubleshooting scenarios, you may need to interact with the TSM services. As with the previous versions, you will issue the same systemctl commands for these scenarios. However, commands should be run as the `tableau` user, and not as root. If you specified a different unprivileged system user during Tableau Server setup, then run the commands as that user.

#### Running systemctl commands

Use the following syntax example to issue request to systemd with the systemctl commands.

Start a session as the unprivileged user. The `-l` flag is critical to set environment variables properly.

```
sudo su -l tableau
```

Then issue commands. For example:

```
systemctl --user status tabadmincontroller_0
```

```
systemctl --user restart tabadmincontroller_0
```

## Security Hardening Checklist

The following list provides recommendations for improving the security ("hardening") of your Tableau Server installation.

Looking for Tableau Server on Windows? See [Security Hardening Checklist](#).

### Installing security updates

Security updates are included in the latest versions and maintenance releases (MR) of Tableau Server. You cannot install security updates as patches. Rather, you must upgrade to a current version or MR to update Tableau Server with the latest security fixes.

Always reference the most current version of this topic after upgrading. The current version includes `/current/` in the topic URL.

For example, the US version URL is: [https://help.tableau.com/current/server/en-us/security\\_harden.htm](https://help.tableau.com/current/server/en-us/security_harden.htm).

#### 1. Update to the current version

We recommend that you always run the latest version of Tableau Server. Additionally, Tableau periodically publishes maintenance releases of Tableau Server that include fixes for known security vulnerabilities. (Information regarding known security vulnerabilities can be found on the Tableau [Security Bulletins](#) page and the [Salesforce Security Advisories](#) page.) We recommend that you review maintenance release notifications to determine whether you should install them.

To get the latest version or maintenance release of Tableau Server, visit the [Customer Portal](#) page.

## 2. Configure SSL/TLS with a valid, trusted certificate

Secure Sockets Layer (SSL/TLS) is essential for helping to protect the security of communications with Tableau Server. Configure Tableau Server with a valid, trusted certificate (not a self-signed certificate) so that Tableau Desktop, mobile devices, and web clients can connect to the server over a secured connection. For more information, see [SSL](#).

## 3. Disable older versions of TLS

Tableau Server uses TLS to authenticate and encrypt many connections between components and with external clients. External clients, such as browsers, Tableau Desktop, Tableau Mobile connect to Tableau using TLS over HTTPS. Transport layer security (TLS) is an improved version of SSL. In fact, older versions of SSL (SSL v2 and SSL v3) are no longer considered to be adequately secure communication standards. As a result, Tableau Server does not allow external clients to use SSL v2 or SSL v3 protocols to connect.

We recommend that you allow external clients to connect to Tableau Server with TLS v1.3 and TLS v1.2.

TLS v1.2 is still regarded as a secure protocol and many clients (including Tableau Desktop) do not yet support TLS v1.3.

TLS v1.3 capable clients will negotiate TLS v1.3 even if TLS v1.2 is supported by the server.

The following `tsm` command enables TLS v1.2 and v1.3 (using the "all" parameter) and disables SSL v2, SSL v3, TLS v1, and TLS v1.1 (by prepending the minus [-] character to a given protocol). TLS v1.3 is not yet supported by all components of Tableau Server.

```
tsm configuration set -k ssl.protocols -v 'all -SSLv2 -SSLv3 -TLSv1  
-TLSv1.1'
```

```
tsm pending-changes apply
```

To modify the protocols that govern SSL for the Tableau Server PostgreSQL repository, see [pgsql.ssl.ciphersuite](#).

You can also modify the default list of cipher suites that Tableau Server uses for SSL/TLS sessions. For more information see the *ssl.ciphersuite* section at tsm configuration set Options.

## 4. Configure SSL encryption for internal traffic

Configure Tableau Server to use SSL to encrypt all traffic between the Postgres repository and other server components. By default, SSL is disabled for communications between server components and the repository. We recommend enabling internal SSL for all instances of Tableau Server, even single-server installations. Enabling internal SSL is especially important for multi-node deployments. See [Configure SSL for Internal Postgres Communication](#).

## 5. Enable firewall protection

Tableau Server was designed to operate inside a protected internal network.

**Important:** Do not run Tableau Server, or any components of Tableau Server on the internet or in a DMZ. Tableau Server must be run within the corporate network protected by an internet firewall. We recommend configuring a reverse proxy solution for internet clients that need to connect to Tableau Server. See [Configuring Proxies and Load Balancers for Tableau Server](#).

A local firewall should be enabled on the operating system to protect Tableau Server in single and multi-node deployments. In a distributed (multi-node) installation of Tableau Server, communication between nodes does not use secure communication. Therefore, you should enable firewalls on the computers that host Tableau Server. See [Configure Local Firewall](#).

To prevent a passive attacker from observing communications between nodes, configure a segregated virtual LAN or other network layer security solution.

See [Tableau Services Manager Ports](#) to understand which ports and services Tableau Server requires.

## 6. Restrict access to the server computer and to important directories

Tableau Server configuration files and log files can contain information that is valuable to an attacker. Therefore, restrict physical access to the machine that is running Tableau Server. In addition, make sure that only authorized and trusted users have access to the Tableau Server files in the `/var/opt/tableau/tableau_server/` directory.

## 7. Generate fresh secrets and tokens

Any Tableau Server service that communicates with repository or the cache server must first authenticate with a secret token. The secret token is generated during Tableau Server setup. The encryption key that internal SSL uses to encrypt traffic to Postgres repository is also generated at during setup.

We recommend that after you install Tableau Server, you generate new encryption keys for your deployment.

These security assets can be regenerated with the `tsm security regenerate-internal-tokens` command.

Run the following commands:

```
tsm security regenerate-internal-tokens
```

```
tsm pending-changes apply
```

## 8. Disable services that you're not using

To minimize the attack surface of the Tableau Server, disable any connection points that are not needed.

### JMX Service

JMX is disabled by default. If it's enabled but you're not using it, you should disable it by using the following:

```
tsm configuration set -k service.jmx_enabled -v false
```

```
tsm pending-changes apply
```

## 9. Verify session lifetime configuration

By default, Tableau Server does not have an absolute session timeout. This means that browser-based client (Web authoring) sessions can remain open indefinitely if the Tableau Server inactivity timeout is not exceeded. The default inactivity timeout is 240 minutes.

If your security policy requires it, you can set an absolute session timeout. Be sure to set your absolute session timeout in a range that allows the longest-running extract uploads or workbook publishing operations in your organization. Setting the session timeout too low may result in extract and publishing failures for long-running operations.

To set the session timeout run the following commands:

```
tsm configuration set -k wgserver.session.apply_lifetime_limit -v true
```

```
tsm configuration set -k wgserver.session.lifetime_limit -v value,
```

where *value* is the number of minutes. The default is 1440, which is 24 hours.

```
tsm configuration set -k wgserver.session.idle_limit -v value, where
```

*value* is the number of minutes. The default is 240.

```
tsm pending-changes apply
```

Sessions for connected clients (Tableau Desktop, Tableau Mobile, Tableau Prep Builder, Bridge, and personal access tokens) use OAuth tokens to keep users logged in by re-establishing a session. You can disable this behavior if you want all Tableau client sessions to be solely governed by the browser-based session limits controlled by the commands above. See [Disable Automatic Client Authentication](#).

## 10. Configure a server allowlist for file-based data sources

As of October 2023 Tableau Server releases, default file-based access behavior has changed. Previously, Tableau Server allowed authorized Tableau Server users to build workbooks that use files on the server as file-based data sources (such as spreadsheets). With the October 2023 releases, access to files stored on Tableau or on remote shares must be specifically configured on Tableau Server using the setting described here.

This setting allows you to limit access by the `tableau` system account only to those directories that you specify.

To configure access to shared files, you must configure allowlist functionality. This lets you limit `tableau` account access to just the directory paths where you host data files.

1. On the computer running Tableau Server, identify the directories where you will host data source files.

**Important** Make sure the file paths you specify in this setting exist and are accessible by the system account.

2. Run the following commands:

```
tsm configuration set -k native_api.allowed_paths -v "path",  
where path is the directory to add to the allowlist. All subdirectories of the specified path  
will be added to the allowlist. You must add a trailing backslash to the specified path. If  
you want to specify multiple paths, separate them with a semicolon, as in this example:
```

```
tsm configuration set -k native_api.allowed_paths -v "/data-  
sources;/HR/data/"
```

```
tsm pending-changes apply
```

## 11. Enable HTTP Strict Transport Security for web browser clients

HTTP Strict Transport Security (HSTS) is a policy configured on web application services, such as Tableau Server. When a conforming browser encounters a web application running HSTS, then all communications with the service must be over a secured (HTTPS) connection. HSTS is supported by major browsers.

For more information about how HSTS works and the browsers that support it, see The Open Web Application Security Project web page, [HTTP Strict Transport Security Cheat Sheet](#).

To enable HSTS, run the following commands on Tableau Server:

```
tsm configuration set -k gateway.http.hsts -v true
```

By default, HSTS policy is set for one year (31536000 seconds). This time period specifies the amount of time in which the browser will access the server over HTTPS. You should consider setting a short max-age during initial roll-out of HSTS. To change this time period, run `tsm configuration set -k gateway.http.hsts_options -v max-age-e=<seconds>`. For example, to set HSTS policy time period to 30 days, enter `tsm configuration set -k gateway.http.hsts_options -v max-age=2592000`.

```
tsm pending-changes apply
```

## 12. Disable Guest access

Core-based licenses of Tableau Server include a Guest user option, which allows any user in your organization to see and interact with Tableau views embedded in web pages.

Guest user access is enabled by default on Tableau Servers deployed with core-based licensing.

Guest access allows users to see embedded views. The Guest user cannot browse the Tableau Server interface or see server interface elements in the view, such as user name, account settings, comments, and so on.

If your organization has deployed Tableau Server with core licensing and Guest access is not required, then disable Guest access.

You can disable Guest access at the server or site level.

You must be a server administrator to disable the Guest account at either the server or the site level.

### To disable Guest access at the server level:

1. In the site menu, click **Manage All Sites** and then click **Settings > General**.
2. For **Guest Access**, clear the **Enable Guest account** check box.
3. Click **Save**.

### To disable Guest access for a site:

1. In the site menu, select a site.
2. Click **Settings**, and on the Settings page, clear the **Enable Guest account** check box.

For more information, see [Guest User](#).

## 13. Set referrer-policy HTTP header to 'same-origin'

Beginning in 2019.2, Tableau Server includes the ability to configure Referrer-Policy HTTP header behavior. This policy is enabled with a default behavior that will include the origin URL for all "secure as" connections (`no-referrer-when-downgrade`), which sends origin referer information only to like connections (HTTP to HTTP) or those that are more secure (HTTP to HTTPS).

However, we recommend setting this value to `same-origin`, which only sends referrer information to same-site origins. Requests from outside the site will not receive referrer information.

To update the referrer-policy to `same-origin`, run the following commands:

```
tsm configuration set -k gateway.http.referrer_policy -v same-origin
```

```
tsm pending-changes apply
```

For more information about configuring additional headers to improve security, see HTTP Response Headers.

## 14. Configure TLS for SMTP connection

Beginning in 2019.4, Tableau Server includes the ability to configure TLS for the SMTP connection. Tableau Server only supports STARTTLS (Opportunistic or Explicit TLS).

Tableau Server can be optionally configured to connect to a mail server. After configuring SMTP, Tableau Server can be configured to email server administrators about system failures, and email server users about subscribed views and data-driven alerts.

To configure TLS for SMTP:

1. Upload a compatible certificate to Tableau Server. See `tsm security custom-cert add`.
2. Configure TLS connection using TSM CLI.

Run the following TSM commands to enable and force TLS connections to the SMTP server and to enable certificate verification.

```
tsm configuration set -k svcmonitor.notification.smtp.ssl_enabled -v true
```

```
tsm configuration set -k svcmonitor.notification.smtp.ssl_required -v true
```

```
tsm configuration set -k svcmonitor.notification.smtp.ssl_check_server_identity -v true
```

By default, Tableau Server will support TLS versions 1, 1.1, and 1.2, but we recommend that you specify the highest TLS version that the SMTP server supports.

## Tableau Server on Linux Administrator Guide

Run the following command to set the version. Valid values are `SSLv2Hello`, `SSLv3`, `TLSv1`, `TLSv1.1`, and `TLSv1.2`. The following example sets the TLS version to version 1.2.:

```
tsm configuration set -k svcmonitor.notification.smtp.ssl_versions -v "TLSv1.2"
```

For more information about other TLS configuration options, see [Configure SMTP Setup](#).

3. Restart Tableau Server to apply changes. Run the following command:

```
tsm pending-changes apply
```

## 15. Configure SSL for LDAP

If your Tableau Server deployment is configured to use a generic LDAP external identity store, we recommend configuring SSL to protect authentication between Tableau Server and your LDAP server. See [Configure Encrypted Channel to LDAP External Identity Store](#).

If your Tableau Server deployment is configured to use Active Directory, we recommend enabling Kerberos to protect authentication traffic. See [Kerberos](#).

## Change List

| Date      | Change   |
|-----------|--|
| May 2018  | Added clarification: Do not disable REST API in organizations that are running Tableau Prep.   |
| May 2019  | Added recommendation for referrer-policy HTTP header.  |
| June 2019 | Removed recommendation to disable Triple-DES. As of version 2019.3, Triple-DES is no longer a default supported cipher for SSL. See <a href="#">What's Changed - Things to Know Before You Upgrade</a> . |

|               |  |
|---------------|--|
| January 2020  | Added recommendation to configure TLS for SMTP.  |
| February 2020 | Added recommendation to configure SSL for LDAP server.   |
| May 2020      | Added TLS v1.3 to the disabled list of TLS ciphers. Added clarification to introduction about topic versioning.                        |
| October 2020  | Added TLS v1.3 as a default supported cipher.  |
| January 2021  | Added clarification: All products enabled by the Data Management license require REST API.   |
| February 2021 | Removed recommendation to disable REST API. The API is now used internally by Tableau Server and disabling it may limit functionality. |

## Manage Licenses

You can manage your Tableau Server licenses and view license usage.

### Licensing Overview

An important administrative role in a Tableau Server deployment is the Tableau portal administrator. The portal administrator manages licensing and the associated keys for the Tableau deployment. As the portal administrator, your first step is to purchase licenses on the [Tableau Customer Portal](#). When you purchase licenses, the portal will return corresponding product keys. To renew your license, visit the [Tableau renewal](#) web page.

Tableau has a number of products (Desktop, Server, Prep Builder, and more). Each of the Tableau products require that you activate licenses by updating the Tableau software with the product keys that are purchased and stored on the Tableau Customer Portal. As the administrator who is tasked with activating Tableau licenses, it is important that you understand the relationship between licenses and keys. See [Understanding License Models and Product Keys](#).

## Activation

Activation is the process of uploading and saving Tableau product keys to Tableau Server. This operation is done with Tableau Services Manager (TSM). TSM is a tool that makes changes to the local operating system and file system and therefore requires administrative access to the local computer. A TSM administrator requires different permissions and access than a Tableau Server administrator, which is the administrative role for day-to-day operation of Tableau Server tasks, such as adding users, sites, managing projects and permissions, etc. See [Administrative roles](#) for more information about various Tableau Server administrative roles.

The following topics describe how to connect to TSM:

- [Sign in to Tableau Services Manager Web UI](#)
- [tsm Command Line Reference](#)

### Online activation

If your Tableau Server installation is able to communicate with the internet, then we recommend using the default online activation method.

- To understand how to activate during the installation process, see [Activate and Register Tableau Server](#).
- To understand how to activate product keys after you have refreshed your subscription, see [Refresh Expiration Date and Attributes for the Product Key](#).
- To understand how to activate product keys after you have added purchased new features or user licenses, see [Add Capacity to Tableau Server](#).

### Offline activation

If Tableau Server is running in an offline environment, where it is not possible to access the Tableau license servers on the internet, then you must activate licenses according to the Tableau offline activation process:

- To understand how to activate offline, see [Activate Tableau Server Offline](#).
- To understand how to deactivate a product key that you activated using offline activation, see [Deactivate Tableau Server Offline](#).

## Lost activation

In some cases license activations can fail after the license has been activated. These failures can occur due to connection failures with local processes or when a change has occurred with the VM or hardware configuration. For example, proxy changes, port blocking, network changes, or altering a machine hardware can cause the licensing activation to fail. If Tableau Server is unable to verify the license, operation may be interrupted and the server will be in an “unlicensed” state.

To view the product keys and the Tableau Server license state, run `tsm licenses list` and `tsm status -v`.

Depending on the product key that is unverified, Tableau Server may operate in a degraded state until the product key is in a valid state. See [Troubleshoot Licensing](#).

## Deactivate

You can activate the same Tableau Server product key on up to three environments. This allows you to test Tableau Server (in a sandbox or QA environments, for example), as well as use Tableau in production. To maximize your activations, you should deactivate your product key when you remove Tableau Server from a computer or close down a VM, unless you will be reinstalling Tableau on the same computer. Doing this gives you the opportunity to use the activation on a different computer. For example, if you move Tableau Server from one computer to another, deactivate the product key, then remove Tableau from the original computer. When you install Tableau on the new computer, you can activate the key there without any conflict. If you are removing Tableau Server to reinstall it on the same computer, you don't need to deactivate the key. Tableau will use the key when reinstalled unless an `obliterate` command was performed with the “-l” option

See [Deactivate Product Key](#).

## Tableau Server licensing and virtual machines (VMs)

If you run Tableau Server on VMs, either locally, or in the cloud, be aware of the potential for complications related to licensing. If you are simply upgrading Tableau Server on the VM, you do not need to take any extra action related to licensing. If you plan to clone the VM to create

either a new production or test environment to upgrade, you need to deactivate any Tableau Server licenses before cloning. If you do not do this, the new VM environment will end up with untrusted licenses, and any attempts to upgrade or start Tableau Server will fail. You may also end up hitting the maximum number of activations for the licenses when trying to activate the product keys on the new VM.

To avoid issues with licensing on VMs, deactivate all Tableau licenses before cloning a VM or allowing it to be permanently shut down.

### Login-based License Management

Login-based license management, helps you manage licensing for users with Creator roles on Tableau Server and Tableau Cloud. Users with Explorer or Viewer roles cannot use this feature. If you're using Role Based Subscriptions with Tableau Server or Tableau Cloud, you can simplify your license management using login-based license management to eliminate separate Tableau Desktop and Tableau Prep Builder product keys. You only need to manage one or more product keys for on-premises Tableau Server, or in the case of Tableau Cloud, you don't need to manage any product keys at all.

See [Login-based License Management](#).

### Adding users

Each user who accesses resources on Tableau Server must be licensed.

- To understand user roles and licensing, see [Understanding License Models and Product Keys](#).
- To understand how to add users, see [Add Users to Tableau Server](#).
- To understand how to activate product keys after you have added purchased new user licenses, see [Add Capacity to Tableau Server](#).

## Understanding License Models and Product Keys

This topic describes the different licensing models and the product keys or subscriptions that may be associated with them. A useful visual of how product keys are represented in Tableau

Server can be found in tsm licenses list. The [Tableau Customer Portal](#) will also display product key information including type and seat count.

When viewing product keys using tsm licenses list (Tableau Server), or in the Tableau Customer Portal (Tableau Desktop and Tableau Prep Builder), note the product specific prefixes.

| Product Key Prefix | Description  |
|--------------------|--|
| TC                 | Tableau Creator product key, can be used to activate or deactivate Tableau Desktop and Tableau Prep Builder.   |
| TD                 | Tableau Desktop product key, can be used to activate or deactivate Tableau Desktop only. This is a legacy product key that is no longer sold or provided.      |
| TS                 | Tableau Server product key, can be used to activate or deactivate Tableau Server. Tableau Server product keys can be role-based, core-based, or feature-based. |

## Term licensing models

Tableau's term license model is defined by the metric that permits use of Tableau Server. Term licenses are also called subscription licenses. Tableau currently sells access to Tableau Server with subscription licenses. In the subscription license model, customers pay a yearly subscription fee. If the subscription expires, the software will stop working.

Subscription licenses are either role-based or core-based subscriptions. A single license key can be purchased with all roles and features and this license is called an Updatable Subscription License (USL). Only one key needs to be activated on Tableau Server to represent the entire purchase.

Previous subscription licenses (non-USL) were provided with one role type per key and the licenses were "stacked" and activated together to obtain the purchased configuration on Tableau Server.

## Tableau Server on Linux Administrator Guide

- A *role-based license* allows you to deploy Tableau Server on a single computer or on multiple computers in a cluster. Each user that accesses Tableau Server must be licensed and assigned a role. Administrators can add users based on available licenses of each type.
- A *core-based license* imposes no constraints on the number of user accounts in Tableau Server. Instead, the license specifies the maximum number of computer cores on which you can run Tableau Server. You can install Tableau Server on a single computer or across multiple computers as a multi-node cluster, as long as the total number of cores in all the computers does not exceed the total number that the license allows.

Not all processes installed with Tableau Server impact the calculation of total number of cores used. A subset of processes is considered "licensed processes." Core licensing is calculated only on computers running licensed processes. If a computer has one or more licensed processes installed on it, the cores on that computer count toward the total cores used. For more information about licensed processes, see [Licensed processes](#).

- An *updatable subscription license*, enables you to consolidate licenses and update your Tableau Servers using a single product key. You can add new features, adjust capacity, and apply license renewals to a single existing Tableau Server license. You no longer need to add new licenses or replace existing ones. USL:
  - Simplifies key management by reducing the number of product keys that you must manage for ease of maintenance.
  - Minimizes service interruptions because you don't have to restart Tableau Server after renewing a license, adjusting capacity, or adding new features.

For Updatable Subscription Licenses (USL), your product key in the Tableau Customer Portal does not change even when updated with new features or changes to role counts. With the non-USL subscription license model, you get a new key in your Customer Portal after each license renewal. A new product key will appear in the TSM web UI after the previous product key expires when viewing a non-USL subscription product key. For Updatable Subscription

Licenses (USL), your product key does not change in the UI or Tableau Customer Portal. In the Tableau Customer Portal, USL licenses display a selected **Is USL Key** checkbox on the **License Detail** page or by **true** in the **Is USL Key** column on the **Licenses** tab.

In the output returned by `tsm licenses list`, the `TYPE` field describes the user license metric. In the Tableau Services Manager Web UI, hover over the `Type` field (or column) to verify if the key is an Updatable Subscription License (USL) product key.

#### Role-based license model

Tableau offers role-based term licenses that grant a range of capabilities at various price points. Four types of role-based term licenses are available: Display, Viewer, Explorer, and Creator.

- *Display licenses* let users share and display Tableau content with a broad, internal audience of users who consume dashboards via shared displays with no interaction. There is no separate site role for Display licenses; when using a Display license, administrators create a dedicated login account for each licensed Display location, which is not the same as an individual user's login account, and assign the maximum site role of Viewer.
- *Viewer licenses* let users view and interact with workbooks in Tableau Server. Viewer licenses also let users access Tableau Mobile, add comments to workbooks, export visuals in various formats, download workbook summary data, create subscriptions for themselves, and receive data-driven alerts.
- *Explorer licenses* are similar to the user-based licenses available in previous Tableau Server releases, and include the capabilities provided with Viewer licenses, and additional capabilities. An Explorer license allows access to workbook authoring capabilities using a web browser, as well as a full set of collaboration features.
- *Creator licenses* permit a wide range of capabilities when using Tableau Server, and also grant use of Tableau Desktop and Tableau Prep Builder. A Creator license allows all of the capabilities available under the Explorer license, as well as the following capabilities when using Tableau Server:
  - Create and publish new workbooks from a new data source.
  - Edit embedded data sources in the Data pane.
  - Create and publish new data connections.

- Use login-based license management activation on Tableau Desktop and Tableau Prep Builder.

**Note:** Tableau Server Administrators will always consume the highest role available. If you activate a product key that contains the Creator role, the Tableau Server Administrator(s) will take this role. If the highest role available on Tableau Server is an Explorer, the Server Administrator will take the Explorer role. If a Creator role is added to a server where no Creators are currently activated, any existing Server Administrator accounts using Explorer licenses will automatically convert to use Creator licenses.

TSM administrator accounts do not require licenses.

For non-USL licenses, product keys are used to activate and add licenses to Tableau Server. When an update to capacity or functionality is purchased with a non-USL product key, the Tableau Server Administrator can activate these additional product keys. For USL product key(s), one product key is activated that contains all roles and features. If a USL license has been updated to change functionality, features, or role counts, no additional product keys will be issues or need to be activated.

For Updatable Subscription License (USL) product key(s), when a key has been updated with a new subscription term, feature, or role count change, the Server ATR service automatically obtains these updates and no additional key(s) need to be activated. USL licenses and Server ATR activations do not require refreshes to obtain these changes. Everything will be handled by the Server ATR service. For a USL product key using the non-Server ATR activation method, refreshes need to occur to obtain the update to the USL product key. For non-USL product keys, when an update to capacity or functionality is purchased, additional product keys are provided in the Tableau Customer Portal that you need to activate on Tableau Server.

If you're using non-USL product keys, select a Tableau Server Creator product key from the Tableau Customer Portal to ensure that you can create a Tableau Server Administrator. Explorer and Viewer product keys can then be activated to add additional licenses. Once the

product keys have been activated, administrators can add users and assign them site roles, which automatically consume available licenses.

In the output returned by `tsm licenses list`, the `CREATOR`, `EXPLORER`, `VIEWER` fields display the number of licenses for each role license type. For non-USL product keys, each role is governed by its own product key. Therefore, if your organization has purchased licenses for all three roles, then you must activate three product keys. For USL product key(s), one key has all roles and features which is reflected in TSM.

### Core-based license model

In a core licensing model, the license defines the number of total computer cores the server can run on, instead of how many users can be added. This means the server can support virtually unlimited users (as Explorers or Viewers; the legacy term for these types of roles was "interactors"). Core-based license also allows a Guest User account, which is not possible with role-based licensing.

However, core licensing on its own does not include Creator seats on the server (those site roles will be grayed out when adding users).

New data sources can only be added to the server by publishing from Tableau Desktop or via a browser by a user with a Creator site role on the server. Therefore, there must either be (a) a user with a Creator site role on the server, or (b) a licensed Tableau Desktop and a user with Explorer (can publish) site role. For route (b), there are two ways to license Tableau Desktop in a core-based server organization:

- At least one role-based Creator license (which includes Tableau Desktop and Tableau Prep Builder), or
- At least one licensed Tableau Desktop that uses a legacy Tableau Desktop product key.

Note that if a Creator license is stacked on a server with core-based licensing, that role-based Creator license will be consumed by an admin. The only way to give a Creator site role to a non-admin user is to first ensure that all admins have Creator licenses. Only then can additional Creator licenses be used to assign a Creator site role to non-admin users.

In the output returned by `tsm licenses list`, the `TYPE` field will display the number of cores that are licensed. Additionally, the `GUEST ACCESS` field will display `true`.

### Embedded Analytics usage-based model

Tableau's Embedded Analytics offering is a usage-based license for Tableau Server that's made available to customers who want to embed Tableau Server functionality into an external facing solution to provide Tableau content and insights to clients outside of their organization.

**Note:** Embedded Analytics licenses cannot be used in the same environment as full-use licenses. To change to an Embedded Analytics license, first deactivate your existing full-use licenses and then activate the Embedded Analytics license.

For example, consider an organization that runs a service where they analyze consumer data and generate reports on behavioral patterns regarding different consumer demographics. In this scenario, Tableau Server acts in support of a specific proprietary application titled 'Demographics Analyzer' and connects with exported TXT files and a SQL database. The organization makes visualizations available to its clients in a secure portal, where clients log in to manage their account and view the results. End users are uniquely identified by the account they use to access the portal; this determines the number of User-Based Embedded Analytics Server licenses.

The Embedded Analytics license is not displayed in the output returned by `tsm licenses list`. To verify the license contact [Customer Success](#).

### Perpetual license model (legacy)

In the past, Tableau sold access to Tableau Server with perpetual licenses. Although these licenses are no longer available, some customers use this licensing arrangement.

In the perpetual license model, customers paid a maintenance subscription that was renewed annually. If maintenance expires, the software continues to work, but the customer loses

access to technical support and software upgrades. Purchasing annual maintenance for perpetual licenses is no longer possible.

Perpetual licenses were either sold for a specific number of users, called interactors, or for a specific number of cores:

- Interactor licensing is a named-user model where customers purchased licenses by the seat, similar to current role-based licensing. However, unlike role-based licensing, where different access roles are priced accordingly, in interactor licensing, licenses were unbound by role. Licensed users could be Server admins, Site admins, Publishers, Interactors, or Viewers. User roles were set by the administrator only as a means to manage access to content and server configuration.

If you activate a valid Server Interactor key on version 2020.4 or later, the Interactor count is mapped to the Explorer role.

Interactor perpetual core licenses cannot use login-based license management. You must purchase a Creator term license, also called a Creator subscription license, in order to use login-based license management with Tableau Desktop or Tableau Prep Builder.

- Perpetual core licensing has the same model as subscription core licensing, it specifies the number of computer cores the software can be run on and supports unlimited users and a guest account.

In the output returned by `tsm licenses list`, the `TYPE` field displays `Perpetual`. Note also that the `MAINT EXP` date is also displayed.

## License editions

License editions include a suite of features and functionality to which users are entitled. License editions cannot be mixed within a deployment, meaning all users on a deployment must be on the same license edition. Consider the needs of your entire deployment when selecting your license edition.

## Tableau Server on Linux Administrator Guide

### Tableau license edition

Tableau license edition is the standard Tableau Server edition. It provides Tableau Server access for each licensed user, governance, collaboration, data prep, and visual analytics functionality.

### Tableau Enterprise license edition

Enterprise edition is designed for sophisticated business environments on Tableau Server. It is ideal for organizations that require advanced administration, security, and data management functionality to scale to more users in more complex data environments and meet Enterprise standards.

For more information and a list of features included with Tableau Enterprise, see [About Tableau Enterprise](#).

**Note:** The Tableau+ license edition is available exclusively for Tableau Cloud. For more information and a list of features included with Tableau+, see [About Tableau+](#) in the Tableau Cloud Help.

## Feature licenses

Feature licenses are sold differently than other licenses. Features with independent licenses must be licensed for every user (or all cores) in the deployment. A deployment includes a licensed production Tableau Server installation and licensed non-production Tableau Server installations that support the production installation.

These features are licensed annually, and in the context of licensing, the availability of these features to the user base are “all or none:”

- Data Management
- Advanced Management
- Login-based License Management

**Note:** Updatable subscription licenses include both features and roles in one license. You no longer need to activate multiple licenses and product key(s) for different features and their associated roles.

## Data Management

The Data Management license includes Tableau Catalog and Tableau Prep Conductor for a single Tableau Server deployment, which may be role-based or core-based. For more information, see [About Data Management](#).

Data Management may require resource cores, which specifies the computing power that is used to run flows for Prep Conductor. Servers with core-based licensing are required to purchase at least four Resource Cores. See [License Data Management](#).

In the output returned by `tsm licenses list`, a single product key for Data Management is indicated by the `DATA MANAGEMENT` field, which displays `true` under the appropriate license.

## Advanced Management

Tableau Server Advanced Management is licensed on a per deployment basis, which may be role-based or core-based. For more information on Advanced Management and the features included, see [About Tableau Advanced Management on Tableau Server](#).

In the output returned by `tsm licenses list`, a single product key for Advanced Management is indicated by the `SERVER MANAGEMENT ADD-ON` field, which displays `true` under the appropriate license.

## Login-based License Management

Login-based license management (LBLM) simplifies licensing for Tableau Desktop and Tableau Prep Builder. Instead of using product keys, these products are activated when a user with a Creator's license authenticates with Tableau Server. If a customer is using Tableau Desktop or Tableau Prep Builder without Tableau Server, LBLM cannot be used.

**Note:** As of Tableau Server version 2023.1, LBLM is supported in offline deployments. To deploy Tableau Server with LBLM enabled, you must configure Tableau Server to use Authorization-To-Run (ATR) Service. For more information, see [Activate Tableau Server Offline](#).

For more information, see [Login-based License Management](#).

In the output returned by `tsm licenses list`, a single product key for login-based licensed management is indicated by the LBLM field, which displays `true` under the appropriate license.

## Updatable Subscription Licensing (USL)

Updatable Subscription Licensing (USL) is the latest improvement to Tableau's license activation and server administration experience.

### Understanding the Basics of USL

Updatable Subscription Licensing simplifies the requirements of license management for Tableau Server by eliminating the need to manage multiple separate Product Keys for various product types, capacities or subscription periods. Instead, all licensed features and attributes of your Tableau Deployment (its "License Entitlement") are provisioned as a single unified Product Key.

Additionally, USL consolidates the delivery of subsequent license renewals, add-ons, and entitlement changes into updates which are made to that single, updateable Product Key over time, so it consistently reflects the complete License Entitlement for its designated Deployment. You can think of each update like adding a layer of new attributes to your existing Product Key; these layered updates each have a unique corresponding Activation ID. When you sync your Server installation with Tableau's licensing service (by activating or refreshing your Product Key), the latest Activation ID is pulled down to your local Server installation in order to reflect your Deployment's updated License Entitlement.

The process required to pull down your Product Key's latest Activation ID differs depending on your Deployment's internet connectivity.

## Activating USL in Online/Connected Environments

In online/connected environments, the USL Product Key used to activate and unlock the License Entitlement for your Deployment remains constant over time.

- By simply activating or refreshing the original USL Product Key (reflected as the “Key Name” in the Tableau Customer Portal), a connected environment will automatically pull down the latest current Activation ID available for your License Entitlement, facilitated by the live communication with Tableau's hosted licensing services.
- For Server installations configured to use Tableau's Authorization to Run (ATR) licensing service, these updates are downloaded silently in the background during periodic Server check-ins with the ATR service; No additional action needed!

## Activating USL in Offline or Disconnected Environments

In offline or disconnected environments, there is no direct communication between Server and Tableau's hosted licensing services, so the USL Product Key cannot be used to automatically retrieve new Activation ID updates.

- Instead, administrators must directly activate the latest Activation ID through Tableau's Offline Activation process to reflect updates to the Deployment's License Entitlement.
- Once a new Activation ID is added to your License Entitlement, no prior Activation ID can be used for activation; they become functionally obsolete.
- For this purpose, the latest current Activation ID is always reflected in the Tableau Customer Portal as the “Offline Activation ID” visible in the License Detail view for your USL Product Key.
- Because new Activation IDs are generated for any update to your License Entitlement, the Offline Activation ID will change repeatedly over time.

**Important:** Offline activation of Tableau requires that customers use the most current Offline Activation ID to activate any new installation of the Software.

### Managing license entitlement updates in offline environments

Given the requirement to leverage the most-current Offline Activation ID when activating your USL Product Key in a disconnected environment, it's important to get your current Offline Activation ID from the Tableau Customer Portal before attempting to activate any new or existing installation of Tableau Server. This may not match the one you last used.

Salesforce's provisioning systems periodically synchronize to ensure complete and accurate fulfillment, and this can generate a new Offline Activation ID for your License Entitlement unrelated to any specific purchase or subscription renewal. Be sure to check the Customer Portal *before* any change to the active licensing in your Deployment, including prior to deploying any new installations of Server Software, to confirm the current Offline Activation ID and ensure successful activation.

The following are some key points related to the Offline Activation ID life cycle:

- Successful activation *will always require*
  - a. Deactivation of the earlier Offline Activation ID, and
  - b. Activation of the current Offline Activation ID.

For Server installations configured to use ATR (offline), deactivation of the earlier Offline Activation ID is handled automatically.

- The issuance of a new Offline Activation ID *will prevent new* activations using any prior Offline Activation ID.

For this reason, be sure to consult the Customer Portal before any licensing update in your deployment.

- The issuance of a new Offline Activation ID *will not impact* any Server environment where you have previously activated your USL Product Key.

- These installations won't reflect your updated License Entitlement until the new Offline Activation ID is directly applied.

## USL Offline Activation Instructions

To activate USL in an offline or disconnected environment:

1. Identify the current Offline Activation ID for your Tableau Server Deployment.

You can find the Offline Activation ID in the Tableau Customer Portal by navigating to the **Licenses** pane and clicking on your USL Product Key to open the License Details view. The 20-digit string is labeled "Offline Activation ID". For further detail, see the Knowledge Base article [Find the Correct Key to Offline Activate on Tableau Server](#)

2. Activate the Offline Activation ID on Tableau Server.

With the Offline Activation ID accessible, follow the steps outlined in the Tableau Help to activate Tableau Server offline (applicable to both USL and pre-USL Product Keys).  
[Activate Tableau Server Offline](#)

## USL offline license entitlement updates

The steps required for changes in your license entitlement in an offline environment depend on your method of activation (ATR or legacy FNO) and your Tableau Server version.

- ATR *and* version 2023.1.0 or higher:

If you activated with ATR and have version 2023.1+ use the new Offline Activation ID from your Customer Portal to update your license entitlement changes. The ATR service handles any other necessary actions.

**Note:** After activating the Offline Activation ID, you will see the Product Key listed in the Tableau Customer Portal and not the Offline Activation ID which was activated. This will allow for ease of management between any ongoing Offline Activation ID changes and product key management.

## Tableau Server on Linux Administrator Guide

- Legacy FNO activation *or* any version before 2023.1.0:
  1. Obtain Current Offline Activation ID from the Customer Portal
  2. Stop Tableau Server:

```
tsm stop
```
  3. Initiate an offline deactivation of the existing, activated key on Server. This Offline Activation ID is now obsolete in your environment. The offline deactivation creates a return request file. Save this file. You need it for a future step.
  4. Initiate an offline activation request for the current Offline Activation ID. This generates an activation request. Save this file for the next step.
  5. Transfer both the return request file and the activation request files to a computer that has internet access.
  6. Navigate to [Offline Activation page](#) and initiate two requests in this order:
    - a. Upload the return request file and download the response file; save and continue.
    - b. Upload the activation request file and download the response file; save and continue.
  7. Transfer both return response file and the activation response file to the disconnected Tableau Server computer.
  8. Apply the return response file.
  9. Apply the activate response file.
  10. Start Tableau Server:

```
tsm start
```

## View Server Licenses

Server administrators can view the license and product key information for Tableau Server.

### Viewing licenses from the Tableau Server web UI

How you navigate to the Licenses page in Tableau Server depends on whether you have a single site, or multiple sites.

- On a server with a single site, click **Settings** and **Licenses**:
- On a multi-site server, click **Manage all sites** on the site menu, **Settings**, and **Licenses**:

**Note:** The **Manage all sites** option only displays when you are signed in as a server administrator.

This page displays information for any licenses that have been activated on your server, including any user-based (term) or core-based licenses.

### Use the TSM web interface

1. Open TSM in a browser:

`http://<tsm-computer-name>:8850`

2. Click **Configuration** , and then click **Licensing** :

The table displays the product key, expiration date, and expiration of maintenance.

**Note:** The TSM Web UI provides a limited amount of licensing information. Use the TSM CLI or the Tableau Server Web UI to see additional licensing information, including the number of each type of user-based license (Creator, Explorer and Viewer).

## Use the TSM CLI

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).
2. Run the following command:

```
tsm licenses list
```

The command lists licenses that are activated on the Tableau Server deployment.

For example, a server with five Creator licenses, five Explorer licenses, 100 Viewer licenses, and Data Management would provide command output similar to the following:

```
C:\Windows\system32>tsm licenses list
Number of product keys: 4
The following license keys will expire soon. Access renewal resources including information on how to renew your software or change your billing preferences here https://www.tableau.com/support/renew
TS90-86E2-BF8A-89EA-38FE  TSPR-3861-0888-8C5A-C79D  TS49-176C-E840-3410-5EAS  TSQJ-8988-5CFA-FD66-29AF
KEY      TYPE      CREATOR  EXPLORER  VIEWER  DATA MANAGEMENT ADD-ON  GUEST ACCESS  LIC EXP  MAINT EXP  UPDATABLE  LBLM  SERVER MANAGEMENT ADD-ON
TS90-86E2-BF8A-89EA-38FE  Term      0         0        100    false                    false         11/30/20  N/A        false      false     false
TSPR-3861-0888-8C5A-C79D  Term      0         0         0      true                     false         11/30/20  N/A        false      false     false
TS49-176C-E840-3410-5EAS  Term      0         5         0      false                    false         11/30/20  N/A        false      false     false
TSQJ-8988-5CFA-FD66-29AF  Term      5         0         0      false                    false         11/30/20  N/A        false      false     false
```

The following fields are returned:

- **KEY:** A globally unique 16-character string that identifies the license.
- **TYPE:** Describes the type of license
  - **Term:** Term licenses map to a subscription schedule and must be renewed. The expiration date is listed under the LIC EXP field.
  - **Perpetual:** Perpetual licenses are purchased once and do not need to be renewed but must be refreshed to update the MAINT EXP or maintenance expiration date.
  - **Cores:** Core licenses are licenses that map to the number of cores on the computers running specific Tableau Server services. Core licensing allows for a guest user access to views on the server or embedded on other web servers. Core licenses also allow for unlimited Explorer and Viewer users.
- **CREATOR:** The number of Creator licenses issued to the Tableau Server deployment.
- **EXPLORER:** The number of Explorer licenses issued to the Tableau Server deployment.
- **VIEWER:** The number of Viewer licenses issued to the Tableau Server deployment.
- **DATA MANAGEMENT:** Tableau Server is licensed with Data Management (True/False). See About Data Management.

- **GUEST ACCESS:** Tableau Server is licensed for a Guest User. See Guest User. The ability to leverage a Guest User requires Core licensing. See TYPE field.
- **LIC EXP:** The date that the license expires and Tableau Server will stop working. Term licenses expire. See TYPE field. Visit the Tableau [Customer Portal](#) to refresh licenses.
- **MAINT EXP:** Applies only to legacy perpetual licenses (TYPE = Perpetual). For Term licenses, this field will output, N/A. MAINT EXP displays the date that the maintenance contract for the Tableau Server deployment expires. To update the license maintenance key see Refresh Expiration Date and Attributes for the Product Key. Visit the Tableau [Customer Portal](#) to view maintenance purchase history and to purchase additional maintenance.
- **UPDATABLE:** Specifies whether the license is an updatable subscription license (True/False).
- **LBLM:** Specifies if login-based license management (LBLM) is enabled for the Tableau Server deployment (True/False). When enabled, LBLM allows users to log into Tableau Server to license their instance of Tableau Desktop or Prep, rather than entering a product key. For more information about LBLM, see Login-based License Management.
- **SERVER MANAGEMENT:** Tableau Server is licensed for Advanced Management (formerly Server Management Add-on) (True/False). For more information about Advanced Management, see About Tableau Advanced Management on Tableau Server.

**Note:** The license terms for Creator, Explorer and Viewer users are set according to the terms of the user-based license (term license), if present. So, a server with only a core-based license will have unlimited Explorer and Viewer users and guest access, but no Creator users. To learn more, see Use role-based licenses on a server with core-based licensing.

## Refresh Expiration Date and Attributes for the Product Key

When using Server ATR and Updatable Subscription Licensing (USL), you don't need to refresh your product key(s) when you purchase a new subscription term, or add roles and/or features to your deployment. That's because USL product keys can be updated to reflect

changes to your Tableau Server license capacity, feature, and subscription term over time, and Server ATR automatically refreshes product key(s) for you as a background process.

**Note:** If you were recently enabled for USL alongside your subscription renewal, you cannot refresh your licensing as outlined here. Instead, refer to the Tableau Customer Portal for the new USL-compatible product key which must be activated within your deployment; see [Activate and Register Tableau Server](#). Your original product keys have not been renewed, and should no longer be used in your deployment.

If you aren't using Server ATR, you can refresh your product key(s) manually. If you refresh a subscription (term) product key before the expiration date occurs, the product key will not change but the expiration date will. This can create a mismatch between the product keys listed in the Tableau Customer Portal and those listed in the Tableau Server TSM product key list. The product key will change when the expiration date occurs or shortly thereafter. If a subscription (term) product key is not refreshed and has expired, Tableau will stop working and you will have to activate a new product key from the Tableau Customer Portal to relicense your Tableau Server installation, regardless of whether you are using Server ATR or manual activation methods.

On the other hand, if the product key is perpetual (legacy) and its maintenance has expired, Tableau will continue to operate but you will not have access to upgrades until the maintenance is renewed. After renewing the maintenance, if you aren't using Server ATR, you must refresh the existing product key to update its maintenance expiration date. The product key will never change. For more information about different product key types and associated licenses, see [tsm licenses list](#).

**Note:** This topic describes how to refresh the expiration date for Tableau Server, Advanced Management, and Data Management. For information about refreshing the maintenance date on Tableau Desktop see [Refresh the product key](#) in the [Tableau Desktop and Tableau Prep Deployment Guide](#).

## Before you begin

Verify the expiration date of your license(s). You can view the expiration date by following the TSM web interface procedure below, or by running `tsm licenses list` in the CLI.

- Compare the date with the date displayed in the [Tableau Customer Portal](#).
- If the portal does not display the date that you expect, contact [Customer Success](#).
- To renew your license, visit the [Tableau renewal](#) web page.

If the TSM date does not match the date displayed in the Tableau Customer Portal and the following refresh operation fails, contact [Tableau Support](#).

**Note:** To refresh your product key in an offline environment, visit the Tableau Customer Portal to obtain the Offline Activation ID for your latest renewal, and then activate it. For more information about offline activation, see [Activate Tableau Server Offline](#). Activate all product keys before starting Tableau Server. Otherwise some users might become unlicensed.

## Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`

2. Click **Configuration** and **Licensing** and click **Refresh All**:

The screenshot shows the Tableau Server web interface. The top navigation bar includes 'STATUS', 'MAINTENANCE', and 'CONFIGURATION'. The 'CONFIGURATION' section is active, and the 'Licensing' page is displayed. The page title is 'Licensing' and the subtitle is 'View and manage Tableau Server licenses, review expiration dates, and activate or deactivate product keys. Learn more'. The 'Current Licenses' section shows a table with columns: Product Key, Type, Creator/Explorer/Viewer, Data Management, Server Management, LBLM, Guest Access, Expires, and Maintenance Ends. A 'Refresh All' button is highlighted in the top right corner of the 'Current Licenses' section. The 'Future Licenses' section is empty, with a message: 'There are no future licenses on this installation of Tableau Server. Click the "Activate License" button above the table to add a valid Product Key. Retrieve Product Keys from the Tableau Customer Portal.'

| Product Key | Type | Creator/Explorer/Viewer | Data Management | Server Management | LBLM | Guest Access | Expires         | Maintenance Ends |
|-------------|------|-------------------------|-----------------|-------------------|------|--------------|-----------------|------------------|
|             | Term | 1000/750/500            | ✓               | ✓                 |      |              | August 15, 2021 | August 15, 2021  |

## Use the TSM CLI

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).
2. Run the following command:

```
tsm licenses refresh
```

## Add Capacity to Tableau Server

You may need to add capacity to your Tableau Server installation to allow you to increase the number of users (if you have a user-based license) or the number of cores (if you have a core-based license).

Tableau will provide you with a new product key that adds capacity to your existing Tableau Server installation. You need to activate this key and use it together with your existing product key(s) to get the combined capacity you are licensed for. Each feature (e.g., "Data Management") and license type (e.g., "Explorer") requires a key. For more information about the relationship between keys and licenses, see `tsm licenses list`.

Follow the steps below to add a product key to Tableau Server.

If your Tableau Server is not connected to the internet, then you must perform an offline activation. See [Activate Tableau Server Offline](#).

**Note:** If you have upgraded to Tableau Server version 2021.1 or later, you no longer need to restart Tableau Server when you add capacity. For more information, see [Zero Downtime Licensing](#).

## Use the TSM web interface

1. Open TSM in a browser:

```
https://<tsm-computer-name>:8850
```

- Click **Licensing** on the **Configuration** tab and click **Activate License**:

The screenshot shows the Tableau Server Configuration page. The top navigation bar includes 'STATUS', 'MAINTENANCE', and 'CONFIGURATION'. The left sidebar lists 'Server Topology', 'Security', 'User Identity & Access', 'Notifications', and 'Licensing'. The main content area is titled 'Licensing' and contains the following elements:

View and manage Tableau Server licenses, review expiration dates, and activate or deactivate product keys. [Learn More](#)

Buttons:

|                       | Product Key | Seat Licenses | Expires          |
|-----------------------|-------------|---------------|------------------|
| <input type="radio"/> | [Redacted]  | 15            | May 1, 2018      |
|                       | trial       | 10            | January 22, 2018 |

Access Tableau Server product keys in the *Customer Portal*. View *Desktop License Usage* for more information about

- Enter or paste your new product key and click **Activate**:

The screenshot shows a dialog box titled 'Activate License'. It contains the following text and elements:

Activate License

Enter a 20-digit Tableau Server Product Key

0000-0000-0000-0000-0000

*I can't find my product key.*

Buttons:

- After activating the license, you may be prompted to register with Tableau. On the Register page, enter your information into the fields and click **Register**.

Register with Tableau. All fields are required.

## Use the TSM CLI

1. Copy the product key to your computer.
2. Run the following command:

```
tsm licenses activate --license-key <license key>
```

3. After activating the license, you may need to register Tableau Server. To do this, create a registration file and then pass it as an option with the `tsm register` command.

- a. Generate a template that you can edit by running the following command:

```
tsm register --template > /path/to/<registration_
file>.json
```

- b. Edit the template file to create your completed registration file.

Here is an example of a registration file in the required format:

```
{
  "zip" : "97403",
  "country" : "USA",
  "city" : "Springfield",
  "last_name" : "Simpson",
  "industry" : "Energy",
  "eula" : "yes",
  "title" : "Safety Inspection Engineer",
  "phone" : "5558675309",
  "company" : "Example",
  "state" : "OR",
  "department" : "Engineering",
  "first_name" : "Homer",
  "email" : "homer@example.com"
}
```

- c. After saving changes to the file, pass it with the `--file` option to register Tableau Server:

```
tsm register --file /path/to/<registration_file>.json
```

For example:

```
tsm register --file /usr/share/tableau-reg-file.json
```

## Activate Tableau Server Offline

When you install Tableau Server, you have to activate at least one product key, but we recommend that you activate all Tableau Server licenses found in the Tableau Customer Portal. Doing this activates the server, and specifies the number of license levels you can assign to users. For offline activations, you should activate the product key listed in the **Offline Activation Id** field in the Tableau Customer Portal. For information about finding the right key, see the [Find the Correct Key to Activate on Tableau Server](#) Knowledge Article.

There are also times you may need to activate licenses after Tableau Server is installed, for example, if you add capacity to your server, or get a new product key. If you don't have your product key, you can get it from the [Tableau Customer Account Center](#).

**Note:** Activating any product key after Tableau Server has already started will require a Tableau Server restart for the changes to take effect.

In most cases, you can activate your key directly from Tableau Server, either during installation, or later, using the Tableau Services Manager (TSM) Licenses page, but there are some circumstances that don't allow you to do this. If your computer is not connected to the internet for example, or has a firewall that restricts access outside your intranet. In these cases you need to do an offline activation.

Tableau Server in a Container only supports license activation using Server ATR. Offline activation using Server ATR is supported in 2023.1 and later. This functionality is available in Containers but requires extra steps and approval. If you need to run Tableau Server in a Container in an air-gapped or offline environment, contact your Account representative for more information.

## Offline activation and login-based license management (LBLM)

Beginning in Tableau Server version 2023.1.0, offline activation is supported for LBLM when your server is configured to use the Authorization-to-Run (ATR) service. You can only configure Tableau Server to use the ATR service during a new install. Upgrading customers with existing server installations need to install a new instance of Tableau Server version 2023.1.0 or later and restore a backup of their existing installation to that new instance. For information on this process, see [Using a Blue/Green approach for upgrading Tableau Server](#). For more information about ATR service, see [Activate Tableau Server Using the Authorization-To-Run \(ATR\) Service](#).

## Offline activation and updateable subscription licenses (USL)

Offline activation of updateable subscription licenses requires special steps. For details, see [Activating USL in Offline or Disconnected Environments](#).

There are two scenarios in which you may need to do an offline activation:

- Offline activation during install—To complete an offline activation when you are installing Tableau Server.
- Offline activation of licenses after install—To complete an offline activation after your server is installed and running.

## Offline activation overview

Offline activation of Tableau Server involves the following steps:

1. Generate an offline activation request file.
2. Copy the offline activation request file to a computer with internet access.
3. Upload the offline activation request file to the [Tableau activation website](#).
4. Download the resulting offline activation response file from the website. You'll use this file to activate Tableau Server

Offline activation file name changes

Beginning in Tableau Server version 2023.1, the Tableau licensing system supports two underlying licensing technologies. From an administrative perspective, the only configuration difference between the two systems is the file types that are generated and consumed for offline activation. The licensing technology is determined during the initial installation of Tableau Server, and cannot be changed after install.

We refer to the legacy (and still supported) version of licensing technology as FlexNet. The latest version of the technology is referred to as Server ATR. For more information, see [Activate Tableau Server Using the Authorization-To-Run \(ATR\) Service](#). The following table describes the file naming nomenclature for each technology. The table also includes the generic reference.

| Generic file name          | Server ATR file names                              | FlexNet file names                   |
|----------------------------|--|--------------------------------------|
| Off-lineActivationRequest  | Off-lineActivationRequestFile_YYYYMMDD.HHMMSS.json | Tableau-OfflineActivationRequest.tlq |
| Off-lineActivationResponse | Off-lineActivationLicensingAtrs.zip                | activation.tlf                       |

**Note:** Since this documentation supports multiple versions of Tableau Server, we will use the generic file name references (OfflineActivationRequest and Off-lineActivationResponse) for the rest of this topic. You can identify the licensing technology your Tableau Server installation uses according to the file type that generated in the steps that follow.

### Use the TSM web interface

If you attempt to activate your product key from the TSM licenses page and see a dialog that says online activation is unavailable, you can activate the key offline. The offline activation

process must be completed once for each product key.

1. Click **Activate License Offline**.

2. Create an offline activation request file (OfflineActivationRequest) for the product key.

Create an OfflineActivationRequest file you will upload to the Tableau activation website. If your product key is not pre-filled in the form, enter your key and click **Create Offline File** to generate an OfflineActivationRequest file on the local computer.

**Step 1: Create, Upload, and Submit an Offline File**

Enter a product key then create, save, and move the Tableau Offline Activation Request file to a computer connected to the Internet. You will then need to upload and submit the offline file to Tableau (Step 2).

The key has 20 characters

\_\_\_\_\_

Access a computer connected to the Internet and go to <http://www.tableau.com/support/activation>. Upload and submit the Tableau Offline Activation Request file created above. This will generate the first Offline Activation file to upload in Step 2.

Copy the OfflineActivationRequest file to a computer with internet access. You need to upload this file to the Tableau activation website to generate an activation response file.

3. Upload and submit the OfflineActivationRequest file.

You will upload and submit the OfflineActivationRequest file to the Tableau activation website. This automatically generates an activation response file (OfflineActivationResponse) that you can download and copy back to the Tableau Server computer.

- a. On the computer where you copied the OfflineActivationRequest file, open a browser and go to <http://www.tableau.com/support/activation> to open the Tableau Support Activation page.
- b. On the Offline Activation page, click **Choose File** to select the OfflineActivationRequest file.
- c. Click **Upload Activation File** to submit the file to the Tableau activation website.
- d. Click the [here](#) link to download the OfflineActivationResponse file to your computer.

## Offline Activation

The activation was successful. Please click [here](#) to download your activation file.

For help creating the offline activation file, see [Activate Tableau Desktop Offline](#) or [Activate Tableau Server Offline](#). ([Linux](#))

- e. Copy the OfflineActivationResponse file to the computer where Tableau Server is installed.
4. Upload the OfflineActivationResponse file.

On the Tableau Server computer, click **Upload Activation File** to upload the OfflineActivationResponse file to Tableau Server. When you do this successfully, the **Activate Product Key** button is enabled.

**Step 2: Upload Activation File**

Upload the Offline Activation file you downloaded from <http://www.tableau.com/support/activation> to activate your server and desktop client offline.

After activating product key, you can go back to Step 1 to enter another product key.

5. Click **Activate Product Key** to complete the offline activation.
6. (Skip this step if you are installing Tableau Server for the first time.)

Restart Tableau Server for licensing changes to take effect.

## Use the TSM CLI

Step 1. Log in to Tableau Services Manager

Before you can proceed you must log in to Tableau Services Manager (TSM). To log in to TSM, run the following command:

```
tsm login -u <username>
```

What if I can't log in?

The account that you use to configure the rest of the installation must be a member of the `tsmadmin` group that was created during initialization. To view the user accounts in the `tsmadmin` group, run the following command:

```
grep tsmadmin /etc/group
```

If the user account is not in the group, run the following command to add the user to the `tsmadmin` group:

```
sudo usermod -G tsmadmin -a <username>
```

## Tableau Server on Linux Administrator Guide

After you have added the user to the `tsmadmin` group, run the `tsm login` command.

### Step 2. Generate an offline activation request file

1. On the initial node, open a terminal session.
2. Type this command to get your offline activation file:

```
tsm licenses get-offline-activation-file -k <product-key> -o  
<target-directory>
```

You can get your product key from the [Tableau Customer Portal](#). The target directory must already exist.

3. Copy the offline activation file (`OfflineActivationRequest`) from the target directory to a computer that has internet access.

### Step 3. Upload the offline activation request to the Tableau activation website

1. On the computer that has internet access, go to the Tableau [Product Activations](#) page.
2. Complete the instructions to upload your `OfflineActivationRequest` file.

This creates an activation response file (`OfflineActivationResponse`).

3. Download the `OfflineActivationResponse` file from the Tableau activation website.

### Step 4. Initialize or activate your license

1. Copy the `OfflineActivationResponse` file to a location accessible from the Tableau Server computer.
2. Run the following command:

```
tsm licenses activate -f <path-and-activation-file>
```

**Note:** When using ATR to activate Tableau Server, `<path-and-activation-file>` should point to the packaged `OfflineActivationResponse` .zip file. Do not unzip the `OfflineActivationResponse` file prior to running this command.

3. (Skip this step if you are installing Tableau Server for the first time.)

Restart Tableau Server for licensing changes to take effect:

```
tsm restart
```

4. (Optional) To verify that all licenses are activated, you can run this command:

```
tsm licenses list
```

If you have completed the steps above, you should see a success message:

```
Activation successful.
```

Tableau Server is activated. If you need additional assistance, contact [Tableau Technical Support](#).

## Deactivate Product Key

There are some scenarios where you must deactivate a product key:

- Changing a hardware configuration
- Changing product keys
- Moving a product key to a new installation

### Before you begin

Verify that you are removing the correct product key(s). You can view license details by running `tsm licenses list` in the CLI.

### Use the TSM web interface

1. Open TSM in a browser:

```
https://<tsm-computer-name>:8850
```

2. Click **Configuration** and **Licensing** .

## Tableau Server on Linux Administrator Guide

|   | Product Key                 | Data Management Add-on | Server Management Add-on | Expires     | Maintenance Ends |
|---|-----------------------------|------------------------|--------------------------|-------------|------------------|
| ⊙ | ⚠ P5C3-H4T5-0N75-M0R3-L04T5 | ✓                      | ✓                        | May 1, 2020 | May 1, 2020      |

Your Tableau license will expire soon. Access renewal resources including information on how to renew your software or change your billing preferences here. [Learn more](#)  
Access Tableau Server product keys in the [Customer Portal](#). View [Desktop License Usage](#) for more information about Tableau Desktop Licenses.

3. Select the product key that you want to deactivate, and then click **Deactivate License**.
4. After the key is deactivated, restart Tableau Server.

**Note:** If no other product keys remain activated before restarting, Tableau Server will not restart in a useable state. If this occurs, you will not be able to use Tableau Server until you activate a new product key in TSM.

### Use the TSM CLI

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).
2. Run the following commands:

```
tsm licenses deactivate --license-key <product-key>
```

```
tsm restart
```

### Deactivate Tableau Server Offline

If Tableau Server does not have Internet access, you can use the instructions in this topic to deactivate Tableau Server. You will need to use a second computer that is able to access the Internet to complete this activation process.

**Note:** At this time, you cannot deactivate Tableau Server if the ATR Service is enabled on your Tableau Server deployment.

1. On the Tableau Server initial node, create a directory to store the offline deactivation file that is created in the next step.
2. Log in to TSM using a Tableau Administrator account, and then run the following command:

```
tsm licenses get-offline-deactivation-file -k <productkey> -o  
<deactivation-file-directory>
```

3. Move the `TableauOfflineDeactivationRequest.tlq` file from the deactivation file directory that you specified in the previous command to a trusted computer that has Internet access.
4. On the trusted computer that has Internet access, open a web browser and visit the Tableau [Product Activations](#) page. Follow the instructions on that page to submit your `TableauOfflineDeactivationRequest.tlq` file.

**Important:** This process will not work with Microsoft Edge browser.

5. When prompted, save the product key return file (`return.tlr`) from the **Product Activations** page.
6. Move the product key return file (`return.tlr`) from the trusted computer that has Internet access to the Tableau Server initial node that runs the Licensing Server service.
7. Log in to TSM using a Tableau Administrator account, and then run the following command:

```
tsm licenses deactivate -f <path-to-license-key-return-file>

tsm restart
```

## Automate Licensing Tasks

You can use `tsm licenses` to perform licensing tasks such as activating or deactivating a Tableau Server product key on- or off-line, and getting associated files for offline activation or deactivation. However, Tableau Server must already be deployed and configured. You can automate these licensing tasks using the [Tableau Services Manager API](#).

```
C:\ProgramData\Tableau\Tableau Server\data\tabsvc\logs\
```

## Troubleshoot Licensing

This topic includes instructions for troubleshooting issues related to Tableau Server licensing.

### Handle an unlicensed server

Tableau offers two licensing models: role-based and core-based. To learn more about role-based and core-based licensing, see [Licensing Overview](#).

role-based licensing requires each active user account to be covered by a license. role-based licenses have a defined capacity, or number of users that they allow. Each user is assigned a unique user name on the server and is required to identify themselves when connecting to the server.

Core-based licensing has no constraints on the number of user accounts in the system, but it does restrict the maximum number of processor cores that Tableau Server can use. You can install Tableau Server on one or more machines to create a cluster, with the restriction that the total number of cores in all the machines does not exceed the number of cores you have licensed and that all of the cores on a particular machine are covered by the license.

### Unlicensed role-based server

The most common reason for a server that has role-based licensing to be unlicensed is an expired product key or an expired maintenance contract.

### Unlicensed core-based server

A core-based server can become unlicensed for a variety of reasons, such as an expired product key or when Tableau Server nodes running licensed processes cannot contact the Tableau Server node running the License Manager service. To learn more about licensed processes, see [Tableau Server Processes](#).

When the server is unlicensed you may not be able to start or administer the server. You can, however, manage your licenses using the `tsm licenses` command.

### Unlicensed server administrator

All Tableau Server administrators require a user license. Tableau Server administrators will always consume the highest role available. If a Creator product key is activated, the Tableau Server Administrator(s) will take this role. If the highest role available on Tableau Server is an Explorer, the Server Administrator will take the Explorer role. If Creator licenses are added to the server, any existing Server Administrator accounts using Explorer licenses will automatically convert to use Creator licenses.

TSM administrator accounts do not require licenses.

If the license that the server administrator is using expires, then the account will become unlicensed and will be unable to sign in.

Verify the expiration date of your license(s) for the administrators on the server:

- Run `tsm licenses list`.
- Compare the date with the date displayed in the [Tableau Customer Portal](#).
- If the portal does not display the date that you expect, contact [Customer Success](#).
- To renew your license, visit the [Tableau renewal](#) web page.
- Run the `tsm licenses activate` command to activate a new license for the administrator account(s).

If the TSM date matches the portal date and the following refresh operation fails, contact [Tableau Support](#).

If the license for your administrator account has expired or will expire soon, you will need to activate a new license for the account. Alternatively, you can unlicense a non-administrator user to free a license for the server administrator account.

If a Tableau Server administrator is using a Creator, Explorer or Viewer license and their license expires, they will use another license of the same type, if available. If no license seats are available the user will become “unlicensed”.

**Important:** Do not restart Tableau Server until you have activated a new license or transferred a site role for the server administrator account.

### Troubleshoot role-based licensing

This section provides information about resolving issues that can occur when adding the role-based Viewer, Explorer and Creator licenses to Tableau Server or Tableau Cloud, or when these licenses expire. The highest available license type is Creator, followed by Explorer, and finally Viewer. To learn more about role-based licensing, see [Licensing Overview](#).

A user or administrator is unlicensed due to license expiration

To avoid having users unexpectedly become unlicensed or move to another site role, you should always do one of the following before the license that they are currently using expires:

- Renew and activate a replacement license. If a user occupies a Creator, Explorer or viewer license and their license expires, they will use another license of the same type, if available.
- Change the site role of those users to allow the use of a license that is not due to expire.

To learn how site roles can be changed to require a different license, see [Set Users' Site Roles](#).

The reassignment of users to new licenses is governed by the following logic:

- When a Server Administrator user occupies a Creator license and their license expires (with no replacement licenses available), they are reassigned to an Explorer license if any Explorer licenses are available. This license reassignment occurs in order of most recent login. Server Administrators displace other users who might be currently using an Explorer license. If no Creator or Explorer licenses are available a Server Administrator becomes unlicensed.
- When a non-Server Administrator user occupies a Creator license and their license expires (with no replacement licenses available), they become unlicensed. To avoid having these users become unlicensed, change their site role prior to license expiration. This is especially important for users in the Site Administrator Creator site role, who must move to the Site Administrator Explorer site role before their Creator license expires to avoid losing Site Administrator capabilities.
- When a non-Server Administrator user occupies an Explorer or Viewer license and their license expires (with no replacement licenses available), they are upgraded to a higher license type, if licenses of that type are available. Specifically, the following occurs when a license expires:
  - Users who occupy an Explorer license will move to a Creator license, if available (with no change to site role).
  - Users who occupy a Viewer license will move to an Explorer license, if available. If no Explorer licenses are available, these users will move to a Creator license, if available (with no change to site role).
  - If no licenses are available at the higher license types, those users are moved to Unlicensed.

Users are reassigned to a new license as described above in order of most recent login, with lower license types reassigned first (first Viewer, then Explorer, and then Creator).

For example: Two users with a Viewer license, a user with the Creator license, and two Server Administrators with a Creator license all have their licenses expire. Four unexpired Explorer licenses are available for these users. In this situation, the following occurs in the order shown below:

1. The user with a Viewer license who logged in most recently is reassigned to an Explorer license.
2. The second user with a Viewer license is reassigned to an Explorer license.

## Tableau Server on Linux Administrator Guide

3. The Server Administrator user with a Creator license who logged in most recently is reassigned to an Explorer license, and then the second Server Administrator with a Creator license is reassigned to the remaining Explorer license.
4. The user with the Creator license becomes unlicensed.

Server Administrator site role is unchanged when using a Creator license

Server Administrators gain Creator capabilities if Creator licenses are available in Tableau Server, with no change to their site role name. All other Tableau Server and Tableau Cloud users gain Creator licenses only if assigned to a site role that includes Creator in its name.

Licenses are not immediately available

When you add a role-based license to Tableau Server, those licenses become available to all users when you restart Tableau Server.

A user with a Viewer license cannot open Tableau Server or Tableau Cloud workbooks from Tableau Desktop

A user with a Viewer license who also has a separate Tableau Desktop license will be unable to open workbooks on Tableau Server or Tableau Cloud using Tableau Desktop. To open workbooks such using Tableau Desktop, that user will need an Explorer or Creator license on Tableau Server or Tableau Cloud.

## Migrate from Core-Based to Role-Based Licensing

You can migrate Tableau Server from a core-based license metric (which counts the processor cores on which you have Tableau Server installed) to a role-based license metric (which counts named users). To learn more about licensing metrics, see [Licensing Overview](#).

### Prepare for migration to role-based licensing

Core-based licenses allow an unlimited number of users, including view-only guest accounts. Every user has a site role when they are added to Tableau Server, and these users and site roles persist when licensing is changed. Because role-based licenses limit the number of users, you should ensure that your new role-based licenses accommodate the number of

users who are currently connecting to Tableau Server, including the users currently using guest accounts.

**Important:** If your new role-based licenses don't accommodate the full number of users, some users will move to the **Unlicensed** site role, which can be very CPU intensive. If you have a large number of users, your application server processes may become unavailable until all the users are processed. This operation could take hours to complete, so plan accordingly.

Before you migrate, verify that you have user licenses and corresponding product keys to allow all users to access Tableau Server after the migration is complete:

- Sign in to the [Tableau Customer Portal](#) to verify licenses and to copy the corresponding product key(s).
- To learn more about site roles, see [Set Users' Site Roles](#).
- To count the number of users in your Tableau Server installation, export a list of users to count them with a tool such as Microsoft Excel. To learn how to export a list of users, see [Export a User List](#).

## Migrate to role-based licensing

To migrate to role-based licensing you must stop Tableau Server, deactivate the core-based product key, activate the role-based product key(s), and then start Tableau Server. Because this process will result in a restart of Tableau Server and cause downtime for Tableau Server users, you should migrate licensing during a period of low usage.

1. Stop Tableau Server:

Use the `tsm stop` command.

2. Deactivate the core-based product key(s):

Use the `tsm licenses deactivate` command with the core-based product key(s).

3. Activate the role-based product key(s):

Use the `tsm licenses activate` command with the role-based product key(s).

4. Start Tableau Server:

Use the `tsm start` command.

## Use role-based licenses on a server with core-based licensing

The 2018.1 release of Tableau Server allows you to add Creator role-based licenses to Tableau Server installations with existing core-based licensing.

**Note:** If you upgrade a Tableau Server installation to 2018.1 without activating role-based licenses, Tableau Server will continue to operate as it did previously, with no changes to Tableau Server UI or permissions except that the legacy **Viewer** site role is renamed to **Read Only**. In version 2018.2, the **Read Only** site role was deprecated and once again became the **Viewer** site role.

When **Creator** licenses are introduced to Tableau Server, all Server Administrator users are required to have **Creator** license roles, which may require additional licenses. Administrators can activate additional **Creator** licenses using the `tsm licenses activate` command in Tableau Server to increase licensed user capacity. Activating these role-based licenses gives you a combination of the capabilities granted by role-based Creator licenses and the capabilities granted by your core-based license. To learn more about the different types of role-based licenses, see [role-based licenses](#).

**Note:** The unlimited number of users who have access to Tableau Server under core-based licensing have equivalent capabilities to users with an **Explorer** license under role-based licensing. **Creator** functionality is limited to the defined user license model(s).

For example, if a Tableau Server installation has a 16 core license that includes guest access, and you added an Updatable Subscription License (USL) product key(s) with 10 Creator licenses, that server would have the following capabilities:

- A limit of 16 processor cores on hardware that runs Tableau Server
- Guest access
- Unlimited Explorer/Viewer licenses (from the unlimited user licenses that come with a core license)
- 10 Creator licenses

Example of completing a migration from core-based licensing

To extend the example above: If the core-based license was then deactivated, the following capabilities would be available:

- No limits on server hardware
- No guest access
- 10 Creator licenses

If you then added 50 Explorer licenses and 200 Viewer licenses, after deactivating your core-based license, the following capabilities would be available:

- No limits on server hardware
- No guest access
- 10 Creator licenses
- 50 Explorer licenses
- 200 Viewer licenses

## Quick Start: Use Login-based License Management with Tableau Server

You can use the following steps to get up and running quickly with login-based license management.

### Step 1: Install Tableau Server

To use login-based license management to activate Tableau, you must install Tableau Server version 2021.1 or later, and activate it with a product key that is enabled for login-based license management. Login-based license management enables Tableau Creator users to sign-in and activate Tableau Desktop or Tableau Prep Builder.

**Note:** If your Tableau Server product key is not enabled for login-based license management in the Tableau Customer Portal, contact your Tableau account representative.

The following topics provide additional information about installing Tableau Server and using login-based license management to activate Tableau Desktop and Tableau Prep Builder:

- Install and Configure Tableau Server

To change login-based license management configuration settings, or to disable login-based license management on Tableau Server, see [Change login-based license management settings](#).

### Step 2: Add authorized users to Tableau Server

After you activate Tableau Server, you can [add authorized users](#). When adding users, you'll need to select the site role for that user, for example Creator, Explorer, or Site Administrator. Users who will activate Tableau Desktop or Tableau Prep Builder must be assigned to a Creator site role (Creator or Site Administrator Creator). For more information on site roles, see [Set Users' Site Roles](#).

### Step 3: Activate Tableau Desktop or Tableau Prep Builder

A Creator user must download and install Tableau Desktop and/or Tableau Prep Builder on their computer before they can be activated using login-based license management. For more information, see "Install Tableau Desktop or Tableau Prep Builder from the User Interface" in the [Tableau Desktop and Tableau Prep Deployment Guide](#).

1. Launch Tableau Desktop or Tableau Prep Builder.

If this is the first time you've launched Tableau Desktop or Tableau Prep Builder, you have the option of starting a 14-day free trial or activating Tableau.

2. Click **Activate Tableau** to skip the free trial.

3. On the **Activate Tableau** screen, click **Activate by signing in to a server**, to sign-in and activate Tableau using login-based license management.
4. When prompted, specify the URL for Tableau Server to sign-in using your credentials.
5. After you are authenticated by Tableau Server, Tableau Desktop and/or Tableau Prep Builder are activated and ready to use.

## Login-based License Management

Login-based license management helps you manage licensing for users with Creator roles on Tableau Server and Tableau Cloud. Users with Explorer or Viewer roles cannot use this feature. If you're using Role Based Subscriptions with Tableau Server or Tableau Cloud, you can simplify your license management using login-based license management to eliminate separate Tableau Desktop and Tableau Prep Builder product keys. You only need to manage one or more product keys for on-premises Tableau Server, or in the case of Tableau Cloud, you don't need to manage any product keys at all.

You only need one Tableau Server or Tableau Cloud site to authorize an individual Tableau Desktop or Tableau Prep Builder. Login-based license management is enabled per production instance of your Tableau Server deployment. You can assign Creator roles to users who use Tableau Server, Tableau Desktop, and Tableau Prep Builder for license activation and centralized license management. In addition, login-based license management gives you more visibility into license usage.

You can use administrative views on Tableau Server and Tableau Cloud to see the assignment and use of Creator seats in one place. Administrative views provide information about who is using your Creator licenses, and shows the most recent license lease and version of both Tableau Desktop and Tableau Prep Builder, which helps you to monitor your Tableau deployments.

The following Tableau products support login-based license management:

## Tableau Server on Linux Administrator Guide

- Tableau Cloud
- Tableau Server 2020.1+
- Tableau Desktop 2020.1+
- Tableau Prep Builder 2020.1.3+

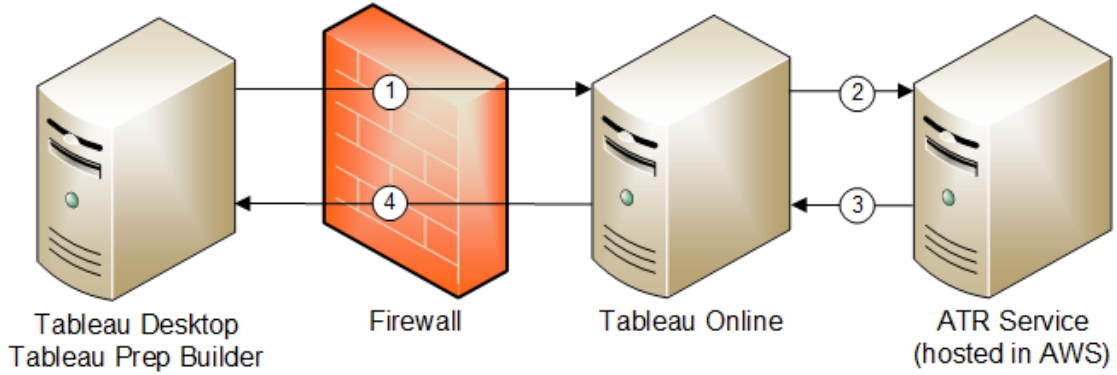

If your Tableau Server is not enabled for login-based license management, contact your Tableau sales representative to obtain a special login-based license management-enabled product key.

### How login-based license management works

When login-based license management is in use, Tableau Desktop or Tableau Prep Builder periodically contacts Tableau Server or Tableau Cloud in order to verify that the user is a Creator and to obtain an authorization to run. Tableau Server or Tableau Cloud contacts the Tableau-hosted authorization-to-run (ATR) service to verify that the Tableau Desktop client is allowed activation. The ATR service, hosted on AWS, verifies and manages the license and the length of the authorization window. The diagrams below show the communication process between the client, Tableau Server or Tableau Cloud, and the licensing service.

Tableau uses common ports (80 and 443) to make internet requests. In most cases, the computer where Tableau Desktop or Tableau Prep Builder is installed and the network it is running on are already configured to allow the necessary access. For more information about the ports used by Tableau, see [Tableau Services Manager Ports](#).

Login-based license management with Tableau Cloud

Login-based license management with Tableau Server

1. You install Tableau Desktop or Tableau Prep Builder and select **Activate with your credentials**. You sign into your Tableau Cloud or Tableau Server site.
2. Tableau Cloud or Tableau Server verifies that you are a Creator. If not, you get an error. If yes, Tableau Cloud or Tableau Server communicates with the ATR service.
3. The ATR service returns an ATR lease to Tableau Cloud or Tableau Server.
4. Tableau Cloud or Tableau Server provides an ATR lease to Tableau Desktop or Tableau Prep Builder to finalize activation.

## Use login-based license management

To use login-based license management, you either need to use Tableau Cloud or you need to install Tableau Server and activate it with a login-based license management enabled product key. The end user needs to be assigned the Creator role on either Tableau Cloud or Tableau Server and that user will need to install Tableau Desktop. Although the user can activate Tableau Desktop on up to two machines, only one Creator seat needs to be allocated.

**Note:** As of Tableau Server version 2023.1, LBLM is supported in offline deployments. To deploy Tableau Server with LBLM enabled, you must configure Tableau Server to use Authorization-To-Run (ATR) Service. For more information, see [Activate Tableau Server Offline](#).

### Step 1: Install Tableau Server

If you already have Tableau Server installed, skip to (Optional) Step 2: Change login-based license management settings. Otherwise, you'll need to install Tableau Server:

1. Refer to the Deploy chapter to install Tableau Server.
2. During activation, you must enter a Tableau Server product key that supports role-based subscription and login-based license management.
3. Add users to your Tableau Server and set them to one of the three Creator roles: Server Administrator, Site Administrator Creator, or Creator. This assigns a Creator license to these users on Tableau Server. For more information, see [Set User's Site Roles](#).

**Important:** If you're using connected clients and login-based license management, do not [disable automatic client authentication](#). In addition, do not sign out of Tableau Server using the connected desktop user interface after enabling login-based license management. Otherwise, login-based license management cannot automatically refresh the license activation or provide current data to the LBLM Usage report on Tableau Server or Tableau Cloud. For more

information about connected desktop, see [Automatically keep Tableau Desktop connected to Tableau Server or Online](#).

(Optional) Step 2: Change login-based license management settings

Login-based license management is enabled by default for Tableau Cloud, Tableau Server, and Tableau Desktop starting with version 2020.1. You can, however, change some login-based license management settings.

## Disable login-based license management on Tableau Server

Although login-based license management is the preferred method of activation for Tableau Desktop and Tableau Prep Builder, you may have Tableau Server installations in your organization used for testing that don't need to use login-based license management. On Tableau Server, you use the Tableau Services Manager (TSM) command line utility to turn off login-based license management.

To turn off login-based license management, at a command prompt, type:

```
tsm configuration set -k licensing.login_based_license_management.enabled -v false

tsm pending-changes apply
```

## Change login-based license management settings on Tableau Desktop or Tableau Prep Builder at install

To change login-based license management settings at the command line, you can run the installer .exe file from your computer's command line as an administrator. If you need to extract the .msi files, follow the instructions to [Extract and run the Windows \(MSI\) installer](#).

## Tableau Server on Linux Administrator Guide

To use a duration length other than the default of 14 days/1209600 seconds, include the `ATRREQUESTEDDURATIONSECONDS` switch. For example:

```
tableauDesktop-64bit-2020-1-0.exe /quiet /norestart ACCEPTTEULA=1  
ATRREQUESTEDDURATIONSECONDS=43200
```

You must run the command from the directory where the .exe file is located or specify a full path to the location of the .exe file on the computer. Do not run the setup program from a shared directory on your network. Instead, download the .exe file to a directory on the computer where you're installing.

The following example shows the Windows installer command that disables login-based license management:

```
tableauDesktop-64bit-2020-1-0.exe /quiet /norestart ACCEPTTEULA=1  
LBLM=disabled
```

or

```
tableauPrepBuilder-64bit-2020-1-0.exe /quiet /norestart ACCEPTTEULA=1  
LBLM=disabled
```

To set the default URL for the Tableau Server you want users to use for activation when using login-based license management, add the `ACTIVATIONSERVER` or `WorkGroupServer` option.

To update the exe:

```
tableauDesktop-64bit-2021-4-0.exe /quiet /norestart ACCEPTTEULA=1  
ACTIVATIONSERVER=http://<tableau_server_url>
```

To update the registry:

```
reg.exe add HKEY_LOCAL_MACHINE\SOFTWARE\Tableau\Tableau 2021.4\Set-  
tings /f /v WorkGroupServer /d https://<tableau_server_url>
```

**Note:** The `ACTIVATIONSERVER` option is only intended for first time activation. If you have previously signed-in to this version of Tableau, you use the `WorkGroupServer` (Windows) or `WorkgroupServer` (macOS) option. For example, if you are using Tableau Desktop version 2021.1 on Windows and have previously signed-in successfully, you would use the `WorkGroupServer` option to specify an activation server. On Tableau Desktop on macOS, you would use the `WorkgroupServer` option. On macOS, this option is case sensitive and uses a lowercase "g".

## Change login-based license management settings on Tableau Desktop by editing the registry

If Tableau Desktop is already installed, you can change login-based license management settings by editing the Windows registry.

To turn off login-based license management:

```
reg.exe add HKEY_LOCAL_MACHINE\SOFTWARE\Tableau\ATR /f /v LBLM /d disabled
```

To make login-based license management the only login option:

```
reg.exe add HKEY_LOCAL_MACHINE\SOFTWARE\Tableau\ATR /f /v LBLM /d required
```

Or, you can enable, disable, or require login-based license management by editing the registry directly:

1. As an administrator on the computer running Tableau Desktop, make a backup of the registry file before you make any changes to it.

2. Edit the registry, and in `HKEY_LOCAL_MACHINE\SOFTWARE\Tableau`, find the hive named ATR and modify the LBLM value to reflect the desired setting:
  - a. Name: LBLM.
  - b. Data: enabled, disabled, or required.
3. Restart Tableau so the changes take effect.

## Change login-based license management settings on Tableau Desktop on macOS

To change login-based license management settings on macOS, run the following commands in a terminal window to update the preferences file, and then install or restart Tableau Desktop.

To turn off login-based license management:

```
sudo defaults write /Library/Preferences/com.tableau.ATR LBLM "disabled"
```

To make login-based license management the only login option:

```
sudo defaults write /Library/Preferences/com.tableau.ATR LBLM "required"
```

To set the default URL for the Tableau Server you want user to use for activation when using login-based license management on macOS.

First time activation:

```
sudo defaults write /Library/Preferences/com.tableau.ATR LBLM "required"
```

Subsequent activations:

```
sudo defaults write /Library/Preferences/com.tableau.Tableau-<version> Settings.WorkgroupServer "https://<tableau_server_url>"
```

**Note:** On Tableau Desktop on macOS, you would use the WorkgroupServer option. On macOS, this option is case sensitive and uses a lowercase "g".

### Login-based license management settings

You use the following settings to change login-based license management, set the ATR duration, and set the activation server URL.

| Setting | Value                          | Description   |
|---------|--------------------------------|---|
| LBLM    | enabled, disabled, or required | <p>Set to <i>enabled</i> (the default), the licensing screens will present the two options for activation (product key, or credentials).</p> <p>Set to <i>disabled</i>, login-based license management will not appear on the licensing screens.</p> <p>Set to <i>required</i>, login-based license management is the only way to activate the Tableau Desktop (when the licensing screen appears, it will offer only the credentials option for activation).</p> <p><b>Note:</b> When LBLM is set to</p> |

|  |                             |   |
|--|-----------------------------|---|
|  |                             | <p>enabled or required, reporting is also enabled.</p>  |
| ATRREQUESTEDDURATIONSECONDS                          | 1209600                     | <p>Sets the authorization to run (ATR) duration (in seconds), which is the length of time that an instance of Tableau Desktop and Tableau Prep Builder is authorized to run. The default is 1209600 seconds (14 days). Do not use commas as separators in the value.</p>                                  |
| ACTIVATIONSERVER                                     | http://<tableau_server_url> | <p>For first time activation, sets the default URL for the Tableau Server you want users to use for activation.</p>   |
| WorkGroupServer (Windows)<br>WorkgroupServer (macOS) | http://<tableau_server_url> | <p>For updates to the Windows registry or macOS plist, sets the default URL for the Tableau Server you want users to use for activation.</p> <p><b>Note:</b> On Tableau Desktop on macOS, you would use the WorkgroupServer option. On macOS, this option is case sensitive and uses a lowercase "g".</p> |

|                           |      |   |
|---------------------------|------|---|
| REPORTINGFREQUENCYSECONDS | 3600 | <p>Sets the default (in seconds) for how often the login-based license management report is sent to Tableau Server or Tableau Cloud. The minimum setting is 60 seconds, and the default is 3600 seconds (one hour). Change this setting to reduce the load on Tableau Server or to reduce network traffic. No matter what the authorization-to-run (ATR) lease duration is set to,</p> <p>REPORTINGFREQUENCYSECONDS sets the time interval that the Tableau Desktop or Tableau Prep Builder client report login-based license management activations back to Tableau Server or Tableau Cloud.</p> |
|---------------------------|------|---|

## Additional configuration for virtual deployments

Tableau Desktop and Tableau Prep Builder periodically contact Tableau Cloud or Tableau Server to verify that Tableau is authorized to run, based on its license. Tableau Cloud or Tableau Server then contacts the ATR service to verify the license and the length of the authorization window.

When configuring a virtual (non-persistent) deployment of Tableau Desktop or Tableau Prep Builder, the duration time should be set to one of the lower values such as 4 or 8 hours in order to avoid an over-use activation error message. After the virtual machine (VM) is returned, the ATR service will handle the activation monitoring.

## Tableau Server on Linux Administrator Guide

The following flags should be used on a source image prior to publishing Tableau Desktop to end users. Each end user will be activating the software by logging into Tableau Server or Tableau Cloud with each new VM delivered. No product keys need to be entered if the end user is a Tableau Creator on Tableau Server or Tableau Cloud.

If you are using login-based license management for Tableau Desktop or Tableau Prep Builder on a VM, you may get an error message that your license information has changed whenever you launch a new VM for Tableau Desktop or Tableau Prep Builder. This error forces a restart, which then asks you to register Tableau Desktop again. This error occurs because the ATR service sends a new token that doesn't match the license cache.

### Microsoft Windows

To prevent the error from occurring on Microsoft Windows, you can use the `SYNCHRONOUSLICENSECHECK` and `SILENTLYREGISTERUSER` options with the Windows installer. For example:

```
tableau-setup-std-tableau-2020 SYNCHRONOUSLICENSECHECK="true"  
SILENTLYREGISTERUSER="true" ATRREQUESTEDDURATIONSECONDS=14400
```

or

```
tableauDesktop-64bit-2020-1-0.exe /quiet /norestart ACCEPTEULA=1  
ATRREQUESTEDDURATIONSECONDS=14400 ACTIVATIONSERVER=http://<tableau_  
server_url> SYNCHRONOUSLICENSECHECK="true" SILENTLYREGISTERUSER=  
R="true"
```

If Tableau Prep Builder and Tableau Desktop are being delivered on one Virtual Desktop, `ATRREQUESTEDDURATIONSECONDS` only needs to be set during Tableau Desktop installation. However, if you plan to install Tableau Prep Builder as a stand-alone, you'll need to set `ATRREQUESTEDDURATIONSECONDS` during Tableau Prep Builder installation.

Or, you can edit the following registry keys on the source image:

```
Reg key path: HKLM\SOFTWARE\Tableau\<Tableau version>\Settings\
```

Reg key (String value, need to set to true to make that feature enabled)

SynchronousLicenseCheck

SilentlyRegisterUser

## macOS

To prevent the error from occurring on macOS, run the following command to set the `LicenseCache.Desktop` flag to 'false'.

```
sudo defaults write ~/Library/Preferences/com.tableau.Tableau-<version>.plist LicenseCache.Desktop false
```

### (Optional) Step 3: Change the authorization to run (ATR) duration

The login-based license management default settings for the authorization to run (ATR) duration are appropriate for most environments, but you can change these default settings if needed. Login-based license management uses the default authorization to run (ATR) duration of 1209600 seconds (14 days), which is the length of time that an instance of Tableau Desktop and Tableau Prep Builder is authorized to run. This means that after the initial authorization, you could use Tableau without any network connection for 14 days before the activation expired.

The default duration value for login-based license management is not appropriate for delivering a non-persistent VM delivery solution to end users. The ATR duration should be lowered to 4 or 12 hours depending on VM use. When a new VM is delivered to an end user, a new authority to run token will be created. When the VM is returned, this token is also returned and is able to be used on the new VM authorization to run request.

**Note:** Login-based license management uses the following hierarchy when determining ATR duration.

1. **ATR Service** – Establishes the minimum (4 hours/14400 seconds) and maximum (90 days/7776000 seconds) ATR durations applicable to all users/installations. It specifies

the default ATR duration (14 days/1209600 seconds) if nothing is specified by Tableau Server or Tableau Desktop.

- 2. Tableau Server** - Can optionally specify a maximum or default ATR duration (`licensing.login_based_license_management.max_requested_duration_seconds` or `licensing.login_based_license_management.default_requested_duration_seconds`) for all Tableau Desktop installations. Using these ATR duration settings, you can globally set the default ATR duration and maximum ATR duration for all Tableau Desktop clients, which eliminates the need to individually sign in to each Tableau Desktop client to set the ATR duration. The ATR Service maximum setting can be between the minimum of 4 hours (14400 seconds) and maximum of 90 days (7776000 seconds).
- 3. Tableau Desktop** – Can optionally specify the ATR duration (`ATRREQUESTEDDURATIONSECONDS`) for the computer on which it is installed. If necessary, you can change the default ATR duration (14 days/1209600 seconds) to a setting within the ATR Service minimum (4 hours/14400 seconds) and maximum (90 days/7776000 seconds). This local ATR duration overrides any durations set by the ATR Service or Tableau Server. However, this default ATR duration cannot be more than the maximum ATR duration set on Tableau Server.

## Change the ATR duration for Tableau Desktop or Tableau Prep Builder using Tableau Server

On Tableau Server, you use the Tableau Services Manager (TSM) command line utility to set the ATR duration.

To set the ATR duration, at a command prompt, type:

```
tsm configuration set -k licensing.login_based_license_management.default_requested_duration_seconds -v <value in seconds>

tsm pending-changes apply
```

To set the ATR maximum duration, at a command prompt, type:

```
tsm configuration set -k licensing.login_based_license_management.max_requested_duration_seconds -v <value in seconds>
```

```
tsm pending-changes apply
```

## Change the ATR duration on Tableau Desktop by editing the registry

To use a duration length other than the default of 14 days/1209600 seconds, update the `ATRRequestedDurationSeconds` registry setting. For example:

1. As an administrator on the computer running Tableau Desktop, make a backup of the registry file before you make any changes to it.
2. Edit the registry, and in `HKEY_LOCAL_MACHINE\SOFTWARE\Tableau\ATR`, update the `ATRRequestedDurationSeconds` as follows (0 uses the default setting):
  - a. Name: Find the string value named `ATRRequestedDurationSeconds`.
  - b. Data: Update the number of seconds the duration should last. For example, add 43200 to set a duration of 12 hours.
3. Restart Tableau so that the changes take effect.

## Change the ATR duration on Tableau Desktop on macOS

To use a duration length other than the default of 14 days/1209600 seconds, include the `ATRRequestedDurationSeconds` preferences setting. For example:

```
sudo defaults write /Library/Preferences/com.tableau.ATR ATRRequestedDurationSeconds -string "43200"
```

### Step 4: Activate Tableau Desktop

The 2020.1 and later versions of both Tableau Desktop for Windows or macOS support login-based license management.

## Tableau Server on Linux Administrator Guide

1. Run Tableau Desktop setup.
2. The Activate Tableau screen will include the **Activate by signing in to a server** option.

3. Click **Activate by signing in to a server** and then do one of the following:
  - If you're using Tableau Cloud, click the Tableau Cloud link.
  - If you're using Tableau Server, enter the Tableau Server URL, and then click **Connect**.

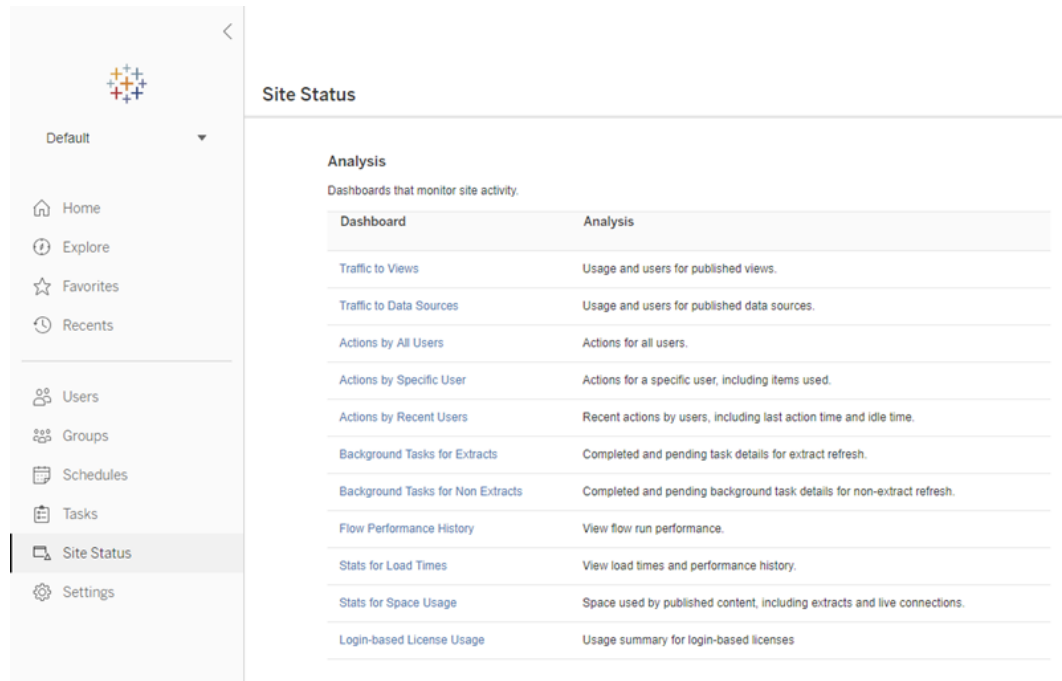

When prompted, enter valid credentials for a user with a Creator role subscription, and then click **OK**.

## View login-based license usage

You can view login-based license usage for Tableau Cloud or Tableau Server. The report shows users, hosts, user role, product, version, activations, Creator seats in use, Creator seats not in use, and when a Creator seat was last used. You can view data for the past 30 days up to a maximum of 183 days.

To view the Login-based license management License Usage administrative view:

1. In Tableau Cloud or Tableau Server, in the navigation pane, click **Site Status**.

2. On the Site Status page, click **Login-based License Usage**.
3. Optional. On the report screen, you can change the time window to show when seats

were last used, filter on actions, filter on user name, and sort by columns.

## Troubleshooting

You may encounter one of the following error messages while using login-based license management. Use the information below to resolve the issue.

Login-based license management is not enabled on Tableau Server

If login-based license management is available as an activation option on Tableau Desktop, but not enabled on Tableau Server, or if Tableau Server does not have a login-based license management capable license, the following error message may be displayed:

*Login-based license management is not enabled on the server you connected to. Select a different server to connect to, use a product key to activate your license, or start a trial to begin working immediately.*

Contact your administrator to ensure that you're using a Tableau Server product key that's enabled for login-based license management. To verify that you have activated the

appropriate product key, in the TSM web UI click **Configuration**, and then click **Licensing**. For guidance on activating licenses, see `tsm licenses activate`. Login-based license management should be enabled by default unless it was previously turned off by the server administrator.

Login-based license management is not enabled on Tableau Desktop

If login-based license management is not enabled on Tableau Desktop, you will not have the option to activate Tableau using your credentials. Prior to version 2020.1, the ability to use login-based license management on Tableau Desktop is not turned on as a default. Check the Tableau Desktop version to ensure the correct version is being used.

If the login-based license management option has been turned off during installation or with an update, see [Step 2: Enable login-based license management](#).

Product key expiration date doesn't change after purchasing a year subscription

After purchasing a renewal of Tableau Server, and the new subscription term is reflected in Tableau Server, it may take up to 24 hours before the new expiration date appears in **Manage Product Keys** on Tableau Desktop.

You do not have a Creator license

When attempting to activate from Tableau Desktop, the following error message may be displayed:

*You do not have a Creator license. Contact your administrator to obtain one.*

This error is displayed if you have not been assigned a Creator role. If you belong to multiple sites on Tableau Cloud or Tableau Server, you need to sign in to the site where you have the Creator role when using login-based license management. Otherwise you'll get this error.

To verify that the product key you have activated on the server includes Creator licenses, open the TSM web UI and click **Configuration**, and then click **Licensing**.

## Tableau Server on Linux Administrator Guide

You have activated the maximum number of computers

When attempting to activate from Tableau Desktop, the following error message may be displayed:

*You have activated Tableau the maximum number of times allowed under your account. You must wait for the license activation on another computer to expire before you can activate Tableau again.*

This error is displayed when you activated Tableau from multiple computers with the same Creator user credentials and exceeded the maximum number of activations. You must wait until the authorization-to-run (ATR) token expires on one of the existing computers before attempting to activate a new computer. If you are using non-persistent virtual machines (VMs), you can shorten the ATR duration to prevent this error from occurring again.

To shorten the ATR token duration for maximum activation

If you encounter this maximum use error when using a non-persistent virtual deployment, it is possible to shorten the ATR duration to 4 hours (14400) seconds to avoid the error in the future. Alternatively, instead of changing the duration on an individual desktop, you can set the default duration on Tableau Server to affect all users.

The following steps shorten the lease on a computer previously activated with login-based license management that will no longer be used, in order to free up a seat to be activated on a new computer:

1. Open a Command Prompt as an administrator on a Tableau Desktop computer that will no longer be used.
2. Navigate to the Tableau binaries (\bin) directory, using the following command.

**Windows:** `cd Program Files\Tableau\Tableau <version>\bin`

**Mac:** `cd /Applications/Tableau\ Desktop\ <version>.app/Contents/MacOS`

3. Run the following command to set the duration to 4 hours, in seconds (e.g., 14400).

Windows: `atrdiag.exe -setDuration 14400`

Mac: `sudo ./atrdiag -setDuration 14400`

4. Delete the previous ATR token using the following command:

Windows: `atrdiag.exe -deleteAllATRs`

Mac: `./atrdiag -deleteAllATRs`

5. Next, overwrite the existing ATR token. Open Tableau Desktop. Tableau displays the “License has Changed” message. Click **Exit** to automatically close and reopen Tableau Desktop.
6. In the registration dialog box, click **Activate**, and then reactivate Tableau Desktop through Tableau Server using login-based license management, which will overwrite the existing token.
7. Close Tableau Desktop and wait for the ATR duration to elapse (e.g., 4 hours) so that the ATR token expires and frees-up a user seat. Do not open Tableau Desktop before the ATR duration has elapsed. Check to make sure the ATR duration has elapsed. The ATR token TTL End should show a date and time in the future (e.g., 4 hours from now).

Windows: `atrdiag.exe`

Mac: `./atrdiag`

8. After the ATR token expires and you can successfully sign in to Tableau Server on a new computer.

To return your computer to an unlicensed state

1. Open a Command Prompt as an administrator.
2. Navigate to the Tableau binaries (`\bin`) directory, using the following command:

## Tableau Server on Linux Administrator Guide

```
cd Program Files\Tableau\Tableau <version>\bin
```

3. Run the following command:

**Windows:** atrdiag.exe -deleteAllATRs

**Mac:** ./atrdiag.exe -deleteAllATRs

**Note:** This removes only the ATR token from the computer. It does not free-up any of the user seats. The user seat is only freed-up after the deleted ATR token expires.

Your Tableau credentials are invalid

When attempting to activate from Tableau Desktop, the following error message may be displayed:

*Your Tableau credentials are invalid. Contact your administrator to reset your account.*

This error is displayed when your Tableau license is not recognized. Contact your administrator..

Your computer's clock is not synchronized to the current time

When attempting to activate from Tableau Desktop, the following error message may be displayed:

*Your computer's clock is not synchronized to the current time. Synchronize your computer's clock to the current time and then try to activate Tableau.*

This error is displayed when your computer's clock is not synchronized with the current time. Synchronize your computer's clock with a time server on the internet or enable automatic time synchronization.

Unable to activate with your credentials

When attempting to activate Tableau, the following error message may be displayed:

*Tableau Server cannot verify your licensing information over the internet. Contact your administrator to check your internet connection.*

This error is displayed when the port `atr.licensing.tableau.com:443` is not open on all Application Server (VizPortal) nodes, or you have a proxy that is not configured properly to forward traffic to Tableau's licensing server.

To diagnose connectivity to Tableau's licensing server, paste the following URL (`https://atr.licensing.tableau.com/_status/healthz`) into a browser or at a curl command prompt.

## Zero Downtime Licensing

With zero downtime licensing, which was introduced in Tableau Server version 2021.1, you can apply most licensing changes to Tableau Server without needing to restart when license end dates, capacity, or installed features are changed.

### When should you restart Tableau Server?

When you apply a license update that does not require a restart, Tableau Server displays the following message: **Updated Licensing details are being applied across Server.**

However, there are some situations when applying a license update that require you to restart Tableau Server. For example, if you are activating or deactivating a product key that reduces features or changes the allowed data source connections, you'll need to restart Tableau Server after making your changes. When a restart is required, Tableau Server will display the following message: **Restart Server to apply updated Licensing details.** The following table lists the times when license changes require you to restart Tableau Server.

| License change                           | Restart required? |
|--|-------------------|
| Extending a license term                 | No                |
| Adding or reducing user license capacity | No                |
| Adding core license capacity             | No                |

|   |     |
|---|-----|
| Reducing core license capacity                            | Yes |
| Adding a Data Management or Advanced Management license   | No  |
| Removing a Data Management or Advanced Management license | Yes |
| Changing allowed data sources                             | Yes |
| Expired product key                                       | Yes |

## About Tableau Enterprise

Tableau Enterprise is our advanced software package to help you explore and manage data faster with Tableau Server. It also makes it easier to purchase the capabilities needed by organizations that require advanced data and deployment management options. It includes Tableau role-based licenses, Data Management, Advanced Management, and eLearning for Creators and Explorers.

### Tableau Enterprise Licensing

Tableau Enterprise is sold on a per-User role-based licensing model, including Creators, Explorers, and Viewers. This model is structured around the specific roles within an organization, each requiring different levels of functionality. With Tableau Enterprise, each role-based license includes Data Management, Advanced Management, and eLearning for Creators and Explorers.

### Tableau Enterprise Feature Table

The following table lists the features that are included with the Tableau Enterprise license edition. Feature availability below is noted for Creator. There are differences in available functionality between Creator, Explorer, and Viewer.

| Feature                  | Description  |
|--------------------------|--|
| <b>Tableau Authoring</b> | Use Tableau Desktop or Tableau web authoring on Tableau Server to create, collaborate, |

|   |  |
|---|--|
|   | and share insights about your data. Tableau provides you a way to identify and solve problems, or highlight key findings in a visual and easily understandable way.  |
| Tableau Prep  | Tableau Prep is a data preparation tool for cleaning, shaping, and combining data for analysis.  |
| eLearning   | Role-based training Tableau Learning Paths provide a clear track to proficiency with the most up-to-date Tableau training content. Assessments help you evaluate where you are in your learning path and give you confidence in your new skills. Accelerate the onboarding process for new employees and help more experienced users get the most out of Tableau capabilities. |
| About Data Management                               | Data Management is a collection of features and functionality that helps customers manage Tableau content and data assets in their Tableau Server environment.   |
| About Tableau Advanced Management on Tableau Server | Advanced Management is a collection of features designed to provide enhanced security, manageability, and scalability capabilities for Tableau Server.   |

## About the Identity Migration

Beginning in version 2022.1, Tableau Server stores and manages identity information using the Identity Service. With the Identity Service, Tableau Server uses a more modern, more secure, and immutable identity structure for the user provisioning and authentication process. Identity migration is a prerequisite for configuring and using [identity pools](#).

**Note:** If you do not plan to use the identity pools capability, we recommend you do not run the identity migration. Running the identity migration without plans to use identity pools will not provide benefits to your Tableau Server deployment.

All new deployments of Tableau Server 2022.1 (and later) use the Identity Service by default and require no additional action from you. As you add new users to Tableau Server, the default Identity Service is used.

For existing deployments, if upgrading Tableau Server to version 2022.1 (or later) and restoring a backup of Tableau 2021.4 (or earlier), you can start the identity migration after Tableau Server upgrade completes to populate the new Identity Service. The identity migration populates supplemental Identity Service tables for all Tableau Server users, which are then used to authenticate users through the Identity Service. The migration runs in the background and won't interrupt or interfere with your users' use of Tableau Server.

As an administrator, you can monitor and manage the migration, including changing when the migration runs or resolving any potential migration conflicts, through a dedicated **Identity Migration** page available from Tableau Server's Users page. This page is available for the duration of the migration process.

## Summary of steps for existing deployments

For existing deployments, you must configure Tableau Server to use the Identity Service after the migration completes to take advantage of the identity structure improvements and configure identity pools.

Step 1: Before you begin

Step 2: Start the identity migration

Step 3: Complete the identity migration

Step 4: Configure Tableau Server to use the Identity Service

## Key terms

- **Identity Service** - a service in Tableau Server 2022.1 (and later) that is responsible for the administration of user identities, including authentication and provisioning. The service uses an identity schema where user identities are represented by Identity Service tables and the legacy "system\_users" table.
- **Identity pools** - an identity management tool that uses provisioning and authentication information to enable user access to Tableau Server. Identity pools enable a more centralized and flexible identity management workflow built on the Identity Service for the storage and management of user identities in Tableau Server.
- **Legacy identity store mode** - a limited identity schema used by Tableau Server 2021.4 (and earlier), where user identities are only represented by the legacy "system\_users" table.
- **Identity migration** - the auditing process that evaluates existing Tableau Server user identities, queries the upstream external identity stores for additional identity information (as appropriate), and imports that additional identity information to the Identity Service.
- **External identity store** - an identity store type external and upstream to Tableau Server where all identity information is stored and managed by an external directory service (Active Directory (AD) or LDAP). If configured, Tableau Server synchronizes to the external directory so that a copy of the identity information exists in Tableau Server.
- **Local identity store** - an identity store type provided by Tableau Server. If configured, Tableau Server stores and manages identity information in the Tableau Server repository without any configured external directory for this information.
- **System user** - a Tableau Server user. A user corresponds to a signin record ("system\_users") in both the Identity Service (through the "system\_users\_identities" table) and legacy identity store mode. A "system\_users" record can potentially have multiple user identities associated with it and enabled to sign in to multiple sites. The link between a "system\_users" record and sites is defined in the "users" table.

## Purpose of the identity migration

When you create a Tableau Server backup, identity information is saved in the identity schema used by the version of Tableau Server the backup was created for. The migration is necessary to populate identity information from the identity schema used in the backup to the identity schema used by the Identity Service.

### Identity schema of Tableau Server 2021.4 and earlier

The identity schema used by the legacy identity store mode consists of two tables, "system\_users" and "domains."

### Identity schema of Tableau Server 2022.1 and later

The identity schema used by the Identity Service includes the legacy "system\_users" tables and supplemental Identity Service tables (\*\_identity\_stores and \*identities) that capture more identity information. The additional tables help reduce issues that can be caused by upstream changes in the external identity stores.

### What happens during the identity migration

When information about user identities are migrated, identity information stored in the legacy "system\_users" table are supplemented with the Identity Service tables.

The type of Identity Service tables that the identity information is supplemented with depends on which identity store type Tableau Server is configured for: local, Active Directory (AD), or Lightweight Directory Access Protocol (LDAP).

- For **AD** identity store types, Identity Service tables only inherit unambiguous attributes or attributes that are not stored in the same database record.

For example, `sAMAccountName` and `userPrincipalName` (UPN) can be stored in the same name record of a legacy "systems\_users" table, which can occur as a result of a complex series of rules. In most cases, the migration is able to correctly interpret and successfully migrate the user identity. However, if the migration produces ambiguous results, you must either manually acknowledge the ambiguity or manually resolve the conflict using the dedicated Identity Migration page. For more information, see [Resolve Identity Migration Conflicts](#).

