(54) Title: METHODS AND COMPOSITIONS FOR MODULATING SIALIC ACID PRODUCTION AND TREATING HEREDITARY INCLUSION BODY MYOPATHY

FIG. 1

(57) Abstract: According to certain embodiments of the present invention, methods for modulating the production of sialic acid in a system are provided, which comprise providing the system with a wild-type GNE-encoding nucleic acid sequence. According to such embodiments, the system may comprise a cell, muscular tissue, or other desirable targets. Similarly, the present invention encompasses methods for producing wild-type GNE in a system that comprises a mutated endogenous GNE-encoding sequence. In other words, the present invention includes providing, for example, a cell or muscular tissue that harbors a mutated (defective) GNE-encoding sequence with a functional wild-type GNE encoding sequence.

**METHODS AND COMPOSITIONS FOR MODULATING SIALIC ACID PRODUCTION
AND TREATING HEREDITARY INCLUSION BODY MYOPATHY**

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority to, and incorporates by reference, U.S. provisional patent application serial number 60/900,034, filed February 7, 2007.

FIELD OF THE INVENTION

[0002] The field of the present invention relates to methods and compositions for modulating sialic acid production in a system. The field of the present invention further relates to methods and compositions for treating and/or preventing Hereditary Inclusion Body Myopathy and/or symptoms thereof.

BACKGROUND OF THE INVENTION

[0003] Hereditary Inclusion Body Myopathy (HIBM2) is a chronic progressive skeletal muscle wasting disorder, which generally leads to complete disability before the age of 50 years. There is currently no effective therapeutic treatment for HIBM2. Development of this disease is related to expression in family members of an autosomal recessive mutation of the GNE gene, which encodes the bifunctional enzyme UDP-GlcNAc 2-epimerase / ManNAc kinase (GNE/MNK). This is the rate-limiting bifunctional enzyme that catalyzes the first 2 steps of sialic acid biosynthesis. Decreased sialic acid production consequently leads to decreased sialylation of a variety of glycoproteins, including the critical muscle protein alpha-dystroglycan (α -DG). This in turn severely cripples muscle function and leads to the onset of the syndrome.

SUMMARY OF THE INVENTION

[0004] According to certain embodiments of the present invention, methods for modulating the production of sialic acid in a system are provided, which comprise providing the system with a wild-type GNE-encoding nucleic acid sequence. According to such embodiments, the system may comprise a cell, muscular tissue, or other desirable targets. Similarly, the present invention encompasses methods for introducing and expressing wild-type GNE in a system that comprises a mutated endogenous GNE-encoding sequence. In other words, the present invention includes providing, for example, a cell or muscular tissue that harbors a mutated (defective) GNE-encoding sequence with a functional wild-type GNE encoding sequence.

[0005] According to additional embodiments of the present invention, methods for treating, preventing, and/or ameliorating the effects of Hereditary Inclusion Body Myopathy are provided. Such methods generally comprise providing a patient with a wild-type GNE-encoding nucleic