- For **LDAP** identity store types, like AD identity store types, Identity Service tables only inherit unambiguous attributes. In most cases, the migration is able to correctly interpret and successfully migrate the user identity. However, if the migration produces ambiguous results, you must either manually acknowledge the ambiguity or manually resolve the conflict using the dedicated Identity Migration page. For more information, see [Resolve Identity Migration Conflicts](#).
- For **Local** identity store types, Identity Service tables inherit the user and domain fields directly. This means, no additional information or manual resolution is required from you. When Tableau Server is configured for this type of identity store, migration of users identities happens after the Tableau Server backup restore process.

## Step 1: Before you begin

Before you begin, identify your Tableau Server upgrade method below to determine next steps in the identity migration.

- If you're performing a **Blue/Green upgrade** or **manually upgrading** Tableau Server by 1) installing Tableau Server on a new machine and then 2) **backing up and**

**restoring Tableau Server using the `tsm maintenance (backup and restore) commands`**, you're required to take some additional steps to initiate the migration.

For next steps, see [Troubleshoot Issues with the Identity Migration](#).

- If you're doing an **“in-place” single-server or multi-node upgrade** of Tableau Server using the method described here, there are no additional steps required from you to initiate the migration. The migration initiates after Tableau Server upgrade to version 2022.1 (or later) is complete.

Skip to [Step 2](#).

- If you're **manually upgrading** Tableau Server by 1) installing Tableau Server on a new machine and then 2) **exporting and importing configuration and topology information using `tsm settings (export and import) commands`**, there are also no additional steps required from you to initiate the migration. The migration initiates after the import process completes on the new Tableau Server machine.

Skip to [Step 2](#).

## Step 2: Start the identity migration

To start the identity migration, you must enable the identity migration capability by using the `tsm command features.IdentityMigrationBackgroundJob`.

**Note:** If you've upgraded to Tableau Server versions 2021.4.21, 2022.1.17, 2022.3.9, and 2023.1.5, the identity migration starts by default and you can skip to [Step 3: Complete the identity migration](#).

1. Open a command prompt as admin on the initial node (where TSM is installed) in the cluster.
2. Run the command the following command:

```
tsm configuration set -k features.IdentityMigrationBackgroundJob -v true
```

After the identity migration begins, you'll see a notification in Tableau Server that links you to the Identity Migration page. The Identity Migration page is where you can monitor the status of the identity migration and identity conflicts that need to be resolved.

## Step 3: Complete the identity migration

To complete the identity migration, all identity conflicts must be resolved or acknowledged before you can enable the Identity Service for Tableau Server.

1. Sign in to Tableau Server as an administrator.
2. From the left navigation pane, select **Users** (or **All Sites > Users** for a multi-site Tableau Server) and then click the **Identity Migration** page to verify the migration has started.

You can monitor and manage its progress using the dedicated Identity Migration page available from Tableau Server's Users page. For more information, see [Manage the Identity Migration](#).

3. Resolve or acknowledge all identity conflicts as described in [Resolve Identity Migration Conflicts](#) so that **All failures** tab displays "0" like in the image below.

| Migration failures ⓘ |            |           |            |           |         |              |
|----------------------|------------|-----------|------------|-----------|---------|--------------|
| All failures         | No matches | Ambiguous | Duplicates | Not local | Unknown | Acknowledged |
| 0                    | 0          | 0         | 0          | 0         | 0       | 29122        |

4. Do *one* of the following:
  - To run the identity migration job now, next to the Migration Overview heading, click the Edit Schedule drop-down arrow, and then select **Run Now**.

- Alternatively, you can wait for the migration job to run during the next scheduled time.
5. After the migration completes, from the Identity Migration page, validate that the Migration Overview shows **100% complete**.

## Step 4: Configure Tableau Server to use the Identity Service

After the identity migration is complete, configure Tableau Server to use the Identity Service to ensure a more secure and immutable identity structure for the user provisioning and authentication process.

1. Open a command prompt as an administrator on the initial node (where TSM is installed) in the cluster.
2. Run the following commands:

```
tsm authentication legacy-identity-mode disable
tsm pending-changes apply
```

**Note:** After running the commands above, the dedicated **Identity Migration** page is removed and no longer accessible. The page is accessible only when `tsm authentication legacy-identity-mode` is enabled.

After Tableau Server is configured to use the Identity Service, when users sign in to Tableau Server, Tableau Server searches for their user identities using their identifiers in the configured identity store. From the identifiers, the universal unique identifiers (UUID) are returned and used to match existing Tableau Server user identities. This process then generates sessions for the users and completes the authentication workflow.

## Manage the Identity Migration

As an administrator, you can monitor and manage the identity migration, including changing when the migration jobs run, through the dedicated Identity Migration page available from Tableau Server's Users page. This page is available for the duration of the migration process.

User List **Identity Migration**

Migration overview [Edit Schedule](#)

User identities are being migrated from the legacy identity store (Tableau system users) to the new global identity service. This one-time migration provides immutable identifiers and increased flexibility and functionality in user and identity management. [Learn more](#)

4,610/8,135 user identities  
56% complete

| Display name                    | Actions | Username | Domain  | Failure type |
|---------------------------------|---------|----------|---------|--------------|
| <input type="checkbox"/> Vijay  | ...     | vde      | tsi.lan | No matches   |
| <input type="checkbox"/> Andrew | ...     | am       | tsi.lan | No matches   |
| <input type="checkbox"/> Aaron  | ...     | avo      | tsi.lan | No matches   |
| <input type="checkbox"/> Jamie  | ...     | jca      | tsi.lan | No matches   |

The migration jobs are designed to run in the background without interrupting or interfering with the use of Tableau Server. If needed, however, you can make adjustments that affect how frequently migration jobs run, when the migration jobs run, and how long the migration jobs can run.

Generally, the migration can take anywhere from 3 minutes to 10 days, depending on the size of your Tableau Server deployment and any changes to the default settings you make during the migration. For example, if you have 10,000 users, the migration can take about 30 minutes.

**Note:** While the migration jobs are running, all authentication and user-related capabilities work normally.

### Manage identity migration jobs

You can manage the following aspects of the identity migration.

### Resolve identity conflicts

To review the identity conflicts you might encounter during the migration, see [Resolve Identity Migration Conflicts](#).

### Change daily migration job schedule

1. Sign in to Tableau Server as an administrator.
2. From the left navigation pane, select **Users** (or **All Sites > Users** for a multi-site Tableau Server) and then click the **Identity Migration** page.
3. Next to the Migration Overview heading, click the **Edit Schedule** button.
4. In the Edit Schedule dialog box, change when and how frequently jobs can run.

**Note:** You can ignore the **Priority** and **Execution** options in this dialog box.

5. When finished, click **Update**.

## Initiate a migration job

1. Sign in to Tableau Server as an administrator.
2. From the left navigation pane, select **Users** (or **All Sites > Users** for a multi-site Tableau Server) and then click the **Identity Migration** page.
3. From any tab, select a user or multiple users.
4. From the Actions menu, select **Retry Migration** or **Acknowledge**, depending on what you need to do.

5. Next to the Migration Overview heading, click the Edit Schedule drop-down arrow.

6. Select **Run Now**.

## Pause the identity migration

1. Sign in to Tableau Server as an administrator.
2. From the left navigation pane, select **Users** (or **All Sites > Users** for a multi-site Tableau Server) and then click the **Identity Migration** page.
3. Next to the Migration Overview heading, click the Edit Schedule drop-down arrow.
4. Select **Disable**.

## Restart the identity migration

1. Sign in to Tableau Server as an administrator.
2. From the left navigation pane, select **Users** (or **All Sites > Users** for a multi-site Tableau Server) and then click the **Identity Migration** page.
3. Next to the Migration Overview heading, click the Edit Schedule drop-down arrow.
4. Select **Enable**.

## Change identity migration settings

To reduce any potential strain the identity migration might have on your Tableau Server, the migration is configured to run with the default settings listed below.

## Migration settings

| Type                                     | tsm command   | Default                       | Procedure  |
|--|---|-------------------------------|--|
| Jobs schedule                            | N/A   | 3:00 AM, daily until complete | Configurable from the Identity Migration page, see Change daily migration job schedule above.  |
| User identity requests per second (rate) | <code>tsm authentication identity-migration configure --rate</code> | Up to 5                       | <p>If needed, you can use the <code>tsm authentication identity-migration</code> command to change the migration settings listed above using the steps below.</p> <ol style="list-style-type: none"> <li>1. Open a command prompt as an admin on the initial node (where TSM is installed) in the cluster.</li> <li>2. Run one or both of the commands described in <code>tsm authentication identity-migration</code>.</li> </ol> <p>For example, to change the individual job runtime and rate from their default values, you can run the following command:</p> <pre>tsm authentication identity-migration configure --job-run-</pre> |

|                                  |   |                    |   |
|----------------------------------|---|--------------------|---|
| <p>Individual job runtime</p>    | <pre>tsm authentication identity-migration con- figure --job-run-time</pre>       | <p>120 minutes</p> | <pre>time 180 --rate 3</pre>  |
| <p>Enable identity migration</p> | <pre>tsm configuration set -k fea- tures.Iden- tityMi- grationBackgroundJob</pre> | <p>false</p>       | <p>By enabling the identity migration, Tableau Server can use the Identity Service to store and manage user identity information.</p> <ol style="list-style-type: none"> <li>1. Open a command prompt as admin on the initial node (where TSM is installed) in the cluster.</li> <li>2. Run the command the following command:</li> </ol> <pre>tsm configuration set -k fea- tures.Iden- tityMi- grationBackgroundJob -v true</pre> <p><b>Note:</b> The identity migration and the Identity Service is a prerequisite for certain capabilities like <b>identity pools</b>. For more information about the tsm command, see features.Iden-</p> |

|  |  |  |                             |
|--|--|--|-----------------------------|
|  |  |  | tityMigrationBackgroundJob. |
|--|--|--|-----------------------------|

## Disable identity migration

If you've upgraded to Tableau Server versions 2021.4.21, 2022.1.17, 2022.3.9, and 2023.1.5, you might need to disable the identity migration. By disabling the identity migration, Tableau Server cannot use the Identity Service to store and manage user identity information.

1. Open a command prompt as admin on the initial node (where TSM is installed) in the cluster.
2. Run the following command:

```
tsm configuration set -k features.IdentityMigrationBackgroundJob -v false
```

**Note:** The identity migration and the Identity Service is a prerequisite for certain capabilities like [identity pools](#).

## Complete the identity migration and configure the Identity Service

After all user conflicts are resolved or addressed and migration jobs run, you must configure Tableau Server to use the Identity Service to complete the identity migration process.

### Step 1: Validate and complete the identity migration

1. Sign in to Tableau Server as an administrator.
2. From the left navigation pane, select **Users** (or **All Sites > Users** for a multi-site Tableau Server) and then click the **Identity Migration** page to verify the migration has started.

You can monitor and manage its progress using the dedicated Identity Migration page available from Tableau Server's Users page. For more information, see [Manage the Identity Migration](#).

3. Resolve or acknowledge all identity conflicts as described in Resolve Identity Migration Conflicts so that **All failures** tab displays "0" like in the image below.

| All failures | No matches | Ambiguous | Duplicates | Not local | Unknown | Acknowledged |
|--------------|------------|-----------|------------|-----------|---------|--------------|
| 0            | 0          | 0         | 0          | 0         | 0       | 29122        |

4. Do *one* of the following:
  - To run the identity migration job now, next to the Migration Overview heading, click the Edit Schedule drop-down arrow, and then select **Run Now**.

- Alternatively, you can wait for the migration job to run during the next scheduled time.
5. After the migration completes, from the Identity Migration page, validate that the Migration Overview shows **100% complete**.

### Step 2: Configure Tableau Server to use the Identity Service

1. Open a command prompt as an administrator on the initial node (where TSM is installed) in the cluster.
2. Run the following commands:

```
tsm authentication legacy-identity-mode disable  
tsm pending-changes apply
```

**Note:** After running the commands above, the dedicated **Identity Migration** page is removed and no longer accessible. The page is accessible only when `tsm authentication legacy-identity-mode` is enabled.

After Tableau Server is configured to use the Identity Service, when users sign in to Tableau Server, Tableau Server searches for their user identities using their identifiers in the configured identity store. From the identifiers, the universal unique identifiers (UUID) are returned and used to match existing Tableau Server user identities. This process then generates sessions for the users and completes the authentication workflow.

## Resolve Identity Migration Conflicts

During the identity migration, Tableau Server might encounter certain user identities that can't be migrated to use the Identity Service. When user identities can't be migrated, they become identity conflicts that require you, the administrator, to manually resolve.

To ensure user identities are migrated correctly, you must resolve or address all identity conflicts before the identity migration can complete using the dedicated **Identity Migration** page.

### Step 1: Resolve identity conflicts

You can resolve identity conflicts in a few ways depending on the conflict type. Regardless of the conflict type, all user identities must be resolved or addressed before you can proceed to [Step 2](#) below and before the identity migration process can complete.

When identity conflicts occur, the identity migration will group the conflicts into types. These types help narrow down the reason why the migration is unable to migrate the user identity automatically.

There are a few reasons why identity conflicts can occur. For example, you might see an identity conflict when the migration has identified a Tableau Server user that matches more than one user identity in the external identity store.

When identity conflicts are identified, you can address them using one of the following options:

- **Retry Migration** - This option moves the selected user identities back into the queue to be migrated again. After the migration jobs run again, it's possible the identity conflicts resolve on their own, the original identity conflicts occur again, or new identity conflicts occur.
- **Acknowledge** - This option moves the selected user identities to the **Acknowledged** tab. When you acknowledge user identities, you understand that 1) those users don't have matching user identities in an identity store and will therefore not be migrated, and 2) those users will be unable to sign in to Tableau Server after you enable the Identity Service in **Step 3** below.
- **Reevaluate** - When conflicts have already been acknowledged, from the **Acknowledged** tab, this option moves the selected user identities back to their conflict state. This option gives you the chance to see the original conflict, resolve the conflict, or acknowledge the identity conflict again.

Quick reference: Identity conflicts

| Conflict type | Applies to configuration | Conflict reason  | Action   |
|---------------|--------------------------|--|--|
| All failures  | All                      | This tab captures all identity conflicts categorized in the No matches, Ambiguous, Duplicate, Not local, and Unknown tabs. | Retry Migration or Acknowledge   |
| No matches    | AD, LDAP                 | The users identities have no matching users in the external identity store.  | Retry Migration or Acknowledge   |
| Ambiguous     | AD, LDAP                 | For the specified user identities, there is more than one possible match in the external identity store.                   | Retry Migration, Acknowledge, or select one of the suggested user identities |

|              |       |  |                                |
|--------------|-------|--|--------------------------------|
| Duplicate    | AD    | Two user identities were created using one AD account. This is an artifact of legacy functionality that is not supported in the Identity Service.  | Retry Migration or Acknowledge |
| Not local    | Local | User identities that are associated with an identity store that is not local. This conflict occurs because manual changes were made that are not supported.                                | Retry Migration or Acknowledge |
| Unknown      | All   | This conflict might indicate an internal Tableau Server error or an identity conflict caused by a reason not listed in this table.   | Retry Migration or Acknowledge |
| Acknowledged | All   | This tab captures all user identities that will not be migrated. Those users will not be able to sign in to Tableau Server after Tableau Server is configured to use the Identity Service. | Retry Migration or Acknowledge |

To resolve a conflict, follow the steps below.

1. Sign in to Tableau Server as an administrator.
2. From the left navigation pane, select **Users** (or **All Sites > Users** for a multi-site Tableau Server) and then click the **Identity Migration** page.

3. Select one or more user identities in the **All Failures** tab or in one of the conflict-specific tabs.
4. From the Actions drop-down menu, click **Retry Migration** or **Acknowledge**.

If you select “Retry Migration,” the user identities might generate different conflict types. In this case, address the conflicts as needed until the **All failures** tab displays "0" like in the image below.

| Migration failures |            |           |            |           |         |              |
|--------------------|------------|-----------|------------|-----------|---------|--------------|
| All failures       | No matches | Ambiguous | Duplicates | Not local | Unknown | Acknowledged |
| 0                  | 0          | 0         | 0          | 0         | 0       | 29122        |

**Note:** User identities that are acknowledged are ignored in Active Directory (AD) and LDAP group syncs moving forward. If users associated with these users identities require access to Tableau Server at a later time, see [Troubleshoot Issues with the Identity Migration](#) for more information.

## Step 2: Complete the identity migration

To complete the identity migration, in addition to all identity conflicts being resolved or addressed, all migration jobs have to run before you can enable the Identity Service for Tableau Server.

1. Do *one* of the following:
  - To run the identity migration jobs now, next to the Migration Overview heading, click the Edit Schedule drop-down arrow, and then select **Run Now**.

- Alternatively, you can wait for the migration to run during the next scheduled time.

2. From the Identity Migration page, validate that the Migration Overview displays **100% complete**.

### Step 3: Configure Tableau Server to use the Identity Service

After the identity migration is complete, configure Tableau Server to use the Identity Service to ensure a more secure and immutable identity structure for the user provisioning and authentication process.

1. Open a command prompt as an administrator on the initial node (where TSM is installed) in the cluster.
2. Run the following commands:

```
tsm authentication legacy-identity-mode disable  
tsm pending-changes apply
```

**Note:** After running the commands above, the dedicated **Identity Migration** page is removed and no longer accessible. The page is accessible only when `tsm authentication legacy-identity-mode` is enabled.

After Tableau Server is configured to use the Identity Service, when users sign in to Tableau Server, Tableau Server searches for their user identities using their identifiers in the configured identity store. From the identifiers, the universal unique identifiers (UUID) are returned and used to match existing Tableau Server user identities. This process then generates sessions for the users and completes the authentication workflow.

## Troubleshoot Issues with the Identity Migration

### Unable to restore backup

After upgrading to Tableau Server 2022.1 (or later), restoring a Tableau Server backup might cause the following error:

*“The backup cannot be restored because Tableau Server uses the new identity service tables by default.”*

This issue might occur when Tableau Server needs to run the identity migration, which is a necessary process to populate the Identity Service. The Identity Service is an identity schema that was introduced beginning with Tableau Server 2022.1 and is used to provision and authenticate users. To prevent any potential issues, the restore process can't proceed when Tableau Server detects that the Tableau Server backup uses a different identity schema than the version that it's being restored to.

**Note:** The Identity Service is the default identity schema in Tableau Server version 2022.1-2022.1.7, 2022.3-2022.3.9, and 2023.1-2023.15.

To resolve this issue, follow the steps described below.

Step 1: Enable `legacy-identity-mode` and restore the backup

1. Open a command prompt as an administrator on the initial node (where TSM is installed) in the cluster.
2. Set Tableau Server 2022.1 (or later) to use the legacy identity store mode by running the following commands:

```
tsm authentication legacy-identity-mode enable  
tsm pending-changes apply
```

Tableau Server must use the legacy identity store mode to populate the Identity Service. For more information about the `tsm` command, see [tsm authentication legacy-identity-mode](#).

- Restore the backup again to enable the migration to initiate by running the following commands:

```
tsm maintenance restore --file <file_name>
tsm start
```

**Important:** After the backup is restored, the migration populates the Identity Service with identity information. For general information about restoring from backup, see [Restore from a Backup](#).

#### Step 2: Validate and complete the identity migration

- Sign in to Tableau Server as an administrator.
- From the left navigation pane, select **Users** (or **All Sites > Users** for a multi-site Tableau Server) and then click the **Identity Migration** page to verify the migration has started.

You can monitor and manage its progress using the dedicated Identity Migration page available from Tableau Server's Users page. For more information, see [Manage the Identity Migration](#).

- Resolve or acknowledge all identity conflicts as described in [Resolve Identity Migration Conflicts](#) so that **All failures** tab displays "0" like in the image below.

| All failures | No matches | Ambiguous | Duplicates | Not local | Unknown | Acknowledged |
|--------------|------------|-----------|------------|-----------|---------|--------------|
| 0            | 0          | 0         | 0          | 0         | 0       | 29122        |

- Do *one* of the following:
  - To run the identity migration job now, next to the Migration Overview heading, click the Edit Schedule drop-down arrow, and then select **Run Now**.

- Alternatively, you can wait for the migration job to run during the next scheduled time.
5. After the migration completes, from the Identity Migration page, validate that the Migration Overview shows **100% complete**.

### Step 3: Configure Tableau Server to use the Identity Service

1. Open a command prompt as an administrator on the initial node (where TSM is installed) in the cluster.
2. Run the following commands:

```
tsm authentication legacy-identity-mode disable  
tsm pending-changes apply
```

**Note:** After running the commands above, the dedicated **Identity Migration** page is removed and no longer accessible. The page is accessible only when `tsm authentication legacy-identity-mode` is enabled.

After Tableau Server is configured to use the Identity Service, when users sign in to Tableau Server, Tableau Server searches for their user identities using their identifiers in the configured identity store. From the identifiers, the universal unique identifiers (UUID) are returned and used to match existing Tableau Server user identities. This process then generates sessions for the users and completes the authentication workflow.

## “Unexpected error” on Identity Migration page

After resolving or acknowledging all user identities from the Identity Migration page, you see an “Unexpected error” message. This message can display when you’ve tried to resolve or acknowledge more than 1000 user identities at one time.

To resolve this issue, select and resolve or acknowledge 1000 or less user identities, and then try again.

For more information about managing identity conflicts, see [Resolve Identity Migration Conflicts](#).

## Migration progress appears unresponsive or stuck

If the migration status or migration progress bar appears unresponsive or stuck, validate that you have resolved and acknowledged all user conflicts under **Migration failures**.

To resolve this issue, ensure all conflicts are resolved and acknowledged by selecting one or more users identities in the **All failures** tab and clicking **Acknowledge** from the Actions drop-down menu. Perform this task until the **All failures** tab displays "0." For more information about managing identity conflicts, see [Resolve Identity Migration Conflicts](#).

| Migration failures ⓘ |            |           |            |           |         |              |
|----------------------|------------|-----------|------------|-----------|---------|--------------|
| All failures         | No matches | Ambiguous | Duplicates | Not local | Unknown | Acknowledged |
| 21547                | 0          | 0         | 5          | 0         | 21542   | 7575         |

| Migration failures ⓘ |            |           |            |           |         |              |
|----------------------|------------|-----------|------------|-----------|---------|--------------|
| All failures         | No matches | Ambiguous | Duplicates | Not local | Unknown | Acknowledged |
| 0                    | 0          | 0         | 0          | 0         | 0       | 29122        |

**Note:** After all identity conflicts have been resolved or addressed, all migration jobs have to run before you can enable the Identity Service for Tableau Server. You can run the migration jobs now by clicking the Edit Schedule drop-down arrow next to the Migration overview heading, and then selecting **Run Now**. When the Migration Overview shows **100% complete**, you can configure Tableau Server to use the Identity Service. For more information, see Step 3: Complete the identity migration.

### "Identity migration is in progress" pop-up persists

The "identity migration is in progress" notification persists despite completing the identity migration because the Identity Service has not been enabled yet. To complete the identity migration the Identity Service needs to be enabled in Step 4: Configure Tableau Server to use the Identity Service so that Tableau Server can use the identity structure that enables identity pools capability.

### Identity Migration page disappears

When the identity migration is complete and Tableau Server is configured to use the Identity Service, the dedicated **Identity Migration** page is removed and no longer accessible. The Identity Migration page is needed only for the identity migration or when `tsm authentication legacy-identity-mode` is enabled.

## Users can't sign in

After the identity migration has completed and the Identity Service enabled, some users are unable to sign in to Tableau Server. In most cases, this issue occurs to users whose identities had conflicts and were subsequently **Acknowledged** during the identity migration. Users identities that were acknowledged are not migrated to the Identity Service and subsequently ignored during Active Directory (AD) or LDAP group syncs going forward.

If users associated with those acknowledged user identities require access to Tableau Server again, manually add the users to Tableau Server. After the users are manually added, subsequent AD or LDAP group syncs recognize the user identities and sync as expected.

## Revert identity migration

If there are issues, such as certain users not being able to sign in to Tableau Server, that you believe are caused by the Identity Service, you can use the `tsm authentication legacy-identity-mode` command to revert back to use the legacy identity store mode. After reverted, both new users who were added after the identity migration and users who could only sign in to Tableau Server before the migration are able to sign in to Tableau Server without any issues.

After reverting from the Identity Service to the legacy identity store mode, you can use the Identity Migration page to run the migration for the problematic user identities. For more information about managing identity conflicts, see [Resolve Identity Migration Conflicts](#).

# Provision and Authenticate Users Using Identity Pools

Introduced in Tableau Server version 2023.1, identity pools are an identity management tool that uses provisioning and authentication information to enable user access to Tableau Server. Identity pools enable a more centralized and flexible identity management workflow built on the [Identity Service](#) for the storage and management of user identities in Tableau Server.

Identity pools do not replace the user provisioning and authentication configurations you make using Tableau Services Manager (TSM) during Tableau Server setup. Instead, identity pools are designed to complement and support additional user provisioning and authentication options you might need in your organization, particularly for organizations where TSM is configured with Active Directory (AD) or Lightweight Directory Access Protocol (LDAP). Identity pools add an alternative method, after Tableau Server setup, that supports Tableau Server administrators to add users, who are often external users, partners, or contractors, to your Tableau Server deployment.

Identity pools are optimized for the following use cases:

- **External users:** A large enterprise organization who doesn't want to add external users to their internal AD.

For example, suppose your organization has two types of employees: regular employees and contract employees. Your regular employees are provisioned through Active Directory (AD) with SAML authentication that is managed through your IdP, Okta. Your contract employees consist of users who are typically assigned temporary group membership or are a part of another organization who provisions users outside of AD and authenticates separately. Identity pools can enable you to add Tableau Server users who are external to your AD.

- **Multiple identity stores:** An organization hosting SaaS applications that sources users from multiple identity stores.

For example, suppose your organization shares Tableau content to multiple external organizations from a single site. You can separate these users using different identity pools configured with local identity stores to more easily identify and manage the users from each organization.

- **Security boundaries between internal organizations:** An organization of multiple acquired child organizations with distinct security boundaries.

For example, you can add users from the newly added organization to an identity pool configured with a local identity store to work around the complexities associated with combining identity stores.

## What are identity pools?

An identity pool has three main components: an identity store to provision users, OpenID Connect (OIDC) authentication, and assigned users.

- **Identity store:** The **identity store** that you source or provision your users can be a local identity store or an external identity store.
  - If a local identity store, an identity pool can be configured to use a new local identity store or an existing local identity store. **Note:** Local authentication is not supported.
  - If an external identity store, an identity pool can only use the same external identity store (AD or LDAP) that you configured in TSM during Tableau Server setup. You can't configure an identity pool to use a different external identity store.

The provisioning and authentication configurations you make in TSM during Tableau Server setup is referred to as the default or “initial pool (TSM configured).”

- **Authentication:** The only supported authentication method for an identity pool is **OIDC**.
- **Users:** In order for users to sign in to Tableau Server, they must either be sourced from the initial pool (TSM configured) or be a member of at least one identity pool.

## When to use identity pools

As a Tableau Server administrator, you can use an identity pool to segment your users into identity cohorts based on where your users are provisioned from and how those users authenticate into Tableau Server. Though the identity store and authentication configurations you

make in TSM during Tableau Server setup, also referred to as the initial pool (TSM configured), remains unchanged, identity pools are configurable from Tableau Server.

**Note:** Identity pools are currently available for server-level configuration only. Identity pools can't be scoped to a site.

## More about identity pools

### Initial pool (TSM configured) versus identity pools

As noted above, the combination of provisioning and authentication configurations you make in TSM during Tableau Server setup is referred to as the "initial pool (TSM configured)". The initial pool (TSM configured) is a required component of the Tableau Server setup process and cannot be modified.

An identity pool, however, is optional and you can create as many identity pools as needed from Tableau Server directly.

### Identity pools impact on users' sign-in experience

By default, when no identity pools are created for Tableau Server, there is no change to how your users navigate to the Tableau Server landing page and sign in to Tableau Server.

When one or more identity pools are created, the Tableau Server landing page displays multiple sign-in options. The primary sign-in option is displayed at the top of the page and is the way your users that belong to the initial pool (TSM configured) can sign in.

Below the primary sign-in option are the secondary sign-in options. Each option represents an identity pool, displayed in the order they were created. Users assigned to those pools must sign in using the option for the identity pool they belong to. To help guide your users to the correct sign-in option, consider adding a description to the identity pool when creating one.

**Note:** All users will see all pools that are configured for your Tableau Server, regardless of their pool membership.

## Username and identifiers in Tableau

A username is the information that represents the system user. An identifier is used to supplement the username information and can be used by external identity stores as alternatives to usernames.

In Tableau, a username is an immutable value that is used to sign in to Tableau and identifiers are mutable values used in Tableau's identity structure as a way to match users to their usernames. Identifiers enable Tableau to be more flexible because they can deviate from the username. If there are changes to the username in the external identity store, Tableau Server administrators can update the identifier to ensure users are matched to the correct usernames.

When you add an existing user to an identity pool, you might expect the ability to set an identifier. For example, if an existing user belongs to an identity pool configured with a local identity store and you want to add them to an identity pool configured with an AD identity store, we ask you to provide the username to search for identifiers associated with that user. On the other hand, if an existing user belongs to an identity pool configured with an AD identity store and you want to add them to an identity pool configured with a local identity store, we ask you to provide an optional identifier. An exception to this is if you want to add a user to the initial pool (TSM configured) that's configured with a local identity store and local authentication. You will be unable to set an identifier for that user.

## Set Up and Manage Identity Pools

To create and manage identity pools, you are required to programmatically make calls against the [Identity Pools Methods](#) using the Tableau REST OpenAPI. To add or manage users in an identity pool, you can use Tableau Server user interface (UI) directly or through the Tableau REST API.

The identity pools setup process is summarized in the following steps.

1. **Configure Tableau Server and establish a session.**

## Tableau Server on Linux Administrator Guide

2. **Provision users** by setting up a new local identity store instance. **Note:** You can skip this step to use an existing local identity store or the external identity store you configured in TSM during Tableau Server setup.
3. **Set up authentication** to authenticate your users to Tableau Server using OpenID Connect (OIDC).
4. **Create an identity pool** that uses the identity store and OIDC authentication you configured.
5. **Add users to an identity pool** by using Tableau Server UI or REST API to enable users to sign in to Tableau Server.

After setup, you can [test](#), [manage](#), and [troubleshoot](#) your identity pools.

**Note:** You can use the [Identity Pools](#) Postman collection in the Salesforce Developer's Postman workspace to learn about, develop, and test the methods described in this topic.

## Prerequisites

Before getting started with identity pools, the following requirements must be met:

- Integration with an OIDC identity provider (IdP), such as Okta, is already configured
- You are running Tableau Server 2023.1 or later
- You have performed the [identity migration](#) if you are running Tableau Server after upgrading from version 2021.4 or earlier

## Get started

Step 1: Configure Tableau Server and establish a session

Enabling changes associated with setting up identity pools require a one-time TSM configuration and a declaration of session and host variables.

1. Open a command prompt as an administrator on the initial node (where TSM is installed) in the cluster.
2. Run the following command:
  - a. `tsm configuration set -k gateway.external_url -v http://<host>`
  - b. `tsm pending-changes apply`

For example, you can run the following commands to configure your Tableau Server, `http://myco`:

```
tsm configuration set -k gateway.external_url -v http://myco
tsm pending-changes apply
```

For more information, see [gateway.external\\_url](#).

3. (Optional) Run the following commands to add a description for the initial pool (TSM configured):

- a. `tsm configuration set -k wgserver.authentication.identity_pools.default_pool_description -v "<description>"`
- b. `tsm pending-changes apply`

For example, you can run the following commands to add a "Sign-in for MyCo employees" description:

```
tsm configuration set -k wgserver.authentication.identity_pools.default_pool_description -v "Sign-in for MyCo employees"
tsm pending-changes apply
```

For more information, see [wgserver.authentication.identity\\_pools.default\\_pool\\_description](#).

4. Sign in to Tableau Server as an administrator and do the following:
  - a. Go to the browser's developer tools and navigate to the application's cookies.
  - b. Note the **workgroup\_session\_id** value.

For example, if working in Chrome, right-click anywhere on the Tableau Server homepage, right-click and select **Inspect**. Click **Application** from the top navigation pane and click **Cookies** from the left navigation pane. Under Cookies, click your Tableau Server name, like `http://myco.com`, and note the **workgroup\_session\_id** value in the center pane.

5. In the script or API developer tool you're using to make identity pools requests using the Tableau REST OpenAPI, do the following:
  - a. Add the `workgroup_session_id` value as a global variable.
  - b. In addition, add port 80, host (your Tableau Server URL), and protocol (HTTP or HTTPS) to your global variables.

For example, the following table shows the global variables necessary for your Tableau Server, `http://myco`.

| Global Variable      | Value   |
|----------------------|---|
| Workgroup session ID | AbC_2ab-cDe-fDwGVzPu1hCQ FJk5Z6OroPCLEDTKk-wDxaeA0YzrIY04f ca608d3c-fc01-4e40-ae5e-9b2131e4e7mm |
| Port                 | 80  |
| Host                 | <code>http://myco</code>  |
| Protocol             | HTTP  |

Step 2: Set up an identity store

Tableau Server requires you to configure an identity store to source or provision your Tableau Server users.

When setting up an identity pool, you can use a new or existing **local identity store**, or you can use an **external identity store**, either Active Directory (AD) or Lightweight Directory Access Protocol (LDAP) if that external identity store was configured during Tableau Server setup.

**Note:** New AD or LDAP instances that are not the AD or LDAP instance you configured in TSM during Tableau Server setup (also referred to as the initial pool (TSM configured)), are not configurable with identity pools.

To set up a new local identity store, use the procedure below. Skip to Step 3: Set up authentication if you want to use an existing local identity store or the identity store you configured during Tableau Server setup.

1. Make a **Sign In** request to the Tableau REST API to generate a credentials token.

Example

URI

```
POST https://myco/api/3.19/auth/signin
```

2. After the credentials token is generated, add the credentials token to the header of all subsequent API requests.
3. Configure the identity store by calling the **Configure Identity Store** endpoint using the Tableau REST API OpenAPI.
4. In the request, specify the following:
  - a. Type. The type value is always 0 for a local identity store type. If you want to use an existing local identity store or the identity store you configured in TSM during Tableau Server setup, you don't need to set up a new local identity store instance. Instead, skip to Step 3: Set up authentication, below.
  - b. Name. The name must be unique.
  - c. Display name. This is optional.

Example

URI

```
https://myco/api/services/authn-service/identity-stores/
```

Request body (JSON)

```
{
  "type": "0",
  "name": "Local identity store #1",
```

```
"display_name": "Local identity store #1"  
}
```

Response body

*None*

### Step 3: Set up authentication

You can configure OpenID Connect (OIDC) authentication method to authenticate your users.

**Note:** OIDC is currently the only authentication method configurable with identity pools, regardless of the identity store type you use with the identity pool.

1. After setting up an identity store, call the [Create Authentication Configuration](#) endpoint using the Tableau REST API OpenAPI.
2. In the request, specify the following:
  - a. Authentication type. The authentication type values is "OIDC".
  - b. iFrame. The iFrame's default value is "false".
  - c. The required OIDC client ID, client secret, configuration URL, ID claim, client authentication, and username claim.
    - The client ID, client secret is provided by your OIDC IdP.
    - The configuration URL is also provided by your IdP. The URL and can typically use the following format: `https://<idp_url>/well-known/openid-configuration`.
    - The ID claim's default value is "sub". For more information, see [Changing the sub claim](#).
    - The client authentication's default value is "CLIENT\_SECRET\_BASIC".
    - The username claim's default value is "email". For more information, see [Default: using email claim to map users](#).

#### **About username claim**

Tableau uses the username claim for identity matching purposes. If you provide identifiers when adding users to Tableau Server, the identifier is used to match the value provided in the username claim. If no identifiers are provided, Tableau defaults to the username set in Tableau Server.

**Notes:**

- If you intend to use this authentication configuration with an identity pool that uses AD as its identity store, make sure that the assigned user has the AD sAMAccountName value in the username claim.
- If you intend to use this authentication configuration with an identity pool that uses LDAP as its identity store, make sure that the assigned user has the LDAP username value in the username claim.

Example

URI

`https://myco/api/services/authn-service/auth-configurations/`

Request body (JSON)

```
{
  "auth_type": "OIDC",
  "iframed_idp_enabled": true,
  "oidc": {
    "client_id": "0oa1hotzhjv4tyCd08",
    "client_secret": "EsKd2NCxY-BiLu_zcIwr2lJZLziT_7sw9Fi6HV3",
    "config_url": "https://dev-532601-admin.oktapreview.com/.well-known/openid-configuration",
    "custom_scope": "",
    "id_claim": "sub",
    "username_claim": "email",
    "client_authentication": "CLIENT_SECRET_BASIC",
    "essential_acr_values": "",
    "voluntary_acr_values": "",
    "prompt": "login,consent",
    "connection_timeout": 100,
  }
}
```

## Tableau Server on Linux Administrator Guide

```
    "read_timeout": 100,  
    "ignore_domain": false,  
    "ignore_jwk": false  
  }  
}
```

### Response body

*None*

### Step 4: Create an identity pool

Depending on the identity store that you configured during Tableau Server setup, the identity pool you create can have only one of the following identity store and authentication method combinations:

- AD identity store + OIDC authentication
- LDAP identity store + OIDC authentication
- Local identity store + OIDC authentication

The first two combinations require that the initial pool (TSM configured) is configured to use AD or LDAP.

The procedure described below creates an identity pool with last combination, "local identity store + OIDC authentication".

1. After configuring OIDC authentication, call the [Create Identity Pool](#) endpoint using the Tableau REST API OpenAPI.
2. In the request, specify the following:
  - a. Name and description for the identity pool. Both the identity pool name and description are visible to all users on the Tableau Server landing page.
  - b. Identity store instance ID and authentication type instance ID.

### **Notes:**

- To get the identity store instance ID and authentication type instance ID, you can call the [List Identity Stores](#) and [List Authentication Configurations](#) endpoints.
- If you want to create an identity pool that uses the identity store you configured in TSM during Tableau Sever setup, the identity store instance value is always '1'.

### Example

#### URI

`https://myco/api/services/authn-service/identity-pools/`

#### Request body (JSON)

```
{
  "name": "MyCo contractors",
  "identity_store_instance": "2",
  "auth_type_instance": "0",
  "is_enabled": true,
  "description": "Sign-in for MyCo contractors"
}
```

#### Example response body

*None*

3. After creating the identity pool, go to your IdP configurations and set the sign-in redirect URI to `http://<host>/authn-service/authenticate/oidc/<identity_pool_id>/login`.

For example, `http://myco/authn-service/authenticate/oidc/57tgfe21-74d2-3h78-bdg6-g2g6h4734564/login`

**Note:** To get the identity pool ID, you can call the [List Identity Pools](#) endpoint.

### Notes:

## Tableau Server on Linux Administrator Guide

- You can create as many identity pools as your organization needs.
- Other identity store types and authentication methods are supported by the initial pool (TSM) configured. For more information, see [Authentication](#).

### Step 5: Add users to identity pool

You can use Tableau Server directly to add users to an identity pool. Users must belong to the initial pool (TSM configured) or be added to an identity pool to sign in to Tableau Server. When adding users to an identity pool, your workflow can change depending on the identity store that was configured with the identity pool.

The procedure below describes how to add users to an identity through the Tableau Server UI. However, you can add users to an identity pool using the Tableau REST API by calling the [Add User to Identity Pool](#) endpoint.

1. Sign in to Tableau Server UI as an administrator.
2. From the left navigation pane, select **Users** (or **All Sites > Users** for a multi-site Tableau Server).
3. Click the **Add Users** button, and select **Create new user** or **Import users from file**.

#### For **Create new user**:

- a. Select the identity pool you want to add the new user to, and then click Next.
  - i. If you selected an identity pool that's configured with an AD or LDAP identity store, enter usernames, assign site membership, and site roles. When finished, click the **Import Users** button.
  - ii. If you selected an identity pool that's configured with a local identity store, enter the username. The dialog box expands so that you can add a display name, an identifier (in most cases), email address, and set site and site roles. When finished, click the **Create User** button.

For more information about usernames and how to assign site membership and site roles, see [Set Users' Site Roles](#).

### **About usernames and identifiers in Tableau**

A username is the information that represents the system user. An identifier is used to supplement the username information and can be used by external identity stores as alternatives to usernames.

In Tableau, a username is an immutable value that is used to sign in to Tableau and identifiers are mutable values used in Tableau's identity structure as a way to match users to their usernames. Identifiers enable Tableau to be more flexible because they can deviate from the username. If there are changes to the username in the external identity store, Tableau Server administrators can update the identifier to ensure users are matched to the correct usernames.

When you add an existing user to an identity pool, you might expect the ability to set an identifier. For example, if an existing user belongs to an identity pool configured with a local identity store and you want to add them to an identity pool configured with an AD identity store, we ask you to provide the username to search for identifiers associated with that user. On the other hand, if an existing user belongs to an identity pool configured with an AD identity store and you want to add them to an identity pool configured with a local identity store, we ask you to provide an optional identifier. An exception to this is if you want to add a user to the initial pool (TSM configured) that's configured with a local identity store and local authentication. You will be unable to set an identifier for that user.

**For Import users from file:**

- a. Upload a .csv file that contains the following columns in the order listed:

```
username, password, display name, license level, admin  
level, publishing capability, email address, identity pool  
name, identifier
```

**Note:** Username and password are the only required columns. However, if you don't specify the identity pool name, the user will be added to the initial pool (TSM configured). For more information, see [CSV Import File Guidelines](#).

For example, suppose you want to add Henry Wilson and Fred Suzuki to the General Contractors identity pool. Your .csv might contain the following values:

```
henryw,henrypassword,Henry Wilson,View-  
er,None,yes,hwilson@myco.com,General Contractors,hwilson  
freds,fredpassword,Fred Suzuki,Creat-  
or,None,no,fsuzuki@myco.com,General Contractors,fsuzuki
```

**Note:** When one or more identity pools are created, the Tableau Server landing page updates to include sign-in options for users that are members of those identity pools. For more information, see [Provision and Authenticate Users Using Identity Pools](#).

### Test identity pools

After setting up an identity pool, we recommend you test it by signing out of Tableau Server and signing in again as a user that belongs to the identity pool. Make sure you complete the sign in process to ensure that OIDC authentication was configured correctly.

**Note:** If you've configured an optional description for the initial pool (TSM configured) in Step 1: Configure Tableau Server and establish a session or have a Server Settings (General and Customization) note for Tableau Server, we suggest that the description is specific to users who sign in using the initial pool (TSM configured) and the Sign In Customization note applies to all users who sign in to Tableau Server.

## Manage identity pools

You can manage the users in identity pools from both the server-level and site-level Users page. On the Users page, you can see which identity pools users belong to and summary details about the identity pool.

For all other identity pools management tasks, including updating an authentication configuration or identity pool and deleting a local identity store or identity pool, use the Tableau REST API OpenAPI described in the [Identity Pools Methods](#).

## Troubleshoot identity pools

### Limitations of identity pools

Identity pools are available with Tableau Server only.

**Note:** Identity pools are currently available for server-level configuration only. Identity pools can't be scoped to a site.

### Tableau Server landing page shows IdP errors

On the Tableau Server landing page, below the primary sign-in option, an IdP-related error message might display next to an identity pool sign-in option. This OIDC authentication-related issue can occur when one or both of the following are true: 1) Tableau Server hasn't been configured to send an external URL to the IdP and 2) the global variables haven't been declared.

To resolve this issue, make sure you complete the procedure described in Step 1: Configure Tableau Server and establish a session above.

### Tableau Server landing page is not showing identity pools

If the identity pools capability is disabled, you can enable it again using the following TSM commands:

```
tsm configuration set -k features.IdentityPools -v true
```

```
tsm configuration set -k features.NewIdentityMode -v true

tsm configuration set -k wgserver.authentication.legacy_identity_mode.enabled -v false

tsm pending-changes apply
```

**Note:** Running these commands causes Tableau Server to restart.

# Add Users to Tableau Server

You can add users to Tableau Server one at a time or in batches. You can add them to the server as unlicensed users, and then add them to sites and assign site roles as you onboard them to Tableau Server. Or you can add users to sites and specify their site roles at the same time, at which point they are ready to sign in.

## Before you begin

- If your Tableau Server is configured with an Active Directory external identity store, review [User Management in Deployments with External Identity Stores](#) to understand how multiple domains, domain naming, NetBIOS, and Active Directory user name format influence Tableau user management.

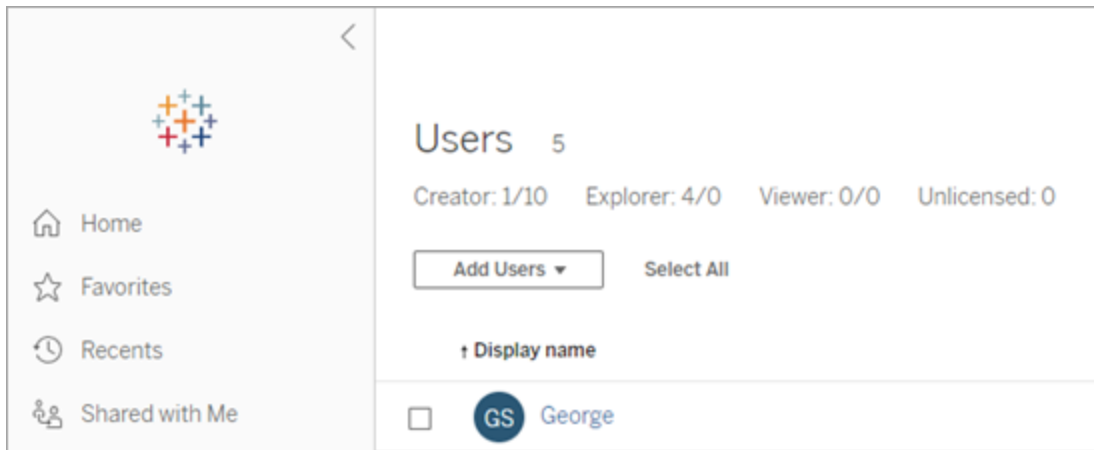

**Note:** In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

- Verify that you have enough user licenses and role licenses for your user base. If you attempt to add a user for a site role that you do not have a license for, then you will receive an error.
- To add user licenses to your Tableau Server deployment, visit the [Tableau Customer Portal](#) to purchase licenses and the corresponding product key(s). After you have purchased licenses, see [Add Capacity to Tableau Server](#) to update the server with the new key(s).

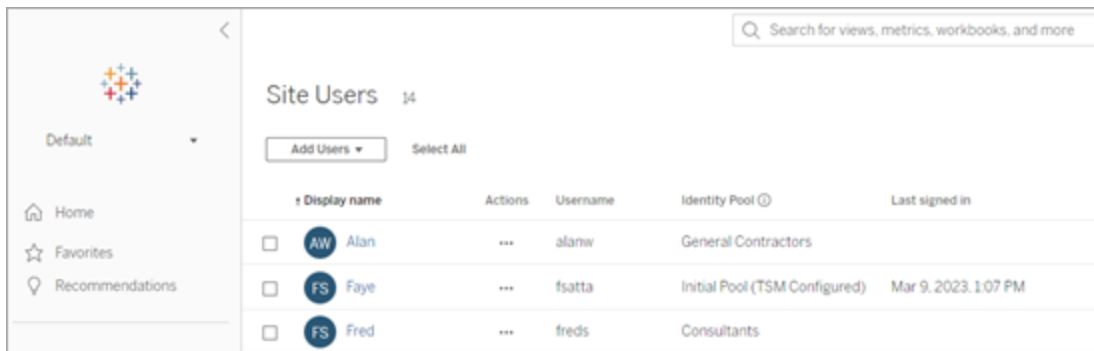

- The steps in this topic describe how to add an individual user and assign their site role. To add users in batches, see Import Users.

## When adding users at the server level versus the site level

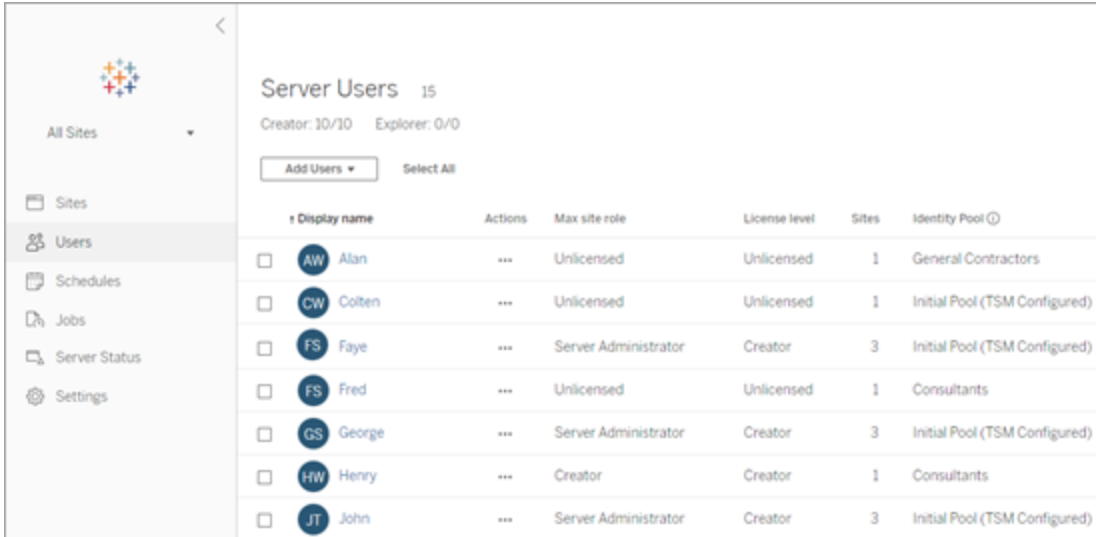

In a single-site environment, server administrators can add users on the **Users** page.

After you add a site to Tableau Server, it becomes a multi-site server with a **Server Users** page (all server users from every site appear here) and a **Site Users** page. Only server administrators can access the **Server Users** page, and both site administrators and server administrators can access the **Site Users** page.

The **Server Users** page is the only place where you can assign users to multiple sites, delete users from the server, and if the server is using local authentication, reset user passwords.

## Add a user to the server

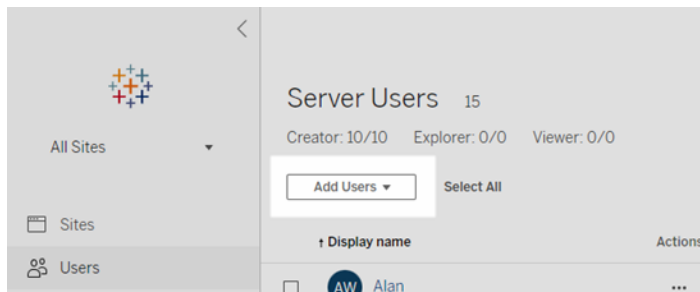

When adding a user, the workflow changes depending on whether at least one **identity pool** is configured for Tableau Server.

### No identity pools configured

If no identity pools are configured, i.e., Tableau Server is only using the user provisioning and authentication configured during Tableau Server setup (also referred to as the initial pool (TSM configured)), follow the steps described below to add a user.

1. In the site menu, select **Manage All Sites > Users**, and then click **Add Users**.

To add a user to a site, you select the site and go to the **Users** page.

## 2. Do one of the following:

- If the server is configured for **local authentication**, click **New User**, and enter a user name. With local authentication, the best way to avoid user name collisions is to provide an email address for the user name. For example, *jsmith@example.com* instead of *jsmith*.

User names are not case sensitive. Characters not allowed in user names include the semi-colon (;) and colon (,).

- If the server is configured for **Active Directory authentication**, click **Active Directory User**. If you are adding a user from the same Active Directory domain that Tableau Server runs on, the server domain will be assumed, and you can type the AD user name without the domain.

**Note:** Do not enter the user's full name; this can cause errors during the importing process.

## 3. If the server is using local authentication, provide the following:

- **Display Name**—Type a display name for the user (e.g., *John Smith*).
- **Password**—Type a password for the user.
- **Confirm password**—Retype the password.
- **Email**—This is optional and can be added at a later time in the user profile settings.
- **Selected users are Server Administrators:** Specify whether the user should be a server administrator.
- **Name (Site Membership) / Site Role:** If the user is not a server administrator, you can assign a user to zero or more sites, along with a site role for each site. You do not have to choose site membership and site role at this time. If you don't

specify site membership and site role for a new server user, the user will be added as a server user only, with a site role of Unlicensed. For details, see Set Users' Site Roles.

- 4. Click **Create**.

**New User**

Username:   
*Username available*

Display name:

Password:

Confirm password:

Email (optional):

All sites

| Site   | Site role <span>ⓘ</span>               |
|--|--|
| <input type="checkbox"/> Documentation - 20 User Limi... |  |
| <input checked="" type="checkbox"/> Finance              | <input type="text" value="Publisher"/> |
| <input type="checkbox"/> Human Resources                 |  |

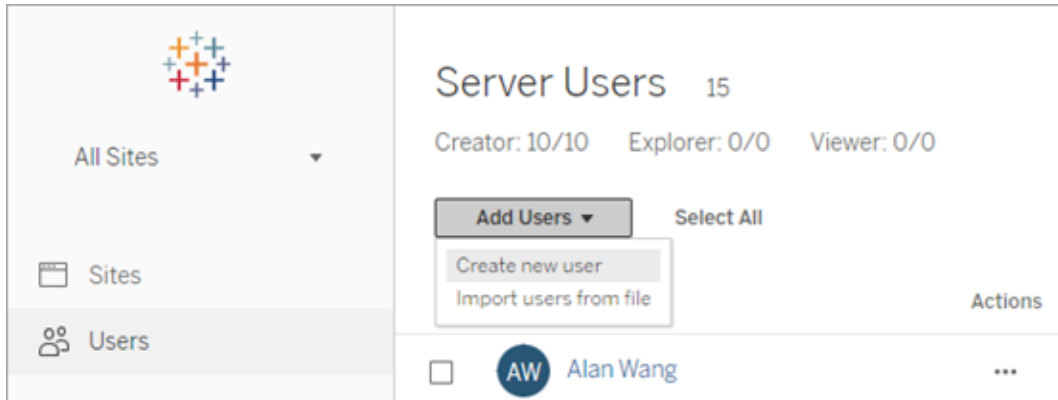

Selected users are Server Administrators

### One or more identity pools configured

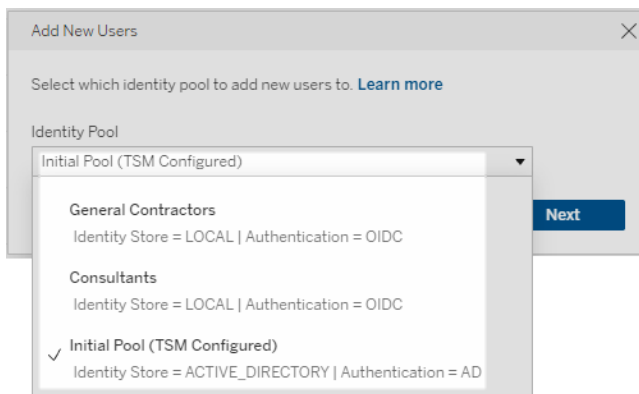

When adding a user, if one or more identity pools are configured, you must first select an identity pool or the **initial pool (TSM configured)**, which is the user provisioning and authentication configured in TSM during Tableau Server setup.

1. In the site menu, select **Manage All Sites > Users**, and then click **Add Users > Create new user**.

To add a user to a site, you select the site and go to the **Users** page.

2. In the Add New Users dialog box, select the identity pool you want to add the user to.

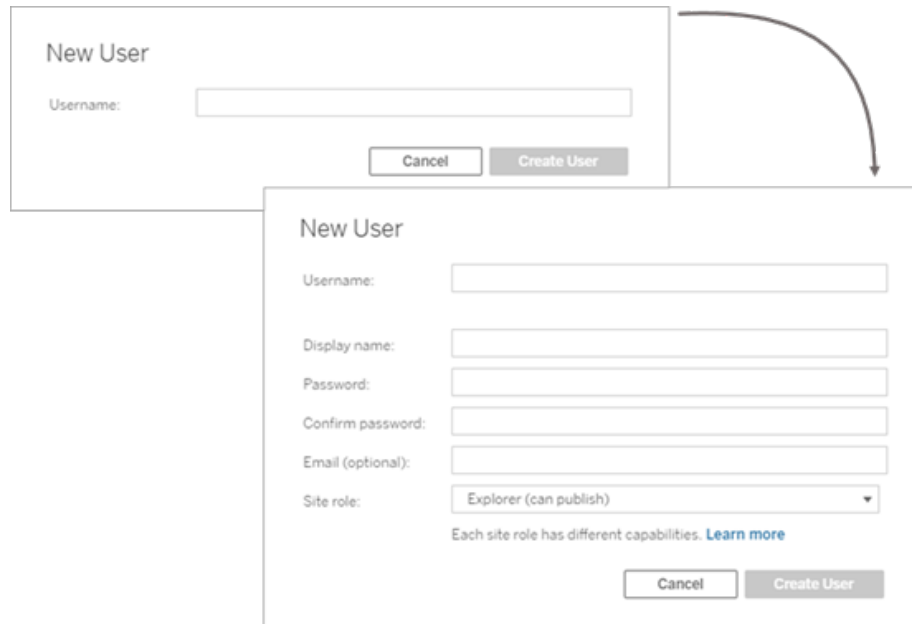

3. Do one of the following:
  - If the identity pool you selected in step 2 is configured for **LOCAL** identity store and **LOCAL** authentication:
    - a. In the New User dialog box, in the **Username** text box, enter a user name. With local authentication, the best way to avoid user name collisions is to provide an email address for the user name. For example,

*jsmith@example.com* instead of *jsmith*.

User names are not case sensitive. Characters not allowed in user names include the semi-colon (;) and colon (,).

b. Enter the following information:

- **Display name**—Type a display name for the user (e.g., *John Smith*).
- **Password**—Type a password for the user.
- **Confirm password**—Retype the password.
- **Email (optional)**—This is optional and can be added at a later time in the user profile settings.
- **Selected users are Server Administrators:** Specify whether the user should be a server administrator.

- **Site Role:** If the user is not a server administrator, you can assign a site role. You do not have to choose site role at this time. If you don't specify site role for a new user, the user will be added as a server user only, with a site role of Unlicensed. For details, see [Set Users' Site Roles](#).
- c. When finished, click **Create User**.
- If the identity pool you selected in step 2 is configured for **LOCAL** identity store with **OIDC** authentication:
  - a. In the New User dialog box, in the **Username** text box, enter a user name. With local authentication, the best way to avoid user name collisions is to provide an email address for the user name. For example, *jsmith@example.com* instead of *jsmith*.

User names are not case sensitive. Characters not allowed in user names include the semi-colon (;) and colon (,).

b. Enter the following information:

- **Display name**—Type a display name for the user (e.g., *John Smith*).
- **Password**—Type a password for the user.
- **Identifier (optional)**—Type the identifier you want to associate with the user. Identifiers are for identity matching purposes. For more information, see *Username and identifiers in Tableau*.
- **Email (optional)**—This is optional and can be added at a later time in the user profile settings.

- **Site and Site role**—If the user is not a server administrator, you can assign a user to zero or more sites, along with a site role for each site. You do not have to choose site membership and site role at this time. If you don't specify site membership and site role for a new server user, the user will be added as a server user only, with a site role of Unlicensed. For details, see [Set Users' Site Roles](#).
  - **Make selected users Server Administrators**—Specify whether the user should be a server administrator.
- c. When finished, click **Create User**.
- If the identity pool you selected in step 2 is configured for **ACTIVE\_DIRECTORY** or **LDAP** identity store:
    - a. Type the AD or LDAP user name without the domain. In this workflow, you're adding a user from the same Active Directory domain that Tableau Server was configured with in TSM during Tableau Server setup. Therefore, the server domain will be assumed, and you can type the AD or LDAP user name without the domain.

**Note:** Do not enter the user's full name; this can cause errors during the importing process.

**Import Users from Active Directory**

Enter Active Directory usernames, separated by semicolons(;).

Site: All sites | Search: Search sites

| Site                     | Site role |
|--------------------------|-----------|
| <input type="checkbox"/> | Default   |
| <input type="checkbox"/> | Site1     |
| <input type="checkbox"/> | Site2     |

Each site role has different capabilities. [Learn more](#)

Make selected users Server Administrators

Cancel Import Users

- b. When finished, click **Import Users**.

## Sign in to the Tableau Server Admin Area

As a server administrator on Tableau Server, you can access admin settings to configure sites, users, projects, and to do other content-related tasks.

If you want to change server settings such as processor, caching, authentication, distributed deployment, and other related configurations, see [Sign in to Tableau Services Manager Web UI](#).

If you are running Tableau Desktop and want to sign in to Tableau Server to publish or access content and data sources, see [Sign in to Tableau Server in Tableau Desktop](#).

Here's how to sign in to the Tableau Server admin pages:

1. Open your browser and enter the server URL. Here are some examples of what the URL might look like:

`http://localhost/` (if you're working directly on the server computer)

`http://MarketingServer/` (if you know the server's name)

`http://10.0.0.2/` (if you know the server's IP address)

If the server is *not* using port 80, you need to include the port number in the URL, as in these examples:

`http://localhost:8000/`

`http://MarketingServer:8080/`

`http://10.0.0.2:8888/`

... where 8000 or 8080 or 8888 is the port that you configured.

Tableau Server displays one of the following pages depending on whether **identity pools** are configured:

- When no identity pools are configured, a page where you can enter a user name and password.

- When identity pools are configured, the Tableau Server landing page with primary (initial pool (TSM configured)) and secondary (identity pools) sign-in

options.

2. Enter the credentials for the server administrator that you created when you finished installing Tableau Server.

You're then taken to the main page of the **Default** site, and you're ready to create users, sites, and manage content.

## Reset the server administrator account and password

If you have lost the password for the initial server administrator account run the following commands:

1. `tsm reset`.
2. `tabcmd initialuser`. See `initialuser`.

## Navigate the Admin Areas of the Tableau Web Environment

As an administrator on Tableau Server or Tableau Cloud, you can access admin settings that aren't available to other users to configure sites, users, projects, and to do other content-related tasks.

The settings in this article refer to the Tableau web environment. Tableau Server administrators with appropriate credentials can also change server settings such as processor, caching, authentication, distributed deployment, and related configurations using the TSM web environment. For information, see [Sign in to Tableau Services Manager Web UI](#).

## Access based on site role and number of sites

The menus you get when you sign in to Tableau Server or Tableau Cloud depend on the following conditions:

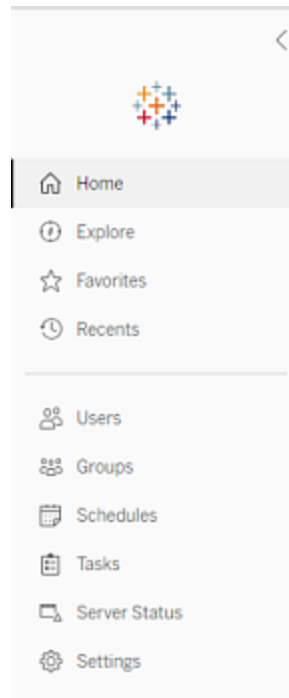

- Whether you're a site or server administrator.

Site administrator access is available on Tableau Cloud and Tableau Server. Server administrator access is only on Tableau Server.

- Whether you have access to only one site or to multiple sites.

### Server administrator

On a **single-site** server, the site selector does not appear, and all other menus are the same.

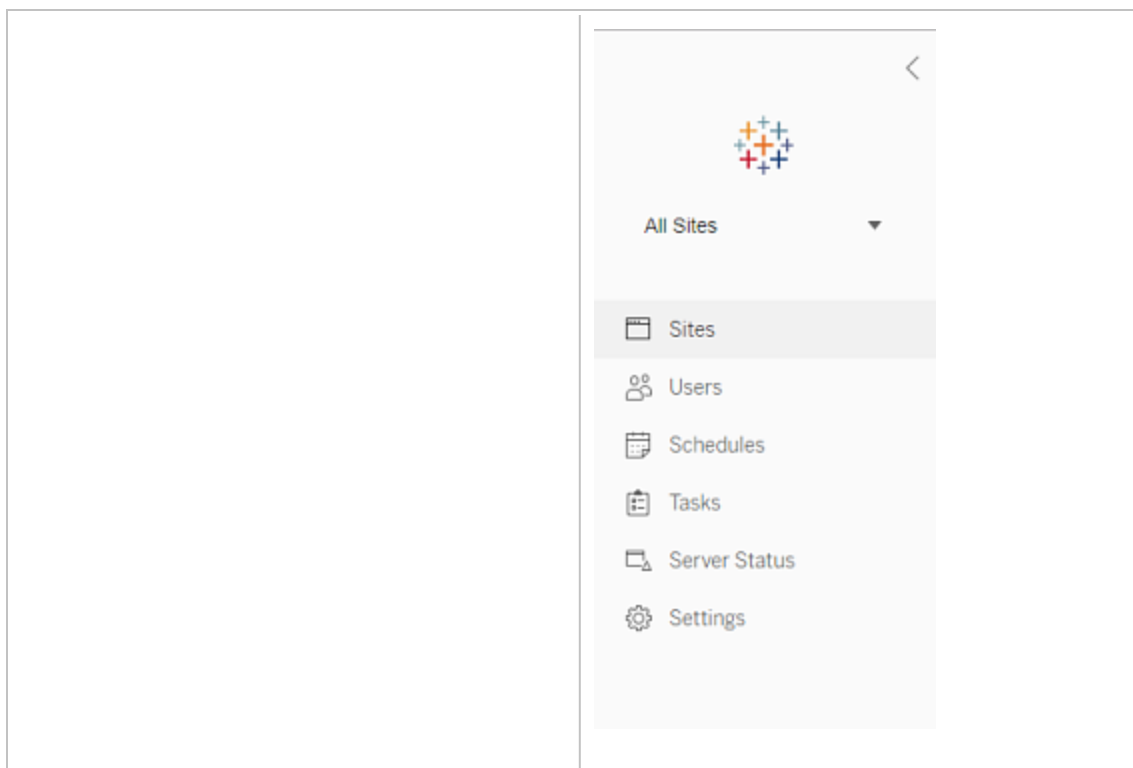

In a **multi-site** environment, menus along the left enable you to modify a specific site or all sites, and to configure users, groups, schedules, tasks, and server settings.

To access server administrator settings that affect all sites, open the site menu by clicking the arrow next to the current site name, and then select **Manage all sites**.

The **Content** and **Group** tabs go away, and the site menu text changes to **All Sites** to let you know you are managing server-wide settings, and options like **Server Status** reflect the server-wide view.

To return to the site administration menus, select **All Sites**, and then select the site you want to manage.

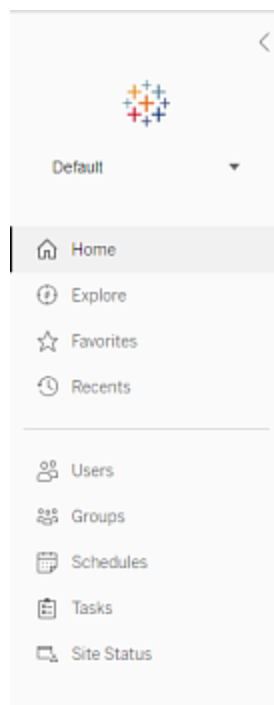

### Site administrator

If you are a site administrator for Tableau Cloud or Tableau Server, and you have access to multiple sites, you'll get menus for selecting which site to manage, and for managing that site's content, users, groups, schedules, and tasks, and for monitoring its status.

The site selector displays the name of the current site. To go to another site, select the site menu, and then select the site name.

If you have access to only one site, the site selector does not appear, but all other menus are the same.

## Server administrator tasks

Server administrators (available with Tableau Server Enterprise only) can do the following:

- Monitor server status and activity.
- Generate log files.
- Add sites and edit site settings. Only server administrators can add sites to the server.
- Add users to the server, and assign users to sites.
- Add and manage site groups.
- Add users to or remove users from [identity pools](#).

To manage settings only for a specific site, you must first navigate to the site. Within each site, you can do the following:

- Administer content: Create projects, move content from one project to another, assign permissions, change ownership of a content resource, and so on.
- Manage schedules for extract refreshes and subscriptions.
- Monitor site activity and record workbook performance metrics.
- Manage storage space limits for content published by users.
- Allow web authoring.
- Enable revision history.
- Allow site administrators to add and remove users.
- Set the maximum number of licenses that site can consume for each license type (Creator, Explorer, Viewer).
- Allow users to subscribe to workbooks and views, and allow content owners to sub-

scribe others to workbooks and views.

- Enable offline snapshots for favorites (iOS only).

## Site administrator tasks

A site administrator on Tableau Cloud or Tableau Server can do the following tasks:

- Administer content: Create projects, move content from one project to another, assign permissions, change ownership of a content resource, and so on.
- View, manage, and manually run schedules for extract refreshes and subscriptions.
- Add and manage site users (if allowed by the server administrator; see [Site Settings Reference](#)).
- Add and manage site groups.
- Monitor site activity.

# Sign in to Tableau Services Manager Web UI

This topic explains how to sign in to the Tableau Services Manager (TSM) web UI. The TSM web pages are used to configure Tableau Server settings such as user authentication, server processes, caching, and other server-related settings. You can also configure TSM from a command line shell. See [tsm Command Line Reference](#).

**Important:** Signing into TSM is *not* the same as signing into Tableau Server. TSM is used to configure the server, and requires an account with administrative privileges on the computer running TSM. Depending on how your enterprise is organized, the TSM administrator could be a user who does not have a Tableau Server account. A Tableau Server administrator has access to administrative pages for creating and editing sites, user, product, and other content-related tasks. For information about signing into Tableau Server as a Tableau Server administrator, see [Sign in to the Tableau Server Admin Area](#).

If you are running Tableau Desktop and want to sign in to Tableau Server to publish or access content and data sources, see [Sign in to Tableau Server in Desktop](#).

## Requirements

- The account that you use to sign in to TSM must have authorization to make changes on the local computer where Tableau Server is installed.

Specifically, the account that you use to sign in to TSM must be a member of the TSM authorization group that was created during initialization. The default name of the TSM authorization group is `tsmadmin`.

To view the user accounts in the TSM authorization group, run the following command in the Bash shell. This example uses the default group name, `tsmadmin`:

```
grep tsmadmin /etc/group
```

If the user account is not in the group, run the following command to add the user to the `tsmadmin` group:

```
sudo usermod -G tsmadmin -a <username>
```

Tableau Server on Linux relies on PAM for core authentication scenarios. For more information about PAM integration for TSM administration, see [TSM Authentication](#).

- If you are running a distributed deployment of Tableau Server, then enter the host name, or IP address of the computer running the initial node. The credentials you enter must have administrative access to the computer running the initial node, as specified above.
- Specify an HTTPS protocol in the server URL. Tableau Server installs a self-signed certificate as part of the installation process. Therefore, the protocol must be specified as `https`. For more information about the self-signed certificate and certificate trust for TSM connections, see [Connecting TSM clients](#).
- Specify the port for TSM web UI (8850) in the URL.

- If you are running a local firewall, open port 8850. See [Configure Local Firewall](#).
- You must specify the hostname or IP address of the computer running TSM. If you have set up a load balancing or proxy solution in front of Tableau Server, do not specify the load balancer or proxy address.
- As a security best practice, do not expose the TSM port (by default, 8850) to the internet.

## Sign in to the TSM web UI

1. Open a browser and enter the Tableau Server URL, and append the dedicated TSM web UI port.

Here are some examples of what the URL might look like:

`https://localhost:8850/` (if you're working directly on the server computer)

`https://MarketingServer:8850/` (if you know the server's name)

`https://10.0.0.2:8850/` (if you know the server's IP address)

2. In the sign-in page that appears, enter your administrator user name and password.

**Note:** Tableau Server creates and configures a self-signed certificate during the installation process. This certificate is used to encrypt traffic to the TSM Web UI. Because it's a self-signed certificate, your browser will not trust it by default. Therefore, your browser will display a warning about the trustworthiness of the certificate

before allowing you to connect.

The screenshot shows the Tableau Services Manager sign-in interface. At the top is the Tableau logo, which consists of a cluster of plus signs followed by the text 'tableau'. Below the logo is the heading 'Sign In to Tableau Services Manager'. Underneath the heading is a note: 'Requires administrator access to the computer where Tableau Server is installed.' There are two input fields: one for 'Username' and one for 'Password'. Below these fields is a green button labeled 'Sign In'.

## Customize Your Server

You can customize the Tableau Server web pages to personalize it for your company or group.

You can perform these customizations:

- Change the server name that appears in the browser tab, tooltips, and messages.
- Change the logos that appear in the web environment.

For more information, see [tsm customize](#).

- Set the language used for the web environment and the locale used for views. See Language and Locale for Tableau Server.
- Install custom fonts on Tableau Server and client computers that connect to Tableau Server. See Use Custom Fonts in Tableau Server.
- Add a custom note to the server sign in page. The Sign In setting lets you add text. You can optionally add a URL to make the text a link. This note will also appear if a user receives a sign in error.

Custom notes do not display on Tableau Mobile. If Tableau Server is configured with [identity pools](#), the Sign In Customization note appears on both the Tableau Server landing page below all sign-in options and on the page where your initial pool (TSM configured) users enter their username and password.

To set a custom note, sign in to a site on Tableau Server. On the left-side navigation pane, select **Manage all sites** from the drop-down site list. Select **Settings** and add a message to **Sign In Customization**.

For more information, see Server Settings (General and Customization).

- Add a custom message to the welcome banner on the home page for all server users to see. The custom message can contain up to 240 characters of text and hyperlinks as well as one paragraph break. Administrators can also disable the default Tableau welcome banner for the server.

To set a custom welcome banner, sign in to a site on Tableau Server. On the left-side navigation pane, select **Manage all sites** from the drop-down site list. Select **Settings**, then navigate to the **Customization** page.

Administrators and project leaders can also add images for projects in thumbnail view.

## Language and Locale for Tableau Server

Tableau Server is localized into multiple languages. Server language and locale settings impact how this affects users. The **Language** setting controls user interface (UI) items such

as menus and messages. The **Locale** setting controls items in views such as number formatting and currency.

Administrators can configure language and locale on a server-wide basis and individual users can configure their own settings (search for "Your Account Settings" in the Tableau Server Help). If a user configures their own language and locale, their settings override the server settings.

### Supported Languages

Tableau Server is localized into multiple languages. See the "Internationalization" section of the [Tableau Server Technical Specification](#) page for more information.

### Default Settings

The default language for Tableau Server is determined during Setup. If the host computer is configured for a language Tableau Server supports, Tableau Server installs with that language as its default. If computer is configured for a language that is not supported, Tableau Server installs with English as its default language.

### How Language and Locale are Determined

Another influence on which language and locale display when a user clicks a view is the user's web browser. If a server user has not specified a **Language** setting on their User Account page, and their web browser is set to a language that Tableau Server supports, the browser's language will be used—even if Tableau Server itself is set to a different language.

Here's an example: Assume that Tableau Server has a system-wide setting of English as the **Language** for all users. Server user Claude does not have a language specified on his Tableau Server User Account page. Claude's browser uses German (Germany) for its language/locale.

When Claude signs in to Tableau Server, the server UI displays in German and when he clicks a view, the view uses the Germany locale for numbers and currency. If Claude had set his user account **Language** and **Locale** to French (France), the UI and view would have been

displayed in French. His user account setting supersedes those of his web browser, and both of those have precedence over the Tableau Server system-wide setting.

Another setting to be aware of is the **Locale** setting in Tableau Desktop (**File > Workbook Locale**). This setting determines the locale of the data in the view, such as which currency is listed or how numbers are formatted. By default, **Locale** in Tableau Desktop is set to **Automatic**. However, an author can override that by selecting a specific locale. Using the above example, if the author of View A set **Locale** to **Greek (Greece)**, certain aspects of the data in View A would display using the Greek (Greece) locale.

Tableau Server uses these settings, in this order of precedence, to determine language and locale:

1. Workbook locale (set in Tableau Desktop)
2. Tableau Server User Account language/locale settings
3. Web browser language/locale
4. Tableau Server Maintenance page language/locale settings
5. Host computer's language/locale settings

## Use Custom Fonts in Tableau Server

You can use custom fonts with Tableau Server. When you do this the safest way to guarantee that users have the experience you intend is to keep the following in mind:

- 
- The fonts need to be installed on the computer where Tableau Server is running. After installing the fonts, restart Tableau Server to use the new fonts.
- The fonts need to be installed on any client computers that will connect to Tableau Server. You need to have the fonts installed locally in order for your browser to properly display them.

- As a best practice, use "web safe" fonts that are installed by default on all major browsers. This increases the likelihood that the fonts will display properly on client machines.
- Different browsers render the same fonts differently, so even when a client browser has the custom font installed, it may look different when viewed in different browsers. This can be especially noticeable with comments or titles where specific spacing is used for an intentional effect.

**Note:** For more information about installing fonts on Linux, refer to your Linux distribution's documentation and support.

## Manage Sites Across a Server

You can plan and manage your sites in Tableau Server. You can manage users and groups for your sites, manage projects and content access, manage data, and create and interact with views on the web.

### Sites Overview

The topics in this section describe the Tableau Server concept of a site and aspects of working with multiple sites. Topics include authentication type each site uses, and what to know about user licenses and administrator-level access to sites.

#### What is a site

You might be used to using the term *site* to mean “a collection of connected computers,” or perhaps as the short form of “website.” In Tableau-speak, we use site to mean a collection of users, groups, and content (workbooks, data sources) that’s walled off from any other groups and content on the same instance of Tableau Server. Another way to say this is that Tableau Server supports multi-tenancy by allowing server administrators to create sites on the server for multiple sets of users and content.

All server content is published, accessed, and managed on a per-site basis. Each site has its own URL and its own set of users (although each server user can be added to multiple sites). Each site's content (projects, workbooks, and data sources) is completely segregated from content on other sites.

For site administrator recommendations for how to set up users on a site, how to structure a site for publishers and other content users, how to give users permissions to share and manage their content, and so on, see the [Manage Individual Sites](#) section.

For information about how users can get their content to Tableau Server, see [Publish Data Sources and Workbooks](#) in the Tableau user help.

## Authentication and sign-in credentials

By default, all sites on a server use the same identity store type. You configure these settings when you install Tableau Server. For information, see [Configure Initial Node Settings](#).

Users who have access to more than one site on the same Tableau Server instance use the same credentials for each site. For example, if Jane Smith has a user name of *jsmith* and a password of *MyPassword* on Site A, she uses those same credentials on Site B. When she signs in to Tableau Server, she'll be able to choose which site she wants to access.

## The Default site

Tableau Server installs with a site named Default. If you maintain a single-site environment on Tableau Server, this becomes the site you work with, and on which your users share their Tableau analysis. If you add sites, Default becomes one of the sites you can select when you sign in to Tableau Server. Default differs from sites that you add to the system in the following ways:

- It can never be deleted but, just like sites that you add, it can be renamed.
- It stores the samples and data connections that ship with Tableau Server.

## Tableau Server on Linux Administrator Guide

- The URL used for Default does not specify a site. For example, the URL for a view named Profits on a site named Sales is `http://localhost/#/site/sales/views/profits`. The URL for this same view on the Default site would be `http://localhost/#/views/profits`.

### Why or why not add sites

On Tableau Server, users, projects, groups, data sources, and workbooks are managed per site. You can add users to multiple sites.

Each environment and its needs is unique. However, as a baseline, Tableau Visionaries and Product Managers tend to recommend using sites for true multi-tenancy needs. In other words, create a new site only when you need to manage a unique set of users and their content completely separately from all other Tableau users and content.

For site administrator recommendations for how to set up users on a site, how to structure a site for publishers and other content users, how to give users permissions to share and manage their content, and so on, see the Manage Individual Sites section.

#### Examples for which it makes sense to use sites

- You are a consultant who manages Tableau analysis for multiple clients, and you want to create a site for each client, to ensure that data from one client is not exposed to another.
- You want to allow Guest user access to a small and contained area of the server.

#### Examples for which projects can work better than sites

- A content-development process in which data sources and reports evolve from sandbox to production phases.

Migrating users and content from one site to another is a laborious process. Although you might have good reasons to use sites for this and similar processes, by creating sites, you as the site administrator compound your ongoing maintenance burden. For each configuration update you make to one site (for example creating new projects and

setting permissions), you usually would need to duplicate the same work on each additional site.

- You want to separate areas of the server by functional area.

Among a group of Tableau users, it's common that some users need to access content in multiple areas. Using sites would encourage publishing the same data sources and reports to multiple sites. This leads to data source proliferation and can negatively impact server performance. Using projects is a simpler way to work with this scenario.

For additional ideas, see the following resources:

- Why use projects in the topic [User Projects to Manage Content Access](#).
- Discussions about sites on the Tableau Community forums. [Here's a link](#) to get you started.

## Administrator-level access to sites

Tableau Server includes three administrator-level site roles: Server Administrator, Site Administrator Creator, and Site Administrator Explorer.

The **Server Administrator** site role always takes the highest license available, and it allows full access to Tableau Server, including all content access. You can find more information about this role in [Server Administrator Overview](#). Server administrators also create sites as needed. (Site administrators don't have permissions to do this.)

A server administrator can assign one of the **Site Administrator** site roles to users to delegate creating and maintaining a specific site's user and content framework. The content framework enables Tableau users to share, manage, and connect to data sources and workbooks.

- Assign **Site Administrator Creator** to administrators who also connect to data, and create and publish data sources or workbooks. This site role takes a **Creator** license.

- Assign **Site Administrator Explorer** if the user manages the content framework but doesn't need to edit the content itself. This site role takes an **Explorer** license, and it allows viewing and interacting access.

By default, the Site Administrator site roles allow creating and managing the site's users and groups, creating projects to organize content on the site, assigning permissions to allow users (groups) to access the content they need, scheduling extract refreshes, and a few other tasks.

A server administrator can deny site administrators' user management tasks. For example, you might do this if you use the Site Administrator Creator role for the data experts. In other words, you want to allow these users to manage connections to underlying data, create and publish "single source of truth" data sources, create top-level projects, and organize content across projects without restriction; but not necessarily add and remove site users.

For each site the server administrator can also limit site administrator access, so that site administrators can manage groups and content, but not add or remove users or set users' site roles.

In some organizations, the same person might be both a server administrator and site administrator for one or more sites. Even so, the tasks performed by a site administrator and a server administrator are distinct.

### Licensing and user limits

You can add server users to multiple sites, and set their site roles and permissions on each site. A user who belongs to several sites does not need a license for each site. Each server user needs only one license. The license that user will use corresponds to the highest site role they have on the server. To learn more about how licenses and site roles intersect, see [Set Users' Site Roles](#).

Server administrators can use the **Limit number of users** setting (select **Site <name> > Settings**) to specify a user limit for the site, or set a site role limit, which limits the number of Creators, Explorers, and Viewers allocated at the site level. To learn more, see [Manage Site Role Limits](#).

Only licensed users are counted. For example, if a site has 90 licensed users (including administrators), 20 unlicensed users, the user count is 90. For information about how to view the number of licenses and site roles across the server, see [View Server Licenses](#).

## Export or Import a Site

**Note:** For detailed information about migrating sites from Tableau Server to Tableau Cloud, see our [Tableau Cloud Manual Migration Guide](#).

You can provision a new Tableau Server site by importing (migrating) information from another site. You do this by exporting the existing site's (the *source* site) information to a file. Then you complete steps to verify and import that information to the *target* site.

### Site Migration Options

You can migrate a site in any of these ways:

- To another site on the same Tableau Server instance.
- To a site on a separate Tableau Server instance.
- From Tableau Server on Windows to Tableau Server on Linux or vice-versa.

**Note:** When migrating sites between instances of Tableau Server, the target site must be on a version of Tableau Server that is the equal to or later than the version of Tableau Server for the source site. Both the source and target sites must be from supported versions of Tableau Server.

## Site Migration Limitations

What information is preserved in a site export

- The export file you create preserves workbooks, projects, data sources, and users. This includes permissions set on content, user favorites lists, and site quotas.
- Users' custom views are preserved; however, depending on the type of site migration, custom view URLs might change in a way that breaks users' bookmarks to their views.
- When you export a site on Tableau Server to import to another Tableau Server site, subscription and extract refreshes schedules are preserved.

What information isn't preserved in a site export

- Usage data, which appears in the site's administrative views, is not preserved. For example, view and data source counts, user actions, and performance data.
- Backgrounder jobs that are in-progress while a site is being exported, will not be exported and will not show up on the new site once the import is complete.
- OAuth access tokens embedded in data connections are reset. For those data sources, you will need to edit the connections and re-authenticate to the underlying data.
- Prep flows and flow schedules are not included. These will need to be manually migrated.
- Content saved to users' Personal Space is not included.

## Prepare the Source and Target Sites

Before you export a site, complete the following checklist to prepare both environments. Some of these instructions depend on whether both sites are on the same server instance or on separate ones.

### Delete stale content

Make sure the source site contains only what you want to import to the new site. As a best practice, remove anything from your source site that you do not want to include in your new site, whether these things will be included in an export/import, or will need to be manually migrated. Delete unused workbooks, data sources, or projects. If you have Prep flows or flow schedules you no longer use, delete these as well.

### Remove obsolete users

Confirm that all server users are licensed, and remove accounts that are no longer in use. You can't remove users during the import process, so if the two sites are on the same server instance, all users you export from the source site are imported to the target site.

### Create or identify the target site

You must import a site file to a site that already exists on the target Tableau Server instance. Because the import process removes anything from the target site that is not included in the import file, we recommend that you import to an empty site. For more information, see [Add or Edit Sites](#).

### Locate site IDs

The tsm command you use to export or import a site requires a parameter that takes the site ID. You can get the site ID from the URL when you are signed in to the site from a web browser.

If only one site exists on the server, that site is named **Default**. When you are signed in to the Default site, the browser URL looks something like this:

```
https://server-name/#/projects
```

In the URL, the absence of the `/site` parameter indicates that it's the Default site. The site ID for the Default site is "Default" without the quotation marks.

## Tableau Server on Linux Administrator Guide

On a multi-site Tableau Server deployment, the browser URL includes `#/site/` followed by the site ID. The following URL would appear if you navigate to the Views page on a site whose site ID is `finance`:

```
https://localhost/#/site/finance/views
```

### Check the identity store

You can export from and import to sites that do not use the same user identity store type, but you will need to modify the mapping files used for the import. This step is built into the import process and described in Step 3: Verify that site settings are mapped correctly.

### Create users on the target server if necessary

The site import process assigns users to the target site. If the source site is on a Tableau Server instance other than the target site, you must create users on the target server before you can perform the import. If the two sites are on the same Tableau Server instance, the target site has access to the existing users, and you can skip this step.

### Configure the target server to deliver subscriptions

Subscriptions are imported, but you must configure the server to deliver them. For more information, see [Set Up a Site for Subscriptions](#).

### Check schedules

The **Schedules** page lists the existing schedules for extract refreshes and subscriptions.

| Schedules 8   |           |           |                 |           |                      |                        |
|---|-----------|-----------|-----------------|-----------|----------------------|------------------------|
| <input type="button" value="+ New Schedule"/> <span style="float: right;">▼ 0 selected</span>                               |           |           |                 |           |                      |                        |
| † Name  | Frequency | Task type | Tasks           | Execution | Next run at          |                        |
| <input type="checkbox"/>  Afternoon-daily  | ...       | Daily     | Subscription    | Parallel  | Aug 4, 2016, 4:00 PM |                        |
| <input type="checkbox"/>  End of the month | ...       | Monthly   | Extract Refresh | 0         | Parallel             | Aug 31, 2016, 11:00 PM |
| <input type="checkbox"/>  Monday morning   | ...       | Weekly    | Subscription    | Parallel  | Aug 8, 2016, 7:00 AM |                        |
| <input type="checkbox"/>  Nightly          | ...       | Daily     | Extract Refresh | 0         | Parallel             | Aug 5, 2016, 12:00 AM  |
| <input type="checkbox"/>  Weekday mornings | ...       | Weekly    | Subscription    | Parallel  | Aug 5, 2016, 6:00 AM |                        |

For migrations **from one Tableau Server site to another**, refreshes and subscriptions assigned to default schedules on the source site are mapped to the same schedules on the target site. If the source site has schedules that do not exist on the target site, and the target site is on another Tableau Server instance, you must create the schedules on the target site that you want the source schedules to map to. You can edit the mapping files to make sure this is done as you expect.

## Tips for importing to a target with fewer users or schedules

When a target site has fewer users or schedules than the source site, many-to-one importing is not supported. How you can address this depends on whether the source and target sites are on the same Tableau Server instance.

You can take any of the following approaches that apply to your site migration use case:

- Remove extra users or schedules from the source site before you export. This is the preferred option if the two sites are on the same server instance.
- Add missing users or schedules to the target site before beginning the import. This is required if the target site is on another server instance.
- Add the missing users or schedules to the target site in the middle of the import process and manually update the mapping files. This is an option only if the sites are on

the same instance.

- Manually map the users or schedules to different users and schedules in the target site during the import process. This is required if a user name differs between servers—for example, the exported user named *adavis@company.com* is defined on the target site as *davisa*.

### Migrating a Site

You must use the `tsm sites` commands to complete the site migration process. The steps below walk you through exporting information from the source site, mapping site settings, and importing the mapped files to the target site.

#### Step 1: Export a site

On the source Tableau Server machine, type the following command:

```
tsm sites export --site-id <source-siteID> --file <filename>
```

Tableau Server must be running when you use the `export` command. During the export process, Tableau Server locks the site you are exporting.

For example, to export a site with site ID **weather-data** to the file **export-file.zip**, type the following:

```
tsm sites export --site-id weather-data --file export-file
```

By default, Tableau Server saves `<export-file>.zip` to `/var/opt/tableau/tableau_server/data/tabsvc/files/siteexports`. For more information, see [tsm File Paths](#).

#### Step 2: Generate the import mapping files

To generate import files for the target site, you need the `.zip` file you created when you completed the steps in Step 1: Export a site.

**Note:** The exported file does not give "Others" read permission by default. Depending on who is importing the file, you may need to adjust the permissions on the file to allow a non-owner to read it.

1. On the target Tableau Server machine, copy the exported .zip file to the directory Tableau Server expects to find the files for importing. For example:
 

```
/var/opt/tableau/tableau_server/data/tabsvc/files/siteimports
```
2. Verify that the target site already exists on Tableau Server, as the import process will not create a new site. For more information, see [Prepare the Source and Target Sites](#).
3. Run the following command on the target Tableau Server machine (Tableau Server must be running):

```
tsm sites import --site-id <target-siteID> --file <export-file.zip>
```

This command generates a set of .csv files that show how source site settings will map to the target site. In the steps described in the next section of this article, you confirm these mappings and adjust them where needed.

By default, these .csv files are generated to a `mappings` directory created under `siteimports`. For example:

```
/var/opt/tableau/tableau_server-  
/data/tabsvc/files/siteimports/working/import_<id>_<date-  
time>/mappings
```

For more information, see [tsm File Paths](#).

### Step 3: Verify that site settings are mapped correctly

The .csv files you generated in the previous section describe how the source site's resources will be assigned to the target site when the import is complete. Items in the files that Tableau Server was unable to map, and that you need to edit, are indicated by a series of question

marks (???). Before you can complete the import process, you must replace the question marks with valid assignments on the target site.

**Important:** Some requirements apply to mapping users, schedules, and published content resources, particularly when the source and target sites are on separate Tableau Server instances. For more information, see [Prepare the Source and Target Sites](#) earlier in this article.

To verify mapping files

1. Navigate to the directory that contains the .csv map files generated by the `tsm sites import` command. By default:

```
/var/opt/tableau/tableau_server-  
/data/tabsvc/files/siteimports/working/import_<id>_<date-  
time>/mappings
```

2. Use your preferred text editor to open one of the .csv files in the `mappings` directory, and do the following.
  - a. Confirm that the mappings are correct.
  - b. If an entry shows a series of question marks (???), replace them with a valid value.

For descriptions of the settings in each of these files, use the tables in [Mapping File Content Reference](#) later in this article.

- c. Save the changes and preserve the CSV file formatting.

Repeat this process for the remaining .csv files.

Step 4: Import the correctly mapped files to the target site

After you verify the site mappings in the .csv files, you can import the settings to the new site to complete the migration process.

1. Run the following command on the target Tableau Server machine:

```
tsm sites import-verified --import-job-dir <import-id-dir-
ectory> --site-id <target-siteID>
```

For example:

```
tsm sites import-verified --import-job-dir /var/-
opt/tableau/tableau_server-
/data/tabsvc/files/siteimports/working/import_ff00_
20180102022014457
--site-id new-site
```

2. When the success message appears, sign in to the new site and confirm that everything was imported as you expected.

**Note:** The `tsm sites import` and `tsm sites export` commands can leave a site in a locked state if an error occurs. To unlock a site, use the `tsm sites unlock` command.

## Mapping File Content Reference

The following tables list the columns in each of the mapping files created when you run the `tsm site import` command.

CSV file name: `mappingsDomainMapperForGroups`

| Column title                    | Can it be edited? | Description   |
|---------------------------------|-------------------|---|
| <code>source_name</code>        | No                | A user group name on the source site.   |
| <code>source_domain_name</code> | No                | The identity store type on the source site: either <b>local</b> (for local identity store) or a domain name (for Active Directory or LDAP |

|                    |      |  |
|--------------------|------|--|
|                    |      | external identity store).  |
| target_domain_name | Yes* | <p>The identity store type on the target site: either <b>local</b> for local identity store, or a domain name (such as example.com or example.lan) for Active Directory or LDAP external identity store.</p> <p>*For the <b>All Users</b> group, keep the <b>target_domain_name</b> value set to <b>local</b>, even if your target server is configured for Active Directory identity store. The <b>All Users</b> group is a special default user group that must exist on every Tableau Server.</p> |

CSV file name: mappingsScheduleMapper

| Column title                 | Can it be edited? | Description  |
|------------------------------|-------------------|--|
| source_name                  | No                | The names of custom and default extract or subscription schedules on the source site.  |
| source_scheduled_action_type | No                | The type of schedule, either <b>Refresh Extract</b> , for extract refreshes, or <b>Subscriptions</b> , for subscription deliveries on the source site.   |
| target_name                  | Yes               | The names of custom schedules on the target site. You can edit this value. For example, if the schedule is named <b>Friday Update</b> on the source site you can rename it <b>Friday Refresh</b> on the target site. |

|                              |     |   |
|------------------------------|-----|---|
| target_scheduled_action_type | No* | <p>The type of schedule, either <b>Refresh Extract</b>, for extract refreshes, or <b>Subscriptions</b>, for subscription deliveries on the target site.</p> <p>*In the rare case that you see question marks (???) in this column, replace them with either <b>Refresh Extract</b> or <b>Subscriptions</b>, to match the entry you see under <b>source_scheduled_action_type</b>.</p> |
|------------------------------|-----|---|

CSV file name: mappingsSiteMapper

| Column title         | Can it be edited? | Description                     |
|----------------------|-------------------|---------------------------------|
| source_url_namespace | No                | The site ID of the source site. |
| target_url_namespace | No                | The site ID of the target site. |

CSV file name: mappingsSystemUserNameMapper

| Column title       | Can it be edited? | Description   |
|--------------------|-------------------|---|
| source_name        | No                | The user name attribute of a user on the source site.   |
| source_domain_name | No                | The identity store type on the source site: either <b>local</b> (for local identity store) or a domain name (for Active Directory or LDAP identity store), or <b>external</b> . |
| target_name        | Yes               | The user name attribute for users who will be assigned to the target site upon import.  |

|                    |     |  |
|--------------------|-----|--|
|                    |     | <p>Confirm that all the user names in the list exist on the target server, and replace question marks (???) with user names that exist on the target server.</p> <p>You cannot create user names by adding rows to the CSV file. Similarly, you cannot remove user names by deleting rows.</p> <p>You can edit a user name in the <b>target_name</b> column to be different from its source user name, as long as the user already exists on the target server with that name.</p> <p>For example, a user can have a <b>source_name</b> value of <b>agarcia@company.com</b> and a <b>target_name</b> value of <b>ash-leygarcia@company.com</b>.</p> <p>You can map a user on the source site to only one user name on the target site.</p> |
| target_domain_name | Yes | <p>The identity store type on the target site: either <b>local</b> (for local identity store) or a domain name (for Active Directory or LDAP external identity store).</p>   |

CSV file name: MappingsScheduleRecurrenceMapperWithAutoCreation

This file does not require updates.

## Add or Delete Sites

Tableau Server comes with one site named Default. Server administrators can add or delete sites as the needs of an organization change.

## Add a site

1. Do one of the following:

- If you're adding a site to the server for the first time, select **Settings > Add a Site**, and then click **Add a Site**.

- If you've added sites before, in the site menu, click **Manage All Sites**, and then click **New Site**.

| Name                          | Users | Site administrators | Max users    |
|-------------------------------|-------|---------------------|--------------|
| Customer Support              | 4     | 2                   | Server limit |
| Default                       | 63    | 8                   | Server limit |
| Development                   | 4     | 2                   | Server limit |
| Documentation - 20 User Limit | 5     | 1                   | 20           |
| Finance                       | 13    | 2                   | Server limit |

2. [Edit the site's settings](#) to customize it for your organization.

## Delete sites

Server administrators can delete sites that have been added to Tableau Server. Deleting a site also removes workbooks and data sources that were published to the site, as well as users. If a user belongs to additional sites, they will not be removed. To permanently delete a user, go to the Server Users page.

**Note:** The Default site cannot be deleted.

1. On the site menu, click **Manage all sites**, and then click **Sites**.
2. Select the site you want to remove, and then on the **Actions** menu, click **Delete**.
3. Click **Delete** in the confirmation dialog box that appears.

## Site Availability

A site can become suspended or locked due to a site import failure, or because a server administrator chooses to suspend the site for a period of time.

When a site is suspended, only the server administrator can activate the site to make it available again.

**Note:** If a site becomes locked and you cannot access the Sites page through the Server interface, use the `tsm sites unlock` command to change the state to active.

### To activate or suspend a site

1. In the site menu, click **Manage All Sites**, and then click **Sites**.
2. Select the site, and then select **Actions** > **Activate** or **Suspend**.

## Manage Site Role Limits

Server administrators can create site role limits to set a maximum number of licenses of each type (Creator, Explorer, or Viewer) that can be consumed on a given site. After a server administrator sets a site role limit, site administrators can add users (thereby automatically consuming licenses) up to that site role limit. If a user is a member of multiple sites across the server, then that user will count against each site's role limit, but will only consume one license (which corresponds to the highest site role they have on the server). Server administrators do not count against site role limits.

To learn more about the capabilities of each site role, see [User-based licenses](#) in the Tableau Server help [Licensing Overview](#). For information for server administrators on how to set up site role limits, see [Site Settings Reference](#).

### Create role limits on a site

Before you can enable site administrators to manage their users, you can [View Server Licenses](#) to determine how to allocate licenses across the Server, or [Add Capacity](#) for new users to the Server.

Server administrators can configure site role limits through the Settings page in the web UI, or through the [REST API](#).

To set a site role limit on a site:

1. Go to the General tab of the Settings page for your site.
  - If you have a single site, on the side navigation, click Settings and General.
  - If you have multiple sites, select the site you want to configure and click Settings and General.
2. Under Managing Users, specify that Server and site administrators can add and remove users.
3. Under Limit the number of users to: select Site Role Limit
4. Set a limit for Creators, Explorers, and Viewers.
5. Click Save

Server administrators can set site role limits within the following restrictions:

- A site role limit cannot exceed the number of licenses of that type that have been activated on the server
- A site role limit cannot be less than the number of users of that site role already present for that site
- If a limit is set for any license type, a limit must be set for every license type.
- If the limit for a role is left blank, the server license limit is used.

### When site role limits are met

If a user is added to a site as an Explorer, they will consume an Explorer license, unless the site has met its role limit set for Explorer. When this happens, a few different things can occur:

- If there are available licenses at a higher tier, the user will be added to the site as an Explorer, but will consume a Creator license.
- If no higher licenses are available, the user is added to the site as an Unlicensed user.

Site role limits can be affected by users consuming licenses that are different than their given site roles (Viewers consuming Explorer licenses, for example). In this case, administrators can unlicense those users, then update the site role quotas. For more information on how to troubleshoot licensing issues, see [Troubleshoot Licensing](#).

## Allow Users to Save Revision History

Revision history enables your users to see how workbooks and data sources (content resources) have changed over time. Each time someone saves (publishes) a content resource, Tableau Server creates a new version, which becomes the current version. It makes the previous version the most recent revision in the revision history list. Revision history gives users confidence to experiment with their content, knowing that their older versions are available.

### Notes

- This information applies to Tableau Server, and is for server administrators who want to allow publishers to work with revisions.
- On Tableau Cloud, workbook and data source revision history are enabled on all sites. Users can save up to 10 revisions.
- For information about working with the content revisions themselves, including potential issues, see [Work with Content Revisions](#) in the User/Analyst section of the Tableau help.

### Permissions users need to work with revision history

To access revision history, a user must have a site role of **Creator** or **Explorer (Can Publish)**, plus the following permissions, depending on the content type:

- Project: **View** and **Save**
- Workbooks in the project: **View**, **Save**, and **Download Workbook/Save As**
- Flows in the project: **View**, **Save**, and **Download Flow/Publish As**
- Data sources in the project: **View**, **Save**, and **Download Data Source**

For virtual connections in the project, you must have a **Creator** site role and the **View** and **Overwrite** permissions. (Virtual connections require Data Management. See About Data Management for details.)

## Enable revision history and set the number of revisions allowed

Revision history is set at the site level, and is enabled by default, with a limit of 25 revisions for each content resource.

1. Sign in to a site as a Server Administrator, and click **Settings**.
2. Under **Revision History**, select **Save a history of revisions**, and enter the maximum number of revisions you want to allow for each content resource.
3. Click **Save**.

When you lower the number of revisions, the most recent revisions are saved. For example, if you set the limit to 15, the 15 most recent versions of the workbook or data source are saved.

**Note:** A content resource's revision history list might not show the changes to the limit until a background cleanup process runs on the server.

## Clear all revisions

Server administrators can delete all previous revisions of published workbooks and data sources from a site. The most recent version of each published workbook and data source is always retained.

1. Sign in to a site as a Server Administrator, and click **Settings**.
2. Under **Revision History**, click **Clear Revision History**.
3. Click **Save**.

## Security for previewing and restoring workbooks

When users select **Restore** or **Preview** for workbook revisions, user passwords are exchanged between the user's browser and the server. Tableau Server encrypts these passwords using public/private key encryption. To ensure these public keys are provided by

Tableau Server, you must configure the server to use SSL (HTTPS). For more information, see [SSL](#).

## See also

[Potential revision history issues](#) in the User/Analyst section of the Tableau help.

## Tableau Mobile App Security Settings

Starting in , you can adjust Tableau Server security policies for the Tableau Mobile app. These policies help keep your data secure by checking to see if mobile devices are compromised, and by limiting certain interactions with the Tableau Mobile app.

The policies apply to only the standard version of Tableau Mobile, not the MAM versions of the app. If you have deployed an MAM app, use the specific to Tableau Mobile, in addition to your MAM system's settings, to secure the app.

### Security settings

Configure security settings for Tableau Mobile either on the site settings page for Tableau Server or using the REST API. For more information about the REST API, see [Mobile Settings Reference](#) in the Tableau REST API Help.

To access the site settings page:

1. Sign into your Tableau Server site as administrator.
2. From the navigation pane, select **Settings**.
3. Select the **Mobile** tab.

Starting in Server 2023.1 settings related to mobile device security are available.

These settings include detecting the following conditions:

- **Jailbreak Detection**

This setting is enabled by default at the **Critical** level and detects whether the app is running on a device that has been jailbroken or rooted.

- **Malware Detection** (Android devices only)

This setting is enabled by default at the **Critical** level and detects whether the device has malware on it.

- **Maximum Days Offline Without a Policy Refresh**

This setting is enabled by default at the **Critical** level with a default maximum of 14 days. It determines if the app can be used on a device that has been offline (and thus without a policy refresh) longer than the configured maximum.

- **Prevent Debugging**

This setting is on by default and cannot be disabled. It detects whether the device has a debugger attached to it.

- **Screen Sharing and Screenshots** (Android devices only)

This setting is enabled by default and determines whether a Tableau Mobile app user can share screenshots or use screen sharing with the app.

You can change the severity level for the Jailbreak Detection and Malware Detection settings:

- **Warn:** Enforce the policy and if it fails, show a dismissible blocking message.
- **Error:** Enforce the policy and if it fails, show a blocking message until the issue is resolved.
- **Critical:** Enforce the policy and if it fails, show a blocking message and the app decides how to handle the logout/clear session through the providers. This is the default.

## Extract Refresh Schedules

Tableau Desktop authors and data stewards can create and publish *extracts*. Extracts are copies or subsets of the original data. Because extracts are imported into the data engine, workbooks that connect to extracts generally perform faster than those that connect to live data. Extracts can also increase functionality.

## Before refreshing extracts

When an extract refresh is performed on extracts created in Tableau 10.4 and earlier (that is, a .tde extract), the extract is upgraded to .hyper extract automatically. While there are many benefits of upgrading to a .hyper extract, you will be unable to open the extract with previous versions of Tableau Desktop. Tableau 2024.2 is the last version where any .tde-based content can be opened. For more information, see [Extract Upgrade to .hyper Format](#).

## Setting up refresh schedules

As a server administrator, you can enable scheduling for extract refresh tasks, and then create, change, and reassign schedules. General scheduling options you change on the server are available as part of the publishing process when a Tableau Desktop user publishes an extract.

Schedules that you create have the following options:

### Priority

The priority determines the order in which refresh tasks are run, where 0 is the highest priority and 100 is the lowest priority. The priority is set to 50 by default.

### Execution mode

The execution mode indicates to the Tableau Server backgrounder processes whether to run refreshes in parallel or serially. Schedules that run in parallel use all available backgrounder processes and serial schedules run on only one backgrounder process. However, a schedule can contain one or more refresh tasks, and each task will only use one backgrounder process, whether in parallel or serial mode. This means that a schedule in parallel execution mode will use all **available** backgrounder processes to run the tasks under it in parallel, but each task will only use one backgrounder process. A serial schedule uses only one backgrounder process to run one task at a time.

By default, the execution mode is set to parallel, so that refresh tasks finish as quickly as possible. You might want to set the execution mode to serial (and set a lower priority) if you have a very large schedule that prevents other schedules from running.

### Frequency

You can set the frequency to hourly, daily, weekly, or monthly.

For information, see [Create or Modify a Schedule](#).

## Refreshing extracts manually

In the Tableau Server web environment, both server and site administrators can run extract refreshes on-demand on the **Schedules** page:

- Select the schedule and click **Actions > Run Now**.

You can also refresh extracts from the command line using the `tabcmd refreshextracts` command. For more information, see [tabcmd Commands](#).

## Refreshing extracts from Tableau Desktop

Tableau Desktop users can refresh extracts they publish and own. They can do this the following ways:

- **At publish time:** When an author publishes a workbook or data source that uses an extract, that author can add it to server refresh schedule. The refresh can be a full or an incremental refresh.

Incremental refreshes reference a column in the extract that has a data type of date, date/time, or integer; such as a timestamp. Tableau uses this column to identify new rows that need to be added to the extract. For more information, see [Refreshing Extracts](#) and [Schedule Extract Refreshes as You Publish a Workbook](#) in the Tableau Help.

- **User interface:** In Tableau Desktop, you can use the **Refresh from Source**, **Add Data From File**, and **Add Data From Data Source** commands to upload an addition to or refresh an extract on Tableau Server. A user might want to do this if Tableau Server doesn't have sufficient credentials to access the underlying data. For more information, see [Updating Extracts on Tableau Server](#) in the Tableau Help.
- **Data Extract command line utility:** The Data Extract command line utility installs with Tableau Desktop. You can use it to append to or refresh a published extract. For more information, see [Tableau Data Extract Command Line Utility](#) in the Tableau Help.

## Enable Extract Refresh Scheduling and Failure Notification

Your publishers can schedule extract refreshes when two conditions are met:

- Tableau Server is configured to send email messages when extract refreshes fail. This is configured by a Tableau Server Manager (TSM) administrator and is on by default. For details, see [Configure Server Event Notification](#).
- The site or sites in which you want to allow publishers to schedule extract refreshes is configured to send email when the refresh fails. This is configured by a server administrator in Tableau Server and is on by default. The instructions below explain how to do this if it is not enabled.

While you're enabling scheduling, you can decide whether also to enable sending email to owners of data sources or workbooks that are refreshed when those extract refreshes do not complete successfully. You can read more about these emails below. When you enable refresh failure notification, the owners of the content that has scheduled refreshes can opt out individually by changing their account settings.

1. Sign in to Tableau Server as a server administrator.
2. Go to the General tab of the Settings page for the site you want to configure for subscriptions:
  - If you have a single site, at the top the browser window, click **Settings** and **General**.

- If you have multiple sites, select the site you want to configure and click **Settings** and **General**.

3. On the **General** page, do the following:

- Scroll to the **Manage Notifications** settings and check **Extract jobs**.

If a scheduled refresh for a particular data source fails, the email goes only to the owner of that data source, not to owners of workbooks that connect to that data source.

- Under **Embedded Credentials**, select both options to let publishers embed credentials and schedule extract refreshes. (Automatic refresh schedules require embedded credentials so Tableau Server can directly access data.)

**Note:** On a multi-site server, failure notifications are a site setting, and embedded credentials are a server setting. To configure embedded credentials on a multi-site server, select **Manage All Sites** and then **Settings**.

## Managing schedules from the server

In your organization it might be more appropriate to manage embedded credentials and refresh schedules centrally from the server. If you do that, you might clear the check boxes in the **Embedded Credentials** section described in the steps above, so that Tableau Desktop publishers do not see schedule options during publishing.

Managing schedules centrally enables you to distribute extract refresh and subscription tasks, so you can run them when most people are offline. It also enables you to oversee which credentials are embedded in connections.

## How refresh failure emails work

The email notification for a failed extract refresh lists the extract name and location on the server, gives the time of last successful refresh, the number of consecutive times the refresh has failed, and suggests the reason for the failure and possible solution.

After five consecutive failures, the refresh schedule is suspended until you or the data owner takes an action to address the cause of the failure, such as updating database credentials or a path to the original data file.

How the last successful refresh date is determined

The last successful refresh date and time are shown when that last refresh occurred within a number of days. By default it is 14 days, and this value is set in `wgserver.alerts.observed_days`. If the number of days since the last successful refresh exceeds the number specified in this setting, the message in the email shows “not in the last *N* days.”

## Create or Modify a Schedule

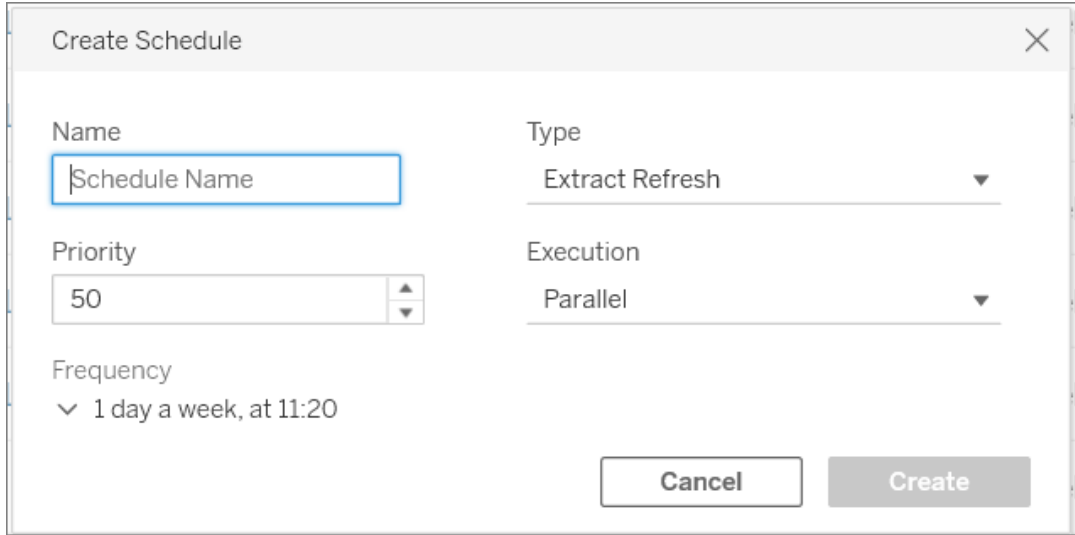

The Schedules page is accessible only by Tableau Server Administrators. It shows a list of schedules, including their name, type, what they're for (scope), the number of tasks, behavior (concurrent or serial processing), and when they are scheduled to run.

**Note:** If you enable custom schedules for subscriptions on one or more sites, users will control schedules for their subscriptions on those sites. To learn more, see [Enable Custom Schedules for Subscriptions](#).

### To create a new schedule

1. In a site, click **Schedules**.
2. Click **New Schedule**.

3. Specify a descriptive **Name** for the schedule.
4. Select a **Task type** the schedule will handle—refreshing extracts, running flows, or delivering subscriptions.
5. You must define a priority from 1 to 100, where 1 is the highest priority. This is the priority that will be assigned to the tasks by default. If two tasks are pending in the queue, the backgrounder will evaluate the task priority for extract refreshes and flows, and the schedule priority for subscriptions to determine which one runs first. For more information, see [How Scheduled Server Jobs are Prioritized](#).
6. **Execution**: choose whether a schedule will run in parallel or serially. Schedules that run in parallel run on all available backgrounder processes so that they can complete faster.

**Note:** Schedules for the same workbook will always run serially, even if you set this option to parallel.

7. Finish defining the schedule. You can define an hourly, daily, weekly, or monthly schedule. The **Frequency** is populated automatically based on the selections you make.

Context menu for 'schedule82':

- Run Now...
- Enable...
- Edit Settings...
- Rename...
- Delete...

3. Finish editing the schedule, and click **Save**.

## Rules for Creating or Modifying Schedules

Following are rules you must follow when creating new or modifying existing schedules.

**Note:** If you have existing schedules that do not follow these rules, you must modify them accordingly. Not doing so, may result in unexpected behavior and the tasks may not run at the scheduled time.

- Schedules that run every 15 or 30 minutes must have start and end times that are on the hour. Examples of on the hour: 5:00 AM to 6:00 AM.
- Daily schedules on any recurrence must have the same start and end minute. For example, 10:35 am to 4:35 pm. The hour can be different. However, if the daily schedule is set to only happen once a day, it needs only a start time and not an end time.

Schedule Flow Tasks

## Enable Custom Schedules for Subscriptions

Custom schedules for subscriptions allow users to receive email messages on a schedule that they define, rather than using a fixed schedule defined by a server administrator. Custom schedules for subscriptions have been available to users of Tableau Cloud since March 2017, and these schedules can now be enabled on a per-site basis in Tableau Server version 2018.2. Enabling custom schedules for subscriptions is a permanent change on any sites where you make this change. Any sites where you don't enable custom schedules remain on fixed schedules defined by a server administrator.

### Enable custom schedules

Before you can enable custom schedules on one or more sites, you must first enable custom schedules on Tableau Server, and then enable custom schedules on one or more sites on that server. To learn more about enabling subscriptions on Tableau Server, see [Set Up a Site for Subscriptions](#).

#### Step 1: Enable custom schedules on Tableau Server

From a command prompt with Tableau administrator permissions, run the following commands:

```
tsm configuration set -k features.SelfServiceSchedules -v true
tsm pending-changes apply
```

This operation will restart Tableau Server.

#### Step 2: Enable custom schedules on a site

1. Log in to Tableau Server as a server administrator using a web browser:

```
https://<hostname>/#/login
```

2. Browse to the **Site Settings** page for a site, and then enable custom schedules:
  1. Click **All Sites**, and then choose one of the sites from the drop-down list.
  2. Click **Settings**.

3. On the **General** tab, under **Subscriptions**, select the following checkbox: **Permanently convert from fixed schedules created by administrators to custom schedules created by users. (You can't undo this).**
4. Click **Save**.

When custom schedules are enabled on a site, all fixed schedules with a subscription are converted to an equivalent custom schedule.

## How Scheduled Server Jobs are Prioritized

### Jobs and Tasks

In Tableau Server, users can schedule extract refreshes, subscriptions, or flows to run periodically. These **scheduled items** are referred to as **tasks**. The Backgrounder process initiates unique instances of these tasks to run them at the scheduled time. The **unique instances of the tasks** that are initiated as a result are referred to as **jobs**. **Jobs** are also created for runs that are initiated **manually**, by clicking the **Run now** option.

For example, an extract refresh task is created to run daily at 9 AM. This is an extract refresh task, and every day at 9 AM, a job will be created for the Backgrounder to run.

You can assign a priority number to Tasks and Schedules using values from 1 to 100. Lower the number, higher the priority, 1 is the highest priority, and 100 is the lowest.

### Priority Rules for Jobs

When processing scheduled extract refreshes, subscriptions and flow runs, Tableau Server prioritizes background jobs in this order:

1. Any job already in process is completed first.
2. Any task or schedule that you initiate manually using **Run now** starts when the next backgrounder process becomes available. Exception to this are the flow tasks and schedules. Flow runs use the assigned task priority to determine the order in when they should run. If there is no task priority assigned it defaults to 0 which is the highest

priority.

Note: Learn how to restrict Run now settings- Server Settings (General and Customization).

3. Jobs with the highest priority (the lowest number) start next, independent of how long they have been in the queue.

For extract refreshes and flows, this is the task priority. The task priority is inherited from the schedule priority when the task is first created. The task priority can be subsequently changed but the task priority returns to the default value when the data source is republished.

For subscriptions, this is the schedule priority. If you have enabled custom schedules for subscriptions, then the priority of those jobs is set to 50.

For example, a job with a priority of 20 will run before a job with a priority of 50, even if the second job has been waiting longer. To change task priority, see [Create or Modify a Schedule](#).

4. Jobs with the same priority are executed in the order they were added to the queue. The first job added to the queue starts first; then the second job starts.
5. When multiple jobs with the same priority are scheduled to run at the same time, they start in the order they were created or enabled. Jobs scheduled for the same time are executed by task type with the fastest category of jobs starting first: flow runs, followed by data driven alerts, followed by system jobs, followed by subscriptions, followed by extract creation, followed by incremental extracts, and then full extracts.

Flows that are scheduled to run as part of a linked task are all assigned the same priority and run in the order they are defined in the linked task. For more information about linked tasks, see [Schedule linked tasks](#).

6. As the last tie breaking measure, the Backgrounder uses the historical run time. Jobs that have run faster in the previous runs, will be prioritized over jobs that have taken longer historically.

**Note:** Setting backgrounder resource limits on a specific site will have an additional queue as these jobs are picked up after other higher priority jobs. For details, see Tableau Server Backgrounder Resource Limits.

The following limitations also impact when the jobs are run:

- The number of concurrent jobs is limited to the number of backgrounder processes you have configured for Tableau Server.
- Separate refreshes for the same extract or data source cannot run at the same time.
- Jobs associated with a schedule that is set to run serially run one at a time.

## Configure Workbook Performance after a Scheduled Refresh

To improve the load times for workbooks, Tableau Server caches the results of queries included in workbooks. For most workbooks, query results are computed and cached when they are first viewed by a user on Tableau Server. However, for workbooks that connect to data extracts, Tableau Server can recompute query results when the corresponding extract refresh tasks run. This reduces the load time for these workbooks when they are first viewed, so this option is turned on by default for workbooks that have been viewed recently.

**Important!** External query cache warmup will be deprecated in version 2023.1. To improve view load times for workbooks, you should allow View Acceleration on your site instead. For more information, see View Acceleration.

## Determine the performance impact

Although this option reduces the initial load time for workbooks, recomputing query results also increases the load on Tableau Server. If your Tableau Server installation is already performance-constrained, you might want to turn this option off or lower the threshold for workbook caching.

Here are some possible reasons why you might want to turn this option off or lower the threshold:

- The Background Tasks for Non Extracts administrative view displays many long-running jobs in the **Warming up external query cache on data change** category.
- The Background Task Delay administrative view displays long delays.
- CPU and memory consumption for the backgrounder processes is consistently high.

However, note that this is only one of the options that impacts the performance of background tasks. For more information about performance, see Performance.

## Turn off workbook caching for the server

To decrease the load on Tableau Server, you can turn off workbook caching after a scheduled refresh at the server-level. If you turn this option off, Tableau Server caches query results for workbooks the first time the workbooks are viewed.

Use the following tsm configuration set option to turn off workbook caching after a scheduled refresh:

```
backgrounder.externalquerycachewarmup.enabled
```

For more information on how to use and apply tsm set options, see tsm configuration set Options.

## Turn off workbook caching for a site

You can also turn off workbook caching after a scheduled refresh for an individual site. For example, you might do this if there is one site in particular that contains many slow workbooks which increase load on the server.

1. Select the site for which you want to turn off workbook caching in the sites drop-down.
2. Click **Settings**.
3. In the **Workbook Performance after a Scheduled Refresh** section, clear the check box.

**Note:** Although this option is available in the settings for an individual site, you must have server administrator permissions to view it.

## Configure the workbook caching threshold

Tableau Server only recomputes query results for workbooks that both have scheduled refresh tasks and have been viewed recently.

You can increase or decrease the number of workbooks that are cached after a scheduled refresh with the following tsm configuration set option:

```
backgrounder.externalquerycachewarmup.view_threshold
```

By default, the threshold is set to 2.0. The threshold is equal to the number of views that a workbook has received in the past seven days divided by the number of refreshes scheduled in the next seven days. (If a workbook has not been viewed in the past seven days, it is unlikely that it will be viewed soon, so Tableau Server does not spend resources recomputing queries for the workbook.)

## Ensure Access to Subscriptions and Data-Driven Alerts

To ensure that users see the Subscribe and Alert buttons in the Tableau Server toolbar and can receive related emails, do the following:

- **Configure SMTP and event notifications on Tableau Server:** See [Set Up a Site for Subscriptions](#).
- **Ensure that users have an email address in Tableau Server:** Users can update their email address on [their account settings page](#).
- **Embed database credentials or don't require them:** To email data in a view, Tableau Server needs to access the data without user involvement. This can be accomplished by using a workbook with embedded database credentials, a Tableau Server data source, or data that doesn't require credentials (such as a file that's included with the workbook at publish time).
- **Ensure that users can access needed workbooks and views:** Access to workbooks and views on the server is controlled by the **View** permission. To receive images of content in email messages, users also need the **Download Image/PDF** permission. For more information, see [Permissions](#).
- **Avoid trusted authentication for embedded views:** If you use restricted tickets (the default) to render an embedded view, the Subscribe and Alert buttons don't appear.  
  
(Alerts only) Ensure that users can access published data sources with View and Connect capabilities.

## Set Up a Site for Subscriptions

When users subscribe to a workbook or view, a snapshot of the view is emailed to them on a scheduled basis, so they can see the latest updates without having to sign into Tableau Server. Administrators, project leaders with appropriate site roles, and content owners have the option to subscribe other users to workbooks and views. For more information, see [Subscribe to Views](#).

**Note:** To create and receive subscriptions, users need access to related databases and views. [See this list of requirements](#) for details.

Looking for Tableau Server on Windows? See [Setup a Server for Subscriptions](#).

## Prerequisite: Configure the server to send subscription emails

Before you can enable subscriptions for a site, you need to complete the steps to enable subscriptions on the server. Follow the steps in these topics to configure subscriptions on the server.

1. Configure SMTP Setup
2. Configure Server Event Notification

## Enable subscriptions

After you have configured SMTP and server event notifications, you can enable subscriptions.

To enable subscriptions:

1. Sign into Tableau Server as a server administrator.
2. Go to the General tab of the Settings page for the site you want to configure for subscriptions:
  - If you have a single site, on the side navigation, click **Settings** and **General**.
  - If you have multiple sites, select the site you want to configure and click **Settings** and **General**.
3. Scroll to **Subscriptions** and select the subscription options for your users.

**Note:** Subscription options are only visible after the TSM administrator has enabled the server-wide configuration option, **Allow users to receive email for views that they have subscribed to**. For details, see [Configure Server Event Notification](#).

- a. Select **Let users subscribe to workbooks and views**
  - b. (Optional) To allow content owners to subscribe other users to their content, select **Let content owners to subscribe other users**.
  - c. (Optional) To allow users to include attachments with their subscriptions, select **Let users add attachments to subscribed workbooks and views**. This option will not be available if the TSM administrator has not enabled attachments in TSM. For details, see [Configure Server Event Notification](#).
4. (Optional) Scroll to **Email Settings**.
- a. Enter an **Email From Address** that will show as the "From" address in email messages.
  - b. Enter an **Email Footer** for email messages.
- A site's "From" address and message footer are also used in emails for [data-driven alerts](#).
5. (Optional) Scroll to **High-Visibility Data Labels in View and Workbook Subscriptions** and select **Include high-visibility quality warnings and high-visibility sensitivity labels in view and workbook subscription emails**. (In earlier versions, scroll to **Data Quality Warnings in Subscriptions** and select **Include data quality warnings in subscription emails**.)

**Note:** Data quality warnings in subscription emails are only visible when Tableau Catalog is enabled. For more information, see [Enable Tableau Catalog](#).

6. Click **Save**.

To specify the subscription schedules available to users, see [Create or Modify a Schedule](#).

### Test subscriptions in a site

1. [Subscribe to a view](#).
2. In the site with the subscription you want to test, on the side navigation, click **Schedules**.
3. Select the schedule you chose for the subscription, and then click **Actions > Run Now**.

A snapshot of the view should be emailed to you within 10 minutes. If you experience an issue, see [Troubleshoot Subscriptions](#).

## Manage all user subscriptions

1. In the side navigation, click **Tasks**, and then click **Subscriptions**.

All user subscriptions for the current site appear, including information like subscriber name, view name, and delivery schedule.

2. Select any subscription you want to update. From the **Actions** menu, select **Change Schedule**, **Change Subject**, **Change Empty View Mode**, or **Unsubscribe**.

(The empty-view option sends subscription emails only when data exists in a view. It's a good choice for high-priority alerts.)

## Suspended Subscriptions

By default, a subscription is suspended after 5 consecutive subscription failures and result in the subscription emails not sent. To change the threshold number of subscription failures that can occur before they are suspended, use the tsm configuration set option, `back-grounder.subscription_failure_threshold_for_run_prevention`. This sets the threshold for the number of consecutive failed subscriptions necessary before suspending the subscription. This is a server-wide setting.

Only Server administrators can configure the threshold number of subscription failures before a subscription is suspended.

Server administrators can opt in to receive email notifications when a subscription is suspended. You can do this by navigating to **My account settings** -> **Subscription Notifications**. This setting is at a site-level so has to be configured for site separately.

### Resume suspended subscriptions

If a subscription fails more than five times, you'll receive a notification email that your subscription has been suspended. There are a few ways to resume a suspended subscription if you're a subscription owner or administrator:

- From the **My Content** area of Tableau web pages, an icon appears in the Last update column to indicate that the subscription is suspended. **Select ... > Resume Subscription** to resume.
- From the **Subscriptions** tab of the affected workbook, an icon appears in the last update column to indicate that the subscription is suspended. **Select ... > Resume Subscription** to resume.
- From the **Subscriptions** tab under **Tasks**, an icon appears in the last update column to indicate that the subscription is suspended. **Select ... > Resume Subscription** to resume (Server administrators only).

When a subscription is resumed, the alert failing count goes back to zero. The next evaluation of the subscription will occur at the next scheduled evaluation time.

### See also

[Subscribe to Views](#) in the Tableau Desktop and web authoring Help.

Project-level administration to learn which site roles allow full Project Leader capabilities.

## Set Up for Data-Driven Alerts

When data reaches important thresholds for your business, data-driven alerts automatically send email notifications to key people users specify. As a Tableau Server administrator, you set up data-driven alerts much like you do subscriptions. For information about how users create and manage these alerts, see [Send Data-Driven Alerts](#) in Tableau User Help.

**Note:** To create and receive data-driven alerts, users need access to related databases and views. [See this list of requirements](#) for details. If alerts are enabled for a site, any user on that site can create them except users with the Viewer role.

## Configure email for data-driven alerts

1. Complete the steps in Configure SMTP Setup so the server can send the email.
2. While viewing a site, click **Settings** at the top of the browser window.
3. Under Email Settings, enter a site-specific "From" address or message footer.

A site's "From" address and message footer are also used in emails for subscriptions.

4. Click **Save**.

## Manage all data-driven alerts in a site

1. At the top of the browser window, click **Tasks**, and then click **Alerts**.
2. Select any alerts you want to update.
3. From the **Actions** menu, do any of the following:
  - Add or remove yourself as a recipient.
  - Edit alerts to change data thresholds, delivery schedules, and the full list of recipients.
  - Change alert ownership to different users, or delete alerts.

## Disable data-driven alerts for a site

Data-driven alerts are supported for all sites by default, but administrators can disable them for specific ones.

1. While viewing a site, click **Settings** on the left-side navigation pane.
2. Under Data-Driven Alerts, uncheck **Let users create alerts and receive alert emails**.
3. Click **Save**.

## Suspend data-driven alerts

By default, an alert is suspended after 350 consecutive alert failures. Server administrators can configure the threshold number of alert failures before an alert is suspended. To change the threshold number of data-driven alert failures that can occur before alerts are suspended, use the **tsm configuration set** option, `dataAlerts.SuspendFailureThreshold`.

This sets the threshold for the number of consecutive failed alerts necessary before suspending the alert. This is a server-wide setting. The threshold value applies to every configured data-driven alert on the server.

### Resume suspended alerts

If an alert fails enough times, you'll receive a notification email that your alert has been suspended. There are a few ways that administrators or alert owners can resume a suspended alert:

- From the Tasks > Alerts area of Tableau web pages, an  icon appears in the Last checked column to indicate that the alert is suspended. Select ... > **Resume Alert** to resume the alert.
- Click **Resume Alert** in the notification email to resume the alert. A notification will either allow you to resume the alert, or indicate that the view has changed and the alert should be deleted.
- From the Alerts panel of the affected view or workbook. To resume the alert from a view or workbook, select **Alert** to open the Alerts panel. An icon appears next to the suspended alert. Select **Actions** > **Resume Alert** on the affected alert to resume.

Alert owners will receive an email notification when the alert is working again.

## Control how often the server checks data-driven alerts

By default, Tableau Server checks every 60 minutes to confirm whether data conditions for alerts are true. If you notice performance impacts, you can customize this time interval with the

`tsm configuration set` option, `dataAlerts.checkIntervalInMinutes`.

Regardless of the `dataAlerts.checkIntervalInMinute` setting, the server also checks alerts whenever extracts in the related workbook are refreshed. To check an alert more frequently than the setting specifies, change the extract-refresh schedule.

## Track the server's alert-checking process

In the Background Tasks for Non Extracts view, you can track the server's alert-checking process by looking for these tasks:

- Find Data Alerts to Check
- Check If Data Alert Condition Is True

The "Find" task limits "Check" tasks to alerts that can currently send related emails. For example, if a user has chosen an email frequency of "Daily at most", after the alert condition becomes true, the server waits 24 hours before checking the alert again.

Each "Check" task uses one server background process, loading the related view to evaluate the alert condition. If all users see the same version of a view, it loads only one time. But if users have applied filters to a view, or the data they see is limited by user-level security, the view loads once for each recipient.

## Identify and fix failing alerts

As an administrator, you can proactively identify failing alerts that users may be unaware of.

To check:

1. Select Status in your site menu.
2. Select Background tasks for non-extracts.
3. From the Task dropdown menu, select Check if Data Alert is True.

4. In the far right, click Error to see a list of failing alerts.
5. Hover over the red failure icon to display a tooltip with alert details.

To determine the alert owner, look for the alert ID number in the data\_alerts table of the Tableau Server Repository. (In the **alert management** area of a site, you can also look for the alert name following the number, but be aware that multiple different alerts may use the same name.)

**Note:** Alert owners are automatically notified when an alert fails ten times. Administrators can customize when alert owners receive notifications. Users won't be notified for alerts that failed prior to upgrading to Tableau Server 2018.1.

 **Check data alert**

Task ID: **1157751**  
Status of Task: **Error**  
Created at: **5/3/2017 10:20:18 AM**  
Start at: **5/3/2017 10:20:18 AM**  
Completed at: **5/3/2017 10:20:19 AM**  
Runtime: **0 sec**  
Priority: **10**  
Backgrounder: **localhost**  
Backgrounder ID: **localhost:0:0**

Data Alert Id: 169 - Stock Summary - 'AVG(Price)' is above 100  
Evaluated for 0 recipients out of 1  
Evaluated true for 0 recipients

Failing alerts are often caused by content changes on Tableau Server. Encourage users to recreate alerts if changes like the following occur:

- A workbook, view, or data field is removed or renamed.
- Database credentials embedded in workbooks expire.
- Data Driven Alerts require embedded credentials for Live Connections, the use of OAuth isn't currently supported with Alerts.
- A data source becomes inaccessible.

**Tip:** To automatically get emailed when alerts fail, follow the steps in [Collect Data with the Tableau Server Repository](#), and connect to the "background\_jobs" table. From that table, create a custom view that includes the "Check If Data Alert Condition Is True" job name and its finish code. Then [set up a data-driven alert](#) to email you whenever a finish code equals 1 (failure).

## Set Up for Metrics

### Retirement of the legacy metrics feature

Tableau's legacy metrics feature was retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. In October 2023, Tableau retired the ability to embed legacy metrics in Tableau Cloud and in Tableau Server version 2023.3. With Tableau Pulse, we've developed an improved experience to track metrics and ask questions of your data. For more information, see [Create Metrics with Tableau Pulse](#) to learn about the new experience and [Create and Troubleshoot Metrics \(Retired\)](#) for the retired feature.

Metrics are a type of Tableau content that tracks the value of an aggregate measure, such as sum of sales. Because metrics refresh frequently and display their current value in an easy-to-glance format, they are useful for monitoring data. To learn more about how users work with metrics, see [Create and Troubleshoot Metrics \(Retired\)](#).

As a Tableau Server administrator, you have the ability to control how often metrics refresh and how failing refreshes are handled. You also can make sure that users are able to create metrics or disable metrics for particular sites or for the entire server.

### Ensure that users can create metrics

When metrics are enabled for a site, all users with a Creator or Explorer (can publish) site role can create metrics, if they have the correct permissions.

Metrics are created from existing views on a Tableau site. To ensure that users can create metrics on a view, verify that:

- Users have the Create/Refresh Metrics permission capability for the workbook that the view belongs to. For more information, see [Permissions](#).
- The password for the data source is embedded, if it is required. For more information, see [Edit Connections on Tableau Server](#).

### Disable metrics for a site

Metrics are enabled on all sites by default. You can disable metrics on a per-site basis.

1. On the site where you want to disable metrics, from the navigation panel, click **Settings**.
2. Under **Metrics Content Type**, uncheck **Enable metrics**.
3. Click **Save**.

When you disable the metrics content type, metrics no longer appear on the site. The data for any existing metrics is retained, but these metrics will no longer refresh. If you re-enable metrics, these metrics will reappear and resume refreshing.

You can also disable metrics on a specific workbook by denying the Create/Refresh Metrics permission capability. For more information, see [Permissions](#).

### Disable metrics for a server

In addition to disabling metrics for specific sites, you can disable metrics server-wide. When disabled at the server level, metrics don't refresh or appear on any sites, metrics processes

don't run, and the site settings for metrics aren't available. Existing metric data is retained, so that if you re-enable metrics, those metrics will be restored.

Metrics are enabled by default. To disable metrics, use the **tsm configuration set** option `metricsservices.enabled`.

## Configure how often metrics refresh

When a metric refreshes, it checks for new data via the view it was created from, known as the connected view. You might want to increase the time between refreshes if you notice a performance impact on your server—or decrease it if your users require more up-to-date data.

Metrics that rely on live data refresh every 60 minutes, by default. To adjust the refresh interval for live data, use the **tsm configuration set** option `metricsservices.checkIntervalInMinutes`. This is a server-wide setting.

Metrics that rely on extract-based data refresh when the extracts refresh. To control how often these metrics refresh, change the extract refresh frequency. For more information, see [Extract Refresh Schedules](#).

## Configure failure notifications for metric refreshes

If a metric is not able to connect to the data it needs to refresh, the refresh will fail. When a metric refresh fails 10 times in a row, the metric owner receives an email notification.

To adjust the number of consecutive failures before a warning email is sent, use the **tsm configuration set** option `metricsservices.failureCountToWarnUser`. This is a server-wide setting.

## Configure when metric refreshes are suspended

If a metric refresh fails 175 times in a row, the refresh is suspended. Once a metric refresh is suspended, the server will no longer attempt to check for new data, until the refresh is manually resumed.

To adjust the number of consecutive failures before a refresh is suspended, use the **tsm configuration set** option `metricservices.maxFailedRefreshAttempts`. This is a server-wide setting.

### Manage metrics

Though metrics are created from a view, they are not tied to the view like alerts or subscriptions. This means you can manage metrics similar to how you manage workbooks, by renaming, moving, tagging, deleting, or setting permissions on a metric.

Find metrics to manage either by navigating the project hierarchy or via the following paths.

- To see all metrics on a site: Navigate to the Explore section, then select **All Metrics**.
- To see metrics created from all the views in a workbook: Navigate to the workbook, then select the **Connected Metrics** tab.
- To see metrics created from a single view: Open the view, then select **Watch > Metrics** from the toolbar.

### Address failing and suspended metric refreshes

Metric refreshes may fail for one of the following reasons.

- The connected view was deleted or modified.
- Permissions changed for the connected view.
- The password for the data source is no longer embedded or is no longer valid.
- The metric owner doesn't have the required site role to refresh the metric. A site role of Creator or Explorer (can publish) is required.
- There was a temporary connectivity issue, which will resolve itself.

**Note:** If the metric refresh is suspended because the owner doesn't have the required site role for it to refresh, you won't be able to resume the refresh unless you change the owner.

For more information on why metric refreshes fail and what users can do to fix them, see [Fix failing refreshes](#).

Encourage users to overwrite a metric if the connected view was modified in a way that caused the refresh to fail, but the view is still available. Users can overwrite a metric by creating a metric with the same name in the same project as the existing metric.

### Resume suspended refreshes

If the cause of the failure is fixed, for example by embedding the correct password for the data source, you can resume the metric refresh.

1. Locate the affected metric. Metrics with suspended refreshes display the text **Refresh Suspended**, instead of the time of last refresh, in grid and list view.
2. On the warning message, click **Resume refresh**.

Tableau attempts to perform the refresh. If this attempt succeeds, you'll receive a confirmation, and the refresh will resume on schedule. If the attempt doesn't succeed, the refresh remains suspended. You or the metric owner can delete or overwrite the metric, or keep it to reference historical data.

## Monitor metric activity with administrative views

Use the administrative views for Tableau Server to monitor metric refreshes and see which users are creating and viewing metrics.

1. Navigate to the site you want to monitor, or monitor server-wide activity by selecting **All Sites** from the site picker.
2. From the navigation panel, click **Site Status** or **Server Status**.
3. Select the dashboard you want to inspect.

- To monitor metric refresh activity, open the Background Tasks for Non Extracts dashboard.

Filter for the tasks **Find Metrics to Update** or **Update All Metrics on a View**.

- To see which users are creating metrics, open the Actions by All Users or Actions by Specific User dashboard.

Filter for the action **Create Metric**.

- To see recent activity involving metrics, open the Actions by Recent Users dashboard.

Look at the list of actions under **What Actions Were Recently Performed?**

## Edit a Published Data Source

Imagine that you've published a data source, and your team is using the data source across a number of workbooks. This is a good start, but you have some changes in mind that will make your data source great. Before you implement these changes, you want to see how your proposed changes look in Tableau. And most importantly, you need to test your changes to ensure they won't negatively impact any existing workbooks that use the data source.

Editing a published data source allows you to test changes and make improvements to your data source while maintaining it as a single source of data.

**Note:** Only users with a site role of Creator can edit publish data sources in the browser.

### Edit and test changes

Whether you're creating a new published data source or editing an existing published data source, you can create joins and edit the schema from the Data Source page without leaving your browser. Then use the Scratchpad to test your changes, create folders, organize hierarchies, and rename fields and aliases before publishing your data source. While editing your data source, you'll have all the same features and functionality that you have when authoring in Tableau Cloud. For more information, see [Web Authoring and Tableau Desktop Feature Comparison](#).

To edit a published data source:

1. From the Start or Explore page, navigate to the data source you want to edit.
2. Click **Edit Data Source**.

3. Click the **Data Source** page to make joins or edit the schema.
4. Click the **Scratchpad** sheet.
5. From the **Data** pane, create folders, organize hierarchies, rename fields and their aliases, or update metadata that are saved with the published data source.
6. Drag and drop fields onto the scratchpad to make sure your changes are working as expected.
7. Click **Publish**.

Just like you can with workbooks, you can also **Publish As** if you want to make a copy of the data source.

**Note:** Personal Spaces don't support published data sources.

## Roll back changes

To revert to the last version of the published data source:

1. Navigate to the data source that you want to revert.
2. Click **File**.
3. Choose **Revert to Published**.

This reverts to the latest published version of that data source.

## Understand supported connections

Editing published data sources doesn't support:

- Tableau Bridge connectors in Tableau Cloud.
- Data sources that use embedded passwords in Tableau Cloud and Tableau Server.

Also, the Data Source page isn't available for published data source connection types that aren't supported, including but not limited to .hyper file types. To see which connection types are supported, see [Creators: Connect to Data on the Web](#).

## Learn about permissions

To edit a published data source, you'll need a Creator license that has Save or Save As permissions for data sources in the respective folder. For more information, see [Permissions](#).

## Edit data sources published by a flow

If you make edits to a data source that was published by a flow, the changes will be overwritten during the next scheduled flow. Instead, edit the data source in the flow. For more information, see [Publish a Flow to Tableau Server or Tableau Cloud](#).

# Managing Background Jobs in Tableau Server

In Tableau Server, users can schedule extract refreshes, subscriptions, or flows to run periodically. These scheduled items are referred to as **Tasks**. The Backgrounder process initiates unique instances of these tasks to run them at the scheduled time. The unique instances of the tasks that are initiated as a result are referred to as **Jobs**. Jobs are also created for runs that are initiated manually, by clicking the **Run Now** option in the web interface, programmatically through REST API, or tabcmd commands.

For example, an extract refresh task is created to run daily at 9 AM. This is an extract refresh task, and every day at 9 AM, a job will be created for the Backgrounder to run. In addition to

user-generated jobs, the Backgrounder also does a number of System jobs on behalf of the user to support general Tableau work flows, such as thumbnail generation.

Running all these jobs can mean that Backgrounder uses a lot of resources at various times during the day. Using the Job Management feature, Server and Site administrators can get more details on these jobs that happen in their Server or Site, and take action on those jobs to better manage server resource usage. System jobs are only viewable by Server administrators, and by default are filtered out..

The **Run Now** settings on the **General** settings page also allows you to manage your resources by either allowing or blocking users from running jobs manually. By default, this option is selected to allow users to run jobs manually. Clear the check box to prevent users from running jobs manually. To learn more about managing Backgrounder resources, see [Tableau Server Backgrounder Process](#).

The Jobs page which contains the information about jobs can be accessed by navigating to the **Existing Tasks** menu of the left navigation menu.

**Note:** Information about jobs can only be viewed by Server and site administrators.

## Overview

This topic describes how to view and understand the information displayed in the Jobs page.

At the top of the page there are high level statistics for the number of **Failed**, **Completed**, and **Canceled** jobs within the past 24 hours. For Server administrators, this also includes System jobs. Applying filters do not change these values.

# Tableau Server on Linux Administrator Guide

Jobs  
Failed Jobs: 175   Completed Jobs: 195   Cancelled Jobs: 215

Sort By: Job Requested Time (newest-oldest) ↓

| ID  | Status      | Priority | Task Type                | Job Requested Time   | Run Time (min) | Queue Time (min) | Average Run... | Average Queue... |
|-----|-------------|----------|--------------------------|----------------------|----------------|------------------|----------------|------------------|
| 975 | Pending     | 78       | Extract Refresh/Creation | Sep 9, 2019, 9:15 AM | 0.0            | 1.5              | 5.4            | 21.6             |
| 678 | Pending     | 24       | Subscription             | Sep 9, 2019, 9:04 AM | 0.0            | 13.0             | 28.6           | 20.5             |
| 356 | Cancelled   | 63       | Extract Refresh/Creation | Sep 9, 2019, 9:03 AM | 13.7           | 0.4              | 21.9           | 28.8             |
| 168 | In Progress | 73       | Subscription             | Sep 9, 2019, 9:01 AM | 3.3            | 12.4             | 32.6           | 18.1             |
| 404 | Completed   | 73       | Extract Refresh/Creation | Sep 9, 2019, 8:58 AM | 10.2           | 8.1              | 17.0           | 4.6              |
| 563 | Pending     | 72       | Extract Refresh/Creation | Sep 9, 2019, 8:54 AM | 0.0            | 22.2             | 30.8           | 8.2              |
| 817 | Pending     | 42       | Extract Refresh/Creation | Sep 9, 2019, 8:54 AM | 0.0            | 22.8             | 16.5           | 3.5              |
| 824 | In Progress | 91       | Extract Refresh/Creation | Sep 9, 2019, 8:52 AM | 4.3            | 20.6             | 6.6            | 17.4             |
| 357 | Completed   | 90       | Extract Refresh/Creation | Sep 9, 2019, 8:50 AM | 14.1           | 12.6             | 24.8           | 12.3             |
| 726 | Completed   | 92       | Extract Refresh/Creation | Sep 9, 2019, 8:49 AM | 1.1            | 26.4             | 33.7           | 36.6             |
| 239 | Cancelled   | 40       | Flow                     | Sep 9, 2019, 8:47 AM | 22.2           | 7.3              | 38.7           | 22.8             |
| 49  | In Progress | 96       | Subscription             | Sep 9, 2019, 8:47 AM | 17.2           | 12.8             | 27.4           | 2.2              |
| 652 | Pending     | 3        | Extract Refresh/Creation | Sep 9, 2019, 8:46 AM | 0.0            | 31.0             | 3.1            | 20.3             |

For each job generated, there is a Job ID, the status of that job, the priority, the type of task that the job was generated from, the current run time - if the job is in-progress, current queue time - if queued, as well as the average run time, and average queue time.

Tableau records historical run times and queue times to compute the average run times and average queue times. Both average run times and average queue times are calculated as weighted averages using the following formula:  $((\text{current run time or queue time average} \times 4) + \text{most recent run time or queue time}) / 5$ .

The Job ID can be useful when viewing jobs on **Admin views** and can also be used to query the **Workgroups Database**. When you click on the Job ID, you will see more detailed information about the job, such as the Job LUID, the project name, the schedule, the content name, content owner, job creator, the last time the job ran successfully, and the site name. The site name is displayed if you navigate to the Jobs page using the **Manage All Sites** menu.

Job Details for Job 617

LUID: 0e2aedec-71c7-4a56-8c2c-b03c47cc5b5a  
 Project: Project1  
 Schedule: Every Sunday - 4:00PM  
 Content: Rust interpreter speed study  
 Content Owner: Sabreen  
 Job Creator: Andres  
 Last Successful Run: Sep 9, 2019, 7:45 AM  
 Site: Site1

**OK**

**Note:** Doing a **Refresh Now** from the **Data Sources** page will only show the LUID information in the **Job Details** dialog box.

**Important:** Jobs that existed 24 hours or newer before an upgrade to Tableau Server 2019.4 will not have data for **Average Queue Time**, **Average Run Time**, **Last Successful Run Time**, and **Job Creator** on the **Jobs** page.

## Task Types

There are several types of tasks:

- **Extracts:** This includes extract creation, incremental extract refreshes, and full extract refreshes. For more information on extract refreshes, see [Quick Start: Refresh Extracts on a Schedule](#).
- **Subscriptions:** Includes subscriptions for workbooks and views. For more information, see [Set Up a Site for Subscriptions](#).
- **Flow:** This includes scheduled flows and manual flow runs. See [Job runtime capacity](#) for information about the maximum runtime for flows and [Concurrent jobs capacity](#) for capacity limits when running concurrent flow jobs. Scheduling more flows than the number of resource blocks you have can result in an error. See the Knowledge Base article [Flow Job Pending](#) for more information.
- **Encryption:** Includes the following:
  - Extract encryption and decryption
  - Flow encryption and decryption
  - Re-key extracts and flows
- **System:** This is all system Jobs that the Backgrounder handles behind the scenes to support Tableau Server.

## Filters

You can filter to see only certain jobs. The available filters are by Job Status type, Task Type, and Time Range. For the Time Range filter, you can choose from past one to 24 hours, in four

hour increments. The option to filter in System Jobs is available if you are a Server Administrator.

## Canceling Jobs

Extract refreshes, subscriptions and flow run jobs can be canceled. You can only cancel one job at a time, and selecting multiple jobs at one time for cancellation is not supported.

When you cancel a job, an email with the time the job was canceled, the affected content, and the time the job ran before being canceled is sent to the recipients that you select in the **Cancel Job** dialog box . In addition you can add your customized notes to be included in the email.

If you do not select any recipients, the job will be canceled, but no email will be sent.

To cancel a job, click on the ellipses next to the Job ID and use the dialog to cancel the job:

Cancel Job
✕

Tableau Server will send an e-mail with the information about the cancelled job. You can provide additional information below, such as a reason for cancelling the job:

0/500

Send an email to:

- Job Creator
- Project Owner
- Site Administrator(s)
- Server Administrator(s)

Cancel
OK

## Status

There are seven types of status that jobs can be in, and hovering over each status will display more relevant information.

- **Completed:** This job shows as **Completed successfully** and you can see the time when the job completed in the tooltip that is displayed when you hover over the status.

✔ Completed

This job successfully completed on Jun 13, 2019, 10:23 AM. [Learn more](#)

- **In Progress:** This job shows as **In Progress**. A time for how long the job has been running for is displayed in the tooltip when you hover over the status.

- **In Progress:** This job is **In Progress**, but is **running late**. Tableau keeps track of the average run times for the same job, and if the current run time is longer than the average run time, then it is considered running late. Times for how much longer than average the job has been running and its average run time is provided in the tooltip that is displayed when you hover over the status.

- **Pending:** This job is currently **Pending**, waiting to be run when there is available Backgrounder capacity. A time for how long the job has been in the queue for is provided in the tooltip that is displayed when you hover over the status.

- **Pending:** The flow cannot be run because the number of Resource Blocks is less than the number of flow you have scheduled and the site has reached its concurrency limit.

- **Pending:** This job is currently **Pending**, but is **running late**. Tableau keeps track of the average queue times for the same job, and if the current queue time is longer than the average queue time then it is considered running late. Times for how much longer than average the job has been queued is provided in the tooltip that is displayed when you hover over the status.

- **Cancelled:** This job was **Cancelled** by a Server or Site administrator. The time the job was canceled and how long it ran for before cancellation is provided in the tooltip that is displayed when you hover over the status.

This job was cancelled on Jun 11, 2019, 9:55 PM after running for 29.5 min. [Learn more](#)

- **Failed:** This job is showing as **Failed**. The time when the job failed, how long it ran for before it failed, and why the job has failed is provided in the tooltip that is displayed when you hover over the status.

 Failed

This job failed on Jun 11, 2019, 4:23 AM after running for 51.6 min because of: Invalid credentials [Learn more](#)

- **Suspended:** This job is showing as **Failed** with a pause icon. If the job fails 5 times consecutively, then the job is suspended. Suspended tasks are still available but Backgrounder will not create jobs for these tasks until they are resumed by the user.

 Failed

This job did not run since it was initiated from a task that is suspended. To run jobs initiated from this task, you must first resume the task. [Learn more](#)

## Tableau Service Manager Jobs

TSM jobs are administrative tasks that help configure and maintain Tableau Server. These jobs run by Tableau Services Manager.

Here are some key TSM jobs:

- **Cleanup:** This job is created when a cleanup command is issued to Tableau Server. The cleanup command deletes old log files and temporary files. For more information on the TSM CLI cleanup command, see `tsm maintenance`.
- **Deployments:** This job is created to apply any configuration updates that you make to Tableau Server. This can be initiated either through the TSM web interface or TSM CLI. For more information on the TSM CLI command, see `tsm pending-changes`. Here are a few examples of configuration updates: enabling SSL, enabling Run as User, and server topology changes.

Depending on how many topology changes are being made, and the complexity, this job can take longer than the previous time it ran successfully. For example, if the previous change was a hot topology change, and the current one is not, the current job can take longer to complete than the previous one.

- **Generate backup:** This job is created when a backup command is issued to Tableau Server. The backup command creates a backup file of Tableau data (data in the File Store and repository). For more information on the TSM CLI backup command, see `tsm maintenance backup`.

The time taken for the backup job to complete depends on the amount of data that needs to be backed up. If the amount of data to be backed up has increased from the last time this job was run, it will take longer for the job to complete compared to the previous time.

- **Initialize Tableau Server:** This job is initiated to initialize Tableau Server during the installation process. For more information on the TSM CLI command, see `tsm initialize`.
- **Restore:** This job is created when a restore command is issued to Tableau Server. The restore command restores a Tableau Server data backup file. For more information on the TSM CLI restore command, see `tsm maintenance`. The time taken for the restore job to complete depends on the size of the backup file. If the backup file is larger than the previous times, the restore job will take more time to complete.

- **Start Server:** The job is created to start all the stopped Tableau Server processes. This can be initiated either through the TSM web interface or TSM CLI. For more information on the TSM CLI command see, `tsm start`.
- **Stop Server:** This job is created to stop all the running Tableau Server processes. This can be initiated either through the TSM web interface or TSM CLI. For more information on the TSM CLI command, see `tsm stop`.

## Canceling tsm Jobs

You can cancel jobs either through the TSM web interface or using the TSM CLI. For more information, see [Cancel TSM Jobs](#).

## Cancel TSM Jobs

TSM Jobs can be canceled through TSM web interface or TSM CLI. There are many TSM jobs, but only certain jobs can be canceled once they are in progress. Any job that hasn't yet started can be canceled using TSM CLI.

**TSM web interface:** For jobs that can be canceled while they are running, the Cancel option is available in the Job dialog box as shown below:

**TSM CLI:** To cancel jobs using TSM CLI, see [tsm jobs](#).

To see more information about TSM jobs in general, see [Tableau Service Manager Jobs](#).

## Canceling Jobs that are in progress

Only certain jobs can be canceled while they are already running: Cleanup, Decommission File Store, Generate Backup, Restart Server, Start Server. The cancel behavior can be different depending on the job and the state of the job at the time it was canceled. This is explained in detail below:

- **Cleanup:** If you cancel a cleanup job, it will stop any services that were started in order to do the cleanup. Depending on when it was canceled, some files may be deleted and some may not have been deleted yet resulting in partial cleanup.
- **Decommission File Store:** If you cancel this job, it returns the Tableau Server File Store topology to the state that it was prior to starting the decommissioning process.

- **Generate Backup:** If you cancel this job, any services used for backup are stopped and Tableau Server will try to delete any files that it created as part of the backup process.
- **Restart Server:**
  - Job is canceled when Tableau Server processes are stopping: The job is canceled, but the services will try to get to a stopped state.
  - Job is canceled while Tableau Server processes are restarting: The job is canceled, but the services will try to restart.
- **Start Server:** The job will be canceled, but the processes will still try to start.
- **Stop Server:** The job will be canceled, but the services will try to stop.

Here are some of the main reasons why you may want to cancel a job:

1. Since tsm jobs can only be run one at a time, you might need to cancel a current job if you need to run another job instead.
2. If the running job includes changes to the Tableau Server that you did not intend to make.

## Administrative Views

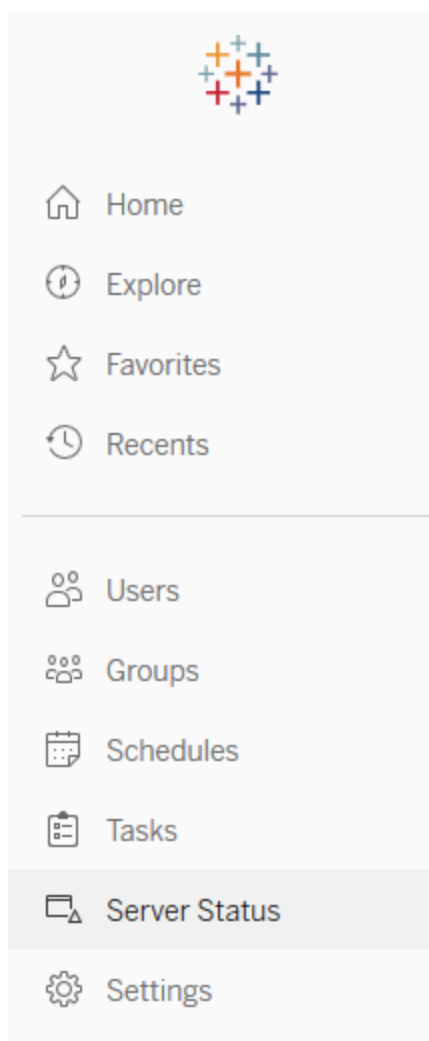

The Status page contains an embedded Tableau workbook with various administrative views. These views help you to monitor different types of server or site activity.

**Note:** You must install PostgreSQL drivers before you can see Administrative views. For more information, see Database Drivers.

### Navigating to administrative views

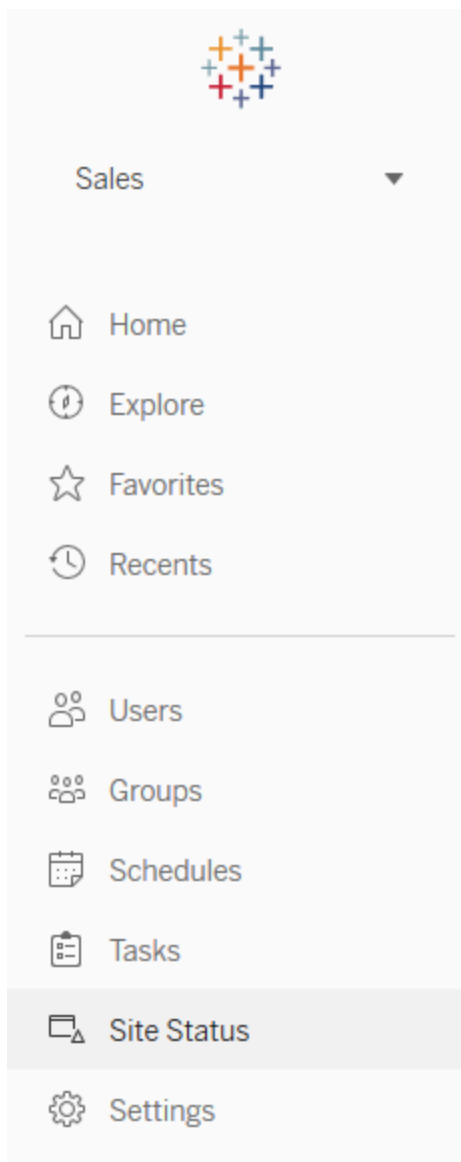

To see administrative views, click **Status**. Site administrators can see administrative views for their site. Administrators of multiple sites can see views for the current site.

On a multi-site server, server administrators can see views for the entire server. Click the site menu, and then click **Manage All Sites** to access the server menus.

To see views for individual sites on a multi-site server, click the site menu, select the site name, and then click **Site Status**.

## Pre-built Administrative Views

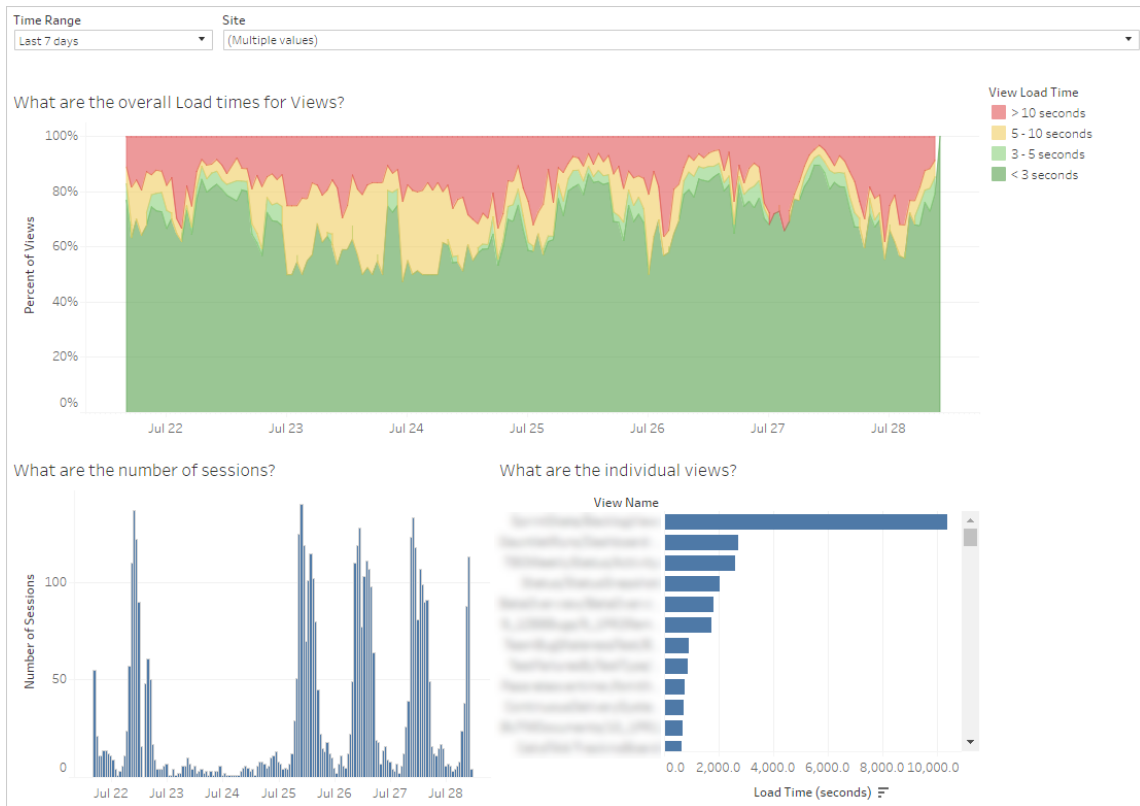

Administrative views are powerful monitoring tools that can help you optimize Tableau Server and better understand how your users are interacting with Tableau content. The administrative views listed to the right are included with Tableau Server. Click on the link for a view to learn more about how to interpret and act on the information the view provides.

To create your own administrative view, see [Create Custom Administrative Views](#).

## Performance of Views

**Note:** This view is only available to server administrators. To access server views on multi-site deployments, click the site menu and select **Manage All Sites**. For information about how to navigate to administrative views, see [Administrative Views](#) .

The Performance of Views administrative view displays how long it takes for views to load and how many sessions are running at a time on the server.

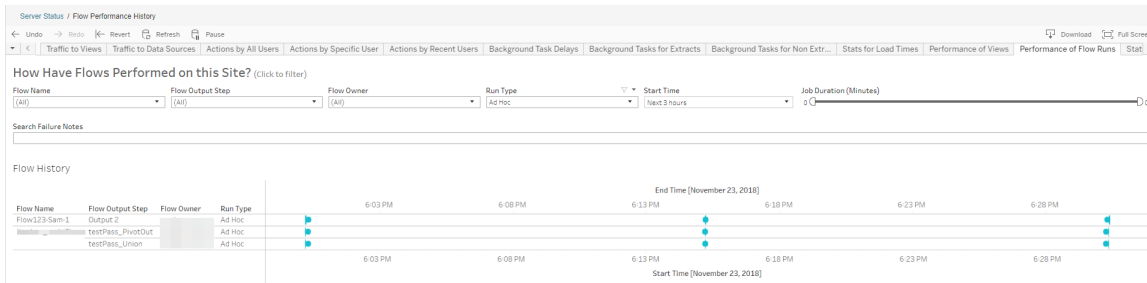

You can compare spikes in the number of sessions with spikes in slow load times to identify the times of day when high user traffic is slowing down the server. You can also look at the individual views by load time to understand which views take the longest to load.

Some views might take a long time to load regardless of when they are viewed. You can identify which workbooks need to be optimized with the **Stats for Load Times** administrative view. Some simple ways to optimize workbooks includes the following:

- Display less information in each view.
- Break up views.
- Reduce the number of filters.
- Use data extracts.

## Performance of Flow Runs

Use this view to see the performance history for all the flows on a site. You can filter by Flow Name, the Output Step Name, Flow Owner, Run Type (Scheduled or Ad Hoc), and the time the flow runs were started. For information about other administrative views available for flows, see Monitor Flow Health and Performance.

Here are some questions you can answer using this view:

- **What flow tasks are currently scheduled?** – To do this, use the Start Time filter and select the time frame you want to look at. For example, to see flow tasks that are scheduled in the next 3 hours, select **Hours -> Next ->** and enter **3**.
- **What is the duration of flow tasks?** - To answer this, click on a mark in the view and you should see details including the task duration.

**How many flows were run ad hoc, and how many were scheduled runs?** - To answer this, use the **Run Type** filter and select **Ad hoc** or **Scheduled**.

**Note:** This is not functional in this release and will not actually filter the data.

In addition to the questions described above, here are some examples of insights you might be able to gather:

- The flows that are running most frequently will have the most marks.
- To see how many flows are running at the same time currently, hover over a mark that shows “**In Progress**” or “**Pending and select “Keep Only**” to filter all flow runs that are currently running.
- To see how many flows are running at the same time during a specific time range, select a range for the **Start Time** filter. For example, you can choose “**Next three hours**” to see which flows will be running in the next three hours.

## Traffic to Views

The Traffic to Views view gives you the ability to see how much of your user traffic goes to views.

You can filter what information is displayed and the time frame it comes from by selecting the view, the workbook, and the time range. Server administrators can specify the site.

Two time lines at the top of the view show you how views are being used over a time range you specify (the default is the last 7 days):

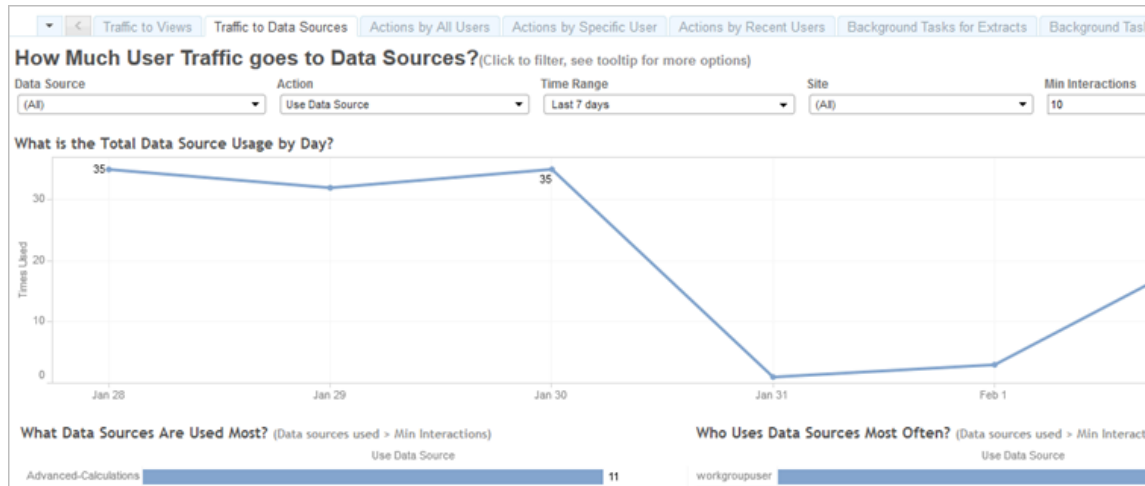

- **What is the Total View Count by Day**—This shows total view count by day, based on the filters you set. Hover your mouse pointer over a point on the line to see the count of views. Select the point to update the other sections of the view based on your selection.
- **What is the Total View Count by Time**—This shows the view count by time of day. The filters and any selection impact this graph.

Two bar graphs at the bottom of the view show results that are filtered by the **Min View Count** filter at the top of the view. These show you the views that are most often accessed, and the users who most frequently access views. Only those views and users with counts greater than or equal to the minimum view count value are displayed:

- **What Views are Seen the Most**—This is a list of the most visited views. Like the other sections of the view, the information is limited by filters and any selection you make.
- **Who Accesses Views Most Often**—This shows the users who most often access the views and is limited by filters and any selection you make.

## Traffic to Data Sources

The Traffic to Data Sources view gives you the ability to see usage of data sources on your Tableau Server installation. This can help you determine which data sources are most heavily used and those that are less often used. You can filter the information you see by selecting the data source, the action taken on that data source, and the time range. Server administrators can specify the site.

A time line at the top of the view shows you how data sources are being used over a time range you specify (the default is the last 7 days):

- **What is the Total Data Source Usage by Day**—This shows total data source usage by day, based on the filters you set. Hover your mouse pointer over a point on the line to see the count. Select the point to update the other sections of the view based on your selection.

Two bar graphs at the bottom of the view show results that are filtered by the **Min Interactions** filter at the top of the view. These show you which data sources are most used, and who uses data sources most often. Only those data sources and users with interaction counts greater than or equal to the minimum interactions value are displayed:

- **What Data Sources are Used Most**—This is a list of the most used data sources. Like the other sections of the view, the information is limited by filters and any selection you make.

- **Who Uses Data Sources Most Often**—This shows the users who most often use the data sources. This is impacted by filters and any selection you make.

## Actions by All Users

The Actions by All Users view gives you insight into how your Tableau Server installation is being used. You can filter the view by actions and by time range. Server administrators can filter by site. The Total Users count shows the number of users who have performed an action. This value is not affected by any filtering. The Active user count shows the number of active users who have performed one of the selected actions.

Up to three separate groups of time lines show you how users are using Tableau Server over a time range you specify (the default is the last 7 days). If no actions are selected for a particular group, that group does not display. Possible groups are:

- **Access & Interactions**—This shows you sign in (log on) activity, view access and data source use.
- **Publish & Download**—This shows publishing and downloading of flows, workbooks and data sources.

- **Subscriptions**—This shows counts of subscription email sent for workbooks and views. It also shows the counts of flow runs.

Use the legend at the bottom to view a subset of the displayed actions. Click a single action to highlight the line for the action, or **Ctrl + Click** on multiple actions to highlight more than one. To clear the selection and display all the selected actions, click on any action in the legend.

## Actions by Specific User

The Actions by Specific User view gives you insight into how individual users are working in your Tableau Server installation. You can filter the view by user name, actions, and time range. Server administrators on multi-site installations can filter by site.

Up to three separate groups of time lines show you how a selected user is using Tableau Server over a time range you specify (the default is the last 7 days). If no actions are selected for a particular group, or if no actions were taken, that group does not display. Possible groups are:

- **Access & Interactions**—This shows you sign in (log on) activity, view access and data source use. This means any interaction with a Data Source by the selected user, including extract refreshes scheduled by that user, or the user accessing a workbook that is associated with that data source.
- **Publish & Download**—This shows publishing and downloading of flows, workbooks and data sources.
- **Subscriptions**—This shows counts of subscription email sent for workbooks and views. It also shows the counts of flow runs.

A bar graph at the bottom of the view shows which items the selected user is using.

Use the legend at the bottom to view a subset of the displayed actions. Click a single action to highlight the line for the action, or **Ctrl + Click** on multiple actions to highlight more than one. To clear the selection and display all the selected actions, click on any action in the legend.

### Actions by Recent Users

The Actions by Recent Users view shows you which signed-in users have been active on Tableau Server over the past 24 hours. This can be useful if you need to perform some maintenance activity and want to know how many and which users this will affect, and what they are doing on Tableau Server.

The view **Active**, **Recently Active**, and **Idle** users that are currently signed in to Tableau Server. For this view, an active user is one who took an action in the last 5 minutes, a recently active user is one who last took an action within 30 minutes, and an idle user is one who last took an action more than 30 minutes ago. The actions are displayed in the lower section of the view.

Select a user to see only the actions that user performed recently. Hover over an action to see details of the action.

## Background Tasks for Extracts

The Background Tasks for Extracts view displays extract-specific tasks that run on the server.

# Tableau Server on Linux Administrator Guide

## Understand this view

To better understand this pre-built administrative view, make note of the following:

- The table, "What Extracts Ran on this Server," lists the extracts that ran in the time period specified in **Timeline**.
- You can click **Success** or **Error** to filter the table based on status.
- You can also click a specific task to update the "How Much Time did Extracts Take" graph for the selected task.
- The table, "How Many Extracts Succeeded or Failed," updates for the status (success or failure) of the task, but the count of extracts that succeeded or failed does not change.

## Status

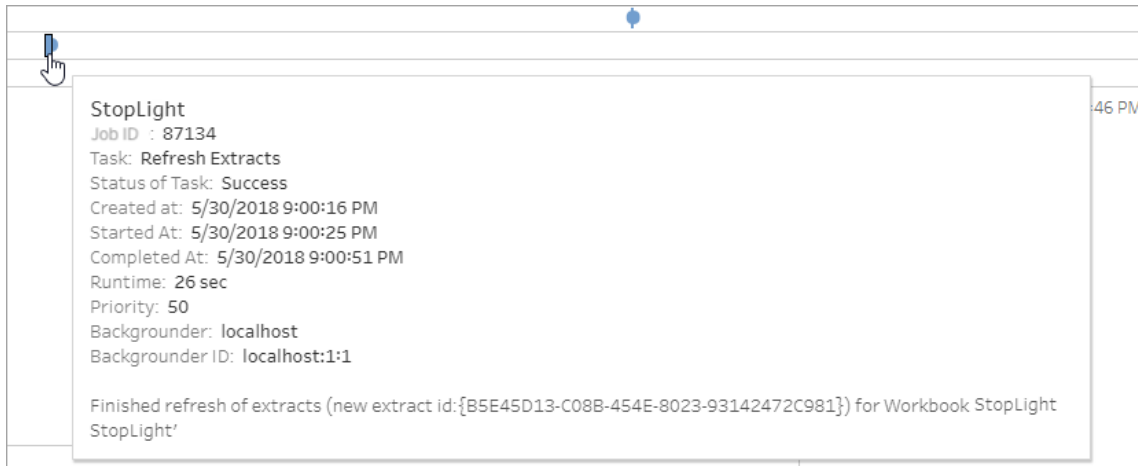

Tasks can have a status of success or error.

| Icon | Description   |
|------|---|
|      | <b>Error</b> —Server was unable to complete the task. |

| Icon  | Description                                |
|---|--|
|  | <b>Success</b> —Server completed the task. |

See details about a task

For details on about the task, use your mouse to hover over the success or error icon.

## Background Tasks for Non Extracts

The Background Tasks for Non Extracts view displays tasks that the server runs that are not related to extract refreshes. For example, edited OAuth connections, subscription notifications, and so on.

A table lists the tasks that ran in the time range specified. Click **Success** or **Error** to filter the table based on status. Select a specific task in the **How Many Tasks Succeeded or Failed on this Site** table to update the **What Background Tasks Ran on this Site** graph for the selected task.

Tasks can have a status of success or error. For details about the task, use your mouse to hover over the success or error icon.

| Icon | Description   |
|------|---|
|      | <b>Error</b> —Server was unable to complete the task. |
|      | <b>Success</b> —Server completed the task.            |

Details that you can see about the task are its ID, status, priority, when it was created, started and completed. You can also see its runtime: the total run time of the background job, which includes the run time of the job plus background job overhead such as initialization and cleanup. You can also see which background runner the job is running on.

## Upgrade Thumbnails Job

In Tableau Server version 2019.1 and later, workbooks and views use higher resolution thumbnails. When you upgrade to Tableau Server version 2019.1 or later, the Backgrounder runs the Enqueue Thumbnails Upgrade job and the Upgrade Thumbnails job, which refreshes thumbnails for any views that have not been edited or published since Tableau version 2018.2 and converts them from low resolution thumbnail images (192 x192 pixels) to high resolution thumbnail images (300 x 300 pixels), as shown in the figure below.

**Note:** Starting in Tableau Server version 2020.2 and later, the Upgrade Thumbnails job is turned off by default. Server Administrators can use `tabcmd` to run the Upgrade Thumbnails job. For more information, see `upgradethumbnails`.

When the Upgrade Thumbnails job refreshes the thumbnail images, the modified date of the view is changed to match the thumbnail update date. The Upgrade Thumbnails job does not change the modified date of workbooks when it updates the contained view's thumbnails.

Depending on the number of workbooks you have, the Upgrade Thumbnails job can run for a few minutes to a few hours. You may notice that CPU usage on Backgrounder nodes is higher than normal during the time that the Upgrade Thumbnails job is running. You may also notice that thumbnail images may appear in low resolution for up to a week after upgrading to Tableau Server 2019.1 or later, while the Upgrade Thumbnails job processes all of the thumb-

nail images used in your workbooks. We recommend that you wait for the Upgrade Thumbnails job to complete before you back up Tableau Server.

After the first run of the Upgrade Thumbnails job, it runs on a predefined weekly schedule. The Upgrade Thumbnails job runs at lowest priority and creates one task per workbook in the `background_jobs` table to upgrade any low resolution thumbnails. Low resolution thumbnails published to Tableau Server by Tableau Desktop version 2018.3 and earlier are automatically cleaned up each week when the Upgrade Thumbnails job runs.

### Troubleshooting

You can check the status of the Upgrade Thumbnails job using the [Background Tasks for Non Extracts administrative view](#). The Upgrade Thumbnails job can display either the success or error status.

#### **Upgrade Thumbnails job failed, or it completed but some thumbnails are still low-resolution.**

The Upgrade Thumbnails job might show error status if your credentials are wrong. In that case, the workbook thumbnails will still appear in fuzzy, low-resolution (192 x192 pixels). Update your credentials, and the Upgrade Thumbnails job will update the workbook thumbnails the next time it runs.

## Background Task Delay

**Note:** This view is only available to server administrators. To access server views on multi-site deployments, click the site menu and select **Manage All Sites**. For information about how to navigate to administrative views, see [Administrative Views](#) .

The Background Task Delay view displays the delay for flow tasks, extract refresh tasks and for subscription tasks—that is, the amount of time between when they are scheduled to run and when they actually run. You can use the view to help you identify places you can improve server performance by distributing your task schedules and by optimizing tasks.

Here are possible reasons for the delays, and ways that you might reduce the delays:

- Many tasks are scheduled for the same time. In the example view, tasks that show long delays are clustered at the same time every day, which creates spikes in the wait time. Note that you can set the **Timeline** filter to a single day to view task delays by hour and identify the hours of the day which have many tasks scheduled at the same time. A solution to this issue can be to distribute the tasks to off-peak hours to reduce load on the server.
- Specific tasks take a long time to run and are preventing other tasks from running. For example, there might be an extract refresh job that is connecting to a slow data source or that is processing a large amount of data. Use the **Background Tasks for Extracts** administrative view to identify which extract refresh tasks are running slowly. You can then optimize the extract refresh task by filtering the data, aggregating the data, or creating multiple data sources for individual tables in a data source.

## Tableau Server on Linux Administrator Guide

- Other server processes are running at the same time and are consuming server resources and slowing down performance. Monitor the CPU and memory usage of server processes to see which processes are consuming the most resources and then adjust the configuration of processes on your server.

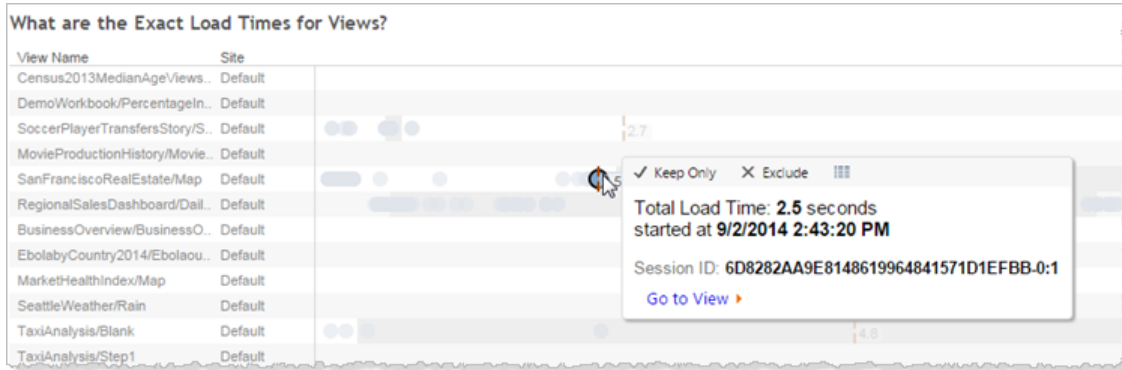

### Stats for Load Times

The Stats for Load Times view shows you which views are the most expensive in terms of server performance. You can filter by view and time range. Server administrators can filter by site. You can also limit the view based on load time in seconds, using the sliding Load Time filter. Load times are for the server. Depending on your client browser and networking, actual load time may vary slightly.

The **Average Load Times** graph shows average load times for views based on the filters you set. Hover over a point to see details. Select a point on the line to update the rest of the view for the selection:

The **Exact Load Times** view shows exact time to load the listed views. A vertical line shows the average load time for each view. Select a mark to see details of a specific instance of the view loading:

## Stats for Space Usage

The Stats for Space Usage view can help you identify which Tableau content uses the most disk space on the server. Disk space usage displays by user, by project, and by the size of the Tableau content (workbook, data source, flow output, or virtual connection) and is rounded down to the nearest number.

Note that virtual connections require Data Management. See About Data Management for details.

To open this view, click **Site Status** on the left nav, and then under Dashboard, click **Stats for Space Usage**.

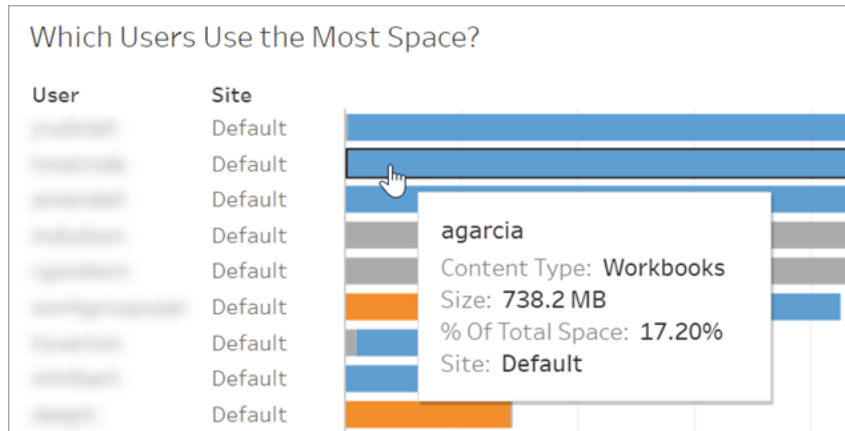

Use the **Min Size** filter to control which Tableau content displays, based on the amount of space they use.

Three bar graphs give you information about space usage on your Tableau Server:

- **Which Users Use the Most Space**—This shows the users who own data sources and workbooks that use the most space. Click a user name to filter the next two graphs for that user. Click the data source bar or the workbook bar for a user to filter the next two graphs for that type of object for that user. Click the selected user or bar to clear the selection.
- **Which Projects Use the Most Space**—This shows the projects with the data sources and workbooks that use the most space. If a user or object type is selected in the Which Users Use the Most Space graph, this displays information specific to the selection.

- **Which Workbooks, Data Sources, Flows, and Virtual Connections Use the Most Space**—This shows which Tableau content uses the most space. The bars are color-coded based on the length of time since the last refresh.

Move your cursor over any bar to display usage details:

Click on a bar to select it and update the other areas of the view based on that selection.

## Server Disk Space

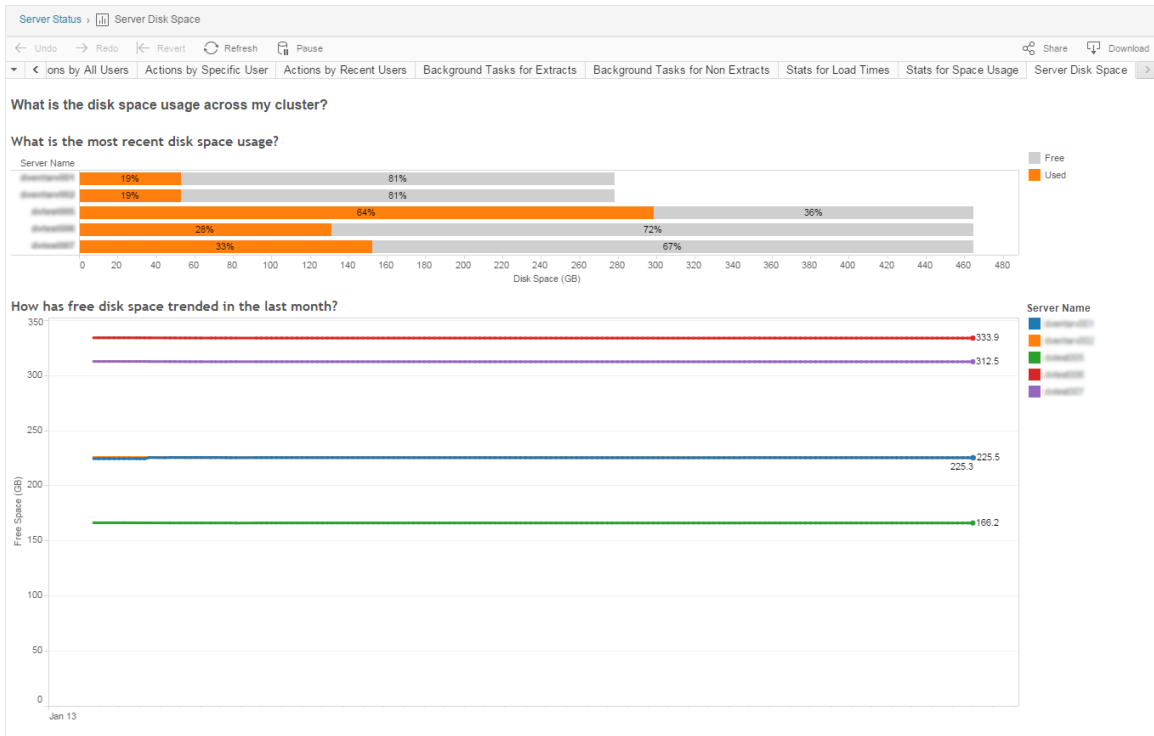

**Note:** This view is only available to server administrators. To access server views on multi-site deployments, click the site menu and select **Manage All Sites**. For information about how to navigate to administrative views, see [Administrative Views](#).

Use the Server Disk Space view to see how much disk space is in use on the computer or computers that run Tableau Server, where disk space refers only to the partition where Tableau Server is installed. You can also use this view to identify sudden changes in disk space usage.

This view reports disk space usage as a decimal GB value. If the operating system of your Tableau Server computers report the value using binary GB, the amounts can differ.

For a distributed installation, the view displays information about each computer in the cluster.

# Tableau Server on Linux Administrator Guide

The Server Disk Space view includes two graphs:

- **What is the most recent disk space usage?**—This graph shows disk space usage for the last 30 days both in gigabytes and as a percentage. Disk space refers only to the partition where Tableau Server is installed.
- **How has free disk space trended in the last month?**—This graph shows changes to disk space usage over the last month. Rest your pointer on a line to view the exact amount of free disk space for a point in time.

When Tableau Server is low on disk space, you can remove files to free space.

**Tip:** You can have Tableau Server notification you when free disk space falls below a threshold that you specify. For more information, see [Configure Server Event Notification](#).

## Login-based License Usage

**Note:** This view is only available to site administrators and server administrators when login-based license management is enabled on Tableau Server. For information about how to navigate to administrative views, see [Administrative Views](#) .

The Login-based License Usage view lets server administrators view login-based license activation usage for Tableau Cloud or Tableau Server. The Login-based License Usage view can help you manage licenses efficiently and determine if you need more or fewer licenses.

This view can help you answer the following questions:

- Who is using a Tableau Desktop or Tableau Prep Builder license in my enterprise?
- Has a Creator role been shared or transferred?
- Has any activation activity occurred on a computer where it should not be?
- On which host is the activation being used?
- Which role is assigned to the user?
- On which Tableau product is the license in use?
- On which Tableau version is the license in use?
- Did the Creator role activate through Tableau Desktop or Tableau Prep Builder?
- Has the Creator seat been activated?
- How many Creator seats are in use?
- How many Creator seats are not in use?
- When was a Creator seat last used?

# Tableau Server on Linux Administrator Guide

In addition to using the login-based license usage administrative view, you can also access login-based license usage data (`identity_based_activation_reporting`, `identity_based_activation_user_role_change`, and `identity_based_activation_admin_view`) in the "workgroup" PostgreSQL database of the Tableau Server repository. Before you can access this data, you must [enable access to the Tableau Server repository](#).

### Filters

On the report screen, you can change the time window to show when seats were last used, filter on actions, filter on user name, and sort by columns.

- **Time Window in Days.** Enter the number of days for which to view login-based license management activated client usage data. You can view data for the past 30 days up to a maximum of 183 days.
- **(All).** Apply all filters to the view.

- **Activated.** Show Creator users that have activated using login-based license management.
- **in use.** Show Creator users who activated using login-based license management whose seats are in use.
- **last used.** Show when the login-based license management client was last used.
- **unassigned.** Show which login-based license management activated Creator seats are currently unassigned.
- **user name.** Show login-based license management activations in use by the specified user.

When you hover over the filter card, a drop-down icon appears. Click the icon to specify whether the view should include data that matches the filter (the default) or exclude data that matches the filter:

### Which creator seats are in use in the last <nn> days?

This area of the dashboard shows a list of three types licenses (activated, in use, and unassigned). Hovering over an activated, in use, or unassigned mark gives you information including the registered user of the copy of Tableau. Click a column head to sort the list.

### Which creator seats have not been used in the last <nn> days

This area of the dashboard shows a list of licenses that have not been used during the specified time period. A timeline shows the last use date. Hovering over a last use mark gives you information including the registered user of the copy of Tableau.

## Desktop License Usage

**Note:** This view is only available to server administrators. To access server views on multi-site deployments, click the site menu and select **Manage All Sites**. For information about how to navigate to administrative views, see [Administrative Views](#) .

The Desktop License Usage view lets server administrators see usage data for Tableau Desktop licenses in your organization. This can help you manage licenses efficiently and determine if you need more or fewer licenses. This view can help you answer the following questions:

- Who is using a Tableau Desktop license in my enterprise?
- Have any licenses been shared or transferred?
- Is any license being used on a computer where it should not be?
- Does a specific user use their license?
- What types of licenses are being used in my enterprise?
- Do I need to convert any trial licenses?

**Note:** To get data about licenses, each copy of Tableau Desktop version 10.0 or later needs to be configured to send data to Tableau Server. This configuration can be done at installation time, using scripting or third-party software to install and configure Tableau, or after installation, by modifying the registry or property list file. For more information, see [Configure Desktop License Reporting](#).

In order to view license data, Desktop License Reporting must be enabled on Tableau Server. See [Enable and configure Desktop license reporting](#).

## Filters

- **Product Keys.** Type a string to filter the dashboard to only those licenses that include the string anywhere in the product key. For example, to see only licenses that begin with TDTD, type TDTD and press Return to filter the view. Click the **X** after the string to reset the filter.
- **Action.** Use this filter to control what the dashboard displays, based on the action taken. Actions are **Activate**, **Use**, and **Return** (deactivate). If the **Use** action is not selected, nothing is displayed in the top bar graph.
- **Department.** Use this filter to control what departments the dashboard displays licenses for. The filter is populated based on the **Department** values specified when Tableau Desktop is registered.
- **Select time duration in days.** Use this slider to specify the time length in days that the dashboard displays information for. The default value is 183 days.

When you hover over the filter card in the first three filters, a drop-down icon appears. Click the icon to specify whether the view should include data that matches the filter (the default) or exclude data that matches the filter:

### Who has used Tableau in the last <nn> days?

This area of the dashboard shows a bar graph of three types of Tableau Desktop licenses (Perpetual, Trial, and Term) and the number of users who have used each license type during the specified time period. Hover over a license type segment to see an explanation of the license type. Click a segment to filter the rest of the dashboard for only that license type. This action filters both the tables that show licenses that have been used and those that have not been. For example, to see a list of term licenses that have been used during the time period, click the Term bar. The "used" and "not been used" lists are filtered to just show term licenses.

## Tableau Server on Linux Administrator Guide

A table of detailed information shows under the bar graph. For each row in the table, action icons display on the right, above a timeline that shows you when the action last took place.

To see a list of the underlying data in a format that allows you to select and copy values like email or product key, click a row in the list of licenses and click the View Data icon:

The data displays in summary form. Click **Full data** to see all the data. From this view you can select and copy individual values, or download the data as a text file.

### What licenses have not been used in the last <nn> days

This area of the dashboard shows a list of licenses that have not been used during the specified time period. A timeline shows the last use date. Hovering over a last use mark gives you information including the registered user of the copy of Tableau.

## Desktop License Expiration

**Note:** This view is only available to server administrators. To access server views on multi-site deployments, click the site menu and select **Manage All Sites**. For information about how to navigate to administrative views, see [Administrative Views](#) .

The Desktop License Expiration view gives server administrators information about which Tableau Desktop licenses in your organization have expired or need maintenance renewal. This can help you manage licenses efficiently. This view can help you answer the following questions:

- What trial or term licenses have expired?
- What perpetual licenses have expired maintenance?
- What perpetual licenses have maintenance renewals coming up?

To renew a license or get additional renewal information, see [How to renew your Tableau licenses](#).

**Note:** In order to get data about licenses, each copy of Tableau Desktop version 10.0 or later needs to be configured to send data to Tableau Server. This configuration can be done at installation time, using scripting or third-party software to install and configure Tableau. For more information, see [Configure Desktop License Reporting](#).

In order to view license data, Desktop License Reporting must be enabled on Tableau Server. See [Enable and configure Desktop license reporting](#).

## Filters:

- **Product Keys**—Type a string to filter the dashboard to only those licenses that include the string. For example, to only see licenses that begin with TDTD, type TDTD and press return to filter the view. Click the "x" after the string to reset the filter.
- **Department**—Use this filter to control what department(s) the dashboard displays licenses for. The filter is populated based on the Department values used when registering copies of Tableau Desktop.
- **Time Duration**—Use this filter to control the length of time for which the dashboard displays information.

The view includes the following tables, which are affected by the filters you set at the top of the view:

- **What keys have expired maintenance**—This table shows the product keys for which maintenance has expired, with a vertical line indicating the point at which the six month window for renewing maintenance closes. If maintenance for a key is expired for more than six months you need to purchase a new key in order to qualify for support or

upgrades.

- **What trial and term licenses have expired**—This shows the trial or term product keys that have expired.
- **What is the maintenance schedule for my keys**—This shows the keys and their maintenance status.

## Backgrounder Dashboard

The **Backgrounder Dashboard** view is an overview of the background jobs. Using this view, you can find more information about:

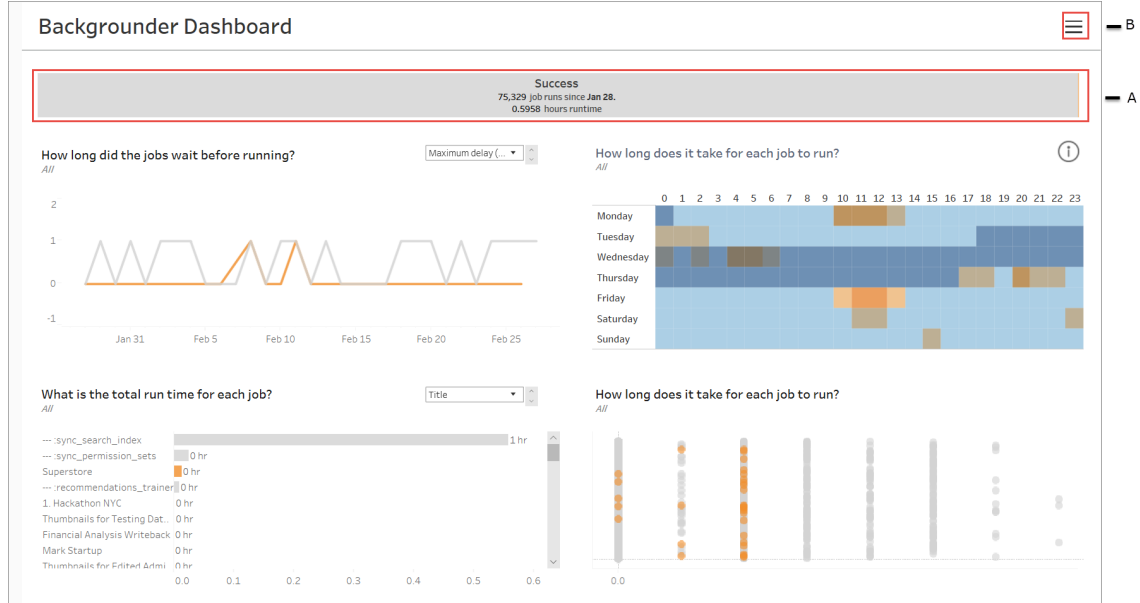

- The time it takes for jobs to run.
- When backgrounder is busy or overloaded.
- Jobs that completed successfully, failed, or canceled.

Note: This view does not include flow run jobs.

In previous versions of Tableau Server, admin views were all displayed in the same workbook, in separate tabs. However, the two new admin views are displayed as separate workbooks and not part of the existing admin view workbook. You can navigate to the new admin views from the Server or Site Status page:

## Summary and Filters

**A** - At the top, is a summary chart that tells you the number of jobs that have succeeded, failed or canceled. You can click on the sections of the bar chart to filter the information by job status. This filter is applied to the entire view and the information displayed includes only jobs with the job status that you selected.

**B** - You can find additional filter options by clicking on the filter icon. A Filter pane is displayed that allows you to filter by **Task type**, **Job executed at**, **Site**, **Project**, **Content owner**, **Schedule**, and **Backgrounder ID**. The Backgrounder ID is unique to a Backgrounder process. You can use this to see the information about the work done by each Backgrounder process. When you select one or more of these filters, they are applied to the entire view.

×

## FILTERS

**Task type**

**Job executed at** ⓘ

**Site** 18 19 20 21 22 23

**Project**

**Owner**

**Schedule name**

**Backgrounder**

**Job Status**

**Priority**  
0 100

**Job Status**  
 Failed  
 Success

Details

The Backgrounder Dashboard has four sections each showing different information about jobs. Each of these sections have more filters in the drop down menu that you can apply to that specific section.

- 1. **The section at the top left** gives you information about the jobs with the selected job status or any filters you selected using the Filter pane. If no selection is made, all jobs are included.

The information displayed also varies based on the selection you make using the drop down:

- 1. **Total run time** : This shows you the total run time for all jobs with the selected job status, and any other filters you selected.

For example, if you selected, Job Status: Failed, and Task type : Subscriptions, the graph shows all subscription jobs that failed.

- 2. **Number of Jobs**: This shows you the number of jobs that ran for the selected job status and any other selected filters.
- 3. **Maximum delay**: This shows you the how long the jobs were queued before running.

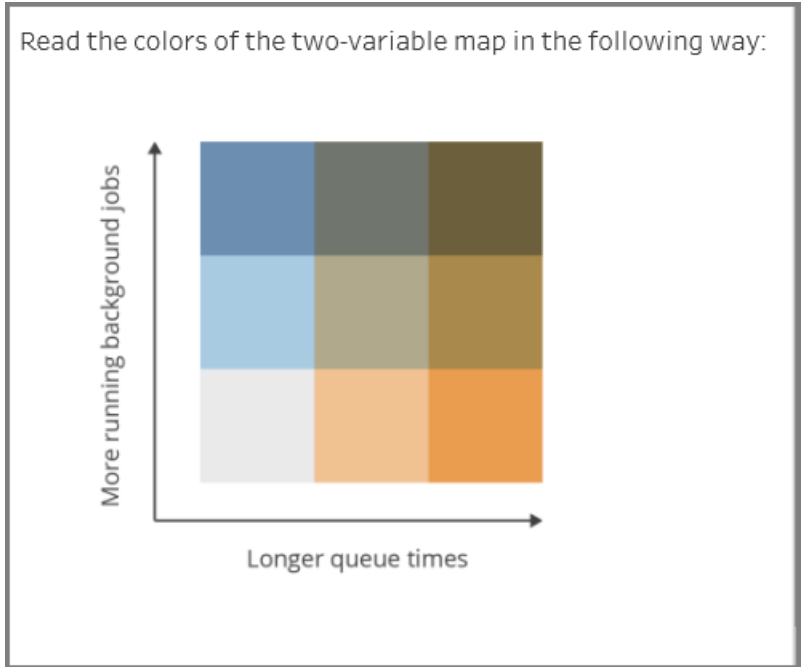

2. **The section at the top right** gives you information on how busy or overloaded the Backgrounder is on a given day and time. The information displayed however depends on the filter selections you made for the job status and other options in the Filter pane.

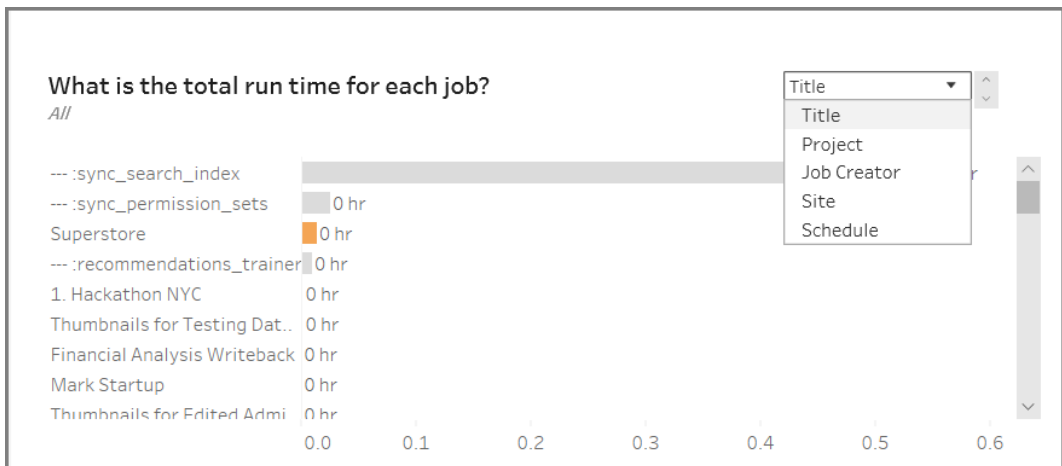

If you click on the information icon at the top right part of this section it, a color legend is displayed.

- The variations in the blue color correlates to the number of jobs running in that time period. The darker the blue, the more jobs that are running.
- The variations in the orange color correlates to the queue times . The darker the orange, the longer the queue time.
- Using both of these metrics, you can identify when the backgrounder is busy (dark blue) or is overloaded (dark orange).

3. **The section at the bottom left** gives you run time information about the jobs with the selected status or any other filters you selected using the Filter pane. If no selection is made, all jobs are included. Select marks in the top sections to populate this section with details for the selected content.

The drop down selections gives you more options and the information displayed changes accordingly:

- When **Title** is selected, the run time information for each individual job is displayed.
- When **Project** is selected, the total run time for each project is displayed.
- When **Job Creator** is selected, the total run time for jobs created by a specific user is displayed.
- When **Site** is selected, the total run time for jobs on that specific site is displayed.
- When **Schedule** is selected, the total run time for jobs using that specific schedule is displayed.

4. **The section at the bottom right** tells you how long it took for each job to run.

## Stale Content

The Stale Content view can be used to identify content that hasn't been used or accessed in the specified time period (displayed as Stale Access Threshold). You can set that time period in days. The minimum value for the time period is 1 day and the maximum is 120 days.

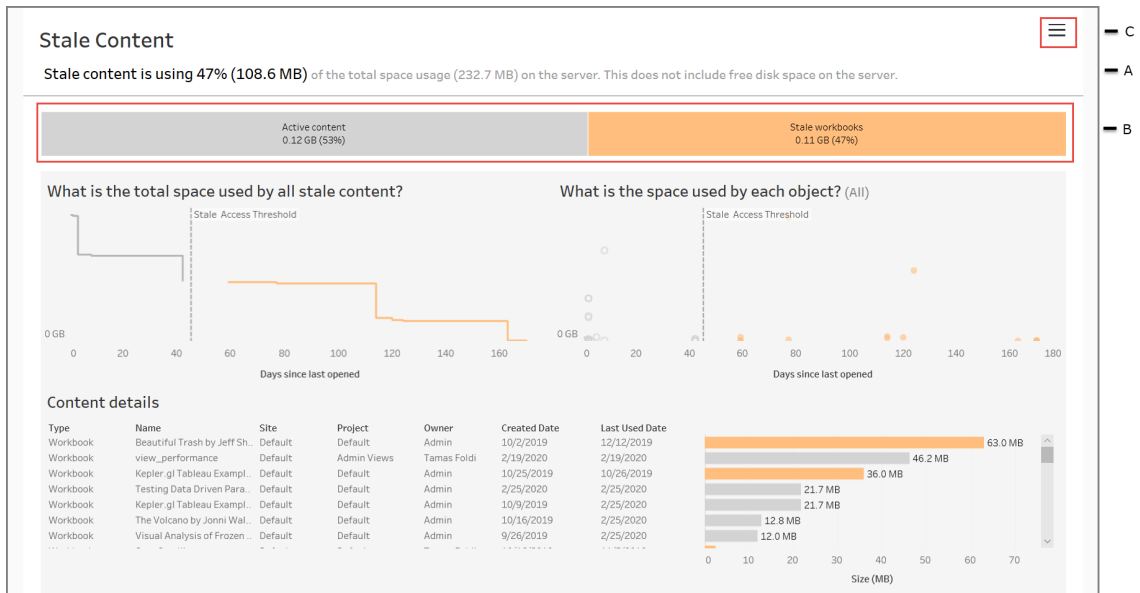

This view also provides the information about the disk space used by stale and active content.

In previous versions of Tableau Server, admin views were all displayed in the same workbook, in separate tabs. However, the two new admin views are displayed as separate workbooks and not part of the existing admin view workbook. You can navigate to the new admin views

from the Server or Site Status page:

### Summary and Filters

**A** - At the top of the view, you will see a statement that summarizes the amount of space that is used by stale content compared to the total space used. The total space used is defined as the sum total of disk space used by active and stale content.

**B** - This summary is followed by a chart that gives you a further breakdown of the types of stale content and content that is considered active - meaning content that has been accessed

## Tableau Server on Linux Administrator Guide

in the time period below the stale threshold. You can click on the bar chart and apply it to filter the data displayed in the view.

**C** - You can see and apply additional filter options by clicking the filter icon. This filter pane includes:

- Stale Threshold
- Site
- Project
- Content Owner
- Size
- Content type

**FILTERS**

Stale Threshold

These filters are applied to the entire view.

#### Details

The Stale Content view has three sections as described below that provides details:

1. **The top left section** shows you the total space used for the selected content. The x-axis shows the number of days that have passed since the content was last opened, and the y-axis shows you the size. The graph also shows the stale threshold.

Set your desired staleness threshold, then use this view to identify content that is the most stale. Click the **Stale Workbooks** or **Stale Datasources** in the bar at the top to filter to the content of interest. Select the marks to the right of the **Stale Access Threshold** to see more details about content. The details are displayed in the bottom left section.

2. **The top right section** shows you the amount of space that is used by each selected content. For example, if you select Stale workbooks, the space used by each stale workbook is displayed. You can use this section to find out which content is the most stale, or is taking the most space.

This section helps you identify content that hasn't been used in a long time. Click the **Stale Workbooks** or **Stale Data Sources** on the bar at the top. Select the oldest set of unused content (marks further to the right) to see more details. The details are displayed in the bottom left section. This can be your next set of content to consider for archiving or deleting as these are contents that nobody has been using, regardless of size.

3. **The section at the bottom** shows detailed information about the selected content as shown below:

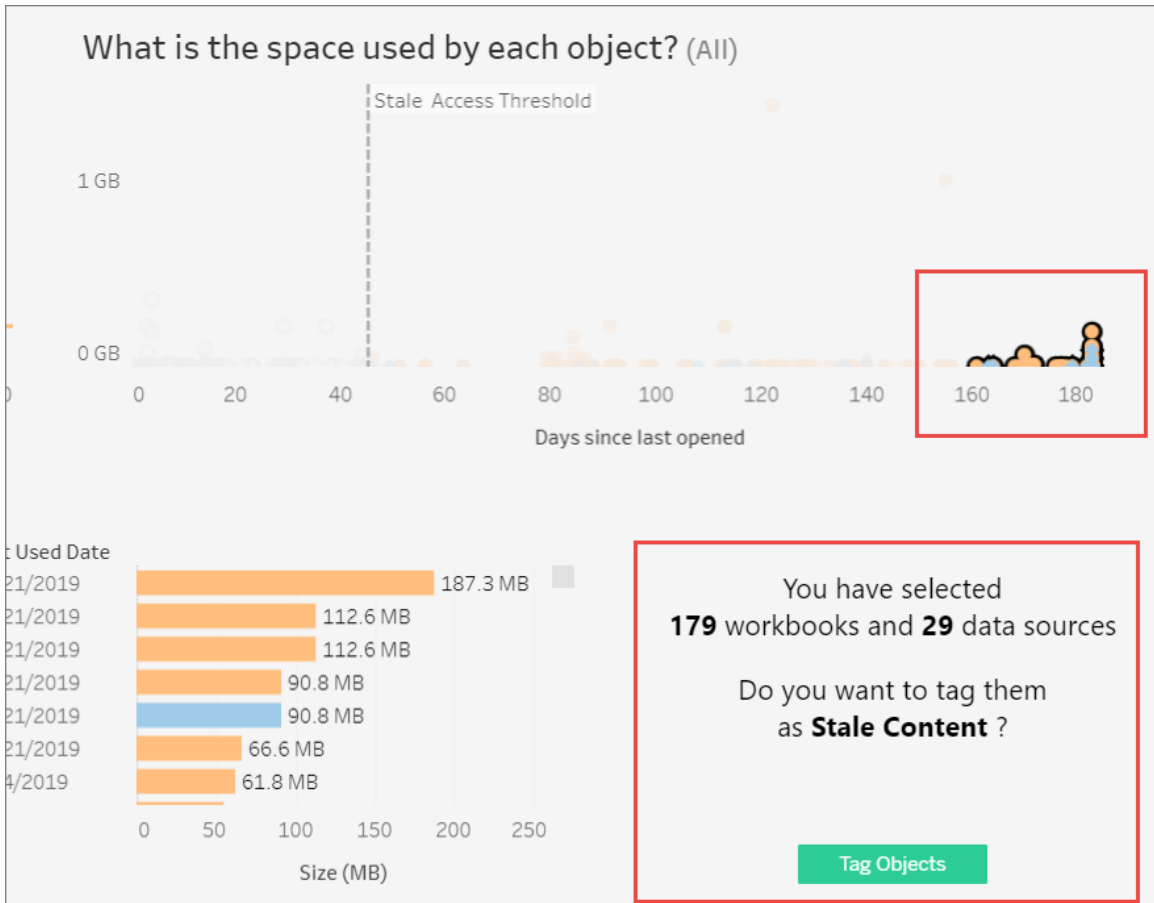

| Type     | Name                          | Site    | Project     | Owner       | Created Date | Last Used Date | Size    |

### Archive or Delete Stale Content

Starting in 2020.3, the Stale Content admin view includes a feature that allows you to select and tag content as stale. You can select content from either the section at the bottom or the top right section. When you make a selection, you will see the number of objects and the type of content that are selected, as seen in the screen shot below. Click the **Tag Objects** button to tag the selected content.

In the screen shot shown below, content that has not been opened in the last 160 days or more are selected to be tagged as stale content.

To find all the tagged content, on Tableau Server web interface, navigate to **Explore**. Select the **Stale Content** filter to see all the content that have the stale content tag. You can now select the content and either move it to a project that you use for archiving or delete the content.

The screenshot shows the Tableau Server 'Explore' interface. The main table lists workbooks with columns for Type, Name, Actions, Views (all-time), Sheets, Size, Project, Owner, and Modified. A search results panel on the right shows a list of tags with their counts. The 'Stale Content' tag is highlighted with a red box and has a count of 229.

| Type | Name                      | Actions | Views (all-time) | Sheets | Size     | Project | Owner           | Modified               |

| □ ☆  | 11 features               | ...     | 1                | 4      | 1.0 MB   | Default | Rupal Rashmi    | Jan 28, 2020, 2:52 PM  |
| □ ☆  | 1101939                   | ...     | 7                | 2      | 4.7 MB   | Default | Matt Morgenroth | Apr 21, 2020, 3:49 AM  |
| □ ☆  | 123 345 lala lala         | ...     | 1                | 2      | 15.7 KB  | Default | Rupal Rashmi    | Jan 28, 2020, 2:51 PM  |
| □ ☆  | 123 abc 456 xyz           | ...     | 1                | 2      | 16.9 KB  | Default | Rupal Rashmi    | Jan 28, 2020, 2:54 PM  |

| Tag           | Count |
|---------------|-------|
| chicken       | 2     |
| HST           | 4     |
| noodle        | 2     |
| Stale Content | 229   |
| test          | 1     |

If you have Advanced Management on your Tableau Server, you can use the Tableau Content Migration Tool to manage archiving stale content on a regular schedule. For example, you can build a plan that runs on a regular schedule that can automatically pick up content tagged as Stale Content and move it to an Archive project. After a certain amount of time, the content in this project can be purged from the system. For more information see, [Migration Plans: Workbooks](#).

## Ask Data Usage

### Important changes for Ask Data and Metrics

Tableau's Ask Data and Metrics features were retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau AI and Tableau Pulse are reimagining the data experience](#).

The Ask Data Usage view is a pre-built dashboard that allows site or server admins to see and understand the usage patterns and value of Ask Data for a site. Admins can see the growth of engagement with Ask Data and monitor the results of internal training or roll-outs. The dashboard highlights the top Ask Data users, data sources, and data source owners, along with some headline value metrics.

To enable Ask Data, see [Disable or Enable Ask Data for a Site](#).

Explore the dashboard

The Ask Data Usage view provides information about Ask Data across the entire site. You can use the following metrics to understand user engagement and help drive self-service analytics adoption in your organization.

At the top of the dashboard, three headline metrics provide an overview of Ask Data usage on the site.

- **Number of Users on Ask Data** - This shows the total number of Ask Data users on the site.

- **Number of Queries on Ask Data** - This shows the total number of Ask Data queries issued on the site.
- **Number of Data Sources Used with Ask Data** - This shows the total number of data sources used with Ask Data.

In the middle of the dashboard, two line charts show you how Ask Data is used over time.

- **Distinct Users Over Time** - This shows the distinct number of Ask Data users over time.
- **Distinct Data Source Owners Over Time** - This shows the distinct number of data source owners over time.

At the bottom of the dashboard, three bar charts list the top Ask Data users, data sources, and data source owners.

- **Top Ask Data Users** - This lists the top Ask Data users and the total number of queries issued by each user.
- **Top Ask Data Data Sources** - This lists the top Ask Data data sources and the total number of queries issued for each data source.

- **Top Ask Data Data Source Owners** - This lists the top Ask Data data source owners and the total number of data sources owned by each user.

## Data Quality Warning History

When Tableau Catalog is enabled in your environment, site administrators can see how data quality warnings are being used on the site using the pre-built admin view, Data Quality Warning History.

For more information about Tableau Catalog, part of Data Management, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

From the Site Status page, select the Data Quality Warning History dashboard:

The dashboard shows how many data quality warnings are active over a period of time. It also shows how many warnings have been changed (created, updated, and deleted) over that same time period.

See warning details

Under the line charts are the details about the data quality warnings, including:

- **Date and Time** - When the warning was created or last changed.
- **Content Type** - The type of asset the warning is set on, such as a database, table, or data source.
- **Content Name** - Name of the asset the warning is set on.
- **Changed By** - Name of the person who created or last changed the warning.
- **Status** - If the warning is active or inactive.
- **Type** - Warning type can be Stale data, Warning, Deprecated, Sensitive data, or Under maintenance.
- **Visibility** - The warning can be configured to have normal (the default) or high visibility.
- **Message** - The message the warning creator wrote to display to users when they see the details of the warning.

### Filter warning history

When you review data quality warning history, you can click a mark on the view to filter the details shown below the view.

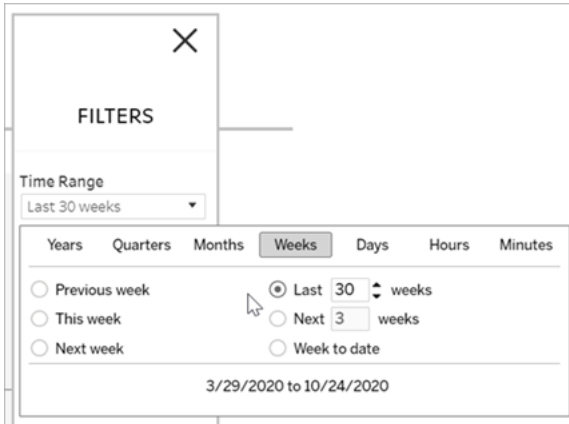

The numbers on the Day axis represent the date within the time range. For example, if today is November 18, and you filter for the last 7 days, the Day axis shows 12-18.

More filters are available when you click the filter icon in the upper right corner: filter by time range and by content type.

## Tableau Server on Linux Administrator Guide

### Filter by time range

You can configure the time range from years to minutes.

### Filter by content type

You can see all the data quality warnings on your site, or you can filter to see warnings for specific types of assets, like data source or table:

### Access data quality warning history data

In addition to using the Data Quality Warning History admin view, you can also access data quality warning history data in the "workgroup" PostgreSQL database of the Tableau Server repository. Before you can access this data, you must [enable access to the Tableau Server repository](#).

See [About the Tableau Data Dictionary](#) for a link to open the latest data dictionary where you can search for these tables with quality warning history data:

- `historical_events`
- `historical_event_types`
- `hist_data_quality_indicators`
- `data_quality_indicators`

Who can do this

To set a data quality warning, you must be a server or site administrator.

## Create Custom Administrative Views

In addition to the pre-built administrative views available on the Maintenance page on the Server, you can use Tableau Desktop to query and build your own analyses of server activity. To do this, you can connect to and query views in the Tableau Server repository using one of two built-in users: the "tableau" or "readonly" user.

To connect to the Tableau Server repository, see [Collect Data with the Tableau Server Repository](#).

- The **tableau** user—The tableau user has access to special views and a subset of tables in repository database. These views and tables are provided so that administrators can create custom administrative views. Tableau makes an effort to limit changes to these tables and views so that custom views built with them do not break.
- The **readonly** user—The readonly user has access to a large number of the repository tables, providing more data about server usage. Administrators can use these to create custom administrative views too, but many of the tables are intended primarily to support the functioning of Tableau Server and may be changed or removed without warning. This means that views created from these tables can break when the database structure is changed.

For examples of custom administrative views, see the [Tableau Community](#). You can also use the temporary workbook that is generated when you view the built-in Administrative views.

## Tableau Server on Linux Administrator Guide

Before you can connect using one of the built-in users, you must enable access to the Tableau Server database. After doing this you can use Tableau Desktop to connect to and query the database as the `tableau` user or the `readonly` user.

The `tsm configuration set option auditing.enabled` controls whether Tableau Server collects historical user activity and other information in the repository. It is enabled by default. Be aware that collecting historical events impacts the size of Tableau Server's backup file (`.tsbak`).

- All `hist_` tables are controlled by the `tsm configuration set option wgserv-er.audit_history_expiration_days`, which controls how many days of event history are kept in the repository and has default value of 183 days.
- The `_http_requests` table is cleaned of all data older than 7 days when you run `tsm maintenance cleanup` with the `--http-requests-table` option. For more information, see [Remove Unneeded Files](#).
- The `_background_tasks` table is cleaned automatically and keeps data for the last 30 days.
- All other tables with names that begin with a "\_" prefix contain current data.

For more information about the tables in the Tableau Server repository, see [Workgroup Database Data Dictionary](#).

# Performance

You can monitor and tune the performance of Tableau Server.

## Tableau Server Performance Overview

When you take the time to understand the performance of Tableau Server, you make it easier to serve your users by improving the efficiency of Tableau Server. Although every server environment is unique, and there are many variables that can impact performance, the general

steps that you take to understand and act on performance data in Tableau Server are the same.

- **Notifications.** Configure email notifications for important server events. For example, you can receive notifications when server processes become unavailable and when the server is running out of disk space.
- **Monitoring.** Collect and analyze data about Tableau Server to understand how well the server is performing.
- **Tuning.** Make adjustments to tasks, process configurations, and more to improve the performance of Tableau Server.
- **Troubleshooting.** Identify bottlenecks in resources, workbooks, and more to improve the performance of Tableau Server.

## General Performance Guidelines

### Hardware and Software

**Add more cores and memory:** Regardless of whether you're running Tableau Server on one computer or several, the general rule is that more CPU cores and more RAM will give you better performance. Make sure you meet the Tableau Server recommended hardware and software requirements.

If you are running Tableau Server in a virtual environment, use your VM host's best practices for vCPU allocation in relation to the number of physical CPU cores on the VM host.

### External repository

For optimal performance for Tableau Server we recommend isolating the repository on a dedicated node in your deployment. If you have an Advanced Management license, consider running the repository as an external database.

If your organization has a peak load of more than 1000 VizQL sessions per hour, we also recommend running Tableau Server on Linux. In this scenario, VizQL sessions refer to any user actions that display or generate visualizations from Tableau Server.

For more information, see [Tableau Server External Repository](#).

## Configuration

**Schedule refreshes for off-peak hours:** Backup tasks tend to stall other background tasks until the backup is completed. Use the Background Tasks for Extracts administrative view to see your refresh and backup task schedules. Your refresh tasks should be scheduled for off-peak hours that don't overlap with your backup window.

**Look at caching:** Caching helps Tableau Server respond to client requests quickly, especially for views that connect to live databases. Use the `tsm data-access caching list` command to confirm the caching frequency is set to `low` (this is the default).

Tableau Server uses a query cache to store query results. The size of the query cache is automatically set based on the amount of available system memory, as long as you have not set it manually. The query cache consists of the logical query cache, the metadata cache, and the native query cache. The default settings are suitable for most situations but it is possible to manually configure them using the TSM command line interface. The TSM settings are: `native_api.InitializeQueryCacheSizeBasedOnWeights`, `native_api.QueryCacheMaxAllowedMB`, `native_api.LogicalQueryCacheMaxAllowedWeight`, `native_api.MetadataQueryCacheMaxAllowedWeight`, `native_api.NativeQueryCacheMaxAllowedWeight`, and `native_api.QueryCacheEntryMaxAllowedInPercent`. For more information, see `native_api.InitializeQueryCacheSizeBasedOnWeights`.

### Consider changing two session memory settings:

- **VizQL session timeout limit:** The default VizQL session timeout limit is 30 minutes. Even if a VizQL session is idle, it is still consuming memory and CPU cycles. If you can make do with a lower limit, use `tsm configuration set Options` to change the

`vizqlserver.session.expiry.timeout` setting.

- **VizQL clear session:** By default, VizQL sessions are kept in memory even when a user navigates away from a view. This reduces the need to rebuild views but consumes more session memory. To free up memory, you can end sessions when users leave views by changing the value of the `vizqlserver.clear_session_on_unload` setting to `true`. (Regardless of this setting, sessions for the Tableau Mobile app are always kept in memory, improving mobile performance.)

**Assess your process configuration:** Tableau Server is divided into six different components called server processes. While their default configuration is designed to work for a broad range of scenarios, you can also reconfigure them to achieve different performance goals. Specifically, you can control on which computers the processes run and how many are run. See Performance Tuning for general guidelines for one-, two-, and three-node deployments.

## Server Resource Manager (SRM)

The Server Resource Manager (SRM) monitors the system resources each Tableau process is using as well as tracking the total usage of Tableau Server on the system. If either a specific process or the product as a whole takes up too much system resources, SRM can notify the processes to free the resources or restart those processes.

The thresholds that determine when SRM will notify or restart a process are set in the SRM configuration options. The Tableau development team has set the default settings based on internal testing and don't recommend you change these settings directly.

If you are seeing excessive system resource usage, we recommend that you contact Tableau Support to help determine if these configuration options need to be modified to solve the problem or issue that you are seeing.

## Performance Monitoring Overview

When you monitor a server, you collect and analyze data that signals whether the server is performing badly or running into problems. For example, if you notice that your server is using

100% of its processing capacity for long periods of time, you know that there's a problem.

The data that you need to collect and analyze can be broken down into the following broad categories:

- Resource usage data—how Tableau Server uses hardware resources like disk space, memory, and processors.
- Session and load time data—how users interact with Tableau Server, including how long it takes for views to load and how many concurrent users there are.
- Background task data—how Tableau Server runs tasks that are not directly tied to a user action. For example, background tasks include extract refresh tasks, subscription tasks, and more.

Some of this data, including load time data and extract refresh data, is already accessible from the administrative views that are built into Tableau Server. However, to collect resource usage data you need to use an external performance monitoring tool. To collect additional load time data and background task data, you can connect to the Tableau Server repository.

For more information on the built-in administrative views, see [Administrative Views](#).

**Note:** To use the sample workbook and to publish views to Tableau Server, you must have Tableau Desktop.

### Collect Data with the Tableau Server Repository

The Tableau Server repository is a PostgreSQL database that stores data about all user interactions, extract refreshes, and more. You can enable access to the repository and use the data in it to help analyze and understand Tableau Server performance.

Looking for Tableau Server on Windows? See [Collect Data with the Tableau Server Repository](#).

After you enable access to the Tableau Server repository, you can create views with data from the repository. The views that you create with this data are sometimes called custom administrative views. In addition to being used for performance monitoring, custom admin views can be used for tracking user activity, workbook activity, and more. For more information on the type of data that you can use for these views, see [Create Custom Administrative Views](#) and [About the Tableau Server Data Dictionary](#). Alternatively, if you are only interested in performance data, you can use the preselected database tables in the sample performance workbook.

### Enable access to the Tableau Server repository

You can use Tableau Desktop to connect to and query the Tableau Server repository using two built-in users. The user named `tableau` has access to several database views you can use as part of building your own analyses of Tableau Server activity. The user named `readonly` has access to additional database tables that you can use to create views for even more in-depth analysis and this is the user we recommend you use.

Before you can connect to the repository, you need to enable access for the `readonly` user to the database. Use the `tsm data-access repository-access enable` command to enable repository access. When you enable repository access, you also create a password for the `readonly` user. You will use this password to access to the repository. You may also need to have port 8060 opened on the repository node so you can connect to the database.

1. Verify that port 8060 is opened on the computer where the repository is installed. This is a requirement if you are connecting remotely.
2. Enable repository access and create a `readonly` user password:

```
tsm data-access repository-access enable --repository-username  
readonly --repository-password <PASSWORD>
```

If your password includes special characters, you may need to escape the characters or enclose the password in quotes. Refer to the documentation for the Linux distro that you are running for information about passing special characters in bash shell.

This command will restart Tableau Server.

**Note:** If you later decide that you want to disable remote access to the Tableau Server repository, use the `tsm data-access repository-access disable` command. The command disables external access to the repository. This will not disable access from localhost. For more information, see `tsm data-access repository-access disable`.

### Connect to the Tableau Server repository

This section describes how to connect to a custom set of tables from Tableau Server repository. For more information on the tables that you can connect to, see [About the Tableau Server Data Dictionary](#).

1. In Tableau Desktop select **Data > Connect to Data**, and then select **PostgreSQL** as the database to connect to.

**Note:** You might need to install the PostgreSQL database drivers. You can download drivers from [www.tableau.com/support/drivers](http://www.tableau.com/support/drivers).

2. In the PostgreSQL connection dialog box, enter the name or URL for Tableau Server in the **Server** box. If you have a distributed server installation, enter the name or IP address of the node where the repository is hosted.

Connect using the port you have set up for the `pgsql.port`, which is 8060 by default.

3. Specify `workgroup` as the database to connect to.
4. Connect using the user and the password you specified.

5. Click the **Require SSL** option if you have configured Tableau Server to use SSL for connecting to the repository. For more information, see [Configure Postgres SSL to Allow Direct Connections from Clients](#).
6. Click **Connect**.

The screenshot shows a 'PostgreSQL' connection dialog box. It includes the following fields and options:

- Server:** tableauserver.myco.com
- Port:** 8060
- Database:** workgroup
- Enter information to sign in to the database:**
  - Authentication:** Username and Password (dropdown menu)
  - Username:** readonly
  - Password:** (masked with dots)
- Require SSL
- [Initial SQL...](#)
- Sign In** (button)

7. Select one or more tables to connect to.

The `tableau` user has access to all of the tables that start with an underscore or with `hist_`. For example, you can connect to `_background_tasks` and `_datasources`. The `hist_` tables include information about server users that isn't currently presented in the Actions by Specific User view. The `readonly` user has access to additional tables that can be used to query other information about server usage.

8. Click **Go to Worksheet**.

### PostgreSQL Version

Use the following steps to find the version of PostgreSQL used by Tableau Server:

1. Log into Tableau Server as a user with sudo access.
2. Use the following command to view the version of PostgreSQL installed on the machine:

```
$ postgres --version psql --version
```

If the above command results in an error, you may need to locate the directory. Use the following steps to locate the directory:

1. `$ locate find /opt/tableau -name psql`
2. Navigate to the path and issue the version command to find the PostgreSQL version:

```
$ postgres psql --version
```

You can also connect to the workgroup database and issue the following query to get the version: `select version()`

### About the Tableau Server Data Dictionary

The Tableau Server Data Dictionary includes information about the tables and views in the "workgroup" PostgreSQL database of the Tableau Server repository. This database provides persistent storage for Tableau Server and is primarily intended to support that application. The Data Dictionary is not a complete description of all tables and fields in the database, and is provided for customers who want to query the database for information about usage on Tableau Server. Because the database and its contents are intended to support Tableau

Server, the structure and contents may change without warning. This means any custom views you build from directly querying the database could break.

**Important:** The Data Dictionary is provided with an **As-Is** level of support. For assistance creating reporting based on the dictionary, including writing queries to the database or updating broken workbooks, please engage with the Tableau Community forums.

[Open the Data Dictionary](#) (new window).

## Performance Tuning

This section describes how to use the performance data that you collect to identify ways to improve the performance of Tableau Server. Because no two server environments are identical, we can't provide hard and fast rules for tuning server performance. However, you can draw conclusions about performance from patterns in the data that you collected.

For example, are there recurring spikes? Do any of the patterns that you notice in the administrative views correspond to similar patterns in a monitoring tool? Observing patterns like this can guide you in testing and incremental tuning.

Most performance tuning for Tableau Server boils down to these general approaches:

- **Optimize for User Traffic:** This tunes the server to respond to user requests and to display views quickly.
- **Optimize for Extracts:** This tunes the server to refresh extracts for published data sources. You might want to optimize for extract refreshes if your organization has a lot of data and the data needs to be as up to date as possible.
- **Optimize for Extract Query-Heavy Environments:** This is a specialized server configuration to optimize for query performance of workbooks that use extracts as their data source.

Rendering views and refreshing extracts generate the most load on the server, so you should optimize for the task that your organization is most interested in.

As a best practice, optimize your workbooks for performance. For more information and resources on how to optimize your workbooks, see [Optimize Workbook Performance](#).

## Optimize for User Traffic

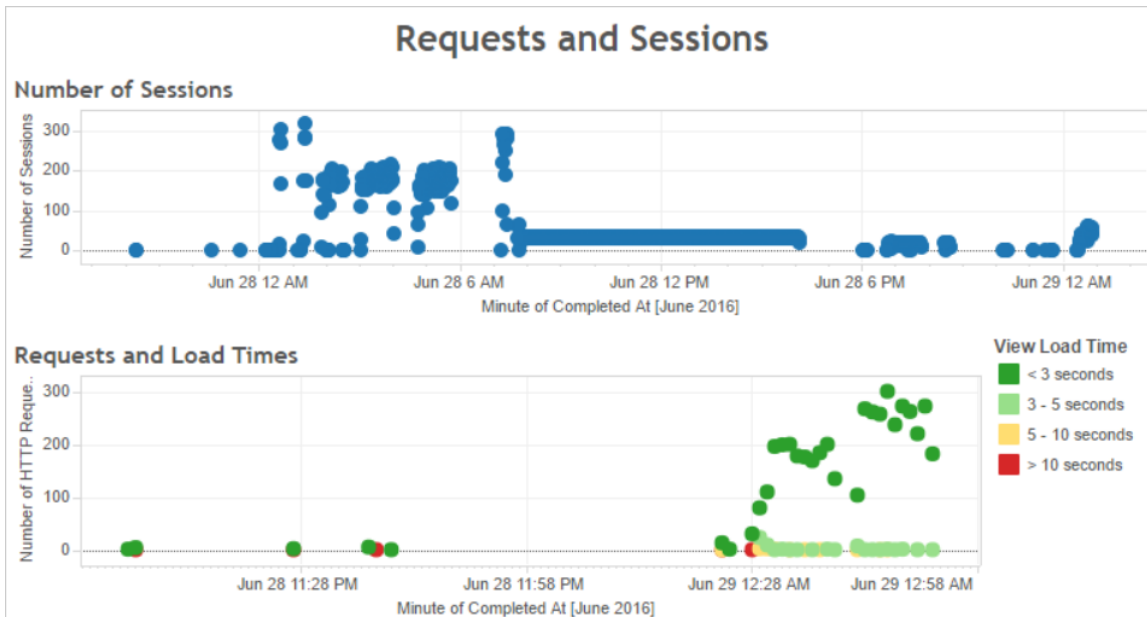

You can optimize for traffic if you have many active Tableau Server users and few published data sources that need extract refreshes.

- When to optimize for user traffic
- [Ways to optimize for user traffic](#)

When to optimize for user traffic

Slow load times for views

Use the **Requests and Sessions** dashboard of the sample performance workbook to analyze how long views take to load.

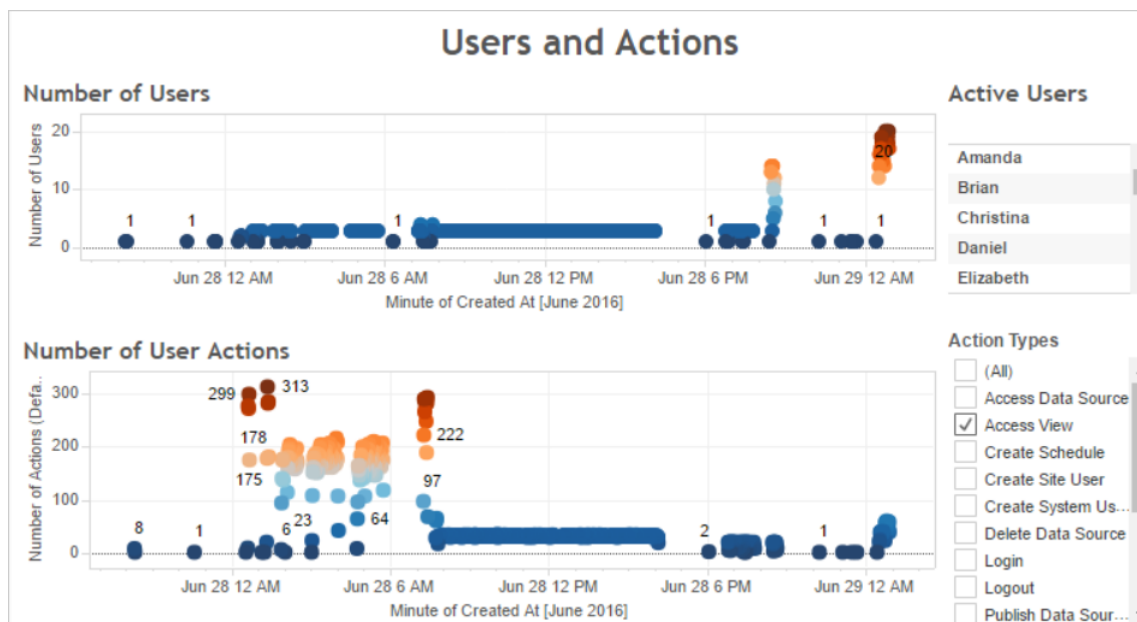

If multiple views take longer than 10 seconds to load, and if the slow load times correspond to a large number of sessions, that can indicate that user traffic is slowing down the server.

However, if a particular view takes a long time to load regardless of when it is viewed, it's a sign that the workbook for the view needs to be optimized. You can identify which workbooks need to be optimized with the Stats for Load Times administrative view. Some simple ways of optimizing workbooks includes displaying less information in each view or breaking up views, reducing the number of filters, and using data extracts.

High resource usage corresponding to user traffic

If your server displays high CPU and memory usage during peak traffic hours, you should optimize for user traffic. To determine peak traffic hours and analyze how many concurrent users are on your server, use the **Users and Actions** dashboard. In addition, you can use the Traffic to Views administrative view to see how much user traffic involves accessing views (as opposed to performing administrative functions, publishing, or other tasks).

If you click a point in the **Number of Users** view, the dashboard displays the users that were active at the time and the number of user actions that those users performed. By default, the only user actions displayed are user views, but you can use the **Action Types** filter to display additional user actions.

## Tableau Server on Linux Administrator Guide

Make a note of the times of day when there are many concurrent users and views so that you can compare this to resource usage. As a rule of thumb, the number of users should correspond to a high number of user actions. However, the view in this example displays an artificially high number of actions for a single user as part of a load generation test. As an example, you can compare the high number of views at 12 AM on June 28th with the resource usage in the dashboard illustrated later.

Use the **CPU Usage** dashboard to display the percent of total CPU usage and the percent of CPU usage for each process. In the following example, note the large spike in total CPU usage and in the VizQL server process at 12 AM on June 28th. Because the VizQL server process loads and render views, the VizQL server process is often the first process to show strain under high user traffic.

**Note:** The percent of CPU usage for individual processes may add up to more than 100 percent. This is because processor utilization for individual processes is measured for a given processor core. By contrast, the total CPU usage is measured for all processor cores.

Use the **Memory Usage** dashboard to display the percent of total memory usage and the average memory usage in gigabytes. As a general rule, memory usage increases steadily with user traffic. Here again the VizQL server process is the first to show strain under high traffic.

Ways to optimize for user traffic

When high user traffic corresponds to high resource usage as it does in the example shown previously, you should optimize for user traffic.

Adjust the number of VizQL server processes

The most effective way of optimizing for user traffic is to adjust the number of VizQL server processes. Add one VizQL server process at a time and measure the effect with performance monitoring. Because VizQL server processes can consume a lot of CPU and memory, adding too many processes can slow down the server instead. If you see consistently high memory usage, try to reduce the number of VizQL server processes to reduce the amount of memory reserved.

For more information about configuring processes, see [Configure Nodes](#).

### Adjust the number of other processes

Although the most effective way of improving performance for user traffic is to adjust the number of VizQL server processes, you can also tune other processes that support the VizQL server process or that prevent the VizQL server process from accessing resources. For example, the VizQL server process makes frequent requests to the cache server process, so you might also want to increase the number of cache server processes. On the other hand, the Backgrounder processes might contend for CPU resources with the VizQL server process. As a result, if you do not need to run frequent extract refreshes, you might reduce the number of processes for the backgrounder. If you do need additional instances of the backgrounder, and if you're running Tableau Server on a cluster, you can move the Backgrounder process to a dedicated node.

### Adjust the VizQL session timeout limit

In the example shown previously, the amount of memory used by the VizQL server process increases with user traffic, and it remains reserved by Tableau Server for some time after the traffic finished. This is because the VizQL server process reserves memory for each session for a specified amount of time. If the VizQL server process uses a high percentage of the available memory, try reducing the timeout for each session to make memory available more quickly.

To do this, use the `tsm configuration set` command to reduce the `vizqlserver.session.expiry.timeout` setting. The default is 30 minutes.

### Refresh the cache less often

If your users do not always need the most up-to-date data, you can optimize for user traffic by configuring Tableau Server to cache and reuse data as much as possible.

To do this, use the `tsm data-access caching list` command to confirm the refresh frequency. The default is `Low`. Use the `tsm data-access caching set` command to change the refresh frequency.

## Assess view responsiveness

When a user opens a view, the components of the view are first retrieved and interpreted, then displayed in the user's web browser. For most views, the display rendering phase occurs in the user's web browser and in most cases, this yields the fastest results and highest level of interactive responsiveness. Handling most interactions in the client web browser reduces bandwidth and eliminates round-trip request latencies. If a view is very complex, Tableau Server handles the rendering phase on the server instead of in the client web browser, because that generally results in the best performance. If you find that views aren't as responsive as you'd like, you can test and change the threshold that causes views to be rendered by the server instead of in the client web browser. For more information, see [Configure Client-Side Rendering](#).

## Configure Client-Side Rendering

When you navigate to a view in Tableau Server, the processing required to display the view, called *rendering*, can be performed by either your client device or Tableau Server. The choice depends on the complexity of the view, which is determined by the number of marks, rows, columns, and more. If a view is less complex, it's faster for a client device to render the view. If a view is more complex, it's faster to send a request to Tableau Server and take advantage of the server's greater computing power.

**Note:** If a view uses the polygon mark type or the page history feature, server-side rendering is always performed, even if client-side rendering is enabled.

## Supported browsers

Client-side rendering is supported in Internet Explorer version 9.0 or higher, Firefox, Chrome, and Safari. All of these web browsers include the HTML 5 `<canvas>` element, which client-side rendering requires.

Client-side rendering is also supported by the Tableau Mobile app.

## Tableau Server on Linux Administrator Guide

Configure the complexity threshold for computers and mobile devices

Because computers have more processing power than mobile devices, Tableau Server performs more client-side rendering on computers than on mobile devices.

As a server administrator, you can configure when client-side rendering happens on computers and mobile devices by adjusting the complexity threshold for each. For example, you might lower the threshold for mobile devices if you notice that views display slowly on them. Or, you might increase the threshold to reduce the number of requests to Tableau Server.

By default, the complexity threshold for computer web browsers is 100. To adjust the complexity threshold for computers, use the following command:

```
tsm configuration set -k vizqlserver.browser.render_threshold -v  
[new value]
```

By default, the complexity threshold for mobile devices is 60. To adjust the complexity threshold for mobile devices, use the following command:

```
tsm configuration set -k vizqlserver.browser.render_threshold_mobile  
-v [new value]
```

For example, to change the mobile threshold to 40, you might enter the following command:

```
tsm configuration set -k vizqlserver.browser.render_threshold_mobile  
-v 40
```

For more information on how to use `tsm option set`, see `tsm configuration set Options`.

### Disable client-side rendering

Client-side rendering is enabled by default and is recommended to improve the performance of views. However, you might want to disable client-side rendering temporarily for testing or if your server is being accessed primarily by computers or mobile devices with very little processing power.

Use the following command to disable client-side rendering:

```
tsm configuration set -k vizqlserver.browser.render -v false
```

For more information on how to use `tsm option set`, see `tsm configuration set Options`.

### Testing with the URL Parameter

To test server-side rendering on a session basis, type `?:render=false` at the end of the view's URL. For example:

```
http://localhost/views/Supplies/MyView?:render=false
```

If client-side rendering is disabled on Tableau Server, enter `?:render=true` to enable it for the session:

```
http://localhost/views/Supplies/MyView?:render=true
```

You can also test particular complexity thresholds on individual views to see if it's appropriate to adjust the server-wide threshold for your server and network conditions. For example, you may find that lower complexity (such as 80) or higher complexity (such as 120) tipping points result in more responsiveness to user interactions. To test a threshold, you can keep the server's default configuration (client-side-rendering enabled) and enter the test threshold number at the end of the view's URL. For example:

```
http://localhost/views/Supplies/MyView?:render=80
```

## Optimize for Extracts

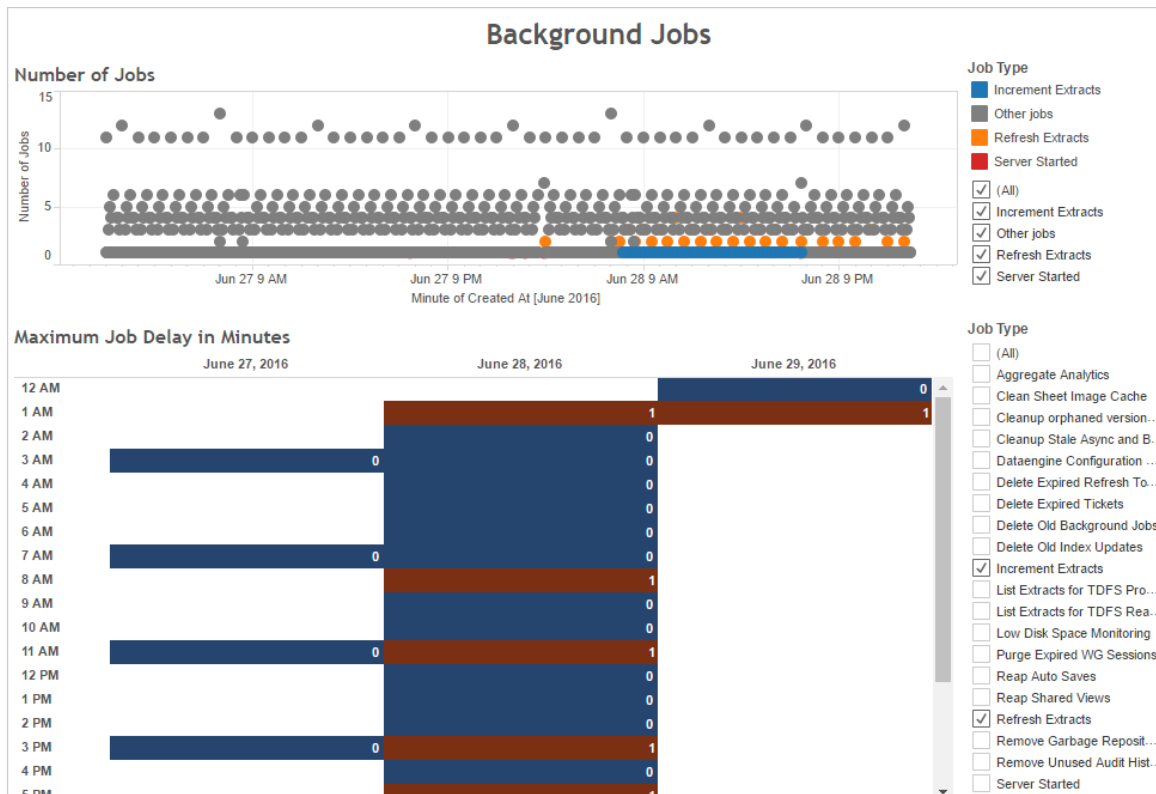

Try to optimize for extracts if the extract schedules correspond to high resource usage or if extracts take a long time to finish.

### When to optimize for extracts

High CPU usage corresponds to extract schedules

Use the **Background Jobs** dashboard of the sample performance workbook to view the number of background jobs run by Tableau Server, including extract refresh jobs. The dashboard also displays how long background jobs are delayed—that is, the amount of time between when a background job is scheduled and when it actually runs. If you see long delays at par-

particular times of the day or if many jobs are running at the same time, try distributing the job schedules across different times of the day to reduce the load on the server.

Also compare the times when there are many background jobs or long delays with the CPU usage of the server. Use the **CPU Usage** dashboard to display the percent of total CPU usage and the percent of CPU usage for each process. Because the background process runs background jobs, it is the first process to show strain when there are many extract refresh jobs or when there are slow extract refresh jobs. Note that the CPU usage of the background process periodically but briefly reaches 100 percent. This indicates that there are intensive refresh jobs on a recurring schedule.

**Note:** The percent of CPU usage for individual processes may add up to more than 100 percent because processor utilization for individual processes is measured for a given processor core. By contrast, the total CPU usage is measured for all processor cores.

Extracts fail or run slowly

Use the Background Tasks for Extracts administrative view to determine how many extracts fail and how long extracts take to complete. Frequent failures can indicate a problem with a particular data source.

# Tableau Server on Linux Administrator Guide

## Ways to optimize for extracts

When high CPU usage corresponds to extract refresh schedules like it does in the example shown previously, you should optimize for extracts.

### Adjust the extract refresh schedule

Use the **Background Jobs** dashboard of the sample performance workbook to identify optimal times for running extracts. In addition to running extracts in off-peak hours, you can distribute extract refreshes to minimize concurrent server load. If extract refreshes continue to cause problems, reduce the frequency of extract refreshes as much as possible in these ways:

- Schedule extracts for times when the server isn't busy.
- Reduce the frequency of refreshes.

## Speed up specific extracts

Use the Background Tasks for Extracts administrative view to identify failing extracts and long-running extracts.

- Reduce the size of extracts. You can help improve server performance by keeping the extract's data set short, through filtering or aggregating, and narrow, by hiding unused fields. To make these changes, use the Tableau Desktop options **Hide All Unused Fields** and **Aggregate data for visible dimensions**. For more information, see [Creating an Extract](#) in the Tableau Help.

For general tips on building well-performing workbooks, search for “performance” in the Tableau Help. To see how workbooks perform after they've been published to Tableau Server, you can create a performance recording. For more information, see [Create a Performance Recording](#).

- Use incremental refresh jobs. Incremental refresh jobs append new rows to an existing extract instead of creating the extract from scratch. This type of extract refresh runs quickly because it processes only the data that has been added since the last time the extract refresh job ran. However, it does not account for data that has been updated rather than appended to a data source. As a result, if you run incremental refresh jobs, you should still occasionally run full refresh jobs. For example, you might run a full refresh job once or twice a week for a data source instead of every day.

## Configure the execution mode for extract refreshes

When you create extract refresh schedules, ensure that they run in parallel execution mode. When you run a schedule in parallel, it runs on all available backgrounder processes, even if the schedule contains only one refresh task. When you run a schedule serially, it only runs on one backgrounder process. By default, the execution mode is set to parallel so that refresh tasks finish as quickly as possible.

However, in some circumstances, it can make sense to set the execution mode to serial. For example, you might set the execution mode to serial if a very large job is preventing other schedules from running because it uses all available backgrounder processes.

### Increase the number of backgrounder processes

A single background process can consume 100 percent of a single CPU core for certain tasks. As a result, the total number of instances you should run depends on the computer's available cores. If you have Tableau Server installed in a cluster and you run backgrounder processes on a separate node, a good rule of thumb is to set the number of backgrounder process to between half the number of cores and the full number of cores of the computer running the backgrounder processes.

For more information about configuring processes, see [Configure Nodes](#).

### Isolate processes

If you have Tableau Server installed in a cluster, you see the largest benefit from moving the backgrounder processes to a separate node to avoid resource contention. This is because the backgrounder process is very CPU-intensive and running it on the same node where other CPU-intensive processes are running can slow down the server. For example, both the VizQL server process and the data engine process can be CPU-intensive. Read the two-node configuration in the [Recommended Baseline Configurations](#) topic for more details.

## Optimize for Extract Query-Heavy Environments

The topic provides guidance on setting up a specific Tableau Server topology and configurations to help optimize and improve performance in an extract query-heavy environment.

**What is an extract query-heavy environment?** Extracts and federated data sources are queried while loading workbooks, views, and dashboards creating a lot of query workload. Therefore, if you have a lot of extracts and federated data sources, you can be said to have a 'extract query-heavy environment'.

**If your environment is extract query-heavy as defined above, the next couple of sections can help you decide if this configuration is right for you.**

When to use this configuration

**Key reasoning behind this configuration:** Hyper is Tableau's memory-optimized Data Engine technology suited for fast data ingests and analytical processing, making it key to optimizing query-heavy workloads. As your extract use grows, we recommend **configuring Data Engine on dedicated nodes of the Tableau Server cluster**. This configuration allows Tableau Server to scale-out the infrastructure to optimize performance when querying extracts.

There are several factors that affect Tableau Server performance when viewing content using extracts and federated data sources. The goal here is to **achieve consistent and reliable query performance** when viewing content on the Server. Use this configuration if one of the following conditions apply to your environment:

- You are seeing wide variability in workbook load times and the workbook uses extracts or federated data sources.
- Your Tableau Server deployment is growing in the number of Creators, Explorers, Viewers, and extract-based content, so you want to scale out efficiently.
- You are seeing resource contention between Data Engine and VizQL Server when File Store is present on the machine.
- You analyze large amounts of data. This configuration helps in optimizing performance in big data scenarios, in both data ingestion and analysis. To learn more about Tableau and big data, see [Hyper-charge big data analytics using Tableau](#).

**Note:** Use Server-side performance recording to determine query execution times. To determine resource usage of Tableau use **Performance monitor** for Windows installations, and *sysstat* or *vmstat* tools for Linux installations.

Benefits of using this configuration

These are the key benefits to configuring dedicated nodes for Data Engine:

## Tableau Server on Linux Administrator Guide

- Dedicated Data Engine nodes will reduce resource contention between extract queries and other resource-intensive workloads such as those processed by VizQL Server.
- Extract queries are load balanced dynamically on the dedicated nodes, taking into account the current state of the system to ensure that no one node is over or under-utilized.
- More consistent performance in user experience when loading extract-dependent workbooks. The focus here is to establish a consistent and reliable performance rather than making individual queries better.
- You have more control over scaling out Tableau Server processes that need more resources. If VizQL Server, Data Engine, and Backgrounder are all running on the same node and slow extract queries are the problem, it will be difficult to see performance improvements by adding a second node with all three processes. With this configuration, you can add more nodes that will specifically improve extract query workloads.
- Helps improve availability and up-time. In the event of a failure and one of the dedicated Data Engine nodes is unavailable, VizQL Server will attempt to route the pending requests on the problem node to other dedicated Data Engine nodes.
- Data Engine leverages as many cores as available on the machine. Given this, you have the flexibility to add more resources to the dedicated Data Engine nodes to reduce query response time and variability on expensive extract queries or add more dedicated Data Engine nodes to get more extract query throughput in your Server.
- Data Engine has a default configuration limiting it to an average 75% of CPU per hour. This is intended to help avoid contention with other Tableau Server processes. If you are running Data Engine on a dedicated node, you can increase this average to 95%. For information on doing this, see `hyper.srm_cpu_limit_percentage`.

### When not to use this configuration

- If you are not experiencing issues with extract-based query load, hardware resources may be better allocated to other portions of Tableau Server.
- On nodes where File Store, Data Engine, and VizQL Server co-exist, you are not seeing resource contention between Data Engine and VizQL Server.
- Before implementing this configuration, it is highly recommended that you evaluate your CPU usage for VizQL Server and for the node where Data Engine that installed with the File Store.

### Configuration

The main goal of this configuration is to have Data Engine on one or more dedicated nodes.

- In deployments where File Store is installed locally, this means configuring File Store on one or more dedicated nodes. Data Engine is automatically installed on the same node as the File Store.
- In deployments where you are configuring External File store, you can still configure Data Engine on dedicated nodes on Tableau Server.

By separating VizQL Server and File Store processes, the load between querying extracts and viewing or interacting with views can be balanced and better managed. This configuration is targeted at consistent performance when querying extracts.

Below is a visual representation of the configuration where the Data Engine/File Store processes have two dedicated nodes, nodes 5 and 6. This is an example where File Store is configured locally which is why the Data Engine and File Store processes are co-located.

The same configuration works for deployments with External File Store, but Node 5 and 6 will have only Data Engine configured in that case.

Additionally, since Node 1 also has the Repository and File Store processes, all of the data needed to perform a backup exist on Node 1 which can improve backup performance.

| External Load Balancer |                       |        |        |        |             |             |
|------------------------|-----------------------|--------|--------|--------|-------------|-------------|
| Process                | Node 1 (Initial Node) | Node 2 | Node 3 | Node 4 | Node 5 (DE) | Node 6 (DE) |
| Cluster Controller     | ✓                     | ✓      | ✓      | ✓      | ✓           | ✓           |
| Gateway                | ✓                     | ✓      | ✓      | ✓      |             |             |
| Application Server     | ✓                     | ✓      |        |        |             |             |
| VizQL Server           | ✓ ✓                   | ✓ ✓    |        |        |             |             |
| Cache Server           | ✓ ✓                   | ✓ ✓    |        |        |             |             |
| Search & Browse        | ✓                     | ✓      |        |        |             |             |
| Backgrounder           |                       |        | ✓ ✓    | ✓ ✓    |             |             |
| Data Server            | ✓ ✓                   | ✓ ✓    | ✓ ✓    | ✓ ✓    |             |             |
| Data Engine            | ✓                     | ✓      | ✓      | ✓      | ✓           | ✓           |
| File Store             | ✓                     |        |        |        | ✓           | ✓           |
| Repository             | ✓                     | ✗      |        |        |             |             |

### Hardware Guidance

To get the most out of this configuration, you will need to experiment with various hardware sizes and configurations to see what best fits your peak load performance objectives. Hyper is a high-performance database technology and the key resources that impact performance are memory, cores, and storage I/O. Understanding how Hyper uses resources to process queries will help you make your hardware selection and understand the reason between different configurations.

- Memory:** When an extract-based query is processed for a user or background process, Tableau Server selects a dedicated Data Engine node to process the query. That dedicated Data Engine node will then copy the extract from local storage, most often the server hard disk, into memory. Having more available system memory allows the operating system better manage memory usage for Tableau. Dedicated Data Engine nodes uses system memory to store the result set of executed queries. If the result set is still valid and the operating system has not cleared it from memory, the result set in memory can be reused.

Tableau Server’s minimum hardware recommendation is 32 GB of memory but if you are expecting a high volume of extract-based workbook loads, you should consider 64

GB or 128 GB. If you are hitting other resource limits in addition to memory (like cores), instead of scaling up to 128 GB of memory, it might be better to scale out to an additional 64 GB dedicated Data Engine node.

The process of copying the extract from local storage into memory can take time and optimizing disk performance may be necessary. Optimizing disk performance is covered in the **Storage I/O** section.

- **Cores:** When processing an extract-based query, the number of cores is an important hardware resource that can impact performance and scalability. CPU cores are responsible for executing a query and having more available cores will result in faster execution time. Generally speaking, doubling the number of cores will reduce the query execution time in half. For example, a 10 second query currently utilizing 4 physical cores or 8 vCPUs, will take 5 seconds if you upgrade to 8 physical cores or 16 vCPUs.

The current Tableau Server minimum hardware recommendation is 8 cores, but if your deployment utilizes extracts, consider 16 or 32 core machines. An important thing to note is that if memory and I/O are your bottlenecks, then increasing available cores will not improve your query performance.

- **Storage I/O:** Hyper is designed to leverage the available performance of your extract storage device to speed up query processing. We recommend picking fast disk storage like Solid State Drives (SSD) with high read/write speeds. Currently, SSDs that utilize NVMe storage protocol offers the fastest available speeds.

**Note:** Sizing resources for dedicated Data Engine nodes only impacts the extract query performance. When loading a workbook, there are many other processes involved that make up total VizQL load request time. The VizQL Server process, for example, is responsible for taking the data from the Data Engine and rendering the visualization.

#### Other Performance Tuning and Optimizations:

There are additional features you can use to optimize performance beyond the basic configuration described above. The optimizations described below are applicable to both local

File Store and External File Store deployments.

- **Extract Query Load Balancing:** To determine where to route the extract query, Data Engine uses a server health metric- the amount of resources Data Engine is consuming and the load from other Tableau processes that may be running on the same node. In addition to evaluating system resources, whether an extract already exists in memory on the node is also taken into account to make sure an extract query is sent to the node that has the most available resources to process the query. This results in more efficient memory and disk utilization and extracts are not duplicated in memory across nodes. See the Extract Query Load Balancing help article for more details.

*The extract query load balancing feature is enabled by default in Tableau Server version 2020.2 and later..*

- **Workload optimizations using node roles:** With Backgrounder and File Store node roles, server administrators have more flexibility and control over which nodes should be dedicated for running extract queries and extract refreshes. As mentioned in the topology diagram above, certain Data Engine nodes are dedicated to processing extract queries and run only the File Store and Data Engine processes. Node Roles are available with Advanced Management. For more information on node roles, see Workload Management through Node Roles.

The diagram below uses the same topology as the basic configuration described above but with the node roles.

| External Load Balancer |                       |        |                     |                        |                 |                 |
|------------------------|-----------------------|--------|---------------------|------------------------|-----------------|-----------------|
| Process                | Node 1 (Initial Node) | Node 2 | Node 3              | Node 4                 | Node 5 (DE)     | Node 6 (DE)     |
| Cluster Controller     | ✓                     | ✓      | ✓                   | ✓                      | ✓               | ✓               |
| Gateway                | ✓                     | ✓      | ✓                   |                        |                 |                 |
| Application Server     | ✓                     | ✓      |                     |                        |                 |                 |
| VizQL Server           | ✓ ✓                   | ✓ ✓    |                     |                        |                 |                 |
| Cache Server           | ✓ ✓                   | ✓ ✓    |                     |                        |                 |                 |
| Search & Browse        | ✓                     | ✓      |                     |                        |                 |                 |
| Backgrounder           |                       |        | ✓ ✓ Extract refresh | ✓ ✓ No Extract refresh |                 |                 |
| Data Server            | ✓ ✓                   | ✓ ✓    | ✓ ✓                 |                        |                 |                 |
| Data Engine            | ✓                     | ✓      | ✓                   | ✓                      | ✓               | ✓               |
| File Store             | ✓                     |        | ✓                   |                        | ✓ Extract query | ✓ Extract query |
| Repository             | ✓                     | ✗      |                     |                        |                 |                 |

- Extract Refreshes Backgrounder node role:** By setting Node 3 to extract-refreshes Backgrounder node role, only incremental refreshes, full refreshes, and encryption/decryption jobs will run on this node. By setting Node 4 to no-extract-refreshes Backgrounder node role, all background jobs other than extract refreshes will run on this node. Data Server and Gateway help the extract refresh jobs when using federated and shadow extracts. For more information on Backgrounder node roles, see File Store node roles.

Additionally, since Node 1 also has the Repository and File Store processes, all of the data needed to perform a backup exist on Node 1 which can improve backup performance.

*The Backgrounder node roles are available with Advanced Management in Tableau Server version 2019.3 and later.*

- Extract Queries File Store node role:** Node 5 and 6 which are the **dedicated** Data Engine nodes have the extract-queries File Store node role to ensure they only process queries for viz loads, subscriptions, and data-driven alerts.
- Extract Queries Interactive File Store node role:** For dedicated Data Engine nodes which have extract-queries File Store node role, server administrators can further

isolate the interactive and scheduled workloads to run on specific **dedicated** Data Engine nodes. This is useful for times when there are a lot of users interacting and loading workbooks during high volume subscription times. For example, let's say there are 1000 subscriptions scheduled for the 8 AM Monday mornings. At the same time, many users are also loading dashboards at the beginning of their day. The combined volume of subscription and user queries can result in users experiencing slower, more variable workbook load times. With the extract-queries-interactive File Store node role, you can designate dedicated Data Engine nodes to only accept queries for interactive users (the ones who are looking at their screens waiting). These dedicated Data Engine nodes that are prioritized for interactive workloads would be protected from the high volume of competing subscription jobs and provide more consistent query times. Additionally, Server Admins can use this node role to better plan for growth since they can add dedicated Data Engine nodes for interactive and scheduled workloads independently. For more information, see File Store node roles.

*The File Store node roles are available with Advanced Management in Tableau Server version 2020.4 and later.*

- **Optimizations using External File Store:** This feature allows you to use a network share as the storage for File Store instead of using the local disk on a Tableau Server node. By having the storage on a centralized location, you can significantly reduce the amount of network traffic spent on replicating data between the File Store nodes. For example, in the case when File Store is using a local disk, when a 1 GB extract is refreshed using local File Store, the 1 GB of data is replicated across the network to all nodes that are running the File Store process. In the case where Tableau Server is configured with External File Store, the 1 GB extract only needs to be copied to the network share once and all File Store nodes can access that single copy. The centralization of storage also reduces the total amount of local storage needed on File Store nodes.

Additionally, Tableau Server backups leverage snapshot technology to significantly reduce the time to complete a backup.

While you don't need a dedicated Data Engine node configuration to gain the benefits of External File Store, the additional workload management features with File Store node role and the Extract Query Interactive node role can be used together. See the Tableau Server External File Store topic for more details.

*External File Store is available with Advanced Management in Tableau Server version 2020.1 and later.*

## When to Add Nodes and Reconfigure

Tableau Server can scale up and out as your needs and requirements evolve. Here are some guidelines to help you figure out whether it's time to add more nodes to your system, reconfigure the server, or both:

- **More than 100 concurrent users:** If your deployment is user-intensive (>100 simultaneous viewers), it's important to have enough VizQL processes—but not so many that they exceed your hardware's capacity to handle them. Also, enabling the Tableau Server **Guest User account** can increase the number of potential simultaneous viewers beyond the user list you may think you have. The administrative view can help you gauge this. For more information, see [Actions by Specific User](#).
- **Heavy use of extracts and frequent extract refreshes:** Extracts can consume a lot of memory and CPU resources. There's no one measurement that qualifies a site as extract-intensive. Having just a few, extremely large extracts could put your site in this category, as would having very many small extracts. Sites where extracts are frequently refreshed (for example, several times a day) are often helped by more emphasis on the background process, which handles refresh tasks. Use the [Background Tasks for Extracts](#) administrative view to see your current refresh rate. Extract heavy sites benefit from isolating the Backgrounder process on its own machine. For more information, see the [two-node configuration in the Recommended Baseline Configurations](#) topic.

- **Query heavy environments:** If you are experiencing slow query performance for Workbooks that use extracts, isolating nodes that handle queries on extracts from VizQL processes can improve and stabilize performance. For more information, see [Optimize for Extract Query-Heavy Environments](#).
- **Downtime potential:** If your server system is considered mission critical and requires a high level of availability, you can configure it so there's redundancy for the server processes that handle extracts, the repository, and the gateway.

## Performance Recording

This section describes how to create performance recordings and use the results to improve workbook performance. With performance recordings, you can view how long workbook events take. For example, you can see how long it takes to connect to a data source, run a query, render data, and more.

### Create a Performance Recording

The Performance Recording feature in Tableau records performance information about key events as you interact with a workbook. You can then view performance metrics in a workbook that Tableau creates to analyze and troubleshoot different events that are known to affect performance:

- Query execution
- Compiling query
- Geocoding
- Connections to data sources
- Layout computations
- Extract generation

- Blending data
- Server rendering (Tableau Server only)

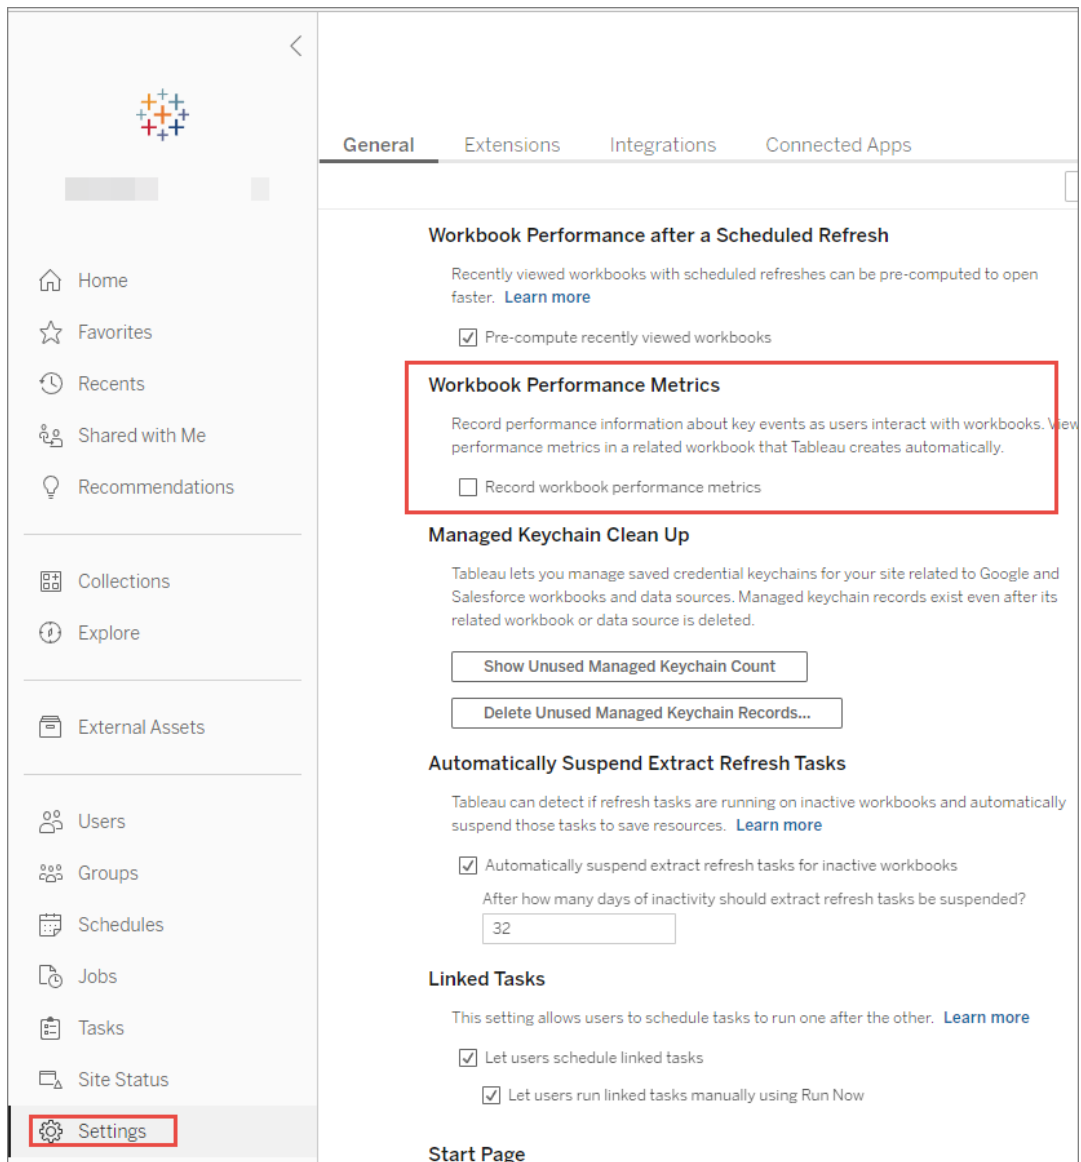

Tableau support may ask that you create a performance workbook as they work with you to diagnose performance issues.

Looking for Tableau Server on Windows? See [Create a Performance Recording](#).

#### Enable Performance Recording for a Site

By default, performance recording is not enabled for a site. A server administrator can enable performance recording site by site.

1. Navigate to the site for which you want to enable performance recording.
2. Click **Settings**:

3. Under Workbook Performance Metrics, select **Record workbook performance metrics**.
4. Click **Save**.

## Start a Performance Recording for a View

1. Open the view for which you want to record performance.

When you open a view, Tableau Server appends ":iid=<n>" after the URL. This is a session ID. For example:

```
http://10.32.139.22/#/views/Coffee_Sales2013/USSalesMarginsByAreaCode?:iid=1
```

2. Type `:record_performance=yes&` at the end of the view URL, immediately before the session ID. For example:

```
http://10.32.139.22/#/views/Coffee_Sales2013/USSalesMarginsByAreaCode?:record_performance=yes&:iid=1
```

3. Click the **Refresh** button in the toolbar.
4. Load the view.

## View a Performance Recording

1. Click **Performance** to open a performance workbook. This is an up-to-the-minute snapshot of performance data. You can continue taking additional snapshots as you continue working with the view; the performance data is cumulative.
2. Move to a different page or remove `:record_performance=yes` from the URL to stop recording.

## Interpret a Performance Recording

Create a recording to evaluate the performance of your workbook. After you have completed the recording, you can download the resulting workbook and open it in Tableau Desktop for analysis.

A performance recording workbook contains two main dashboards: Performance Summary and Detailed Views. The Performance Summary dashboard provides a high-level overview of the most time-consuming events. The Detailed Views dashboard provides a lot more detail

and is intended to be used by advanced users when building workbooks. The **Detailed Views** dashboard is only visible when the performance recording workbook is opened using Tableau Desktop.

For information on how to create a performance recording in Tableau Server, see [Create a Performance Recording](#).

### Performance Summary

The **Performance Summary** dashboard contains three views: **Timeline**, **Events**, and **Query**.

#### Timeline

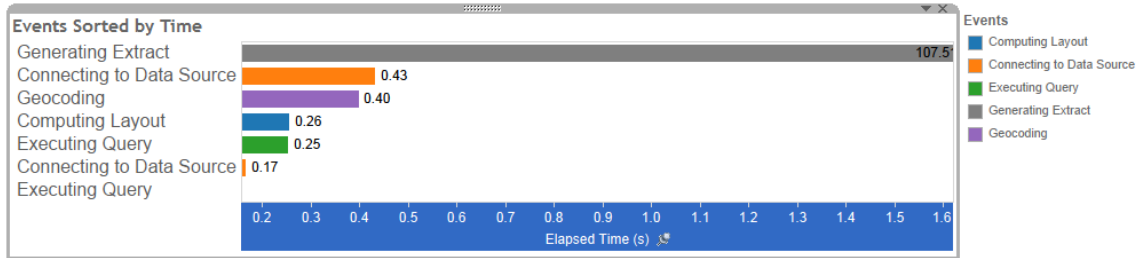

The uppermost view in the performance summary recording dashboard shows the events that occurred during recording, arranged chronologically from left to right. The bottom axis shows elapsed time since Tableau started, in seconds.

In the Timeline view, the **Workbook**, **Dashboard**, and **Worksheet** columns identify the context for events. The **Event** column identifies the nature of the event, and the final column shows each event's duration and how it compares chronologically to other recorded events:

#### Events

The middle view in a performance summary dashboard shows the events, sorted by duration (greatest to least). Events with longer durations can help you identify where to look first if you want to speed up your workbook.

Different colors indicate different types of events. The range of events that can be recorded is:

- Computing layouts

If layouts are taking too long, consider simplifying your workbook.

- Connecting to data source

Slow connections could be due to network issues or issues with the database server.

- Compiling query

This event captures the amount of time spent by Tableau in generating the queries.

Long compile query times indicate that the queries generated are complex. The complexity may be due to too many filters, complex calculations, or generally due to a complex workbook. Examples of complex calculations include, lengthy calculations, LOD calculations, or nested calculations. Try simplifying the workbook, using action filters or moving calculations to the underlying database.

- Executing query

- For live connections, if queries are taking too long, it could be because the underlying data structure isn't optimized for Tableau. Consult your database server's documentation. As an alternative, consider using an extract to speed performance.
- For extracts, if queries are taking too long, review your use of filters. If you have

## Tableau Server on Linux Administrator Guide

a lot of filters, would a context filter make more sense? If you have a dashboard that uses filters, consider using action filters, which can help with performance.

- Generating extract

To speed up extract generation, consider only importing some data from the original data source. For example, you can filter on specific data fields, or create a sample based on a specified number of rows or percentage of the data.

- Geocoding

To speed up geocoding performance, try using less data or filtering out data.

- Blending data

To speed up data blending, try using less data or filtering out data.

- Server rendering

You can speed up server rendering by running additional VizQL Server processes on additional machines.

### Query

If you click on an **Executing Query** event in either the **Timeline** or **Events** section of a performance summary dashboard, the text for that query is displayed in the Query section.

If you are connected to a published data source, the query text is displayed in XML. If you are connected to the data source directly, the query is displayed in SQL like shown below:

#### Query

```
SELECT "State"."ID" AS "ID",  
       "StateSynonyms"."Name" AS "State_Name",  
       "State"."ParentID" AS "State_ParentID"  
FROM "StateSynonyms"  
INNER JOIN "State" ON (("State"."ID" = "StateSynonyms"."ParentID") AND ("State"."MapCode" = "StateSynonyms"."MapCode"
```

If it makes sense, you can use the query text to work with your database team on optimizing at the database level. Sometimes the query is truncated and you'll need to look in the Tableau log

to find the full query. Most database servers can give you advice about how to optimize a query by adding indexes or other techniques. See your database server documentation for details.

Sometimes for efficiency, Tableau combines multiple queries into a single query against the data. In this case, you may see an **Executing Query** event for the Null worksheet and zero queries being executed for your named worksheets.

### Detailed Timeline

This view is the detailed version of the **Timeline** view that shows all events and separating individual items that were grouped in the **Timeline** view. It is intended to be used by advanced users during workbook designs.

### Detailed Views

The **Detailed Views** dashboard contains **Depth**, **Exclusive CPU**, **Inclusive CPU**, and **Elapsed Time** views.

### Depth

The **Depth** view is the uppermost view in the **Detailed Views** dashboard and provides insight into what happens when a request is made. This view is the most useful when filtered to a single user request. Examples of user requests are: loading a view, selecting a mark, or changing a filter.

Each bar on the depth view represents a single activity. An activity is a unit of work that is done as part of processing a user request. A single user request results in multiple activities. The length of each bar on the depth view is proportional to the elapsed time for the activity that the bar represents.

High level activities appear at the top of the view. Activities lower down are child activities generated by high level activities.

Hovering over each bar provides additional details about the activity and also highlights the corresponding row in the **CPU** and **Elapsed Time** view described in the next section.

In order to narrow down on what parts of the request took the most time, investigate long running activities at the highest levels.

### CPU and Elapsed Time

The **CPU** and **Elapsed Time** views appear lowermost in the **Detailed Views** dashboard. You can toggle between **Exclusive CPU**, **Inclusive CPU** and **Elapsed Time** views by clicking on the radio buttons.

Select a View

|  |  |
|--|--|
| <input checked="" type="radio"/> Exclusive CPU | - Exclusive CPU time is useful for identifying activities that consume majority of the CPU   |
| <input type="radio"/> Inclusive CPU            | - Inclusive CPU time is useful for identifying high level activities that consume majority of the CPU (either themselves or due to activities that they sponsor) |
| <input type="radio"/> Elapsed Time             | - Elapsed time is useful for identifying activities that took the most wall clock time   |

While the **Depth** view can help in quick visual identification of long running activities, it may not necessarily highlight activities that happen multiple times with each instance taking a small amount of time. The **Exclusive CPU**, **Inclusive CPU**, and the **Elapsed Time** views provide aggregate statistics for each activity. The number of times an activity took place is shown in the **Count** column and the total amount of time taken by a single activity is shown using the bar chart.

Sometimes for efficiency, Tableau combines multiple queries into a single query against the data. In this case, you may see an **Executing Query** event for the Null worksheet and zero queries being executed for your named worksheets.

## Performance Monitoring Tools

This topic describes external resources that you can use to monitor and tune performance.

Tableau Server includes several tools that you can use to monitor server performance and health. For more information about these tools, see [Performance Monitoring Overview](#).

**Disclaimer:** This topic includes information about third-party and community supported products. Please note that while we make every effort to keep references to third-party and community content accurate, the information we provide here might change without notice. For the most up-to-date information, please consult the documentation for products referenced here. To learn more about community supported tools, see [Support levels for IT and developer tools](#).

- **TabJolt.** A load and performance testing tool that you can use to understand how Tableau Server scales with your workloads, in your environment, and to inform your scalability and capacity needs. Here are some key use cases for when you would use TabJolt:
  - To establish a baseline for server performance and test deployments before pushing them to production environments.
  - In a new Tableau Server, to help understand how the new server scales in your environment, specifically to your hardware and workload?
  - Before upgrading to understand the new version will scale in your environment.
  - To find the best server deployment configuration, given your hardware, workbooks and environments.
- **Replayer.** A tool that can replay log-based real user traffic from a Tableau Server against any other server or configuration. It replays Tableau Server single- or multi-user sessions. Here are some ways that Replay can be used:

## Tableau Server on Linux Administrator Guide

- Playback specific Tableau Server sessions, and filter the session based upon start time or RequestID.
- Use it to simulate load conditions so that you can test how to scale and balance your Tableau Server installations.
- Perform regression testing by running and comparing end-to-end user scenarios for Tableau Server upgrades.
- Capture and report HTTP exceptions that occur in a single-user session.
- Replay a defect, so that you can troubleshoot and verify that it is fixed.
- **Scout**. An exploratory tool that captures performance metrics across any workbooks on both Tableau Desktop and Tableau Server Here are some ways that Scout can be used:
  - Find slow workbooks on Server.
  - Validate performance improvements or regressions after making server configuration or topology changes.
  - Validate that workbooks and dashboards are loading properly after upgrading to new Tableau Server.
  - Validate that workbooks are still working properly after data source changes.
- **Sitescope**. An agentless application monitoring tool.
- **Zabbix**. An open-source, real-time monitoring tool.
- **Splunk**. A tool for monitoring and analyzing machine data, including logs.
- **Graylog**. An open-source log management tool.

## Configure Client-Side Rendering

When you navigate to a view in Tableau Server, the processing required to display the view, called *rendering*, can be performed by either your client device or Tableau Server. The choice

depends on the complexity of the view, which is determined by the number of marks, rows, columns, and more. If a view is less complex, it's faster for a client device to render the view. If a view is more complex, it's faster to send a request to Tableau Server and take advantage of the server's greater computing power.

**Note:** If a view uses the polygon mark type or the page history feature, server-side rendering is always performed, even if client-side rendering is enabled.

## Supported browsers

Client-side rendering is supported in Internet Explorer version 9.0 or higher, Firefox, Chrome, and Safari. All of these web browsers include the HTML 5 `<canvas>` element, which client-side rendering requires.

Client-side rendering is also supported by the Tableau Mobile app.

## Configure the complexity threshold for computers and mobile devices

Because computers have more processing power than mobile devices, Tableau Server performs more client-side rendering on computers than on mobile devices.

As a server administrator, you can configure when client-side rendering happens on computers and mobile devices by adjusting the complexity threshold for each. For example, you might lower the threshold for mobile devices if you notice that views display slowly on them. Or, you might increase the threshold to reduce the number of requests to Tableau Server.

By default, the complexity threshold for computer web browsers is 100. To adjust the complexity threshold for computers, use the following command:

```
tsm configuration set -k vizqlserver.browser.render_threshold -v  
[new value]
```

By default, the complexity threshold for mobile devices is 60. To adjust the complexity threshold for mobile devices, use the following command:

## Tableau Server on Linux Administrator Guide

```
tsm configuration set -k vizqlserver.browser.render_threshold_mobile  
-v [new value]
```

For example, to change the mobile threshold to 40, you might enter the following command:

```
tsm configuration set -k vizqlserver.browser.render_threshold_mobile  
-v 40
```

For more information on how to use tsm option set, see [tsm configuration set Options](#).

### Disable client-side rendering

Client-side rendering is enabled by default and is recommended to improve the performance of views. However, you might want to disable client-side rendering temporarily for testing or if your server is being accessed primarily by computers or mobile devices with very little processing power.

Use the following command to disable client-side rendering:

```
tsm configuration set -k vizqlserver.browser.render -v false
```

For more information on how to use tsm option set, see [tsm configuration set Options](#).

### Testing with the URL Parameter

To test server-side rendering on a session basis, type `?:render=false` at the end of the view's URL. For example:

```
http://localhost/views/Supplies/MyView?:render=false
```

If client-side rendering is disabled on Tableau Server, enter `?:render=true` to enable it for the session:

```
http://localhost/views/Supplies/MyView?:render=true
```

You can also test particular complexity thresholds on individual views to see if it's appropriate to adjust the server-wide threshold for your server and network conditions. For example, you may find that lower complexity (such as 80) or higher complexity (such as 120) tipping points

result in more responsiveness to user interactions. To test a threshold, you can keep the server's default configuration (client-side-rendering enabled) and enter the test threshold number at the end of the view's URL. For example:

```
http://localhost/views/Supplies/MyView?:render=80
```

## View Acceleration

Administrators and workbook owners who have Creator or Explorer licenses can accelerate workbooks. Administrators can suspend individual views or turn off acceleration for their site. View Acceleration loads views faster by precomputing and fetching the workbook's data in a background process. There are two potential bottlenecks when loading a view:

1. Querying (fetching data from the data source).
2. Rendering (creating the visuals, such as drawing shapes or rendering a map).

The time it takes to load a workbook depends on the combined time it takes to do these two steps. However, not all views can be accelerated. View Acceleration improves the performance of the first step (querying). If the view is loading slowly for reasons other than querying, View Acceleration won't improve the workbook's performance.

When users create custom views on top of an accelerated view, the ten most used custom views are precomputed automatically. These accelerated custom views don't count against the view limit. Custom views that haven't been accessed in the last 14 days won't be accelerated. If you directly accelerate a custom view, both the original view and the custom view are accelerated.

### Accelerate your view

1. Sign in to a site on Tableau Cloud or Tableau Server.
2. From the Home or Explore page, navigate to the view you want to accelerate.

3. Choose the **Accelerate** icon, and select the switch to **Accelerate**.

You can also accelerate views from the workbook page in one of three ways:

1. Select the desired view and choose **Acceleration > On** from the **Actions** menu.

2. Select the **More options(...)** menu for the desired view and choose **Acceleration > On**.

3. To accelerate all views in the workbook, choose **Acceleration > On** from the **More options (...)** menu.

**Note:** View Acceleration isn't available in Tableau Desktop.

## Understand why View Acceleration is unavailable, suspended, or ineffective

View Acceleration is unavailable

There are a few scenarios in which acceleration isn't available for a view.

| Issue   | Resolution   |
|---|--|
| The view doesn't have historical data for the time required to execute queries.             | Every time a view loads, it takes a few minutes for the viz data to be available. For a newly created view, load the view and wait a few minutes before trying to accelerate it.   |
| The historical time taken to execute queries for the view is less than 2 seconds.           | Acceleration isn't supported for such views because acceleration won't significantly improve the performance of the view.  |
| The view doesn't have embedded credentials.   | To precompute the data, Tableau needs to automatically connect to the data source in the background without any user interaction. As a result, View Acceleration is only supported for workbooks with embedded connection credentials. |
| The view has user-based functions, or the view has a data source with user-based functions. | Currently, Tableau doesn't support accelerating such views. Examples of user-based functions are USERDOMAIN() and USERNAME().  |
| The view's owner is inactive.   | To precompute the data, the owner must be an active user. Tableau doesn't support accelerating a view if its owner is inactive. <a href="#">Change the ownership</a> to an active user.  |
| The view's data freshness policy is less than 2 hours.                                      | Cost can be high for accelerating views that are refreshed so frequently, and Tableau doesn't want to overload your site performance. For more information, see <a href="#">Set a Data Freshness Policy</a> .                          |
| The site has reached the  | <a href="#">Update site settings</a> to increase the maximum number of views   |

|  |  |
|--|--|
| limit for the number of views that can be accelerated. | that can be accelerated, or choose No limit. |
|--|--|

View Acceleration is suspended

There are a few scenarios in which acceleration is suspended.

| Issue   | Resolution   |
|---|--|
| The view's acceleration was suspended.  | <a href="#">Re-enable acceleration for the view.</a>   |
| There are background acceleration jobs running to precompute the data for the view. | <p>If the jobs fail regularly, the view is auto suspended. The jobs may fail if:</p> <ul style="list-style-type: none"> <li>• A view's credentials have expired. <a href="#">Update the view's credentials.</a></li> <li>• The owner of the view becomes inactive. <a href="#">Change the ownership</a> to an active user.</li> <li>• The view's data source was deleted. Contact the view's owner to update the data source.</li> <li>• The job to precompute the data takes too long and times out. View Acceleration has a maximum runtime of 30 minutes. Contact the view's owner to optimize the workbook.</li> </ul> |

View Acceleration is ineffective

View Acceleration reduces the time it takes to execute queries of a view. If the time taken to execute queries isn't the bottleneck for the viz load time, you won't notice a significant improvement in performance during a viz load. Likewise, a view usually has many queries. You can't accelerate queries with transient functions, such as `now()` or using relative date filters. If a view has a long-running query with transient functions, you won't notice an improvement in performance during a viz load.

## Refresh accelerated views

### Event based refresh of accelerated views

In workbooks that have an extract, all accelerated views are refreshed when the extract refresh completes. When a workbook is republished or renamed, all accelerated views in the workbook are refreshed.

### Schedule based refresh of accelerated views

Schedules for refreshing accelerated views can only be configured if a workbook has at least one live data source.

Accelerated views for workbooks utilizing live data sources are refreshed based on the workbook's data freshness policies. If there isn't a schedule set for refreshing the data, the default data freshness policy is used. For more information, see [Edit a workbook data freshness policy](#).

## Manage View Acceleration on your site

By default, View Acceleration is allowed.

1. Sign in to your site on Tableau Server.
2. From the left pane, choose **Settings**.
3. From the **General** tab, scroll to the **View Acceleration** section.
4. Select the check box to allow creators and explorers to accelerate views in their workbooks. Clear the check box to turn off View Acceleration for the site.

5. Enter the maximum number of views that can be accelerated for your site, or choose **No limit**.

The screenshot shows the 'View Acceleration' configuration page in Tableau Server. The page has a navigation bar with tabs for 'General', 'Licenses', 'Extensions', 'Customization', and 'Integrations'. The 'General' tab is selected. Under the 'View Acceleration' heading, there is a description: 'Allow views to be accelerated for faster loading time. [Learn more](#)'. Below this is a checked checkbox labeled 'Allow creators and explorers to accelerate views in their workbooks'. Further down, there is a section titled 'Set the maximum number of views that can be accelerated for this site'. This section contains two radio button options: 'No limit. Be sure to monitor backgrounder functioning. [Learn more](#)' (which is unselected) and '100 Views' (which is selected). The number '100' is entered in a text input field next to the selected radio button.

## Accelerate recommended views

Based on a workbook's query time and usage, Tableau sometimes recommends acceleration to improve the performance of slower and more popular views and dashboards. If acceleration is available for a view, users can recommend acceleration for a view once every 30 days.

When a user visits a view, they'll see the option to Recommend Acceleration to the site admin or workbook owner.

When the site admin or workbook owner visits the same view, they'll see the option to accelerate the view, and they'll see how many users have recommended acceleration.

### Manage Views recommended for acceleration

As a site admin, you can see when Tableau has recommended acceleration for a view:

1. Sign in to your Tableau site.
2. From the left pane, choose **Tasks**.
3. From the **Acceleration status** column, check for views with a **Recommended** status. You can also use the **Filter** in the right-side pane to filter for views with a **Recommended** status.

Personalized recommendations for acceleration as a workbook owner or admin:

1. Sign in to your Tableau site.
2. From the top-right of the page, choose the account menu icon.
3. Select **My Content**.
4. Select the **Performance** tab.
5. From the **Actions** column, choose **Accelerate**.

### Automatically suspend acceleration to save resources

To conserve resources, administrators can automatically suspend acceleration for views that are consistently failing. Administrators can set a threshold for the number of times an acceleration task can fail per day, week, or month before the acceleration is automatically suspended.

1. Sign in to your Tableau site.
2. From the left pane, choose **Settings**.
3. From the **General** tab, scroll to the **View Acceleration** section.
4. Set the maximum number of failures allowed per day, week, or month.

5. Choose **Save**.

## View and manage accelerated workbooks

1. Sign in to your Tableau site.
2. From the left pane, choose **Tasks**.
3. Select the **Accelerated Views** tab.
4. Choose the **Actions** menu (...) to Resume or Suspend Acceleration for the selected view or views.

| Extract Refreshes 1      |             | Flows 0 |              | Subscriptions 0 |       | Alerts 0        |         | Accelerated Views 4 |  |
|--------------------------|-------------|---------|--------------|-----------------|-------|-----------------|---------|---------------------|--|
| Select All               |             |         |              |                 |       |                 |         |                     |  |
|                          | ↓ View name | Actions | Workbook     | Location        | Owner | Views (1 month) | Average |                     |  |
| <input type="checkbox"/> | Sheet 24    | ...     | single_query | Default         | Jane  | 0               |         |                     |  |
| <input type="checkbox"/> | Sheet 1     | ...     | ive          | Default         | Jane  | 0               |         |                     |  |

## Manage View Acceleration notifications

Administrators can manage whether to receive notifications for views that are automatically suspended.

## Tableau Server on Linux Administrator Guide

1. Sign in to your Tableau site.
2. From the left pane, choose **Settings**.
3. From the **General** tab, scroll to the **Manage Notifications** section.
4. To receive notifications for views that are automatically suspended, check the box for **View Acceleration**.
5. Choose **Save**.

When views are automatically suspended, notifications are sent to site and server administrators. The notification includes information about why the view was suspended and the time that the view was suspended. Select the notification to go to the **Accelerated Views** tab of the **Tasks** page. From this page, administrators can filter the Acceleration Status to find views that were automatically suspended.

## Understand user context for precomputation

Precomputation for accelerated workbooks is performed with the user context of only one user. This user is either:

- The owner of the workbook (if there are no user filters in the workbook or data source, or if there are user filters on the data source but the data source is a published data source).
- or-
- The user that was selected for thumbnail generation the last time the workbook was published (if there are user filters on the workbook and the data source isn't a published data source).

## Understand the cost of View Acceleration

Enabling this feature increases the computation load and number of jobs on Tableau Server background processes because View Acceleration fetches the required data from data sources in a background process. A background job to precompute the data of an enabled workbook is run if any of the following happen:

- The workbook and published data source are republished (this includes the web-authoring save).
- An extract used by the workbook is refreshed.

Administrators should consider those costs before enabling View Acceleration for many workbooks, or scheduling acceleration jobs too frequently.

- Workbooks that are being heavily edited and republished might not be suitable because each republish triggers a precomputation. We recommend acceleration for workbooks that are published for consumption.
- If a workbook uses multiple extracts, then their refresh triggers precomputation of the data. Thus, frequent extract refreshes for enabled workbooks could cause a spike in background job load, especially given that, by design, View Acceleration jobs are run after the successful extract refresh.
- The precomputed data for workbooks is stored as materialized views in Hyper.

## Extract Query Load Balancing

In Tableau Server version 2020.2 and later, load balancing for extract-based queries has improved and may result in faster load times for extract-based dashboards. Large deployments that are extract heavy and have a high volume of dashboard loads will probably see the most improvement, particularly if they have Hyper running on standalone nodes. Smaller deployments where Hyper is running on nodes that are shared with other server processes may also see performance improvements.

Hyper logs a server health metric about the amount of resources Hyper is consuming and also takes into account load from other Tableau processes that may be running on the same server node. Based on this information, extract queries will be sent to a node that has available resources to process the query. In addition to evaluating system resources, the load balancer improves the chance that the node you are routed to has the extract already cached. This reduces the number of duplicate extracts across nodes and improves memory and I/O usage.

To use this feature, the Cache Server process must be active. For more information, see [Tableau Server Cache Server](#). If Cache Server process is not enabled, load balancing will automatically revert to the previous functionality.

This feature is turned on by default. To disable it, use the following tsm commands:

## Tableau Server on Linux Administrator Guide

```
tsm configuration set -k hyper_standalone.consistent_hashing.enabled  
-v false
```

```
tsm configuration set -k hyper_standalone.health.enabled -v false
```

Apply the changes using the following tsm command: `tsm pending-changes apply`

For more information, see `tsm configuration set Options`.

# Monitoring Tableau Server

You can configure SMTP and alerts and subscriptions to aid in monitoring Tableau Server.

## Configure SMTP Setup

Tableau Server can email server administrators about system failures, and email server users about subscribed views and data-driven alerts. First, however, you need to configure the SMTP server that Tableau Server uses to send email. After configuring SMTP, complete the steps to configure notifications (Configure Server Event Notification), then when you start or restart the server, it will trigger an email notification, which confirms that you have set up notifications correctly.

Configuring SMTP requires that you restart Tableau Server services.

## Secure SMTP

To enable and configure TLS for SMTP, you must use the TSM CLI as described in this topic. Tableau Server only supports STARTTLS (Opportunistic or Explicit TLS).

If your organization does not use public certificates for verifying TLS connections, then you can upload a private certificate to Tableau Server to verify trusted connections. For more information, see the `tsm security custom-cert add` command.

You may also configure SMTP TLS for encryption-only by disabling the certificate validation process. For more information, see the section, *Configuration file reference*, in the *Use the TSM CLI* tab below.

## Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see *Sign in to Tableau Services Manager Web UI*.

2. Click **Notifications** on the **Configuration** tab and click **Email Server**.
3. Enter the SMTP configuration information for your organization:

The screenshot shows the Tableau Server Configuration page for Email Server settings. The page has a dark blue header with tabs for STATUS, MAINTENANCE, and CONFIGURATION. The CONFIGURATION tab is active. Below the header, there's a section for Notifications with a sub-tab for Email Server. The main content area is titled 'Configure email server' and contains several input fields for SMTP configuration: SMTP server address (smtp.example.lan), Username (tableau-notify@example.lan), Password (masked with dots), Port Number (25 (Default)), Send all emails from (no-reply@example.lan), Send server health email to (tableau-health@example.lan), and Tableau Server URL (https://tableau.example.lan). At the bottom, there are 'Cancel' and 'Save Pending Changes' buttons.

4. Click **Save Pending Changes** after you've entered your configuration information.
5. Click **Pending Changes** at the top of the page:

6. Click **Apply Changes and Restart**.
7. Run the `tsm email test-smtp-connection` to view and verify the connection configuration. See `tsm email test-smtp-connection`.

## Use the TSM CLI

For the initial configuration of SMTP, we recommend that you use the configuration file template below to create a json file. You can also set any single configuration key listed below with the syntax described in `tsm configuration set`.

1. Copy the following json template to a file.

**Important:** The template below includes common options for most deployments. After you copy the template to a text file, you must edit the option values for your SMTP server requirements. You may need to remove or add options. See the reference section that follows for more information about all supported SMTP key options.

```
{
  "configKeys": {
    "svcmonitor.notification.smtp.server": "SMTP server host
name",
    "svcmonitor.notification.smtp.send_account": "SMTP user name",
    "svcmonitor.notification.smtp.port": 443,
    "svcmonitor.notification.smtp.password": "SMTP user account
password",
    "svcmonitor.notification.smtp.ssl_enabled": true,
    "svcmonitor.notification.smtp.from_address": "From email
address",
    "svcmonitor.notification.smtp.target_addresses": "To email
address1,address2",
    "svcmonitor.notification.smtp.canonical_url": "Tableau Server
```

```

    URL"
  }
}

```

2. Run the `tsm settings import -f file.json` to pass the json file with the appropriate values to Tableau Services Manager to configure Tableau Server for SMTP. Tableau Services Manager will validate the entity values.
3. Run the `tsm pending-changes apply` command to apply the changes. See `tsm pending-changes apply`.
4. Run the `tsm email test-smtp-connection` to view and verify the connection configuration. See `tsm email test-smtp-connection`.

#### SMTP CLI configuration reference

This table lists all of the options that can be used to configure SMTP with TSM CLI.

| Option  | Description  |
|---|--|
| <code>svc-monitor.notification.smtp.server</code>       | Address of SMTP server.<br><br>Example:<br><br>"svc-monitor.notification.smtp.server":<br>"mail.example.com" |
| <code>svc-monitor.notification.smtp.send_account</code> | User name for SMTP account.  |
| <code>svc-monitor.notification.smtp.port</code>         | Port number for SMTP server. The default is 25.  |

| Option   | Description  |
|--|--|
| <code>svc-<br/>mon-<br/>itor.notification.smtp.password</code>                       | <p>Password for SMTP server account.</p> <p>Example:</p> <pre>"svc-<br/>mon-<br/>itor.no-<br/>tific-<br/>ation.smtp.password": "password"</pre>  |
| <code>svc-<br/>mon-<br/>itor.notification.smtp.ssl_<br/>enabled</code>               | <p>Specifies whether the connection to the SMTP server is encrypted. The default is false.</p>   |
| <code>svc-<br/>mon-<br/>itor.notification.smtp.ssl_<br/>required</code>              | <p>If enabled, Tableau Server will refuse to connect to SMTP servers without using TLS. The <code>svc-monitor.notification.smtp.ssl_enabled</code> option must also be set to true.</p> <p>The default is false.</p>   |
| <code>svc-<br/>mon-<br/>itor.notification.smtp.ssl_<br/>check_server_identity</code> | <p>If set to true, Tableau Server will check the SMTP server identity as specified by <a href="#">RFC 2595</a>. These additional checks based on the content of the server's certificate are intended to prevent man-in-the-middle attacks.</p> <p>The default is false.</p> |
| <code>svc-<br/>mon-<br/>itor.notification.smtp.ssl_<br/>trust_all_hosts</code>       | <p>When using TLS, trust certificates from all mail servers, ignoring the validity of the certificate's chain of trust. By setting this key to true, TLS will be used only to encrypt the traffic to the</p>   |

| Option  | Description  |
|---|--|
|   | <p>SMTP host.</p> <p>The default is false.</p>   |
| <pre>svc- mon- itor.notification.smtp.ssl_ ciphers</pre>  | <p>The default and supported sets of cipher suites is defined by the version of JDK that is installed with Tableau Server. See the section below, TLS ciphers, for a list of supported and default ciphers.</p> <p>To update the cipher suites used by Tableau Server for SMTP TLS connections, enter a white space-separated list of cipher suites for this value. For example, "TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA256 TLS_DHE_DSS_WITH_AES_128_GCM_SHA256 TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384".</p> |
| <pre>svc- mon- itor.notification.smtp.ssl_ versions</pre> | <p>The default TLS versions enabled on this version of Tableau Server are TLSv1, TLSv1.1, TLSv1.2 and TLSv1.3.</p> <p>TLS version support is defined by the version of JDK that is installed with Tableau Server.</p> <p>Supported versions of TLS are SSLv2Hello, SSLv3, TLSv1, TLSv1.1, TLSv1.2, TLSv1.3.</p> <p>To update the versions used by Tableau Server for SMTP TLS connections, enter a white space-separated list of versions for this value. For example, "TLSv1.2 TLSv1.3".</p>            |

| Option  | Description   |
|---|---|
| <code>svc-monitor.notification.smtp.from_address</code>     | <p>Email address that will send an notification if there's a system failure. The email address must have valid syntax (for example, ITalerts@bigco.-com or noreply@mycompany), but it does not have to be an actual email account on Tableau Server. (Some SMTP servers may require an actual email account, however.)</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>Note:</b> You can override the system-wide email address on a per-site basis. For more information, see <a href="#">What is a site.</a></p> </div> <p>Example:</p> <pre>"svcmonitor.notification.smtp.from_address": "donot-reply@example.com"</pre> |
| <code>svc-monitor.notification.smtp.target_addresses</code> | <p>Email address to receive notifications. If email notifications are enabled, you need to include at least one address. Separate multiple addresses with commas.</p> <p>Example:</p> <pre>"svc-monitor.notification.smtp.target_addresses": "iluvdata@example.com"</pre>   |
| <code>svc-monitor.notification.smtp.canonical_url</code>    | <p>URL of the Tableau Server. Enter <code>http://</code> or <code>https://</code>, followed by the name or IP address of the Tableau server. Used in the footer of subscription email.</p>  |

| Option | Description   |
|--------|---|
|        | <p>Example:</p> <pre> "svc- mon- itor.notification.smtp.canonical_ url": "http://myserver.example.com" </pre> |

### TLS ciphers

The following is a list of TLS ciphers that are supported by the JDK that is included with Tableau Server. In this version of Tableau Server, all of these ciphers are enabled by default. You can specify a custom list of ciphers for your SMTP configuration by entering a white-space separated list with the option, `svcmonitor.notification.smtp.ssl_ciphers`, as described in the table above.

|                                      |   |
|--------------------------------------|---|
| TLS_RSA_WITH_AES_128_CBC_SHA256      | TLS_ECDH_RSA_WITH_AES_256_GCM_SHA384    |
| TLS_DHE_DSS_WITH_AES_256_GCM_SHA384  | TLS_ECDH_RSA_WITH_AES_128_GCM_SHA256    |
| TLS_ECDH_RSA_WITH_AES_256_CBC_SHA384 | TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA    |
| TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA  | TLS_RSA_WITH_AES_256_CBC_SHA256         |
| TLS_RSA_WITH_AES_128_GCM_SHA256      | TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384 |
| TLS_ECDH_RSA_WITH_AES_128_CBC_SHA256 | TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256 |
| TLS_DHE_DSS_WITH_AES_128_CBC_SHA     | TLS_DHE_DSS_WITH_AES_256_CBC_SHA        |

|  |   |
|--|---|
| SHA256                                 | SHA                                     |
| TLS_DHE_RSA_WITH_AES_128_CBC_SHA256    | TLS_DHE_RSA_WITH_AES_256_CBC_SHA256     |
| TLS_RSA_WITH_AES_256_GCM_SHA384        | TLS_EMPTY_RENEGOTIATION_INFO_SCSV       |
| TLS_ECDH_ECDSA_WITH_AES_256_CBC_SHA384 | TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA    |
| TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA     | TLS_DHE_DSS_WITH_AES_256_CBC_SHA256     |
| TLS_RSA_WITH_AES_256_CBC_SHA           | TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256 |
| TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA256 | TLS_DHE_RSA_WITH_AES_256_CBC_SHA        |
| TLS_DHE_DSS_WITH_AES_128_GCM_SHA256    | TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256   |
| TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384  | TLS_ECDH_RSA_WITH_AES_128_CBC_SHA       |
| TLS_DHE_RSA_WITH_AES_256_GCM_SHA384    | TLS_DHE_RSA_WITH_AES_128_CBC_SHA        |
| TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256  | TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA      |
| TLS_DHE_RSA_WITH_AES_128_GCM_SHA256    | TLS_ECDH_ECDSA_WITH_AES_128_GCM_SHA256  |
| TLS_ECDH_RSA_WITH_AES_256_CBC_         | TLS_DHE_DSS_WITH_AES_128_CBC_           |

|   |  |
|---|--|
| SHA                                     | SHA                                    |
| TLS_ECDH_ECDSA_WITH_AES_256_CBC_SHA     | TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384  |
| TLS_RSA_WITH_AES_128_CBC_SHA            | TLS_ECDH_ECDSA_WITH_AES_256_GCM_SHA384 |
| TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 | TLS_AES_256_GCM_SHA384                 |
| TLS_AES_128_GCM_SHA256                  |  |

## Configure Server Event Notification

A Tableau Services Manager (TSM) administrator can configure Tableau Server to allow notifications for the following events:

- Content updates
  - Extract failures (enabled by default)
  - Subscription views for users (disabled by default)
- Server health monitoring
  - Server status changes (disabled by default)
  - Desktop License reporting (disabled by default)
- Drive space
  - Email alerts when disk space crosses or remains below pre-configured thresholds (disabled by default)
  - Recording usage history (enabled by default)

**Note:** You need to configure SMTP before you can configure subscriptions or notifications. For more information, see [Configure SMTP Setup](#).

### Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850.`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click **Notifications** on the **Configuration** tab and click **Events**.
3. Configure notification settings for your organization:

- Content updates

- **Send emails for extract refresh failures**

When this option is enabled (the default), a server administrator can configure email notifications to be sent when extract refreshes fail. These messages are configured at the site level, so even if this option is enabled, messages are not sent unless the **Send email to data source and workbook owners when scheduled refreshes fail** option is enabled for a site (this is enabled by default). For details, see [Enable Extract Refresh Scheduling and Failure Notification](#).

- **Allow users to receive email for views that they have subscribed to**

When this option is enabled (by default is it disabled), a server administrator can configure a site to send subscription email. These email messages are configured at the site level and can only be configured when this option is enabled. For details, see [Set Up a Site for Subscriptions](#).

When users subscribe to a workbook or view, a snapshot of the view is emailed to them on a scheduled basis, so they can see the latest updates without having to sign into Tableau Server.

To allow users to attach PDF renderings on subscription emails, select **Let users add attachments to subscribed views**.

- Server health monitoring
  - **Send emails for Tableau Server process events (up, down, and fail-over)**

Tableau Server sends an email message when the data engine, file store, gateway, or repository server processes stop or restart, or when the initial Tableau Server node stops or restarts.

If you are running a single-server installation (all processes on the same computer), health alerts are only sent when Tableau Server is up. No "down" alerts are sent. If you are running a distributed installation that's configured for failover, a DOWN alert means that the active repository or a data engine instance has failed and the subsequent UP alert means that the passive instance (repository) or second instance (data engine) of that process has taken over.

**Note:** Tableau Server is designed to be self-correcting. If a service or process stops responding or goes down, Tableau Server attempts to restart it. This can take 15 to 30 minutes to complete. Because of this, reacting immediately to service or process alerts can be counter-productive, especially in an installation with redundant services that can handle requests while one restarts.

- **Enable Tableau Desktop License reporting**

License reporting data originates in Tableau Desktop and is sent to Tableau Server. When this option is enabled, Tableau Server will generate and display the administrative report for Desktop License reporting. For information on the report, see Desktop License Usage.

- Drive space

Enable notifications (alerts) for remaining disk space on your Tableau Server.

- **Send emails when unused drive space drops below thresholds**

You can configure Tableau Server to send email notifications when disk space usage on any node crosses a threshold, or remains below the threshold. And you can configure how often threshold notifications are sent.

There are two thresholds you must set, **Warning threshold** and **Critical threshold**. Thresholds are expressed in percentage of disk space remaining. The critical threshold must be less than the warning threshold.

You also specify the **Send threshold alert every** option. This determines how often, in minutes, warning and critical notifications should be sent. The default value is 60 minutes.

- **Record disk space usage information and threshold violations for use in custom administrative views**

When you configure Tableau Server to record disk space usage, information about free disk space is saved in the repository and you can view the usage history using the Administrative Views.

4. Click **Save Pending Changes** after you've entered your configuration information.
5. Click **Pending Changes** at the top of the page:

6. Click **Apply Changes and Restart**.

## Use the TSM CLI

The various notification values described above can be set individually with the `tsm configuration set` command. Alternatively, you can construct a json file and pass all configuration values in one operation. Both methods are described in this section.

### Set notification values individually

The following table shows the key/value pairs that map to the notification events described earlier in this topic. Use the `tsm configuration set` command with the following syntax to set a single key/value pair:

```
tsm configuration set -k <config.key> -v <config_value>
```

For example, to enable job failure notifications, run the following command:

```
tsm configuration set -k backgrounder.notifications_enabled -v true
```

| Notification option   | Key  | Value                         |
|---|--|-------------------------------|
| Extract failures or Flow run failures                       | <code>backgrounder.notifications_enabled</code>          | <code>true   false</code>     |
| Enable subscription views for user                          | <code>subscriptions.enabled</code>                       | <code>true   false</code>     |
| Enable PDF attachments for subscriptions                    | <code>subscriptions.attachments_enabled</code>           | <code>true   false</code>     |
| Maximum attachment size (MB) for subscription notifications | <code>subscriptions.max_attachment_size_megabytes</code> | integer value, default is 150 |

## Tableau Server on Linux Administrator Guide

|  |  |  |
|--|--|--|
| Server status changes                                  | <code>svcmonitor.notification.smtp.enabled</code>      | <code>true   false</code>                  |
| License reporting                                      | <code>features.DesktopReporting</code>                 | <code>true   false</code>                  |
| Remaining space thresholds: enable email notifications | <code>storage.monitoring.email_enabled</code>          | <code>true   false</code>                  |
| Remaining space thresholds: warning percentage         | <code>storage.monitoring.warning_percent</code>        | integer value, for example, 20             |
| Remaining space thresholds: critical percentage        | <code>storage.monitoring.critical_percent</code>       | integer value, for example, 15             |
| Set email interval                                     | <code>storage.monitoring.email_interval_min</code>     | integer value, in minutes, for example, 25 |
| Record usage history                                   | <code>storage.monitoring.record_history_enabled</code> | <code>true   false</code>                  |

After you are done setting values, you must run the following command:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not

require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Set all notification values with a single json file

To make all notifications settings with a single configuration, you can pass a json file.

Copy and edit the following template to create a file for your configuration.

```
{
  "configKeys": {
    "backgrounder.notifications_enabled": true,
    "subscriptions.enabled": true,
    "subscriptions.attachments_enabled": true,
    "subscriptions.max_attachment_size_megabytes": 150,
    "svcmonitor.notification.smtp.enabled": true,
    "features.DesktopReporting": true,
    "storage.monitoring.email_enabled": true,
    "storage.monitoring.warning_percent": 20,
    "storage.monitoring.critical_percent": 15,
    "storage.monitoring.email_interval_min": 25,
    "storage.monitoring.record_history_enabled": true
  }
}
```

After you have saved the file, pass it with the following command:

```
tsm settings import -f <path-to-file.json>
```

To apply changes, run the following command:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do

not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Maintenance

You should perform regular maintenance on Tableau Server, such as creating backups, synchronizing Active Directory groups, and removing unneeded files.

### Backup and Restore

A Tableau Server administrator should perform regular database maintenance, monitor disk usage on the server, clean up unnecessary files to free up space on the server, and back up Tableau Server and its data. Taking these steps can help ensure that Tableau Server runs with maximum efficiency.

You can use the Tableau Services Manager (TSM) command line tool to back up and restore your Tableau data. Tableau data includes data extract files, as well as Tableau Server's own PostgreSQL database, which stores workbook and user metadata, and server configuration data. Tableau Server log files capture activity and can help you diagnose problems. Logs are written to folders on the server and you can archive and remove them to save disk space.

**Note:** You can use the `tsm maintenance restore` command to restore Tableau Server backups created using `tabadmin backup` and `tsm maintenance backup`. Database backups made in other ways, and virtual machine snapshots are not valid sources for restoring Tableau Server.

You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.

## Platform compatibility

You can use a backup created with Tableau Server on Linux to restore Tableau Server on Windows version 2018.2 and later.

You cannot use a backup created with Tableau Server on Linux to restore earlier versions of Tableau Server on Windows (version 2018.1 and earlier).

You can use a backup created with Tableau Server on Windows (version 2018.2 and earlier) to restore Tableau Server on Linux. For more information about restoring a Windows backup on Tableau Server on Linux, see [Migrate Tableau Server from Windows to Linux](#).

## Disk Space Usage for Backup and Restore

The free disk space required to create a backup varies depending on the amount of data in the Tableau Server repository and file store services, and their collocation with the tabadmincontroller service. During backups, the background tasks for cleaning up old extracts are temporarily paused. This means that, for the duration of the backup, extract refreshes will leave extra files in place, adding to disk space usage. If your backup takes a long time, or if your organization uses many extracts that are regularly updated, this can result in a significant amount of temporary disk space usage. These temporary files will be removed after the backup is complete.

The following table lists the disk space requirements for backup based on whether the node hosts the repository, file store, controller, or some combination of them. In multi-node Tableau Server environments you need to estimate the required disk space on each node.

| Repository | File Store | Controller | Disk Space Required   |
|------------|------------|------------|---|
| ✓          |            |            | 3x repository data + 250 MB<br><br>To obtain an estimate of the repository data, check the size of <code>&lt;data directory&gt;/pgsql/data/base</code> directory. |

|   |   |   |   |
|---|---|---|---|
|   |   |   | To obtain the exact size of the repository data, open the backup file and use the size of the workgroup.pg_dump file.   |
|   | ✓ |   | 1.5x file store data<br><br>To obtain an estimate of file store data (extracts, flows, etc.), check the size of <code><data directory>/dataengine</code> directory. |
|   |   | ✓ | 3x repository data + 250 MB + 2.5x file store data  |
| ✓ | ✓ |   | 3x repository data + 250 MB + 1.5x file store data  |
|   | ✓ | ✓ | 3x repository data + 250 MB + 1.5x file store data  |
| ✓ |   | ✓ | 3x repository data + 250 MB + 2.5x file store data  |
| ✓ | ✓ | ✓ | 3x repository data + 250 MB + 1.5x file store data  |

Restore disk space requirements

You must have adequate disk space for the database restore process to run successfully.

To restore Tableau Server:

- On controller nodes, you need free space equal to at least the size of the backup archive.

- On repository nodes, you need free space equal to at least three times the size of the repository data in the backup archive, plus 250 MB, plus the size of the postgres data directory.
- On file store nodes, you need free space equal to at least twice the size of the dataengine folder in the backup archive.

## Best Practices for Backing Up Tableau Server

We recommend following these security and performance best practices.

### Protect backup file

While configuration secrets are encrypted when stored on disk internally, when these configurations are exported to a backup file, some secrets are written into the file in plain text. It is up to the administrator to take measures to protect the backup file. There are a variety of options available:

- Write the file to an encrypted file system.
- Write the file to a disk that is physically protected and restricted to specific users.
- Encrypt the backup file.

### Maximize backup efficiency

There are several ways you can maximize backup efficiency. Your environment can impact how effective each of these is, so test with your data to see what works best.

### **Optimizing with topology configurations:**

- Co-locating File Store on the same node as the Administration Controller can reduce the length of time it takes to back up Tableau Server by reducing or eliminating the need to transfer data between nodes during the backup process. This is especially true if your organization uses many extracts.
- Co-locating the repository (postgres) with the Administration Controller node can also help to reduce back up time, but the time savings is less significant than that of the File Store.

The Administration Controller is usually on the initial node, unless you have had an initial node failure and moved the controller to another node.

### Optimizing with backup strategies:

Backup is a resource intensive process. If possible, doing your backups during off peak hours is a generally a good strategy. But this however, depends on your requirements and how often Tableau Server data is updated and what your restore requirements. For a detailed explanation of backup and disaster recovery, see [Tableau Server Disaster Recovery](#). Here are some backup strategies and adopt them to your requirements

- **Type of storage:** Solid State disks are recommended in general for backups. SSD helps make your backups faster and complete sooner compared to traditional spinning disks.
- **Backup compression:** You have the option of running your backups with or without compression. When you do your backup with compressions, your backup size will be comparatively smaller, but you may see a slower performance. So if your goal is more focused on speed, choose the `--skip-compression` option:

Use the `--skip-compression` option when backing up Tableau Server. This creates the backup without using compression, and results in a larger backup file but can reduce the amount of time it takes for the backup to complete. For more information, see `tsm maintenance backup`.

- **Snapshot backup:** This option is only available if you have configured your Tableau Server with External File Store. Although the performance of snapshot backups depend on the type of network attached storage, in general snapshot backups are faster than the traditional Tableau Server backups. For more information see, [Tableau Server External File Store](#).

## Perform a Full Backup and Restore of Tableau Server

You can use the following steps to back up your Tableau Server deployment. Specifically, these steps describe how to recover a clone of a server from a collection of backup data and

assets.

**Note:** The backup process can take a long time to run. Since no other jobs can be run while backup is running, we recommend that you run backup during non-business hours.

## Backup data types

There are two types of backup data that Tableau Server can generate. We recommend performing regular backups of each type in case you must restore a server in a recovery scenario:

- **Data managed by Tableau Server:** consists of the Tableau PostgreSQL database or repository, and File Store, which contains workbook and user metadata, data extract files, and site configuration data. When you use TSM to create a backup, all of this data is saved in a single file with a .tsbak extension. This data is backed up with the `tsm maintenance backup` command.

**Note:** When an external File Store is configured you cannot use the `tsm maintenance backup` command to back up Tableau Server Data. For information on how to back up this data, see [Backup and Restore with External File Store](#).

- You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.
- You can only restore a backup file to a version of Tableau Server version that is the same or newer than the version the backup was created on. You cannot restore to an older version of Tableau.
- **Important:** If you perform Blue/Green upgrades or manually upgrade Tableau Server 2021.4 (or earlier) using the [tsm maintenance \(backup and restore\)](#) method, you must enable `legacy-identity-mode` before you can restore to

Tableau Server 2022.1 (or later). For more information, see [Troubleshoot Issues with the Identity Migration](#).

- Beginning with version 2022.3, backups created using `tabadmin` ("pre-TSM backups") are not supported. You cannot restore a pre-TSM backup to Tableau Server version 2022.3 or later.
- **Configuration and Topology data:** includes most of the server configuration information required to fully recover a server. SMTP, alerting, some authentication assets, are all examples of configuration data that are exportable for backup. Topology data defines how your Tableau Server processes are configured in both single-server and multiple node deployments. Configuration and topology data is backed up with the `tsm settings export` command.

**Note:** You can change the file path used by the `tsm maintenance backup` command from the default value. For more information, see [tsm File Paths](#).

### Backup assets that require a manual process

Some configuration data is not included in the `tsm settings export` command and must therefore be documented and restored manually. The following configuration data is excluded from the `tsm settings export` operation. Your backup maintenance process should include documenting the following Tableau Server configuration data:

- System user accounts. Tableau Server setup creates an unprivileged user account, `tableau`. This account is used to access Tableau Server resources. This account can be changed during setup. If you have not changed this account, then you do not need to document it.
- TSM group membership. There are two groups created by Tableau Server: `tableau` and `tsmadmin`. If you configured alternative groups when you installed Tableau Server, then you'll need to document the group names.

In all cases you should document the user accounts that are in these groups. To view membership in a group, run the following command `grep <group_name> /etc/group`.

- Coordination Service deployment configuration. If you are running a multinode cluster, document which nodes are running the Coordination Services process. To view process configuration on your nodes, run `tsm topology list-nodes -v`.
- Customization settings. If your organization uses custom header or sign-in logos for Tableau Server web pages, you should include a copy of those assets with your backup portfolio. See `tsm customize`.
- Most authentication assets. While the locations for files may be included in an exported `settings.json` file, most certificate files, key files, keytab files or other authentication-related assets are not backed up by TSM. Verify that any of these assets you are trying to move won't need to be recreated.

There are three exceptions:

- The public certificate and private key for the internal PostgreSQL database (if enabled) are backed up.
- The certificate and key for external SSL are backed up and included in the configuration data.
- The custom certificate installed by `tsm security custom-cert add` (if added) is backed up.

However, all other authentication-related assets are not backed up. For example, if you have enabled access to the PostgreSQL database with the `tsm data-access repository-access enable` command, be sure to document the name/password pairs for each account you've configured. These credentials are not backed up. The certificate and key for mutual SSL are not included in the back up.

- LDAP assets. Keytab files, configuration files, and or other LDAP-related assets are not backed up by TSM.

## Tableau Server on Linux Administrator Guide

Internal server secrets and repository passwords are crypto-related configurations that are not exported. However, you do not need to document configuration values. New secrets will be created as part of the restoration process when you initialize the new instance.

### Backing up Tableau Server for recovery

Tableau Server includes commands that you run to generate backup data for Tableau Server.

**Note:** When backing up Tableau Server on Linux, the unprivileged user must have write access to the network share where the backup files are written. Otherwise, backup will fail.

To back up server topology and configuration data, use the `tsm settings` command.

1. Topology and configuration data are included when you run the `tsm settings export` command. The data is exported as a json file. Specify the name and location of the json file by running the following command:

```
tsm settings export -f <filename>.json
```

**Note:** Because the backup contains secrets, we recommend that you encrypt the backup and store it in a secure place. For more information about Tableau Server secrets, see [Manage Server Secrets](#).

2. Back up repository and File Store data. Repository data is backed up with the `tsm maintenance backup` command. Specify the name and location of the backup file by running the following command:

```
tsm maintenance backup -f <filename>.tsbak -d
```

The backup file is assembled in a temporary location in the data directory and then written to the directory defined in the TSM `basefilepath.backuprestore` variable:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/backups/<file-name>.tsbak
```

For more information about where backup files are written, and how to change that location, see [tsm File Paths](#). **Note:** Even when you change the backup location, the backup process uses a temporary location in the data directory to assemble the backup file.

**Note:** When File Store is configured external to Tableau Server you cannot use the `tsm maintenance backup` command to backup Tableau Server Data. For more information on how to backup this data, see [Backup and Restore with External File Store](#).

### Restoring core Tableau Server functionality

The procedure below uses the assets from the previous two sections to rebuild a Tableau Server in a recovery scenario.

**Note:** If you need to restore only the repository on an otherwise functional Tableau Server, see [Restore from a Backup](#). If you are running a distributed deployment, and your initial node has failed, see [Recover from an Initial Node Failure](#).

Topology and configuration backup data must be from Tableau Server on Linux. You cannot restore configuration data from a backup file that was generated on Tableau Server on Windows. To restore a backup made from Tableau Server on Windows to Tableau Server on Linux, see [Migrate Tableau Server from Windows to Linux](#).

You must have the following assets ready:

- **Topology and configuration data:** This is the json file that is generated by the `tsm settings export` command.
- **Repository backup file:** This is the file with a `.tsbak` extension that is generated by the `tsm maintenance backup` command.

You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.

When you use `tsm maintenance restore` to restore your Tableau data, data extract files and the contents of the PostgreSQL database are overwritten with the content in the backup file (`.tsbak`). If you are running a distributed installation of Tableau Server, perform the restore on the node running the TSM Controller (this is usually the initial node).

- Backup assets: These assets include the list of documented configurations as noted in the previous section.

## To restore a standalone Tableau Server

1. On the computer where you want to restore Tableau Server, Install and Initialize TSM. If your organization used non-default system user accounts, as described in an early section of this topic, then you must specify the users during this step.
2. Activate and Register Tableau Server.
3. (Optional). Configure Local Firewall.
4. (Optional). Verify LDAP.
5. Initialize Tableau Server. See Configure Initial Node Settings.
6. Import topology and configuration data. Copy the topology and configuration json backup file to the computer. Import the json file by running the following command:

```
tsm settings import -f <filename>.json
```

7. (Optional). Apply pending changes. At a command prompt, run:

```
tsm pending-changes apply
```

8. Restart Tableau Server. At a command prompt, run:

```
tsm restart
```

9. Restore repository data. See [Restore from a Backup](#).

10. (Optional). Repopulate TSM group membership. Add users to groups with this command:

```
sudo usermod -G <group_name> -a <username>
```

## To restore a Tableau Server cluster

1. On the initial node, Install and Initialize TSM. If your organization used non-default system user accounts, as described in an early section of this topic, then you must specify the users during this step.
2. On the initial node, Activate and Register Tableau Server.
3. (Optional). On the initial node, Configure Local Firewall.
4. On the initial node verify LDAP (optional), and initialize Tableau Server. See [Configure Initial Node Settings](#).
5. On the initial node, run `tsm topology nodes get-bootstrap-file --file <path\file>.json`.
6. Copy the bootstrap.json file to all additional nodes in the cluster.
7. On each additional node in the cluster:

## Tableau Server on Linux Administrator Guide

- a. Install the Tableau Server package.
- b. Navigate to the scripts directory.
- c. Initiate communication between initial node and the additional node:

```
sudo ./initialize-tsm -b <path-to-bootstrap>.json -u  
<admin-user-on-first-node> --accepteula
```

8. On the initial node, run `tsm topology list-nodes -v` and ensure that the node names have not changed from exported topology settings. *If the node names have changed, topology settings should be manually updated with new names, or the processes should be manually configured.*
9. The Cluster Controller process is required on every node and needs to be added explicitly. From the initial node, add an instance of the Cluster Controller to each additional node, where `<nodeID>` is the ID of one of the additional nodes. Add the process to each node separately. In this example we are adding the Cluster Controller to nodes 2 and 3:

```
tsm topology set-process -n node2 -pr clustercontroller -c 1  
tsm topology set-process -n node3 -pr clustercontroller -c 1  
tsm pending-changes apply
```

10. From the initial node, Deploy a Coordination Service Ensemble . The ensemble configuration must match your previous configuration.
11. On the initial node, import topology and configuration data. Copy the topology and configuration json backup file to the computer. Import the json file by running the following command:

```
tsm settings import -f <filename>.json
```

12. On the initial node, apply pending changes. At a command prompt, run:

```
tsm pending-changes apply
```

13. On the initial node, restart Tableau Server. At a command prompt, run:

```
tsm restart
```

14. On the initial node, restore repository data. See [Restore from a Backup](#).
15. On the initial node, repopulate TSM group membership. Add users to groups with this command:

```
sudo usermod -G <group_name> -a <username>
```

### Restore other functionality

If the previous server was configured with the following features, then you will need to re-enable and reconfigure them on the restored server:

- Authentication solutions: OpenID, external SSL, and trusted authentication. See [Authentication](#).
- Site customizations: See [tsm customize](#).
- Enable access to PostgreSQL repository: See [tsm data-access repository-access enable](#).

### Reencrypt Extracts After Restore

Optionally, if you are using the extract encryption at rest feature, after the backup is restored, you can reencrypt the extracts using different encryption keys. See [Extract Encryption at Rest](#).

Run `tabcmd reencryptextracts <site-name>` to reencrypt extracts on a given site. For more information, see [reencryptextracts](#). Run this command on every site where you are storing encrypted extracts. Depending on the number of encrypted extracts on the site, this operation could consume significant server processing load. Consider running this operation outside of business hours.

## Back up Tableau Server Data

Regularly backing up Tableau Server is an important step in proper administration and maintenance of your server. You can use the `tsm maintenance restore` command to restore Tableau Server backups created using the `tsm maintenance backup` command. Database backups made in other ways, and virtual machine snapshots are not valid sources for restoring Tableau Server, so it is critical that you have an up-to-date backup.

You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.

Looking for Tableau Server on Windows? See [Back Up Tableau Server Data](#).

Tableau Server data includes data extract files, as well as the Tableau PostgreSQL database, which contains workbook and user metadata, and configuration data. When you use TSM to create a backup, all of this data is saved in a single file with a `.tsbak` extension. If you are running a distributed installation of Tableau Server data from all the nodes is backed up.

The frequency of your backups depends on your environment, including how much use your server gets and how much and frequently the content and users change. Any changes or updates that happen after your backup will be lost if there is a system failure and you need to restore Tableau Server. The more activity there is, the more often you need to back the server up.

In addition to regular backups, you should *always* create a backup before upgrading to a new version of Tableau Server. The upgrade process does not create a backup except when the version of PostGRES is being updated, and then the upgrade process creates a PostGRES-only backup to be used internally.

To help protect against data loss, after you create the backup, you should store the .tsbak file on a computer that is not a part of your Tableau Server installation.

### Disk Space Usage for Backup

The free disk space required to create a backup varies depending on the amount of data in the Tableau Server repository and file store services, and their collocation with the tabadmincontroller service. During backups, the background tasks for cleaning up old extracts are temporarily paused. This means that, for the duration of the backup, extract refreshes will leave extra files in place, adding to disk space usage. If your backup takes a long time, or if your organization uses many extracts that are regularly updated, this can result in a significant amount of temporary disk space usage. These temporary files will be removed after the backup is complete.

The following table lists the disk space requirements for backup based on whether the node hosts the repository, file store, controller, or some combination of them. In multi-node Tableau Server environments you need to estimate the required disk space on each node.

| Repository | File Store | Controller | Disk Space Required  |
|------------|------------|------------|--|
| ✓          |            |            | <p>3x repository data + 250 MB</p> <p>To obtain an estimate of the repository data, check the size of <code>&lt;data directory&gt;/pgsql/data/base</code> directory.</p> <p>To obtain the exact size of the repository data, open the backup file and use the size of the <code>workgroup.pg_dump</code> file.</p> |
|            | ✓          |            | <p>1.5x file store data</p> <p>To obtain an estimate of file store data</p>  |

|   |   |   |   |
|---|---|---|---|
|   |   |   | (extracts, flows, etc.), check the size of <data directory>/dataengine directory. |
|   |   | ✓ | 3x repository data + 250 MB + 2.5x file store data                                |
| ✓ | ✓ |   | 3x repository data + 250 MB + 1.5x file store data                                |
|   | ✓ | ✓ | 3x repository data + 250 MB + 1.5x file store data                                |
| ✓ |   | ✓ | 3x repository data + 250 MB + 2.5x file store data                                |
| ✓ | ✓ | ✓ | 3x repository data + 250 MB + 1.5x file store data                                |

### Optimizing Tableau Server Backup

There are several ways you can maximize backup efficiency. Your environment can impact how effective each of these is, so test with your data to see what works best.

#### Optimizing with topology configurations:

- Co-locating File Store on the same node as the Administration Controller can reduce the length of time it takes to back up Tableau Server by reducing or eliminating the need to transfer data between nodes during the backup process. This is especially true if your organization uses many extracts.
- Co-locating the repository (pgsql) with the Administration Controller node can also help to reduce back up time, but the time savings is less significant than that of the File Store.

The Administration Controller is usually on the initial node, unless you have had an initial node failure and moved the controller to another node.

#### Optimizing with backup strategies:

Backup is a resource intensive process. If possible, doing your backups during off peak hours is a generally a good strategy. But this however, depends on your requirements and how often Tableau Server data is updated and what your restore requirements. For a detailed explanation of backup and disaster recovery, see [Tableau Server Disaster Recovery](#). Here are some backup strategies and adopt them to your requirements

- **Type of storage:** Solid State disks are recommended in general for backups. SSD helps make your backups faster and complete sooner compared to traditional spinning disks.
- **Backup compression:** You have the option of running your backups with or without compression. When you do your backup with compressions, your backup size will be comparatively smaller, but you may see a slower performance. So if your goal is more focused on speed, choose the `--skip-compression` option:

Use the `--skip-compression` option when backing up Tableau Server. This creates the backup without using compression, and results in a larger backup file but can reduce the amount of time it takes for the backup to complete. For more information, see `tsm maintenance backup`.

- **Snapshot backup:** This option is only available if you have configured your Tableau Server with External File Store. Although the performance of snapshot backups depend on the type of network attached storage, in general snapshot backups are faster than the traditional Tableau Server backups. For more information see, [Tableau Server External File Store](#).

Create a backup using the TSM command line interface (CLI)

Use the `tsm maintenance backup` command to create a backup of the data managed by Tableau Server. This data includes data extract files and the Tableau PostgreSQL database, which contains workbook and user metadata.

**Note:** When backing up Tableau Server on Linux to a network location, the unprivileged user must have write access to the network share where the backup files are written or the backup will fail.

To back up server configuration data, use the `tsm settings` command. When you use the `tsm maintenance backup` command, the current date is appended to the backup file:

```
tsm maintenance backup -f <backup_file> -d
```

For more information, see `tsm maintenance backup`.

### Create a pre-upgrade backup

You should always create a backup before upgrading Tableau Server. You can create a backup while Tableau Server is running and minimize the amount of time the server is unavailable during upgrade. The process for creating a pre-upgrade backup is the same as for creating regular backups, with one additional consideration for distributed installations.

**Note:** Uninstall Tableau Server from any nodes that you are not including in your new installation to avoid conflicts between the older nodes and the new installation.

### Backups during upgrades

During a Tableau Server upgrade, when necessary, a temporary backup of the database may be created to allow for migrations that occur as part of upgrades. This is done during the upgrade and in most cases has no noticeable impact to the upgrade process. In certain special cases there can be additional impacts:

- Upgrades to Tableau Server 2022.1 (or later) from version 2021.4 (or earlier)—If you perform Blue/Green upgrades or manually upgrade Tableau Server 2021.4 (or earlier) using the `tsm maintenance (backup and restore)` method, you must enable `legacy-identity-mode` before you can restore to Tableau Server 2022.1 (or later). For more

information, see [Troubleshoot Issues with the Identity Migration](#).

- Major version postgresql updates—If an upgrade includes a major version update to the database used for the Tableau repository, the internal upgrade backup is done without compression to save time. This requires additional temporary disk space during the upgrade process.

Tableau Server versions that include a major version database update; 2020.4.

## Scheduling and Managing Backups

Beginning in 2020.4.0 you can use tsm commands to schedule a backup. You need to do this from the command line (there is no TSM UI to schedule backups). The `tsm maintenance backup` command allows you to create and update backup schedules. The `tsm schedules` commands give you the ability to view, delete, pause, resume, and update schedules.

To schedule a backup:

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).
2. Run the following command:

```
tsm maintenance backup -f <backup-file> -sr <recurrence> -st
<time-to-run> -sd <days-to-run> -sn <schedule-name>
```

For example, to create a backup schedule named "monthly-backup" that runs on the 15th of each month at 2 am and generates a file called `<yyyy.mm.dd.hh.mm>-ts-mid_month_backup.tsbak`:

```
tsm maintenance backup -f ts-mid_month_backup -sr monthly -st
02:00 -sd 15 -sn monthly-backup
```

To view a scheduled backup:

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).
2. Run the following command:

```
tsm schedules list
```

You can sort the schedules by scheduled run time, earliest to latest, or by name using the `--next-run` or `--schedule-name` options. You can alternately display details for a single schedule using the `--schedule-id` option. When you view a single schedule you see additional details about it, including when it was created, how many times it has run, and specific options used when it is run. Job options are shown in JSON format as "Job args".

To update a scheduled backup:

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).
2. Run the following command:

```
tsm schedules update --schedule-id <ID> --schedule-time <time-to-run> --schedule-recurrence <frequency> --schedule-days <day-to-run>
```

**Note:** To add or change a name, use the `tsm-maintenance-backup` command.

To suspend or resume a backup schedule:

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).
2. Run one of the following commands:

- To suspend a schedule:

```
tsm schedules suspend --schedule-id <scheduleID>
```

- To resume a suspended schedule:

```
tsm schedules resume --schedule-id <scheduleID>
```

### Script the backup process

If you back up often, you might want to create a script that performs the backup and related tasks for you. These tasks include:

- Clean up files and folders before running the backup.
- Running the backup itself.
- Copying the backup file to a separate computer for safekeeping.

This section discusses `tsm` commands you can use together to perform a backup and related tasks.

For additional information about scripting TSM commands, see the [Tableau Community Forums](#).

### Remove log files and clear temporary folders

You can clean old Tableau Server log file and temporary files to reduce the time it takes to create a backup, and to ensure the backup file is as small as possible.

To clean log files older than a few days, run the following command:

```
tsm maintenance cleanup
```

### Run the backup

**Note:** When backing up Tableau Server on Linux to a network location, the unprivileged user must have write access to the network share where the backup files are written or the backup will fail.

To create the backup, use the `tsm maintenance backup` command:

## Tableau Server on Linux Administrator Guide

```
tsm maintenance backup --file <backup_file> --append-date
```

Note the following about the command:

- Add `--append-date` to the command to include the date in the backup file name.
- The backup file is assembled in a temporary location in the data directory and then written to the directory defined in the TSM `basefilepath.backuprestore` variable:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/backups/<filename>.tsbak
```

For more information about where backup files are written, and how to change that location, see [tsm File Paths](#). **Note:** Even when you change the backup location, the backup process uses a temporary location in the data directory to assemble the backup file.

Copy the backup file to another computer

As a best practice, after the backup is created, copy the backup file to another location that is separate from Tableau Server.

## Restore from a Backup

Use the `tsm maintenance restore` command to restore your Tableau Server data. You might do this if you had a system failure and need to restore your data, if you need to switch back to a previous version of Tableau Server (for example, if there is a problem with an upgrade), or if you are moving Tableau Server to new hardware. You can use the `tsm maintenance restore` command to restore Tableau Server backups created using `tabadmin backup` and `tsm maintenance backup`.

Limitations when restoring Tableau Server

- If you perform Blue/Green upgrades or manually upgrade Tableau Server 2021.4 (or earlier) using the [tsm maintenance \(backup and restore\)](#) method, you must enable `legacy-identity-mode` before you can restore to Tableau Server 2022.1 (or later). For more information, see [Troubleshoot Issues with the Identity Migration](#).

- Database backups made in other ways, and virtual machine snapshots are not valid sources for restoring Tableau Server.
- When you use `tsm maintenance restore` to restore your Tableau data, data extract files and the contents of the PostgreSQL database are overwritten with the content in the backup file (`.tsbak`). If you are running a distributed installation of Tableau Server, perform the restore on the node running the TSM Controller (this is usually the initial node).
- You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.
- You can only restore a backup file to a version of Tableau Server version that is the same or newer than the version the backup was created on. You cannot restore to an older version of Tableau.
- Beginning with version 2022.3, backups created using `tabadmin` ("pre-TSM backups") are not supported. You cannot restore a pre-TSM backup to Tableau Server version 2022.3 or later.
- During restore, the restore process will initiate a full re-indexing of the content and external assets managed by Tableau Server. This process consumes CPU resources which may be noticeable during backup and restore.

#### Restore Tableau Server from a backup file

**Note:** This operation includes steps that you may need to perform using the TSM command line.

## Tableau Server on Linux Administrator Guide

1. (Optional) Copy the `.tsbak` file to the default file location.

The `restore` command expects a backup file in the directory defined in the TSM `base-filepath.backuprestore` variable. By default:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/backups/
```

For more information about file paths and how to change them, see [tsm File Paths](#).

**Note:** If you are restoring a backup that was copied into the backups folder, ensure that the unprivileged user (by default, `tableau`), has at least Read access to the backup file. Otherwise, the restore process may not be able to unzip the backup file and the restore will fail.

2. Stop the server. At a command prompt, type:

```
tsm stop
```

3. Restore from a backup file. At a command prompt, type:

```
tsm maintenance restore --file <file_name>
```

In the above line, replace `<file_name>` with the name of the backup file you want to restore from.

**Note:** If you encounter errors when trying to restore from backup, see [Troubleshoot Tableau Server on Linux](#).

4. Restart the server:

```
tsm start
```

## Server Maintenance

As an administrator, you will want to check the status of the server, analyze and monitor the activity on the server, manage scheduled tasks, or perform certain maintenance activities such as clearing saved data connection passwords. In addition, there are several settings that you may want to specify to customize the user experience for people using the server. You can do some of these tasks from the General page of the Status page and others from the Settings page.

### View Server Process Status

You can view server process status can be by running a TSM CLI command or by accessing TSM Web UI or Admin pages on Tableau Server.

#### Viewing process status with TSM CLI

Run the following command:

```
tsm status -v
```

This command outputs all of the processes that are configured on the instance and their corresponding status.

#### Viewing process status in web UI

There are two locations in Tableau Server or Tableau Services Manager (TSM) where administrators can view the state of Tableau processes. You may be able to access one or both of these locations, depending on how your account and server are set up. Most of the process status information that displays is duplicated on both Status pages. This section explains each page, and identifies what is unique for each one.

**Note** The status pages displayed in both web UI locations show a subset of the total processes configured on a given node. To view all processes, you must run the TSM CLI command, `tsm status -v`.

## Tableau Server on Linux Administrator Guide

- The Tableau Services Manager (TSM) status page is accessible in TSM and can be viewed by TSM administrators. You must be able to log into TSM to see this page. For information about signing into TSM, see [Sign in to Tableau Services Manager Web UI](#).
- The Tableau Server status page appears in the Tableau Server web UI and is accessible by Tableau Server administrators. This page includes Tableau Server processes, along with links to troubleshooting documentation if a process is not running as expected. If you hover your mouse pointer over the status indicator for a process, a tooltip shows the node name and the port the process is running on. The Tableau Server status page does not show TSM processes. For information about signing into Tableau Server as an administrator, see [Sign in to the Tableau Server Admin Area](#).

### Tableau Services Manager (TSM) Status page

The TSM Status page shows you the state of server processes, including TSM Controller and License Server. These two processes do not display on the Tableau Server Status page.

|  <span>STATUS</span> <span>MAINTENANCE</span> <span>CONFIGURATION</span> |         |       |       |
|---|---------|-------|-------|

| Data Engine        | ✓               | ✓               | ✓               |
| File Store         | ✓               | ✓               |                 |
| Repository         | ✓               |                 |                 |

Possible status indicators are listed at the bottom of the table:

When Tableau Server is functioning properly, most processes will show as Active, Busy or Passive (Repository):

- **Active**—The process is functioning as intended. See File Store in Troubleshoot Server Processes for details on possible active states.
- **Busy**—The process is completing some task. See File Store and Repository in Troubleshoot Server Processes for more information.

- **Passive**—The repository is in passive mode, or a process cannot receive traffic. See Repository and Index and Search Server in Troubleshoot Server Processes for more information.
- **Unlicensed**—The process is unlicensed.
- **Down**—The process is down. The implications of this differ depending on the process.
- **Status unavailable**—Tableau Server is unable to determine the status of the process.

If there is additional information, a message displays below the status icon and links to appropriate documentation:

**Note:** Tableau Server is designed to be self-correcting. If a service or process stops responding or goes down, Tableau Server attempts to restart it. This can take 15 to 30 minutes to complete. Because of this, reacting immediately to service or process alerts can be counter-productive, especially in an installation with redundant services that can handle requests while one restarts.

For more information about troubleshooting process status, see Troubleshoot Server Processes.

### External Node

Some processes can be configured external to Tableau Server. For example, File Store can be configured on a SAN or NAS, the repository can be deployed to an AWS RDS instance. In such cases, the Tableau Server Status page will show these processes on **External Node** with status **E**, and the Tableau Services Manager (TSM) status page will show these processes on **external** with a check mark to indicate that the process is configured externally.

**Tableau Server Manager (TSM) status page showing File Store as configured external to Tableau Server:**

# Tableau Server on Linux Administrator Guide

The screenshot shows the Tableau Server status page with the following data:

| Process                                 | node1 | external |
|---|-------|----------|
| Gateway                                 | ✓     |          |
| Application Server                      | ✓     |          |
| Interactive Microservice Container      | ✓     |          |
| VizQL Server                            | ✓     |          |
| Cache Server                            | ✓     |          |
| Cluster Controller                      | ✓     |          |

**Tableau Server status page showing File Store as configured external to Tableau Server:**

## Access Status Remotely

**Note:** The information in this article refers to the Tableau Server status page. For information about the Tableau Server status page and the TSM status page, see [View Server Process Status](#).

You must be a Tableau Server administrator to see the Server Status page, but you can grant remote access to other computers to allow access to a machine-readable (XML) version of the Status table by non-admin users and by computers other than the initial Tableau Server node. One reason you might do this is as part of a remote monitoring process.

To grant remote access to Tableau Server status:

1. Open a command prompt as an administrator and type the following:

```
tsm configuration set -k wgserver.systeminfo.allow_referrer_ips
-v <ip address>
```

In the above command, <ip address> is the IPv4 address of the computer for which you want to enable remote access to the Tableau Server status XML.

## Tableau Server on Linux Administrator Guide

For example:

```
tsm configuration set -k wgserver.systeminfo.allow_referrer_ips
-v 10.32.139.31
```

If you are enabling remote access for more than one computer, use commas to separate each IP address.

```
tsm configuration set -k wgserver.systeminfo.allow_referrer_ips
-v 10.32.139.31,10.32.139.35
```

### 2. Commit the configuration change:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Now, users of computers with the IP addresses that have been added can view Tableau process status by entering the URL `http://<server>/admin/systeminfo.xml` in a browser or from a command line (for example, `curl http://j-smith/admin/systeminfo.xml`).

If Tableau Server has been configured to work with a load balancer or proxy server, use the hostname or IP address of the initial Tableau Server node to access the XML version of the status page.

For details on the XML that is returned, see [Get Process Status as XML](#).

### Get Process Status as XML

To get a machine-readable version of the server process status, that is, a version of the status formatted in XML, use the following URL:

```
http://my_tableau_server/admin/systeminfo.xml
```

You must be signed in to Tableau Server to view the machine-readable process status, or have [enabled remote access](#).

The server returns a status report similar to the following:

```
<systeminfo xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <machines>
    <machine name="my_tableau_server">
      <repository worker="my_tableau_server:8060" status="Active" preferred="false"/>
      <dataengine worker="my_tableau_server:27042" status="Active"/>
      <applicationserver worker="my_tableau_server:8600" status="Active"/>
      <apiserver worker="my_tableau_server:8000" status="Active"/>
      <vizqlserver worker="my_tableau_server:9100" status="Active"/>
      <dataserver worker="my_tableau_server:9700" status="Active"/>
      <backgrounder worker="my_tableau_server:8250" status="Active"/>
      <gateway worker="my_tableau_server:80" status="Active"/>
      <searchandbrowse worker="my_tableau_server:11000" status="Active"/>
      <cacheserver worker="my_tableau_server:6379" status="Active"/>
      <filestore worker="my_tableau_server:9345" status="Active" pendingTransfers="0" failedTransfers="0" syncTimestamp="2015-02-27T20:30:48.564Z"/>
      <clustercontroller worker="my_tableau_server:12012" status="Active"/>
      <coordination worker="my_tableau_server:12000" status="Active"/>
    </machine>
  </machines>
  <service status="Active"/>
</systeminfo>
```

### Status values in the XML

- `<process>` **worker** - The name of the node running the process and the port the process is using.
- **status** - The status of the process on the node. Possible values are: `Active`, `Passive`, `Unlicensed`, `Busy`, `Down`, `ReadOnly`, `ActiveSyncing`, `StatusNotAvailable`, `StatusNotAvailableSyncing`, `NotAvailable`, `DecommissionedReadOnly`, `DecomisioningReadOnly`, and `DecommissionFailedReadOnly`
- **pendingTransfers** - A count of the workbook or data source extracts the node needs to get to be fully synced. These represent items that were published to this file store node, and items that were published to other file store nodes and need to be copied to this node.
- **failedTransfers** - A count of the workbooks or data sources that did not transfer successfully to this file store node during the last automated job. The automated job normally runs about every 15 to 30 minutes, but may take longer when transferring a large number of extracts or large extracts.

Failed transfers do not necessarily indicate a problem with Tableau Server. The recurring automated job will normally transfer files that failed during the previous sync. Reasons for failed file transfers are listed in the logs.

- **syncTimestamp** - The time in UTC of the last automated job that ran and synchronized files.

### Troubleshoot Server Processes

**Note:** The information in this article refers to the Tableau Server status page. For information about the Tableau Server status page and the TSM status page, see [View Server Process Status](#).

When Tableau Server is functioning properly, processes will show as Active, Busy or Passive (Repository). If there is additional information, a message appears below the status icon:

Possible status indicators are:

**Note:** Tableau Server is designed to be self-correcting. If a service or process stops responding or goes down, Tableau Server attempts to restart it. This can take 15 to 30 minutes to complete. Because of this, reacting immediately to service or process alerts can be counter-productive, especially in an installation with redundant services that can handle requests while one restarts.

The following sections provide troubleshooting recommendations for status messages that you may see.

#### Cluster Controller

This message will only display if you have more than two nodes.

#### **Status: Down; Message: "Node degraded"**

One or more of the following are true:

- Repository on the node is stopped.
- Node cannot respond to failover elsewhere on the cluster.
- If Tableau Server is configured for high availability and this is the active repository, failover to the second repository occurs.
- No status available for repository or file store on this node.

No action is necessary unless the cluster controller is regularly down or is down for an extended period of time.

If that occurs, take the following actions, in order, until the problem is resolved:

1. Check disk space. If disk space is limited, save the log files (use `tsm maintenance ziplogs`) in case you need them for Support, then remove unnecessary files.
2. Restart Tableau Server.
3. If Cluster Controller continues to show as down, save the log files (`tsm maintenance ziplogs`) and contact Support.

### File Store

File Store status only reflects the state of the File Store when the page was loaded.

An active status () with no message indicates that no extracts were being synchronized when the page was loaded. It is possible that the recurring "catch-all" job is running and synchronizing extracts.

#### **Status: Busy; Message: "Synchronizing"**

"Synchronizing," usually indicates that extracts were being synchronized across File Store nodes when the page was loaded.

However, the "synchronizing" message is also returned following installation (both single-node and multi-node). After Tableau initializes the status should disappear within 15 or 20 minutes.

#### **Status: Down; "Data Extracts unavailable"**

On a single-node installation: "Data Extracts unavailable" indicates that existing extracts may be available but publish/refresh will fail. On multi-node installations, this message indicates that extract synchronization will fail for this node.

No action is necessary unless the File Store is regularly down or is down for an extended period of time.

If that occurs, take the following actions, in order, until the problem is resolved:

1. Check disk space. If disk space is limited, save the log files (use `tsm maintenance ziplogs`) in case you need them for Support, then remove unnecessary files.
2. Restart Tableau Server.
3. If File Store continues to show as down, save the log files (`tsm maintenance ziplogs`) and contact Support.

### Status: Busy; "Decommissioning"

This message indicates that this File Store is in read-only mode and that any unique files on this node are being replicated to other File Store nodes.

To remove this node, wait until the status message changes to "Ready for removal".

### Status: Active; "Ready for removal"

This message indicates that the File Store is in read-only mode.

You can safely stop (`tsm stop`) the cluster and remove File Store processes, or remove entire node.

### Status: Active; "Decommission failed"

This message indicates that the File Store is in read-only mode, and that at least one unique file failed to replicate to another File Store node.

To resolve a failed decommissioning:

1. Run the `tsm topology filestore decommission` command again.
2. Check disk space on other File Store nodes. Decommissioning will fail if another File Store node does not have enough space to store all the extracts.
3. Check the `tsm.log` file on the initial node and additional nodes for errors.
4. Stop Tableau Server (`tsm stop`) and then try running the `tsm topology filestore decommission` command again.
5. Put the File Store node back into read/write mode (`tsm topology filestore recommission`), collect logs, and then contact Support.
6. With Support: copy and merge `extracts` directory from this File Store node to the same directory on another File Store node.

## Tableau Server on Linux Administrator Guide

### Index and Search Server

 **Status: Passive; Message: n/a**

In multi-node environments, a passive status indicates that the node is working as intended, but cannot join the cluster and receive traffic.

To get the Index and Search Server process to active status:

1. Use the `tsm topology set-process` command to remove passive Index and Search Server processes from the nodes.

```
tsm topology set-process -n <Node> -pr indexandsearchserver -c  
0
```

2. Apply the changes (`tsm pending-changes apply`).
3. Restart Tableau Server (`tsm restart`).
4. Use the `tsm topology set-process` command to add the Index and Search Server process to nodes one at a time.

```
tsm topology set-process -n <Node> -pr indexandsearchserver -c  
1
```

5. Apply the changes (`tsm pending-changes apply --ignore-warnings`).
6. Restart Tableau Server (`tsm restart`).
7. Use the `tsm status` command to check the status of `indexandsearchserver` on affected nodes.

### Repository

 **Status: Busy; Message: "Setting up"**

The "Setting up" message indicates one or more of the following states:

- Passive repository is being synchronized with active repository.
- Repository is not ready to handle failover.
- Repository may have gotten more than two minutes behind active repository and is being setup again (this is faster than waiting for a sync).
- Failover occurred and this former active repository is rejoining the cluster.

Wait until the repository status message changes to "Passive".

If this message does not appear, or if it is taking a long time:

1. Check disk space and free space if possible.
2. Check cluster controller logs for errors.
3. Restart node.

 **Status: Busy; Message: "Synchronizing"**

Repository is synchronizing, for example after a failover.

 **Status: Down; Message: n/a**

When the Repository shows a status of down and there is no message, then the Repository is in one of the following states:

- If the installation is configured for high availability, failover of the repository occurred.
- Processes are restarting with updated database connection configurations after failover.
- If another active repository is not available, Tableau Server is down.

Take these actions in order until a step resolves the problem:

1. Wait several minutes for cluster controller to attempt to restart.
2. Restart Tableau Server (`tsm restart`).
3. Check disk space. If disk space is limited, save the log files (use `tsm maintenance ziplogs`) in case you need them for Support, then remove unnecessary files.
4. Restart Tableau Server.
5. If repository continues to show as down, save the log files (`tsm maintenance ziplogs`) and contact Support.

 **Status: Passive; Message: n/a**

A passive status with no message indicates that the node is working as intended and that it is ready for failover if needed.

VizQL Server

 **Status: Unlicensed; Message: n/a**

For information about unlicensed status for a VizQL Server process, see [Handle an Unlicensed Server Process](#).

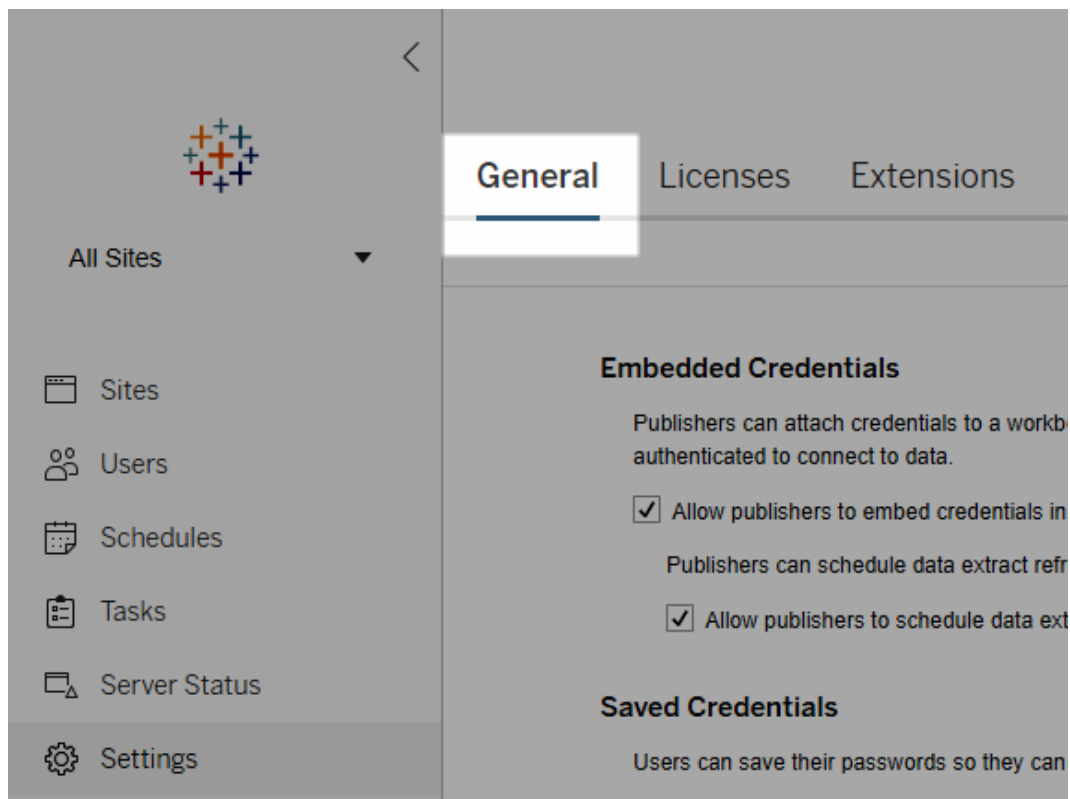

### Clear Saved Data Connection Passwords

As the administrator, if you enable users to save data source passwords, server users can save data source passwords across multiple visits and browsers so they are not prompted for their credentials each time they connect to a data source.

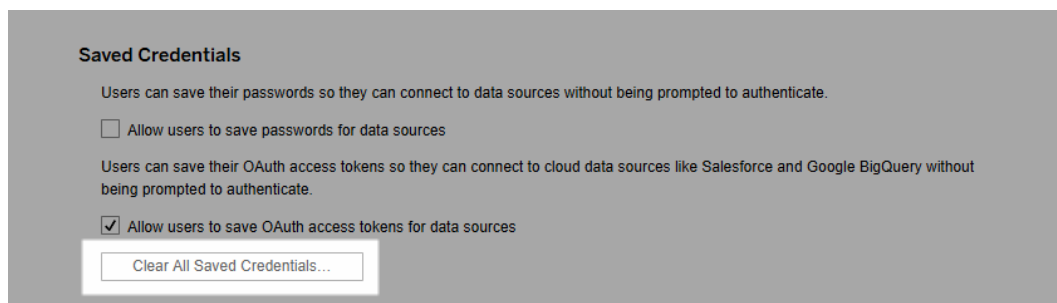

You can reset the data source passwords for all Tableau Server users. Doing this forces them to sign in to the data sources the next time they visit a view that requires database authentication. Server users can also clear their saved data connection passwords on an individual basis using their User Preferences page.

To clear saved data connection passwords for all server users:

1. In a single-site server, click **Settings > General**. On a multi-site server, select **Manage all sites**, then click **Settings > General**.

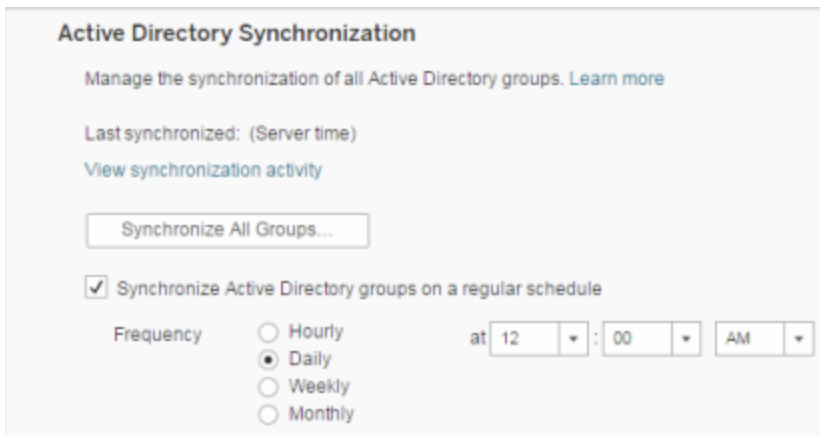

2. Under Saved Credentials, click **Clear All Saved Credentials**.

## Synchronize External Directory Groups on the Server

As a server administrator, you can synchronize all external directory (such as Active Directory) groups (that have been configured on Tableau Server) on a regular schedule or on-demand on the **General** tab of the **Settings** page for the server.

**Note:** In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

Before you begin

Before synchronizing groups as described in this topic, you must first import the external directory group into Tableau Server. See [Create Groups via Active Directory](#).

Synchronize external directory groups on a schedule

1. **Single-site:** Click **Settings > General**.  
**Multisite:** In the site menu, click **Manage All Sites** and then click **Settings > General**.
2. Scroll down the page to **Active Directory Synchronization**, and then select **Synchronize Active Directory groups on a regular schedule**.

**Active Directory Synchronization**

Manage the synchronization of all Active Directory groups. [Learn more](#)

Last synchronized: (Server time)

[View synchronization activity](#)

Synchronize All Groups...

Synchronize Active Directory groups on a regular schedule

Frequency  Hourly  Daily  Weekly  Monthly

at 12 : 00 AM

3. Select the frequency and time of synchronization.
4. Click **Save**.

**Note:** Beginning in versions 2021.1.23, 2021.2.21, 2021.3.20, 2021.4.15, 2022.1.11, 2022.3.3, 2023.1, a default time limit of 4 hours limits how long a scheduled group synchronization can take before it is canceled. A server administrator can change this time limit if your scheduled synchronization is of very large groups, or taking longer than the default. For more information, see [Synchronize All Active Directory Groups on a Schedule](#) and `backgrounder.timeout.sync_ad_group`.

Synchronize all external directory groups on demand

At any time, you can synchronize external directory (such as Active Directory) groups with Tableau Server to ensure that new users and changes in the external directory are reflected in all external directory groups on Tableau Server.

1. **Single-site:** Click **Settings**> **General**.

**Multisite:** In the site menu, click **Manage All Sites**, and then click **Settings**> **General**.

2. Under **Active Directory Synchronization**, click **Synchronize All Groups**.

View synchronization activity

You can view the results of synchronization jobs in the **Background Tasks for Non Extracts** administrative view. **Queue Active Directory Groups Sync** is the task that queues and indicates the number of **Sync Active Directory Group** tasks to be run.

1. **Single-site:** Click **Status**.
- Multisite:** In the site menu, click **Manage All Sites** and then click **Status**.
2. Click the **Background Tasks for Non Extracts** link.
3. Set the **Task** filter to include **Queue Active Directory Groups Sync** and **Sync Active Directory Group**.

You can quickly navigate to this administrative view by clicking the **View synchronization activity** link in the **Settings** page for the server.

Set the minimum site role for users in an external directory group

In the **Groups - Details** page, you can set the minimum site role for group users to be applied during Active Directory synchronization.

This setting does not run synchronization; instead, it sets the minimum site role to applied to the group every time synchronization runs. The result is that when you synchronize external directory groups, new users are added to the site with the minimum site role. If a user already exists, the minimum site role is applied if it gives the user more access in a site. If you don't set a minimum site role, new users are added as **Unlicensed** by default.

**Note:** A user's site role can be promoted but never demoted based on the minimum site role setting. If a user already has the ability to publish, that ability will always be maintained. For more information on minimum site role, see Site roles and Active Directory import and synchronization.

1. In a site, click **Groups**.
2. On the Groups page, select a group.

Click **Actions > Minimum Site Role**.

3. Select the minimum site role, and then click **Change Site Role**.

What happens when users are removed in the source external directory?

Users cannot be automatically removed from the Tableau Server through an external directory sync operation. Users that are disabled, deleted, or removed from groups in the external directory remain on Tableau Server so that administrators can audit and reassign the user's content before removing the user's account completely. For more information, see Sync behavior when removing users from Active Directory.

Improving group synchronization performance

External directory synchronization is performed by the backgrounder process. The Backgrounder process is the same process that is used for managing and creating extracts, and is also used to generate subscription content. In large organizations with dynamic group membership and heavy extract usage, the external directory group synchronization process may be disruptive. We recommend running group synchronization during non-business hours.

By default, the Backgrounder process performs synchronization in a serial operation. This means that each group is synchronized, one after the other, in a single Backgrounder process. If you are running multiple instances of Backgrounder processes either on a single Tableau Server or across a distributed deployment, consider enabling parallel processing for external directory synchronization. When parallel Backgrounder processing is enabled, the group synchronization is distributed across multiple Backgrounder processes for better performance.

To enable parallel backgrounder processing for group synchronization, open TSM CLI and enter the following commands:

```
tsm configuration set -k backgrounder.enable_parallel_adsync -v true  
  
tsm pending-changes apply
```

### Set the Default Start Page for All Users

In a new deployment, when users sign in to the Tableau Server web authoring environment, they are taken to the Home screen, which displays a role-based welcome banner. Home also displays recent views, favorites, and the site's most-viewed content. As the server administrator, you can change users' default landing page at the server and site level. For example,

you can show all workbooks, and when the user signs in, they see the workbooks they have access to.

To set the default start page for all users

1. Display the page or filtered view you want to be the default page users see when they sign in to the site.
2. Select your profile icon in the upper right area of the page.
3. To set the start page for:
  - All users on a site: click **Set as Start Page** and **For Users on this Site**.
  - All users on the server: click **Set as Start Page** and **For All Server Users**.

### User-set start pages and hierarchy

Users can set their own start pages from their profile icon, and can reset their start pages in their account settings (for information, search for “Access Your Profile and Account Settings” in the online Tableau Server Help for your operating system).

If a user sets their own start page, it will override any start page set by a server administrator. The next time that user signs in, they will land on the start page they've set. If a server administrator sets start pages for both a server and a site, users will default to the start page set for themselves (if any), then the site start page, then the server start page. If neither a user or an administrator has set a start page, users will default to Home.

## Access Sites from Connected Clients

By default, Tableau Server allows users to access a site directly from a Tableau *client*. It allows this access after the user provides credentials the first time they sign-in from the client. A client in this case is a Tableau application or service that can exchange information with Tableau Server. Examples of Tableau clients include Tableau Desktop, Tableau Prep Builder, and Tableau Mobile.

Tableau Server establishes a *connected client* by creating a secure refresh token that uniquely identifies a user when the user signs in from the client.

## Disable Automatic Client Authentication

After Tableau connected clients (e.g., Tableau Desktop, Tableau Mobile, Tableau Prep Builder, etc.) and personal access tokens (PATs) successfully sign in to Tableau Server, they are automatically authenticated in the future. Both connected client sessions and PATs are managed by refresh tokens.

By default, refresh tokens reset after a year. If a refresh token has not been used in 14 days, then it will expire. As a server administrator, you can change these values by setting the `refresh_token.absolute_expiry_in_seconds` and `refresh_token.idle_expiry_in_seconds` options. See [tsm configuration set Options](#).

As a Tableau Server administrator you can also disable automatic authentication for connected clients. In this case, session expiration is solely governed by Tableau Server session behavior, which manages web authoring sessions. See [9. Verify session lifetime configuration](#). Web authoring sessions are not considered a "connected client," and they do not use refresh tokens.

To immediately disconnect connected clients from Tableau Server and require users to sign in every time they connect:

1. Sign in to Tableau Server as a server administrator.
2. In the site menu, click **Manage All Sites**, and then click **Settings > General**.

3. Under **Connected Clients**, clear the **Let clients to automatically connect to Tableau Server** check box.
4. Click **Save** button at the top or bottom of the page.

**Note:** This setting described above only applies to connected clients and does not affect the creation and redemption of PATs.

## Remove Unneeded Files

As a best practice, you should regularly monitor disk space usage on your server. If the Tableau Server computer runs low on disk space, the impact to can be significant, including ultimately causing a failure. If you determine that space is getting low, you can archive any you want to save, and purge unneeded files, freeing up space for Tableau.

### Monitoring disk space usage

There are several things you can do to monitor disk space usage:

- **Notifications:** You can configure Tableau Server to send notifications when disk space reaches predetermined levels. For more information, see [Configure Server Event Notification](#).
- **Administrative views:** You can use a pre-built administrative view to help monitor disk space usage. For more information, see [Server Disk Space](#).

### Reducing disk space usage

To make more disk space available, you can take the following steps:

- **Archive log files:** Tableau Server generates log files when running. These can be helpful in troubleshooting issues, and when you are working with Tableau Support, but you do not need to leave them in place indefinitely. To save disk space without losing logs, you can archive them with the `tsm maintenance ziplogs` command, and then copy the ziplogs archive to a computer that is not part of the Tableau installation for safe keeping. For more information, see [Log File Snapshots \(Archive Logs\)](#).

## Tableau Server on Linux Administrator Guide

- **Clean up unwanted files:** After archiving any logs you want to save, use the `tsm maintenance cleanup` command to remove log files older than seven days, temporary files, and optionally, rows from the `http_requests` table in the Tableau Server repository. You should run the cleanup command regularly. For more information about which files are removed, see `tsm maintenance cleanup`.
- **Remove other files:** Over time Tableau Server can generate files that do not need to be left in place. In addition to the files mentioned above, be aware of files like old backups from previous versions. Tableau Server backup files have a `.tsbak` extension. We strongly recommend regularly backing up Tableau, and saving the backup files to a computer that is not part of the Tableau Server installation for safe keeping, but once you save the file in another location, you can delete it from the Tableau computer. For more information on backup files, including how to create them and where they are saved, see [Back up Tableau Server Data](#).

## Server Settings (General and Customization)

The following settings are available on the **General** and **Customization** pages in **Server - Settings**.

Many of these settings move from the Server Settings page to the Site Settings page when there is more than one site on the server. These are marked with "Moves to Site Settings on multi-site servers."

### General

| Setting  | Description   |
|--|---|
| <b>Site Name and ID</b><br><br>Moves to Site Settings on multi-site servers. | Specifies the site name seen in the user interface and the ID seen in the site URL. (If you are editing the Default site, you cannot change the ID.)<br><br>You can't change the "#/site" portion of the URL (for example, <code>http://localhost/#/site/sales</code> ). In multi-site server environments, these segments appear in the URL for sites other than the Default site. |

|   |  |
|---|--|
| <p><b>Storage</b></p> <p>Moves to Site Settings on multi-site servers.</p>          | <p>Select either <b>Server Limit</b> or <b>GB</b>, and for the latter enter the number of gigabytes you want as a limit for storage space for published workbooks, extracts, and other data sources.</p> <p>If you set a server limit and the site exceeds it, publishers will be prevented from uploading new content until the site is under the limit again. Server administrators can track where the site is relative to its limit using the Max Storage and Storage Used columns on the Sites page.</p>  |
| <p><b>Revision History</b></p> <p>Moves to Site Settings on multi-site servers.</p> | <p>Specifies the number of previous versions of workbooks, flows, and data sources that are stored on the server.</p>  |
| <p><b>Managing Users</b></p> <p>Moves to Site Settings on multi-site servers.</p>   | <p>Determines whether only server administrators can add and remove users and change their site roles, or whether site administrators can too.</p> <p>If you allow site administrators to manage users, specify how many users they can add to the site by selecting one of the following:</p> <ul style="list-style-type: none"> <li>• Server Limit adds the number of available server seat licenses. For a server with core-based licensing, there is no limit.</li> <li>• Site Limit lets site administrators add users up to a limit you specify.</li> <li>• Site Role Limit lets site administrators add users of each site role up to the license limit you specify for the site.</li> </ul> <p>For more information, see <a href="#">View Server Licenses</a>.</p> |
| <p><b>Web Authoring</b></p>   | <p>Controls whether browser-based authoring is enabled for the site. When web authoring for workbooks is dis-</p>  |

|   |   |
|---|---|
| <p>Moves to Site Settings on multi-site servers.</p>  | <p>abled, users can't create or edit published workbooks from the server web environment but instead must use Tableau Desktop to republish the workbook. When web authoring for flows is disabled, users can't create or edit published flows from the server web environment but instead must use Tableau Prep Builder to re-publish the flow.</p> <p>For more information, see <a href="#">Set a Site's Web Authoring Access and Functions</a> in Tableau Cloud Help.</p> |
| <p><b>Tableau Prep Conductor</b></p> <p>Moves to Site Settings on multi-site servers.</p>                         | <p>Controls whether users with appropriate permissions can schedule and monitor flows. Tableau Prep Conductor is part of Tableau Data Management. For more information, see <a href="#">About Tableau Prep Conductor</a>.</p>   |
| <p><b>Tableau Catalog</b></p> <p>Moves to Site Settings on multi-site servers.</p>                                | <p>Turns off Catalog capabilities when Tableau Server or a Tableau Cloud site is licensed with Data Management. For more information, see <a href="#">Disable Catalog</a>.</p>  |
| <p><b>Email Settings</b></p> <p>Moves to Site Settings on multi-site servers.</p>                                 | <p>Specifies the From address and message footer seen in automatic emails for alerts and subscriptions.</p>   |
| <p><b>Workbook Performance after a Scheduled Refresh</b></p> <p>Moves to Site Settings on multi-site servers.</p> | <p>Pre-computes recently viewed workbooks with scheduled refreshes to open them faster. For more information, see <a href="#">Configure Workbook Performance after a Scheduled Refresh</a>.</p>   |
| <p><b>Workbook Performance Metrics</b></p> <p>Moves to Site Settings on multi-site servers.</p>                   | <p>Lets site users collect metrics on how workbooks perform, such as how quickly they load To initiate recording, users must add a parameter to the workbook's URL. For more information, see <a href="#">Create a Performance Recording</a>.</p>   |

|  |   |
|--|---|
| <p><b>Managed Keychain Clean Up</b></p> <p>Moves to Site Settings on multi-site servers.</p>                               | <p>Lets site administrators manage saved credential key-chains for OAuth connections on the site. For more information, see <a href="#">OAuth Connections</a>.</p>  |
| <p><b>Automatically Suspend Extract Refresh Tasks</b></p> <p>Moves to Site Settings on multi-site servers.</p>             | <p>To save resources, Tableau can automatically suspend extract refresh tasks for inactive workbooks. This feature applies only to refresh schedules that run weekly or more often. For more information, see <a href="#">Automatically Suspend Extract Refreshes for Inactive Workbooks</a> in Tableau Cloud Help.</p> |
| <p><b>User Visibility</b></p> <p>Moves to Site Settings on multi-site servers.</p>   | <p>Controls what user and group names are visible to other users. For more information, see <a href="#">Manage User Visibility</a> in Tableau Cloud Help.</p>   |
| <p><b>Availability of Ask Data</b></p> <p>Moves to Site Settings on multi-site servers.</p>                                | <p>Controls whether Ask Data is enabled or disabled by default for data sources. Ask Data lets users query data using conversational language and automatically see visualizations. For more information, see <a href="#">Automatically Build Views with Ask Data</a> in Tableau user Help.</p>                         |
| <p><b>Availability of Explain Data</b></p> <p>Moves to Site Settings on multi-site servers.</p>                            | <p>Controls whether site users with the appropriate permissions can run Explain Data and authors can access Explain Data Settings. For more information, see <a href="#">Control Access to Explain Data</a>. To learn more about Explain Data, see <a href="#">Discover Insights Faster with Explain Data</a>.</p>      |
| <p><b>Automatic Access to Metadata about Databases and Tables</b></p> <p>Moves to Site Settings on multi-site servers.</p> | <p>Automatically grants users certain capabilities to external assets using derived permissions. For more information, see <a href="#">Turn off derived permissions</a> in Tableau Cloud Help.</p>  |
| <p><b>Sensitive Lineage Data</b></p> <p>Moves to Site Settings on multi-</p>   | <p>Specifies whether sensitive lineage data should be obfuscated or filtered when users don't have the appropriate</p>  |

|   |   |
|---|---|
| <p>site servers.</p>  | <p>permissions to related metadata. For more information, see <a href="#">Sensitive lineage data</a>.</p>   |
| <p><b>Extract Encryption at Rest</b></p> <p>Moves to Site Settings on multi-site servers.</p> | <p>Lets you encrypt .hyper extracts while they are stored on Tableau Server. Server administrators can enforce encryption of all extracts on their site or allow users to encrypt all extracts associated with particular published workbooks or data sources. For more information, see <a href="#">Extract Encryption at Rest</a>.</p>  |
| <p><b>Tableau Mobile</b></p> <p>Moves to Site Settings on multi-site servers.</p>             | <ul style="list-style-type: none"> <li>• Enable offline previews</li> </ul> <p>Controls whether offline previews are generated for display when users access the site on Tableau Mobile. For more information, see <a href="#">Manage Tableau Mobile Data on Devices</a> in the Tableau Mobile Deployment Guide.</p> <ul style="list-style-type: none"> <li>• Enable app lock</li> </ul> <p>Requires a biometric method or device passcode for users to open the site on Tableau Mobile. For more information, see <a href="#">Enable App Lock for Added Security</a> in the Tableau Mobile Deployment Guide.</p> |
| <p><b>Sharing</b></p> <p>Moves to Site Settings on multi-site servers.</p>                    | <p>Allows users to share items directly with other users. When an item is shared, the recipients get a notification and the item is added to their Shared with Me page. If this is not enabled, users can only copy a link to share. For more information, see <a href="#">Share Web Content</a> in Tableau user Help.</p>  |
| <p><b>Comments</b></p> <p>Moves to Site Settings on multi-site servers.</p>                   | <p>Controls whether users can add remarks in a Comments side pane for each view and @mention other Tableau users to notify them via email. For more information, see</p>  |

|   |   |
|---|---|
|   | <a href="#">Comment on Views</a> in Tableau user Help.  |
| <b>Data-Driven Alerts</b><br>Moves to Site Settings on multi-site servers.        | Lets users automatically receive emails when data reaches key thresholds. For more information, see <a href="#">Send Data-Driven Alerts</a> in Tableau user Help.   |
| <b>Tagging</b><br>Moves to Site Settings on multi-site servers.                   | Specifies the number of tags that users can add to items. The default limit is 50 tags, and the maximum is 200. For more information, see <a href="#">Use Tags</a> .  |
| <b>Recommendations for Views</b><br>Moves to Site Settings on multi-site servers. | Controls whether recommendations show on the site and whether the names of users who have looked at recommended items show on recommendation tooltips. <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>Note:</b> If you use Tableau Server, your administrator can disable Recommendations.</p> </div>  |
| <b>Request Access</b><br>Moves to Site Settings on multi-site servers.            | Lets users send access requests to content or project owners. For more information, see <a href="#">Let Site Users Request Access to Content</a> in Tableau Cloud Help.   |
| <b>Cross-Database Joins</b><br>Moves to Site Settings on multi-site servers.      | Determines where the join process happens when joining data from multiple sources. For more information, see <a href="#">Combine Tables from Different Databases</a> in Tableau user Help.  |
| <b>Metrics Content Type</b><br>Moves to Site Settings on multi-site servers.      | Controls whether metrics are available on the site. When enabled, users can create metrics from views and metrics appear as a content type. When disabled, metrics won't appear on the site or continue to sync; however, you can re-enable the feature to bring back previously created metrics. For more information, see "Set Up for Metrics" in <a href="#">Tableau Cloud Help</a> or <a href="#">Tableau Server Help</a> . |

|  |   |
|--|---|
|  | <p><b>Retirement of the legacy metrics feature</b></p> <p>Tableau's legacy metrics feature was retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. In October 2023, Tableau retired the ability to embed legacy metrics in Tableau Cloud and in Tableau Server version 2023.3. With Tableau Pulse, we've developed an improved experience to track metrics and ask questions of your data. For more information, see <a href="#">Create Metrics with Tableau Pulse</a> to learn about the new experience and <a href="#">Create and Troubleshoot Metrics (Retired)</a> for the retired feature.</p>   |
| <p><b>Site Time Zone for Extracts</b></p> <p>Moves to Site Settings on multi-site servers.</p>                                 | <p>The default time zone for extract-based data sources in a site is Coordinated Universal Time (UTC). Site administrators can set a different time zone. For more information, see <a href="#">Set the Site Time Zone for Extracts</a> in Tableau Cloud Help.</p>  |
| <p><b>Run Now</b></p> <p>On multi-site servers this appears on both Server Settings (at bottom of page) and Site Settings.</p> | <p>Server administrators can use this setting to allow or block users from manually running extract refreshes, flow runs, and subscriptions. This setting can be applied at the server level to include all the sites on Tableau Server or applied at the site level to include only specific sites.</p> <ul style="list-style-type: none"> <li>• By default, this option is set to allow users to run jobs manually. Clear the check box to prevent users from running jobs manually.</li> <li>• This applies only to jobs that are manually initiated by a user from the web interface, REST API calls, or tabcmd commands. Jobs initiated from scheduled tasks will continue to run at the schedule time and will not be affected.</li> <li>• Select <b>Run Now</b> to allow users to change the con-</li> </ul> |

|   |  |
|---|--|
|   | <p>nection type (Live/Extract) of data sources on the web.</p>   |
| <p><b>Manage Notifications</b></p> <p>Moves to Site Settings on multi-site servers.</p> | <p>Controls how site users can receive notifications for events such as extract jobs, flow runs, or when another user shares content with them or mentions them in a comment. Notifications can be seen in their Tableau site via the notification center or sent by email. When a notification is enabled, users can configure their notification preferences on their Account Settings page.</p> |
| <p><b>Flow Subscriptions</b></p> <p>Moves to Site Settings on multi-site servers.</p>   | <p>Controls whether flow owners can schedule and send emails with flow output data to themselves and others. When you allow flow subscriptions, you can control whether flow output data is included in the subscription email and whether flow output files are attached to the email. For more information, see <a href="#">Notify Users of Successful Flow Runs</a>.</p>                        |
| <p><b>Web Page Objects</b></p> <p>Moves to Site Settings on multi-site servers.</p>     | <p>Controls whether these dashboard objects can display target URLs. For more information, see <a href="#">Security for Web Page objects</a> in Tableau user Help.</p>   |
| <p><b>Personal Space</b></p> <p>Moves to Site Settings on multi-site servers.</p>       | <p>Allows Creator and Explorer site users to create and save content to a private Personal Space. When Personal Space is turned on, you can set user storage limits. For more information, see <a href="#">Create and Edit Private Content in Personal Space</a>.</p>  |
| <p><b>Collections</b></p> <p>Moves to Site Settings on multi-site servers.</p>          | <p>Controls whether collections are available. When you turn on collections, users can create collections to organize content and browse collections made available by other users. For more information, see <a href="#">Organize Items in a Collection</a>.</p>  |
| <p><b>OAuth Clients Registry</b></p>  | <p>For a subset of connectors, you can register a custom OAuth client for the site to override an OAuth client that</p>  |

|   |  |
|---|--|
|   | <p>has been configured for the server. By registering a custom OAuth client, you enable new and existing connections to use the site-level OAuth client instead of the server-wide OAuth client. For more information, see <a href="#">Configure a custom OAuth for a site</a>.</p>  |
| <p><b>View Acceleration</b></p>               | <p>Controls whether Creator and Explorer site users can accelerate the views in their workbooks for faster loading times. When you allow view acceleration, you can set a maximum number of views to be accelerated, and you can choose to automatically suspend acceleration for views that repeatedly fail the acceleration task. For more information, see <a href="#">View Acceleration</a>.</p> |
| <p><b>Start Page</b></p>                      | <p>Links to the server's current default start page for all users. For more information on how to change the default start page, see <a href="#">Set the Default Start Page for All Users</a>. Individual users will be able to override this setting (search for "Access Your Profile and Account Settings" in the Tableau Server Help for details).</p>  |
| <p><b>Guest Access</b></p>                    | <p>Allows users to view and interact with embedded views without having to sign in to a Tableau Server account. Permission can be assigned to the Guest User account to control the interactivity allowed for each view. This option is only available if you have a core-based server license.</p>  |
| <p><b>Embedded Credentials in Content</b></p> | <ul style="list-style-type: none"> <li>• Let publishers embed credentials in a data source, flow, or workbook</li> </ul> <p>Allows publishers to attach passwords to published workbooks or flows that will automatically authenticate web users to connect to data sources. The passwords are attached to workbooks or flow inputs and are only accessible on</p>                                   |

|                                     |  |
|-------------------------------------|--|
|                                     | <p>the server. For example, when a workbook is opened in Tableau Desktop, users still need to enter a user name and password to connect to the data source. When this setting is turned off, all existing embedded passwords are saved but are not used for authentication. If you turn the setting back on, users don't have to re-embed the passwords.</p> <ul style="list-style-type: none"> <li>• Let publishers schedule flow runs and extract refreshes</li> </ul> <p>Allows publishers to assign workbooks or flows to schedules. This option is only available if <b>Let publishers embed credentials in a data source, flow, or workbook</b> is enabled. When this setting is enabled, Tableau Desktop users will see scheduling options in the Publish dialog box.</p> |
| <p><b>Sign In Customization</b></p> | <p>Add a custom note to the server sign in page. The Sign In setting lets you add text. You can optionally add a URL to make the text a link. This note will also appear if a user receives a sign in error.</p> <p>Custom notes do not display on Tableau Mobile. If Tableau Server is configured with <b>identity pools</b>, the Sign In Customization note appears on both the Tableau Server landing page below all sign-in options and on the page where your initial pool (TSM configured) users enter their username and password.</p> <p>To set a custom note, sign in to a site on Tableau Server. On the left-side navigation pane, select <b>Manage all</b></p>   |

|   |   |
|---|---|
|   | <p><b>sites</b> from the drop-down site list. Select <b>Settings</b> and add a message to <b>Sign In Customization</b>.</p> <p>For more information, see <i>Customize Your Server</i>.</p>  |
| <p><b>Recommendations Training Schedule</b></p> | <p>Recommendations take two forms: recommendations for data sources and tables (for Tableau Desktop) and recommendations for views (for Tableau Server). Recommendations are based on the popularity of content and on content used by other users determined to be similar to the current user.</p> <p>The training schedule controls how often the server checks for new content and new usage information to keep the recommendations up to date. New content includes new and updated data sources and workbooks. New usage information includes information such as "Laura Rodriguez used the Food Catering data source" and "Henry Wilson accessed the Monthly Sales view."</p> <p>If you notice an impact on server performance, schedule this process to occur at a time when the server load is low. To track performance impact, look for the "Recommendations Trainer" or "View Recommendations Trainer" tasks in the Background Tasks for Non Extracts view.</p> <p>If you want to disable Recommendations, change the <b>tsm configuration set</b> option "recommendations.enabled" to false. If you want to disable only recommendations for views, change the option "recommendations.vizrecs.enabled" to false.</p> |
| <p><b>Connected Clients</b></p>                 | <p>Controls whether mobile users must sign in and provide their credentials every time they connect to Tableau</p>  |

|  |  |
|--|--|
|  | <p>Server, or if users can connect with their devices to Tableau Server without providing credentials after they authenticate their device successfully the first time. For more information, see <a href="#">Disable Automatic Client Authentication</a>.</p>   |
| <p><b>Language and Locale</b></p>                | <p>Controls the language used for the server user interface and the locale used for views. Individual users can override this setting on their Account Settings page. Also, web browser settings are evaluated first to determine which language and locale should be used. For more information, see <a href="#">Language and Locale for Tableau Server</a>.</p>  |
| <p><b>Saved Credentials for Data Sources</b></p> | <ul style="list-style-type: none"> <li>• Let users save passwords for data sources <p>Allows users to choose "Remember my password" and save data source passwords across multiple visits, browsers, and devices. (By default, users can choose to "Remember my password until I sign out," which lets them save their password only for a single browser session.)</p> <p>As an administrator, you can <a href="#">clear all saved passwords</a> at any time. In addition, users can clear their own saved passwords.</p> </li> <li>• Let users save OAuth access tokens for data sources <p>Allows users to store access tokens with their user preferences. Access tokens are provided by cloud data sources that support OAuth connections, and they are used instead of user names and passwords to grant access to the data.</p> </li> </ul> |

|  |   |
|--|---|
| <p><b>Linked Tasks</b></p> <p>On multi-site servers this appears on both Server Settings and Site Settings.</p>    | <p>Server administrators can use this setting to enable users to schedule flow tasks to run one after the other. They can also enable users to trigger the scheduled flow tasks to run using <b>Run Now</b>.</p> <p>This setting can be applied at the server level to include all the sites on Tableau Server. The setting can be disabled at the site level to include only specific sites.</p> <p>If the setting is turned off after linked tasks are scheduled, any tasks that are running will complete and the scheduled linked tasks are hidden and no longer show on the <b>Scheduled Tasks</b> tab.</p> <p>For more information, see <a href="#">Schedule linked tasks</a>.</p>  |
| <p><b>Flow Parameters</b></p> <p>On multi-site servers this appears on both Server Settings and Site Settings.</p> | <p>Enables users to schedule and run flows that include parameters.</p> <p>Administrators can also enable flow parameters to accept any value. If this option is enabled, any flow user can enter any value in a parameter, potentially exposing data that the user should not have access to.</p> <p>Parameters can be entered in an input step for file name and path, table name, or when using custom SQL queries, in an output step for file name and path and table name, and in any step type for filters or calculated values.</p> <p>Flow parameter settings can be applied at the server level to include all sites on Tableau Server. The settings can be disabled at the site level to include only specific sites.</p> |

|  |   |
|--|---|
|  | For more information about using parameters, see <a href="#">Create and Use Parameters in Flows</a> in the Tableau Prep help.   |
| <p><b>Active Directory Synchronization</b></p> <p>Only appears when server is configured for AD identity store.</p>                      | Controls the synchronization of all Active Directory groups in Tableau Server based on a schedule that you specify after you select the option <b>Synchronize Active Directory groups on a regular schedule</b> . For more information, see Synchronize External Directory Groups on the Server.  |
| <p><b>Reset to Default Settings</b></p>  | Returns any server settings described here that have been changed since setup back to their original state.   |
| <p><b>Assertions for Group Membership</b></p> <p>On multi-site servers this appears on both Server Settings and Site Settings pages.</p> | <p>Enables local group membership to be controlled and managed by the IdP or through the connected app by dynamically asserting group membership when a user authenticates to Tableau Server. Requires additional configuration in the SAML assertion or JSON web token (JWT). For more information, see Dynamic group membership using assertions.</p> <p><b>Note:</b> This server-wide setting must be enabled to allow the site-level setting to be enabled.</p> |
| <p><b>Group Sets</b></p> <p>Moves to site Settings on multi-site servers.</p>  | Enables the <b>Group Sets</b> page and the ability to create group sets. Group sets can be used by certain users (server admins, site admins, project owners, and content owners) to apply permission rules that require users to be members of all groups in the group set to access content whose permissions are dependent on the group set. For more information, see Work with Group Sets  |

## Customization

| Setting | Description |
|---------|-------------|
|---------|-------------|

|                              |   |
|------------------------------|---|
| <p><b>Welcome Banner</b></p> | <p>Add a custom message to the welcome banner on the home page for all server users to see. The custom message can contain up to 240 characters of text and hyperlinks as well as one paragraph break. Administrators can also disable the default Tableau welcome banner for the server.</p> <p>For more information, see <a href="#">Customize Your Server</a>.</p> |
|------------------------------|---|

Mobile

| <b>Setting</b>  | <b>Description</b>   |
|---|--|
| <b>Tableau Mobile</b>   |  |
| App Lock  | Requires a biometric method or device passcode for users to open this site on Tableau Mobile. For more information, see <a href="#">Enable App Lock for Added Security</a> in the Tableau Mobile Deployment Guide.   |
| Offline Previews  | Controls whether offline previews are generated for display when users access the site on Tableau Mobile. For more information, see <a href="#">Manage Tableau Mobile Data on Devices</a> in the Tableau Mobile Deployment Guide.  |
| <p><b>Mobile Security Policies</b></p> <p>Added in version 2023.1.0</p> | <p>Some security policies are enabled automatically and cannot be disabled. Mobile security policies are not available for MAM versions of Tableau Mobile.</p> <p><b>Note:</b> Mobile Security policies configured at the site level override Server-level Mobile Security policies.</p> |
| Jailbreak Detection   | Controls whether a Tableau Mobile app user with a device that has been "jailbroken" or "rooted" is allowed to access   |

|   |   |
|---|---|
|   | content on Tableau, and what level of response occurs when a jailbroken or rooted device is detected. For more information, see Tableau Mobile App Security Settings.                         |
| Malware Detection (Android only)              | Controls whether malware detection is enabled for mobile devices, and what level of response occurs when malware is detected. For more information, see Tableau Mobile App Security Settings. |
| Maximum Days Offline Without Policy Refresh   | Controls whether there is a maximum number of days a mobile device can be offline and still use the app. For more information, see Tableau Mobile App Security Settings.                      |
| Prevent Debugging                             | Controls whether debuggers are prevented on mobile devices. For more information, see Tableau Mobile App Security Settings.   |
| Screen Sharing and Screenshots (Android only) | Controls whether a Tableau Mobile user is able to take screenshots or use screen sharing while in the app. For more information, see Tableau Mobile App Security Settings.                    |

## Stop or Restart the Tableau Server Computer

As a best practice, you should *always* stop Tableau Server before you stop or restart the computer it is running on. This is true whether you are running Tableau on virtual machines (VMs), or on dedicated hardware. You should never turn off a computer without first stopping Tableau Server. Shutting down the computer while Tableau is running can cause problems restarting Tableau Server, and may result in unexpected results.

To be safe, follow these steps, whether you have a scripted process to shut down your systems, or manually shut down your computers:

1. Stop Tableau Server.

You can do this either from the command line, using the `tsm stop` command, or from the TSM Web UI, by clicking **Tableau Server is running**, and selecting **Stop Tableau Server**.

**Note:** Some TSM processes will continue to run, even after you stop Tableau Server. This is normal, and you can go ahead and stop your computer. The running services are designed to shut themselves off when the computer is stopped.

2. Once Tableau is stopped, stop your computer.
3. When you are ready, restart your computer. This might be after you have completed planned maintenance, or after leaving the computer off for some extended period of down time.
4. Start Tableau Server.

You can do this either from the command line, using the `tsm start` command, or from the TSM Web UI, by clicking **Tableau Server is stopped**, and selecting **Start Tableau Server**.

TSM will start automatically when the computer starts, so you can run `tsm` commands even though Tableau Server is stopped.

## tsm Command Line Reference

The topics in this section include reference content for Tableau Services Manager (TSM) command line interface (CLI) to support Tableau Server.

TSM is used to manage installation and configuration of Tableau Server. To learn more about TSM, see [Tableau Services Manager Overview](#).

You can automate the installation and configuration tasks supported by the TSM CLI using the TSM API. To learn more about the prerelease (Alpha) TSM API, see [Tableau Services Manager API](#).

Looking for tsm commands for Tableau Server on Windows? See [tsm Commands](#).

## Using the tsm CLI

You can run tsm commands on the initial node (the node where TSM is installed), or on any additional node in the cluster.

To run tsm commands, you need to open a command prompt.

1. Open a command prompt with an account that is a member of the `tsmadmin` group on a node in the cluster.
2. Run the command you want. If you are running the command from a node other than the initial node, include the `-s` option to specify the URL of the initial node by name (not IP address), and include the TSM port, 8850.

To see the version of TSM and Tableau Server from the initial node:

```
tsm version
```

To see the version of TSM and Tableau Server from an additional node:

```
tsm version -s https://<initial_node_name>:8850
```

For example:

```
tsm version -s https://myTableauHost:8850
```

## Authenticating with tsm CLI

Beginning in the 2019.2 release of Tableau Server, running tsm commands will not require you to enter a password if the following are true:

- The account you are running commands with is a member of the TSM-authorized group, by default, the `tsmadmin` group. The Tableau unprivileged user (by default, the `tableau` user) and root account may also run TSM commands.
- You are running commands locally on the Tableau Server that is running the Tableau Server Administration Controller service. By default, the Tableau Server Administration Controller service is installed and configured on the initial node in a distributed deployment.

### Logging into tsm CLI locally

If you are running tsm commands on the local computer with user account that is a member of a TSM-authorized group, then you will not need to specify a password. In this case, just run the command, for example:

```
tsm version
```

### Logging into tsm CLI remotely

If you are running TSM commands from a node in a cluster where the Tableau Server Administration Controller service is not running, then you must authenticate a session with the Tableau Server Administration Controller service on the remote computer before you can run commands. For example, run the following command:

```
tsm login -s <server_name> -u <account_name>
```

Where `<server_name>` is the name of the node where the Tableau Server Administration Controller service is running and `<account_name>` is an account that is a member of a TSM-authorized group.

After running this command, you will be prompted for a password. After the account has been authenticated, you can run TSM commands.

As a security best practice, do not expose the TSM port (by default, 8850) to the internet.

## Viewing and adding accounts to the TSM-authorized group

The TSM-authorized group is created during server installation. By default, the TSM-authorized group that is named `tsmadmin`. If you created an alternative TSM-authorized group during installation, then substitute your group name for `tsmadmin` in the following code examples.

To view the user accounts in the `tsmadmin` group, run the following command:

```
grep tsmadmin /etc/group
```

To add a user account to the `tsmadmin` group:

```
sudo usermod -G tsmadmin -a <username>
```

## Scripting and automating with tsm CLI

To run automation on a Tableau Server without a password in the script file, run the script on the initial node and with an account in the proper TSM-authorized group. See the "Authenticating" section above for more details.

## Viewing help content in the shell

To view minimal help content from a command line, use the `tsm help category`.

### Synopsis

```
tsm help [category] [command]
```

### Commands

```
tsm help
```

Help for all tsm commands

## Tableau Server on Linux Administrator Guide

```
tsm help <category>
```

Show help for a specific command category. For example, `tsm help authentication`.

```
tsm help <category> <command>
```

Show help for a specific command. For example, `tsm help authentication open-id`.

```
tsm help commands
```

List all top-level commands or categories.

## Categories

### tsm authentication

You can use the `tsm authentication` commands to enable, disable, and configure user authentication options for Tableau Server.

- **identity-migration**
- **kerberos**
  - configure
  - disable
  - enable
- **legacy-identity-mode**
  - enable
  - disable
- **list**
- **mutual-ssl**
  - configure
  - disable
  - enable

- **openid**
  - configure
  - disable
  - enable
  - get-redirect-url
  - map-claims
- **pat-impersonation**
  - disable
  - enable
- **saml**
  - configure
  - disable
  - enable
  - export-metadata
  - map-assertions
- **sitesaml**
  - disable
  - enable
- **sspi**
  - disable
  - enable
- **trusted**

## tsm authentication identity-migration configure

Change the default job settings for the identity migration. For more information, see [Manage the Identity Migration](#).

### Synopsis

```
tsm authentication identity-migration configure -job-run-time
```

```
tsm authentication identity-migration configure -rate
```

## Options

`-j, --job-run-time <number>`

Optional.

Determines the longest allowable time, in minutes, the scheduled migration job can run.  
Default value is 120 minutes.

`-r, --rate <number>`

Optional.

Determines the number of requests during a migration job that can run per second.  
Default value is 5 requests per second.

## `tsm authentication kerberos <commands>`

Enable, disable, and configure Kerberos user authentication on Tableau Server. See [Configure Kerberos](#).

### Synopsis

```
tsm authentication kerberos configure --keytab-file <keytab_
file.keytab> [global options]
```

```
tsm authentication kerberos enable [global options]
```

```
tsm authentication kerberos disable [global options]
```

### Options for kerberos configure

`-kt, --keytab-file <keytab_file.keytab>`

Required.

Specifies the service .keytab file used for requests to the KDC.

**tsm authentication legacy-identity-mode <commands>**

Enable or disable legacy identity store mode that might be required during the identity migration. Review the [Unable to restore backup](#) section to determine when to use this command.

For more information, see [About the Identity Migration](#).

**Synopsis**

```
tsm authentication legacy-identity-mode enable
```

```
tsm authentication legacy-identity-mode disable
```

**tsm authentication list**

List the server's existing authentication-related configuration settings.

**Synopsis**

```
tsm authentication list [--verbose][global options]
```

**Options**

v, --verbose

Optional.

Show all configured parameters.

**tsm authentication mutual-ssl <commands>**

Enable, disable, and configure mutual SSL for user authentication on Tableau Server. To learn more about mutual SSL, see [Configure Mutual SSL Authentication](#).

Before you enable mutual SSL, you must enable and configure SSL for external communication. For information, see [Configure SSL for External HTTP Traffic to and from Tableau Server](#).

## Tableau Server on Linux Administrator Guide

### Synopsis

```
tsm authentication mutual-ssl configure [options] [global options]
```

```
tsm authentication mutual-ssl disable [global options]
```

```
tsm authentication mutual-ssl enable [global options]
```

### Options

```
-cf, --ca-cert <certificate-file.crt>
```

Optional.

Specifies the location and file name for the certificate file. The file must be a valid, trusted certificate from a Certificate Authority (for example, Verisign).

```
-fb, --fallback-to-basic <true | false>
```

Optional.

Specifies whether Tableau Server should accept user name and password for authentication if SSL authentication fails.

Default value is `false`, to indicate that when configured for mutual SSL, Tableau Server does not allow a connection when SSL authentication fails. However, Tableau Server accepts username and password authentication from REST API clients, even if this option is set to `false`.

```
-m, --user-name-mapping <upn | ldap | cn>
```

Optional.

Specifies the user name syntax (UPN, LDAP or CN) to retrieve from identity store or directory. The syntax must match the format for Subject or Subject Alternative Name on the user certificate.

```
-rf, --revocation-file <revoke-file.pem>
```

Optional.

Specifies the location and file name for the certificate revocation list file. This file can be a .pem or .der file.

## tsm authentication openid <commands>

Enable, disable, and configure OpenID Connect (OIDC) user authentication on Tableau Server.

### Synopsis

```
tsm authentication openid configure [options] [global options]
```

```
tsm authentication openid disable [global options]
```

```
tsm authentication openid enable [global options]
```

```
tsm authentication openid get-redirect-url [global options]
```

```
tsm authentication openid map-claims [options] [global options]
```

### Options for openid configure

**Note:** Options must be set during initial configure, or during reconfigure. Individual options cannot be set separately.

```
-a, --client-authentication <string>
```

Required.

Specifies custom client authentication method for OpenID Connect.

To configure Tableau Server to use the Salesforce IdP, set this value to `client_secret_post`.

```
-cs, --client-secret <string>
```

Required.

Specifies the provider client secret. This is a token that is used by Tableau to verify the authenticity of the response from the IdP. This value is a secret and should be kept securely.

`-cu, --config-url <url>`

Required.

Specifies location of the provider configuration discovery document that contains OpenID provider metadata. If the provider hosts a public JSON file, use `--config-url`. Otherwise, specify a path on the local computer and file name using `--metadata-file` instead.

`-mf, --metadata-file <file-path>, --config-file <config-file.json>`

Optional.

Specifies the local path to the static OIDC discovery JSON document.

`-i, --client-id <client-id>`

Required.

Specifies the provider client ID that your IdP has assigned to your application.

`-id, --ignore-domain <true | false>`

Optional. Default: `false`

Set this to `true` if the following are true:

- You are using email addresses as usernames in Tableau Server
- You have provisioned users in the IdP with multiple domain names
- You want to ignore the domain name portion of the `email` claim from the IdP

Before you proceed, review the user names that will be used as a result of setting this option to `true`. User name conflicts may occur. In the case of a user name conflict, the risk of information disclosure is high. See Requirements for Using OpenID Connect.

`-if, --iframed-idp-enabled <true | false>`

Optional. Default: `false`

Specifies if the IdP is allowed inside of an iFrame. The IdP must disable clickjack protection to allow iFrame presentation.

`-ij, --ignore-jwk <true | false>`

Optional. Default: `false`

Set this to `true` if your IdP does not support JWK validation. In this case, we recommend authenticating communication with your IdP using mutual TLS or another network layer security protocol.

`-r, --return-url <return-url>`

The URL of your server. This is typically is the public name of your server, such as `"http://example.tableau.com"`.

`-sn, --custom-scope-name <string>`

Optional.

Specifies a custom scope user-related value that you can use to query the IdP. See Requirements for Using OpenID Connect.

#### Options for openid map-claims

Use these options to change the default OIDC claims Tableau Server will use when communicating with your IdP. See Requirements for Using OpenID Connect.

## Tableau Server on Linux Administrator Guide

```
-i, --id <string>
```

Optional. Default: `sub`

Change this value if your IdP does not use the `subclaim` to uniquely identify users in the ID token. The IdP claim that you specify should contain a single, unique string.

```
-un, --user-name <string>
```

Optional. Default: `email`

Change this value to the IdP claim that your organization will use to match user names as stored in Tableau Server.

### **tsm authentication pat-impersonation <commands>**

Enable and disable personal access token impersonation for administrators on Tableau Server.

For more information about personal access token impersonation, see [Personal Access Tokens](#).

#### Synopsis

```
tsm authentication pat-impersonation disable [global options]
```

```
tsm authentication pat-impersonation enable [global options]
```

To view whether personal access token impersonation is enabled, run the following command:

```
tsm authentication list
```

### **tsm authentication saml <commands>**

Configure Tableau Server to support single-sign on using the SAML 2.0 standard, enable or disable SAML for a site, map assertion attribute names between Tableau Server and the identity provider (IdP).

## Available commands

```
tsm authentication saml configure [options] [global options]
```

```
tsm authentication saml disable [options] [global options]
```

```
tsm authentication saml enable [options] [global options]
```

```
tsm authentication saml export-metadata [options] [global options]
```

```
tsm authentication saml map-assertions [options]
```

## tsm authentication saml configure

Configure the SAML settings for the server. Specify the SAML certificate and metadata files, provide additional required information, set additional options.

If you are configuring SAML for the first time or have previously disabled it, you must run this command with `tsm authentication saml enable`. For more information, see [Configure Server-Wide SAML](#).

### Synopsis

```
tsm authentication saml configure [options] [global options]
```

### Options

`-e, --idp-entity-id <id>`

Required for initial SAML configuration; otherwise optional. IdP entity ID value.

Typically this is the same as the Tableau Server return URL (specified in the `--idp-return-url` parameter). The entity ID that you enter is used as a base for generating site-specific entity IDs. For example, if you enter the following:

```
http://tableau-server
```

A site configured for SAML might display the following entity ID:

`http://tableau-server/samlservice/public/sp/metadata?alias=48957410-9396-430a-967c-75bdb6e002a0`

To find a site's entity ID, go to the site's **Settings** page, and select the **Authentication** tab. When SAML is enabled, the entity ID is shown under the first step for configuring site-specific SAML, exporting metadata.

`-r, --idp-return-url <idp-return-url>`

Required for initial SAML configuration; otherwise optional. The SAML return URL configured in the IdP. This is typically the Tableau Server external URL; for example, `https://tableau-server`.

#### Notes

- `http://localhost` does not work for an external server.
- Adding a trailing slash to the URL (`https://tableau-server/`) is not supported.

`-i, --idp-metadata <idp-metadata.xml>`

Required for initial SAML configuration; otherwise optional. Provide the location and name of the XML metadata file you exported from the IdP's settings.

For example, `/var/opt/tableau/tableau_server/data/saml/<metadata-file.xml>`

`-cf, --cert-file <certificate.crt>`

Required for initial SAML configuration; otherwise optional. The location and file name for the x509 certificate file for SAML. For requirements for the certificate file, see SAML Requirements.

For example, `/var/opt/tableau/tableau_server/data/saml/<file.crt>`

`-kf, --key-file <certificate.key>`

Required for initial SAML configuration; otherwise optional. Location and name of the key file that goes along with certificate.

For example, `/var/opt/tableau/tableau_server/data/saml/<file.key>`

`-a, --max-auth-age <max-auth-age>`

Optional. Default value is -1 (beginning in Tableau Server version 2020.4.15, 2021.1.12, 2021.2.9, 2021.3.8, 2021.4.4, 2022 and later). Previous default value was 7200 (2 hours).

The maximum number of seconds allowed between a user's authentication and processing of the AuthNResponse message.

We recommend you keep this default value, which disables the check for maximum authentication age. If this value is different from your IdP, users signing in to Tableau Server can see a sign-in error. For more information about this error, see the [Intermittent Error "Unable to Sign In" with SAML SSO on Tableau Server](#) article in the Tableau Knowledge Base.

`-d, --desktop-access <enable | disable>`

Optional. Default value is enable.

This option only applies to server-wide SAML. Use SAML to sign in to the server from Tableau Desktop. If single sign-on from Tableau client applications does not work with your IdP, you can set this to `disable`.

`-m, --mobile-access <enable | disable>`

Optional. Default value is enable.

Allow using SAML to sign in from older versions of Tableau Mobile app. Devices running Tableau Mobile app version 19.225.1731 and higher ignore this option. To disable devices running Tableau Mobile app version 19.225.1731 and higher, disable SAML as a client login option on Tableau Server.

## Tableau Server on Linux Administrator Guide

```
-so, --signout <enable | disable>
```

Optional. Enabled by default.

Enable or disable SAML sign out for Tableau Server.

```
-su, --signout-url <url>
```

Optional. Enter the URL to redirect to after users sign out of the server. By default this is the Tableau Server sign-in page. You can specify an absolute or a relative URL.

### Example

```
tsm authentication saml configure --idp-entity-id https://tableau-server --idp-metadata /var/opt/tableau/tableau_server-data/saml/<metadata.xml> --idp-return-url https://tableau-server --cert-file /var/opt/tableau/tableau_server/data/saml/<file.crt> --key-file /var/opt/tableau/tableau_server/data/saml/<file.key>
```

## tsm authentication saml enable and saml disable

Enable or disable server-wide SAML authentication. In this context, all sites and users that you enable for SAML go through a single identity provider.

### Synopsis

```
tsm authentication saml enable [global options]
```

```
tsm authentication saml disable [global options]
```

## tsm authentication saml export-metadata

Export the Tableau Server .xml metadata file that you will use to configure the SAML IdP.

### Synopsis

```
tsm authentication saml export-metadata [options] [global options]
```

## Options

`-f, --file [/path/to/file.xml]`

Optional.

Specifies the location and file name in which the metadata will be written. If you don't include this option, `export-metadata` saves the file to the current directory, and names it `samlmetadata.xml`.

`-o, --overwrite`

Optional.

Overwrites an existing file of the same name specified in `-f`, or of the default name if `-f` is not included. If a file specified in `-f` exists, and `-o` is not included, the command does not overwrite the existing file.

## tsm authentication saml map-assertions

Maps attributes between the IdP and Tableau Server. Provide the name that the IdP uses for the attribute specified in each argument.

### Synopsis

```
tsm authentication saml map-assertions --user-name <user-name>
[global options]
```

### Options

`-r, --user-name <user-name-attribute>`

Optional. The attribute in which the IdP stores the user name. On Tableau Server, this is the same as the display name.

`-e, --email <email-name-attribute>`

Do not use. This option is not supported by Tableau.

## Tableau Server on Linux Administrator Guide

```
-o, --domain <domain-name-attribute>
```

Optional. The attribute in which the IdP stores the domain name. Use this option if you add users from a domain that's different from the domain of the Tableau Server computer. For more information, see [When running multiple domains](#).

```
-d --display-name <display-name-attribute>
```

Do not use. This option is not supported by Tableau.

### Example for saml map-assertions

```
tsm authentication saml map-assertions --user-name=<SAMAccountName>  
--domain=<FQDM> or tsm authentication saml map-assertions --user-name=  
e=jnguyen --domain=example.myco.com
```

## tsm authentication sitesaml enable and sitesaml disable

Set the server to allow or disallow SAML authentication at the site level. Enabling site-specific SAML gives you access to the **Settings > Authentication** tab in the Tableau Server web UI. The **Authentication** tab contains the site-specific SAML configuration settings.

Use the `sitesaml enable` command with `saml configure` if you haven't yet configured the server to allow site-specific SAML. For more information, see [Configure Site-Specific SAML](#).

### Synopsis

```
tsm authentication sitesaml enable [global options]
```

```
tsm authentication sitesaml disable [global options]
```

## tsm authentication sspi <commands>

This command will only work on Tableau Server on Windows. If you attempt to enable SSPI on Tableau Server on Linux, an error will be returned.

Enable or disable automatic sign-in using Microsoft SSPI.

If you use Active Directory for authentication, you can optionally enable automatic logon, which uses Microsoft SSPI to automatically sign in your users based on their Windows user-name and password. This creates an experience similar to single sign-on (SSO).

Do not enable SSPI if you plan to configure Tableau Server for SAML, trusted authentication, a load balancer, or for a proxy server. SSPI is not supported in these scenarios.

### Synopsis

```
tsm authentication sspi disable [global options]
```

```
tsm authentication sspi enable [global options]
```

As with all authentication commands, you must run `tsm pending-changes apply` after running this command.

### tsm authentication trusted <commands>

Configure trusted authentication (trusted tickets) for user authentication on Tableau Server.

### Synopsis

```
tsm authentication trusted configure [options] [global options]
```

### Options

```
-th, --hosts <string>
```

Optional.

Specifies the trusted host names (or IPv4 addresses) of the web servers that will be hosting pages with Tableau content.

For multiple values, enter the names in a comma-separated list where each value is encapsulated in double-quotes.

For example:

## Tableau Server on Linux Administrator Guide

```
tsm authentication trusted configure -th "192.168.1.101",  
"192.168.1.102", "192.168.1.103"
```

or

```
tsm authentication trusted configure -th "webserv1", "web-  
serv2", "webserv3"
```

`-t, --token-length <integer>`

Optional.

Determines the number of characters in each trusted ticket. The default setting of 24 characters provides 144 bits of randomness. The value can be set to any integer between 9 and 255, inclusive.

### Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm configuration

You can use the `tsm configuration` commands to get, set, and update configuration key values.

### "Unknown key" responses

Certain configuration keys will return an "Unknown key" response when you attempt to get their current value, or set a new value. If this happens, verify that you have the key spelled correctly, including proper capitalization. To change the value, use the `--force-keys` option on the `tsm configuration set` command. For a list of configuration keys you can change, see [tsm configuration set Options](#).

## "Null" value responses

Certain configuration keys have a specific default value but will return a "Null" response when you attempt to get their current value. These keys use a default that is derived from the Tableau Server code. If a key is listed as having a specific default in tsm configuration set Options and the `tsm configuration get` command returns "Null" for the current value, the default value is determined by code running Tableau Server. You can set the key value using `tsm configuration set`, but this is not necessary unless you want to change the value.

- `tsm configuration get`
- `tsm configuration list-dynamic-keys`
- `tsm configuration set`

## tsm configuration get

View the current server configuration and topology.

### Synopsis

```
tsm configuration get --key <config.key> [global options]
```

### Option

`-k, --key`

Required.

Get the current value of the specified configuration key.

## tsm configuration list-dynamic-keys

View all the configuration keys that can be configured dynamically (without restarting Tableau Server).

## Synopsis

```
tsm configuration list-dynamic-keys [global options]
```

## tsm configuration set

Set or import server configuration or topology.

Quotes around the `<config.key>` and the `<config_value>` are optional unless there are spaces, in which case you must use quotes around the key or value.

**Note:** After setting a configuration key value you must apply the pending configuration changes using `tsm pending-changes apply`. Until you do, the new value will not be used by Tableau or show up in the results of a `tsm configuration get` command. You can view pending changes using `tsm pending-changes list`. For more information, see `tsm pending-changes`.

## Synopsis

```
tsm configuration set --key <config.key> --value <config_value>
[global options]
```

## Options

```
-k, --key <config.key>
```

Required.

Configuration key.

```
-v, --value <config_value>
```

Required. Beginning in the March maintenance releases (versions 2021.2.10, 2021.3.9, 2021.4.5), if you do not include this option, you will be prompted for the value.

## Tableau Server on Linux Administrator Guide

Configuration value.

`-d`

Optional.

Reset the configuration value to its default.

`-frc, --force-keys`

Optional.

Force a key to be added to configuration even if it did not previously exist.

### Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port 8850, and use the server name not the IP address. For example

`https://<tsm_hostname>:8850`. If no server is specified,  
`https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm configuration set Options

Below is a list of configuration options or keys that you can set with the `tsm configuration set` command. In many cases you can find out the current value of a configuration key with the `tsm configuration get` command.

This list is not intended to be an exhaustive list of Tableau Server configuration settings. It represents a subset of configuration keys that can be set by server administrators. Finally, some keys used internally by Tableau Server do not appear in this list.

**Note:** Configuration keys are case-sensitive.

## Using the tsm CLI

You can run `tsm` commands on the initial node (the node where TSM is installed), or on any additional node in the cluster.

To run `tsm` commands, you need to open a command prompt.

## Tableau Server on Linux Administrator Guide

1. Open a command prompt with an account that is a member of the `tsmadmin` group on a node in the cluster.
2. Run the command you want. If you are running the command from a node other than the initial node, include the `-s` option to specify the URL of the initial node by name (not IP address), and include the TSM port, 8850.

To see the version of TSM and Tableau Server from the initial node:

```
tsm version
```

To see the version of TSM and Tableau Server from an additional node:

```
tsm version -s https://<initial_node_name>:8850
```

For example:

```
tsm version -s https://myTableauHost:8850
```

## Basic Use of tsm configuration keys

### Setting a configuration key

```
tsm configuration set -k <config.key> -v <config_value>
```

In some cases, you must include the `--force-keys` option to set a configuration value for a key that has not been set before. For more information, see "Unknown key" responses.

After setting a configuration key value you must apply the pending configuration changes using `tsm pending-changes apply`. Until you do, the new value will not be used by Tableau or show up in the results of a `tsm configuration get` command. You can view pending changes using `tsm pending-changes list`. For more information, see `tsm pending-changes`.

### Resetting a configuration key to default

To reset a configuration key back to its default value, use the `-d` option:

```
tsm configuration set -k <config.key> -d
```

## Viewing the current value of a configuration key

To see what a configuration key is currently set to, use the `configuration get` command:

```
tsm configuration get -k <config.key>
```

There are two special cases that will not return a useful current value for a key:

- In certain cases you cannot get a configuration value for a key that has not been explicitly set. Instead the `tsm configuration get` command will return an "Unknown key" response. For more information, see "Unknown key" responses.
- For certain keys with predefined default values, the `tsm configuration get` command will return a "Null" response. For more information, see "Null" value responses.

## Configuration Keys

`adminviews.disabled`

Default value: `false`

Disables access to the Tableau Administrative views. By default, access to views is enabled (this option is set to "false").

`api.server.enabled`

**Version:** Deprecated in version 2023.1. You cannot disable the REST API in version 2023.1 and later.

Default value: `true`

Allows access to the [Tableau Server REST API](#).

By default, this functionality is enabled. We strongly recommend that you maintain this setting. Disabling the REST API will disrupt the functionality of a broad range of Tableau features. It will not improve performance or enhance security. If you choose to disable the REST API on your Tableau Server installation, test the functionality you require carefully.

Functionality impacted by disabling the REST API includes:

auditing.enabled

Default value: `true`

Allows access to the PostgreSQL (Tableau Server's own database) historical auditing tables.

backgrounder.default\_run\_now\_priority

Default value (integer): 0

This setting controls what priority is assigned to run now jobs, with 0 being the highest priority. Values should be specified should be in the range of 0 – 100.

backgrounder.enable\_parallel\_adsync

**Version:** Added in version 2018.3.6

Default value: `false`

Controls whether parallel processing of external directory group synchronization jobs is allowed when there are multiple backgrounders. By default a scheduled synchronization of external directory groups is handled serially, by a single backgrounder. Set this to `true` to enable parallel processing on multiple backgrounder instances.

backgrounder.externalquerycachewarmup.enabled

**Version:** Deprecated in version 2023.1. To improve view load times for workbooks, allow View Acceleration on your site instead.

Default value: `false`

Controls the caching of workbook query results after scheduled extract refresh tasks.

`backgrounder.externalquerycachewarmup.view_threshold`

**Version:** Deprecated in version 2023.1. To improve view load times for workbooks, allow View Acceleration on your site instead.

Default value: 2.0

The threshold for caching workbook query results after scheduled extract refresh tasks. The threshold is equal to the number of views that a workbook has received in the past seven days divided by the number of refreshes scheduled in the next seven days.

The following two *backgrounder* command options determine how long a flow task can run before the flow background task is canceled. These two commands together determine the total timeout value for flow tasks.

`backgrounder.extra_timeout_in_seconds`

Default value: 1800

The number of seconds beyond the setting in `backgrounder.querylimit` before a background job is canceled. This setting makes sure that a stalled job does not hold up subsequent jobs. The setting applies to processes listed in `backgrounder.timeout_tasks`. 1800 seconds is 30 minutes.

`backgrounder.default_timeout.run_flow`

Default value: 14400

The number of seconds before a flow run task is canceled. 14,400 seconds is 4 hours.

`backgrounder.failure_threshold_for_run_prevention`

Default value: 5

The number of consecutive failures of a subscription, extract, or flow run job before that job is suspended. Suspending continuously failing jobs helps preserve backgrounder resources for other jobs. To disable suspension of failing background tasks, set this to -1.

`backgrounder.log.level`

**Version:** Added in version 2020.3.0.

Default value: `info`

The logging level for the backgrounder process. This is dynamically configurable, so if you are only changing this you do not have to restart Tableau Server. For more information, see [Change Logging Levels](#).

`backgrounder.querylimit`

Default value: `7200`

Longest allowable time, in seconds, for completing a single extract refresh job. 7200 seconds = 2 hours.

**Note:** If a background job reaches this time limit, it may continue to run for an additional several minutes while being canceled.

`backgrounder.restrict_serial_collections_to_site_level`

Default value: `false`

In Tableau Server, you can schedule extract refreshes, subscriptions, or flows to run periodically. These scheduled items are referred to as tasks. The Backgrounder process initiates unique instances of these tasks to run them at the scheduled time. The unique instances of the tasks that are initiated as a result are referred to as jobs.

This setting affects schedules that are configured to run serially. By default, when a schedule is configured to run serially, all jobs using that schedule will run serially. When this setting is set to `true`, jobs running on different sites can run in parallel. Jobs for scheduled tasks on the same site will continue to run serially.

The example below illustrate this scenario:

Tableau Server includes a schedule named "Daily" to run jobs every day at 7 am. The "Daily" schedule is configured to run serially. Site "HR" and site "Payroll" each have multiple scheduled tasks that use the schedule, "Daily". When this setting is set to `true`, jobs for these scheduled tasks on Site "HR" can run in parallel with jobs on site "Payroll", whereas jobs on the same site will still only run serially.

`backgrounder.notifications_enabled`

Default value: `true`

Controls whether extract refresh and flow run alerts are enabled for all sites on the server. By default alerts are enabled. To disable the alerts for all sites on a server, set this to `false`.

Extract alerts can be enabled or disabled on a site basis by site administrators in site settings, or at the user level in user settings.

`backgrounder.sort_jobs_by_type_schedule_boundary_heuristics_milliSeconds`

Default value: `60000`

Controls the time window that identifies backgrounder jobs which are determined to have the same scheduled start time.

The backgrounder process orders work that is scheduled at the same time to be executed by job type, running the fastest category of jobs first: Subscriptions, then Incremental Extracts, then Full Extracts.

Jobs are batched to determine which jobs are scheduled at the "same time". A value 60,000 milliseconds (the default) indicates jobs for schedules starting within a 1 minute window should be classified in the same batch and so are ordered by type within that batch.

`backgrounder.subscription_failure_threshold_for_run_prevention`

Default value: `5`

Determines the number of consecutive subscription failures that must occur before alerting for a condition is suspended. When set to the default of `5`, alerting is suspended after `5`

## Tableau Server on Linux Administrator Guide

consecutive subscription failures. A value of `-1` will allow notification email to continue indefinitely. This threshold is server-wide, so applies to all subscriptions defined on the server.

`backgrounder.subscription_image_caching`

Default value: `true`

Controls whether backgrounder will cache images that are generated for subscriptions. Cached images do not have to be regenerated each time so caching improves subscription performance. By default image caching is enabled. To disable image caching for all sites on a server, set this to `false`.

`backgrounder.timeout_tasks`

Default value: The default value may be different, depending on your version of Tableau Server. To see the default value list for your version of Tableau, run the `tsm configuration get` command:

```
tsm configuration get -k backgrounder.timeout_tasks
```

The list of tasks that can be canceled if they run longer than the combined values in `backgrounder.querylimit` and `backgrounder.extra_timeout_in_seconds`. The list of tasks is delimited with commas. The default list represents all the possible values for this setting.

`backgrounder.timeout.single_subscription_notify`

**Version:** Added in version 2021.2.

Default Value: 1800 seconds (30 minutes)

This is the maximum allowable time specified in seconds for completing a single subscription job.

`backgrounder.timeout.sync_ad_group`

**Version:** Added in version 2021.1.23, 2021.2.21, 2021.3.20, 2021.4.15, 2022.1.11, 2022.3.3, 2023.1.

**Default Value:** 14400 seconds (4 hours)

This is the maximum allowable time, specified in seconds, for completing an Active Directory group sync. This applies to *scheduled* group synchronizations done by the backgrounder service and prevents long-running syncs from running indefinitely. This does not impact group synchronizations done using the Tableau Server UI or the REST API.

`backgrounder.vInstances_max_overflow_queue_size`

**Version:** Added in version 20221.2.

**Default Value:** 1000

The maximum number of jobs that can be in the secondary queue. A secondary queue is created when the number of jobs running is at the set concurrency limit. The default maximum is set to 1000 jobs - meaning if there are more than 1000 jobs when the concurrency limit is hit, anything more than 1000 jobs will not be queued. Use the `backgrounder.vInstance_max_overflow_queue_size tsm` command to make changes to the overflow maximum queue size.

The values should be specified in whole numbers.

`backup.zstd.thread_count`

**Version:** Added in version 2021.1.0. This key is dynamically configurable. For more information, see [Tableau Server Dynamic Topology Changes](#)

**Default value:** 2

The number of threads that should be used when creating a backup.

Increasing this number can improve backup performance, but we recommend thread count not exceed the number of logical processors on the Tableau Server computer, up to four.

## Tableau Server on Linux Administrator Guide

### `basefilepath.backuprestore`

**Default value:** `/var/opt/tableau/tableau_server/data/tabsvc/files/backups/`

The location in which the `tsm maintenance backup` command creates the backup. This is also the location where the backup file must be when restored using the `tsm maintenance restore` command or the `tsm maintenance send-logs` command. After setting this, you should run the `tsm maintenance validate-backup-basefilepath` command (available in version 2022.1 and later) to verify that permissions are set properly for the location. For more information, see [tsm File Paths](#).

### `basefilepath.log_archive`

**Default value:** `/var/opt/tableau/tableau_server/data/tabsvc/files/log-archives/`

The location in which the `tsm maintenance ziplogs` command creates the zipped archive. For more information, see [tsm File Paths](#).

### `basefilepath.site_export.exports`

**Default value:** `/var/opt/tableau/tableau_server-  
/data/tabsvc/files/siteexports/`

The location in which the `tsm sites export` command creates the export file. For more information, see [tsm File Paths](#).

### `basefilepath.site_import.exports`

**Default value:** `/var/opt/tableau/tableau_server-  
/data/tabsvc/files/siteimports/`

The location in which the `tsm sites import` command expects the import file to be located. For more information, see [tsm File Paths](#).

### `clustercontroller.log.level`

**Version:** Added in version 2020.3.0.

Default value: `info`

The logging level for Cluster Controller. This is dynamically configurable, so if you are only changing this you do not have to restart Tableau Server. For more information, see [Change Logging Levels](#).

`clustercontroller.zk_session_timeout_ms`

Default value: `300000`

The length of time, in milliseconds, that Cluster Controller will wait for the Coordination Service (ZooKeeper), before determining that failover is required.

`dataAlerts.checkIntervalInMinutes`

Default value: `60`

The frequency, in minutes, at which Tableau Server checks to determine if data-alert conditions are true.

(The server also checks whenever extracts related to data alerts are refreshed.)

`dataAlerts.retryFailedAlertsAfterCheckInterval`

Default value: `true`

Determines how often Tableau Server rechecks failing data alerts. When set to `true`, the server rechecks failing alerts at the frequency defined by `dataAlerts.checkIntervalInMinutes`. When set to `false`, the server rechecks failing alerts every five minutes, more quickly notifying alert recipients if data conditions have changed, but reducing server performance.

(The server also checks whenever extracts related to data alerts are refreshed.)

`dataAlerts.SuspendFailureThreshold`

Default value: `350`

## Tableau Server on Linux Administrator Guide

Determines the number of consecutive data alert failures that must occur before alerting for a condition is suspended. When set to the default of 350, alerting is suspended after roughly two weeks of alerts. This threshold is server-wide, so applies to any data alert defined on the server.

`databaseservice.max_database_deletes_per_run`

**Version:** Added in version 2021.2.

Default value: null

Use this option to adjust the maximum number of embedded external assets (databases and tables) that can be deleted each time the backgrounder process, controlled by `features.DeleteOrphanedEmbeddedDatabaseAsset`, runs. If this option is left empty, the default maximum number of embedded external assets that can be deleted is 100.

For more information, see `features.DeleteOrphanedEmbeddedDatabaseAsset`.

`dataserver.log.level`

**Version:** Added in version 2020.3.0.

Default value: `info`

The logging level for Data Server. This is dynamically configurable, so if you are only changing this you do not have to restart Tableau Server. For more information, see [Change Logging Levels](#).

`elasticserver.vmopts`

**Version:** Added in version: 2019.1. Removed: 2022.1

**This configuration option is not valid for Tableau Server versions 2022.1 and later.** For Tableau Server versions 2022.1 and later, use `indexandsearchserver.vmopts` configuration option

Default value: `"-Xmx<default_value> -Xms<default_value>"`

The default value varies based on the amount of system memory. The JVM maximum heap size is scaled to be 3.125% of the total system RAM.

Controls the Elastic Server heap size. Because the default value scales automatically, use this option to override the default value only when absolutely necessary. Append the letter 'k' to the value to indicate kilobytes, 'm' for megabytes, or 'g' to indicate gigabytes. As a general rule, set initial heap size (`-Xms`) equal to the maximum heap size (`-Xmx`) to minimize garbage collections.

`excel.shadow_copy_all_remote.enabled`

**Version:** Added in versions 2019.1.5, 2019.2.1.

Default value: `false`

Controls whether Tableau Server creates a "shadow copy" of a shared Excel spreadsheet (`.xlsx` or `.xlsm`) that is being used as a live data source. When enabled, this option prevents Excel users from seeing a "Sharing Violation Error" and a message that the file is "currently in use." This option can have a performance impact with large Excel files. If Excel users do not need to edit the shared file, you do not need to enable this option.

**Note:** Tableau Server always attempts to create a shadow copy of a `.xls` file. This option does not change that behavior.

`extractservice.command.execution.timeout`

**Version:** Added in version 2021.4.

Default value: 7200 seconds

Sets the timeout value for VConn extract refresh run time.

**Example:** `tsm configuration set -k extract-service.command.execution.timeout -v <timeout_in_seconds> --force-keys`

**Note:** You must use the `--force-keys` option to change this value.

`features.ActiveMQ`

**Version:** Added in version 2021.4.

Default value: `true`

Controls whether Tableau Server uses the Apache ActiveMQ service (Tableau Server Messaging Service) for the internal messaging mechanism.

`features.DeleteOrphanedEmbeddedDatabaseAsset`

**Version:** Added in version 2021.2.

Default value: `true`

Controls a background process, for Tableau Catalog (or Tableau Metadata API), that deletes embedded external assets (databases and tables) that are no longer associated with downstream Tableau content. This process runs everyday at 22:00:00 UTC (coordinated universal time) and can delete a maximum of 100 external assets each day until there are no remaining external assets without connections to downstream Tableau content. You can set this option to `false` to stop this process from running. Alternatively, you can also adjust the maximum number of external embedded assets that can be deleted using `dataservice.max_database_deletes_per_run`.

For more information see, [Troubleshoot missing content](#).

`features.DesktopReporting`

Default value: `false`

Controls whether Desktop License Reporting is enabled on the server. When set to `false` (the default), no Administrative Views related to desktop licenses are available. Set this to `true` to enable license reporting and to make license usage and expiration Administrative

Views visible on the Server Status page. **Note:** Desktop License Reporting must be enabled on the client (Tableau Desktop) in order for information to be reported to Tableau Server.

features.IdentityMigrationBackgroundJob

**Version:** Added in version 2022.1. Default value was changed to `false` in versions 2021.4.22, 2022.1.18, 2022.3.10, 2023.1.6, and 2023.3.

Default value: `false`

Controls the process that performs the identity migration. When set to `true`, the identity migration runs in existing deployments immediately after upgrading Tableau Server to version 2022.1 (or later) and restoring a backup of Tableau Server version 2021.4 (or earlier). Set to `false` (default) to disable the identity migration.

For example, to start the identity migration, run the following:

```
tsm configuration set -k features.IdentityMigrationBackgroundJob -v true
```

For more information, see [About the Identity Migration](#).

**Note:** If the identity migration is disabled, Tableau Server cannot use the Identity Service to store and manage user identity information. Using the Identity Service is a prerequisite for certain capabilities like [identity pools](#).

features.IdentityPools

**Version:** Added in version 2023.1

Default value: `false`

A component of the identity pools capability that needs to be enabled if you perform a new Tableau Server installation. Requires `feature.NewIdentityMode` and `wgserv-er.authentication.legacy_identity_mode.enabled`. Set to `true` to enable identity pools. Set to `false` (default) to disable identity pools.

For example, to enable identity pools, run the following:

## Tableau Server on Linux Administrator Guide

```
tsm configuration set -k features.IdentityPools -v true
tsm configuration set -k features.NewIdentityMode -v true
tsm configuration set -k wgserver.authentication.legacy_identity_mode.enabled -v false
tsm pending-changes apply
```

For more information, see [Troubleshoot identity pools](#).

`features.MessageBusEnabled`

**Version:** Added in version 2019.4.

**Default value:** `true`

Controls whether Tableau Server uses the new internal messaging mechanism.

`features.NewIdentityMode`

**Version:** Added in version 2022.1

**Default value:** `false`. The default value was changed from `true` to `false` in 2023.1.6.

A prerequisite of the identity pools capability. Requires `wgserver.authentication.legacy_identity_mode.enabled` to be set to `false` to enable identity pools. Set to `true` to disable identity pools.

```
tsm configuration set -k features.IdentityPools -v true
tsm configuration set -k features.NewIdentityMode -v true
tsm configuration set -k wgserver.authentication.legacy_identity_mode.enabled -v false
tsm pending-changes apply
```

For more information, see [Troubleshoot identity pools](#).

`features.PasswordlessBootstrapInit`

**Default value:** `true`

Controls whether Tableau Server allows embedded credentials in bootstrap files. When enabled (the default), embedded credentials are included in the bootstrap file unless you specify that they should not be included. Set this to `false` if credentials should never be included in any bootstrap file you generate. For more information on generating bootstrap files, see `tsm topology nodes get-bootstrap-file`.

This option was added beginning with Tableau Server version 2019.3.

`features.PasswordReset`

Default value: `false`

Applies only to servers that use local authentication. Set to `true` to let users reset their passwords with a "Forgot password" option on the sign-in page.

`filestore.empty_folders_reaper.enabled`

**Version:** Added in 2020.x (2020.1.14, 2020.2.11, 2020.3.6, 2020.4.2) and 2021.1.x. The default value was changed to `true` in 2021.2.

Default value: `true`

Enables the job that "reaps" (removes) empty Filestore folders.

`filestore_empty_folders_reap.frequency_s`

**Version:** Added in 2020.x (2020.1.14, 2020.2.11, 2020.3.6, 2020.4.2).

Default value: 86400 (24 hours)

Specifies in minutes, how often to run the job that removes empty Filestore folders.

`features.Hyper_DisallowTDEPublishing`

**Version:** Defaults to `true` beginning in version 2023.1.0

Default value: `true`

## Tableau Server on Linux Administrator Guide

Specifies if users can upload .tde format files. This format was replaced by .hyper format beginning in version of 10.5 of Tableau Server but were not blocked from upload. Starting with Version 2024.3, .tde format files are no longer usable. The files were automatically converted to .hyper format if one of several actions were performed. For more information, see [Extract Upgrade to .hyper Format](#).

filestore.log.level

features.Hyper\_DisallowTDEPublishing

**Version:** Added in version 2020.3.0

Default value: `info`

The logging level for File Store. This is dynamically configurable, so if you are only changing this you do not have to restart Tableau Server. For more information, see [Change Logging Levels](#).

filestore.reapemptyfoldersholdoffms

**Version:** Added in 2020.x (2020.1.14, 2020.2.11, 2020.3.6, 2020.4.2). This is not yet available in 2021.1.

Default value: 300000 (5 minutes)

Specifies in milliseconds, the amount of time to wait before removing empty Filestore folders.

floweditor.max\_datafile\_upload\_size\_in\_kb

**Version:** Added in version 2020.4

Default value: 1048576

For Tableau Prep flow web authoring, the maximum size of delimited text files (for example, CSV or TXT) that can be uploaded to Tableau Server.

gateway.external\_url

**Version:** Added in version 2023.1

Default value: Null

Required when OpenID Connect (OIDC) authentication is configured in TSM during Tableau Server setup or with identity pools. Specifies the Tableau Server URL used by the identity provider (IdP) to redirect users who authenticate into Tableau. The gateway external URL is the same URL that you specified as the redirect URL with your IdP, which is used for matching purposes.

For example, to redirect the IdP associated with OIDC authentication configuration to your Tableau Server, `http://myco`, run the following command:

```
tsm configuration set -k gateway.external_url -v http://myco
```

`gateway.http.cachecontrol.updated`

Default value: `false`

The Cache-Control HTTP header specifies whether the client browser should cache content sent from Tableau Server. To disable caching of Tableau Server data on the client, set this option to `true`.

`gateway.http.hsts`

Default value: `false`

The HTTP Strict Transport Security (HSTS) header forces browsers to use HTTPS on the domain where it is enabled.

`gateway.http.hsts_options`

Default value: `"max-age=31536000"`

By default, HSTS policy is set for one year (31536000 seconds). This time period specifies the amount of time in which the browser will access the server over HTTPS.

`gateway.httpd.loglevel`

**Version:** Added in 2021.3.0.

Default value: `notice`

Specifies the logging level for the Gateway (Apache HTTPD server). By default this is set to `notice`. Other options include `debug`, `info`, `warning`, `error`. If you change the logging level, be aware of potential impact to disk space usage and performance. As a best practice, return the logging level to the default after you have gathered the information you need. For detailed information on Apache logging, see the [Apache HTTP documentation](#).

`gateway.httpd.shmcb.size`

**Version:** Added in 2021.4

Default value: `2048000`

Specifies the amount of memory in bytes for the circular buffer when using the `shmcb` storage type. This configuration key doesn't apply when using the `dbm` storage type.

`gateway.httpd.socache`

**Version:** Added in 2021.4

Default value: `shmcb`

Specifies the storage type of the global/inter-process SSL Session Cache. By default, this is set to `shmcb`, with another configurable option `dbm`. For more information about `shmcb` and `dbm` storage types, see [SSLSessionCache Directive](#) on the Apache website.

`gateway.http.request_size_limit`

Default value: `16380`

The maximum size (bytes) of header content that is allowed to pass through the Apache gateway on HTTP requests. Headers that exceed the value set on this option will result in browser errors, such as HTTP Error 413 (Request Entity Too Large) or authentication failures.

A low value for `gateway.http.request_size_limit` can result in authentication errors. Single sign-on solutions that integrate with Active Directory (SAML and Kerberos) often

require large authentication tokens in HTTP headers. Be sure to test HTTP authentication scenarios before deploying into production.

We recommend setting `tomcat.http.maxrequestsize` option to the same value that you set for this option.

`gateway.http.x_content_type_nosniff`

Default value: `true`

The X-Content-Type-Options response HTTP header specifies that the MIME type in the Content-Type header should not be changed by the browser. In some cases, where MIME type is not specified, a browser may attempt to determine the MIME type by evaluating the characteristics of the payload. The browser will then display the content accordingly. This process is referred to as "sniffing." Misinterpreting the MIME type can lead to security vulnerabilities. The X-Content-Type-Options HTTP header is set to 'nosniff' by default with this option.

`gateway.http.x_xss_protection`

Default value: `true`

The HTTP X-XSS-Protection response header is sent to the browser to enable cross-site scripting (XSS) protection. The X-XSS-Protection response header overrides configurations in cases where users have disabled XSS protection in the browser. The X-XSS-Protection response header is enabled by default with this option.

`gateway.log.level`

**Version:** Added in version 2020.3.0.

Default value: `info`

The logging level for Gateway. This is dynamically configurable, so if you are only changing this you do not have to restart Tableau Server. For more information, see [Change Logging Levels](#).

## Tableau Server on Linux Administrator Guide

`gateway.public.host`

Default value: `<hostname>`

The name (URL) of the server, used for external access to Tableau Server. If Tableau Server is configured to work with a proxy server or external load balancer, it is the name entered in a browser address bar to reach Tableau Server. For example, if Tableau Server is reached by entering `tableau.example.com`, the name for `gateway.public.host` is `tableau-example.com`.

`gateway.public.port`

Default value: `80` (`443` if SSL)

Applies to proxy server environments only. The external port the proxy server listens on.

`gateway.slow_post_protection.enabled`

Default value: `true`

When enabled, this can provide some help in protecting against slow POST (Denial-of-Service) attacks by timing out POST requests that transfer data at extremely slow rates.

**Note:** This will not eliminate the threat of such attacks, and could have the unintended impact of terminating slow connections.

`gateway.slow_post_protection.request_read_timeout`

Default value: `header=10-30,MinRate=500 body=30,MinRate=500`

When enabled by the preceding option, `gateway.slow_post_protection.enabled`, this option sets the Apache `httpd` `ReadRequestTimeout`. The `httpd` directive is documented at [Apache Module `mod\_reqtimeout`](#). The primary use of this option is as a defense the Slowloris attack. See the Wikipedia entry, [Slowloris \(computer security\)](#).

**Note:** Older versions use a default value: `header=15-20,MinRate=500 body-y=10,MinRate=500`

`gateway.timeout`

Default value: 7200

Longest amount of time, in seconds, that the gateway will wait for certain events before failing a request (7200 seconds = 2 hours).

`gateway.trusted`

Default value: IP address of proxy server machine

Applies to proxy server environments only. The IP address(es) or host name(s) of the proxy server.

`gateway.trusted_hosts`

Default value: Alternate names of proxy server

Applies to proxy server environments only. Any alternate host name(s) for the proxy server.

`hyper.file_partition_size_limit`

Default value: 0

When set to 0, the size is set to unlimited and will use all the disk space that is available.

This option is used to set the disk space limit for a query that spools to disk. If your disk space usage by the `spool.<id>.tmp` file is higher than where you need it to be for your environment, it means that queries are spooling and taking up disk space. Use this option to limit the amount of disk space that any one query can use. The `spool.<id>.tmp` file can be found in the temp folder of the user account running Tableau Server. You can specify this value in K(KB), M (MB), G(GB), or T(TB) units. For example, you can specify the size limit as 100G when you want to limit the disk space usage to 100 GB.

## Tableau Server on Linux Administrator Guide

For more information about spooling see the Memory and CPU Usage section in Tableau Server Data Engine.

`hyper.global_file_partition_size_limit`

Default value: 0

When set to 0, the size is set to unlimited and will use all the disk space that is available.

This option is used to set the disk space limit for all queries that spool to disk. If your disk space usage by the `pool.<id>.tmp` file is higher than where you need it to be for your environment, it means that queries are spooling and taking up disk space. The `pool.<id>.tmp` file can be found in the temp folder of the user account running Tableau Server. Use this option to limit the amount of disk space in sum total that all queries use when spooling to disk. You can specify this value in K(KB), M(MB), G(GB), or T(TB) units. For example, you can specify the size limit as 100G when you want to limit the disk space usage to 100 GB. Tableau recommends that you start with this configuration when fine tuning your spooling limits.

For more information about spooling see the Memory and CPU Usage section in Tableau Server Data Engine.

`hyper.enable_accesspaths_symbolic_canonicalization`

Default value: `false`

On Windows OS systems, in order to resolve symlinks, Hyper needs to have access to the directory where extracts are stored and all its parent directories. If this is not the case, you may see an error message in the Hyper log that says: **Unable to obtain canonical path for** `//dirA/subdir/myextract.hyper ... Access is denied.`

In such cases, you can set this to `true` so Data Engine (Hyper) will not try to resolve symlinks when using canonical paths.

**Note:** Setting the value to `true` also implies that Hyper can no longer guarantee to guard against a potential attacker who manages to place a symlink to escape the allowed set of directories which Hyper is configured to allow access to.

`hyper.log_queries`

Default value: `true`

When set to `true`, query information is logged.

By default query information is logged. If however you find that the log files are too large for the amount of disk space available, you can set it to `false` to disable logging query information. Tableau recommends leaving this configuration set to `true`.

`hyper.log_query_cpu`

Default value: `false`

Use this setting to log how much time each query takes and the CPU usage.

`hyper.log_timing`

Default value: `false`

This setting is useful to find out more information about the queries, like compilation and parsing times. By default this setting is disabled. You can turn this by setting the value to `true` to collect more details about your queries. Note, however that this will increase the size of your data engine log files (`\logs\hyper`).

`hyper.log_troublesome_query_plans`

Default value: `true`

When set to `true`, logs query plans of query that are identified as problematic. Queries that are either canceled, running slower than 10 seconds, or if the queries are spooling to disk fall

into this category. The information in the logs can be useful to troubleshoot problematic queries. You can change the setting to `false` if you are concerned about the size of the logs.

`hyper.memory_limit`

Default value: 80%

Controls the maximum amount of memory used by Hyper. Specify the number of bytes. Append the letter 'k' to the value to indicate kilobytes, 'm' to indicate megabytes, 'g' to indicate gigabytes, or 't' to indicate terabytes. For example, `hyper.memory_limit="7g"`. Alternatively, specify the memory limit as a percentage of the overall available system memory. For example, `hyper.memory_limit="90%"`.

`hyper.memtracker_hard_reclaim_threshold`

Default value: 80%

This setting only applies to Windows. Hyper keeps decompressed and decrypted parts of the extract in memory to make subsequent accesses faster. This setting controls when worker threads will start writing this data out to a disk cache to reduce memory pressure. If given as a percentage, the value is interpreted as a percentage of the overall `hyper.memory_limit` setting. For example, `hyper.memtracker_hard_reclaim_threshold="60%"`. Absolute values can be specified as 'k' (kilobytes), 'm' (megabytes), 'g' (gigabytes), or 't' (terabytes). For example, `hyper.memtracker_hard_reclaim_threshold="10g"`. The value should be larger than the `hyper.memtracker_soft_reclaim_threshold`.

`hyper.memtracker_soft_reclaim_threshold`

Default value: 50%

This setting only applies to Windows. When interacting with a Hyper file, Hyper will write out some data for caching or persisting the data. Windows has the special behavior that it locks freshly written data into memory. To avoid swapping, we force out the data when Hyper reaches the configured limit for the reclaim threshold. When the soft reclaim threshold is reached, Hyper will try to reclaim cached data in the background to attempt to stay below the reclaim threshold. In situations where swapping would happen otherwise, triggering

reclamation in Hyper can lead to a better outcome. Therefore, if your Tableau Server installation experiences a lot of swapping, this setting can be used to attempt to reduce the memory pressure.

Specify the number of bytes. Append the letter 'k' to the value to indicate kilobytes, 'm' to indicate megabytes, 'g' to indicate gigabytes, or 't' to indicate terabytes. Alternatively, specify the value as a percentage of the overall configured memory for Hyper. For example, `hyper-.memtracker_soft_reclaim_threshold="20%"`.

#### `hyper.network_threads`

Default value: 150%

Controls the number of network threads used by Hyper. Specify either the number of network threads (for example, `hyper.network_threads=4`) or specify the percentage of threads in relation to the logical core count (for example, `hyper.network_threads="300%"`).

Network threads are used for accepting new connections and sending or receiving data and queries. Hyper uses asynchronous networking, so many connections can be served by a single thread. Normally, the amount of work that is done on network threads is very low. The one exception is opening databases on slow file systems, which can take a long time and block the network thread. If connection times are slow when you try to view or edit dashboards that use extracts and have not been used in a while and you frequently see “asio-continuation-slow” messages in the Hyper log and long “construct-protocol” times to Hyper in the Tableau log, try to increase this value.

#### `hyper.objectstore_validate_checksums`

Default value: `false`

A boolean setting that controls file integrity checks in Hyper. When set to `true`, Hyper will check the data in an extract file when it is first accessed. This allows silent corruption and corruption that would crash Hyper to be detected. In general, it is advisable to turn this setting on except for installations with very slow disks where it could cause performance regressions.

## Tableau Server on Linux Administrator Guide

`hyper.query_total_time_limit`

Default value: 0 (which means unlimited)

Sets an upper bound on the total thread time that can be used by individual queries in Hyper. Append 's' to the value to indicate seconds, 'min' to indicate minutes, or 'h' to indicate hours.

For example to restrict all queries to a total time usage of 1500 seconds of total thread time, run the following command:

```
tsm configuration set -k hyper.query_total_time_limit -v 1500s
```

If a query runs longer than the specified limit, the query will fail and an error will be returned. This setting allows you to automatically control runaway queries that would otherwise use too many resources.

Hyper executes queries in parallel. For example, if a query executes for 100 seconds and during this time is running on 30 threads, the total thread time would be 3000 seconds. The thread time of each query is reported in the Hyper log in the “query-end” log entries in the “total-time” field.

`hyper.session_memory_limit`

Default value: 0 (which means unlimited)

Controls the maximum memory consumption that an individual query can have. Specify the number of bytes. Append the letter 'k' to the value to indicate kilobytes, 'm' to indicate megabytes, 'g' to indicate gigabytes, or 't' to indicate terabytes.

For example, to set the memory limit to 900 megabytes, run the following command:

```
tsm configuration set -k hyper.session_memory_limit -v 900m.
```

Alternatively, to specify the session memory limit as a percentage of the overall available system memory run the following command:

```
tsm configuration set -k hyper.session_memory_limit -v 90%.
```

Lowering this value can help when a query is using excessive amounts of memory and making other queries fail over a long period of time. By lowering the limit, the single big query would fail (or resort to spooling if spooling isn't turned off) and not have a negative impact on other queries.

`hyper.srm_cpu_limit_percentage`

Default value (in percent): 75

Specifies the maximum hourly average CPU usage permitted by Hyper. If exceeded, Data Engine will restart itself to minimize impact to other processes on the computer.

By default Data Engine will restart itself if it averages more than 75% usage of CPU over an hour. This value should not be changed except when working with Tableau Support, or if you are running Data Engine on a dedicated server node. If Data Engine is running on a dedicated node, you can safely increase this value to 95 percent to take full advantage of available computer hardware. For details on running Data Engine on a dedicated node, see [Optimize for Extract Query-Heavy Environments](#).

To increase this to 95%:

```
tsm configuration set -k hyper.srm_cpu_limit_percentage -v 95 --
force-keys
```

```
tsm pending-changes apply
```

To reset this to the default of 75%:

```
tsm configuration set -k hyper.srm_cpu_limit_percentage -v 75 --
force-keys
```

```
tsm pending-changes apply
```

`hyper_standalone.consistent_hashing.enabled`

Default value: `true`

## Tableau Server on Linux Administrator Guide

Improves the chance that the extract for a query is already cached. If the node with the extract cached cannot support additional load, you will be routed to a new node and the extract will be loaded into cache on the new node. This results in better system utilization because extracts are only loaded into memory if there is load that justifies the need.

`hyper_standalone.health.enabled`

Default value: `true`

Switches the load balancing metric from random selection to picking the Data Engine (Hyper) node based on a health score that is made of up of a combination of current Hyper activity and system resource usage. Based on these values, the load balancer will pick the node that is most capable of handling an extract query.

`hyper.temp_disk_space_limit`

Default value: `100%`

Sets the upper limit of disk space at which Hyper will stop allocating space for temporary files. This setting can help to stop the hard disk from filling up with temporary files from Hyper and running out of disk space. If disk space reaches this threshold, Hyper will attempt to recover automatically without administrator intervention.

Specify it as percentage of the overall available disk space to be used. For example, `hyper.temp_disk_space_limit="96%"`. When set to 100%, all of the disk space that is available can be used.

For Data Engine to start, the configured amount of disk space must be available. If not enough disk space is available, you will see a Data Engine log entry that says, "Disk limit for temporary files has been reached. Please free up disk space on the device. See the Hyper log for more information: No space left on device".

`hyper.hard_concurrent_query_thread_limit`

Default value: `150%`

Use this option to set the maximum number of threads Hyper should use for running queries. Use this when you want to set a hard limit on the CPU usage. Specify either the number of threads or specify the percentage of threads in relation to the logical core count. Hyper will most likely not use more resources than are configured by this setting but Hyper background and network threads are not affected by this setting (though they tend to not be CPU intensive).

It is important to consider that this setting controls the number of concurrent queries that can be executed. So, if you decrease this setting, the chance of queries needing to wait for currently running queries to complete increases, which may affect workbook load times.

`hyper.soft_concurrent_query_thread_limit`

Default value: 100%

Use this option to specify the number of threads that a single query can be parallelized across if sufficiently many threads are available given the `hard_concurrent_query_thread_limit` setting. Specify either the number of threads or specify the percentage of threads in relation to the logical core count.

To illustrate this, here is a simplified example:

Let's say you set this value to 10 threads, this means queries can be parallelized up to 10 threads. If only 2 queries are running, the remaining 8 threads are used to parallelize the 2 queries.

The `hyper.hard_concurrent_query_thread_limit`, and `hyper.soft_concurrent_query_thread_limit` options work together to give you some options to manage your CPU usage while maximizing available CPU resources to complete queries faster. If you don't want the Data Engine to use all the available CPU on the machine, change it to less than 100% to a percentage that is optimal for your environment. The soft limit is a way for you to limit CPU usage but allow it to go beyond the soft limit up to the hard limit if necessary.

**Note:** The *hyper.hard\_concurrent\_query\_thread\_limit* and *hyper.soft\_concurrent\_query\_thread\_limit* options replace *hyper.num\_job\_worker\_threads* and *hyper.num\_task\_worker\_threads* options available in Tableau Server versions 2018.3 and earlier, and are retired and no longer available. For information on the *hyper.num\_job\_worker\_threads* and *hyper.num\_task\_worker\_threads*, see [tsm configuration set Options](#).

`hyper.use_spooling_fallback`

Default value: `true`

When set to `true`, it allows spooling to disk when querying extracts exceeds set RAM usage (80% of installed RAM). In other words, it allows Hyper to execute a query using the disk if it exceeds RAM usage.

Tableau recommends that you use the default setting. You can turn this off by setting the value to `false` if you are concerned about disk usage. If you turn this setting off, queries that use more than 80% of installed RAM will be canceled. Spooling queries usually take substantially longer to finish.

For more information about spooling see the Memory and CPU Usage section in Tableau Server Data Engine.

`indexandsearchserver.vmopts`

**Version:** Added in version: 2022.1.

Default value: `"-Xmx<default_value> -Xms<default_value>"`

The default value is based on the amount of system memory and is 3.125% of the total system RAM.

Controls the Index and Search Server heap size. Because the default value scales automatically, use this option to override the default value only when absolutely necessary. Append the letter 'k' to the value to indicate kilobytes, 'm' for megabytes, or 'g' to indicate

gigabytes. As a general rule, set initial heap size (`-Xms`) equal to the maximum heap size (`-Xmx`) to minimize garbage collections.

`jmx.security.enabled`

**Version:** Added in version: 2022.1.

Default value: `false`

JMX is disabled by default, so secure JMX is also disabled. If you are enabling JMX we strongly recommend you enable secure JMX.

This is set to `true` and turns secure JMX on with SSL and basic username/password authentication for readonly access when you run the `tsm maintenance jmx enable` command and answer `y` when prompted to enable security features for JMX:

```
tsm maintenance jmx enable
```

```
We do not recommend you enable JMX unsecured on a production environment. Would you like to enable security features for JMX?
```

```
(y/n): y
```

`jmx.ssl.enabled`

**Version:** Added in version: 2022.1.

Default value: `true`

Enforces SSL for JMX. This option defaults to `true` but has no effect unless `jmx.security.enabled` is also set to `true`. To enable JMX security, run the `tsm maintenance jmx enable` command. Answer `y` when prompted to leave SSL enabled, or `n` to disable SSL:

```
tsm maintenance jmx enable
```

```
...
```

```
Would you like to enable SSL?
```

```
(y/n): n
```

## Tableau Server on Linux Administrator Guide

`jmx.ssl.require_client_auth`

**Version:** Added in version: 2022.1.

**Default value:** `false`

This is set to `true` when you run the `tsm maintenance jmx enable` command and answer `y` when prompted to require client authentication (mTLS):

```
tsm maintenance jmx enable
...
Would you like to require client authentication (mTLS)?
(y/n) : y
```

To complete configuration you must have a client cert and place this in the correct location on your client computer.

`jmx.ssl.user.name`

**Version:** Added in version: 2022.1.

**Default value:** `tsmjmxuser`

This is set when you install or upgrade Tableau Server.

`jmx.ssl.user.password`

**Version:** Added in version: 2022.1.

**Default value:** `<generated>`

This is set when you install or upgrade Tableau Server.

`jmx.user.access`

**Version:** Added in version: 2022.1.

**Default value:** `readonly`

You can change this to `readwrite` when you run the `tsm maintenance jmx enable` command and answer `y` when prompted to add `readwrite` access:

```
tsm maintenance jmx enable
...
JMX access is readonly by default. Would you like to add readwrite
access?
(y/n): y
```

`licensing.login_based_license_management.default_requested_duration_seconds`

Default value: 0

Set to the duration (in seconds) that a user's login-based license can be offline with no connection to Tableau Server before they are prompted to activate again. This duration is always refreshed when Tableau Desktop is in use and can connect to Tableau Server.

`licensing.login_based_license_management.enabled`

Default value: `true`

Set to `true` to enable login-based license management. Set to `false` to disable login-based license management.

**Note:** In order to use login-based license management, you must activate a product key that is enabled for login-based license management. You can use the `tsm licenses list` to see which product keys have login-based license management enabled.

`licensing.login_based_license_management.max_requested_duration_seconds`

Default value: 7776000

Set to the maximum duration (in seconds) that a user's login-based license can be offline with no connection to Tableau Server before they are prompted to activate Tableau again. The maximum value is 7776000 seconds (90 days). This duration is always refreshed when Tableau Desktop is in use and can connect to Tableau Server.

## Tableau Server on Linux Administrator Guide

`maestro.app_settings.sampling_max_row_limit`

Default value: 1000000

Sets the maximum number of rows for sampling data from large data sets with Tableau Prep on the web.

`maestro.input.allowed_paths`

Default value: ""

By default, access to any directory will be denied, and only publishing to Tableau Server with content that is included in the `tflx` file is allowed.

A list of allowed network directories for flow input connections. You must enable Tableau Prep Conductor to schedule flows on your Tableau Server. For more information, see Tableau Prep Conductor.

The following rules apply and must be considered when configuring this setting:

- Paths should be accessible by Tableau Server. These paths are verified during server startup and at flow run time.
- Network directory paths have to be absolute and cannot contain wildcards or other path traversing symbols. For example `\\myhost\myShare\*` or `\\myhost\myShare*` are invalid paths and would result in all the paths as disallowed. The correct way to safely list any folder under *myShare* would be `\\myhost\myShare` or `\\my-host\myShare\`.

**Note:** The `\\myhost\myShare` configuration will not allow `\\my-host\myShare1`. In order to safely list both of these folders one would have to safely list them as `\\myhost\myShare; \\myhost\myShare1`.

- The value can be either `*` meaning that any path, including local (with the exception of some system paths configured using “`native_api.internal_disallowed_paths`”), or a list of

paths, delimited by “;”.

**Note:** If a path is both on the flows allowed list and `internal_disallowed` list, `internal_disallowed` takes precedence.

**Important:**

This command overwrites existing information and replaces it with the new information you provided. If you want to add a new location to an existing list, you must provide a list of all the locations, existing and the new one you want to add. Use the following commands to see the current list of input and output locations:

```
tsm configuration get -k maestro.input.allowed_paths
tsm configuration get -k maestro.output.allowed_paths
```

For more information and details about configuring allowed directories for flow input and output connections, see [Step 4: Safe list Input and Output locations](#).

`maestro.output.allowed_paths`

Default value: ""

By default, access to any directories will be denied.

A list of allowed network directories for flow output connections. You must enable Tableau Prep Conductor to schedule flows on your Tableau Server. For more information, see [Tableau Prep Conductor](#).

The following rules apply and must be considered when configuring this setting:

- Paths should be accessible by Tableau Server. These paths are verified during server startup and at flow run time.
- Network directory paths have to be absolute and cannot contain wildcards or other path traversing symbols. For example `\\myhost\myShare\*` or

`\\myhost\myShare*` are invalid paths and would result in all the paths as disallowed. The correct way to safelist any folder under *myShare* would be `\\myhost\myShare` or `\\myhost\myShare\`.

**Note:** The `\\myhost\myShare` configuration will not allow `\\myhost\myShare1`. In order to safe list both of these folders one would have safe list them as `\\myhost\myShare; \\myhost\myShare1`.

- The value can be either `*` meaning that any path, including local (with the exception of some system paths configured using “`native_api.internal_disallowed_paths`”), or a list of paths, delimited by “;”.

**Note:** If a path is both on the flows allowed list and `internal_disallowed` list, `internal_disallowed` takes precedence.

For more information and details about configuring allowed directories for flow input and output connections, see Step 4: Safe list Input and Output locations.

`maestro.output.write_to_mssql_using_runas`

**Version:** Added in version: 2022.3.1

**Default value:** `false`

When enabled, flow outputs published to Tableau Server are allowed write access to a Microsoft SQL Server database using Run As credentials. The credentials used by the Run As service account must have write permission to the database. Evaluate your security and deployment requirements before enabling the `maestro.output.write_to_mssql_using_runas` setting. For more information, see [Run As Service Account](#).

**Note:** This command requires the `--force-keys` option. For example: `tsm configuration set -k maestro.output.write_to_mssql_using_runas -v true --force-keys`.

`maestro.sessionmanagement.maxConcurrentSessionPerUser`

Default value: 4

Sets the maximum number of flow web editing sessions that a user can have open at one time.

`metadata.ingestor.blocklist`

Default value: null

When configured, Tableau Catalog blocks specified content from being ingested. To specify which content to block, you must identify the blocklist values, which is a combination of both the site ID, content type, and content ID of the content you want to block, from the server “non-interactive” log files. Blocklist values must be separated by a comma.

**Important:** You should only use this option when directed to do so by Tableau Support.

For example, you can use the `tsm configuration set --force-keys -k metadata.ingestor.blocklist` to block ingestion of a combination of data sources, workbooks, and flows using the following command:

```
tsm configuration set --force-keys -k metadata.ingestor.blocklist -v "sites/1/datasources/289, sites/2/datasources/111, sites/1/-workbooks/32, sites/3/workbooks/15, sites/1/flows/13, sites/1/-flows/18"
```

To validate blocked content, review the server “noninteractive” log files for the following events:

## Tableau Server on Linux Administrator Guide

- Skipping ingestion for
- Successfully updated blocklist to

For example:

```
Skipping ingestion for contentType [Workbook], contentId [sites/1/datasources/289], siteDisabled [false], swallowEvent [false], contentBlocked [true]
```

```
Skipping ingestion for contentType [Workbook], contentId [sites/3/workbooks/15], siteDisabled [false], swallowEvent [false], contentBlocked [true]
```

and

```
Successfully updated blocklist to: [sites/1/datasources/289, sites/1/workbooks/32, sites/2/datasources/111]
```

**metadata.ingestor.pipeline.throttleEventsEnable**

Default value: `false`

Controls whether indexing of new and updated content, also called eventing, is regulated across all sites on the server. By default, event throttling is turned off. To turn on event throttling, change this setting to `true` using the following command:

```
tsm configuration set -k metadata.ingestor.pipeline.throttleEventsEnable -v true --force-keys
```

For more information about event throttling, see [Enable Tableau Catalog](#).

**metadata.ingestor.pipeline.throttleLimit**

Default value: `20`

When event throttling is enabled, this is the maximum number of new and updated content items that can be indexed during a specified period of time. Once the specified limit is reached for a specific item, indexing is deferred.

By default, the limit is set to 20 and can't be set to lower than 2. You can use the following command to change the limit:

```
tsm configuration set -k metadata.ingestor.pipeline.throttleLimit -
v 25 --force-keys
```

Throttled events can be identified in the server "noninteractive" log files as `ingestor event flagged for removal by throttle filter`.

`metadata.ingestor.pipeline.throttlePeriodLength`

Default value: 20

When event throttling is enabled, this is the period of time, in minutes, a specified maximum number of new and updated content items can be indexed. Once the specified time is reached, indexing of any additional new and updated content is deferred.

By default, the time is set to 30 minutes. You can use the following command to change the time:

```
tsm configuration set -k metadata.in-
gestor.pipeline.throttlePeriodLength -v PT45M --force-keys
```

`metadata.query.limits.time`

Default value: 20

This is the longest allowable time, in seconds, for a Catalog or Metadata API query to run before a timeout occurs and the query is canceled. Tableau recommends incrementally increasing the timeout limit to *no more than* 60 seconds using the following command:

```
tsm configuration set -k metadata.query.limits.time -v PT30S --
force-keys
```

**Important:** This option should be changed only if you see the error described here, Timeout limit and node limit exceeded messages. Increasing the timeout limit can utilize more CPU for longer, which can impact the performance of tasks across Tableau Server. Increasing the

timeout limit can also cause higher memory usage, which can cause issues with the interactive microservices container when queries run in parallel.

`metadata.query.limits.count`

Default value: 20000

This is the number of objects (which can loosely map to the number of query results) that Catalog can return before the node limit is exceeded and the query is canceled. Tableau recommends incrementally increasing the timeout limit, to *no more than* 100,000 using the following command:

```
tsm configuration set -k metadata.query.limits.count -v 3000 --force-keys
```

**Important:** This option should be changed only if you see the error described here, Timeout limit and node limit exceeded messages. Increasing the node limit can cause higher memory usage, which can cause issues with the interactive microservices container when queries run in parallel.

`metadata.query.throttling.enabled`

Version: Added in version 2023.3

Default value: `true`

Controls whether **Metadata API** query throttling is enabled. Metadata API query throttling is a feature designed to prevent a server's API responses from negatively impacting overall performance. When set to `true` (the default), if a request to the Metadata API exceeds the defined threshold, a `RATE_EXCEEDED` error is returned.

If Metadata API users are seeing frequent `RATE_EXCEEDED` errors, an administrator can try to adjust throttling using the `metadata.query.throttling.tokenRefilledPerSecond` and `metadata.query.throttling.queryCostCapacity` settings. Alternatively, the administrator can disable throttling entirely by setting `metadata.query.throttling.enabled`

value to `false`. Doing so would prevent the performance-protecting benefits of the feature however.

`metadata.query.throttling.queryCostCapacity`

Version: Added in version 2023.3

Default value: 20000000

A number representing the capacity that the **Metadata API** has for answering queries. Each request to the Metadata API has a calculated cost that is subtracted from this number when it's executed. (Using a token bucket model, this is the maximum amount of tokens that can be in the bucket.)

If Metadata API users are seeing frequent `RATE_EXCEEDED` errors, an administrator can adjust throttling settings. They should adjust `metadata.query.throttling.tokenRefilledPerSecond` and test the results before trying to adjust `metadata.query.throttling.queryCostCapacity`. Alternatively, the administrator can disable throttling entirely by setting `metadata.query.throttling.enabled` to `false`. Doing so would prevent the performance-protecting benefits of the feature however.

`metadata.query.throttling.tokenRefilledPerSecond`

Version: Added in version 2023.3

Default value: 5555

A number representing the amount of **Metadata API** query capacity that's regenerated every second. (Using a token bucket model, this is the number of tokens that are put into the bucket every second.)

If Metadata API users are seeing frequent `RATE_EXCEEDED` errors, an administrator can adjust throttling settings. They should adjust `metadata.query.throttling.tokenRefilledPerSecond` and test the results before trying to adjust `metadata.query.throttling.queryCostCapacity`. Alternatively, the administrator

can disable throttling entirely by setting `metadata.query.throttling.enabled` to `false`. Doing so would prevent the performance-protecting benefits of the feature however.

`metricservices.checkIntervalInMinutes`

**Version:** Retired in version 2024.2.

Default value: 60

Controls the interval, in minutes, between refreshes for metrics that rely on live data sources. A metric refreshes when the server checks for new data via the metric's connected view.

`metricservices.enabled`

**Version:** Added in version: 2022.3. Retired in version 2024.2.

Default value: `true`

When set to `false`, the metrics content type is disabled for all sites on a server. For more information, see [Disable metrics for a server](#).

### Retirement of the legacy metrics feature

Tableau's legacy metrics feature was retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. In October 2023, Tableau retired the ability to embed legacy metrics in Tableau Cloud and in Tableau Server version 2023.3. With Tableau Pulse, we've developed an improved experience to track metrics and ask questions of your data. For more information, see [Create Metrics with Tableau Pulse](#) to learn about the new experience and [Create and Troubleshoot Metrics \(Retired\)](#) for the retired feature.

`metricservices.failureCountToWarnUser`

**Version:** Retired in version 2024.2.

Default value: 10

Controls the number of consecutive refresh failures that must occur before the metric owner is warned. When set to the default of 10, a metric refresh must fail 10 times in a row before the owner is sent a notification about the failure.

`metricservices.maxFailedRefreshAttempts`

**Version:** Retired in version 2024.2.

Default value: 175

Controls the number of consecutive refresh failures that must occur before a metric refresh is suspended.

`mobile.deep_linking.on_prem.enabled`

Default value: `true`

Controls whether links to Tableau Server are treated as deep links by the Tableau Mobile app. When set to `true`, links to supported content types open in the app. When set to `false`, links open in the mobile browser. For more information see, [Control deep linking for Tableau Mobile](#).

`monitoring.dataengine.connection_timeout`

Default value: 30000

The length of time, in milliseconds, that Cluster Controller will wait for the data engine, before determining that a connection timeout occurred. The default is 30,000 milliseconds (30 seconds).

`native_api.allowed_paths`

Default value: ""

**Note:** In Tableau Server releases (including maintenance releases) before October 2023, this setting was configured to allowed access to all paths by default.

## Tableau Server on Linux Administrator Guide

Use this setting to specify an allowlist for access to files stored on Tableau or on remote shares. This scenario allows authorized Tableau Server users to build workbooks that use files on the server as file-based data sources (such as spreadsheets).

This setting allows you to limit access only to those directories that you specify. The `tableau` system account access is therefore limited to the directory paths where you host data files.

`tsm configuration set -k native_api.allowed_paths -v "path"`, where *path* is the directory to add to the allowlist. All subdirectories of the specified path will be added to the allowlist. If you want to specify multiple paths, separate them with a semicolon, as in this example:

```
tsm configuration set -k native_api.allowed_paths -v "/data-sources;/HR/data"
```

**Important:** Make sure the file paths you specify in this setting exist and are accessible by the system account.

`native_api.connection.limit.<connection class>`

Set parallel query limit for the specified data source (connection class). This overrides the global limit for the data source.

`native_api.connection.globallimit`

Default value: 16

Global limit for parallel queries. Default is 16 except for Amazon Redshift which has a default of 8.

`native_api.ExplainDataEnabled`

Default value: `true`

This option controls whether Explain Data is enabled or disabled for the server. For more information about Explain Data, see [Get Started with Explain Data](#) in the Tableau Help.

This option was added beginning with Tableau Server version: 2019.3.

`native_api.force_alternative_federation_engine`

Default value: `false`

Override the operation restrictions when joining data from a single file connection and a single SQL database connection. Set this option to `True` to force Tableau to process the join using the live database connection.

`native_api.ProtocolTransitionLegacyFormat`

Default value: `false`

Use the legacy name format for constrained delegation.

The name format was changed in version 10.1 to allow cross-domain protocol transition (S4U). If this causes problems with existing configurations and you don't need cross-domain protocol transition, configure Tableau Server to use the old behavior by setting this to `true`.

`native_api.unc_mountpoints`

Default value: `none`

Specifies UNC and FQDN path for shared Windows directories that are accessed by Tableau Server on Linux. Each path must also be referenced in a corresponding `auto.cifs` file. Separate each path by a semicolon, for example:

```
'//files-  
rv01/devel-  
opment;/m-  
nt/-  
files-
```

## Tableau Server on Linux Administrator Guide

```
rv01/development-  
opment; //-  
filesrv01.example.lan/development; /mnt/filesrv01/development '
```

Subsequent updates to the `native_api.unc_mountpoints` value will overwrite the existing value. Therefore, each time you add a Windows share, you must include all shares in the updated value.

For more information, see the Community wiki topic, [Connecting to a Windows Shared Directory](#).

`native_api.InitializeQueryCacheSizeBasedOnWeights`

Default value: `True`

Controls whether the query cache size is initialized automatically based on the amount of available system memory. The query cache consists of the logical query cache, metadata cache, and native query cache. By default, this functionality is enabled.

`native_api.QueryCacheMaxAllowedMB`

The maximum size of the query cache in megabytes. This value varies based on the amount of system memory. The query cache consists of the logical query cache, metadata cache, and native query cache. Use the table below to determine your default value:

| System Memory       | Default Value for Tableau Server | Default Value for Tableau Desktop |
|---------------------|----------------------------------|-----------------------------------|
| 64 GB and more      | 3200 MB                          | 1600 MB                           |
| From 32 GB to 64 GB | 2400 MB                          | 1200 MB                           |
| From 16 GB to 32 GB | 1600 MB                          | 800 MB                            |
| 16 GB and less      | 800 MB                           | 400 MB                            |

`native_api.LogicalQueryCacheMaxAllowedWeight`

Default value: 70

The weight of logical query cache size limit in the total query cache size.

`native_api.MetadataQueryCachMaxAllowedWeight`

Default value: 4

The weight of metadata query cache size limit in the total query cache size.

`native_api.NativeQueryCacheMaxAllowedWeight`

Default value: 26

The weight of native query cache size limit in the total query cache size.

`native_api.QueryCacheEntryMaxAllowedInPercent`

Default value: 60

Specifies the maximum size of query results that can be put into the query cache. It is set as the percentage of the total query cache size. For example, if the logical query cache size is 100 MB and `native_api.QueryCacheEntryMaxAllowedInPercent` is set to 60 percent, then only query results that are smaller than 60 MB can be put into the logical query cache.

`native_api.UserInfoInGeneratedSQLEnabled`

Default value: `false`

Determines if **query tagging** is enabled for all content on a Tableau Server. When true, queries sent from Tableau to customer SQL databases will include metadata about the source of the query. The resulting content in customer database logs can be used for troubleshooting performance or other issues.

`nlp.concepts_shards_count`

Default value: 1

**Note:** The default shard count value is sufficient for most Tableau Server installations.

Controls the number of data shards for the Concepts index of Ask Data, field names, field synonyms, and analytical terms stored in shards in:

- The Index and Search Server for 2022.1 and later versions.
- Elastic Server for 2019.1 - 2021.4

The shard count partitions the search index to reduce total index size, which may improve the performance of Ask Data's semantic parser. Adjusting the shard count is another performance enhancement measure that you can take along with increasing the heap size through `elasticsearchserver.vmopts` or `indexandsearchserver.vmopts`, depending on the version of Tableau Server that you are running.

Tableau recommends increasing the shard count by 1 for every 50 GB. To reduce the number of times you need to adjust the shard count, calculate the total index size by adding 50% to the current index. For example, if the total index size is less than 50 GB, then 1 shard is sufficient. Actual performance will vary depending on the server, the rate at which the index size grows, and other factors.

- 0 to 50 GB: 1
- 50 GB to 100 GB: 2
- 100 GB to 150 GB: 3

You can use the following command to increase the Concepts index shard count from default to 2:

```
tsm configuration set -k nlp.concepts_shards_count -v 2  
nlp.values_shards_count
```

Default value: 1

Controls the number of data shards for the Concepts index of Ask Data, field names, field synonyms, and analytical terms stored in shards in:

- The Index and Search Server for 2022.1 and later versions.
- Elastic Server for 2019.1 - 2021.4

The shard count partitions the search index to reduce total index size, which may improve the performance of Ask Data's semantic parser. Adjusting the shard count is another performance enhancement measure that you can take along with increasing the heap size through `elasticserver.vmopts` or `indexandsearchserver.vmopts`, depending on the version of Tableau Server that you are running.

Tableau recommends increasing the shard count by 1 for every 50 GB. To reduce the number of times you need to adjust the shard count, calculate the total index size by adding 50% to the current index. For example, if the total index size is less than 50 GB, then 1 shard is sufficient. Actual performance will vary depending on the server, the rate at which the index size grows, and other factors.

- 0 to 50 GB: 1
- 50 GB to 100 GB: 2
- 100 GB to 150 GB: 3

You can use the following command to increase the Values index shard count from default to 2:

```
tsm configuration set -k nlp.values_shards_count -v 2
```

`nlp.defaultNewSiteAskDataMode`

Default value: `disabled_by_default`

Use this option to set the initial value of the Ask Data Mode when a site is created. For more information see [Disable or Enable Ask Data for a Site](#).

Valid options are `disabled_by_default` and `disabled_always`.

This option was added beginning with Tableau Server versions: 2019.4.5, 2020.1.3.

## Tableau Server on Linux Administrator Guide

### noninteractive.vmopts

**Default value:** `"-XX:+UseConcMarkSweepGC -Xmx<default_value>g -XX:+ExitOnOutOfMemoryError"`

The default value varies based on the amount of system memory. The JVM maximum heap size is scaled to be 6.25% of the total system RAM.

This option controls the JVM maximum heap size for Tableau Catalog ingestion. Because the default value scales automatically, use this option to override the default value only when absolutely necessary by modifying the `-Xmx<default_value>g` argument. For example, you can use the following command to increase the max heap size to 2 GB:

```
tsm configuration set -k noninteractive.vmopts -v "-XX:+UseConcMarkSweepGC -Xmx2g -XX:+ExitOnOutOfMemoryError"
```

For more information, see [Memory for non-interactive microservice containers](#).

### pgsql.port

**Default value:** 8060

Port that PostgreSQL listens on.

### pgsql.preferred\_host

Specifies the computer name of the node with the preferred repository installed. This value is used if the `--preferred` or `-r` option is specified with the `tsm topology failover-repository` command.

**Example:**

```
tsm configuration set -k pgsql.preferred_host -v "<host_name>"
```

**Note:** The `host_name` is case-sensitive and must match the node name shown in the output of `tsm status -v`.

`pgsql.ssl.ciphersuite`

**Default value:** HIGH:MEDIUM:!aNULL:!MD5:!RC4

Specifies the cipher algorithms that are allowed for SSL for the Repository.

For acceptable values and formatting requirements, see [ssl\\_ciphers](#) on the Postgres website.

`pgsql.ssl.max_protocol_version`

**Default value:** TLSv1.3

Sets the maximum SSL/TLS protocol version to use when connecting to the repository over SSL.

**Valid values:** TLSv1, TLSv1.1, TLSv1.2, TLSv1.3

`pgsql.ssl.min_protocol_version`

**Default value:** TLSv1.2

Sets the minimum SSL/TLS protocol version to use when connecting to the repository over SSL.

**Valid values:** TLSv1, TLSv1.1, TLSv1.2, TLSv1.3

`pgsql.verify_restore.port`

**Default value:** 8061

Port used to verify the integrity of the PostgreSQL database. See tsm maintenance backup for more information.

`ports.blocklist`

**Version:** Added in version 2021.1

**Default value:** no ports blocked in the range used for automatic port assignment.

## Tableau Server on Linux Administrator Guide

Used to specify ports within the port assignment range that should not be used by Tableau when dynamically assigning ports. This is useful when you know that another application is using a port within the range. Separate multiple ports with commas, for example:

```
tsm configuration set -k ports.blocklist -v 8000,8089, 8090
```

For more information on using the `ports.blocklist` key, see [Blocking specific ports within the range](#)

`recommendations.enabled`

Default value: `true`

Controls the recommendations feature, which powers recommendations for data sources and tables (for Tableau Desktop) and recommendations for views (for Tableau Server). Recommendations are based on the popularity of content and on content used by other users determined to be similar to the current user.

`recommendations.vizrecs.enabled`

Default value: `true`

Controls recommendations for views for Tableau Server users. This option is a child of `recommendations.enabled` and will have no effect if the parent option is set to false. When the parent option is set to true, and this option is set to false, data sources and tables will still be recommended to Tableau Desktop users, but recommendations for views on Tableau Server will be disabled.

`redis.max_memory_in_mb`

Default value: `1024`

Specifies the size in megabytes of the cache server external query cache.

`refresh_token.absolute_expiry_in_seconds`

Default value: `31536000`

Specifies the number of seconds for absolute expiration of refresh tokens and personal access tokens (PATs).

Refresh tokens are used by connected clients (Tableau Desktop, Tableau Prep Builder, Tableau Mobile, etc.) for authentication to Tableau Server after initial sign-in.

To remove limits set the value to `-1`. To disable refresh tokens and PATs, see [Disable Automatic Client Authentication](#).

`refresh_token.idle_expiry_in_seconds`

Default value: `1209600`

Specifies the number of seconds when idle refresh tokens expire. The refresh tokens are used by connected clients (Tableau Desktop, Tableau Prep Builder, Tableau Mobile, etc.) for authentication to Tableau Server after initial sign-in. To remove limits set the value to `-1`.

`refresh_token.max_count_per_user`

Default value: `24`

Specifies the maximum number of refresh tokens that can be issued for each user. If the maximum number of users sessions is not enough, increase this value or set it to `-1` to entirely remove this refresh token limit.

`rsync.timeout`

Default value: `600`

Longest allowable time, in seconds, for completing file synchronization (600 seconds = 10 minutes). File synchronization occurs as part of configuring high availability, or moving the data engine and repository processes.

`schedules.display_schedule_description_as_name`

Default value: `false`

## Tableau Server on Linux Administrator Guide

Controls whether a schedule name displays when creating a subscription or extract refresh (the default), or the "schedule frequency description" name describing the time and frequency of the schedule displays. To configure Tableau Server to display timezone-sensitive names for schedules, set this value to `true`.

When true, the "schedule frequency description" is also displayed after the schedule name on the schedule list page.

`schedules.display_schedules_in_client_timezone`

Default value: `true`

Shows the "schedule frequency description" in the timezone of the user when true (uses the client browser timezone to calculate the "schedule frequency description").

`schedules.ignore_extract_task_priority`

Default value (boolean): `False`

This setting controls whether or not task priority is considered for determining the job rank which determines when to pull jobs off the queue. Setting this to `true` disables editing the task priority on tasks, and only schedule priority will be considered for determining the job rank.

`searchserver.connection_timeout_milliseconds`

**Version:** Added in version 2019.1. Deprecated in version 2022.3. Retired in version 2023.3.

Default value, in milliseconds: `100000`

Specifies, in milliseconds, the amount of time Search & Browse clients will wait to establish a connection to the Search & Browse server.

On especially busy Tableau Server computers, or if you see log errors "Failed zookeeper health check. Refusing to start SOLR." increase this value.

For more information, see Client session timeouts.

searchserver.index.bulk\_query\_user\_groups

**Version:** Retired in version 2022.3.

Default value: `true`

Specifies whether querying of site users is done in bulk when importing or deleting users with a CSV file. When set to `true` (the default) indexing is done as in bulk.

searchserver.javamemopts

**Version:** Added in version 2019.1. Retired in 2023.3

Default value: `-Xmx512m -Xms512m -XX:+ExitOnOutOfMemoryError -XX:-UsePerfData`

Determines JVM options for SOLR.

Of all configurable options, the maximum heap memory, configured by the `-Xmx` parameter, is the most important when tuning the searchserver. In most cases this should be set as high as is possible, up to 24 GB, based on available physical memory on the Tableau Server computer. To change only the max heap memory, specify the entire default string but only change the value for `-Xmx`.

Valid values for `-Xmx` depend on available memory on the Tableau Server computer, but cannot be greater than 24 GB. For more information, see [Search & Browse Max Heap Memory](#).

searchserver.startup.zookeeper\_healthcheck\_timeout\_ms

**Version:** Added in version 2020.1. Retired in version 2023.3.

Default value, in milliseconds: `300000`

Specifies, in milliseconds, the amount of time Tableau Server should wait for a successful Zookeeper health check on startup.

On especially busy Tableau Server computers, or if you see log errors "Failed zookeeper health check. Refusing to start SOLR." increase this value.

For more information, see Zookeeper connection health check timeout at startup.

`searchserver.zookeeper_session_timeout_milliseconds`

**Version:** Retired in version 2022.3.

Default value, in milliseconds: 100000

Specifies, in milliseconds, the amount of time Search & Browse clients will wait to establish a connection to the Coordination Service (Zookeeper).

For more information, see Client session timeouts.

`ServerExportCSVMaxRowsByCols`

**Version:** Added in version 2020.3.

Default value: 0 (no limit)

Specifies the maximum number of cells of data that can be downloaded from View Data into a CSV file. By default, there is no limit. Specify the number of cells. For example to set a limit of 3 million:

```
tsm configuration set -k ServerExportCSVMaxRowsByCols -v 3000000
```

```
tsm pending-changes apply
```

`service.jmx_enabled`

Default value: `false`

Setting to `true` enables JMX ports for optional monitoring and troubleshooting.

`service.max_procs`

Default value: <number>

Maximum number of server processes.

`service.port_remapping.enabled`

Default value: `true`

Determines whether or not Tableau Server will attempt to dynamically remap ports when the default or configured ports are unavailable. Setting to `false` disables dynamic port remapping.

`sheet_image.enabled`

Default value: `true`

Controls whether you can get images for views with the REST API. For more information, see [REST API Reference](#).

`ssl.ciphersuite`

Default

value: `HIGH:MEDIUM:!EXP:!aNULL:!MD5:!RC4:!3DES:!CAMELLIA:!IDEA:!SEED`

Specifies the cipher algorithms that are allowed for SSL for Gateway.

For acceptable values and formatting requirements, see [SSLCipherSuite](#) on the Apache website.

`ssl.client_certificate_login.blocklisted_signature_algorithms`

Default value:

- Version 2020.4.0:

```
sh1withrsaencryption,
sh1withrsa
```

- Version 2020.4.1 and later:

```
sh1withrsaencryption,
sh1withrsa,
sh1withrsaandmgf1,
sh1withdsa,
sh1withecdscsa
```

## Tableau Server on Linux Administrator Guide

The default value blocks certificates with the SHA-1 signing algorithm. Specifies the client signing algorithms that are blocked for SSL. To disable blocking of all signature algorithms, run this key with an empty set of quotes.

For more information about this key, see the Knowledge Base article, [Mutual SSL Fails After Upgrading if Certificates Signed with SHA-1](#).

`ssl.client_certificate_login.min_allowed.elliptic_curve_size`

Default value: 256

Specifies the minimum elliptic curve size required for ECDSA client certificates that are authenticating with Tableau Server over mutual SSL. If a client presents an ECDSA client certificate that does not satisfy this minimum curve size, the authentication request will fail.

This option was introduced in Tableau Server version 2021.1.

`ssl.client_certificate_login.min_allowed.rsa_key_size`

Default value: 2048

Specifies the minimum key size for RSA client certificates that are authenticating with Tableau Server over mutual SSL. If a client presents an RSA client certificate that does not satisfy this minimum key size, the authentication request will fail.

This option was introduced in Tableau Server version 2021.1.

`ssl.protocols`

Default value: `all +TLSv1.2 -SSLv2 -SSLv3 -TLSv1.3`

Specifies the SSL protocols that Tableau Server supports for TLS connections for Gateway. Acceptable values derive from the [Apache SSLProtocol Directive](#). We recommend following SSL protocol configuration as described in Security Hardening Checklist.

`storage.monitoring.email_enabled`

Default value: `false`

Controls whether email notifications are enabled for server disk space monitoring. By default, email notifications are enabled. To enable notifications for disk space monitoring, set this to `true`.

SMTP must be configured for notifications to be sent. For details, see [Configure SMTP Setup](#).

`storage.monitoring.warning_percent`

Default value: 20

Warning threshold of remaining disk space, in percentage of total disk space. If disk space falls below this threshold, a warning notification is sent.

`storage.monitoring.critical_percent`

Default value: 10

Critical threshold of remaining disk space, in percentage of total disk space. If disk space falls below this threshold, a critical notification is sent.

`storage.monitoring.email_interval_min`

Default value: 60

How often, in minutes, that email notifications should be sent when disk space monitoring is enabled and a threshold is crossed.

`storage.monitoring.record_history_enabled`

Default value: `true`

Determines whether free disk space history is saved and available to view in Administrative Views. To disable history storage for monitoring, set `storage.monitoring.record_history_enabled` to `false`.

`subscriptions.enabled`

Default value: `false`

Controls whether subscriptions are configurable system-wide. See [Set Up a Site for Subscriptions](#).

`subscriptions.timeout`

Default value: 1800

Length of time, in seconds, for a view in a workbook subscription task to be rendered before the task times out. If this time limit is reached while a view is being rendered, the rendering continues, *but any subsequent view in the workbook is not rendered*, and the job ends in error. In the case of a single-view workbook, this value will never result in the rendering being halted due to a timeout.

`svcmonitor.notification.smtp.enabled`

Default value: `false`

Controls whether email notifications are enabled for server process events. By default notifications are sent when processes go down, fail over, or restart. To enable server process notifications, set this to `true`.

SMTP must be configured for notifications to be sent. For details, see [Configure SMTP Setup](#).

`svcmonitor.notification.smtp.mime_use_multipart_mixed`

**Version:** Added in version: 2020.1.8, 2020.2.5, 2020.3.1

Default value: `false`

Controls whether subscription HTML MIME attachments are sent as *multipart/related* (the default) or *multipart/mixed*.

In rare cases, email clients may not properly parse emails sent by Tableau Server. Many times this can be fixed by setting this property to `true`. Known clients include iOS Mail and Microsoft Outlook (when paired with Exchange S/MIME encryption).

`tabadmincontroller.auth.expiration.minutes`

Default value: 120

Controls how long session cookies are valid. By default this is set to 120 minutes. This value also determines how long the embedded credentials in a node bootstrap file are valid. For more information, see [tsm topology nodes get-bootstrap-file](#).

`tdsservice.log.level`

**Version:** Added in version 2020.3.0

Default value: `info`

The logging level for the Data Source Properties service. This is dynamically configurable, so if you are only changing this you do not have to restart Tableau Server. For more information, see [Change Logging Levels](#).

`tomcat.http.maxrequestsize`

Default value: 16380

The maximum size (bytes) of header content that is allowed to pass through the Apache gateway on HTTP requests. Headers that exceed the value set on this option will result in browser errors, such as HTTP Error 413 (Request Entity Too Large) or authentication failures.

A low value for `tomcat.http.maxrequestsize` may result in authentication errors. Single sign-on solutions that integrate with Active Directory (SAML and Kerberos) often require large authentication tokens in HTTP headers. Be sure to test HTTP authentication scenarios before deploying into production.

We recommend setting `gateway.http.request_size_limit` option to the same value that you set for this option.

`tomcat.http.proxyHost`

Specifies forward proxy host name for OpenID requests to the IdP. See [Configure Tableau Server for OpenID Connect](#).

## Tableau Server on Linux Administrator Guide

`tomcat.http.ProxyPort`

Specifies forward proxy port for OpenID requests to the IdP. See [Configure Tableau Server for OpenID Connect](#).

`tomcat.https.proxyHost`

Specifies forward proxy host name for OpenID requests to the IdP. See [Configure Tableau Server for OpenID Connect](#).

`tomcat.https.ProxyPort`

Specifies forward proxy port for OpenID requests to the IdP. See [Configure Tableau Server for OpenID Connect](#).

`tomcat.https.port`

Default value: 8443

SSL port for Tomcat (unused).

`tomcat.server.port`

Default value: 8085

Port that tomcat listens on for shutdown messages.

`tomcat.useSystemProxies`

Default value: `false`

Specifies whether tomcat components (OpenID) require access to the forward proxy configuration on the local Windows operating system. See [Configure Tableau Server for OpenID Connect](#).

`tomcatcontainer.log.level`

Default value: `info`

The logging level for microservices in the Interactive Microservice Container and Non-Interactive Microservice Container. This is dynamically configurable starting in version 2020.4, so if you are only changing this you do not have to restart Tableau Server. For more information, see [Change Logging Levels](#).

`tsm.log.level`

Default value: `info`

Logging level for TSM services. These logs include information that can be useful if you have problems with TSM services: Administration Agent, Administration Controller, Client File Service, Cluster Controller, Service Manager, and License Service. This configuration key does not change the logging level for Coordination Service or for maintenance processes. For more information, see [Change Logging Levels](#) and [Tableau Server Processes](#).

`tsm.controlapp.log.level`

Default value: `info`

Logging level for `control_<app>` services. These logs include information that can be useful if you are running into problems starting or reconfiguring a TSM or Tableau Server process. For more information, see [Change Logging Levels](#).

`usernotifications.reap_after_days`

Default value: `30`

Number of days after which a user notification will be deleted from the server.

`vizportal.adsync.update_system_user`

Default value: `false`

Specifies whether email addresses and display names of users are changed (even when changed in Active Directory) when an Active Directory group is synchronized in Tableau Server. To ensure that user email addresses and display names are updated during syn-

## Tableau Server on Linux Administrator Guide

chronization, set `vizportal.adsync.update_system_user` to `true`, and then restart the server.

`vizportal.alwaysUseEmbeddedShareLinks`

**Version:** Added in version 2021.3.0

Default value: `false`

Specifies whether the **Copy Link** option should include the "embed=y" parameter. Starting in version 2019.4, by default it does not include this parameter. Setting this configuration key to `true` changes the behavior so that the "embed=y" parameter is included. For details about using the **Copy Link** option to share links for embedding in web pages, see [Embed Views into Webpages](#) in the Tableau Desktop and Web Authoring Help.

`vizportal.art_skip_list`

**Version:** Added in version 2024.2.

Default value: `null`

Use this configuration key to specify aspects of Tableau Server functionality that does not use Activity and Resource Tracing (ART) and will generate large amounts of unnecessary data while ART is enabled.

This key is used together with `vizportal.log_art_java` and `vizportal.enable_art` for troubleshooting issues with Application Server (VizPortal). When set to [need info here about what it gets set to.] To learn how to use this configuration setting, see [Troubleshooting problems with Application Server](#).

`vizportal.commenting.delete_enabled`

Default value: `true`

When set to `true`, lets users delete comments on views. You can delete a comment if you created it, are the content owner, a project leader with an appropriate site role, or are an admin-

istrator. To learn which site roles are required for full project leader access, see Project-level administration.

`vizportal.csv_user_mgmt.index_site_users`

**Version:** Deprecated in version 2022.3. Retired (removed entirely) in version 2023.3.

Default value: `true`

Specifies whether indexing of site users is done user by user when importing or deleting users with a CSV file. When set to `true` (the default) indexing is done as each user is added or deleted. To delay the indexing of the site users until after the entire CSV file has been processed, set this to `false`.

`vizportal.csv_user_mgmt.bulk_index_users`

**Version:** Deprecated in version 2022.3. Retired (removed entirely) in version 2023.3.

Default value: `false`

Specifies whether indexing of site users is done in bulk when importing or deleting users with a CSV file. When set to `false` (the default) indexing is done individually. To have the indexing done in bulk after the CSV file has been processed, set this to `true`.

`vizportal.enable_art`

**Version:** Added in version 2024.2.

Default value: `false`

This configuration key is used together with `vizportal.log_art_java` and `vizportal.art_skip_list` for troubleshooting issues with Application Server (VizPortal). When set to `true`, this enables Activity and Resource Tracing in Application Server. To learn how to use this configuration setting, see Troubleshooting problems with Application Server.

`vizportal.log_art_java`

**Version:** Added in version 2024.2.

## Tableau Server on Linux Administrator Guide

Default value: `false`

This configuration key is used together with `vizportal.enable_art` and `vizportal.art_skip_list` for troubleshooting issues with Application Server (VizPortal). When set to true, this enables Activity and Resource Tracing in Application Server. To learn how to use this configuration setting, see [Troubleshooting problems with Application Server](#).

`vizportal.log.level`

Default value: `info`

The logging level for vizportal Java components. Logs are written to `/var/opt/tableau/tableau_server/data/tabsvc/logs/vizportal/*.log`.

Set to `debug` for more information. Using the debug setting can significantly impact performance, so you should only use this setting when directed to do so by Tableau Support.

Beginning with version 2020.4.0, this is dynamically configurable, so if you are only changing this you do not have to restart Tableau Server. For more information, see [Change Logging Levels](#).

`vizportal.oauth.connected_apps.max_expiration_period_in_minutes`

**Version:** Added in version 2021.4.

Default value: `10`

The maximum period of time, in minutes, the JSON web token (JWT) is valid. At the time the JWT is verified, Tableau Server checks that the time period specified in the JWT doesn't exceed this default value. This setting is used when a Tableau connected app has been configured on Tableau Server using the [Tableau REST API](#).

For example, to change maximum period to 5 minutes, run the following command:

```
tsm configuration set -k vizportal.oauth.external_authorization_server.max_expiration_period_in_minutes -v 5
```

vizportal.oauth.external\_authorization.enabled

**Version:** Added in version 2021.4.

Default value: `false`

In Tableau Server 2024.2 and later, **Enable connected apps** option is enabled for Tableau Server. In Tableau Server 2023.2 and earlier, specifies whether the **Enable OAuth Access for Embedding Content** option is enabled for Tableau Server.

Use this option to register an external authorization server (EAS) with Tableau Server so that you can enable application integration. For more information, see [Configure Connected Apps with OAuth 2.0 Trust](#).

To enable this option, run the following command:

```
tsm configuration set -k vizportal.oauth.external_authorization.enabled -v true
```

vizportal.oauth.external\_authorization\_server.blocklisted\_jws\_algorithms

**Version:** Added in version 2021.4.

Default value: `ES256K`

When an external authorization server (EAS) is registered or connected app is configured, you can use this command to specify the signing algorithm used in JSON web token (JWT) header. For more information, see [Configure Connected Apps with OAuth 2.0 Trust](#) or [Use Tableau Connected Apps for Application Integration](#).

For example, if needed, you might run the following command to remove the algorithm:

```
tsm configuration set -k vizportal.oauth.external_authorization_server.blocklisted_jws_algorithms -v
```

**Important:** The example command above allows unsafe signing algorithms and should only be used to troubleshoot errors.

## Tableau Server on Linux Administrator Guide

`vizportal.oauth.external_authorization_server.issuer`

**Version:** Added in version 2021.4.

Default value: `null`

Required. Use this command to specify the issuer URL. The issuer URL is required to register the external authorization server (EAS) with Tableau Server. For more information, see [Configure Connected Apps with OAuth 2.0 Trust](#).

For example, if your EAS is Okta, you might run a command similar to the following:

```
tsm configuration set -k vizportal.oauth.external_authorization_server.issuer -v "https://dev-12345678.okta.com/oauth2/abcdefgh9abc8eFghi76j5"
```

`vizportal.oauth.external_authorization_server.jwks`

**Version:** Added in version 2021.4.

Default value: `null`

When an external authorization server (EAS) is registered, you can use this command to specify the JSON web key set (JWKS) URL. The JWKS URL is required if the identity provider (IdP) doesn't expose the external authorization server metadata endpoint.

For example, if your IdP is Amazon Cognito, you might run a command similar to the following:

```
tsm configuration set -k vizportal.oauth.external_authorization_server.jwks -v "https://cognito-idp.us-west-2.amazonaws.com/us-west-2_Ab129faBb/.well-known/jwks.json"
```

`vizportal.oauth.external_authorization_server.max_expiration_period_in_minutes`

**Version:** Added in version 2021.4.

Default value: `10`

The maximum period of time, in minutes, the JSON web token (JWT) is valid. At the time the JWT is verified, Tableau Server checks that the time period specified in the JWT doesn't exceed this default value. This setting is used when an EAS has been registered with Tableau Server. For more information, see [Configure Connected Apps with OAuth 2.0 Trust](#).

For example, to change maximum period to 5 minutes, run the following command:

```
tsm configuration set -k vizportal.oauth.external_authorization_
server.max_expiration_period_in_minutes -v 5
```

`vizportal.openid.client_authentication`

Specifies custom client authentication method for OpenID Connect.

To configure Tableau Server to use the IdPs that require the `client_secret_post`, set this value to `client_secret_post`.

An example would be when connecting to the Salesforce IDP, which requires this.

`vizportal.openid.essential_acr_values`

**Version:** Added in version 2020.4.

Specifies a list of authentication context class reference (ACR) values to provide the OpenID Connect IdP as an essential claim request. The IdP is responsible for ensuring that authentication meets the expected criteria. If the `vizportal.openid.essential_acr_values` configuration key is populated, Tableau Server acts as the relying party and will inspect the ACR claim in the token response. Tableau Server will only warn if the ACR claim doesn't match the expected configuration key value.

To set this option, enter the ACR values in order of preference, enclosed by double-quotes. You must separate multiple values by a comma and space, as in this example:

```
tsm configuration set -k vizportal.openid.essential_acr_values -v
"value1, value2"
```

`vizportal.openid.full_server_request_logging_enabled`

Default value: `false`

Specifies whether to do full logging of OpenID activity.

Set this to `true` when troubleshooting OpenID Connect issues to gather more detailed logs and allow you to better troubleshoot.

As with all logging-related configurations, we recommend that after you are finished troubleshooting and collecting logs, you reset this key to its default (`false`). This limits the amount of information logged, and keeps the log file sizes to a minimum.

`vizportal.openid.voluntary_acr_values`

**Version:** Added in version 2020.4.

Specifies a list of authentication context class reference (ACR) values to provide the OpenID Connect IdP as a voluntary claim request. The IdP is responsible for ensuring that authentication meets the expected criteria. If the `vizportal.openid.voluntary_acr_values` configuration key is populated, Tableau Server acts as the relying party and will inspect the ACR claim in the token response. The authentication request will fail if the ACR claim is missing or the provided claim value doesn't match the expected configuration key value.

To set this option, enter the ACR values in order of preference, enclosed by double-quotes. You must separate multiple values by a comma and space, as in this example:

```
tsm configuration set -k vizportal.openid.voluntary_acr_values -v  
"value1, value2"
```

`vizportal.rest_api.cors.allow_origin`

Specifies the origins (sites) that are allowed access to the REST API endpoints on Tableau Server when `vizportal.rest_api.cors.enabled` is set to `true`. You can specify more than one origin by separating each entry with a comma (,).

```
tsm configuration set -k vizportal.rest_api.cors.allow_origin -v  
https://mysite, https://yoursite
```

If `vizportal.rest_api.cors.enabled` is `false`, the origins listed by this option are ignored. For more information, see [Enabling CORS on Tableau Server](#).

**Note:** You can use an asterisk (\*) as a wild card to match all sites. This is not recommended as it allows access from any origin that has access to the server and can present a security risk. Do not use an asterisk (\*) unless you fully understand the implications and risks for your site.

`vizportal.rest_api.cors.enabled`

Default value: `false`

Controls whether Tableau Server allows Cross Origin Resource Sharing (CORS). When set to `true`, the server allows web browsers to access the [Tableau REST API](#) endpoints. You can use this option and the REST API to create custom portals. By default, this functionality is not enabled. To specify which origins (sites) have access, use the `vizportal.rest_api.cors.allow_origin` option. Only the origins specified with this option are allowed to make requests to the Tableau Server REST API. For more information, see [Enabling CORS on Tableau Server](#).

`vizportal.site_user_group_count_enabled`

**Version:** Added in version 2022.3.5 and later, 2023.1.0 and later.

Default value: `false`

Controls whether Site Users page will include a column showing the group count for each user.

`vizqlserver.allow_insecure_scripts`

Default value: `false`

## Tableau Server on Linux Administrator Guide

Allows a workbook to be published to the server from Tableau Desktop, and to be opened from the server, even if the workbook contains SQL or R expressions that are potentially unsafe (for example, a SQL expression that could potentially allow SQL injection). When this setting is `false` (the default), publishing a workbook or opening it from the server results in an error message, and the workbook is blocked. Before you set this value to `true` review the Knowledge Base article, [Blocking or Allowing Insecure Scripts in Tableau Server](#).

`vizqlserver.browser.render`

Default value: `true`

Views under the threshold set by `vizqlserver.browser.render_threshold` or `vizqlserver.browser.render_threshold_mobile` are rendered by the client web browser instead of by the server. See [Configure Client-Side Rendering](#) for details.

`vizqlserver.browser.render_threshold`

Default value: `100`

The default value represents a high level of complexity for a view displayed on a PC. Complexity factors include number of marks, headers, reference lines, and annotations. Views that exceed this level of complexity are rendered by the server instead of in the PC's web browser.

`vizqlserver.browser.render_threshold_mobile`

Default value: `60`

The default value represents a high level of complexity for a view displayed on a tablet. Complexity factors include number of marks, headers, reference lines, and annotations. Views that exceed this level of complexity are rendered by the server instead of in the tablet's web browser.

`vizqlserver.clear_session_on_unload`

Default value: `false`

Determines whether or not VizQL sessions are kept in memory when a user navigates away from a view or closes their browser. The default value (`false`) keeps sessions in memory. To close VizQL sessions on leaving a view or closing a browser, set this to `true`.

`vizqlserver.force_maps_to_offline`

**Version:** Added in version 2020.4.0.

Default value: `false`

Determines whether Tableau Server runs in offline mode for maps. This is useful in disconnected environments where access to the internet and the map server is restricted. To enable offline mode for maps, set this value to `true`. For more information about installing and configuring Tableau Server in an environment without internet access, see [Install Tableau Server in a Disconnected \(Air-Gapped\) Environment](#).

`vizqlserver.geosearch_cache_size`

Default value: 5

Sets the maximum number of different geographic search locale/language data sets that can be loaded into server memory at the same time. When the server receives a geographic search request for locale/language data set that is not in memory, it will load the set into memory. If loading the data set will exceed the specified limit, the least recently used locale/language data set is cleared from memory so the requested one can be loaded. The minimum value is 1. Each cache takes approximately 60 MB in memory (so if you set this to 10, the memory usage would be 600 MB (60 \* 10)).

`vizqlserver.initialsql.disabled`

Default value: `false`

Specify whether to ignore initial SQL statements for all data sources. Set this to `true` to ignore initial SQL:

```
tsm configuration set -k vizqlserver.initialsql.disabled -v true
```

## Tableau Server on Linux Administrator Guide

`vizqlserver.log.level`

Default value: `info`

The logging level for VizQL Server Java components. Logs are written to `/var/opt/tableau/tableau_server/data/tabsvc/logs/vizqlserver/*.log`.

Set to `debug` for more information. Using the debug setting can significantly impact performance, so you should only use it when directed to do so by Tableau Support.

Beginning with version 2020.3.0, this is dynamically configurable, so if you are only changing this you do not have to restart Tableau Server. For more information, see [Change Logging Levels](#).

`vizqlserver.NumberOfWorkbookChangesBetweenAutoSaves`

Default value: 5

Auto recover configuration for web authoring. Specifies the number of changes that a user must make to trigger auto save. Take care when changing this value. Auto recover functionality may impact the performance of web authoring and other viz-related operations on Tableau Server. We recommend tuning this value by making incremental adjustments over time.

`vizqlserver_<n>.port`

The port a VizQL server instance (specified by "<n>") is running on.

`vizqlserver.querylimit`

Default value: 1800

Longest allowable time for updating a view, in seconds. 1800 seconds = 30 minutes. This configuration option impacts VizQL Server and Data Server.

`vizqlserver.RecoveryAttemptLimitPerSession`

Default value: 3

Auto recover configuration for web authoring. The maximum number of attempts to recover the same session. Take care when changing this value. Auto recover functionality may impact the performance of web authoring and other viz-related operations on Tableau Server. We recommend tuning this value by making incremental adjustments over time.

`vizqlserver.session.expiry.minimum`

Default value: 5

Number of minutes of idle time after which a VizQL session is eligible to be discarded if the VizQL process starts to run out of memory.

`vizqlserver.session.expiry.timeout`

Default value: 30

Number of minutes of idle time after which a VizQL session is discarded.

`vizqlserver.sheet_image_api.max_age_floor`

Default value: 1

The amount of time, in minutes, to cache images that are generated by the Query View Image method of the REST API. For more information, see the [REST API Reference](#) in the REST API help.

`vizqlserver.showdownload`

Default value: `true`

Controls the display of the **Tableau Workbook** option of the Download menu in views. When set to `false`, the Tableau Workbook option is unavailable.

**Note:** This setting does not remove the option for users in Web Edit mode.

`vizqlserver.showshare`

Default value: `true`

Controls the display of Share options in views. To hide these options, set to false.

**Note:** Users can override the server default by setting the "showShareOptions" JavaScript or URL parameter.

`vizqlserver.url_scheme_whitelist`

Specifies one or more URL schemes to allow (safe list) when using [URL actions](#) on views and dashboards. The schemes `http`, `https`, `gopher`, `mailto`, `news`, `sms`, `tel`, `tsc`, and `tsl` are allowed (safe listed) by default. This command can contain multiple comma and space-separated values, as in this example:

```
tsm configuration set -k vizqlserver.url_scheme_whitelist -v  
scheme1, scheme2
```

The values you specify overwrite previous settings. Therefore, you must include the full list of schemes in the `set` command. (You cannot amend the list of schemes by running the `set` command repeatedly.)

`vizqlserver.web_page_objects_enabled`

Default value: `true`

Controls whether Web Page objects in dashboards can display target URLs. To prevent web pages from appearing, set to false.

`vizqlserver.WorkbookTooLargeToCheckpointSizeKiB`

Default value: 5120

Auto recover configuration for web authoring. Size limit (KB) for a workbook that will auto save. Workbooks larger than this value will not be auto-saved. Take care when changing this value. Auto recover functionality may impact the performance of web authoring and other viz-related operations on Tableau Server. We recommend tuning this value by making incremental adjustments over time.

**Note:** Older versions of Server use a default value: 1024

vizqlserver.workflow\_objects\_enabled

Default value: `true`

Determines whether the Tableau External Actions Workflow object can be added to dashboards.

webdataconnector.refresh.enabled

Deprecated. Use `tsm data-access web-data-connectors allow` instead.

Determines whether extract refreshes for web data connectors (WDCs) are enabled in Tableau Server. To disable refresh for all WDCs, set the value for this key to `false`, as shown below:

```
tsm configuration set --key webdataconnector.refresh.enabled --
value false
```

To learn more, see [Web Data Connectors in Tableau Server](#).

webdataconnector.whitelist.fixed

Deprecated. Use `tsm data-access web-data-connectors add` instead.

Specifies one or more web data connectors (WDCs) that can be used by to access data connections that are accessible over HTTP or HTTPS. This command is formatted as JSON data on a single line, with all double-quotes (") escaped using a backslash (\).

For example to add a San Francisco Film Locations WDC to the safe list:

```
tsm configuration set --key webdataconnector.whitelist.fixed --
value "'{\\"https://tableau.data.world:443\\": {\\"properties\\": {
\\"secondary_whitelist\\": [\\"(https://data.world/)(.*)\\" ] } } }'"
```

To learn more, see [Web Data Connectors in Tableau Server](#).

## Tableau Server on Linux Administrator Guide

`webdataconnector.enabled`

Deprecated. Use `tsm data-access web-data-connectors allow` instead.

Default value: `true`

When set to `true`, you can use `tsm` commands to manage web data connectors on the server.

`webdataconnector.whitelist.mode`

Default value: `mixed`

Determines how Tableau Server can run web data connectors. Supported modes are:

- `mixed`. Users can run connectors that are on an allowlist (safe list) of URLs. This mode originally also allowed users to run WDCs that had been imported. Importing WDCs is no longer supported.
- `fixed`. Users can run connectors that are on an allowlist (safe list) of URLs.
- `insecure`. Users can run any connector.

**Important:** Use the `insecure` option *only* for development and testing. Because connectors run custom code, running connectors that have not been vetted can pose a security threat.

`wgserver.audit_history_expiration_days`

Default value: `183`

Specifies the number of days after which historical events records are removed from the PostgreSQL database (the Tableau Server database).

`wgserver.authentication.legacy_identity_mode.enabled`

**Version:** Added in version 2022.1

Default value: `false` for Tableau Server 2022.1 and later. For pre-2022.1 Tableau Server deployments upgraded to 2022.1 or later, default value is `true`.

Set to `false` to use identity pools.

For more information, see Troubleshoot identity pools.

`wgserver.authentication.identity_pools.default_pool_description`

**Version:** Added in version 2023.1

Default value: Null

Optionally, you can add a description for the initial pool (TSM configured) to the Tableau Server landing page and is visible to all users. When one or more identity pools are created, this description is added below the primary sign-in option and can be used to help guide users that belong to the initial pool (TSM configured) to the correct sign-in option.

For example, to add a “Regular employees sign in here” description, you can use the following command:

```
tsm configuration set -k wgserver.authentication.identity_pools.default_pool_description -v "Regular employees sign in here"
```

**Note:** The initial pool (TSM configured) description is different from the Sign In Customization note. The Sign In Customization note is displayed on the Tableau Server landing page below all sign-in options and on the page where your initial pool (TSM configured) users enter their username and password.

`wgserver.change_owner.enabled`

Default value: `true`

Controls whether the ownership of a workbook, data source or project can be changed. Other options include `false` and `adminonly`.

`wgserver.clickjack_defense.enabled`

Default value: `true`

## Tableau Server on Linux Administrator Guide

When set to `true`, helps prevents a malicious person from "clickjacking" a Tableau Server user. In a clickjack attack, the target page is displayed transparently over a second page, and the attacker gets the user to click or enter information in the target page while the user thinks he or she is interacting with the second page.

For more information, see Clickjack Protection.

`wgserver.domain.accept_list`

**Version:** This was added in version 2020.4.0 and replaces `wgserver.domain.whitelist`.

Default value: `null`

Allows connection from Tableau Server to secondary Active Directory domains. A secondary domain is one that Tableau Server connects to for user synchronization, but is a domain where Tableau Server is not installed. Tableau Server will attempt to connect to secondary domains for user and group synchronization. In some cases, Tableau Server may be unable to connect to the secondary domain, which will result in the error, "Domain not in accept list (errorCode=101015)."

Setting the `wgserver.domain.accept_list` option is required by a fix for the security vulnerability, [\[Important\] ADV-2020-003: Tableau Server Forced Authentication](#). As of February 2020, the fix for this vulnerability is included in all latest versions and maintenance releases of Tableau Server.

To set this option, enter the secondary domain enclosed by double-quotes. Multiple domains must be separated by a comma and a space. For example, `tsm configuration set -k wgserver.domain.accept_list -v "example.org, domain.com"`.

Wildcard functionality is not supported. For example, if Tableau connects to `sub1.example.org` and `sub2.example.org`, then both domains must be added.

Updating the `wgserver.domain.accept_list` option overwrites the existing value. Therefore, if you are adding a new domain to an existing set of domains stored in the value, include all existing domains with the new domain when you set the option. You can retrieve the full list

of existing domains by running `tsm configuration get -k wgserver-domain.accept_list`.

`wgserver.domain.ldap.domain_custom_ports`

Default value: null

Allows you to map child domains and their LDAP ports. Domain and port are separated by a colon (:) and each domain:port pair is separated by a comma (,) using this format: `FQDN1:port,FQDN2:port`

**Example:** `tsm configuration set -k wgserver.domain.ldap.domain_custom_ports -v child-domain1.lan:3269,childdomain2.lan:3269,childdomain3.lan:389`

`wgserver.domain.password`

Default value: null

Specifies password for the user account that is used for LDAP connection. See External Identity Store Configuration Reference.

`wgserver.domain.username`

Default value: null

Specifies name for the user account that is used for LDAP connection. See External Identity Store Configuration Reference.

`wgserver.domain.whitelist`

**Important:** This key has been deprecated as of version 2020.4.0. Use `wgserver-domain.accept_list` instead.

Default value: null

## Tableau Server on Linux Administrator Guide

Allows connection from Tableau Server to secondary Active Directory domains. A secondary domain is one that Tableau Server connects to for user synchronization, but is a domain where Tableau Server is not installed. Tableau Server will attempt to connect to secondary domains for user and group synchronization. In some cases, Tableau Server may be unable to connect to the secondary domain, which will result in the error, "Domain not in whitelist (errorCode=e=101015)."

`wgserver.extended_trusted_ip_checking`

Default value: `false`

Enforces IP client matching for trusted ticket requests.

`wgserver.ignore_domain_in_username_for_matching`

**Version:** Added in versions 2021.4.21, 2022.1.17, 2022.3.9, and 2023.1.5

Default value: `false`

When you enable SAML, you can configure Tableau Server to ignore the domain portion of the SAML username attribute when matching the identity provider (IdP) user name to a user account on Tableau Server. You might ignore the domain portion of the username attribute when you already have users defined in Tableau Server that match the prefix portion of a username attribute but not the domain portion of the username attribute. For more information, see the [Ignore domain when matching SAML username attribute](#) section in the SAML Requirements topic.

For example, to ignore the domain name in the SAML username attribute, run the following command:

```
tsm configuration set -k wgserver.ignore_domain_in_username_for_matching -v true
```

### Important:

- We do not recommend ignoring the domain name without taking precautions. Specifically, verify that user names are unique across the configured domains that you've

created in your IdP.

- This command only works in Tableau Server deployments that are in `legacy-identity-mode` or deployments that have not been updated through the [identity migration](#) to use the Identity Service.

`wgserver.restrict_options_method`

Default value: `true`

Controls whether Tableau Server accepts HTTP OPTIONS requests. If this option is set to `true`, the server returns HTTP 405 (Method Not Allowed) for HTTP OPTIONS requests.

`wgserver.saml.blocklisted_digest_algorithms`

**Version:** Added in version 2021.1.

Default value: `SHA1`

Specifies the hashing algorithms that are not allowed for any relevant SAML certificate signatures or SAML assertion digest method or signature methods. When set, certificates or assertions that are signed & hashed with a blocklisted algorithm will be rejected and fail.

There are multiple places where SHA-1 could be used on both the Tableau and IdP side. For example:

- Certificates uploaded with TSM that are used by Tableau Server to sign the request that is sent to the IdP.
- Certificates in the IdP metadata used to verify the AuthnResponse (signature) received from the IdP using the public key in the Certificate.
- Incoming assertions signed and hashed with SHA-1 (DigestMethod set to SHA-1 and SignatureMethod set to SHA-1).

The default value was changed to (`SHA1` in Tableau Server 2021.2. For more information about upgrading to 2021.2 with SAML configured, see the Knowledge Base article, [Tableau Server Using SAML Authentication Fails to Start or Rejects Login After Upgrade to Tableau Server 2021.2](#).

`wgserver.saml.forceauthn`

**Version:** Added in version 2019.3.

Default value: `false`

When set to `true`, if the Tableau user session expires, Tableau Server will re-authenticate the user with the IdP. This option can also be used to ask the IdP to prompt the user for re-authentication, even if the user has an active IdP session.

`wgserver.saml.idpattribute.username`

Specifies the name of the attribute in which your SAML IdP stores user names. By default, this is set to `username`. If the attribute name that your IdP uses contains spaces, enclose it in quotation marks. For more information, see [Configure Server-Wide SAML](#) or [Configure Site-Specific SAML](#).

`wgserver.saml.iframe_idp.enabled`

Default value: `false`

Default of `false` means that when users select the sign-in button on an embedded view, the IdP's sign-in form opens in a pop-up window.

When you set it to `true`, and a server SAML user who is already signed in navigates to a web page with an embedded view, the user will not need to sign in to see the view.

You can set this to `true` only if the IdP supports signing in within an `iframe`. The `iframe` option is less secure than using a pop-up, so not all IdPs support it. If the IdP sign-in page implements clickjack protection, as most do, the sign-in page cannot display in an `iframe`, and the user cannot sign in.

If your IdP does support signing in via an `iframe`, you might need to enable it explicitly. However, even if you can use this option, it disables Tableau Server clickjack protection for SAML, so it still presents a security risk.

wgserver.saml.maxassertiontime

Default value: 3000

Specifies the maximum number of seconds, from creation, that a SAML assertion is usable.

wgserver.saml.min\_allowed.elliptic\_curve\_size

Default value: 256

**Version:** Added in version 2021.1 but did not include a default value. In 2021.2, the default value was set to 256.

This option specifies the minimum allowed ECDSA curve size for the certificate used for SAML authentication. If you upload a certificate that has an ECDSA curve size less than 256, TSM will log an error when you apply changes.

If you are upgrading to Tableau Server 2021.2 or later and your SAML certificate uses an ECDSA curve size less than 256, Tableau Server will not start after upgrading. We recommend uploading a new certificate with 256 (or larger) ECDSA curve size before upgrading. Alternatively, you can run this command to set a lower ECDSA curve size on older versions (pre-2021.1) of Tableau Server before you upgrade. If you are running this command on a version prior to 2021.1, you must include the `--force-keys` option with the command. For more information about upgrading to 2021.2 with SAML configured, see the Knowledge Base article, [Tableau Server Using SAML Authentication Fails to Start or Rejects Login After Upgrade to Tableau Server 2021.2](#).

wgserver.saml.min\_allowed.rsa\_key\_size

Default value: 2048

**Version:** Added in version 2021.1 but did not include a default value. In 2021.2, the default value was set to 2048.

This option specifies the minimum allowed RSA key length for the certificate used for SAML authentication. If you upload a certificate that has an RSA key length less than 2048, TSM will log an error when you apply changes.

## Tableau Server on Linux Administrator Guide

To run SAML authentication with a 1024 RSA key length (not recommended), set this value to 1024.

If you are upgrading to Tableau Server 2021.2 or later and your SAML certificate uses a key length less than 2048, Tableau Server will not start after upgrading. We recommend uploading a new certificate with 2048 (or larger) key length before upgrading. Alternatively, you can run this command to set a lower key strength on older versions (pre-2021.1) of Tableau Server before you upgrade. If you are running this command on a version prior to 2021.1, you must include the `--force-keys` option with the command. For more information about upgrading to 2021.2 with SAML configured, see the Knowledge Base article, [Tableau Server Using SAML Authentication Fails to Start or Rejects Login After Upgrade to Tableau Server 2021.2](#).

`wgserver.saml.responseskew`

Default value: 180

Sets the maximum number of seconds difference between Tableau Server time and the time of the assertion creation (based on the IdP server time) that still allows the message to be processed.

`wgserver.saml.sha256`

Default value: `true`

When set to `true`, Tableau Server will hash message signatures and digests with SHA-256 in SAML assertions to the IdP. Set this option to `false` only if your IdP rejects assertions containing SHA-256 hashed content.

`wgserver.session.apply_lifetime_limit`

Default value: `false`

Controls whether there is a session lifetime for server sessions. Set this to `true` to configure a server session lifetime.

`wgserver.session.idle_limit`

Default value: 240

The number of minutes of idle time before a sign-in to the web application times out.

`wgserver.session.lifetime_limit`

Default value: 1440

The number of minutes a server session lasts if a session lifetime is set. The default is 1440 minutes (24 hours). If `wgserver.session.apply_lifetime_limit` is `false` (the default) this is ignored.

`wgserver.unrestricted_ticket`

Default value: `false`

Specifies whether to extend access to server resources for users authenticated by trusted tickets. Default behavior allows users to access views only. Setting this to `true` allows users with valid trusted tickets to access server resources (projects, workbooks, and so on) as if they had signed in using their credentials.

`workerX.gateway.port`

Default value: 80 (443 if SSL)

External port that Apache listens on for workerX (where a “worker” is the term used for subsequent server nodes in the cluster). `worker0.gateway.port` is Tableau Server’s external port. In a distributed environment, `worker0` is the initial Tableau Server node.

`workerX.vizqlserver.procs`

Default value: <number>

Number of VizQL servers.

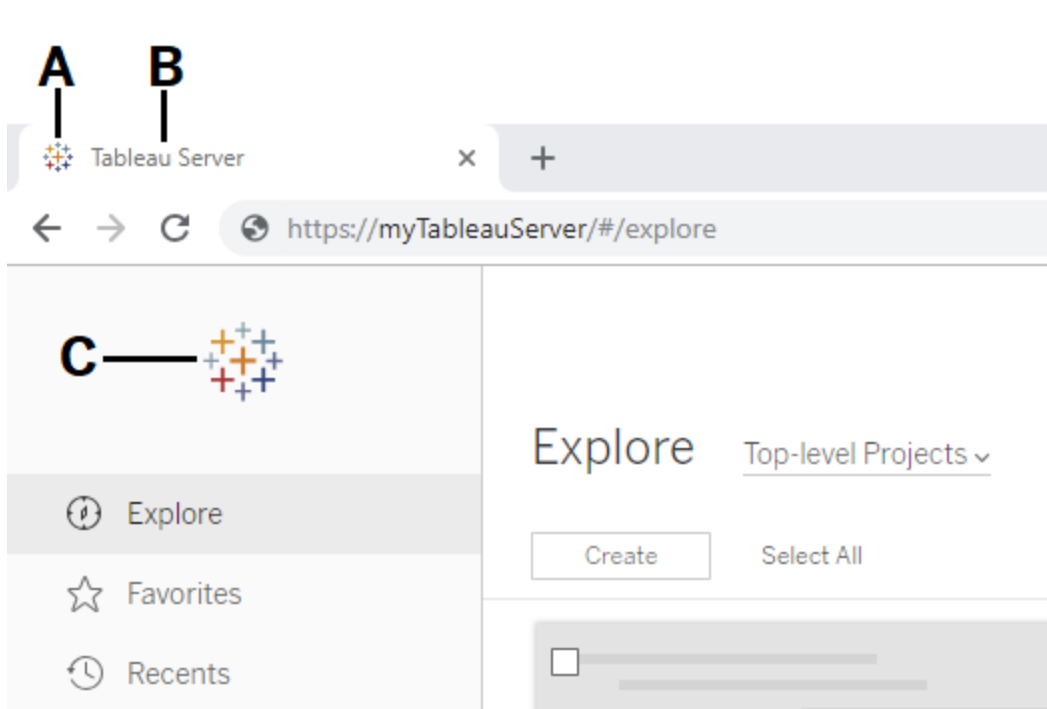

`zookeeper.config.snapCount`

Specifies the number of transactions necessary to cause the Coordination Service to create a snapshot of the logs. By default this value is 100,000 transactions. If your Coordination Service is not writing enough transactions to result in snapshots, the automatic cleanup of snap-

shots older than five days will not take place, and you may lose disk space to the transaction logs. By default transaction logs and snapshots are created in the Tableau data directory.

## tsm customize

You can use the `tsm customize` command to customize the look and feel of the Tableau Server client browser experience.

| Logo                            | Option flag                | Minimum size/Maximum size, in pixels | Recommended size, in pixels |
|---------------------------------|----------------------------|--------------------------------------|-----------------------------|
| <b>A</b> - Window tab logo      | cannot be changed          | cannot be changed                    | cannot be changed           |
| <b>B</b> - Server name          | <code>--server-name</code> | does not apply                       | does not apply              |
| <b>C</b> - Header logo          | <code>--header-logo</code> | 32 by 32 min, 160 by 160 max         | 48 by 48                    |
| <b>Not shown</b> - Sign in logo | <code>--signin-logo</code> | 3000 by 3000 max                     |                             |

| Logo  | Option flag                 | Minimum size/Maximum size, in pixels | Recommended size, in pixels |
|---|-----------------------------|--------------------------------------|-----------------------------|
| Header logo/Sign in logo  | <code>--logo</code>         | 32 by 32 min, 160 by 160 max         | 48 by 48                    |
| <b>Not shown</b> - Logo shown when navigation pane is minimized | <code>--compact-logo</code> | 32 by 32 max                         | 32 by 32                    |

The image files you use should be in GIF, JPEG, or PNG format.

The background colors on the header and sign in page are not the same. If you use the same image for both locations (if you use the `--logo` option, for example) your logo might look different depending on where it appears in the server interface.

As part of your disaster recovery plan, we recommend keeping a backup of the customization image files in a safe location off of the Tableau Server. The image files that you add to Tableau Server will be stored and distributed to other nodes by the Client File Service. However, the files are not stored in a recoverable format. See Tableau Server Client File Service.

### Synopsis

```
tsm customize [options] [global options]
```

After you run the `customize` command, you must run the following command to apply changes:

```
tsm pending-changes apply
```

### Options

**Note:** Use the path and image file name cannot include any spaces.

## Tableau Server on Linux Administrator Guide

```
--compact-logo "<path-to-logo>"
```

Optional.

Specify a path to the image file that will be displayed when the navigation pane size is minimized. The maximum (and optimal) size is 32 by 32 pixels.

```
--header-logo "<path-to-logo>"
```

Optional.

Specify a path to the image file that will be displayed in the header only.

```
--logo "<path-to-logo>"
```

Optional.

Path to a single image file that will display for both the header and the sign-in window.

```
--restore-defaults
```

Optional.

Reset all customization options to default install state.

```
--server-name <server_name>
```

Optional.

Server name that appears in the browser tab, tooltips, and messages.

```
--signin-logo "<path-to-logo>"
```

Optional.

Specify a path to the image file that will be displayed for sign-in window only.

## Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm data-access

You can use the `tsm data-access` commands to configure data caching, enable or disable data repository access, enable SAML for single sign-on, and configure settings for Web Data Connectors (WDCs).

- caching
  - [data-access caching list](#)
  - [data-access caching set](#)
- repository
  - [repository-access disable](#)
  - [repository-access enable](#)
  - [repository-access list](#)
- set-saml-delegation
  - [set-saml-delegation configure](#)
  - [set-saml-delegation disable](#)
  - [set-saml-delegation enable](#)
- web-data-connectors
  - [web-data-connectors add](#)
  - [web-data-connectors allow](#)
  - [web-data-connectors delete](#)
  - [web-data-connectors list](#)

### tsm data-access caching list

Displays data connection caching settings. To learn more about data connection caching settings, see [Configure Data Cache](#).

#### Synopsis

```
tsm data-access caching list [global options]
```

## tsm data-access caching set

Sets data connection caching settings. To learn more about data connection caching settings, see [Configure Data Cache](#).

### Synopsis

```
tsm data-access caching set [options] [global options]
```

### Options

```
-r, --refresh-frequency
```

Optional.

Sets the frequency to refresh cached data with a new query to the underlying data source. You can specify a number to define the maximum number of minutes that data should be cached. You can also specify **low** to cache and reuse data for as long as possible, or **always** (equivalent to **0**) to refresh data each time that a page is loaded. If this option is not specified, it defaults to **low**.

## tsm data-access repository-access disable

Disable external access to the Tableau PostgreSQL database for the default remote user. This will not disable access from localhost.

### Synopsis

```
tsm data-access repository-access disable [options]
[global options]
```

### Options

```
--repository-username <username>
```

Required.

The username, either **tableau** or **readonly**, with access to the data repository.

## Tableau Server on Linux Administrator Guide

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 1500 (25 minutes).

```
--ignore-prompt
```

Optional.

Suppress the prompt for restart and restart Tableau Server.

### tsm data-access repository-access enable

Enables access to the Tableau PostgreSQL database.

By default, PostgreSQL traffic uses port 8060 (TCP). If you are running a local firewall, be sure to allow traffic for this port. To change the PostgreSQL port, see [Ports that are not dynamically mapped](#).

#### Synopsis

```
tsm data-access repository-access enable [options] [global options]
```

#### Options

```
--repository-password <password>
```

Required.

Sets (or changes) the password to access the data repository for the specified username.

```
--repository-username <username>
```

Required.

The username, either **tableau** or **readonly**, with access to the data repository.

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 1500 (25 minutes).

```
--ignore-prompt
```

Optional.

Suppress the prompt for restart and restart Tableau Server.

### **tsm data-access repository-access list**

Lists users who have access to the Tableau PostgreSQL database.

Synopsis

```
tsm data-access repository-access list [global options]
```

### **tsm data-access set-saml-delegation configure**

Setup single sign-on for SAML SAP HANA so that Tableau Server functions as an Identity Provider (IdP) that provides single sign-on for users making SAP HANA data connections.

Synopsis

```
tsm data-access set-saml-delegation configure [options]
[global options]
```

Options

```
-kf, --cert-key <cert-key>
```

Optional.

The SAML certificate key file.

## Tableau Server on Linux Administrator Guide

`-cf, --cert-file <file-path>`

Optional.

The location of the SAML certificate file.

`-uf, --username-format <username-format>`

Optional.

Username format. Valid format keys are: 'username', 'domain\_and\_username', and 'email'.

`-uc, --username-case <username-case>`

Optional.

Username case. Valid case keys are: 'lower', 'upper', and 'preserve'.

.

### **tsm data-access set-saml-delegation disable**

Disable single sign-on for SAML SAP HANA.

Synopsis

```
tsm data-access set-saml-delegation disable [global options]
```

### **tsm data-access set-saml-delegation enable**

Enable single sign-on for SAML SAP HANA.

Synopsis

```
tsm data-access set-saml-delegation enable [global options]
```

### **tsm data-access web-data-connectors add**

Add a web data connector (WDC) to the WDC safe list.

## Synopsis

```
tsm data-access web-data-connectors add [options] [global options]
```

## Options

```
-n, --name <name>
```

Required.

The name for the WDC that will be displayed in the Tableau Server data source list. This name must be enclosed in single quotes (') or double quotes ("). Use double quotes (") if the name includes a space.

```
-sec, --secondary <secondary-URL-1>, <secondary-URL-2>
```

Required if the WDC uses secondary domains.

A comma-delimited list of URLs that indicates which domains the connector can make requests to or receive data from, for example, external JavaScript libraries, REST APIs, or local files. Do not enclose the URLs in quotes. To add an entire domain to this secondary safe list, you can use a wildcard expression `.*` at the end of the URL, as shown in the following example: `https://www.example.com/*.*`

Note that on Windows, you could include parentheses (`.*`) around the wildcard, but it isn't necessary. On Linux, the parentheses will cause an error. Use `.*` as the wildcard.

If you don't know whether the WDC uses secondary domains, or what the secondary domains are, you might need to contact the WDC's developer. You can also choose to use `http://.*` and `https://.*` wildcard URLs to allow all domains. However, to increase security, we strongly recommend that you use more specific URLs.

```
--url <URL>
```

Required.

The URL for the WDC (formatted as `<scheme>://<host>:<port>/<path>`, for example `https://www.tableau.com:443/example/`). For many WDCs the

<port> value is 443, which is the default port used for HTTPS, but you can check the value for your connector by looking at the data source details on Tableau Server or Tableau Cloud. Note that you can't use a wildcard (. \*) as part of the URL for the WDC.

## tsm data-access web-data-connectors allow

Enable or disable WDC refreshes. Also, enable or disable the use of WDCs on Tableau Server.

### Synopsis

```
tsm data-access web-data-connectors allow [options] [global options]
```

### Options

Use one or both options. At least one of `--refreshes` or `--type` is required.

```
-r, --refreshes <refreshes-allowed>
```

Optional if `--type` is specified.

Set to `false` to disallow WDC refreshes or `true` to allow WDC refreshes.

```
-t, --type <WDC-allowed>
```

Optional if `--refreshes` is specified.

Set to `none` to disallow the use of WDCs on Tableau Server (and omit WDCs from backups) or `all` to allow the use of WDCs.

## tsm data-access web-data-connectors delete

Delete a specified WDC, or all WDCs, from the Tableau Server safe list.

### Synopsis

```
tsm data-access web-data-connectors delete [options]  
[global options]
```

## Options

`--all`

Optional.

This option will delete all WDCs.

`--url <URL>`

Optional.

The URL for the WDC to delete.

## **tsm data-access web-data-connectors list**

List all WDCs currently on the safe list.

### Synopsis

```
tsm data-access web-data-connectors list [options] [global options]
```

## Options

### Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

## Tableau Server on Linux Administrator Guide

```
--password 'my password'
```

```
-s, --server https://<hostname>:8850
```

### Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

```
--trust-admin-controller-cert
```

### Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

```
-u, --username <user>
```

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm email

Use the `tsm email` command to view and test your SMTP configuration.

For more information about configuring SMTP, see [Configure SMTP Setup](#).

### tsm email test-smtp-connection

Run this command to test the SMTP connection. When run, TSM will attempt to establish a connection with the SMTP server that you have configured for Tableau Server. TSM will also return a connection status and the details of the SMTP configuration.

In some cases, the command will return a false-positive status. For example, if your Postfix SMTP server is set to require TLS, but Tableau Server is not configured for TLS, the connection is established and TSM will report a successful connection. However, in this scenario, Postfix actually rejects the email message after TSM has connected.

## Synopsis

```
tsm email test-smtp-connection [global options]
```

## Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm initialize

You can use the `tsm initialize` command to initialize Tableau Server.

**Note:** You must apply or discard pending changes before running `tsm initialize` or the initialize will fail. Apply pending changes using the `tsm pending-changes apply` command. Discard any pending changes you do not want to apply using `tsm pending-changes discard`.

### Synopsis

```
tsm initialize [options] [global options]
```

### Options

`-r, --start-server`

Optional. Leave the server running after initialization is complete.

## Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm jobs

You can use the `tsm jobs` commands to list, reconnect to, and cancel jobs.

- `cancel`
- `list`
- `reconnect`

### tsm jobs cancel

Cancel a job on the server. Any job can be canceled before it starts running (when queued). Only certain jobs can be canceled when they are already running: Cleanup, Decommission File Store, Generate Backup, Restart Server, Start Server. For more information about canceling jobs, see [Cancel TSM Jobs](#).

#### Synopsis

```
tsm jobs cancel --id <jobID> [global options]
```

#### Options

```
-i, --id <jobID>
```

Required.

Id of the job to cancel.

### tsm jobs list

List asynchronous jobs on the server.

#### Synopsis

```
tsm jobs list [--status <status>] [global options]
```

## Options

`-t, --status <status>`

Optional.

Filter for jobs that match the given status.

## `tsm jobs reconnect`

Reconnect to an asynchronous job to display its progress. If no job id is specified, it reconnects to the latest job.

### Synopsis

```
tsm jobs reconnect[--id <jobID>] [global options]
```

## Options

`-i, --id <jobID>`

Optional.

Specifies the id of the job that should be reconnected.

## Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

## Tableau Server on Linux Administrator Guide

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

```
-s, --server https://<hostname>:8850
```

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

```
--trust-admin-controller-cert
```

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

```
-u, --username <user>
```

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm licenses

You can use the `tsm licenses` commands to manage server license tasks like activating or deactivating a Tableau Server product key on- or off-line, and getting associated files for offline activation or deactivation.

- `tsm licenses activate`
- `tsm licenses atr-configuration get`
- `tsm licenses atr-configuration set`

- `tsm licenses deactivate`
- `tsm licenses get-offline-activation-file`
- `tsm licenses get-offline-deactivation-file`
- `tsm licenses list`
- `tsm licenses refresh`

## tsm licenses activate

Activates a Tableau Server product key.

### Synopsis

```
tsm licenses activate --license-key <product-key> [global options]
```

### Options

```
-f, --license-file <file.tlf>
```

Required if doing offline activation.

Specifies the license file (<file>.tlf) used for offline activation.

```
-k, --license-key <product-key>
```

Required if activating a valid product key.

Specifies the product key to use for online activation.

```
-t, --trial
```

**Note:** This option is only available in versions earlier than 2023.3.0. For trial licensing with later versions, contact your account representative.

Required if activating a trial license.

Activate a trial license.

## **tsm licenses atr-configuration get**

View the Server authentication-to-run (ATR) duration. The ATR duration is the length of time that Tableau Server is authorized to run before the license must be renewed.

### **Synopsis**

```
tsm licenses atr-configuration get --duration [global options]
```

### **Options**

`--duration`

Displays the current authentication-to-run (ATR) in seconds. For example, 432000 (5 days).

## **tsm licenses atr-configuration set**

Set the Server authentication-to-run (ATR) duration. The ATR duration is the length of time that Tableau Server is authorized to run before the license must be renewed.

### **Synopsis**

```
tsm licenses atr-configuration set --duration <duration_in_seconds>  
[global options]
```

### **Options**

`--duration <duration_in_seconds>`

Sets the authorization-to-run (ATR) duration (in seconds). For example, 432000 (5 days).

## tsm licenses deactivate

Deactivates a Tableau Server product key either online or offline.

### Synopsis

```
tsm licenses deactivate --license-key <product-key>
[global options]
```

### Options

```
-f, --license-file <return_file.tlr>
```

Required if doing offline deactivation.

Specifies the license file (<file>.tlf) used for offline deactivation.

```
-k, --license-key <product-key>
```

Required if deactivating a product key.

Specifies the product key to use for online deactivation.

## tsm licenses get-offline-activation-file

Generate an offline activate file to use for activating Tableau Server offline. To learn more, see [Activate Tableau Server Offline](#).

**Note:** You can only activate one product key at a time unless you're using Server ATR. With Server ATR, you can provide a comma delimited list of product keys in the offline activation file to simultaneously activate multiple product keys.

### Synopsis

```
tsm licenses get-offline-activation-file --license-key <product-
key> --output-dir <path> [global options]
```

### Options

`-k, --license-key <product-key>`

**Required.**

Specifies the product key to use for offline activation.

`-o, --output-dir <path>`

**Required.**

The location where the offline activation file should be saved. This location must exist.

### **tsm licenses get-offline-deactivation-file**

Generate an offline deactivation file to use for deactivating Tableau Server offline. To learn more, see [Deactivate Tableau Server Offline](#).

### Synopsis

```
tsm licenses get-offline-deactivation-file --license-key <product-key> --output-dir <path> [global options]
```

### Options

`-k, --license-key <product-key>`

**Required.**

Specifies the product key to use for offline deactivation.

`-o, --output-dir <path>`

**Required.**

The existing location where the offline deactivation file should be saved.

## tsm licenses list

Lists licenses that are activated on the Tableau Server deployment.

For example, a server with five Creator licenses, five Explorer licenses, 100 Viewer licenses, and Data Management would provide command output similar to the following:

```

C:\Windows\system32>tsm licenses list
Number of product keys: 4
The following license keys will expire soon. Access renewal resources including information on how to renew your software or change your billing preferences here https://www.tableau.com/support/renew
TS90-06E2-8EF8-89EA-30EE  TS9R-3861-6888-8E5A-C79D  TS4D-176C-EB48-3418-5E45  TSQJ-6988-5CF8-F066-23AF
KEY      TYPE      CREATOR  EXPLORER  VIEWER  DATA MANAGEMENT ADD-ON  GUEST ACCESS LIC EXP  MAINT EXP  UPDATABLE  LBLN  SERVER MANAGEMENT ADD-ON
TS90-06E2-8EF8-89EA-30EE  Term      0         0        100    false                  false      11/30/20  N/A      false  false  false
TS9R-3861-6888-8E5A-C79D  Term      0         0         0      true                   false      11/30/20  N/A      false  false  false
TS4D-176C-EB48-3418-5E45  Term      0         5         0      false                  false      11/30/20  N/A      false  false  false
TSQJ-6988-5CF8-F066-23AF  Term      5         0         0      false                  false      11/30/20  N/A      false  false  false

```

The following fields are returned:

- **KEY:** A globally unique 16-character string that identifies the license.
- **TYPE:** Describes the type of license
  - Term: Term licenses map to a subscription schedule and must be renewed. The expiration date is listed under the LIC EXP field.
  - Perpetual: Perpetual licenses are purchased once and do not need to be renewed but must be refreshed to update the MAINT EXP or maintenance expiration date.
  - Cores: Core licenses are licenses that map to the number of cores on the computers running specific Tableau Server services. Core licensing allows for a guest user access to views on the server or embedded on other web servers. Core licenses also allow for unlimited Explorer and Viewer users.
- **CREATOR:** The number of Creator licenses issued to the Tableau Server deployment.
- **EXPLORER:** The number of Explorer licenses issued to the Tableau Server deployment.
- **VIEWER:** The number of Viewer licenses issued to the Tableau Server deployment.
- **DATA MANAGEMENT:** Tableau Server is licensed with Data Management (True/False). See About Data Management.
- **GUEST ACCESS:** Tableau Server is licensed for a Guest User. See Guest User. The ability to leverage a Guest User requires Core licensing. See TYPE field.
- **LIC EXP:** The date that the license expires and Tableau Server will stop working. Term licenses expire. See TYPE field. Visit the Tableau [Customer Portal](#) to refresh licenses.
- **MAINT EXP:** Applies only to legacy perpetual licenses (TYPE = Perpetual). For Term licenses, this field will output, N/A. MAINT EXP displays the date that the maintenance contract for the Tableau Server deployment expires. To update the license maintenance key see Refresh Expiration Date and Attributes for the Product Key. Visit the

Tableau [Customer Portal](#) to view maintenance purchase history and to purchase additional maintenance.

- **UPDATABLE:** Specifies whether the license is an updatable subscription license (`True/False`).
- **LBLM:** Specifies if login-based license management (LBLM) is enabled for the Tableau Server deployment (`True/False`). When enabled, LBLM allows users to log into Tableau Server to license their instance of Tableau Desktop or Prep, rather than entering a product key. For more information about LBLM, see [Login-based License Management](#).
- **SERVER MANAGEMENT:** Tableau Server is licensed for Advanced Management (formerly Server Management Add-on) (`True/False`). For more information about Advanced Management, see [About Tableau Advanced Management on Tableau Server](#).

### Synopsis

```
tsm licenses list [global options]
```

## tsm licenses refresh

Update the maintenance expiration date of all product keys on Tableau Server.

### Synopsis

```
tsm licenses refresh [global options]
```

## Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

```
-s, --server https://<hostname>:8850
```

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

```
--trust-admin-controller-cert
```

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

```
-u, --username <user>
```

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm login

Use the `tsm login` command to log in to Tableau Services Manager from a remote node.

If the account you are logged in as is a member of the TSM-authorized group, you do not need to provide credentials to run commands when running `tsm` CLI locally. For more information, see [Authenticating with tsm CLI](#).

## Synopsis

```
tsm login [global options]
```

## Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm logout

You can use the `tsm logout` command to log out of Tableau Services Manager (TSM).

### Synopsis

```
tsm logout [global options]
```

### Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

## Tableau Server on Linux Administrator Guide

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port 8850, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm maintenance

You can use the `tsm maintenance` commands to manage server maintenance tasks like creating backups or restoring Tableau Server from a previously created backup.

- `tsm maintenance backup`
- `tsm maintenance cleanup`
- `tsm maintenance jmx`
  - `tsm maintenance jmx disable`
  - `tsm maintenance jmx enable`
- `tsm maintenance metadata-services`
  - `tsm maintenance metadata-services disable`
  - `tsm maintenance metadata-services enable`
  - `tsm maintenance metadata-services get-status`
- `tsm maintenance reindex-search`

- `tsm maintenance reset-searchserver`
- `tsm maintenance restore`
- `tsm maintenance send-logs`
- `tsm maintenance snapshot-backup` (external file store)
  - `tsm maintenance snapshot-backup complete`
  - `tsm maintenance snapshot-backup prepare`
  - `tsm maintenance snapshot-backup restore`
- `tsm maintenance validate-backup-basefilepath`
- `tsm maintenance validate-resources`
- `tsm maintenance ziplogs`

## tsm maintenance backup

Creates a backup of the data managed by Tableau Server. This data includes the Tableau PostgreSQL database (the repository) which contains workbook and user metadata, and extract (.hyper files, and .tde files for versions 2024.2 and older) files. This data does not include configuration data. See [Perform a Full Backup and Restore of Tableau Server](#).

**Note:** Do not use this command on Tableau Server installations with External File Store. See [Backup and Restore with External File Store](#).

### Optimizing with topology configurations:

- Co-locating File Store on the same node as the Administration Controller can reduce the length of time it takes to back up Tableau Server by reducing or eliminating the need to transfer data between nodes during the backup process. This is especially true if your organization uses many extracts.
- Co-locating the repository (pgsql) with the Administration Controller node can also help to reduce back up time, but the time savings is less significant than that of the File Store.

## Tableau Server on Linux Administrator Guide

The Administration Controller is usually on the initial node, unless you have had an initial node failure and moved the controller to another node.

The backup file is assembled in a temporary location in the data directory and then written to the directory defined in the TSM `basefilepath.backuprestore` variable:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/backups/<file-name>.tsbak
```

For more information about where backup files are written, and how to change that location, see [tsm File Paths](#). **Note:** Even when you change the backup location, the backup process uses a temporary location in the data directory to assemble the backup file.

### Synopsis

```
tsm maintenance backup --file <backup_file> [options]
[global options]
```

### Options

`-f, --file <backup_file>`

Required.

For more information about backing up the repository data, see [Back up Tableau Server Data](#) for more information.

`-d, --append-date`

Optional.

Append the current date to the end of the backup file name.

**Note:** Backups created using a schedule automatically include a date/time at the beginning of the backup file name. If you also use the `-d` option your file name will include the

date twice. For more information about scheduling backups, see [Scheduling and Managing Backups](#).

`-i, --description <string>`

Optional.

Include the specified description of the backup file.

`--ignore-prompt`

Optional. Added in version 2020.2.

Back up without prompting, even if the File Store is not on the same node as the Administration Controller (usually the initial node). Use this prompt if automating backups (for example, with scripts).

`-k, --skip-verification`

Optional.

Do not verify the integrity of the database backup.

`--multithreaded`

Optional. Added in version 2021.1

By default, a single thread is used when creating a Tableau Server backup. When this option is specified, a backup is created using multiple threads. Two threads are used by default, when this option is specified. You can change the number of threads used by setting the `backup.zstd.thread_count` configuration key.

`--override-disk-space-check`

Optional.

Attempt to create a backup even when there is a low disk space warning.

## Tableau Server on Linux Administrator Guide

`-po, --pg-only`

Optional.

Generates only the repository backup.

`--request-timeout <timeout in seconds>`

Optional.

Number of seconds to wait for the command to finish. Default value is 86400 (1440 minutes).

`-sd, --schedule-days <day[,day]>`

Optional. Added in version 2020.4.

Days on which to run the schedule. Use 1-7 for weekly schedule (1 for Monday, 7 for Sunday), 1-31 for monthly schedules (if a month does not include the specified day, the last day of the month is used). Separate multiple values with commas.

`-si, --schedule-id <ID>`

Optional. Added in version 2020.4.

Specify the ID of an existing schedule you want to update.

`--skip-compression`

Optional.

Create a backup without using compression. This results in a larger backup file but can reduce the amount of time it takes to complete the backup. If using this in a multi-node installation, we strongly recommend you have a File Store instance configured on your initial node.

`-sn, --schedule-name <name>`

Optional. Added in version 2020.4.

Specify the name for a schedule you are creating or updating.

```
-sr, --schedule-recurrence <frequency>
```

Optional. Added in version 2020.4.

Frequency of schedule recurrence. Valid options are "daily", "weekly", or "monthly".

```
-st, --schedule-time <HH:MM>
```

Optional. Added in version 2020.4.

The time a schedule should be run, in 24-hour format: HH:MM.

## Examples

This example creates a backup called `ts_backup-<yyyy-mm-dd>.tsbak` in the `/var/opt/tableau/tableau_server/data/tabsvc/files/backups/` directory:

```
tsm maintenance backup -f ts_backup -d
```

This example creates a recurring weekly backup schedule named "weekly-saturday-backup" that runs every Saturday at noon and creates a backup called `<yyyy.mm.dd.hh.mm>-ts_saturday_backup.tsbak`:

```
tsm maintenance backup -f ts_saturday_backup -sr weekly -st 12:00 -sd 6 -sn weekly-saturday-backup
```

For more details on managing scheduled backups, see [Scheduling and Managing Backups](#).

## tsm maintenance cleanup

By default the `tsm maintenance cleanup` command deletes temporary files and log files older than one day. Command options can modify retention length and which files are deleted.

The impact of this command depends on whether Tableau Server is running.

## Tableau Server on Linux Administrator Guide

- If the server is running, most old files and `http_requests` table entries can be deleted, but any files in use (locked by the operating system) cannot be deleted, so temporary files and active log files are not removed. To delete temporary files and current log files, you must stop the server before running this command. To delete `http_requests` table entries, use the `-q` option.
- If the server is stopped `http_requests` entries cannot be deleted.

If you are running Tableau Server on a distributed deployment, run this command on the node that is running the Administration Controller (also referred to as the *TSM Controller*) process. By default and in most cases, the controller is on the initial node in the cluster.

**Note:** This command was added in Tableau Server version 10.5.1 and some options were added in version 2018.1.

### Synopsis

```
tsm maintenance cleanup [options] [global options]
```

### Options

`-a, --all`

Optional.

Perform all cleanup operations with default retention values. Equivalent to running the `cleanup` command with the following options: `-l -t -r -q -ic`.

```
--http-requests-table-retention <# of days>
```

Optional.

Default: 7 days

Specify the number of days of `http_requests` table entries that should be retained. Use this option with the `-q` option to specify the number of days of table entries to

retain, overriding the default of 7 days. This option specifies table entry retention age but does not trigger actual deletion of table entries. Use this together with the `-q` option, which triggers deletion of entries.

`-ic, --sheet-image-cache`

Optional. Added in version 2019.4.

Clear the image cache. This cache can contain images for offline previews, snapshots for subscription email messages, and subscription pdfs, as well as any images requested from the publish rest API endpoint (see [rest\\_api\\_ref.htm](#) for more information).

`-l, --log-files`

Optional.

Delete log files that are older than 1 day. Files in the subdirectories under `data/t-absvc/logs` will be deleted.

`--log-files-retention <# of days>`

Optional.

Default: 1 (24 hours)

Delete logs older than this number of days. Use this to override the default retention period of 1 day. This command does not apply to temporary files.

`-q, --http-requests-table`

Optional.

Delete old `http_requests` table entries. Tableau Server must be running for table entries to be deleted. This option is ignored if Tableau Server is stopped. This option can be used alone to specify deletion of entries older than the default retention period (7 days), or together with the `--http-requests-table-retention` to specify a non-default retention period.

## Tableau Server on Linux Administrator Guide

**Note:** Deleting `http_requests` table entries permanently removes data that is available to custom administrative views. Be sure removing this data will not impact any custom views you need.

`-r, --redis-cache`

Optional.

Clear the Redis cache.

`--request-timeout <timeout in seconds>`

Optional.

Default: 3600

Wait the specified amount of time for the command to finish.

`-t, --temp-files`

Optional.

Delete all files and subdirectories in the following directories:

- `/var/opt/tableau/tableau_server/data/tabsvc/temp`: To delete files under each Tableau Server process directory, you must stop Tableau Server before running the command. If you execute the command while Tableau Server is running, only directories storing files for expired (not running) sessions are deleted.
- `/var/opt/tableau/tableau_server/data/tabsvc/httpd/temp`
- `/var/opt/tableau/tableau_server/temp`

### Examples

This example cleans up all log files older than 2 days old:

```
tsm maintenance cleanup -l --log-files-retention 2
```

## tsm maintenance jmx disable

**Version:** Command added in version 2022.1.

Use the `tsm maintenance jmx disable` command to disable JMX on Tableau Server.

Running this command requires a restart of Tableau Server, including TSM services.

### Synopsis

```
tsm maintenance jmx disable [options] [global options]
```

### Options

```
--ignore-prompt
```

Optional.

Disable JMX without prompting.

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish.

## tsm maintenance jmx enable

**Version:** Command added in version 2022.1.

Use the `tsm maintenance jmx enable` command to enable JMX on Tableau Server.

This command is interactive, prompting you for applicable options if you don't provide them as command line parameters.

This command requires a restart of Tableau Server, including TSM services.

### Synopsis

```
tsm maintenance jmx enable
```

## Options

`--access <readonly | readwrite>`

Optional.

Enable JMX with either `readonly` or `readwrite` access. Default is `readonly`.

`--ignore-prompt`

Optional.

Enable JMX without prompting for additional security options. This enables JMX with SSL and restarts Tableau Server if you do not include any other command options. For example:

```
tsm maintenance jmx enable --ignore-prompt
```

`--no-ssl`

Optional.

Enable JMX without SSL.

`--request-timeout <timeout in seconds>`

Optional.

Wait the specified amount of time for the command to finish.

`--ssl-client-auth`

Optional.

Enable JMX requiring client auth for SSL.

`--unsecured`

Optional.

Enable JMX with no security features enabled (this is not recommended). This is the equivalent of setting the `service.jmx_enabled` configuration key to `true` in pre-2022.1 versions.

## tsm maintenance metadata-services disable

**Version:** Command added in version 2019.3.

Use the `tsm maintenance metadata-services disable` command to disable the Tableau Metadata API.

Disabling the Metadata API stops continuous ingestion and indexing of information about the content on Tableau Server, deletes the index of information about the content published to Tableau Server and assets associated with that content, and disables the ability to both query the Metadata API and access Tableau Catalog.

Running this command stops and starts some services used by Tableau Server, which causes certain functionality, such as Recommendations, to be temporarily unavailable to your users.

### Synopsis

```
tsm maintenance metadata-services disable
```

### Option

```
--ignore-prompt
```

Optional.

Dismiss the confirmation prompt when disabling the Metadata API.

## tsm maintenance metadata-services enable

**Version:** Command added in version 2019.3.

Use the `tsm maintenance metadata-services enable` command to enable the Tableau Metadata API for Tableau Server.

## Tableau Server on Linux Administrator Guide

If Tableau Server is licensed with the Data Management, enabling the Metadata API enables Tableau Catalog.

When enabling the Metadata API, information about the content on Tableau Server is ingested and then indexed to the Metadata API Store. The Metadata API can be used to query schema, lineage, and user managed metadata about the content published to Tableau Server. After the Metadata API is enabled, metadata is continuously ingested and indexed until the Metadata API is disabled.

When running this command, keep the following in mind:

- This command stops and starts some services used by Tableau Server, which causes certain functionality, such as Recommendations, to be temporarily unavailable to your users.
- A new index of metadata is created and replaces the previous index every time this command is used.

For more information about the Tableau Catalog, see, [About Tableau Catalog](#).

### Synopsis

```
tsm maintenance metadata-services enable
```

### Option

```
--ignore-prompt
```

Optional.

Dismiss the confirmation prompt when enabling the Metadata API.

### **tsm maintenance metadata-services get-status**

**Version:** Command added in version 2019.3.

Use the `tsm maintenance metadata-services get-status` command to get status information on Metadata Services.

Status on Metadata Services indicates if the Metadata API Store has been initialized or if the Tableau Metadata API is running or not.

### Synopsis

```
tsm maintenance metadata-services get-status
```

## tsm maintenance reindex-search

Use the `tsm maintenance reindex-search` command to rebuild the search index.

### Synopsis

```
tsm maintenance reindex-search [options] [global options]
```

### Option

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish.

## tsm maintenance reset-searchserver

**Version:** This command was retired (removed) in 2023.3.0 when Search and Browse (also called Search Server) was retired. Search and Browse has been replaced by Index and Search Server.

**Note:** Running this command on version 2023.3.0 or later will not do anything.

Resets the search server to a clean state, deleting search information and rebuilding the search index.

### Synopsis

```
tsm maintenance reset-searchserver [options] [global options]
```

### Option

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish.

## tsm maintenance restore

Restore Tableau Server using the specified backup file. Restoring a backup file does not restore any configuration data. See [Perform a Full Backup and Restore of Tableau Server](#).

You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.

Beginning with version 2022.3, backups created using `tabadmin` ("pre-TSM backups") are not supported. You cannot restore a pre-TSM backup to Tableau Server version 2022.3 or later.

### Synopsis

```
tsm maintenance restore --file <file_name> [--restart-server]
[global options]
```

### Options

```
-f, --file <file_name>
```

Required.

Specifies the backup file to restore from.

The `restore` command expects a backup file in the directory defined in the TSM `basefilepath.backuprestore` variable. By default:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/backups/
```

For more information about file paths and how to change them, see [tsm File Paths](#).

`-ak, --asset-key-file <file_name>`

Optional. Deprecated in version 2021.4.0.

Specify this option only if you are restoring from assets that were created by `tabadmin` on Tableau Server (versions 2018.1 and earlier).

Name of asset key file to restore from. The asset key file is created by the `tabadmin assetkeys` command. The file must be in the predefined backup/restore location on the server.

`-k, --skip-identity-store-verification`

Optional. Specify this option only if you are restoring from a backup file that was created by `tabadmin` on Tableau Server (versions 2018.1 and earlier).

Do not use this key in an attempt to change identity store type from Tableau Server that created original backup file. To change the identity store, see [Changing the Identity Store](#).

`-po, --pg-only`

Optional.

Restores only the repository.

`-r, --restart-server`

Optional.

Restart the server after the restore.

`--request-timeout <timeout in seconds>`

Optional.

Wait the specified amount of time for the command to finish.

## tsm maintenance send-logs

Upload the specified file to Tableau and associate it with a support case. To successfully upload files to Tableau, your Tableau Server must be able to communicate with the send-logs server at <https://report-issue.tableau.com>.

### Synopsis

```
tsm maintenance send-logs --case <case_number> --email <contact_email> --file <path/to/file> [global options]
```

### Options

`-c, --case <case_number>`

Required.

Support case number.

`-e, --email <contact_email>`

Required.

Contact email.

`-f, --file <path/to/file>`

Required.

Specifies the location and name of the log file archive to send.

`--request-timeout <timeout in seconds>`

Optional.

Wait the specified amount of time for the command to finish.

## tsm maintenance snapshot-backup complete

**Version:** Command added in version 2020.1 and only available when Tableau Server is configured for External File Store.

Complete the snapshot backup process on Tableau Server. Run this after you have taken a snapshot backup of your external storage.

The *tsm maintenance snapshot-backup prepare* and the *tsm maintenace snapshot-backup complete* commands are used to create a backup of Tableau Server data for Tableau Server installations that are configured with External File Store. For more information, see [Backup and Restore with External File Store](#)

### Synopsis

```
tsm maintenance snapshot-backup complete [options] [global options]
```

### Options

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish.

## tsm maintenance snapshot-backup prepare

**Version:** Command added in version 2020.1 and only available when Tableau Server is configured for External File Store.

Prepares for snapshot backup. Once the preparation step is complete, you may take a snapshot backup of your network storage.

The *tsm maintenance snapshot-backup prepare* and the *tsm maintenace snapshot-backup complete* commands are used to create a backup of Tableau Server data for Tableau Server installations that are configured with External File Store. For more information, see [Backup and Restore with External File Store](#)

## Tableau Server on Linux Administrator Guide

### Synopsis

```
tsm maintenance snapshot-backup prepare [options] [global options]
```

### Options

```
--include-pg-backup
```

Optional. Added in version 2021.1. Prior versions always included a backup of the External Repository.

Optional.

A backup of the Repository is made and copied to the network share. This is only applicable to deployments where both External Repository and External File Store are configured. For more information, see Backup and Restore with External File Store.

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish.

### tsm maintenance snapshot-backup restore

**Version:** Command added in version 2020.1 and only available when Tableau Server is configured for External File Store.

Restores the repository backup from the storage snapshot to Tableau Server.

For more information, see Backup and Restore with External File Store.

### Synopsis

```
tsm maintenance snapshot-backup restore [options] [global options]
```

## Options

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish.

## tsm maintenance validate-backup-basefilepath

**Version:** Command added in version 2022.1.

Validate that the backup/restore base filepath location has correct permissions to allow backup and restore functions to work properly. Run this after setting the basefilepath for backup and restore. For more information, see [Change the current file location](#) .

## Synopsis

```
tsm maintenance validate-backup-basefilepath [options]
[global options]
```

## Options

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish.

## tsm maintenance validate-resources

Validate workbooks and data sources for a site. Use this command before migrating a site, to detect issues with site resources such as workbooks and data sources that will cause a site import to fail. Some resource problems can be corrected by republishing from local sources. Other problems might require assistance from Tableau Support.

## Tableau Server on Linux Administrator Guide

### Synopsis

```
tsm maintenance validate-resources --site-id <site ID>  
[global options]
```

### Options

```
-id,--site-id <site ID>
```

**Required.**

ID for the site whose resources you are validating.

```
-r,--repair
```

**Optional.**

Attempt to repair invalid resources. Those that cannot be repaired are noted in output.

```
--request-timeout <timeout in seconds>
```

**Optional.**

Wait the specified amount of time for the command to finish.

## tsm maintenance ziplogs

Use the `ziplogs` command to create an archive of Tableau Server log files.

**Note:** If you cannot run the `ziplogs` command successfully, you can manually zip the Tableau Server logs. For more information, see [Troubleshoot Tableau Server on Linux](#).

### Synopsis

```
tsm maintenance ziplogs [options] [global options]
```

## Options

`-a, --all`

Optional.

Include all files except PostgreSQL data.

`-d, --with-postgresql-data`

Optional.

Include the PostgreSQL data folder if Tableau Server is stopped or PostgreSQL dump files if Tableau Server is running. This flag is ignored for deployments running with a Tableau Server External Repository.

`--enddate "<mm/dd/yyyy H:mm>"`

Optional. Time option (H:mm) added in version 2021.4.0.

The last date of log files to be included. This option must be used with `--startdate` and cannot be used with `--minimumdate`. If this option is not specified, up to two days of logs will be included, starting at 00:00 GMT.

If you include the time option you must use quotes around date and time. The time option uses GMT, however, the resulting log files will be written using the local time zone of the Tableau Server machine.

Example: If the local time zone of the Tableau Server machine is PDT and you want the log files to begin at 7am PDT and end at 7pm PDT on 07/28/2022, use the following:

```
tsm maintenance ziplogs -f logs.zip --startdate "07/28/2022
14:00" --enddate "07/29/2022 02:00"
```

`-f, --file <name>`

Optional.

## Tableau Server on Linux Administrator Guide

Specify a name for the zipped archive file. If no name is provided the archive is created as `logs.zip`. The file is written to the directory defined in the TSM `basefilepath.log_archive` variable. By default:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/log-archives/
```

For more information about file paths and how to change them, see [tsm File Paths](#).

`-i, --description <string>`

Optional.

Include the specified description of the archive file.

`-l, --with-latest-dump`

Optional.

When any service crashes, Tableau Server generates a dumpfile. Set this option to include the most recent service crash dumpfile. If you do not set this option, then no dumpfile will be included in the resulting ziplog.

`-m, --minimumdate <mm/dd/yyyy>`

Optional.

Earliest date of log files to be included. If not specified, a maximum of two days of log files are included. Format of date should be "`mm/dd/yyyy`". This option cannot be used with `--startdate` and `--enddate` or `--all`.

`--nodes`

Optional. Added in version 2020.3.

Specify the nodes for which to create a ziplog file. If not specified, ziplog files are created for all nodes and saved to the initial node. Separate nodes with a comma. For example, to gather logs for nodes 2 and 4:

```
tsm maintenance ziplogs --nodes node2,node4
```

`-o, --overwrite`

Optional.

For an overwrite of an existing ziplog file. If a file by the same name already exists and this option is not used, the ziplogs command will fail.

By default the file is written to:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/log-archives/
```

For more information about file paths and how to change them, see [tsm File Paths](#).

`--request-timeout <seconds>`

Optional.

Number of seconds to wait for the command to finish. Default value is 7200 (120 minutes).

`--startdate "<mm/dd/yyyy H:mm>"`

Optional. Time option (H:mm) added in version 2021.4.0.

The last date of log files to be included. This option must be used with `--enddate` and cannot be used with `--minimumdate`. If this option is not specified, up to two days of logs will be included, starting at 00:00 GMT.

If you include the time option you must use quotes around date and time. The time option uses GMT, however, the resulting log files will be written using the local time zone of the Tableau Server machine.

Example: If the local time zone of the Tableau Server machine is PDT and you want the log files to begin at 7am PDT and end at 7pm PDT on 07/28/2022, use the following:

## Tableau Server on Linux Administrator Guide

```
tsm maintenance ziplogs -f logs.zip --startdate "07/28/2022
14:00" --enddate "07/29/2022 02:00"
```

### Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm pending-changes

Use the `tsm pending-changes` commands to apply, discard, or view pending configuration and topology changes to Tableau Server.

Passwords and secrets that you enter during TSM configuration are encrypted after you save them. Secrets remain encrypted until, during, and after you apply pending changes. For more information about secret storage, see [Manage Server Secrets](#).

- `tsm pending-changes apply`
- `tsm pending-changes discard`
- `tsm pending-changes list`

### tsm pending-changes apply

Use the `tsm pending-changes apply` command to apply pending configuration and topology changes to Tableau Server.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt.

#### Synopsis

```
tsm pending-changes apply [global options]
```

## Options

`-iw, --ignore-warnings`

Optional.

Ignore warning level constraints.

`--ignore-prompt`

Optional.

Suppress the prompt for restart. This only suppresses the prompt. The restart behavior is unchanged.

`--request-timeout <timeout in seconds>`

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

## **tsm pending-changes discard**

Use the `tsm pending-changes discard` command to discard pending configuration and topology changes to Tableau Server.

### Synopsis

```
tsm pending-changes discard [options] [global options]
```

## Options

`--config-only`

Optional.

Discard only pending configuration changes.

`--topology-only`

Optional.

Discard only pending topology changes.

## **tsm pending-changes list**

Lists pending configuration and topology changes to Tableau Server. Any changes that do not require a server restart will be listed as not requiring a restart. If none of the pending changes require a restart, a message displays saying the changes do not require a server restart. If any change in the list requires a restart, the entire list of pending changes will result in a restart. For more information on dynamic configuration or topology changes, see Tableau Server Dynamic Topology Changes.

### **Synopsis**

```
tsm pending-changes list [options] [global options]
```

### **Options**

`--config-only`

Optional.

List only pending configuration changes.

`--topology-only`

Optional.

List only pending topology changes.

### **Global options**

`-h, --help`

Optional.

## Tableau Server on Linux Administrator Guide

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm register

You can use the `tsm register` command to register Tableau Server. This command lets you either display the registration file template (using the `--template` option) or provide the path to a completed registration file (using the `--file` option). You must use one of these two options when calling the `tsm register` command.

### Synopsis

```
tsm register --template | --file <registration-filename>  
[global options]
```

### Options

```
--file <registration-filename>
```

Required.

Path to the file that contains the registration data.

```
--template
```

Required.

Display registration filetemplate.

### Global options

```
-h, --help
```

Optional.

Show the command help.

```
-p, --password <password>
```

Required, along with `-u` or `--username` if no session is active.

## Tableau Server on Linux Administrator Guide

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

```
-s, --server https://<hostname>:8850
```

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

```
--trust-admin-controller-cert
```

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

```
-u, --username <user>
```

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm reset

Use the `tsm reset` command to clear the initial admin user so that you can enter a new one. After you run `tsm reset` you must rerun the `tabcmd initialuser` command to create a new initial admin. The new name cannot be the same username as the previous admin user.

If your organization is using Active Directory or LDAP for the Tableau identity store, then the account and password you specify must match an account in the directory.

## Synopsis

```
tsm reset[option] [global options]
```

## Option

```
-d, --delete-all-sessions
```

Optional.

Delete all active user sessions when the server is reset.

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

## Global options

```
-h, --help
```

Optional.

Show the command help.

```
-p, --password <password>
```

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

```
-s, --server https://<hostname>:8850
```

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port 8850, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm restart

You can use the `tsm restart` command to restart Tableau Server. The command stops the server if necessary, and then starts it.

### Synopsis

```
tsm restart [global options]
```

### Option

`--request-timeout <timeout in seconds>`

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

## Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm schedules

**Note:** These commands only apply to backup jobs scheduled using the `tsm maintenance backup` command. They do not apply to jobs run by the backgrounder (ex: extract refreshes, flows, subscriptions).

You can use the `tsm schedules` commands to manage scheduled backup jobs. To create a scheduled backup job, use the `tsm maintenance backup` command. For details, see [tsm maintenance backup](#). For more details on managing scheduled backups, see [Scheduling and Managing Backups](#).

- `tsm schedules delete`
- `tsm schedules list`
- `tsm schedules resume`
- `tsm schedules suspend`
- `tsm schedules update`

### tsm schedules delete

Delete the specified schedule.

#### Synopsis

```
tsm schedules delete [-si <scheduleID> | -sn <scheduleName>]  
[global options]
```

## Options

`-si, --schedule-id <scheduleID>`

Required if `--schedule-name` is not used.

Id of the schedule to delete.

`-sn, --schedule-name <scheduleName>`

Required if `--schedule-id` is not used.

Name of the schedule to delete.

**tsm schedules list**

List schedules on the server.

## Synopsis

```
tsm schedules list [--next-run | --schedule-id <scheduleID> | --
schedule-name <scheduleName>] [global options]
```

## Options

`-nr, --next-run`

Optional.

Sort the schedules by their "next run" time, earliest to latest.

`-si, --schedule-id <scheduleID>`

Optional.

Id of the schedule to list the details of.

## Tableau Server on Linux Administrator Guide

`-sn, --schedule-name <scheduleName>`

Optional.

Sort the schedules by their names, in alphabetical order.

### **tsm schedules resume**

Resume the specified suspended schedule.

#### Synopsis

```
tsm schedules resume [-si <scheduleID> | -sn <scheduleName>]  
[global options]
```

#### Options

`-si, --schedule-id <scheduleID>`

Required if `--schedule-name` is not used.

Id of the schedule to resume.

`-sn, --schedule-name <scheduleName>`

Required if `--schedule-id` is not used.

Name of the schedule to resume.

### **tsm schedules suspend**

Suspend the specified schedule.

#### Synopsis

```
tsm schedules suspend [-si <scheduleID> | -sn <scheduleName>]  
[global options]
```

## Options

`-si, --schedule-id <scheduleID>`

Required if `--schedule-name` is not used.

Id of the schedule to suspend.

`-sn, --schedule-name <scheduleName>`

Required if `--schedule-id` is not used.

Name of the schedule to suspend.

## tsm schedules update

Update the specified schedule.

### Synopsis

```
tsm schedules update[-si <scheduleID> -st <time_to_run> -sr <recurrence_frequency> -sd <day-or-days>] [global options]
```

## Options

`-si, --schedule-id <scheduleID>`

Required.

Id of the schedule to update.

`-sr, --schedule-recurrence <frequency>`

Required.

Recurrence frequency of the schedule. Valid options are "daily", "weekly", or "monthly".

## Tableau Server on Linux Administrator Guide

`-st, --schedule-time <HH:MM>`

Required.

The time a schedule should be run, in 24-hour format: HH:MM.

`-sd, --schedule-days <day[,day]>`

Optional.

Days on which to run the schedule. For weekly schedules, use 1-7 where 1 is Monday, and 7 is Sunday. For monthly schedules, use 1-31. If a day doesn't exist for a specific month (30 for February, for example) the last valid day of the month is used. Separate multiple values with commas.

## Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port 8850, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm security

Use the `tsm security` commands to configure Tableau Server support for external (gateway) SSL or repository (Postgres) SSL. Repository SSL configuration includes the option to enable SSL over direct connections from Tableau clients—including Tableau Desktop, Tableau Mobile, and web browsers—to the repository.

  - `tsm security repository-ssl enable`
  - `tsm security repository-ssl get-certificate-file`
  - `tsm security repository-ssl list`
- `tsm security rotate-coordination-service-secrets`
- As of the 2020.2 release, to configure Rserve and TabPy analytics extensions, use the Tableau Server admin pages. See [Configure Connections with Analytics Extensions](#).

### Prerequisites

Before you configure SSL, you must acquire certificates, and then copy them to the computer that runs the Tableau Server gateway process. Additional preparation is required for enabling direct connections from clients. To learn more, see the following articles:

Configure SSL for External HTTP Traffic to and from Tableau Server

Configure SSL for Internal Postgres Communication

For information about mutual (two-way) SSL, see [Configure Mutual SSL Authentication and `tsm authentication mutual-ssl` commands](#).

## tsm security authorize-credential-migration

Authorizes a Tableau user to migrate embedded credentials from a Tableau Server installation to a Tableau Cloud site using Content Migration Tool. Both Tableau Server and Tableau Cloud must have an Advanced Management license to migrate content. For more information, see [Migrate Workbooks and Data Sources with Embedded Credentials](#).

You can cancel authorization using the `tsm security cancel-credential-migrations` command.

### Synopsis

```
tsm security authorize-credential-migration --source-site-url-namespace <Tableau Server site ID> --destination-site-url-namespace <Tableau Cloud site ID> --destination-server-url <Tableau Cloud site url> --authorized-migration-runner <username> --destination-public-encryption-key <public key>
```

### Options

`--source-site-url-namespace`

Required. Site ID of the Tableau Server site. The site ID is used in the URL to uniquely identify the site.

For example, a site named West Coast Sales might have a site ID of west-coast-sales.

`--destination-site-url-namespace`

## Tableau Server on Linux Administrator Guide

Required. Site ID of the Tableau Cloud site. The site ID is used in the URL to uniquely identify the site.

`--destination-server-url`

Required. URL of the pod that your Tableau Cloud site is deployed to. The URL you specify must include a trailing slash (/).

Your pod is shown in the first portion of the site URL after signing in to Tableau Cloud. For example, `https://10az.online.tableau.com/` is the United States - West (10AZ) pod. For more information about pods, see the [Salesforce Trust](#) page.

`--authorized-migration-runner`

Required. Username of the Tableau Server user authorized to migrate embedded credentials.

`--destination-public-encryption-key`

Required. Specify the public key generated on the Tableau Cloud site.

`--expiration-time-in-days`

Optional. Number of days before authorization expires. Default value is 7 days.

**Version:** Retired in version 2023.1. Beginning in 2023.1.0 this option is no longer valid and will generate an error if used. The expiration value is hard-coded as 7 days.

### Example

The following example authorizes user “admin” to migrate workbooks and published data sources with embedded credentials from Tableau Server site “ExampleA” to Tableau Cloud site “ExampleB”. The authorization will expire in 9 days.

```
tsm security authorize-credential-migration --source-site-url-namespace ExampleA --destination-site-url-namespace ExampleB --destinationServerUrl https://10ay.online.tableau.com/ --authorized-
```

```
migration-runner admin --destination-public-encryption-key <public  
key> --expiration-time-in-days 9
```

## tsm security cancel-credential-migrations

Cancels granted authorizations for migrating embedded credentials using Content Migration Tool. For more information, see [Migrating Workbooks and Data Sources with Embedded Credentials](#).

### Synopsis

```
tsm security cancel-credential-migrations --source-site-url-  
namespace <Tableau Server site ID>
```

### Options

`--source-site-url-namespace`

Required. Site ID of the Tableau Server site. The site ID is used in the URL to uniquely identify the site.

For example, a site named West Coast Sales might have a site ID of west-coast-sales.

## tsm security custom-cert add

Adds a custom CA certificate to Tableau Server. This certificate is optionally used to establish trust for TLS communication between a SMTP server and Tableau Server.

If a custom certificate already exists, this command will fail. You can remove the existing custom certificate using the `tsm security custom-cert delete` command.

**Note:** The certificate that you add with this command may be used by other Tableau Server services for TLS connections.

As part of your disaster recovery plan, we recommend keeping a backup of the certificate file in a safe location off of the Tableau Server. The certificate file that you add to Tableau Server

will be stored and distributed to other nodes by the Client File Service. However, the file is not stored in a recoverable format. See [Tableau Server Client File Service](#).

### Synopsis

```
tsm security custom-cert add --cert-file <file.crt> [global options]
```

### Options

```
-c, --cert-file <file.crt>
```

Required. Specify the name of a certificate file in valid PEM or DER format.

## tsm security custom-cert delete

Removes the server's existing custom certificate. Doing this allows you to add a new custom certificate.

### Synopsis

```
tsm security custom-cert delete[global options]
```

## tsm security custom-cert list

List details of custom certificate.

### Synopsis

```
tsm security custom-cert list[global options]
```

## tsm security custom-indexandsearch-ssl add

Add custom certificates for Index and Search Server for Tableau Server 2023.1 and newer. The SSL implementation is based on [Opensearch.org](#) TLS implementation. See [Configuring TLS certificates](#) for more information.

`--admin <file.crt>`

Required.

Admin certificate file. Specify the path to a valid PEM-encoded x509 certificate with the extension `.crt`.

`--admin-key <file.key>`

Required.

Specify the path to a valid RSA or DSA private key file (PKXA #8), with the extension `.key` by convention.

`-- ca <file.crt>`

Required.

Trusted CA file. Specify the path to a valid PEM-encoded x509 certificate with the extension `.crt`.

`--node <file.crt>`

Required.

Node certificate file. Specify the path to a valid PEM-encoded x509 certificate with the extension `.crt`. This command will distribute this certificate to each node in the cluster. Use a wild card certificate to allow the full array of node Distinguished Names (DNs) in a single certificate.

`-- node-key <file.key>`

Required.

Specify the path to a valid RSA or DSA private key file (PKXA #8), with the extension `.key` by convention.

## Synopsis

```
tsm security custom-indexandsearch-ssl add --node <file.crt> --
admin <file.crt> --node-key <file.key> --admin-key <file.key> --ca
<file.crt> [parameters] [global options]
```

## `tsm security custom-indexandsearch-ssl list`

List details of Index and Search Server SSL custom certificate configuration.

### Synopsis

```
tsm security custom-indexandsearch-ssl list[global options]
```

### tsm security custom-tsm-ssl disable

Disable the custom SSL certificate for connections to TSM Controller. Revert back to an automatically-managed, self-signed certificate.

### Synopsis

```
tsm security custom-tsm-ssl disable [global options]
```

### tsm security custom-tsm-ssl enable

Enable the custom SSL certificate for connections to TSM Controller for Tableau Server 2023.1 and newer. If you have already enabled SSL and need to update an expired certificate, use this command.

```
-cf,--cert-file <file.crt>
```

Required.

Specify the path to a valid PEM-encoded x509 certificate with the extension `.crt`. The subject name on certificate must match host name or IP address of the Tableau computer where the Administration Controller is running. By default, the Administration Controller runs on the initial node of a Tableau Server deployment.

```
-kf,--key-file <file.key>
```

Required.

Specify the path to valid RSA or DSA private key file (PKXA #8), with the extension `.key` by convention. This key cannot be passphrase-protected.

```
--chain-file <file.crt>
```

Optional.

Specify the path to a certificate chain file (`.crt`)

The chain file is a concatenation of all the certificates that form the certificate chain for the server certificate.

All certificates in the file must be x509 PEM-encoded and the file must have a .crt extension (not .pem).

`--skip-validation`

Optional

Pass this option to skip certificate authority root verification.

### Synopsis

```
tsm security custom-tsm-ssl enable --key-file <file.key> --cert-
file <file.crt> [global options]
```

### **tsm security custom-tsm-ssl list**

List details of TSM custom certificate configuration.

### Synopsis

```
tsm security custom-tsm-ssl list [global options]
```

### **tsm security external-ssl disable**

Removes the server's existing SSL configuration settings and stops encrypting traffic between external clients and the server.

### Synopsis

```
tsm security external-ssl disable [global options]
```

### **tsm security external-ssl enable**

Enable and specify certificate and key files for SSL over external HTTP communication.

### Synopsis

```
tsm security external-ssl enable --cert-file <file.crt> --key-  
file <file.key> [options] [global options]
```

### Options

```
--cert-file <file.crt>
```

Required. Specify the name of a valid PEM-encoded x509 certificate with the extension .crt.

```
--key-file <file.key>
```

Required. Specify a valid RSA or DSA private key file, with the extension .key by convention.

```
--chain-file <chainfile.crt>
```

Specify the certificate chain file (.crt)

A certificate chain file is required for Tableau Desktop on the Mac. In some cases, a certificate chain file may be required for Tableau Mobile.

Some certificate providers issue two certificates for Apache. The second certificate is a chain file, which is a concatenation of all the certificates that form the certificate chain for the server certificate.

All certificates in the file must be x509 PEM-encoded and the file must have a .crt extension (not .pem).

```
--passphrase
```

Optional. Passphrase for the certificate file. The passphrase you enter will be encrypted while at rest.

**Note:** If you create a certificate key file with a passphrase, you cannot reuse the SSL certificate key for SAML.

```
--protocols <list protocols>
```

Optional. List the Transport Layer Security (TLS) protocol versions you want to allow or disallow.

TLS is an improved version of SSL. Tableau Server uses TLS to authenticate and encrypt connections. Accepted values include protocol versions supported by Apache. To disallow a protocol, prepend the protocol version with a minus (-) character.

Default setting: "all, -SSLv2, -SSLv3"

This default explicitly does not allow clients to use SSL v2 or SSL v3 protocols to connect to Tableau Server. However, we recommend that you also disallow TLS v1 and TLS v1.1.

Before you deny a specific version of TLS, verify that the browsers from which your users connect to Tableau Server support TLS v1.2. You might need to preserve support for TLSv1.1 until browsers are updated.

If you do not need to support TLS v1 or v1.1, use the following command to allow TLS v1.2 (using the value `all`), and explicitly deny SSL v2, SSL v3, TLS v1, and TLS v1.1.

```
tsm security external-ssl enable --cert-file file.crt --key-  
file file.key --protocols "all -SSLv2 -SSLv3 -TLSv1 -TLSv1.1"
```

## tsm security external-ssl list

Displays a list of settings related to the configuration of gateway external SSL. The list includes the names of the certificate files in use, but not their location.

### Synopsis

```
tsm security external-ssl list [global options]
```

## tsm security kms set-mode aws

Set the KMS mode to AWS.

You will need the full ARN string from AWS KMS. This string is in the "General configuration" section of the AWS KMS management pages. The ARN is presented in this format:

`arn:aws:kms:<region>:<account>:key/<CMK_ID>`, for example, `arn:aws:kms:us-west-2:867530990073:key/1abc23de-fg45-6hij-7k89-110mn1234567`.

For more information, see [AWS Key Management System](#).

### Synopsis

```
tsm security kms set-mode aws --key-arn "<arn>" --aws-region
"<region>" [global options]
```

### Options

`--key-arn`

Required. The `--key-arn` option takes a direct string copy from the ARN in the "General configuration" section of the AWS KMS management pages.

`--aws-region`

Required. Specify a region as shown in the Region column in the [Amazon API Gateway table](#).

### Example

For example, if your AWS KMS instance is running in `us-west-2` region, your account number is `867530990073`, and your CMK key is `1abc23de-fg45-6hij-7k89-110mn1234567`, then the command would be:

```
tsm security kms set-mode aws --aws-region "us-west-2" --key-arn
"arn:aws:kms:us-west-2:867530990073:key/1abc23de-fg45-6hij-7k89-
110mn1234567"
```

## tsm security kms set-mode azure

Set the KMS mode to Azure Key Vault.

**Note:** The KMS mode will display as "Azure Key Vault" when you run `tsm security kms status`, but you set it as "azure".

You will need the name of the Azure key vault and the name of the key in Azure.

For more information, see [Azure Key Vault](#).

### Synopsis

```
tsm security kms set-mode azure --key-name "<key_name>" --vault-
name "<vault_name>" [global options]
```

### Options

`--key-name`

Required. The name of the asymmetric key stored in the Azure Key Vault.

`--vault-name`

Required. Name of the Azure Key Vault.

### Example

For example, if your Azure Key Vault is named `tabsrv-keyvault` and your key is `tabsrv-sandbox-key01`, then the command would be:

```
tsm security kms set-mode azure --key-name "tabsrv-sandbox-key01" -
-vault-name "tabsrv-keyvault"
```

## tsm security kms set-mode local

Set or reset the KMS mode to local. Local is the default KMS mode. For more information, see Tableau Server Key Management System.

### Synopsis

```
tsm security kms set-mode local [global options]
```

## tsm security kms status

View the status of KMS configuration. The status returned includes:

- Status: OK indicates that the KMS is accessible by Tableau, or by the controller node if a multi-node installation.
- Mode: Local, AWS, or Azure Key Vault. Indicates what KMS mode is being used.
- Encrypt and decrypt master encryption key:

KMS stores a collection of master extract keys (MEKs). Each MEK has:

- An ID, for example, 8ddd70df-be67-4dbf-9c35-1f0aa2421521
- Either a “encrypt or decrypt key” or “decrypt-only key” status. If a key is “encrypt or decrypt”, Tableau Server will encrypt new data with it. Otherwise, the key will only be used for decryption
- A creation timestamp, for example, “Created at: 2019-05-29T23:46:54Z.”
- First transition to encrypt and decrypt: a timestamp indicating when the key became an encrypt or decrypt key.
- Transition to decrypt-only: a timestamp indicating when the key transitioned to decrypt-only.

Other values returned depend on the KMS mode.

When the KMS mode is AWS, the following is returned:

- The ARN (ID) of the customer master key (CMK) .
- The region the CMK is in.
- The ID of the root master key (RMK) in use. The RMK is a key that is encrypted by the CMK. Tableau Server decrypts the CMK by making calls to AWS KMS. The RMK is then

used to encrypt/decrypt the master extract key (MEK). The RMK can change, but there will be only one at a time.

When the KMS mode is Azure Key Vault, the following is returned:

- Vault name: The name of the Azure key vault.
- Azure Key Vault key name: The name of the key in the vault.

### Synopsis

```
tsm security kms status [global options]
```

### tsm security maestro-rserve-ssl disable

Disable the Rserve connection.

For more information, see [Use R \(Rserve\) scripts in your flow](#).

### tsm security maestro-rserve-ssl enable

Configure a connection between an Rserve server and Tableau Server version 2019.3 or later.

For more information, see [Use R \(Rserve\) scripts in your flow](#).

### Synopsis

```
tsm security maestro-rserve-ssl enable --connection-type <maestro-
rserve-secure | maestro-rserve> --rserve-host <Rserve IP address or
host name> --rserve-port <Rserve port> --rserve-username <Rserve
username> --rserve-password <Rserve password> --rserve-connect-
timeout-ms <Rserve connect timeout>
```

### Options

`--connection-type`

Select `maestro-rserve-secure` to enable a secure connection or `maestro-rserve` to enable an unsecured connection. If you select `maestro-rserve-secure`, specify the certificate file path in the command line.

`--rserve-host`

Host

`--rserve-port`

Port

`--rserve-username`

Username

`--rserve-password`

Password

`--rserve-connect-timeout-ms`

The connect timeout in milliseconds. For example `--rserve-connect-timeout-ms 900000`.

### **tsm security maestro-tabpy-ssl disable**

Disable the TabPy connection.

For more information, see [Use Python scripts in your flow](#).

### **tsm security maestro-tabpy-ssl enable**

Configure a connection between a TabPy server and Tableau Server version 2019.3 or later.

For more information, see [Use Python scripts in your flow](#).

### Synopsis

```
tsm security maestro-tabpy-ssl enable --connection-type <maestro-
tabpy-secure | maestro-tabpy> --tabpy-host <TabPy IP address or
host name> --tabpy-port <TabPy port> --tabpy-username <TabPy user-
name> --tabpy-password <TabPy password> --tabpy-connect-timeout-ms
<TabPy connect timeout>
```

### Options

`--connection-type`

Select `maestro-tabpy-secure` to enable a secure connection or `maestro-tabpy` to enable an unsecured connection. If you select `maestro-tabpy-secure`, specify the certificate file `-cf<certificate file path>` in the command line.

`--tabpy-host`

Host

`--tabpy-port`

Port

`--tabpy-username`

Username

`--tabpy-password`

Password

`--tabpy-connect-timeout-ms`

The connect timeout in milliseconds. For example `--tabpy-connect-timeout-ms 900000`.

## **tsm security regenerate-internal-tokens**

This command performs the following operations:

1. Stops Tableau Server if it is running.
2. Generates new internal SSL certificates for Postgres repository the search server.
3. Generates new passwords for all of the internally managed passwords.
4. Updates all Postgres repository passwords.
5. Generates a new encryption key for asset key management and encrypts the asset key data with the new key.
6. Generates a new encryption key for configuration secrets (master key) and encrypts the configuration with it.
7. Reconfigures and updates Tableau Server with all of these secrets. In a distributed deployment, this command also distributes the reconfiguration and updates across all nodes in the cluster.
8. Regenerates a new master key, adds it to the master keystore file, and then creates new security tokens for internal use.
9. Starts Tableau Server.

If you plan to add a node to your cluster after you have run this command, then you will need to generate a new node configuration file to update the tokens, keys, and secrets that are generated by this command. See [Install and Configure Additional Nodes](#).

For more information about internal passwords see [Manage Server Secrets](#).

### Synopsis

```
tsm security regenerate-internal-tokens [options] [global options]
```

## Options

```
--ignore-prompt
```

Optional.

Perform a restart (if necessary) without prompting. This option only suppresses the prompt. The restart behavior is unchanged.

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

## tsm security repository-ssl disable

Stop encrypting traffic between the repository and other server components, and stop support for direct connections from Tableau clients.

### Synopsis

```
tsm security repository-ssl disable [global-options]
```

## tsm security repository-ssl enable

When the repository is local, enables SSL and generates the server's .crt and .key files used for encrypted traffic between the Postgres repository and other server components.

Starting in version 2021.4, when using an external repository, imports the server's .crt and .key files used to encrypt traffic between external PostgreSQL repository and Tableau Server components.

Enabling this also gives you the option to enable SSL over direct connections from Tableau clients to the server.

### Synopsis

```
tsm security repository-ssl enable [options] [global options]
```

### Options

`-i, --internal-only`

Optional. This option only applies when the repository is local to Tableau Server and is not configured external to Tableau Server. This option should not be used for Tableau Server configured with External Repository.

When set to `--internal-only`, Tableau Server uses SSL between the repository and other server components, and it supports but does not require SSL for direct connections through **tableau** or **readonly** users.

If this option is not set, Tableau Server requires SSL for traffic between the repository and other server components, as well as for direct connections from Tableau clients (for connections through the **tableau** or **readonly** users).

When you specify this option, you must also complete the steps described in [Configure Postgres SSL to Allow Direct Connections from Clients](#).

`-c, --certificate`

Optional. Added in version 2021.4. This option is only applicable to Tableau Server configured with External Repository and can be used to enable or disable SSL connections post installation.

This option allows you to enable the use of SSL/TSL connections between Tableau Server and the External Repository. When using this option, provide the full path to the SSL certificate file including the file name for the External Repository. This file is the same as the one used when enabling the external repository.

### `tsm security repository-ssl get-certificate-file`

Get the public certificate file used for SSL communication with the Tableau repository. SSL must be enabled for repository communication before you can retrieve a certificate. The

certificate file is distributed automatically to internal clients of the repository in the Tableau Server cluster. To enable remote clients to connect over SSL to the repository, you must copy the public certificate file to each client.

This command works only for Tableau Server that uses a local Repository and will result in an error when Tableau Server is configured with an External Repository.

#### Synopsis

```
tsm security repository-ssl get-certificate-file [global-options]
```

#### Options

`-f, --file`

Required.

Full path and file name (with .cert extension) where the certificate file should be saved. If a duplicate file exists it will be overwritten.

### tsm security repository-ssl list

Returns the existing repository (Postgres) SSL configuration.

#### Synopsis

```
tsm security repository-ssl list [global-options]
```

### tsm security rotate-coordination-service-secrets

**Version:** Added in version 2022.1

Generates new certificates, keys, and trust stores used by the Coordination Service for secure connections.

#### Synopsis

```
tsm security rotate-coordination-service-secrets [options]
[global options]
```

### Options

`--coord-svc-restart-timeout <seconds>`

Optional.

Wait the specified number of seconds for Coordination Service to restart. Default: 1200 (20 minutes).

`--ignore-prompt`

Optional.

Perform a restart (if necessary) without prompting.

`--request-timeout <seconds>`

Optional.

Wait the specified number of seconds for the command to finish. Default: 1800 (30 minutes).

### Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

`--password 'my password'`

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm settings

You can use the `tsm settings` commands to export (get) and import (set) configuration values.

- `tsm settings clone`
- `tsm settings export`
- `tsm settings import`

**Important:** The server configuration file referenced in this topic includes a copy of the master keystore file used for encrypting configuration secrets. We strongly recommend

that you take additional measures to secure the node configuration file, using mechanisms as described in [Securing secrets for import and export operations](#).

## tsm settings clone

Create a "clone payload" that consists of the Tableau Server installation's configuration and topology (including external services and ports). This payload can be used to recreate an exact copy of the Server installation. This command is designed to work best with a Server installation that includes an external repository and external filestore. For details on using the clone payload to create a copy of an installation, see [Clone Tableau Server](#).

### Synopsis

```
tsm settings clone --output-directory <output-directory>
[global options]
```

### Options

```
-d, --output-directory <output-directory>
```

Required.

Specifies the location to which the clone payload will be written.

## tsm settings export

Export the current server configuration and topology to a file.

The following files are not exported or imported with the `tsm settings import` or `tsm settings export` commands. You must manage these files manually:

- SAML certificate file
- SAML key file
- SAML IdP metadata file
- OpenID.static.file

- Kerberos.keytab file
- LDAP Kerberos keytab file
- LDAP Kerberos conf file
- Mutual SSL certificate file
- Mutual SSL revocation file
- Customization header logo file
- Customization sign-in logo file
- Customization compact logo file

### Synopsis

```
tsm settings export --output-config-file <path/to/output_file.json>
[global options]
```

### Options

```
-f, --output-config-file <file>
```

Required.

Specifies the location and name of the file created by this operation.

## tsm settings import

Import server configuration or topology.

The following files are not exported or imported with the `tsm settings export` or `tsm settings import` commands. You must manage these files manually:

- SAML certificate file
- SAML key file
- SAML IdP metadata file
- OpenID.static.file
- Kerberos.keytab file
- LDAP Kerberos keytab file
- LDAP Kerberos conf file
- Mutual SSL certificate file
- Mutual SSL revocation file
- Customization header logo file

## Tableau Server on Linux Administrator Guide

- Customization sign-in logo file
- Customization compact logo file

### Synopsis

```
tsm settings import --import-config-file <path/to/import_file.json>  
[global options]
```

### Options

```
-f, --import-config-file <FILE>
```

Required.

Path to input file.

```
--config-only
```

Optional.

```
--topology-only
```

Optional.

```
-frc, --force-keys
```

Optional.

Force a key to be added to configuration even if it did not previously exist.

### Global options

```
-h, --help
```

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm sites

You can use the `tsm sites` commands to export an existing site for import to a new site (also referred to as site migration), and to import the new site. An `unlock` command is available in case an error leaves a site locked.

## Tableau Server on Linux Administrator Guide

The `tsm sites` commands will use your local file store to hold the export and import data. If you are running a multinode Tableau cluster, then you must run the `tsm sites` commands on a Tableau Server that is running the Data Engine process. For information about the Data Engine process and the processes that require it, see [Tableau Server Processes](#).

**Note:** When migrating sites between instances of Tableau Server, the target site must be on a version of Tableau Server that is the equal to or later than the version of Tableau Server for the source site. Both the source and target sites must be from supported versions of Tableau Server.

For comprehensive steps for migrating a site, see [Export or Import a Site](#).

- `tsm sites export`
- `tsm sites import`
- `tsm sites import-verified`
- `tsm sites unlock`

### `tsm sites export`

Export a specified Tableau Server site to a .zip file. You can export a site to archive its settings at a specific point in time, or to complete the first step of a site migration process.

**Note:** The `tsm sites import` and `tsm sites export` commands can leave a site in a locked state if an error occurs. To unlock a site, use the `tsm sites unlock` command.

#### Synopsis

```
tsm sites export --site-id <source-siteID> --file <export-file>
[options] [global options]
```

## Options

`-f, --file <export-file>`

Required.

Specify the name of the file to which Tableau Server saves all of the site's information.

This file is generated to the directory defined in the TSM `basefilepath.site_export.exports` variable. By default:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/siteexports
```

For more information about file paths and how to change them, see [tsm File Paths](#).

`-id, --site-id <source-siteID>`

Required.

The site ID for the site you are exporting. You can get the site ID from the URL when you're signed in to the site from a web browser. For information about locating the site ID, see [Prepare the Source and Target Sites](#).

`-ow, --overwrite`

Optional.

Overwrite an export file of the same name that already exists.

`--request-timeout <timeout in seconds>`

Optional.

Wait the specified amount of time for the command to finish. Default value is 43200 (720 minutes).

## tsm sites import

This command uses the .zip file you created using `tsm sites export` to generate a set of .csv files that show how the exported source site settings will map to the new target site.

By default, the .zip file is generated and saved to the `siteexports` directory at:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/siteexports
```

Before you use this command, you must copy the .zip file to the directory in which Tableau will expect it. This location is defined in the TSM `basefilepath.site_import.exports` variable. By default, the import directory is:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/siteimports
```

For more information about file paths and how to change them, see [tsm File Paths](#).

**Note:** The `tsm sites import` and `tsm sites export` commands can leave a site in a locked state if an error occurs. To unlock a site, use the `tsm sites unlock` command.

### Synopsis

```
tsm sites import --file <export-file.zip> --site-id <target-siteID>  
[options] [global options]
```

### Options

```
-f, --file <export-file.zip>
```

Required.

Name of the .zip file created by the `tsm sites export` process, and which you must copy to the import directory. By default:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/siteimports
```

`-id, --site-id <target-siteID>`

Required.

The site ID for the new site you are importing to (the target site). For information about locating the site ID, see [Prepare the Source and Target Sites](#).

`-c, --continue-on-ignorable-errors`

Optional.

Continue site import if errors occur which can be ignored. These errors can indicate issues with the import of a specific workbook or data source.

`-k, --no-verify`

Optional.

Skip verification of mapping files.

`-m, --override-schedule-mapper <mapping-file.csv>`

Optional.

Schedule mapping file to override the normal mapping by name.

`--request-timeout <timeout in seconds>`

Optional.

Wait the specified amount of time for the command to finish. Default value is 7200 (120 minutes).

## **tsm sites import-verified**

Specify the directory that contains an exported site's .csv mapping files, to import to a new site. This is the final step of a site migration process.

### Synopsis

```
tsm sites import-verified --import-job-dir <importjob-directory> --  
site-id <target-siteID> [options] [global options]
```

### Options

```
-id, --site-id <target-siteID>
```

#### Required.

The site ID for the new site you are importing to (the target site). For information about locating the site ID, see [Prepare the Source and Target Sites](#).

```
-w, --import-job-dir <importjob-directory>
```

#### Required.

The parent of the `mappings` directory that contains the `.csv` files from the exported (source) site. The name of this parent directory includes the import id and date and time. For example:

```
/var/opt/tableau/tableau_server-  
/data/tabsvc/files/siteimports/working/import_ff00_  
20180102022014457
```

```
--request-timeout <timeout in seconds>
```

#### Optional.

Wait the specified amount of time for the command to finish. Default value is 7200 (120 minutes).

### tsm sites unlock

Use this command to unlock a site.

## Options

`-id, --site-id <target-siteID>`

Required.

The site ID for the site you are unlocking. For information about locating the site ID, see [Prepare the Source and Target Sites](#).

`-d, --desired-state <state to leave unlocked site in>`

Optional.

The state the site should be left in after it is unlocked. Options are "active" and "suspended". The default is "active" if not specified.

For example:

```
tsm sites unlock -id mysite -d suspended
```

`--request-timeout <timeout in seconds>`

Optional.

Wait the specified amount of time for the command to finish. Default value is 300 (5 minutes).

## Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

## Tableau Server on Linux Administrator Guide

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

```
-s, --server https://<hostname>:8850
```

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

```
--trust-admin-controller-cert
```

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

```
-u, --username <user>
```

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm start

You can use the `tsm start` command to start Tableau Server. If the server is already running this command does nothing.

### Synopsis

```
tsm start [option][global options]
```

## Option

`--request-timeout <timeout in seconds>`

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

## Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port 8850, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm status

You can use the `tsm status` command to display the status of Tableau Server and individual services (processes) that run as part of Tableau Server.

### Synopsis

```
tsm status [global options]
```

### Options

`-v, --verbose`

Optional.

Display status for every node in the Tableau Server cluster.

`tsm status` will return one of these potential statuses for a Tableau Server node:

- **RUNNING:** The node is running without error statuses for any service or process.
- **DEGRADED:** The node is running with one or more primary services - such as the repository - in an error state. If you have a single instance of the Messaging service and it fails, Tableau Server will continue to function but the status shows as degraded and event messages may be lost. For more information, see [Tableau Server Messaging](#)

Service.

- `ERROR`: All primary services or processes are in an error state on the node.
- `STOPPED`: The node is stopped, with no error statuses.

When running `tsm status` with the `--verbose` option, TSM will return a status for each individual service (process). Possible status messages include:

- `is running`: The service is running.
- `status is unavailable`: The status cannot be determined - such as when services are starting up.
- `is in a degraded state`: The service is running, but returning errors. This status indicates the service failed to install properly, has not been configured, or has failed in some way.
- `is in an error state`: The service is running, but returning errors. This status indicates the service failed to install properly, or has not been configured.
- `is synchronizing`: The File Store process is synchronizing with another instance of File Store.
- `is decommissioning`: The File Store process is being decommissioned.
- `is running (Active Repository)`: The active repository is running. This is the expected status.
- `is running (Passive Repository)`: The passive repository is running. This is the expected status when there are two repositories configured.
- `is stopped`: The service is stopped. This does not mean a service is in an error or problem state. Some services only run when needed (the Database Maintenance service for example).

## Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm stop

You can use the `tsm stop` command to stop Tableau Server. If Tableau Server is already stopped, this command does nothing.

### Synopsis

```
tsm stop [option] [global options]
```

### Options

```
--ignore-node-status <nodeID>
```

Optional.

Ignore the status for the specified node or nodes when determining if the server has stopped. Useful if removing a bad node. Separate multiple nodes with commas.

For example, if nodes 2, 3 and 5 are not properly responding: `tsm stop --ignore-node-status node2,node3,node5`

**Note:** Option added in version 2020.1

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

### Global options

```
-h, --help
```

Optional.

## Tableau Server on Linux Administrator Guide

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm topology

Use the `tsm topology` commands to prepare File Store nodes for safe removal or to put them back into read-write mode. You can also initiate a repository failover, get a list of nodes or ports, get the bootstrap configuration file required to add additional nodes to your cluster, remove nodes, configure external repository, and external File Store.

**Important:** When making changes to topology, you need to apply those pending changes for the changes to take effect. For more information, see `tsm pending-changes`.

- `cleanup-coordination-service`
- `deploy-coordination-service`
- `external-services`
  - `gateway`

## `tsm topology cleanup-coordination-service`

**Note:** Beginning with version 2020.1.0, all coordination service ensemble commands require input for a "y/n" prompt confirming that a server restart will take place. To run these commands without input, include the `--ignore-prompt` option.

Use the `tsm topology cleanup-coordination-service` command to remove the non-production Tableau Server Coordination Service ensemble after you deploy a new ensemble. This command removes the old Coordination Service instances on all nodes in the non-production Coordination Service ensemble and is required after you deploy a new Coordination Service ensemble. To learn more about Coordination Service ensembles, see [Deploy a Coordination Service Ensemble](#) .

In version 2020.1.0 and later, the `tsm topology deploy-coordination-service` command also removes the old ensemble. There is no need to run this command separately unless the deployment fails.

### Synopsis

```
tsm topology cleanup-coordination-service [option] [global options]
```

## Option

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 2700 (45 minutes).

## tsm topology deploy-coordination-service

**Note:** Beginning with version 2020.1.0, all coordination service ensemble commands require input for a "y/n" prompt confirming that a server restart will take place. To run these commands without input, include the `--ignore-prompt` option.

You can use the `tsm topology deploy-coordination-service` command to deploy the Tableau Server Coordination Service. This command deploys a Coordination Service ensemble, which is a set of Coordination Service instances that run on specified nodes in your server cluster. To learn more about Coordination Service ensembles, including how many nodes in your cluster should have a Coordination Service instance, see [Deploy a Coordination Service Ensemble](#) .

In version 2020.1.0 and later, the `tsm topology deploy-coordination-service` command also removes the old ensemble. There is no need to run the `cleanup-coordination-service` command separately.

### Synopsis

```
tsm topology deploy-coordination-service --nodes
<nodeID,nodeID,...> [option] [global-options]
```

### Options

```
-n, --nodes <nodeID,nodeID,...>
```

Required.

Node IDs of nodes to include in the new Coordination Service ensemble, separated by commas. You can specify 1, 3, or 5 Coordination Service nodes, depending on the total number of nodes in your cluster. For more information, see [The Coordination Service Quorum](#).

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 2700 (45 minutes).

## tsm topology external-services gateway disable

Disable all instances of Independent Gateway on Tableau Server.

### Synopsis

```
tsm topology external-services gateway disable [options] [global options]
```

### Options

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 2700 (45 minutes).

## tsm topology external-services gateway enable

Enable instances of Independent Gateway on Tableau Server .

### Synopsis

```
tsm topology external-services gateway enable [options] [global options]
```

## Options

`-c, --config <configuration-file>`

## Required

Specifies the name of the JSON file containing configuration details for all instances of Independent Gateway.

**tsm topology external-services gateway update**

Use this command to update the configuration of Independent Gateway in Tableau Server. You need to do this if you add or remove additional instances of Independent Gateway, or if you upgrade Independent Gateway. Gather any changes on the Independent Gateway computers and update the configuration file before running this command.

## Synopsis

```
tsm topology external-services gateway update [option] [global options]
```

## Option

`-c, --config <configuration-file>`

## Required

Specifies the name of the JSON file containing configuration details for all instances of Independent Gateway.

**tsm topology external-services list**

Use the `tsm topology external-service-list` command to get a the service that is used for Tableau Server External Repository. For example, if you have configured Tableau Server to use Amazon RDS, you will see the following message:

*These externally configured services are in use by Tableau Server:*

*-pgsql*

### Synopsis

```
tsm topology external-service list [global options]
```

### Option

There are no options for this command.

## tsm topology external-services repository disable -n nodeN

Use the `tsm topology external-services repository disable` command to stop using the external repository and reconfigure the installation to use a local repository. This will migrate the data to a local repository and configure Tableau Server to use the local repository.

### Synopsis

```
tsm topology external-services repository disable -n nodeN
```

### Option

`-n, --node-name <nodeID>`

Required.

Specifies the node ID of the node where the repository should be moved to.

**Important:** This does not stop or delete the RDS instance. For more information on how to delete an RDS instance, see [Deleting a DB Instance](#) on the AWS web site.

## tsm topology external-services repository enable

Use the `tsm topology external-services repository enable` command to configure Tableau Server to use an external repository. This command can be used during installation of a new Tableau Server to configure the external repository. If this command is run on an already existing and running Tableau Server, it will migrate the data from the local node to the external repository and configure Tableau Server to use the external repository after the migration is complete.

## Synopsis

```
tsm topology external-services repository enable -f <filename>.json
-c <ssl certificate file>.pem
```

## Options

--f <file name>

Required.

Full path and file name where the configuration file is saved. For more information, see [Re-Configure Tableau Server Repository](#).

--c <ssl certificate file>

Required for versions 2021.2 and 2021.2.1. Optional for versions 2021.2.2 and later.

For SSL configurations, download the certificate file and specify the file for use with this option.

1. **Amazon RDS:** See [Using SSL to Encrypt the Connection to a DB Instance](#).
2. **Azure Database:** See [Configure TLS connectivity for Azure Database for PostgreSQL](#).
3. **Stand-alone PostgreSQL Instance:** See [Configure SSL](#).

--no-ssl

Optional. This option is available in version 2021.2.2 and later.

This means SSL is not required when connecting to the External Repository. If you do not need to use encrypted connections, you must also configure the External Repository to allow unencrypted connections. When you use this option, connections will be encrypted if the external repository is configured to support TLS/SSL connections. Otherwise, Tableau Server will use non-encrypted connections.

Skips the check to see if the external repository is already configured for use with Tableau Server. This option is typically not recommended, as it may lead to the same

repository being used by multiple Tableau Server installations which can cause errors. This option may be useful for testing or disaster recovery purposes.

`--skip-state-check`

Optional. This option is available in version 2022.3.0 and later.

Skips the check to see if the external repository is already configured for use with Tableau Server. This option may be useful for testing or disaster recovery purposes but is not recommended for normal use, as it may result in the same repository being used by multiple Tableau Server installations.

### **tsm topology external-services repository replace-host**

This command updates Tableau Server configuration settings to use the specified external repository. Use the `tsm topology external-services repository replace-host` command to reconfigure Tableau Server to use the new external repository immediately without moving data to it from your current external repository. You may need to manually migrate the data. You should only do this after you have fully evaluated and understand the impact of the potential data loss.

This command can be used in the following scenarios:

- **Planned expiration of the SSL certificates used by RDS instances:** RDS instances need to be updated with the new certificates, and Tableau Server needs to be configured to use the new certificate file to connect to the RDS instance.
- **Disaster recovery:** Use this to connect to a new RDS instance in disaster recovery scenarios. For more information, see [Create a PostgreSQL DB Instance on AWS Relational Database Service \(RDS\)](#)

#### **Synopsis**

```
tsm topology external-services repository replace-host -f <file-name>.json -c <ssl certificate file>.pem
```

## Options

`-f <file name>`

Required.

Full path and file name where the configuration file is saved. For more information, see [Re-Configure Tableau Server Repository](#).

`-c <ssl certificate file>`

Optional.

The certificate file is the certificate to be imported to allow connections to the instance. For RDS, this is the CA cert used to sign the certificate of the instance. This is usually the latest root certificate `rds-ca-XXXX-root.pem` file. Use this parameter to update Tableau server if the certificate has changed on the RDS instance.

For more information, see [Using SSL/TLS to Encrypt a Connection to a DB Instance](#).

For more information on how to get the .pem file, see [Using SSL to Encrypt a Connection to a DB Instance](#).

`--ignore-prompt`

Optional.

Run this command without prompts.

## `tsm topology external-services storage disable`

Configure Tableau Server to run File Store locally. Use this command to disable External File Store and move the File Store data to your Tableau Server.

### Synopsis

```
tsm topology external-services storage disable [options] [global options]
```

### Options

```
-fsn <nodeID, nodeID, ...>
```

#### Required

Specify the nodes that you want to configure File Store. You can specify more than one node. The data will be migrated to the first node in the list and then replicated to other nodes.

For more information, see [Reconfigure File Store](#) .

## tsm topology external-services storage enable

Configure Tableau Server with External File Store. External File Store uses SAN or NAS to store File Store data.

### Synopsis

```
tsm topology external-services storage enable [options] [global options]
```

### Options

```
--network-share <network share mount point>
```

#### Required

Specify the mount point of the network share you want to use for your External File Store. For example: `/mnt/<network share name>/tableau`

For more information, see [Reconfigure File Store](#) .

## tsm topology external-services storage switch-share

Use this command to move your external services to a different network share. An example of this might be when your current network attached storage is at the end of life and you need to use a new network attached storage with new hardware. For more information, see [Reconfigure File Store](#) .

## Synopsis

```
tsm topology external-services storage switch-share [option]
[global options]
```

## Option

```
--network-share <network share mount point>
```

### Required

Specify the mount point of the network share you want to switch to. For example:

```
/mnt/<network share name>/tableau
```

## tsm topology failover-repository

You can use the `tsm topology failover-repository` to manually initiate a repository failover from the current active repository to the second, passive repository.

The `tsm topology failover-repository` command is persistent. The failover repository remains the active repository until you issue the command again, or, if Tableau Server is configured for it, until automatic failover occurs. If you have a preferred active repository configured, use the `--preferred` option to switch back to that repository. For more information about configuring a preferred active repository, see [Tableau Server Repository](#). If Tableau Server is configured for high availability, failover of the repository is automatic when necessary. Use the `failover-repository` command to manually fail over the repository.

## Synopsis

```
tsm topology failover-repository --preferred | --target <node_id>
[global options]
```

## Options

```
-r, --preferred
```

Required if `-t` or `--target` is not used.

Use the configured preferred node as the target for repository failover.

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

```
-t, --target <node_id>
```

Required if `-r` or `--preferred` is not used.

The node id of the target node onto which failover will occur. Find the node id by using the `tsm topology list-nodes` command.

## tsm topology filestore decommission

You must use the `tsm topology filestore decommission` command to prepare a file store node or nodes for safe removal. This command puts the specified nodes into read-only mode and ensures there is no unique content on the specified nodes.

If decommissioning results in a single file store node, you must use the `--override` option or the decommission will fail.

### Synopsis

```
tsm topology filestore decommission --nodes <nodeID,nodeID,...>  
[options] [global options]
```

### Options

```
-n, --nodes <nodeID,nodeID,...>
```

Required.

List of one or more nodes to decommission, specified by node ID and separated by commas.

`--delete-filestore`

Optional.

Forces the removal of the file store, even if it has not been decommissioned. You should only use this option if the node the file store is on is in a error state and decommissioning cannot be done. Any unique files on the node will be permanently deleted.

`-o, --override`

Optional.

Overrides warnings or failures that would normally occur if removing the target File Store node would reduce the number of remaining file store nodes to one. This option cannot be used with the `--delete-filestore` option.

`--request-timeout <timeout in seconds>`

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

## tsm topology filestore recommission

Use the `tsm topology filestore recommission` command to revert any decommissioned nodes back to read-write mode.

### Synopsis

```
tsm topology filestore recommission --nodes <nodeID,nodeID,...>
[global options]
```

### Options

`-n, --nodes <nodeID,nodeID,...>`

Required.

List of one or more nodes to recommission, specified by node ID and separated by commas.

## tsm topology list-nodes

Display the nodes in the cluster and (optionally) the services on each node.

### Synopsis

```
tsm topology list-nodes [options] [global options]
```

### Options

`-v, --verbose`

Optional.

Shows each node ID, the node role (for more information, see `set-node-role` below), the node address, and the processes on each node.

## tsm topology list-ports

Display the ports in the cluster.

### Synopsis

```
tsm topology list-ports [options] [global options]
```

### Options

`--node-name <nodeID>`

Optional.

Specify the node to list ports for.

```
--service-name
```

Optional.

Specify the service to list ports for.

## tsm topology node-nickname list

Display the node nicknames for nodes in the cluster.

### Synopsis

```
tsm topology node-nickname list [options] [global options]
```

### Options

```
--nodes <nodeID,nodeID,...>
```

Optional.

Specify the node IDs of the nodes to list with nicknames.

## tsm topology node-nickname remove

Remove the nickname from the specified node or nodes.

### Synopsis

```
tsm topology node-nickname remove [options] [global options]
```

### Options

```
--all
```

Required if `--nodes` is not specified.

Remove the nicknames from all nodes in the cluster.

```
--nodes <nodeID,nodeID,...>
```

Required if --all is not specified.

Specify the node ID of the node or nodes whose nicknames should be removed.

## tsm topology node-nickname set

Set the nickname for the specified node.

### Synopsis

```
tsm topology node-nickname set [options] [global options]
```

### Options

```
-id, --node <nodeID>
```

Required.

Specify the node to set the nickname for.

```
-nn, --nickname <name>
```

Required.

The nickname for the specified node.

## tsm topology nodes get-bootstrap-file

You can use the `tsm topology nodes get-bootstrap-file` command to get the bootstrap file that is required to add a new node to the cluster.

**Important:** The bootstrap file contains a copy of the master keystore file used for encrypting the configuration secrets. The file can also embedded credentials which are valid for a pre-determined amount of time (see `tabadmincontroller.auth.expiration.minutes`) and serve as a session cookie. We strongly recommend that you take additional measures to secure the

bootstrap file.

The following command set provides an example method to encrypt the bootstrap file output. This method is similar to the encryption process described in more detail at [Securing secrets for import and export operations](#).

Note however, the method here must be passed as separate arguments with trailing `&& \` operators as follows:

```
mkfifo -m 600 /tmp/secure1 && \

tsm topology nodes get-bootstrap-file --file /tmp/secure1 && \

gpg --symmetric --batch --yes --passphrase-file ~/.secret-
s/pgppassphrase.txt --cipher-algo AES256 --output encrypted.enc <
/tmp/secure1 && \

rm /tmp/secure1
```

### Synopsis

```
tsm topology nodes get-bootstrap-file --file <path\file>.json
[global options]
```

### Options

`-f, --file <file>`

**Required.**

Full path and file name where the configuration file will be saved. If a duplicate file exists it will be overwritten.

`-nec, --no-embedded-credential`

**Optional.**

Added in version 2019.3.

By default embedded credentials are included in the bootstrap file. Use this option if credentials should not be included in the bootstrap file. Embedded credentials are temporary, and expire based on the value of the `tabadmincontroller.auth.expiration.minutes` configuration key, by default 120 minutes.

**Note:** You can disable the ability to include embedded credentials at the server level, using a configuration option. For more information, see `features.PasswordlessBootstrapInit`.

### `tsm topology remove-nodes`

Remove nodes from the cluster.

To complete removal of a node, you also must run the `tsm pending-changes apply` command. Some scenarios require that you move or redeploy processes before removing nodes. See [Remove a Node](#).

If you remove a node and want to re-add it to the cluster, you need to first run the `obliterate` script to clean Tableau off it, then reinstall the node using the normal process for adding a new node. For more information, see [Remove Tableau Server from Your Computer and Install and Configure Additional Nodes](#).

**Note:** To remove a node from a cluster it must have been configured with a process at some point in the past. If you are removing a node on which you've not configured any processes, then you must add a process on it, run `tsm pending-changes apply`, and then remove the node.

#### Synopsis

```
tsm topology remove-nodes --nodes <nodeID,nodeID,...>
[global options]
```

## Options

`-n, --nodes <nodeID,nodeID,...>`

Required.

Specify the node or nodes to remove. If specifying multiple nodes, separate node IDs with a comma.

## tsm topology set-node-role

Set the Backgrounder and Extract Queries node roles. This determines the type of tasks that will be performed on the nodes. The following node roles can be useful if you have a multi-node cluster. Different node roles may require licenses for Advanced Management or Data Management, or for both. For more information about license requirements, see [Workload Management through Node Roles](#).

**Note:** Making configurations to node roles require a restart of the server and will require some downtime. For more information, see [tsm pending-changes](#).

## Synopsis

```
tsm topology set-node-role [options] [global options]
```

## Options

`-n, --nodes <nodeID,nodeID,...>`

Required.

List of one or more nodes to set node roles for, specified by node ID and separated by commas and without spaces between nodes.

## Tableau Server on Linux Administrator Guide

```
-r --role <all-jobs,flows,no-flows,extract-refreshes,sub-  
scriptions,extract-refreshes-and-subscriptions,no-extract-  
refreshes,no-subscriptions,no-extract-refreshes-and-sub-  
scriptions,extract-queries,extract-queries-interactive>
```

### Required

Sets the role for the nodes specified. The valid values for this option are:

- all-jobs: Backgrounder will run all types of jobs.
- flows :Backgrounder will run only flow run jobs.
- no-flows: Backgrounder will not run flow run jobs.
- extract-refreshes: Backgrounder will run only extract refresh jobs. This includes, incremental refreshes, full refreshes, encryption and decryption of all extracts including extracts that flow outputs generate.
- subscriptions: Backgrounder will run only subscription jobs.
- extract-refreshes-and-subscriptions: Backgrounder will run extract-refreshes, encryption and decryption of all extracts including extracts that flow outputs create, and subscription jobs.
- no-extract-refreshes: Backgrounder will run all jobs except extract-refreshes, extract encryption and decryption including extracts created from flow outputs.
- no-subscriptions: Backgrounder will run all jobs except subscriptions.
- no-extract-refreshes-and-subscriptions: Backgrounder will run all jobs except extract-refreshes, encryption and decryption of all extracts including extracts created from flow outputs, and subscriptions.
- extract-queries: The nodes selected will run as all-jobs and will prioritize the processing of extract queries.
- extract-queries-interactive: The nodes selected will run as all-jobs and will prioritize the processing of interactive extract queries, such as those that run when

a user is looking at their screen and waiting for an extract-based dashboard to load. This is an advanced setting and it should only be used if the cluster has a heavy subscription and alert job workload that causes users to experience degraded performance on viz load times that run around the same time as scheduled loads.

- **system:** Backgrounder will run only system maintenance jobs that interact with other Tableau Server processes, such as cleaning crashed jobs, reaping database events, and syncing Active Directory.
- **no-system:** Backgrounder will run all jobs except system maintenance jobs.

## tsm topology set-ports

Set the ports for a service instance.

### Synopsis

```
tsm topology set-ports --node-name <nodeID> --port-name <port_name>
--port-value <port_value> [options] [global options]
```

### Options

```
-i, --instance <instance_id>
```

Optional.

Specifies the instance id of the service. Defaults to 0 (zero) if not specified.

```
-n, --node-name <nodeID>
```

Required.

Specifies the node ID of the node.

```
-pn, --port-name <port_name>
```

Required.

The name of the port to be set, in this format: `service_name:port_type`. If no port type is specified, the primary port is assumed. For port name syntax, see [Dynamically mapped ports](#).

`-pv, --port-value <port_value>`

Required.

The port to set.

`-r, --restart`

Optional.

Suppress the prompt for restart and restart Tableau Server when necessary.

### tsm topology set-process

Set the number of instances of a process on a node. If a node already has the specified process, the number is updated to match the specified count.

- You can only set one process at a time. If you specify more than one process, any process after the first one will be silently ignored.
- You must set a process one node at a time. If you specify more than one node, the command will display an "invalid node name" error.

When you update the number of processes on nodes, you also need to apply pending changes. In most cases this also requires a server restart (you will be prompted), but there are special cases where you can make dynamic topology changes without needing to restart the server. For more information, see [Tableau Server Dynamic Topology Changes](#).

**Note:** For a complete list of process names, see [Tableau Server Processes](#).

## Synopsis

```
tsm topology set-process --count <process_count> --node <nodeID> --
process <process_name> [global options]
```

## Options

```
-c, --count <process_count>
```

Required.

The process count (number of instances) to set.

```
-n, --node <nodeID>
```

Required.

Specifies the node ID of the node on which to set the process.

```
-pr, --process <process_name>
```

Required.

The name of the process to be set.

## tsm topology toggle-coordination-service

**Note:** Beginning with version 2020.1.0, all coordination service ensemble commands require input for a "y/n" prompt confirming that a server restart will take place. To run these commands without input, include the `--ignore-prompt` option.

You can use the `tsm topology toggle-coordination-service` command to switch between coordination service ensembles. To learn more about Coordination Service ensembles, see [Deploy a Coordination Service Ensemble](#).

In version 2020.1.0 and later, the `tsm topology deploy-coordination-service` command also switches to the new ensemble. There is no need to run this command separately.

## Tableau Server on Linux Administrator Guide

### Synopsis

```
tsm topology toggle-coordination-service [option] [global options]
```

### Option

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

### Global options

```
-h, --help
```

Optional.

Show the command help.

```
-p, --password <password>
```

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

```
-s, --server https://<hostname>:8850
```

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm user-identity-store

You can use the `tsm user-identity-store` commands to modify the settings of the identity store for Tableau Server after the initial configuration.

The initial configuration of the identity store is part of the installation process. See [Configure Initial Node Settings](#).

For introduction to identity store concepts, see [Identity Store](#).

For LDAP/Active Directory configuration reference table, see [External Identity Store Configuration Reference](#).

- [get-group-mappings](#)
- [get-user-mappings](#)
- [list](#)
- [set-connection](#)
- [set-group-mappings](#)
- [set-user-mappings](#)
- [verify-group-mappings](#)
- [verify-user-mappings](#)

## **tsm user-identity-store get-group-mappings [options]**

Displays identity store group mappings.

### **Synopsis**

```
tsm user-identity-store get-group-mappings [global options]
```

## **tsm user-identity-store get-user-mappings [options]**

Displays identity store user mappings.

### **Synopsis**

```
tsm user-identity-store get-user-mappings [global options]
```

## **tsm user-identity-store list [options]**

Lists user-identity configuration.

### **Synopsis**

```
tsm user-identity-store list [options] [global options]
```

### **Options**

`-v, --verbose`

Optional.

Lists all configuration parameters.

## **tsm user-identity-store set-connection [options]**

Sets identity store connection parameters.

### **Synopsis**

```
tsm user-identity-store set-connection --kerbkeytab <kerbkeytab>  
[options] [global options]
```

## Options

`-b,--bind <username and password | Kerberos>`

Optional.

Set LDAP bind type.

`-d,--domain <domain>`

Optional.

Domain name.

`-hn,--hostname <hostname>`

Optional.

The hostname of the LDAP server. You can enter a hostname or an IP address for this value. The host that you specify here will be used for user/group queries on the primary domain. In the case where user/group queries are in other domains, Tableau Server will query DNS to identify the appropriate domain controller.

`-kc,--kerbconfig <kerbconfig>`

Optional.

Kerberos configuration file path.

`-kp,--kerbprincipal <kerbprincipal>`

Optional.

Kerberos Principal.

`-kt,--kerbkeytab <kerbkeytab>`

Required.

Kerberos keytab file path.

```
-l, --port <port>
```

Optional.

Set LDAP Port value.

```
-lp, --ldappassword <ldappassword>
```

Optional.

LDAP Password.

```
-lu, --ldapusername <ldapusername>
```

Optional.

Set LDAP Username value.

```
-n, --nickname <nickname>
```

Optional.

NetBIOS name (nickname).

## **tsm user-identity-store set-group-mappings [options]**

Sets identity store group mappings and configures LDAP directories that implement an arbitrary or custom schema.

### **Synopsis**

```
tsm user-identity-store set-group-mappings [options]  
[global options]
```

## Options

`-b,--basefilter <groupbasefilter>`

Optional.

Set group BaseFilter value.

`-cn,--classnames <group_classnames>`

Optional.

Override default user classname values (contains "group" string) with the values you set here. You can provide multiple classnames separated by commas.

`-d,--description <description>`

Optional.

Group description.

`-e,--groupemail <groupemail>`

Optional.

Group email value.

`-m,--member <member>`

Optional.

Set the group members.

`-n,--groupname <groupname>`

Optional.

Name of the group.

## **tsm user-identity-store set-user-mappings [options]**

Sets identity store user mappings and configures LDAP directories that implement an arbitrary or custom schema.

### **Synopsis**

```
tsm user-identity-store set-user-mappings --certificate <certificate> [options] [global options]
```

### **Options**

```
-c, --certificate <certificate>
```

Optional.

Users' certificate file location.

```
-cn, --classnames <user_classnames>
```

Optional.

Override default user classname values ("user" and "inetOrgPerson") with the values you set here. You can provide multiple classnames separated by commas.

```
-dn, --displayname <displayname>
```

Optional.

Display name of the user.

```
-e, --email <email>
```

Optional.

Users' email address.

```
-jpg, --jpegphoto <jpegfile>
```

Optional.

Users' jpeg image location.

`-m, --memberof <groupname>`

Optional.

Group that the user is a member of.

`-t, --thumbnail <thumbnail>`

Optional.

Users' thumbnail location.

`-ub, --basefilter <userbasefilter>`

Optional.

Users' BaseFilter.

`-uu, --ldapusername <ldapusername>`

Optional.

User name.

## **tsm user-identity-store verify-group-mappings [options]**

Validates configuration for LDAP group mapping.

### **Synopsis**

```
tsm user-identity-store verify-group-mappings --verify <group_name>  
[global options]
```

### Options

`-v, --verify <group_name>`

Optional.

Name of group to search for.

## **tsm user-identity-store verify-user-mappings [options]**

Validates configuration for LDAP user mapping.

### Synopsis

```
tsm user-identity-store verify-user-mappings --verify <user_name>
[global options]
```

### Options

`-v, --verify <user_name>`

Optional.

Name of user to search for.

## **Global options**

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

```
-s, --server https://<hostname>:8850
```

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

```
--trust-admin-controller-cert
```

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

```
-u, --username <user>
```

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm version

You can use the `tsm version` command to get the versions of TSM and Tableau Server.

### Synopsis

```
tsm version [global options]
```

## Global options

`-h, --help`

Optional.

Show the command help.

`-p, --password <password>`

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces or special characters, enclose it in quotes:

```
--password 'my password'
```

`-s, --server https://<hostname>:8850`

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port `8850`, and use the server name not the IP address. For example `https://<tsm_hostname>:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

`--trust-admin-controller-cert`

Optional.

Use this flag to trust the self-signed certificate on the TSM controller. For more information about certificate trust and CLI connections, see [Connecting TSM clients](#).

`-u, --username <user>`

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

## tsm File Paths

Certain tsm commands read files from or write files to default locations. These default locations are determined by `basefilepath` configuration keys defined for each command. You can use tsm to view the current value of the keys, and to change the locations.

### Default locations for files

During the `tsm maintenance backup`, `restore`, `send-logs`, and `ziplogs` processes, and the `tsm sites export` and `sites import` processes, Tableau Server uses default locations for the files created or used by these commands.

For details on disk space requirements for backing up Tableau Server, see [Disk Space Usage for Backup](#).

By default:

- `tsm maintenance commands`:
  - **backup**—The backup `.tsbak` file is created in a temporary location in the data directory on the initial node and then saved in:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/backups/
```

- **restore**—The restore process restores a backup file from:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/backups/
```

- **send-logs**—The `send-logs` sends the logs file from:

```
/var/opt/tableau/tableau_server/data/tabsvc/files/backups/
```

- **ziplogs**—The `ziplogs` file is generated in:

## Tableau Server on Linux Administrator Guide

```
/var/opt/tableau/tableau_server/data/tabsvc/files/log-archives
```

- tsm sites

- **export**—The export .zip file is generated to the following directory:

```
/var/opt/tableau/tableau_server-  
/data/tabsvc/files/siteexports
```

- **import**—During the import process, Tableau Server looks for files in:

```
/var/opt/tableau/tableau_server-  
/data/tabsvc/files/siteimports
```

### Get the current file location

You can see the current file location for a specific command using `tsm configuration get`:

- For tsm maintenance commands:

- backup, restore, and send-logs:

```
tsm configuration get -k basefilepath.backuprestore
```

- ziplogs:

```
tsm configuration get -k basefilepath.log_archive
```

- For tsm sites commands:

- export

```
tsm configuration get -k basefilepath.site_export.exports
```

- import

```
tsm configuration get -k basefilepath.site_import.exports
```

## Change the current file location

You can change the expected file locations using the `tsm configuration set` command to update the `basefilepath` variables. For details about specific base file paths, see [tsm configuration set Options](#).

Changing a `basefilepath` variable does not move existing files from the original directory to the new directory. If you want existing backup, restore, log files, or site export or import files to reside in the new directory you specify, you must move them manually. You are responsible for creating the new location and for setting the correct permissions to allow tsm access to any files that will be placed there, and to the directory structure containing those files. For more information about permissions and tsm, see [Files and Permissions in TSM](#). If you change the backup/restore base file path, you should run the `tsm maintenance validate-backup-basefilepath` command (available in version 2022.1 and later) to verify the permissions are properly set.

The `tsm maintenance backup` command assembles the backup in a temporary location in the data directory before saving the backup file to the location specified by the `basefilepath.backuprestore` variable. Changing the `basefilepath` does not impact where the `tsm maintenance backup` command assembles the backup file.

- For tsm maintenance commands:
  - To change the backup, restore, or send-logs directory, run the following command:

```
tsm configuration set -k basefilepath.backuprestore -v
"/new/directory/path"
```

- To change the ziplogs directory:

## Tableau Server on Linux Administrator Guide

```
tsm configuration set -k basefilepath.log_archive -v "/new/directory/path"
```

- For tsm sites commands:
  - To change the sites export directory:

```
tsm configuration set -k basefilepath.site_export.exports -v "/new/directory/path"
```

- To change the sites import directory:

```
tsm configuration set -k basefilepath.site_import.exports -v "/new/directory/path"
```

After you change a default file location you need to do the following:

1. Apply pending changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

2. Stop Tableau Server:

```
tsm stop
```

3. Restart the TSM Controller (as *tableau* system account):

```
sudo su -l tableau -c "systemctl --user restart tabadmincontroller_0.service"
```

4. Wait several minutes for the controller to restart. You can confirm the controller has restarted with this command:

```
tsm status -v
```

When you can run that command and the Tableau Server Administration Controller is listed as 'running' the controller has restarted.

5. Start Tableau Server:

```
tsm start
```

## Entity Definitions and Templates

You can use the entity definitions and templates with the `tsm settings import` command to configure various Tableau Server settings.

### Configuration File Example

This article provides an example of a complete JSON configuration file, with `gatewaySettings` and `identityStore` entities specified. In addition, a configuration key sets the gateway timeout to 900 seconds.

Your configuration file will look different depending on the options you need to set.

You might set multiple `.json` configuration files during installation. To set the values for each file in Tableau Server, you run the following command, once for each configuration file:

```
tsm settings import -f path-to-file.json
```

After you set the configuration files, run `tsm pending-changes apply` to apply the changes from all of the `.json` files you've set.

```
{
  "configEntities": {
    "gatewaySettings": {
      "_type": "gatewaySettingsType",
      "port": 80,
      "publicHost": "localhost",
      "publicPort": 80
    },
    "identityStore": {
      "_type": "identityStoreType",
      "type": "local",
      "domain": "example.lan",
      "nickname": "EXAMPLE"
    }
  },
  "configKeys": {
    "gateway.timeout": "900"
  }
}
```

### Entities vs keys

As shown in the example above, there are two classes of configuration parameters: `configEntities` and `configKeys`.

#### **configEntities**

Certain types of configuration are done through entity sets that map to specific scenarios, such as the identity store and gateway configurations. When you pass a set of `configEntities` with the `tsm settings import -f path-to-file.json` command, TSM validates the configuration. If values passed are invalid, TSM will provide an error. This enables you to make changes during the configuration process, rather than experience a configuration failure at initialization or run time.

Entities can be set only by including a `configEntities` block in a `.json` file.

**Important:** All files that are referenced in `configEntities` must be located on the local computer. Do not specify UNC paths.

## **configKeys**

Entities cover only a small portion of the configuration values that can be set. Hundreds of keys correspond to parameters stored in `.yaml` files. Tableau Server uses these parameters to store all of the configuration information for all services.

You can set individual keys with the `tsm configuration` command. But during deployment, setting them along with other configuration scenarios in JSON files, as shown above, is more convenient.

Unlike `configEntities`, `configKeys` are not validated.

**Note:** We do not recommend setting parameters that are not documented in `tsm configuration set Options`.

## **gatewaySettings Entity**

You must configure the gateway settings for the Tableau Server computer.

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
tsm settings import -f /path/to/file.json
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the

## Tableau Server on Linux Administrator Guide

`--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### Gateway settings

The gateway settings in the template below specify the HTTP settings for Tableau Server. We recommend using SSL/TLS. Tableau Server is hard-coded to use port 443 for SSL/TLS. Therefore, if you enable SSL, you do not need to update the `gatewaySettings` entity.

### Configuration template

Use this template to configure the gateway settings.

**Important:** All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see [Configuration File Example](#).

```
{
  "configEntities": {
    "gatewaySettings": {
      "_type": "gatewaySettingsType",
      "port": 80,
      "sslRedirectEnabled": true,
      "publicHost": "localhost"
    }
  }
}
```

### Configuration file reference

This table includes all of the options that can be included with the `"gatewaySettings"` entity set.

`_type`

Required.

Value: "gatewaySettingsType"

Do not change.

port

Specifies HTTP port. Default is port 80.

sslRedirectEnabled

Options: true or false.

publicHost

Specifies host name for http/s service.

trustedIPs

Specifies trusted IP addresses that communicate with Tableau Server. Trusted IP addresses include upstream proxy servers and servers that are used for trusted authentication with Tableau Server. See [Configuring Proxies and Load Balancers for Tableau Server](#) and [Add Trusted IP Addresses or Host Names to Tableau Server](#).

If you are running Tableau Server in a cluster then all other nodes of the cluster will automatically be included in the corresponding configuration file that this entity updates. Therefore, if you specify a new value for `trustedIPs`, then you must include the IP addresses for the other nodes in the value.

This option takes a list of strings, which requires passing each IP or host in quotes, separated by a comma (no space) and within brackets. For example:

```
["192.168.1.101", "192.168.1.102", "192.168.1.103"] or ["web-serv1", "webserv2", "webserv3"].
```

trustedHosts

Specifies trusted IP addresses that communicate with Tableau Server. Typically, this value contains a list of upstream proxy servers. The values in `trustedHosts` are used to

determine client request targets.

If you are running Tableau Server in a cluster then all other nodes of the cluster will automatically be included in the corresponding configuration file that this entity updates.

Therefore, if you specify a new value for `trustedIPs`, then you must include the IP addresses for the other nodes in the value.

This option takes a list of strings, which requires passing each IP or host in quotes, separated by a comma (no space) and within brackets. For example:

```
["192.168.1.101", "192.168.1.102", "192.168.1.103"] or ["web-  
serv1", "webserv2", "webserv3"].
```

## identityStore Entity

Tableau Server requires an identity store to store user and group information. Review Authentication and Identity Store topics before configuring the identity store for the first time. After you have installed the identity store on Tableau Server, you cannot change it without reinstalling the server.

**Important:** All entity options are case sensitive.

### Before you begin

Review the following information:

- If you will not be using the local identity store, then you will be using some version of LDAP. In this case, work with your directory/LDAP administrator to configure Tableau Server for your LDAP schema and bind requirements.
- Tableau Server configuration is optimized for Active Directory. If you are installing into Active Directory, we recommend configuring the identity store with Configure Initial Node Settings.
- LDAP bind is independent of user authentication. For example, you can configure Tableau Server to use simple bind to authenticate to the LDAP directory and then configure Tableau Server to authenticate users with Kerberos after installation.

- Do not connect to LDAP with simple bind over an unsecured connection. By default, LDAP with simple bind sends data in cleartext. Use LDAPS to encrypt traffic with simple bind. See [Configure Encrypted Channel to LDAP External Identity Store](#).
- To use Kerberos authentication for the LDAP bind with Tableau Server service, then you'll need a keytab file for GSSAPI bind, as described in the sections below. See also, [Understanding Keytab Requirements](#). In the context of Kerberos, GSSAPI bind is all you need during the base installation of Tableau Server. After you install the server, you can then [configure Kerberos for user authentication](#) and [Kerberos delegation to data sources](#).
- In this topic, we make the distinction between *LDAP* (the protocol for connecting to directory services) and an *LDAP server* (an implementation of a directory service). For example, `slapd` is an LDAP server that is part of the OpenLDAP project.
- Validate the LDAP configuration before initializing the server, see [Configure Initial Node Settings](#).
- Import JSON configuration files only as part of the initial configuration. If you need to make LDAP changes after you have imported the JSON configuration file and initialized Tableau Server, do not attempt to re-import the JSON file. Rather, make individual key changes with native `tsm` commands or with `tsm configuration set`. See [External Identity Store Configuration Reference](#).

## Configuration templates

The JSON templates in this section are used to configure Tableau Server with different identity store scenarios. Unless you're configuring a local identity store, you will need to select and edit a configuration file template that is specific to your LDAP environment.

Consider using the [Tableau Identity Store Configuration Tool](#) to help generate your LDAP JSON configuration file. The tool itself is not supported by Tableau. However, using a JSON file created by the tool instead of creating a file manually does not change the supported status of your server.

Select an identity store configuration template to edit:

## Tableau Server on Linux Administrator Guide

- Local
- LDAP - Active Directory
- OpenLDAP - GSSAPI Bind
- OpenLDAP - Simple Bind

For more explanation about configuration files, entities, and keys see Configuration File Example.

### Local

Configure local as the identity store type if your organization does not already have an Active Directory or LDAP server for user authentication. When you select local as the identity store type, you use Tableau Server to create and manage users.

An alternative way to configure Tableau Server for local identity store is to run Setup GUI and select "Local" during the installation process. See Configure Initial Node Settings.

```
{
  "configEntities": {
    "identityStore": {
      "_type": "identityStoreType",
      "type": "local"
    }
  }
}
```

#### Important

The LDAP configuration templates below are examples. The templates, as presented, will not configure LDAP connectivity in your organization.

You must work with your directory administrator to edit the LDAP template values for a successful deployment.

Additionally, all files that are referenced in configEntities must be located on the local computer. Do not specify UNC paths.

## LDAP - Active Directory

Tableau Server configuration is optimized for Active Directory. If you are installing into Active Directory, configure the identity store with Configure Initial Node Settings.

An encrypted connection to Active Directory is required. See Configure Encrypted Channel to LDAP External Identity Store.

If for some reason you are unable to configure the identity store to communicate with Active Directory with TSM web interface, use this JSON template to configure Tableau Server to connect to Active Directory. This template uses GSSAPI (Kerberos) bind to authenticate Tableau Server service to Active Directory. Tableau Server includes support for Active Directory schema. Therefore, if you set the "directoryServiceType" option to "activedirectory" then you do not need to provide schema info in the "identityStoreSchemaType" option.

If you are installing Tableau Server for Linux into Active Directory, and the computer where you are installing Tableau Server is already joined to the domain, then the computer will already have a Kerberos configuration file and a keytab file. Strictly speaking, you can use these files for GSSAPI bind, but we don't recommend using them. Instead, contact your Active Directory administrator and request a keytab specifically for the Tableau Server service.

```
{
  "configEntities":{
    "identityStore": {
      "_type": "identityStoreType",
      "type": "activedirectory",
      "domain": "your-domain.lan",
      "nickname": "YOUR-DOMAIN-NICKNAME",
      "directoryServiceType": "activedirectory",
      "bind": "gssapi",
      "kerberosKeytab": "<path to local key tab file>",
      "kerberosConfig": "/etc/krb5.conf",
      "kerberosPrincipal": "your-principal@YOUR.DOMAIN"
    }
  }
}
```

```
    }  
  }  
}
```

We recommend binding to Active Directory with GSSAPI. However, you can connect with simple bind and LDAPS. To connect with simple bind, change `bind` to `simple`, remove the three Kerberos entities, and add the `port/sslPort`, `username`, and `password` options. The following example shows Active Directory with simple bind json.

```
{  
  "configEntities":{  
    "identityStore": {  
      "_type": "identityStoreType",  
      "type": "activedirectory",  
      "domain": "your-domain.lan",  
      "nickname": "YOUR-DOMAIN-NICKNAME",  
      "directoryServiceType": "activedirectory",  
      "hostname": "optional-ldap-server",  
      "sslPort": "636",  
      "bind": "simple",  
      "username": "username",  
      "password": "password"  
    }  
  }  
}
```

### OpenLDAP - GSSAPI bind

Use the template below to configure OpenLDAP with GSSAPI bind. Do not use this template if your organization is running Active Directory. If you are installing into Active Directory, use the template above, LDAP - Active Directory.

In most cases, organizations that use OpenLDAP with GSSAPI (Kerberos) will use a keytab file to store credentials. In the following example, a keytab file is used for authentication credentials.

However, you can provide credentials through the `username` and `password` entities.

You can also specify both a keytab and a username and password pair. In this case, Tableau Server will attempt to use the keytab, but if authentication fails for any reason it will fallback and use the username and password credentials.

```
{
  "configEntities":{
    "identityStore": {
      "_type": "identityStoreType",
      "type": "activedirectory",
      "domain": "your-domain.lan",
      "nickname": "YOUR-DOMAIN-NICKNAME",
      "directoryServiceType": "openldap",
      "bind": "gssapi",
      "kerberosKeytab": "<path to local key tab file>",
      "kerberosConfig": "/etc/krb5.conf",
      "kerberosPrincipal": "your-principal@YOUR.DOMAIN",
      "identityStoreSchemaType": {
        "userBaseFilter": "(objectClass=inetOrgPerson)",
        "userUsername": "user",
        "userDisplayName": "displayname",
        "userEmail": "email",
        "userCertificate": "certificate",
        "userThumbnail": "thumbnail",
        "userJpegPhoto": "photo",
        "groupBaseFilter": "(objectClass=groupofNames)",
        "groupName": "groupname",
        "groupEmail": "groupemail",
        "groupDescription": "groupdescription",
        "member": "member",
        "distinguishedNameAttribute": "",
        "serverSideSorting": "",
        "rangeRetrieval": "",
        "userClassNames": ["inetOrgPerson","someClass2"],
        "groupClassNames": ["groupOfU-
niqueNames1","groupOfUniqueNames2"]
      }
    }
  }
}
```

```
    }  
  }  
}
```

### OpenLDAP - Simple bind

```
{  
  "configEntities":{  
    "identityStore": {  
      "_type": "identityStoreType",  
      "type": "activedirectory",  
      "domain": "my.root",  
      "nickname": "",  
      "hostname": "optional-ldap-server",  
      "port": "389",  
      "directoryServiceType": "openldap",  
      "bind": "simple",  
      "username": "cn=username,dc=your,dc=domain",  
      "password": "password",  
      "identityStoreSchemaType": {  
        "userBaseFilter": "(objectClass=inetOrgPerson)",  
        "userUsername": "user",  
        "userDisplayName": "displayname",  
        "userEmail": "email",  
        "userCertificate": "certificate",  
        "userThumbnail": "thumbnail",  
        "userJpegPhoto": "photo",  
        "groupBaseFilter": "(objectClass=groupofNames)",  
        "groupName": "groupname",  
        "groupEmail": "groupemail",  
        "groupDescription": "groupdescription",  
        "member": "member",  
        "distinguishedNameAttribute": "",  
        "serverSideSorting": "",  
        "rangeRetrieval": "",  
        "userClassNames": ["inetOrgPerson","someClass2"],
```

```

        "groupClassNames": ["groupOfU-
niqueNames1", "groupOfUniqueNames2"]
    }
}
}
}

```

## Configuration template reference

### Shared identity store options

#### type

Where you want to store user identity information. Either `local` or `activedirectory`. (If you want to connect to any LDAP server, select `activedirectory`.)

#### domain

The domain of the computer where you installed Tableau Server.

#### nickname

The nickname of the domain. This is also referred to as the NetBIOS name in Windows environments.

The `nickname` option is required for all LDAP entities. If your organization does not require a nickname/NetBIOS, then pass a blank key, for example: `"nickname": ""`.

### LDAP GSSAPI bind options

#### directoryservicetype

The type of directory service that you want to connect to. Either `activedirectory` or `openldap`.

#### kerberosConfig

The path to the Kerberos configuration file on the local computer. If you are installing into Active Directory, we don't recommend using the existing Kerberos configuration

file or keytab file that may already be on the domain-joined computer. See Identity Store.

### `kerberosKeytab`

The path to the Kerberos keytab file on the local computer. It is recommended that you create a keytab file with keys specifically for Tableau Server service and that you do not share the keytab file with other applications on the computer. For example, on Linux, you might place the keytab file in the `/var/opt/tableau/keytab` directory.

### `kerberosPrincipal`

The service principal name for Tableau Server on the host machine. The keytab must have permission for this principal. Do not use the existing system keytab at `/etc/krb5.keytab`. Rather, we recommend that you register a new service principal name. To see principals in a given keytab, run the `klist -k` command. See Understanding Keytab Requirements.

## LDAP simple bind options

### `directoryservicetype`

The type of directory service that you want to connect to. Either `activedirectory` or `openldap`.

### `hostname`

The hostname of the LDAP server. You can enter a hostname or an IP address for this value. The host that you specify here will be used for user/group queries on the primary domain only. If user/group queries are in other domains (not in the primary domain), Tableau Server will not use this value, but instead will query DNS to identify the appropriate domain controller.

### `port`

Use this option to specify the non-secure port of the LDAP server. Plaintext is usually 389.

`sslPort`

Use this option to enable LDAPS. Specify the secure port of the LDAP server. LDAPS is usually port 636. To use LDAPS you must also specify hostname option. See [Configure Encrypted Channel to LDAP External Identity Store](#).

`username`

The user name that you want to use to connect to the directory service. The account that you specify must have permission to query the directory service. For Active Directory, enter the username, for example, `jsmith`. For LDAP servers, enter the distinguished name (DN) of the user that you want to use to connect. For example, you might enter `cn=username,dc=your-local-domain,dc=lan`.

`password`

The password of the user that you want to use to connect to the LDAP server.

## LDAPS and subdomains

If you're enabling LDAPS in Active Directory and connecting to subdomains, you'll need to run the following TSM command to configure the LDAPS port (TCP 636) for subdomains. The command takes arguments that specify `subdomainFQDN:port`.

**Example:** `tsm configuration set -k wgserver.domain.ldap.domain_custom_ports -v subdomain1.lan:636,subdomain2.lan:636,subdomain3.lan:636`

For more information, see [tsm configuration set Options](#).

## Shared LDAP options

The following options can be set for generic LDAP, OpenLDAP, or Active Directory implementations.

`bind`

The way that you want to authentication communication from the Tableau Server service to the LDAP directory service. Enter `gssapi` for GSSAPI (Kerberos).

## Tableau Server on Linux Administrator Guide

### `domain`

In Active Directory environments, specify the domain where Tableau Server is installed, for example, "example.lan".

For non-AD LDAP: the string you enter for this value is displayed in the "Domain" column of user management tools. You can enter an arbitrary string, but the key cannot be blank.

### `root`

LDAP only. Do not specify for Active Directory.

If you do not use a dc component in the LDAP root or you want to specify a more complex root you need to set the LDAP root. Use the "o=my,u=root" format. For example, for the domain, `example.lan`, the root would be "o=example,u=lan".

### `membersRetrievalPageSize`

This option determines the maximum number of results returned by an LDAP query. For example, consider a scenario where Tableau Server is importing an LDAP group that contains 50,000 users. Attempting to import such a large number of users in a single operation is not a best practice. When this option is set to 1500, Tableau Server imports the first 1500 users in the first response. After those users are processed, Tableau Server requests the next 1500 users from the LDAP server, and so forth. We recommend that you modify this option only to accommodate the requirements of your LDAP server.

### `identityStoreSchemaType` options

If you configure an LDAP connection to an LDAP server, you can enter schema information specific to your LDAP server in the `identityStoreSchemaType` object.

**Important** If you are connecting to Active Directory ("`directoryServiceType`": "`activedirectory`"), then do not configure these options.

### `userBaseFilter`

The filter that you want to use for users of Tableau Server. For example, you might specify an object class attribute and an organization unit attribute.

`userUsername`

The attribute that corresponds to user names on your LDAP server.

`userDisplayName`

The attribute that corresponds to user display names on your LDAP server.

`userEmail`

The attribute that corresponds to user email addresses on your LDAP server.

`userCertificate`

The attribute that corresponds to user certificates on your LDAP server.

`userThumbnail`

The attribute that corresponds to user thumbnail images on your LDAP server.

`userJpegPhoto`

The attribute that corresponds to user profile images on your LDAP server.

`groupBaseFilter`

The filter that you want to use for groups of users of Tableau Server. For example, you might specify an object class attribute and an organization unit attribute.

`groupName`

The attribute that corresponds to group names on your LDAP server.

`groupEmail`

The attribute that corresponds to group email addresses on your LDAP server.

`groupDescription`

The attribute that corresponds to group descriptions on your LDAP server.

### `member`

The attribute that describes the list of users in a group.

### `distinguishedNameAttribute`

The attribute that stores the distinguished names of users. This attribute is optional, but it greatly improves the performance of LDAP queries.

### `serverSideSorting`

Whether the LDAP server is configured for server-side sorting of query results. If your LDAP server supports server-side sorting, set this option to `true`. If you are unsure whether your LDAP server supports this, enter `false`, as misconfiguration may cause errors.

### `rangeRetrieval`

Whether the LDAP server is configured to return a range of query results for a request. This means that groups with many users will be requested in small sets instead of all at once. LDAP servers that support range retrieval will perform better for large queries. If your LDAP server supports range retrieval, set this option to `true`. If you are unsure whether your LDAP server supports range retrieval, enter `false`, as misconfiguration may cause errors.

### `groupClassNames`

By default Tableau Server looks for LDAP group object classes containing the string “group”. If your LDAP group objects do not fit the default class name, override the default by setting this value. You can provide multiple classnames separated by commas. This option takes a list of strings, which requires passing each class in quotes, separated by a comma (no space) and within brackets. For example:

```
["basegroup", "othergroup"].
```

### `userClassNames`

By default Tableau Server looks for LDAP user object classes containing the string “user” and “inetOrgPerson”. If your LDAP user objects do not use these default class names, override the default by setting this value. You can provide multiple classnames separated by commas. This option takes a list of strings, which requires passing each

class in quotes, separated by a comma (no space) and within brackets. For example:  
`["userclass1",userclass2"]`.

## Importing the JSON file

After you have finished editing the JSON file, pass the file and apply settings with the following commands:

```
tsm settings import -f path-to-file.json
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## kerberosSettings Entity

Before you configure Kerberos authentication, review Kerberos Requirements.

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
tsm settings import -f /path/to/file.json
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do

not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Configuration template

Use this template to configure Kerberos settings.

**Important:** All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.

After you have finished with the initial configuration of Kerberos authentication, use the `tsm authentication kerberos <commands>` sub-category to set additional values.

```
{
  "configEntities": {
    "kerberosSettings": {
      "_type": "kerberosSettingsType",
      "enabled": "true",
      "keytabFile": "/path/to/keytab_file"
    }
  }
}
```

## Configuration file reference

The following list includes all of the options that can be included with the `"kerberosSettings"` entity set.

| Option | Value |
|--------|-------|
|--------|-------|

|                      |  |
|----------------------|--|
| <code>enabled</code> |  |
|----------------------|--|

**Options:** `true` or `false`.

Enables Kerberos authentication.

`keytabFile`

Required.

Path to valid Kerberos keytab file.

`dbClasses`

Comma-separated list of database classes for global credentials. May be required for connecting to Cloudera data sources.

## mutualSSLSettings Entity

Before you configure mutual SSL, review [Configure SSL for External HTTP Traffic to and from Tableau Server](#).

The `mutualSSLSettings` entity combines both SSL and mutual SSL configuration. Mutual SSL requires that external SSL has been enabled and properly configured.

The TSM entities use JSON and key-value pairs. Use the configuration file template below to create a `.json` file. Provide values for the appropriate keys for your environment, and then pass the `.json` file to Tableau Server with the following commands:

```
tsm settings import -f <path-to-file.json>
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Configuration template

Use this template to configure mutual SSL settings.

**Important:** All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.

```
{
  "configEntities": {
    "mutualSSLSettings": {
      "_type": "mutualSSLSettingsType",
      "sslEnabled": true,
      "proxyLogin": false,
      "clientCertRequired": true,
      "caCertFile": "required",
      "keyFileName": "required",
      "keyPassphrase": "",
      "chainFile": "",
      "revocationFile": "",
      "redirect": false,
      "fallbackToPassword": true,
      "protocols": "",
      "cipherSuite": "",
      "forceHttpsForPublicEmbed": false
    }
  }
}
```

## Configuration file reference

sslEnabled

Enable SSL. This is a prerequisite to enabling mutual SSL.

`clientCertRequired` (MutualSSL)

Set to true to enable mutual SSL authentication. Set to false to disable.

`caCertFile` (MutualSSL)

Required.

Specify the CA-issued certificate file for two-way SSL. The file path must be readable by Tableau Server.

`certFileName`

Specify the file that contains the concatenation of PEM encoded CA certificates that form the certificate chain for the server certificate.

Alternatively the referenced file can be the same as `caCertFile` when the CA certificates are directly appended to the server certificate for convenience.

`keyFileName`

If the key is not combined with the certificate, use this configuration key to point to the key file. If you have both an RSA and a DSA private key, you can configure both in parallel (for example, to also allow the use of DSA ciphers).

`keyPassphrase`

Optional. Passphrase for the certificate file. The passphrase you enter will be encrypted while at rest.

**Note:** If you create a certificate key file with a passphrase, you cannot reuse the SSL certificate key for SAML.

`revocationFile`

Specifies the file path for an SSL CA Certificate Revocation List (.crl) file.

### `Redirect`

Default: `true`. Specifies whether Tableau Server should redirect http requests as https requests to the appropriate endpoint.

### `clientCertMapping` (MutualSSL)

Specifies the method for retrieving the user name from the certificate.

Accepted values: `ldap`, `upn`, `cn`

- For a server using local authentication, the default setting is `upn` (User Principal Name).
- When Tableau Server authentication is configured for Active Directory (AD), the default is `ldap` (Lightweight Directory Access Protocol). This tells the server to go to AD to validate the user, and it ignores the names inside the certificate.

You can set `cn` for either authentication type to use the CN in the Subject DN in the certificate.

For more information, see [Mapping a Client Certificate to a User During Mutual Authentication](#).

### `fallbackToPassword` (MutualSSL)

Set to `true` to give users the option to sign in to Tableau Server through their user name and password if mutual SSL authentication fails. Set to `false` to disallow this fallback option.

### `protocols`

List the Transport Layer Security (TLS) protocol versions you want to allow or disallow.

Default value: `"all -SSLv2 -SSLv3"`

However, we recommend the using the following setting:

```
"all -SSLv2 -SSLv3 -TLSv1 -TLSv1.1"
```

For more information, see `tsm security external-ssl enable`. For general information, see the Apache online documentation.

`cipherSuite`

List ciphers to allow or disallow for SSL.

Default value:

```
"HIGH:MEDIUM:!aNULL:!MD5:!RC4:!3DES:!CAMELLIA:!IDEA:!SEED"
```

See the [OpenSSL ciphers](#) page for cipher list format. Use caution when changing this option. The default values disallow ciphers that are no longer considered adequately secure.

`proxyLogin`

Default: `false`. Indicates that Tableau Server uses a proxy for SSL on sign-in only. It controls the protocol the server reports to Tableau Desktop for sign-in APIs.

`forceHTTPForPublicEmbed`

Default value: `false`. Forces the code for embedded views to use SSL.

## openIDSettings Entity

Before you configure OpenID authentication, review [Requirements for Using OpenID Connect](#).

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
tsm settings import -f path-to-file.json
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### Configuration template

Use this template to configure OpenID settings.

**Important:** All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.

After you have finished with the initial configuration of OIDC, use the `tsm authentication openid <commands>` sub-category to set additional values.

```
{
  "configEntities": {
    "openIDSettings": {
      "_type": "openIDSettingsType",
      "enabled": true,
      "clientId": "required",
      "clientSecret": "required",
      "configURL": "required if staticFile value is not set",
      "staticFile": "required if configURL value is not set",
      "externalURL": "required"
    }
  }
}
```

### Configuration file reference

The following list includes all of the options that can be included with the "openIDSettings" entity set.

`_type`

Required.

Do not change.

`enabled`

Required.

Set to `true`.

`clientId`

Required.

Specifies the provider client ID that your IdP has assigned to your application. For example, `"laakjwdlnaoiloadjkwha"`.

`clientSecret`

Required.

Specifies the provider client secret. This is a token that is used by Tableau to verify the authenticity of the response from the IdP. This value is a secret and should be kept securely.

For example, `"fwahfkjaw72123="`.

`configURL`

Required.

Specifies provider configuration URL. If you do not specify a configuration URL, then delete this option and specify a path and file name for `staticFile` instead.

`staticFile`

Required.

## Tableau Server on Linux Administrator Guide

Specifies the local path to the static OIDC discovery JSON document. If you do not specify a static file, then delete this option and specify a url for `configURL` instead.

`externalURL`

Required.

The URL of your server. This is typically is the public name of your server, such as `http://example.tableau.com`.

`connectionTimeout`

Optional.

Specifies connection timeout span in seconds. Default is 10.

`readTimeout`

Optional.

Specifies read timeout span in seconds. Default is 30.

`ignoreDomain`

Set this to `true` if the following are true:

- You are using email addresses as usernames in Tableau Server
- You have provisioned users in the IdP with multiple domain names
- You want to ignore the domain name portion of the `email` claim from the IdP

Before you proceed, review the user names that will be used as a result of setting this option to `true`. User name conflicts may occur. In the case of a user name conflict, the risk of information disclosure is high. See Requirements for Using OpenID Connect.

`ignoreJWK`

Set this to `true` if your IdP does not support JWK validation. In this case, we recom-

mend authenticating communication with your IdP using mutual TLS or another network layer security protocol. Default is `false`.

#### `customScope`

Specifies a custom scope user-related value that you can use to query the IdP. See Requirements for Using OpenID Connect.

#### `idClaim`

Change this value if your IdP does not use the `subclaim` to uniquely identify users in the ID token. The IdP claim that you specify should contain a single, unique string.

#### `usernameClaim`

Change this value to the IdP claim that your organization will use to match user names as stored in Tableau Server.

#### `clientAuthentication`

Specifies custom client authentication method for OpenID Connect.

To configure Tableau Server to use the Salesforce IdP, set this value to `client_secret_post`.

#### `iFramedIDPEnabled`

Set to `true` to allow IdP displayed in an iFrame. The IdP must disable clickjack protection to allow iFrame presentation.

## samlSettings Entity

This article contains a template and reference for configuring server-wide SAML on Tableau Server, using a configuration file with keys and values for the `samlSettings` entity. This information supplements the SAML configuration steps in Configure Server-Wide SAML.

To create a SAML configuration template and apply it to Tableau Server, you complete the following steps:

1. Review the following two sections that describe the template and how it's structured (Template categories and definitions and `samlSettings` configuration template).
2. Paste the JSON code shown in the template into a new text file, and save it using a `.json` extension.
3. Use the SAML configuration entity reference to help you provide values where required.
4. Add optional key/value pairs specific to your environment. For example, if your SAML certificate key file requires a passphrase, you will need to specify the password in the `wgserver.saml.key.passphrase` parameter using the `tsm configuration set` command.
5. Pass the configuration file to Tableau Server.

### Template categories and definitions

The template uses placeholders for each key value. These placeholders are categorized as follows:

- **Required:** Attributes with the `"required"` value must be replaced with valid data before you run the configuration command. Review the configuration file reference for valid values.
- **Hard-coded:** Attribute names that are prepended with an underscore (`_`), for example `"_type"` hold hard-coded values. Do not change these values.
- **Default values:** Attributes that are set to a value that is not `"required"` are default values. These are required attributes that you can change as appropriate for your environment.
- **Empty sets:** Values that are empty (`" "`) can be passed as they are, or you can provide a value for your installation.

**Important:** All entity options are case sensitive.

## samlSettings configuration template

Paste this code into a text file and customize it for your environment, using the reference below.

```
{
  "configEntities": {
    "samlSettings": {
      "_type": "samlSettingsType",
      "enabled": true,
      "returnUrl": "required",
      "entityId": "required",
      "certFile": "required",
      "keyFile": "required",
      "idpMetadataFile": "required",
      "idpDomainAttribute": "",
      "idpUsernameAttribute": "required"
    }
  }
}
```

## SAML configuration entity reference

The following list includes all of the options you can include with the "samlSettings" entity set.

### idpMetadataFile

Required. The path and file name for the XML file generated by the IdP. The XML metadata must include the user name attribute (assertion).

If you completed the steps described in Configure Server-Wide SAML the value you

## Tableau Server on Linux Administrator Guide

enter here would be:

```
/var/opt/tableau/tableau_server/data/saml/<metadata-file.xml>
```

enabled

true | false

Required. Indicates whether SAML authentication is enabled. Do not set this option to `true` before setting other required SAML configuration options.

returnURL

This is typically the external URL that Tableau Server users enter in their browser to access the server, such as `https://tableau_server.example.com`. This value is used to create the ACS URL attribute when configuring the IdP.

entityId

Required. Service provider (in this case, Tableau Server) entity ID value.

Identifies your Tableau Server configuration to the IdP. We recommend that you enter the same value as the `returnURL` option.

idpUsernameAttribute

Required. In the IdP metadata, find the attribute that is used to specify user name values, and enter the name of that attribute. Default is `username`.

certFile

Required. Enter the location and file name of the x509 certificate (`.crt`) file for SAML. For example:

```
/var/opt/tableau/tableau_server/data/saml/<file.crt>
```

For more information, see [SAML Requirements and Configure Server-Wide SAML](#).

keyFile

Required. Specify the location of the private key (.key) file that accompanies the certificate file. For example:

```
/var/opt/tableau/tableau_server/data/saml/<file.key>
```

**Note:** If you are using a RSA PKCS#8 key that requires a passphrase, you must set the passphrase using a configKey entity (see Configuration File Example) or with tsm configuration set. The key for the passphrase using these methods is `wgserver.saml.key.passphrase`. The value must be a non-null string.

idpDomainAttribute

For organizations that use LDAP or Active Directory, this value specifies which SAML attribute Tableau Server will reference to determine the domain name. For example, if your IdP specifies the domain name in the `domain` attribute, then you would specify `domain` for this value. **Note:** For organizations that have users signing in from multiple domains, this value is required.

If you do not provide a value for this key, the value used depends on the Tableau Server identity store setting:

- For local identity store, the `idpDomainAttribute` value is ignored.
- For Active Directory or LDAP identity stores, Tableau uses the FQDN from the configuration setting `wgserver.domain.default`.

To get the value for `wgserver.domain.default`, you can run the following command:

```
tsm configuration get --key wgserver.domain.default
```

desktopNoSAML

true | false

## Tableau Server on Linux Administrator Guide

Optional. Allow users to use SAML authentication when they sign in from Tableau Desktop.

By default this is not set, so the effective behavior is equivalent to setting it to `false`. If single sign-on from Tableau client applications does not work with your IdP, you can set this to `true` to disable SAML authentication through Tableau Desktop.

`appNoSAML`

`true | false`

Optional. Allow using SAML to sign in from older versions of Tableau Mobile app. Devices running Tableau Mobile app version 19.225.1731 and higher ignore this option. To disable devices running Tableau Mobile app version 19.225.1731 and higher, disable SAML as a client login option on Tableau Server.

`logoutEnabled`

`true | false`

Optional. Enables single logout for users who have logged on with SAML. The default is `true`.

The IdP configuration metadata must include a single logout endpoint with POST binding.

This setting applies only for server-wide SAML

When set to `false`, Tableau Server will not attempt single logout.

`logoutUrl`

Optional. Enter the URL to redirect to after users sign out of the server. Setting this option requires that `logoutEnabled` is set to `true`.

By default this is the Tableau Server sign-in page. You can specify an absolute or a relative URL.

`maxAuthenticationAge`

Optional. Specifies the maximum number of seconds allowed between a user's authentication with the IdP and processing of the AuthNResponse message. The default value is -1 which means `maxAuthenticationAge` is unset or ignored by default. Prior to February 2022, the default value was 7200 (2 hours).

To optimize session length use the same timeout value as is set on the IdP.

`maxAssertionTime`

Optional. Specifies the maximum number of seconds, from creation, that a SAML assertion is usable. Default value is 3000 (50 minutes).

`sha256Enabled`

`true` | `false`

Optional. The type of signature Tableau Server will use when sending messages to the IdP. When set to `true`, Tableau Server will sign messages with the SHA 256 signature algorithm. When set to `false`, Tableau Server will sign messages with SHA 1. Default is `true`.

This option sets the signature algorithm to the following messages that Tableau Server signs:

- AuthnRequest messages when `signRequests` is enabled.
- LogoutRequest messages if `logoutEnabled` is enabled.

`signRequests`

`true` | `false`

Optional. Specifies whether Tableau Server will sign the AuthnRequests that are sent to the IdP. Signed requests are not always necessary for all IdPs. We recommend signing requests to ensure the most secure option when configuring SAML. To verify whether your IdP accepts signed request, inspect the IdP metadata: if `wantAuth-`

`nRequestsSigned` is set to `true`, then your IdP will accept signed requests.

Default value is `true`. To disable signed requests, set this option to `false`.

### `acceptableAuthnContexts`

Optional. Sets the `AuthNContextClassRef` SAML attribute. This optional attribute enforces validation of certain authentication "contexts" in IdP initiated flows. Set a comma-separated set of values for this attribute. When this attribute is set, Tableau Server validates that the SAML response contains at least one of the values listed. If the SAML response does not contain one of the configured values, authentication will be rejected, even if the user has successfully authenticated with the IdP.

Leaving this option blank will result in default behavior: any successfully authenticated SAML response will result in a user being granted a session within Tableau Server.

### `iFramedIdpEnabled`

`true` | `false`

Optional. Default value is `false`, meaning that when users select the sign-in button on an embedded view, the IdP's sign-in form opens in a pop-up window.

When you set it to `true`, and a server SAML user who is already signed in navigates to a web page with an embedded view, the user will not need to sign in to see the view.

You can set this to `true` only if the IdP supports signing in within an iframe. The iframe option is less secure than using a pop-up, so not all IdPs support it. If the IdP sign-in page implements clickjack protection, as most do, the sign-in page cannot display in an iframe, and the user cannot sign in.

If your IdP does support signing in via an iframe, you might need to enable it explicitly. However, even if you can use this option, it disables Tableau Server clickjack protection for SAML, so it still presents a security risk.

## Pass the configuration file to Tableau Server

After you have provided an appropriate value for each entity you include in the configuration template, use the following commands to pass the `.json` file and apply settings to Tableau

Server.

```
tsm settings import -f path-to-file.json
```

```
tsm pending-changes apply
```

## See also

After you complete the initial SAML configuration, use `tsm authentication mutual-ssl <commands>` to set additional values.

For the command-line reference for configuring SAML, see `tsm authentication saml <commands>`.

## sapHanaSettings Entity

Use the `sapHanaSettings` entity to configure SAML delegation for SAP HANA.

Review [Configure SAP HANA SSO](#) before you continue.

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
tsm settings import -f path-to-file.json
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Tableau Server on Linux Administrator Guide

### SAP HANA SAML settings

The settings in the template below specify the settings for Tableau Server in a SAML delegation scenario with SAP HANA.

#### Configuration template

Use this template to configure trusted authentication settings.

All that are referenced in configEntities must be located on the local computer. Do not specify UNC paths.

**Important:** All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.

```
{
  "configEntities": {
    "sapHanaSettings": {
      "_type": "sapHanaSettingsType",
      "enabled": "true",
      "usernameFormat": "username",
      "usernameCase": "preserve",
      "certFile": "path-to-cert_file",
      "keyFile": "path-to-key_file"
    }
  }
}
```

#### Configuration file reference

This table includes all of the options that can be included with the "gatewaySettings" entity set.

enabled

Required.

**Values:** true or false

usernameFormat

**Values:** username, domain\_and\_username, or email

Specifies user name credential format.

usernameCase

**Values:** lower, upper, or preserve

Specifies user input name case.

certFile

Specifies file path and name for the certificate file on the local computer.

For example, "/var/opt/tableau/tableau\_server/data/saml/saml\_certificate.crt".

keyFile

Specifies file path and name for the certificate key on the local computer.

For example, "/var/opt/tableau/tableau\_server/data/saml/saml\_key.der".

## shareProductUsageDataSettings Entity

Before you configure this entity, see Product usage data to better understand the behavioral and usage data that Tableau collects. (Your confidential database values are never included.)

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
tsm settings import -f /path/to/file.json
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### Configuration template

Use this template to configure product usage data settings.

**Important:** All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.

```
{
  "configEntities": {
    "shareProductUsageDataSettings": {
      "_type": "shareProductUsageDataSettingsType",
      "enabled": "true"
    }
  }
}
```

### Configuration file reference

The following list includes all of the options that can be included with the "shareProductUsageDataSettings" entity set:

`_type`

**Required value:** `shareProductUsageDataSettingsType`

`enabled`

Options: `true` or `false`

The default, `true`, shares product usage data from your server with Tableau.

## trustedAuthenticationSettings Entity

Before you configure trusted authentication, review Trusted Authentication.

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
tsm settings import -f /path/to/file.json
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

## Configuration template

Use this template to configure trusted authentication settings.

**Important:** All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.

After you have finished with the initial configuration of trusted authentication, use the `tsm authentication trusted <commands> sub-category` to set additional values.

```
{  
  "configEntities": {  
    "trustedAuthenticationSettings": {
```

```
        "_type": "trustedAuthenticationSettingsType",
        "trustedHosts": ["webserv1", "webserv2", "webserv3"]
    }
}
```

## Configuration file reference

The following list includes all of the options that can be included with the "trustedAuthenticationSettings" entity set.

trustedHosts

Required.

IP address or host names of web servers that request trusted tickets from Tableau Server.

This option takes a list of strings, which requires passing each IP or host in quotes, separated by a comma (no space) and within brackets. For example:

```
["192.168.1.101", "192.168.1.102", "192.168.1.103"] or ["webserv1", "webserv2", "webserv3"].
```

The values you specify overwrite previous settings. Therefore, you must include the full list of hosts when you configure this value.

tokenLength

Optional.

The value can be set to any integer between 9 and 255, inclusive.

Determines the number of characters in each trusted ticket. The default setting of 24 characters provides 144 bits of randomness. This option is ignored unless `useV2Tickets` is set to `true`, which is not a recommended best practice.

logLevel

Optional.

`all | debug | info | warn | error | fatal | off`

**Default:** `info`

Specifies logging level for processes related to creating and redeeming trusted tickets.

See [Change Logging Levels](#).

`timeoutInSeconds`

Optional.

**Default:** `180`

Specifies the length of time (in seconds) to invalidate trusted tickets after they are created.

`tryCount`

Optional.

Integer.

**Default:** `10`

Specifies the number of times to attempt to create a trusted ticket entry.

`use9DigitToken`

Optional.

`true | false`

**Default:** `false`

When set to `true`, tickets are 9 digits long (as in version 8.0 and earlier) and the option `tokenLength` is ignored. This option is intended for temporary support of legacy code.

**Warning:** Setting this option to `true` severely and negatively impacts the security strength of trusted ticket authentication.

`useV2Tickets`

Optional.

`true | false`

Default: `false`

Specifies whether Tableau Server should return a legacy URL format for trusted ticket requests. The legacy URL format includes a 24 character, Base64-encoded string. Beginning with Tableau Server 10.3, the URL that is returned has been updated and includes a Base64-encoded UUID and a 24 character secure random string. Only set option this to `true` if you have deployed trusted tickets with custom code that requires the legacy URL format. We recommend instead, updating your custom code to accept the new URL format.

□

## web-data-connector-settings Entity

This entity is used to manage web data connector (WDC) settings. To learn more about using WDCs in Tableau Server, see [Web Data Connectors in Tableau Server](#) and [tsm data-access](#).

Use the configuration file template below to create a `.json` file. After you have filled in the options with the appropriate values, pass the `.json` file and apply settings with the following commands:

```
tsm settings import -f /path/to/file.json
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--`

`ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

### Web data connector settings

The web data connector (WDC) settings in the template below specify whether WDCs are enabled, whether refresh of WDCs is enabled, and the primary and secondary safe lists. The safe lists indicate which WDC URLs are approved for use in your Tableau Server installation, and the domains or URLs that a connector can send requests to and receive requests from.

### Configuration template

Use this template to configure the WDC settings.

**Important:** All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see [Configuration File Example](#).

## Single WDC

```
{
  "configEntities": {
    "web-data-connector-settings": {
      "_type": "webDataConnectorSettingsType",
      "refreshEnabled": true,
      "whitelist": {
        "https://www.example.com:443/wdc/": {
          "secondaryWhitelist": [
            "https://www.example.com/*.*",
            "https://www.coolapi.com/*.*"
          ]
        }
      }
    }
  },
}
```

```
        "enabled": true
      }
    }
  }
}
```

## Multiple WDCs

```
{
  "configEntities": {
    "web-data-connector-settings": {
      "_type": "webDataConnectorSettingsType",
      "refreshEnabled": true,
      "whitelist": {
        "https://www.example.com:443/wdc/": {
          "secondaryWhitelist": [
            "https://www.example.com/.*"
          ]
        },
        "https://www.mysite.com:443/coolwdc/": {
          "secondaryWhitelist": [
            "https://www.mysite.com/.*",
            "https://www.coolapi.com/.*"
          ]
        }
      },
      "enabled": true
    }
  }
}
```

### Configuration file reference

This table includes all of the options that can be included with the `web-data-connector-settings` entity set.

`_type`

Required.

**Value:** `webDataConnectorSettingsType`

Do not change.

`refreshEnabled`

Set to `false` to disable refresh of WDCs. Defaults to `true`.

`whitelist`

Required.

Can contain one or more matching sets of safe lists and secondary safe lists (one set per WDC). The first URL provided is the safe list, where you specify the WDC URL and port, formatted as follows:

```
<scheme>://<host>:<port>/<path>
```

For many WDCs the `<port>` value is 443, which is the default port for HTTPS, but you can check the value for your connector by looking at the data source details on Tableau Server or Tableau Cloud.

`secondaryWhitelist`

Required.

Specifies the domains or URLs that a connector can send requests to and receive requests from, for example, external JavaScript libraries, REST APIs, or local files. To add an entire domain to this secondary safe list, you can use a wildcard expression `.*` at the end of the URL, as shown in the following example:

```
https://www.example.com/.*
```

`enabled`

Set to `false` to disable use of WDCs. Defaults to `true`.

# tabcmd

**Note:** The tabcmd command-line utility version 2.0 is available at [Tableau tabcmd](#). This new version allows you to run tabcmd commands on MacOS and Linux, and to authenticate using personal access tokens (PATs). Version 2.0 is built on public endpoints available in the Python-based Tableau Server Client (TSC). This latest version has limited support for Tableau Server.

Tableau provides the tabcmd command-line utility which you can use to automate site administration tasks on your Tableau Server site. For example, creating or deleting users, projects, and groups.

**Note:** In Tableau versions prior to 2024.1, tabcmd version 1 does not work for exporting vizzes.

This utility is included with Tableau Server, and is automatically installed on the server nodes. You can also run it from other computers, even computers that are not part of your Tableau Server installation, but to do so you need to download the tabcmd installer from the Tableau website. For more information, see [Install tabcmd](#) below.

## Install tabcmd

**Note:** These instructions are for installing the tabcmd 1.0 command-line utility. To install the tabcmd 2.0 command-line utility, go to [Tableau tabcmd](#) (new window).

When Tableau Server or Tableau Cloud is upgraded to a new version, if an updated version of tabcmd is required, you can download it from the [Tableau Server Releases](#) page on the Tableau website.

For Tableau Server, we recommend you download the version that matches your server version. For Tableau Cloud, we recommend you always download the latest version to avoid

issues caused by version incompatibilities. In either case, using an out of date version of `tabcmd` can cause errors and unpredictable results.

1. Open a web browser and go to the [Tableau Server Releases](#) page. Go to this page even if you use Tableau Online.
2. If you're using:
  - **Tableau Cloud**, use [Tableau tabcmd 2.0](#) (new window).
  - **Tableau Server (Windows or Linux)**: select the release that matches your server version.

In either case, if the expanded information shows maintenance releases, select the latest maintenance release or the one that matches your server version.

This takes you to the release notes page, called Resolved Issues, where you can read about security improvements and resolved issues.

3. Scroll to the **Download Files** section under the resolved issues, select the `tabcmd` download link that is compatible with the computer on which you'll run the `tabcmd` commands.

## Download Files

### Windows

- [TableauServerTabcmd-64bit-2020-1-3.exe \(93 MB\)](#)
- [TableauServer-64bit-2020-1-3.exe \(1540 MB\)](#)

### Linux

- [tableau-tabcmd-2020-1-3.noarch.rpm \(10 MB\)](#)
- [tableau-tabcmd-2020-1-3\\_all.deb \(10 MB\)](#)
- [tableau-server-2020-1-3.x86\\_64.rpm \(1647 MB\)](#)
- [tableau-server-2020-1-3\\_amd64.deb \(1649 MB\)](#)

The remaining steps refer to this computer as “the tabcmd computer.”

4. Save the installer to the tabcmd computer, or a location accessible from that computer (a mounted drive, for example).
5. Complete the installation steps as appropriate for the operating system of the tabcmd computer:

- ## Windows

By default tabcmd is installed to `C:\Program Files\Tableau\Tableau Server\<version>\extras\Command Line Utility`. You can change this during installation and recommend that you install tabcmd to a folder named `tabcmd` at the root of the `C:\` drive (`C:\tabcmd`). This can make it easier to locate and run, and will accommodate some limitations with the Windows operating system if you add the tabcmd directory to the Windows PATH.

**Note** The tabcmd Setup program does not add the tabcmd directory to the Windows PATH variable. You can add it manually, or you can include the full path to tabcmd each time you call it.

You can install tabcmd in two ways on Windows:

- Double-click the installer to follow the steps in the UI:
  - a. Accept the license agreement.
  - b. If you want to install to a non-default location, click **Customize** and type or browse to the location you want to install tabcmd to.
  - c. Click **Install**.

If you are prompted by Windows Defender Firewall or User Account Control, click **Allow access**.

- Run the installer from a command prompt:
  - a. Open a command prompt as administrator on the tabcmd computer.
  - b. Navigate to the directory where you copied the tabcmd installer.
  - c. Install tabcmd:

```
tableau-setup-tabcmd-tableau-<version_code>-x64.exe /quiet ACCEPTTEULA=1
```

To install to a non-default location:

```
tableau-setup-tabcmd-tableau-<version_code>-x64.exe /quiet ACCEPTTEULA=1 INSTALLDIR=R"<path\to\install\directory>"
```

For example:

```
tableau-setup-tabcmd-tableau-<version_code>-x64.exe /quiet ACCEPTTEULA=1 INSTALLDIR=R"C:\tabcmd"
```

For a complete list of command line options you can use with the `tabcmd` installer, run the installer with a `/?`. For more information on `tabcmd` installer command line options, see [Install Switches and Properties for tabcmd \(Windows\)](#).

The `tabcmd` Setup program creates logs in `C:\Users\<user>\AppData\Local\Temp` you can use if you have problems installing `tabcmd`. The logs use the naming convention `Tableau_Server_Command_Line_Utility_(<version_code>)_#####.log`.

### • Linux

**Note:** To run `tabcmd` on a Linux computer, you must have Java 11 installed. On RHEL-like systems, this will be installed as a dependency when you install `tabcmd`. On Ubuntu systems, you need to install Java 11 separately if it is not already installed.

As of July 2022, Debian distributions are no longer supported. For more information, see [this Tableau Community post](#).

- a. Log on as a user with `sudo` access to the `tabcmd` computer.
- b. Navigate to the directory where you copied the `.rpm` or `.deb` package that you downloaded.
  - On RHEL-like distributions, including CentOS, run the following command:

```
sudo yum install tableau-tabcmd-<version>.noarch.rpm
```
  - On Ubuntu, run the following command:

```
sudo apt-get install ./tableau-tabcmd-<version>_
all.deb
```

To uninstall tabcmd from a Linux computer, see the documentation for the Linux variety you are running.

6. (Optional) Add the fully qualified location where tabcmd is installed to your system path to allow you to run tabcmd commands without changing to that location, or specifying the location with each command. Steps to do this depend on the type and version of your operating system. For more information, see [PATH\\_\(variable\)](#).

## How to use tabcmd

The basic steps for using tabcmd are as follows:

1. Open the Command Prompt as an administrator.

**Note:** Do not use PowerShell to run tabcmd commands on Windows. Using PowerShell can cause unexpected behavior.

2. On a Windows computer, if you installed tabcmd on a computer other than the initial node, change to the directory where you installed tabcmd.

On a Linux computer, you do not need to change to the install directory.

3. Run the tabcmd command.

When you use tabcmd, you must establish an authenticated server session. The session identifies the server or Tableau Cloud site and the user running the session. You can start a session first, and then specify your command next, or you can start a session and execute a command all at once.

**Important:** If you are using `tabcmd` to perform more than one task, you must run tasks one after another (serially), rather than at the same time (in parallel).

Commands (such as `login`) and the options (such as `-s`, `-u`, etc.) are not case sensitive, but the values you provide (such as `User@Example.com`) are case sensitive.

## Examples

The following command demonstrates starting a session with the Tableau Server named `tab-server.mycompany.com`:

```
tabcmd login -s http://tabserver.mycompany.com -u admin -p mypassword
```

The next example shows a command that deletes a workbook named `Sales_Workbook`:

```
tabcmd delete "Sales_Workbook"
```

Here's how to accomplish all of the above with one command—note that you do not need `login` here:

```
tabcmd delete "Sales_Workbook" -s http://tabserver.mycompany.com -u admin -p mypassword
```

A Tableau Server can run multiple sites. When a workbook is on the Default site of a multi-site server you don't need to specify Default, the above command is sufficient. However, if the command applies to something on a site other than Default, you need to specify the site ID for that site (see `login`). Here's the same command for a workbook that's on the West Coast Sales site (site ID `wsales`):

```
tabcmd delete "Sales_Workbook" -s http://tabserver.mycompany.com -t wsales -u admin -p mypassword
```

The options `-s`, `-t`, `-u`, and `-p` are among the `tabcmd` global variables, which can be used with any command.

For more information, see [tabcmd Commands](#).

## Status messages and logs

When a command is successful, `tabcmd` returns a status code of zero. A full error message for non-zero status codes is printed to **stderr**. In addition, informative or progress messages may be printed to **stdout**.

A full log named **tabcmd.log** that includes debugging, progress, and error messages is written to `<home dir>/tableau/tabcmd/`.

## tabcmd Commands

**Note:** The `tabcmd` command-line utility version 2.0 is available at [Tableau tabcmd](#). This new version allows you to run `tabcmd` commands on MacOS and Linux, and to authenticate using personal access tokens (PATs). Version 2.0 is built on public endpoints available in the Python-based Tableau Server Client (TSC). This latest version has limited support for Tableau Server.

Looking for Tableau Server on Windows? See [tabcmd Commands](#).

You can use the following commands with the `tabcmd` command line tool:

- `addusers` (to group)
- `createextracts`
- `creategroup`
- `createproject`
- `createsite`
- `createsiteusers`
- `createusers`
- `decryptextracts`
- `delete workbook-name or datasource-name`
- `deleteextracts`
- `deletegroup`
- `deleteproject`
- `deletesite`

## Tableau Server on Linux Administrator Guide

deletesiteusers  
deleteusers  
editdomain  
editsite  
encryptextracts  
export  
get *url*  
initialuser  
listdomains  
listsites  
login

removeusers  
reset\_openid\_sub  
rnschedule  
set  
syncgroup  
upgradethumbnails  
validateidpmetadata  
version

### **addusers** *group-name*

Adds users to the specified group.

#### **Example**

```
tabcmd addusers "Development" --users "users.csv"
```

## Options

`--users`

Add the users in the given `.csv` file to the specified group. The file should be a simple list with one user name per line. User names aren't case sensitive. The users should already be created on Tableau Server.

For more information, see [CSV Import File Guidelines](#).

`--[no-]complete`

When set to `complete` this option requires that all rows be valid for any change to succeed. If not specified, `--complete` is used.

## Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

## Tableau Server on Linux Administrator Guide

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## createextracts

Creates extracts for a published workbook or data source.

## Options

`-d, --datasource`

The name of the target data source for extract creation.

`--embedded-datasources`

A space-separated list of embedded data source names within the target workbook. Enclose data source names with double quotes if they contain spaces. Only available when creating extracts for a workbook.

`--encrypt`

Create encrypted extract.

`--include-all`

Include all embedded data sources within target workbook. Only available when creating extracts for workbook.

`--parent-project-path`

Path of the project that is the parent of the project that contains the target resource. Must specify the project name with `--project`.

`--project`

The name of the project that contains the target resource. Only necessary if `--workbook` or `--datasource` is specified. If unspecified, the default project 'Default' is used.

`-u, -url`

The canonical name for the resource as it appears in the URL.

`-w, -workbook`

The name of the target workbook for extract creation.

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### `creategroup` *group-name*

Creates a group. Use `addusers` (for local groups) to add users after the group has been created. Use `syncgroup` (for Active Directory groups) to create and synchronize a Tableau Server group with an Active Directory group.

#### **Example**

```
tabcmd creategroup "Development"
```

#### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token

## Tableau Server on Linux Administrator Guide

remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

--

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### `createproject` *project-name*

Creates a project.

#### Example

```
tabcmd createproject -n "Quarterly_Reports" -d "Workbooks showing quarterly sales reports."
```

#### Options

`-n, --name`

Specifies the name of the project that you want to create.

`--parent-project-path`

Specifies the name of the parent project for the nested project as specified with the `-n` option. For example, to specify a project called "Nested" that exists in a "Main" project, use the following syntax: `--parent-project-path "Main" -n "Nested"`.

`-d, --description`

Specifies a description for the project.

#### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

## Tableau Server on Linux Administrator Guide

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, tabcmd (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

--

Specifies the end of options on the command line. You can use -- to indicate to `tabcmd` that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### **createsite *site-name***

Creates a site.

#### **Examples**

Create a site named West Coast Sales. A site ID of `WestCoastSales` will be automatically created, the site will have no storage quota limit, and site administrators will be able to add and remove users:

```
tabcmd createsite "West Coast Sales"
```

Create a site named West Coast Sales with a site ID of `wsales`:

```
tabcmd createsite "West Coast Sales" -r "wsales"
```

Prevent site administrators from adding users to the site:

```
tabcmd createsite "West Coast Sales" --no-site-mode
```

Set a storage quota, in MB:

```
tabcmd createsite "West Coast Sales" --storage-quota 100
```

### Options

`-r, --url`

Used in URLs to specify the site. Different from the site name.

`--user-quota`

Maximum number of users that can be added to the site.

`--[no-]site-mode`

Allows or denies site administrators the ability to add users to or remove users from the site.

`--storage-quota`

In MB, the amount of workbooks, extracts, and data sources that can be stored on the site.

`--extract-encryption-mode`

The extract encryption mode for the site can be **enforced**, **enabled** or **disabled**. For more information, see Extract Encryption at Rest.

`--run-now-enabled`

Allow or deny users from running extract refreshes, flows, or schedules manually. **true** to allow users to run tasks manually or **false** to prevent users from running tasks manually. For more information, see Server Settings (General and Customization).

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

## Tableau Server on Linux Administrator Guide

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

--

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### `createsiteusers filename.csv`

Adds users to a site, based on information supplied in a comma-separated values (CSV) file. If the user isn't already created on the server, the command creates the user before adding that user to the site.

The CSV file must contain one or more user names and can also include (for each user) a password, full name, license type, administrator level, publisher (yes/no), and email address. For information about the format of the CSV file, see [CSV Import File Guidelines](#).

As an alternative to including administrator level and publisher permissions in the CSV file, you can pass access level information by including the `--role` option and specifying the site role you want to assign users listed in the CSV file.

By default, users are added to the site that you're logged in to. To add users to a different site, include the global `--site` option and specify that site. (You must have permissions to create users on the site you specify.)

If the server contains multiple sites, you can't add server (system) administrators through the `createsiteusers` command. Use `createusers` instead. If you specify the `Server-Administrator` site role for the `--role` option, the command returns an error. If the CSV file includes `System` as value for administrator, the value is ignored and the user is assigned

## Tableau Server on Linux Administrator Guide

the `Unlicensed` license type.

If the server contains only one site (the default site), you can specify `system` for the administrator value for a user, or even assign the `ServerAdministrator` site role using the `--role` option, if you want all users in the CSV file to be server administrators.

By default, this command creates users using a synchronous operation (it waits for all operations to complete before proceeding). You can use the `--no-wait` option to specify an asynchronous operation.

### Local authentication

If the server is configured to use local authentication, the information in the CSV file is used to create users.

### Active Directory authentication

If the server is configured to use Active Directory authentication, user information is imported from Active Directory, and password and friendly name information in the CSV file is ignored. Further, if a user is specified in the CSV file but no corresponding user exists in Active Directory, the user is not added to Tableau Server. For Active Directory users, because the user name is not guaranteed to be unique across domains, you must include the domain as part of the user name. You can specify this as either `domain\username` or `username@domain.com`; however, we recommend using the `domain\username` format. For more information, see [User Management in Deployments with External Identity Stores](#).

### Example

```
tabcmd createsiteusers "users.csv" --role "Explorer"
```

### Options

`--admin-type`

Deprecated. Use the `--role` option instead.

`--auth-type`

Sets the authentication type (`Local` or `SAML`) for all users in the `.csv` file. If unspecified, the default is `Local`.

**Note:** To use SAML authentication, the site must be configured for site-specific SAML in Tableau Server settings. For information, see [Configure Site-Specific SAML](#).

`--[no-]complete`

Deprecated. Default error behavior: if there are more than 3 errors within a ten-row span, then the command will fail.

`--no-publisher`

Deprecated. Use the `--role` option instead.

`--nowait`

Don't wait for asynchronous jobs to complete.

`--publisher`

Deprecated. Use the `--role` option instead.

`--role`

Specifies a site role for all users in the `.csv` file. When you want to assign site roles using the `--role` option, create a separate CSV file for each site role.

Valid values are: `ServerAdministrator`, `SiteAdministratorCreator`, `SiteAdministratorExplorer`, `SiteAdministrator`, `Creator`, `Explorer-CanPublish`, `Publisher`, `Explorer`, `Interactor`, `Viewer`, and `Unlicensed`.

The default is `Unlicensed` for new users and unchanged for existing users. Users are added as `unlicensed` also if you have a user-based server installation, and if the

`createsiteusers` command creates a new user, but you have already reached the limit on the number of licenses for your users.

**Note:** On a multi-site Tableau Server, if you want to assign the `Server-Administrator` site role using the `--role` option, use the `createusers` command instead of `createsiteusers`.

`--silent-progress`

Don't display progress messages for the command.

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### **`createusers filename.csv`**

Create users in Tableau Server, based on information supplied in a comma-separated values (CSV) file.

The CSV file must contain one or more user names and can also include (for each user) a password, full name, license type, administrator level, publisher (yes/no), and email address. For information about the format of the CSV file, see [CSV Import File Guidelines](#).

As an alternative to including administrator level and publisher permissions in the CSV file, you can pass access level information by including the `--role` option and specifying the site role you want to assign users listed in the CSV file.

If the server has only one site (the default site), the user is created and added to the site. If the server has multiple sites, the user is created but isn't added to any site. To add users to a site, use `createsiteusers`.

If you have a user-based server installation, and if the command creates a new user but you have already reached the limit on the number of licenses for your users, the user is added as an unlicensed user.

### Local authentication

If the server is configured to use local authentication, the information in the CSV file is used to create users.

### Active Directory authentication

If the server is configured to use Active Directory authentication, user information is imported from Active Directory, and password and friendly name information in the CSV file is ignored. Further, if a user is specified in the CSV file but no corresponding user exists in Active Directory, the user is not added to Tableau Server. For Active Directory users, because the user name is not guaranteed to be unique across domains, you must include the domain as part of the user name. You can specify this as either `domain\username` or `username@domain.com`; however, we recommend using the `domain\username` format. For more information, see [User Management in Deployments with External Identity Stores](#).

### Example

```
tabcmd createusers "users.csv" --role "ServerAdministrator"

tabcmd createusers "users.csv"
```

## Options

`--admin-type`

Deprecated. Use the `--role` option instead.

`--[no-]complete`

Deprecated. Default error behavior: if there are more than 3 errors within a ten-row span, then the command will fail.

`--no-publisher`

Deprecated. Use the `--role` option instead.

`--nowait`

Don't wait for asynchronous jobs to complete.

`--publisher`

Deprecated. Use the `--role` option instead.

`-r, --role`

Specifies a site role for all users in the `.csv` file. When you want to assign site roles using the `--role` option, create a separate CSV file for each site role.

**Valid values are:** `ServerAdministrator`, `SiteAdministratorCreator`, `SiteAdministratorExplorer`, `SiteAdministrator`, `Creator`, `ExplorerCanPublish`, `Publisher`, `Explorer`, `Interactor`, `Viewer`, and `Unlicensed`.

On a multi-site server, the command doesn't assign the user to a site. Therefore, the only site roles the command can successfully assign are `ServerAdministrator` and

Unlicensed. If you specify any other site role, the command assigns the `Unlicensed` role.

On a single-site server, the user is created and added to the default site using the role that you specify.

If you have a user-based server installation, and if the command creates a new user but you have already reached the limit on the number of licenses for your users, the user is added as an unlicensed user.

`--silent-progress`

Don't display progress messages for the command.

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

## Tableau Server on Linux Administrator Guide

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## decryptextracts

Decrypt all extracts on a site. If no site is specified, extracts on the default site will be decrypted. For more information, see [Extract Encryption at Rest](#).

Depending on the number and size of extracts, this operation may consume significant server resources. Consider running this command outside of normal business hours.

### Example

```
tabcmd decryptextracts "West Coast Sales"
```

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or "") or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### ***delete workbook-name or datasource-name***

Deletes the specified workbook or data source from the server.

This command takes the name of the workbook or data source as it is on the server, not the file name when it was published.

#### **Example**

```
tabcmd delete "Sales_Analysis"
```

## Options

`-r, --project`

The name of the project containing the workbook or data source you want to delete. If not specified, the “Default” project is assumed.

`--parent-project-path`

Specifies the name of the parent project for the nested project as specified with the `-r` option. For example, to specify a project called "Nested" that exists in a "Main" project, use the following syntax: `--parent-project-path "Main" -r "Nested"`.

`--workbook`

The name of the workbook you want to delete.

`--datasource`

The name of the data source you want to delete.

## Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

## Tableau Server on Linux Administrator Guide

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or "") or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## deleteextracts

Deletes extracts for a published workbook or data source.

### Options

`-d, --datasource`

The name of the target data source for extract deletion.

`--embedded-datasources`

A space-separated list of embedded data source names within the target workbook. Enclose data source names with double quotes if they contain spaces. Only available when deleting extracts for a workbook.

`--encrypt`

Create encrypted extract.

`--include-all`

Include all embedded data sources within target workbook.

`--parent-project-path`

Path of the project that is the parent of the project that contains the target resource. Must specify the project name with `--project`.

`--project`

The name of the project that contains the target resource. Only necessary if `--workbook` or `--datasource` is specified. If unspecified, the default project 'Default' is used.

`-u, -url`

The canonical name for the resource as it appears in the URL.

`-w, -workbook`

The name of the target workbook for extract deletion.

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## `deletegroup` *group-name*

Deletes the specified group from the server.

### Example

```
tabcmd deletegroup "Development"
```

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

## Tableau Server on Linux Administrator Guide

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an

empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

--

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### `deleteproject` *project-name*

Deletes the specified project from the server.

Using `tabcmd`, you can specify only a top-level project in a project hierarchy. To automate tasks you want to perform on a project within a parent project, use the equivalent Tableau [REST API](#) call.

#### Example

```
tabcmd deleteproject "Designs"
```

#### Option

```
--parent-project-path
```

Specifies the name of the parent project for the nested project as specified with the command. For example, to specify a project called "Designs" that exists in a "Main" project, use the following syntax: `--parent-project-path "Main" "Designs"`.

#### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either

## Tableau Server on Linux Administrator Guide

an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

--

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## `deletesite` *site-name*

Deletes the specified site from the server.

### Example

```
tabcmd deletesite "Development"
```

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

## Tableau Server on Linux Administrator Guide

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### `deletesiteusers filename.csv`

Removes users from from the site that you're logged in to. The users to be removed are specified in a file that contains a simple list of one user name per line. (No additional information

is required beyond the user name.)

By default, if the server has only one site, or if the user belongs to only one site, the user is also removed from the server. On a Tableau Server Enterprise installation, if the server contains multiple sites, users who are assigned the site role of **Server Administrator** are removed from the site but aren't removed from the server.

If the user owns content, the user's role is change to **Unlicensed**, but the user isn't removed from the server or the site. The content is still owned by that user. To remove the user completely, you must change the owner of the content and then try removing the user again.

If the user was imported from Active Directory, the user is removed from the site and possibly from the server. However, the user isn't deleted from Active Directory.

### Example

```
tabcmd deletesiteusers "users.csv"
```

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or "") or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

**deleteusers *filename.csv***

Deletes the users listed in the specified comma-separated values (.csv) file.

The .csv file should contain a simple list of one user name per line.

**Example**

```
tabcmd deleteusers "users.csv"
```

**Options**

```
--[no-]complete
```

When set to `--complete` this option requires that all rows be valid for any change to succeed. If not specified, `--complete` is used.

**Global options**

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

```
-h, --help
```

Displays the help for the command.

```
-c, --use-certificate
```

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

## Tableau Server on Linux Administrator Guide

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## editdomain

**Note:** As a best practice, you should back up Tableau Server before you edit the domain. The domain is saved in the Tableau repository, and if it's incorrectly changed, administrators may not be able to sign in.

Changes the nickname or full domain name of an Active Directory domain on the server. A domain “nickname” is the Windows NetBIOS domain name.

You can modify the nickname for any domain the server is using. In general, you can modify the full domain name for any domain except the one that you used to sign in. However, if the user name that you're currently signed in with exists in both the current domain and the new domain, you can modify the full name for the current domain.

To ensure that Tableau Server can connect to other Active Directory domains, you must also specify secondary domains that Tableau Server connects to by setting the `wgserver.domain.whitelist` option with TSM. For more information about secondary domains and configuring the connection, see `wgserver.domain.whitelist`.

Review [User Management in Deployments with External Identity Stores](#) to understand how multiple domains, domain name mapping, and user names interact with Tableau Server.

To see a list of domains, use [listdomains](#).

### Examples

```
tabcmd editdomain --id 2 --nickname "new-nickname"
```

```
tabcmd editdomain --id 3 --name "new-name"
```

### Options

`--id`

The ID of domain to change. To get a list of domain IDs, use [listdomains](#).

`--name`

The new name for the domain.

`--nickname`

The new nickname for the domain.

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

## Tableau Server on Linux Administrator Guide

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### `editsite` *site-name*

Changes the name of a site or its web folder name. You can also use this command to allow or deny site administrators the ability to add and remove users, or prevent users from running certain tasks manually. If site administrators have user management rights, you can specify how many users they can add to a site.

#### Examples

```
tabcmd editsite wc_sales --site-name "West Coast Sales"
```

```
tabcmd editsite wc_sales --site-id "wsales"
```

## Tableau Server on Linux Administrator Guide

```
tabcmd editstsite wsales --status ACTIVE
```

```
tabcmd editstsite wsales --user-quota 50
```

### Options

`--site-name`

The name of the site that's displayed.

`--site-id`

Used in the URL to uniquely identify the site.

`--user-quota`

Maximum number of users who can be members of the site.

`--[no-]site-mode`

Allow or prevent site administrators from adding users to the site.

`--status`

Set to `ACTIVE` to activate a site, or to `SUSPENDED` to suspend a site.

`--storage-quota`

In MB, the amount of workbooks, extracts, and data sources that can be stored on the site.

`--extract-encryption-mode`

The extract encryption mode for the site can be **enforced**, **enabled** or **disabled**. For more information, see [Extract Encryption at Rest](#). Depending on the number and size of

extracts, this operation may consume significant server resources.

`--run-now-enabled`

Allow or deny users from running extract refreshes, flows, or schedules manually. **true** to allow users to run tasks manually or **false** to prevent users from running tasks manually. For more information, see [Server Settings \(General and Customization\)](#).

## Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

## Tableau Server on Linux Administrator Guide

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## encryptextracts

Encrypt all extracts on a site. If no site is specified, extracts on the default site will be encrypted. For more information, see [Extract Encryption at Rest](#).

Depending on the number and size of extracts, this operation may consume significant server resources. Consider running this command outside of normal business hours.

### Example

```
tabcmd encryptextracts "West Coast Sales"
```

## Tableau Server on Linux Administrator Guide

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### export

Exports a view or workbook from Tableau Server and saves it to a file. This command can also export just the data used for a view. View data is exported at the summary level. To export detail-level data, you must use the Tableau Server UI. For details, see [Download Views and Workbooks](#).

Note the following when you use this command:

- **Permissions:** To export, you must have the **Export Image** permission. By default, this permission is Allowed or Inherited for all roles, although permissions can be set per workbook or view.
- **Exporting data:** To export just the data for a view, use the `--csv` option. This exports the summary data used in a view to a `.csv` file.
- **Specifying the view, workbook, or data to export:**
  - Use part of the URL to identify what to export, specifically the `"workbook/view"` string as it appears in the URL for the workbook or view. Don't use

the “friendly name,” and exclude the `:iid=<n>` session ID at the end of the URL.

For example, the Tableau sample view *Order Details* in the *Superstore* workbook has a URL similar to this: `<server_name>/#/views/Superstore/OrderDetails?:iid=2`

To export the *Order Details* view, use the string `Superstore/OrderDetails`.

Do *not* use `Superstore/Order Details`, or `Superstore/OrderDetails?:iid=2`.

- If the server is running multiple sites and the view or workbook is on a site other than Default, Use `-t <site_id>`.
- To export a workbook, get the URL string by opening a view in the workbook, and include the view in the string you use.

In the above example, to export the *Superstore* workbook, use the string `Superstore/OrderDetails`.

- To export a workbook, it must have been published with **Show Sheets as Tabs** selected in the Tableau Desktop Publish dialog box.

**Note:** The Tableau workbook that contains the **administrative views** can't be exported.

- To filter the data you download, add a parameter filter using this format:

```
?<filter_name>=value
```

or, if filtering on a parameter and that parameter has a display name that matches the name of a measure or dimension:

```
?Parameters.<filter_name>=value
```

- **The saved file's format:** Your format options depend on what's being exported. A workbook can only be exported as a PDF using the `--fullpdf` argument. A view can be exported as a PDF (`--pdf`) or a PNG (`--png`).
- **The saved file's name and location** (optional): If you don't provide a name, it will be derived from the view or workbook name. If you don't provide a location, the file will be saved to your current working directory. Otherwise, you can specify a full path or one that's relative to your current working directory.

**Note:** You must include a file name extension such as `.csv` or `.pdf`. The command doesn't automatically add an extension to the file name that you provide.

- **Dashboard web page objects not included in PDF exports:** A dashboard can optionally include a web page object. If you're performing an export to PDF of a dashboard that includes a web page object, the web page object won't be included in the PDF.
- **Non-ASCII and non-standard ASCII characters and PDF exports:** If you're exporting a view or workbook with a name that includes a character outside the ASCII character set, or a non-standard ASCII character set, you need to URL encode (percent-encode) the character.

For example if your command includes the city Zürich, you need to URL encode it as `Z%C3%BCrich`:

```
tabcmd export "/Cities/Sheet1?locationCity=Z%C3%BCrich" -full-  
pdf
```

### Clearing the Cache to Use Real-Time Data

You can optionally add the URL parameter `?refresh=yes` to force a fresh data query instead of pulling the results from the cache. If you're using `tabcmd` with your own scripting and the `refresh` URL parameter is being used a great deal, this can have a negative impact on

performance. It's recommended that you use `refresh` only when real-time data is required—for example, on a single dashboard instead of on an entire workbook.

## Examples

### Views

```
tabcmd export "Q1Sales/Sales_Report" --csv -f "Weekly-Report.csv"

tabcmd export -t Sales "Sales/Sales_Analysis" --pdf -f "C:\Tableau_
Workbooks\Weekly-Reports.pdf"

tabcmd export "Finance/InvestmentGrowth" --png

tabcmd export "Finance/InvestmentGrowth?:refresh=yes" --png
```

### Workbooks

```
tabcmd export "Q1Sales/Sales_Report" --fullpdf

tabcmd export "Sales/Sales_Analysis" --fullpdf --pagesize tabloid -
f "C:\Tableau_Workbooks\Weekly-Reports.pdf"
```

## Options

`-f, --filename`

Saves the file with the given filename and extension.

`--csv`

View only. Export the view's data (summary data) in `.csv` format.

`--pdf`

View only. Export as a PDF.

`--png`

## Tableau Server on Linux Administrator Guide

View only. Export as an image in `.png` format.

`--fullpdf`

Workbook only. Export as a PDF. The workbook must have been published with **Show Sheets as Tabs** enabled.

`--pagelayout`

Sets the page orientation (`landscape` or `portrait`) of the exported PDF. If not specified, its Tableau Desktop setting will be used.

`--pagesize`

Sets the page size of the exported PDF as one of the following: `unspecified`, `letter`, `legal`, `note folio`, `tabloid`, `ledger`, `statement`, `executive`, `a3`, `a4`, `a5`, `b4`, `b5`, or `quarto`. Default is `letter`.

`--width`

Sets the width in pixels. Default is 800 px.

`--height`

Sets the height in pixels. Default is 600 px.

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either

## Tableau Server on Linux Administrator Guide

an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, tabcmd (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

--

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## get url

Gets the resource from Tableau Server that's represented by the specified (partial) URL. The result is returned as a file.

Note the following when you use this command:

- **Permissions:** To get a file, you must have the **Download/Web Save As** permission. By default, this permission is allowed or inherited for all roles, although permissions can be set per workbook or view.
- **Specifying a view or workbook to get:** You specify a view to get using the `"/views/<workbookname>/<viewname>.<extension>"` string, and specify a workbook to get using the `"/workbooks/<workbookname>.<extension>"` string. Replace `<workbookname>` and `<viewname>` with the names of the workbook and view as they appear in the URL when you open the view in a browser and replace `<extension>` with the type of file you want to save. Don't use the session ID at the end of the URL (`?:iid=<n>`) or the "friendly" name of the workbook or view.

For example, when you open a view *Regional Totals* in a workbook named *Metrics Summary*, the URL will look similar to this:

```
/views/MetricsSummary_1/RegionalTotals?:iid=1
```

Use the string `/views/MetricsSummary_1/RegionalTotals.<extension>` to get the view.

Use the string `/workbooks/MetricsSummary_1.<extension>` to get the workbook.

When downloading workbooks and views from Tableau Server, the content of the `.twb` or `.twbx` file is stored in plain text. All data, including filter values that may give semantic clues to the data, will be readable by anyone who opens the file.

- **File extension:** The URL must include a file extension. The extension determines what's returned. A view can be returned in PDF, PNG, or CSV (summary data only) format. A Tableau workbook is returned as a TWB if it connects to a published data source or uses a live connection, or a TWBX if it connects to a data extract.

**Note:** If you're downloading a view to a PDF or PNG file, and if you include a `--filename` parameter that includes the `.pdf` or `.png` extension, you don't have to include a `.pdf` or `.png` extension in the URL.

- **The saved file's name and location** (optional): The name you use for `--filename` should include the file extension. If you don't provide a name and file extension, both will be derived from the URL string. If you don't provide a location, the file is saved to your current working directory. Otherwise, you can specify a full path or one that's relative to your current working directory.
- **PNG size** (optional): If the saved file is a PNG, you can specify the size, in pixels, in the URL.

### Clearing the cache to use real-time data

You can optionally add the URL parameter `?:refresh=yes` to force a fresh data query instead of pulling the results from the cache. If you're using `tabcmd` with your own scripting, using the `refresh` parameter a great deal can have a negative impact on performance. It's recommended that you use `refresh` only when real-time data is required—for example, on a single dashboard instead of on an entire workbook.

### Examples

**Views**

```
tabcmd get "/views/Sales_Analysis/Sales_Report.png" --filename
"Weekly-Report.png"
```

```
tabcmd get "/views/Finance/InvestmentGrowth.pdf" -f "Q1Growth.pdf"
```

```
tabcmd get "/views/Finance/InvestmentGrowth" -f "Q1Growth.pdf"
```

```
tabcmd get "/views/Finance/InvestmentGrowth.csv"
```

```
tabcmd get "/views/Finance/InvestmentGrowth.png?:size=640,480" -f
growth.png
```

```
tabcmd get "/views/Finance/InvestmentGrowth.png?:refresh=yes" -f
growth.png
```

**Workbooks**

```
tabcmd get "/workbooks/Sales_Analysis.twb" -f "C:\Tableau_Work-
books\Weekly-Reports.twb"
```

**Global options**

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

```
-h, --help
```

Displays the help for the command.

```
-c, --use-certificate
```

## Tableau Server on Linux Administrator Guide

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## initialuser

Create the initial Server administrative user on a server that doesn't have an initial administrative user defined. This creates a Server administrator. This doesn't create a TSM administrator.

Enclose values in single quotes.

**Note:** The **tabcmd initialuser** command doesn't require authentication to Tableau Server, but you must run the command on the initial server node.

### Notes:

- The **tabcmd initialuser** command doesn't require authentication to Tableau Server, but you must run the command on the initial server node.
- The `username` value cannot include an at sign (@) unless the user name suffix matches Tableau Server's primary domain. For example, if Tableau Server connects to domain "myco.com", a user name of "user@example.com@myco.com" cannot be used.

### Examples

```
tabcmd initialuser --username 'admin' --password 'password' --server http://localhost
```

```
tabcmd initialuser --username 'admin' --password 'password' --friendly 'Tableau Admin' --server http://localhost
```

To prompt for the password in the shell, don't include the `--password` parameter in the command. For example:

```
tabcmd initialuser --username 'admin' --server http://localhost
```

## Options

`-f, --friendly`

Creates the initial Server administrative user with the display name.

## Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

## Tableau Server on Linux Administrator Guide

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## listdomains

Displays a list of the Active Directory domains that are in use on the server, along with their nicknames and IDs. If the server is configured to use local authentication, the command returns only the domain name `local`.

### Example

```
tabcmd listdomains
```

### Global options

## Tableau Server on Linux Administrator Guide

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or "") or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

--

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### listsites

Returns a list of sites to which the logged in user belongs.

#### Example

```
tabcmd listsites --username adam --password mypassword
```

#### Options

`--get-extract-encryption-mode`

The extract encryption mode for the site can be **enforced**, **enabled** or **disabled**. For more information, see [Extract Encryption at Rest](#).

#### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either

## Tableau Server on Linux Administrator Guide

an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, tabcmd (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

--

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## login

Logs in a Tableau Server user.

Use the `--server`, `--site`, `--username`, `--password` global options to create a session.

**Note:** When you use the `tabcmd login` command, you can't use SAML single sign-on (SSO), even if the server is configured to use SAML. To log in, you must pass the user name and password of a user who has been created on the server. You will have the permissions of the Tableau Server user that you're signed in as. For more information, see [Set Users' Site Roles and Permissions](#).

If you want to log in using the same information you've already used to create a session, just specify the `--password` option. The server and user name stored in the cookie will be used.

If the server is using a port other than 80 (the default), you will need to specify the port.

You need the `--site (-t)` option only if the server is running multiple sites and you're logging in to a site other than the Default site. If you don't provide a password you will be prompted for one. If the `--no-prompt` option is specified and no password is provided the command will fail.

Once you log in, the session will continue until it expires on the server or the `logout` command is run.

### Example

## Tableau Server on Linux Administrator Guide

Logs user jsmith in to the Tableau Server running on their local machine:

```
tabcmd login -s http://localhost -u jsmith -p password
```

Logs administrator in to the Sales site on sales-server:

```
tabcmd login -s http://sales-server -t Sales -u administrator -p  
password
```

```
tabcmd login -s http://sales-server:8000 -t Sales -u administrator -  
p password
```

Logs administrator in to the Sales site on sales-server using SSL, but doesn't validate the server's SSL certificate:

```
tabcmd login --no-certcheck -s https://sales-server -t Sales -u  
administrator -p password
```

Establishes a forward proxy and port for localhost:

```
tabcmd login --proxy myfwdproxyserver:8888 -s http://localhost -u  
jsmith -p password
```

Logs user jsmith in to the reverse proxy using SSL:

```
tabcmd login -s https://myreverseproxy -u jsmith -p password
```

### Options

`-s, --server`

If you're running the command from a Tableau Server computer that's on your network, you can use `http://localhost`. Otherwise, specify the computer's URL, such as `http://bigbox.myco.com` or `http://bigbox`.

If the server is using SSL, you will need to specify `https://` in the computer's URL.

For Tableau Cloud, specify the full URL including the pod that your site is deployed to.  
For example: `https://prod-useast-b.online.tableau.com`.

`-t, --site`

Include this option if the server has multiple sites, and you're logging in to a site other than the default site.

The site ID is used in the URL to uniquely identify the site. For example, a site named West Coast Sales might have a site ID of `west-coast-sales`.

`-u, --username`

The user name of the user logging in. For Tableau Cloud, the user name is the user's email address.

`-p, --password`

Password for the user specified for `--username`. If you don't provide a password you will be prompted for one.

`--password-file`

Allows the password to be stored in the given `filename.txt` file rather than the command line, for increased security.

`-x, --proxy`

Use to specify the HTTP proxy server and port (Host:Port) for the `tabcmd` request.

`--no-prompt`

Don't prompt for a password. If no password is specified, the `login` command will fail.

`--no-proxy`

Don't use an HTTP proxy server.

`--cookie`

Saves the session ID on login. Subsequent commands won't require a login. This value is the default for the command.

`--no-cookie`

Don't save the session ID information after a successful login. Subsequent commands will require a login.

`--timeout SECONDS`

The number of seconds the server should wait before processing the `login` command. Default: 30 seconds.

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or "") or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## logout

Logs out of the server.

### Example

```
tabcmd logout
```

## publish *filename.twb(x)*, *filename.tds(x)*, or *filename.hyper*

Publishes the specified workbook (.twb(x)), data source (.tds(x)), or extract (.hyper) to Tableau Server.

If you're publishing a workbook, by default, all sheets in the workbook are published without database user names or passwords.

The permissions initially assigned to the workbook or data source are copied from the project that the file is published to. Permissions for the published resource can be changed after the file has been published.

If the workbook contains user filters, one of the thumbnail options must be specified.

### Example

```
tabcmd publish "analysis.twbx" -n "Sales_Analysis" --db-username
"jsmith" --db-password "secret-password"
```

```
tabcmd publish "analysis_sfdc.hyper" -n "Sales Analysis"
--oauth-username "user-name" --save-oauth
```

If the file isn't in the same directory as tabcmd, include the full path to the file.

### Example

```
tabcmd publish "\\computer\volume\Tableau Workbooks\analysis.twbx"
-n "Sales_Analysis" --db-username "jsmith" --db-password "secret-
password"
```

## Tableau Server on Linux Administrator Guide

```
tabcmd publish "\\computer\volume\Tableau Workbooks\analysis_sfd-  
c.hyper" -n "Sales Analysis" --oauth-username "username" --save-  
oauth
```

### Options

`-n, --name`

Name of the workbook or data source on the server. If omitted, the workbook, data source, or data extract will be named after filename.

`-o, --overwrite`

Overwrites the workbook, data source, or data extract if it already exists on the server.

`-r, --project`

Publishes the workbook, data source, or data extract into the specified project. Publishes to the "Default" project if not specified.

`--parent-project-path`

Specifies the name of the parent project for the nested project as specified with the `-r` option. For example, to specify a project called "Nested" that exists in a "Main" project, use the following syntax: `--parent-project-path "Main" -r "Nested"`.

`--db-username`

Use this option to publish a database user name with the workbook, data source, or data extract.

`--db-password`

Use this option to publish a database password with the workbook, data source, or extract.

`--save-db-password`

Stores the provided database password on the server.

`--oauth-username`

The email address of the user account. Connects the user through a preconfigured OAuth connection, if the user already has a saved access token for the cloud data source specified in `--name`. Access tokens are managed in user preferences.

For existing OAuth connections to the data source, use this option instead of `--db-username` and `--db-password`.

`--save-oauth`

Saves the credential specified by `--oauth-username` as an embedded credential with the published workbook or data source.

Subsequently, when the publisher or server administrator signs in to the server and edits the connection for that workbook or data source, the connection settings will show this OAuth credential as embedded in the content.

If you want to schedule extract refreshes after publishing, you must include this option with `--oauth-username`. This is analogous to using `--save-db-password` with a traditional database connection.

`--thumbnail-username`

If the workbook contains user filters, the thumbnails will be generated based on what the specified user can see. Can't be specified when `--thumbnail-group` option is set.

`--thumbnail-group`

If the workbook contains user filters, the thumbnails will be generated based on what the specified group can see. Can't be specified when `--thumbnail-`

## Tableau Server on Linux Administrator Guide

`username` option is set.

`--tabbed`

When a workbook with tabbed views is published, each sheet becomes a tab that viewers can use to navigate through the workbook. Note that this setting will override any sheet-level security.

`--append`

Append the extract file to the existing data source.

`--replace`

Use the extract file to replace the existing data source.

`--disable-uploader`

Disable the incremental file uploader.

`--restart`

Restart the file upload.

`--encrypt-extracts`

Encrypt extracts when you publish a workbook, data source, or extract to the server. For more information, see [Extract Encryption at Rest](#).

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token

remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

## Tableau Server on Linux Administrator Guide

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

--

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## publishsamples

### Description

Publishes Tableau Sample workbooks to the specified project. Any existing samples will be overwritten.

### Syntax

```
tabcmd publishsamples -n [project name] [Global options]
```

### Example

Publish samples to the Inside Sales project on the Default site, as user jsmith.

```
tabcmd publishsamples -n "Inside Sales" -t "" -s localhost --user-  
name "jsmith" --password "secret-password"
```

### Options

`-n, --name`

Required. Publishes the Tableau samples into the specified project. If the project name includes spaces, enclose the entire name in quotes.

`--parent-project-path`

## Tableau Server on Linux Administrator Guide

Specifies the name of the parent project for the nested project as specified with the `-n` option. For example, to specify a project called "Nested" that exists in a "Main" project, use the following syntax: `--parent-project-path "Main" -n "Nested"`.

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### reencryptextracts

Reencrypt all extracts on a site with new encryption keys. This command will regenerate the key encryption key and data encryption key. You must specify a site. For more information, see [Extract Encryption at Rest](#).

Depending on the number and size of extracts, this operation may consume significant server resources. Consider running this command outside of normal business hours.

#### Examples

```
tabcmd reencryptextracts "Default"
```

```
tabcmd reencryptextracts "West Coast Sales"
```

## Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

## Tableau Server on Linux Administrator Guide

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### `refreshextracts` *workbook-name* or *datasource-name*

Performs a full or incremental refresh of extracts belonging to the specified workbook or data source.

This command takes the name of the workbook or data source as it appears on the server, not the file name when it was published. Only an administrator or the owner of the workbook or data source is allowed to perform this operation.

**Note:** This method will fail and result in an error if your Server Administrator has disabled the **RunNow** setting for the site. For more information, see [Tableau Server Settings](#).

### Examples

```
tabcmd refreshextracts --datasource sales_ds
```

```
tabcmd refreshextracts --project "Sales External" --datasource
sales_ds
```

## Tableau Server on Linux Administrator Guide

```
tabcmd refreshextracts --project "Sales External" --parent-project-  
path "Main" --project "Sales External" --datasource sales_ds
```

```
tabcmd refreshextracts --workbook "My Workbook"
```

```
tabcmd refreshextracts --url SalesAnalysis
```

```
tabcmd refreshextracts --workbook "My Workbook" --addcalculations
```

```
tabcmd refreshextracts --datasource sales_ds --removecalculations
```

### Options

`--incremental`

Runs the incremental refresh operation.

`--synchronous`

Adds the full refresh operation to the queue used by the Backgrounder process, to be run as soon as a Backgrounder process is available. If a Backgrounder process is available, the operation is run immediately. The refresh operation appears on the Background Tasks report.

During a synchronous refresh, `tabcmd` maintains a live connection to the server while the refresh operation is underway, polling every second until the background job is done.

**Note:** The `--synchronous` option isn't available for data sources refreshed with Tableau Bridge.

`--workbook`

The name of the workbook containing extracts to refresh. If the workbook has spaces in its name, enclose it in quotes.

`--datasource`

The name of the data source containing extracts to refresh.

`--project`

Use with `--workbook` or `--datasource` to identify a workbook or data source in a project other than *Default*. If not specified, the Default project is assumed.

`--parent-project-path`

Specifies the name of the parent project for the nested project as specified with the `--project` option.

For example:

- To specify a project called "Nested" that exists in a "Main" project, use the following syntax:
  - `--parent-project-path "Main" --project "Nested"`
- To specify a project called "Nested2" that is nested within the "Nested" project:
  - `--parent-project-path "Main/Nested" --project "Nested2"`

`--url`

The name of the workbook as it appears in the URL. A workbook published as "Sales Analysis" has a URL name of "SalesAnalysis".

`--addcalculations`

Use with `--workbook` to materialize calculations in the embedded extract of the workbook or `--datasource` to materialize calculations in the extract data source. Adds the operation to the queue used by the Backgrounder process. If a Backgrounder process is available, the operation runs immediately. This operation appears on the [Background Tasks for Extracts](#) administrative view.

## Tableau Server on Linux Administrator Guide

`--removecalculations`

Use with `--workbook` or `--datasource` to remove calculations that were previously materialized. Adds the operation to the queue used by the Backgrounder process. If a Backgrounder process is available, the operation runs immediately. This operation appears on the [Background Tasks for Extracts](#) administrative view.

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

## Tableau Server on Linux Administrator Guide

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### reset\_openid\_sub

Clears OpenID Connect identifiers (sub values) that have already been associated with Tableau Server identities. See [Changing IdPs in Tableau Server for OpenID Connect](#).

#### Example

```
tabcmd reset_openid_sub --target-username jsmith
```

#### Options

`--target-username`

Clears sub value for the specified individual user.

`--all`

Clears sub values for all users.

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

## Tableau Server on Linux Administrator Guide

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## `removeusers` *group-name*

Removes users from the specified group.

### Example

```
tabcmd removeusers "Development" --users "users.csv"
```

### Options

`--users`

Remove the users in the given `.csv` file from the specified group. The file should be a simple list with one user name per line.

`--[no-]complete`

Requires that all rows be valid for any change to succeed. If not specified `--complete` is used.

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or ") or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is

saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### `runschedule` *schedule-name*

Runs the tasks in the specified schedule for the site that you're currently logged into. You can't run this for all sites using `tabcmd`. To run the tasks in the schedule for all sites, log into the web interface, from the **Schedules** page, select **All Sites**, and then do a **Run Now** on the schedule.

This command takes the name of the schedule as specified on the server.

This command isn't available for Tableau Cloud.

**Note:** This method will fail and result in an error if your Server Administrator has disabled the **RunNow** setting for the site. For more information, see [Tableau Server Settings](#).

### **Example**

```
tabcmd runschedule "5AM Sales Refresh"
```

## Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

## Tableau Server on Linux Administrator Guide

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### ***set setting***

Enables the specified setting on the server. Details about each setting can be seen on the Maintenance page on the server.

Use an exclamation mark in front of the setting name to disable the setting. You can enable or disable the following settings:

- `allow_scheduling`
- `embedded_credentials`
- `remember_passwords_forever`

### **Example**

```
tabcmd set embedded_credentials
```

### Global options

## Tableau Server on Linux Administrator Guide

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or "") or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

--

Specifies the end of options on the command line. You can use -- to indicate to `tabcmd` that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### `syncgroup` *group-name*

Synchronizes a Tableau Server group with an Active Directory group. If the Tableau Server group doesn't already exist, it's created and synchronized with the specified Active Directory group.

If the group name itself includes an "@" (other than as the domain separator) you need to refer to the symbol using the hex format "\0x40".

#### **Example**

```
tabcmd syncgroup "Development"
```

```
tabcmd syncgroup "Dev\0x40West"
```

**Note:** If you synchronize a group that you're a member of, changes that you make using this command don't apply to your user. For example, if you use this command to remove the administrator right from users in a group that you're a member of, you're still an administrator when the command finishes.

## Options

`--grant-license-mode <grant-license-mode>`

Specifies whether a role should be granted on sign in. Default is `on-sync`. Valid values are `on-login`, `on-sync`. If no value is specified, `on-sync` is assumed and the default role will be granted when the group is synchronized. For more information, see [Modifying user roles with Grant role on sign in](#).

`--no-publisher`

Deprecated. Use the `--role` option instead.

`--overwritesiterole`

Allows a user's site role to be overwritten with a less privileged one when using `--role`. By default, a user site role can be promoted when using `--role`, but can't be demoted. Because the `--overwritesiterole` option will demote user site roles, use it with caution.

`--publisher`

Deprecated. Use the `--role` option instead.

`-r, --role`

Specifies a site role for users in the group. The default is `Unlicensed`.

**Valid values are:** `SiteAdministratorCreator`, `SiteAdministratorExplorer`, `SiteAdministrator`, `Creator`, `ExplorerCanPublish`, `Publisher`, `Explorer`, `Interactor`, `Viewer`, `Unlicensed`.

`--silent-progress`

Don't display progress messages for the command.

## Tableau Server on Linux Administrator Guide

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or "") or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

### upgradethumbnails

Starts and stops the Upgrade Thumbnails job. To learn more, see Upgrade Thumbnails Job.

#### Examples

To start the Upgrade Thumbnail job:

```
tabcmd upgradethumbnails --server <serverURL>
```

To stop the in progress Upgrade Thumbnail job:

```
tabcmd upgradethumbnails --server <serverURL> --stop
```

#### Options

`--stop`

When specified, stops the in progress Upgrade Thumbnails job. If this option isn't specified, the Upgrade Thumbnail job will be started.

## Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

## Tableau Server on Linux Administrator Guide

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## validateidpmetadata

Identifies Tableau Server sites that are configured with IdPs using the insecure digest algorithm, SHA-1. This command also identifies IdPs that are using certificates with an insufficient RSA key size or elliptic curve size.

**Note:** This command is only available for site-specific SAML. For more information, see [Configure Site-Specific SAML](#).

### Options

`--digest-algorithms <ALGORITHMS>`

A space-separated list of digest algorithms. Legal values are `sha1` and `sha256`. If not specified, server uses values from server configuration setting, `wgserv-er.saml.blocklisted_digest_algorithms`.

## Tableau Server on Linux Administrator Guide

`--min-allowed-elliptic-curve-size <SIZE>`

If not specified, server uses values from server configuration setting, `wgserver.saml.min_allowed.elliptic_curve_size`.

`--min-allowed-rsa-key-size <SIZE>`

If not specified, server uses values from server configuration setting, `wgserver.saml.min_allowed.rsa_key_size`.

`--site-names <SITENAMES>`

A space-separated list of site names on which to perform certificate validation. If not specified, then all sites are inspected.

### Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or "") or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

## Tableau Server on Linux Administrator Guide

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

## version

Displays the version information for the current installation of the `tabcmd` utility.

**Example**

```
tabcmd version
```

## Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** [Configure Mutual SSL](#)
- **Linux:** [Configure Mutual SSL](#)

`-s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

`-t, --site`

Indicates that the command applies to the site specified by the Tableau Server site ID, surrounded by single quotes or double quotes. To specify the Default site, use either an empty string with single or double quotes (" or """) or use Default in double quotes ("Default"). Site ID is case-sensitive when using a cached authentication token. If you do not match case you may be prompted for a password even if the token is still valid.

`-x, --proxy`

Host:Port

Uses the specified HTTP proxy.

`--no-prompt`

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

`--no-proxy`

When specified, an HTTP proxy will not be used.

`--no-certcheck`

When specified, `tabcmd` (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default, the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default, the process will wait until the server responds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

**Tip:** For `Tabcmd` 1.0 commands available for Tableau Cloud, see [tabcmd commands](#).

## Install Switches and Properties for `tabcmd` (Windows)

**Note:** The `tabcmd` command-line utility version 2.0 is available at [Tableau tabcmd](#). This new version allows you to run `tabcmd` commands on MacOS and Linux, and to authenticate using personal access tokens (PATs). Version 2.0 is built on public endpoints available in the Python-based Tableau Server Client (TSC). This latest version has limited support for Tableau Server.

You can use the following switches when installing the Tableau Server Command Line Utility (`tabcmd`) version 2019.4.0 or later from the command line on Windows.

**Note:** There are no equivalent switches for the Linux version of the `tabcmd` installer.

| Switch   | Description  | Comments   |
|--|--|--|
| <code>/install repair uninstall /layout "&lt;directory&gt;"</code> | Run Setup to either install, repair, or uninstall tabcmd, or with <code>/layout</code> , create a complete local copy of the installation bundle in the directory specified. | Default is to install, displaying UI and all prompts. If no directory is specified on a fresh install, <code>C:\Program Files\Tableau\Tableau Server-&lt;br&gt;\&lt;version&gt;\extras\Command Line Utility</code> is assumed. |
| <code>/passive</code>  | Run Setup with minimal UI and no prompts.  |  |
| <code>/quiet /silent</code>  | Run Setup in unattended, fully silent mode. No UI or prompts are displayed.  | <b>Note:</b> Use either <code>/silent</code> or <code>/quiet</code> , not both.  |
| <code>/norestart</code>  | Run Setup without restarting Windows, even if a restart is necessary.  | <b>Note:</b> In certain rare cases, a restart cannot be suppressed, even when this option is used. This is most likely when an earlier system restart was skipped, for example, during installation of other                   |

|                                    |  |   |
|------------------------------------|--|---|
|                                    |  | software.   |
| <pre>/log "&lt;log-file&gt;"</pre> | <p>Log information to the specified file and path.</p> <p>By default log files are created in the user's %TEMP% folder with a naming convention of Tableau_Server_Command_Line_utility_&lt;version_code&gt;.log.</p> | <p>If no file location is specified, the log file is written to the user's TEMP folder (C:\Users\<username>\AppData\Local\Temp). Check this log file for errors after installation.</username></p> <p>Example: &lt;Setup file&gt; /silent /log "C:\Tableau\Logs\tabcmd-Install" ACCEPTTEULA=1</p> |

| Properties        | Description                 | Comments  |
|-------------------|-----------------------------|---|
| ACCEPTTEULA=1   0 | Accept the End User License | If not included when using /passive, /silent or /quiet, Setup fails silently. |

|   |  |   |
|---|--|---|
|   | <p>Agreement (EULA). Required for quiet, silent, and passive install. 1 = accept the EULA, 0 = do not accept the EULA.</p> | <p>If included but set to 0, Setup fails.</p>   |
| <p>INSTALLDIR-<br/>R="&lt;path\to\installation\directory&gt;"</p> | <p>Install tabcmd to the specified non-default install location.</p>   | <p>Specifies the location to install tabcmd. If not used, tabcmd is installed to C:\Program Files\Tableau\Server\&lt;version_code&gt;\extras\Command Line Utility</p> <p><b>Example:</b> &lt;Setup file&gt; /silent<br/>INSTALLDIR-<br/>R="C:\tabcmd"</p> |

# Troubleshooting

You can use the following topics to troubleshoot and resolve issues with Tableau Server.

## Troubleshoot Tableau Server on Linux

Follow the suggestions in this topic to resolve common issues with Tableau Server. For additional troubleshooting steps based on process status viewed on the Status page, see [Troubleshoot Server Processes](#).

The following table displays the default locations of the installation, data, logs, and scripts directories:

| Directory     | Default location  |
|---------------|---|
| Installation: | <code>/opt/tableau/tableau_server</code>  |
| Data:         | <code>/var/opt/tableau/tableau_server/data</code>                                     |
| Logs:         | <code>/var/opt/tableau/tableau_server/data/tabsvc/logs/</code>                        |
| Scripts:      | <code>/opt/tableau/tableau_server-<br/>/packages/scripts.&lt;version_code&gt;/</code> |

## General Troubleshooting Steps

Many Tableau Server issues can be addressed or tested with one or more of these basic steps:

### Clean install

Install Tableau Server on Linux on a computer that has never had Tableau installed on it. If you are reusing a computer or VM that has had a previous version of Tableau Server installed, follow the steps in [Remove Tableau Server from Your Computer](#) to clean Tableau off your computer before you install the new version.

## Tableau Server on Linux Administrator Guide

If you run into problems installing Tableau Server you may need to entirely remove Tableau from your computer and do a clean install. See [Remove Tableau Server from Your Computer](#) for details.

### Disk space

Make sure there is enough disk space on each computer running Tableau Server. Limited disk space can cause a failure to install, a failure to upgrade, or problems running Tableau Server.

### Remove old log files

If you are running out of disk space you can clean up old Tableau Server log files. These can take up space and as a best practice you should remove them regularly.

### Version 10.5.x

If you have version 10.5.1 and higher, run this command at a terminal prompt to clean up log files you do not need:

```
tsm maintenance cleanup
```

### Version 10.5.0

If you are running version 10.5.0 of Tableau Server on Linux, the cleanup command is not available and you need to run these commands at a terminal prompt:

```
sudo find /var/opt/tableau/tableau_server/data/tabsvc/temp/* -mtime  
+2 -type f -delete
```

```
sudo find /var/opt/tableau/tableau_server/data/tabsvc/logs/* -mtime  
+2 -type f -delete
```

**Important:** The Linux file system makes it possible to delete files that are open and if you do this the Tableau processes may not be able to recreate the files. This will result in empty log files. To fix this you can stop Tableau Server, restart the TSM Controller, and restart Tableau again:

1. Stop Tableau Server:

```
tsm stop
```

2. Restart the TSM Controller:

```
sudo systemctl restart tabadmincontroller_0.service
```

3. Wait several minutes for the controller to restart. You can confirm the controller has restarted with this command:

```
tsm status -v
```

When you can run that command and the Tableau Server Administration Controller is listed as 'running' the controller has restarted.

4. Start Tableau Server:

```
tsm start
```

#### Manually gather logs

If you cannot run `tsm maintenance ziplogs` for any reason (for example, if you have a critical failure before you run `tsm initialize`), you can manually collect and zip the logs by running these commands in a terminal window on each node in the Tableau Server deployment:

```
cd /var/opt/tableau/tableau_server/data/tabsvc/  
  
cp /var/opt/tableau/tableau_server/logs/app-install.log logs  
  
cp ~/.tableau/tsm/tsm.log logs  
  
tar -czvf ~/logs.tar.gz logs
```

This creates a file called `logs.tar.gz` in your home directory. You can upload or send this file to Tableau.

### Restart server

Restart Tableau Server. Issues related to indexing and processes not fully started can be resolved by restarting Tableau Server in a controlled way. To restart Tableau Server, use the `tsm restart` command. This will stop all the processes associated with Tableau Server and then restart them.

### Edit installation and configuration files using Linux

You should edit or create any files used to install or configure Tableau Server on Linux using a Linux operating system. Files created using Microsoft Windows will cause errors in Tableau Server on Linux installation and configuration because Linux operating systems end files with a line-feed (LF) character, whereas Windows ends files with a carriage-return character and a line-feed character (CR LF). Non-Linux (CR LF) file endings can cause errors during Automated Installation of Tableau Server if they appear in the `config.json`, `reg_tmpl.json` or `secrets` files used by the automated installer. Non-Linux (CR LF) file endings can also cause errors during registration or when configuring identity store settings or gateway settings.

### Check systemd logs

If Tableau Server will not start, and you do not find anything useful in the Tableau logs (see [Work with Log Files](#) for more information) you can check the systemd logs for messages related to the TSM Service starting and stopping. The logs are stored at `/var/log/messages` (RHEL-like distros) or `/var/log/syslog` (Ubuntu). We recommend using the `journalctl` command to search and parse the systemd logs.

## Installing Tableau Server

### Install fails due to hardware requirements

Tableau Server cannot install if the computer you are installing on does not meet the minimum hardware requirements. For details on requirements, see [Before you install...](#)

### Install fails due to timeouts

If you install Tableau Server on a computer with limited resources, for example, a computer that just meets the minimum hardware requirements, you can run into problems where `tsm`

commands timeout due to slow response. You can specify a longer timeout by using the global `--request-timeout` option on all `tsm` commands. For more information on the `--request-timeout` option, see for example, `tsm initialize`.

Install fails with "Failed to initialize the instance of the temporary database"

Tableau Server on Linux only supports UTF-8 character encoding. If your Linux locale is missing the UTF-8 encoding, your installation can fail with an error similar to this one:

```
Failed to initialize the instance of the temporary database
```

To check if your locale is using UTF-8 encoding, run the `localectl` command at a command prompt. The resulting output should look something like this (your locale may be different):

```
[tableauserver-centos1a ~]$ localectl
System Locale: LANG=en_US.UTF-8
[tableauserver-centos1a ~]$
```

If the `LANG` value does not include `.UTF-8` then you need to run `localectl` to add it:

```
sudo localectl set-locale LANG=<your_locale>.UTF-8
```

**Note:** In some cases `localectl` may not complete (timeout) if your version of `systemd` is old. Updating `systemd` may fix this problem and allow you to set the UTF-8 encoding. On RHEL-like systems, use this command to update `systemd`: `sudo yum update systemd`

Installation fails on a virtual machine in Parallels

Parallels is currently not supported. If you install Tableau Server on a Linux virtual machine in Parallels, the install might fail.

## Tableau Server on Linux Administrator Guide

### Tableau Server doesn't start

If Tableau Server does not start or is running in a degraded state, run the `tsm restart` command. This will shut down any processes that are running, and restart Tableau Server.

### Cannot start Tableau Server after installation

Tableau Server might not start if your computer's hostname changes after installation. One of the main reasons why the hostname might change is if you use the `cloud-init` package on CentOS. If you use the `cloud-init` package, *reboot the computer* where you want to install Tableau Server before you begin the installation process. Alternatively, you can fix the hostname without rebooting by running the following command:

```
sudo hostnamectl set-hostname `hostnamectl --static`
```

The `cloud-init` package is commonly used to initialize new virtual machines, configure SSH public key authentication, and more. For example, some CentOS images use `cloud-init`, and `cloud-init` is commonly used in OpenStack deployments. However, the version of `cloud-init` included by default in the CentOS 7.x repositories (`cloud-init 0.7.5-10.el7.centos.1`) has a **known issue** that prevents your computer from displaying its Fully Qualified Domain Name (FQDN) along with its hostname until after it restarts.

Because the Tableau Server installation process uses your computer's hostname to configure server processes and generate TLS certificates, Tableau Server might not start if it is configured to use a hostname without the FQDN.

To determine if your computer is displaying the correct hostname, run the `hostnamectl` command. In the following example, the command displays a transient hostname which indicates that it will not return the FQDN and must be restarted.

```
$ hostnamectl
  Static hostname: server01.example.com
Transient hostname: server01
[...]
```

Alternatively, in the following example, the command displays the correct hostname and FQDN:

```
$ hostnamectl
   Static hostname: server01.example.com
[...]
```

### Cannot create initial administrator account with multiple Active Directory (AD) domains

When you create the initial administrator account on Tableau Server, you might see the following error if you selected AD as the authentication type:

```
Failed to authenticate username and password
```

This occurs when Tableau Server attempts to connect to multiple AD domains. For example, you might see this error if you install Tableau Server on a computer that is part of one domain and you attempt to authenticate AD users that are part of another domain.

### Fonts

Tableau Server uses the fonts installed on the system to render workbooks based on the fonts used when a workbook was created. When a font is not available, Tableau Server will use the closest equivalent based on font families; this is true for both Windows and Linux Servers. On Linux Servers missing fonts may be more obvious because Linux ships with fewer included fonts than Windows and OS/X systems do. This matters because many workbooks are authored in Tableau Desktop on Windows or on Mac.

Tableau Server on Linux ships with the following fonts:

- Arial
- Courier
- Georgia
- Times New Roman
- Verdana
- Trebuchet MS
- Tableau Font

Workbooks which use fonts other than these may appear differently than expected when viewed on Tableau Server on Linux, due to missing fonts. To resolve this issue, install the appropriate fonts onto all nodes in your Tableau Server installation.

### Support for Asian character sets

If you see empty boxes where you expect to see Asian characters in workbooks that are displayed on Tableau Server, then you should install the language-appropriate font packages in your Linux environment.

## Initializing Tableau Server

TSM initialization fails because the `tableau` user account exists but is not a member of the group `tableau`.

When you install and initialize Tableau Services Manager (TSM) and Tableau Server, the initialization script (`initialize-tsm`) creates the users and groups needed to run, or confirms that the existing ones are configured with the required characteristics. By default the script creates a user called `tableau` and adds it to a group called `tableau`. If a `tableau` user already exists but is not part of the `tableau` group, the script fails with a warning.

If this happens you can fix the conflict by using a `--unprivileged-user` flag to specify a different user, and the user will be created and added to the `tableau` group.

For example, to specify a user named `tableauserver`, you would run the script from the `/opt/tableau/tableau_server/packages/scripts.<version_code>` directory using this command:

```
sudo ./initialize-tsm --unprivileged-user="tableauserver" --
accepteula
```

For a complete list of options that can be used with the `initialize-tsm` script, use the `-h` option:

```
sudo ./initialize-tsm -h
```

### Error initializing Tableau Server on unsupported system locale

If you attempt to install Tableau Server on a computer with a locale that is not one of the supported locales, you will get an error during installation.

Tableau Server will run on a system using one of the following locales:

de\_DE, en\_GB, en\_US, es\_ES, fr\_FR, it\_IT, ja\_JP, ko\_KR, pt\_BR, zh\_CN, zh\_TW

fr\_CA (as of version 2022.3)

th\_TH, sv\_SE (version 2023.1)

Any other locale will generate the error.

Error initializing Tableau Server when en\_US.utf8 is not included in locale list

If you attempt to install Tableau Server on a computer that does not have `en_US.utf8` in the locale list, the initialization will fail with an error. To see if `en_US.utf8` is included, type `locale -a` at a shell prompt.

If `en_US.utf8` is not listed, you can add `en_us` to the locale list by typing `sudo locale-gen en_US.UTF-8` at a shell prompt on Ubuntu, or `sudo localedef -i en_US -f UTF-8` at a shell prompt on RHEL-like distributions.

Error: status 10 - initializing Tableau Server when data directory path includes a period

If you attempt to install Tableau Server and specify a data directory with a path that includes a period ("."), initialization will fail with errors including:

```
Connection timed out
```

and

```
ERROR: TSM services returned status 10
```

To avoid this issue, choose a data directory that does not include a period in its path.

Error initializing Tableau Server after reinstallation

If you uninstall and reinstall Tableau Server, you can encounter an error initializing Tableau Server. For example, you might see the following error:

```
ERROR com.tableau.tabadmin.webapp.asyncjobs.JobStepRunner - Running
step WaitForConfigure failed
```

## Tableau Server on Linux Administrator Guide

```
com.tableau.tabadmin.webapp.exceptions.ServiceFailedStateException
```

This error occurs when artifacts remain from a previous installation that cause services to fail to start. To prevent this error, use the `tableau-server-obliterate` script in the `/opt/tableau/tableau_server/packages/scripts.<version_code>` folder. For more information about completely removing Tableau Server, see [Remove Tableau Server from Your Computer](#).

## Activating Tableau Server

Tableau Server license activation fails

In certain cases activation of the Tableau product key using the `tsm licenses activate -k <product_key>` command fails with an error:

```
License Server not available
```

This can happen if your computer is unable to connect through TCP port 443 to the Tableau licensing server at `licensing.tableau.com`.

To resolve this you need to configure your network and/or host-based firewalls to allow access to that address and port, or activate Tableau offline. For more information, see [Activate Tableau Server Offline](#).

## Reindexing Tableau Server Search & Browse

Problems that can be solved by reindexing Search & Browse

Symptoms of an index that needs to be rebuilt include:

- A blank list of sites when a user attempts to log in
- A blank list of projects when a user tries to select a project
- Missing content (workbooks, views, dashboards)
- Unexpected or inaccurate alerts (for example, an "refresh failed" alert on a workbook that does not include an extract)

If you see any of these behaviors, rebuild the Search & Browse index using the `tsm maintenance reindex-search` command.

## Restarting Tableau Server

Restarting Tableau Server or applying changes fails

If one of the Tableau Server services fails, you might see an error when you attempt to restart the server or apply configuration changes.

To see if a failed service is causing the error, type the following command:

```
tsm status -v
```

To find out why a service failed, view the `tabadminagent` and `tabadmincontroller` log files in the data directory. For example, a service might fail because of concurrency issues or port configuration issues. Please include any issues you encounter in your feedback.

As a workaround, you can attempt to resolve the failure by removing and re-adding the service in TSM. Once the service has started, you can retry your previous configuration change or retry restarting the server with the `tsm restart` command.

Error restarting Tableau Server after adding or configuring a node

If you add a or configure the node without a Gateway process, Tableau Server might fail to restart and you could see errors like these:

```
ERROR : com.tableau.tabadmin.configuration.PortConfigurationExtractor - Unable  
to find port config key worker1.gateway.port
```

and

```
Message: Missing port configuration value for key 'worker1.gateway.port'
```

These errors appear in the `gateway.log` file and occur when a Tableau Server node is configured with either an Application Server or VizQL Server but without a Gateway. A Gateway process is required if either Application Server or VizQL Server is running on a node.

## Backup/Restore

Problems related to restoring a backup created by Tableau Server can be the result of permissions issues. Proper permissions are necessary for both the file that TSM is restoring, and the location of the file. When TSM handles the backup, it puts the file in a default location and sets permissions appropriately. You can run into permission problems if you are restoring a backup that was copied to your Linux server, or a backup from a non-default location on your server. For details about using a non-default location, including how to change the location, see [tsm File Paths](#).

Errors may include:

```
Server Was Denied Access to File
```

or

```
Restoring the backup '<backup>.tsbak' was unsuccessful
```

or

```
Comparing authentication methods failed
```

The Tableau Server backup and restore processes must have:

- Read permission—The processes need to access the `.tsbak` backup file directly.
- Execute permission—The processes also require execute permissions to the directory structure in which the `.tsbak` file is placed.

When TSM creates a backup in the default location, it sets the permissions it needs. If you copy a file to the Linux server, or move it to a non-default directory, the permissions may not allow the TSM processes proper access. You need to verify that both the file, and the directory tree that contains it, allow access by the TSM user *tableau*. The file permissions must give the *tableau* user read access to the `.tsbak` file. You can do this by setting the group on the file to the *tableau* group, and giving that group read access. The directory permissions must give the

*tableau* user read access. You can do this by setting the group on the directory to the *tableau* group, and giving that group read and execute access on the directories.

For detailed information about TSM and file permissions, see Files and Permissions in TSM.

## File locations

Changing basefilepath does not change the location of an existing file

Several tsm commands write files to default locations. You can change these default locations for each command using a tsm set command, but doing so does not move any existing files from the original location to the new one, and it does not create the new location. You are responsible for creating the new location, and for making sure it has the correct permissions to allow tsm access to any files in the location, and the entire directory structure that contains the files.

For more information about changing default locations for backup, restore, site import and export, and ziplogs files, see tsm File Paths.

For information about tsm permissions, see Files and Permissions in TSM.

## TSM commands

TSM command line does not show progress for long-running tasks

If you run a tsm command such as restore or ziplogs that takes more than 2 hours to complete, the command will continue to run until completion on the server. To display the progress of the job, use the `tsm jobs reconnect` command.

## Opening Firewall ports

Manually opening firewall ports on Ubuntu

The current version of Tableau Server does not support the `ufw` firewall that is used on Ubuntu. For customers that do not want to install `firewalld` on Ubuntu, another option is to manually open those ports. The following steps will confirm that `ufw` is running, and open TCP ports 8850 and 80 to connections from any source address:

## Tableau Server on Linux Administrator Guide

1. Run the following command to confirm `ufw` is running:

```
sudo ufw status
```

If the result is `Status: inactive`, you will need to enable `ufw` and ensure that you can continue to connect via `ssh`, which is outside the scope of these release notes.

2. Run the following command to allow access to port 8850:

```
sudo ufw allow 8850
```

3. Run the following command to allow access to port 80:

```
sudo ufw allow 80
```

### OpenID fails on first sign-in attempt

If you have configured Open ID Connect authentication for Tableau Server, the first sign-in attempt fails. To successfully log in, users must retry authentication after the initial failure.

### Administrative views do not display

The Status tab of Tableau Server includes links to visualizations that display server metrics. These visualizations require the PostgreSQL driver to access the appropriate data from the Tableau Server repository. The PostgreSQL driver is not installed automatically, so if you have not installed the driver, the views will not display. For more information, see [Database Drivers](#).

**Note:** To use administrative views, the PostgreSQL driver must be installed on any node that runs the VizQL Server process.

### Changing locale on view

When you change your user locale after opening a view, any subsequent attempt to open the view will fail with an "unexpected error." You can still open views that you have not previously opened.

To work around this issue, sign out of Tableau Server after changing your locale, and then sign back in. All views will display properly.

## Work with Log Files

Tableau Server creates log files as a normal part of its activities. You may need to use the server log files when you are troubleshooting issues with Tableau Server or if Tableau Support requests logs from you to help you resolve an issue.

You can create a zipped log file archive using the `tsm maintenance ziplogs` command. The zipped archive contains copies of the logs you can unzip and look at, or send to Tableau Support. Once you have a copy of the archive, you can delete the archive from your server. For more information on log file archives, see [Log File Snapshots \(Archive Logs\)](#).

This collection of topics provides information about how to create log file archives, the contents of specific log files, and details about when and how you might want to look at a log.

## Contents of Tableau Server Logs

Every Tableau Server process writes information about what it is doing to its own log file. Singly these give detailed information on the actions of each process. Taken together these log files contain detailed information about internal communication between components of Tableau Server while processing users' requests or performing automated tasks. Tableau Server logs only contain technical information useful for troubleshooting; the status of different components, actions taken by different processes, communication attempts, queries to the database (not including results), and timings of requests, for example.

Log files could contain some specific data such as names of database servers, as well as their IP addresses and ports, names or IP addresses of Tableau Server computers, and URLs and names of the workbooks and views accessed by users.

Log files do not contain any sensitive customer data such as passwords, results of the queries, or data shown on the views.

**Note:** When logging at the `DEBUG` level, full environment information is gathered when Tableau starts. This means that if you have any sensitive information in an environment variable, it may be included in a log. Logging at the default `INFO` level only gathers safe environment information.

The `tsm maintenance ziplogs` command allows users to not only generate a zipped archive of log files, but also to include Tableau Server repository data if the `-d` option is specified. The repository contains metadata from Tableau Server (for example, usernames, groups, projects, permissions on Tableau Server, extract refresh schedules). The repository also includes layout and connection information for the workbooks, but does not have any data such as passwords, actual data from the database or data shown on the view.

Data displayed in views comes from extract files or databases, and is cached in memory. It is not saved in logs or, in the case of live connections, in separate files on Tableau Server computers. Extract files are stored on Tableau Server computers as `.hyper` files in the `data-engine` folder, but are never included in the zipped log archive.

## Investigating Tableau Server Issues

The range and complexity of possible issues with Tableau Server means that there is no simple process you can use to investigate all problems, but a general approach would include these steps:

1. **Clean up** existing log files to reduce their size. For more information, see [Remove Unneeded Files](#).

**Important:** If there is a chance you will want to get help from Tableau Support troubleshooting an issue, be sure to create a zipped archive of your logs before cleaning them up. The clean up can delete important information Support may need. For details on creating log archives, see [Log File Snapshots \(Archive Logs\)](#).

2. **Set the appropriate logging level.** This is something that Tableau Support will instruct you on. For more information including impact of different log levels, see [Change Logging Levels](#).
3. **Reproduce the issue** you are troubleshooting so the logs capture the events related to the problem.
4. **Create an archive** of the logs. For more information see [Log File Snapshots \(Archive Logs\)](#).

**Important:** Use this archive when looking at the log files. You should not edit, move or delete any files directly on the server.

5. **Review the TSM Administration Controller log** (`/tabadmincontroller/tabadmincontroller_node<n>-<n>.log`) to understand any configuration or deployment done by TSM from the command line, Web UI, or API, including jobs started by TSM. Start with the controller log. This is where you'll get most useful information.

**Note:** The `tsm.log` is less wordy than the `tabadmincontroller_*.log` but can provide useful, complimentary troubleshooting information.

6. **Review the Apache logs** (`/httpd/access.####_##_##_##_##.log` and `/httpd/error.log`) for requests that may be related to the issue you are investigating.

The Apache logs will contain a fair amount of "noise" that does not apply to issues you are experiencing.

- If you find a request that seems to be related to your issue, search the `vizqlserver` directory for entries that include the unique request ID from the Apache logs.
- Look for the response code and message associated with the request ID.
- Search for the name of the workbook, view, dashboard, or data source that is related to your issue. Make sure to look for a relevant timestamp.

## Tableau Server on Linux Administrator Guide

- If you find a request that seems to be related to your issue, look at the response code associated with the request. (200s are good, 500s indicate problems.)
- Locate the unique request ID associated with the request you've identified (the unique request ID is a 24 character alphanumeric string at the very end of the request).

### 7. Review the log archive further to search for other messages and possible errors.

- Use the request ID from the Apache logs to search the `vizqlserver` folder of the log archive for files containing related log entries. Look for indications of a problem (for example, error messages or long-running queries).
- The free, open source tool, Logshark can be a useful option for reviewing log archives. For more information, see [Troubleshooting Tableau Server](#) in the Tableau Blueprint.

### 8. Review script logging.

Tableau Server includes logs for most of the bash scripts that are included in the `scripts` directory at `/opt/tableau/tableau_server/packages/scripts.<version_code>/`. These logs are saved to the `/var/tmp` directory each time a script is run.

By default: `/var/opt/tableau/tableau_server/data/tabsvc/logs/`

### 9. Contact support

If you are not able to solve the issue yourself, or if requested by Tableau Support, send the zipped archive to Tableau.

## Tableau Server Logs and Log File Locations

Tableau Server generates log files as a normal part of its functioning. Each service that runs as part of Tableau Server generates its own logs. These log files include information about what is happening on the server, what the service or process is doing, and what, if any errors or warnings are generated. The extent of information in the logs depends on which service is writing the logs, what the logging levels are set to, and what is happening on the server.

Looking for Tableau Server on Windows? See [Server Log File Locations](#).

Log files can be useful in helping to identify and fix issues that Tableau Server is having. In some cases, system administrators may be able to look at logs and find clues to what is happening, but in most situations the Tableau Server logs are most useful for Tableau Support. When you open a case with Support, you may be asked to send log files from your server.

**Note:** The specific directories and logs generated by Tableau Server depend on the version of server you are running, and which processes you have configured. New services and processes are added periodically to support new functionality. For details about processes or services you might find logs for, see [Tableau Server Processes](#).

#### Tableau Server log files on an active cluster

As a best practice you should not edit or delete log files in an active Tableau Server installation. Doing this can cause unexpected behavior or server downtime. Most Tableau Server logs are written to a location in the data directory. Some logs are written to other locations.

The easiest and safest way to gather and view server log files is to create a log archive, which is a zipped collection of logs from all nodes in a cluster. If you think you may need old logs for any reason, for example, to compare with new logs after doing an upgrade, or to send to Tableau Support when troubleshooting a server issue, create a zip archive, and move the archive to a safe location that is not part of your Tableau Server infrastructure. For more information about log files in a log archive, see [Server Log Files in a zipped archive](#).

Logs can take up a good deal of space, especially on a heavily used server. You can use the `tsm maintenance cleanup` command to remove logs you no longer want or need. but if you think you may need your existing logs, consider archiving them before cleanup.

## Tableau Server on Linux Administrator Guide

### Primary log locations on a working Tableau Server installation

Most of the Tableau Server logs are written to the data directory, `/var/opt/tableau/tableau_server/data/tabsvc/logs/`. Subdirectories are created for each instance of a service, with a name that includes the service name and the version code. For example:

```
/var/opt/tableau/tableau_server/data/tabsvc/logs/backgrounder
```

### Configuration file locations on a working Tableau Server installation

In addition to logs for each service or process, a `config` subdirectory contains configuration information about the service.

```
/var/opt/tableau/tableau_server/data/tabsvc/config/backgrounder
```

Tableau Support may ask you to gather some of these if you are working with them on a server issue. The contents can be analyzed by Support.

### Logs that are not written in the primary location

A few logs are not part of the main set of logs, and are written to locations other than the normal log directories:

- **The TSM log.** The `tsm.log` file is located in `<home_dir>/tableau/tsm`.
- **The install log.** The `app-install.log` file is located in `/var/opt/tableau/tableau_server/logs`.
- **The upgrade log.** The `app-upgrade.log` file is located in `/var/opt/tableau/tableau_server/logs`.
- **Bash script logs.** Most Tableau Server bash scripts located in the `/scripts` directory (`/opt/tableau/tableau_server/packages/scripts.<version>`) generate their own logs. These are written to the `/var/tmp` directory each time a script is run.

### Server Log Files in a zipped archive
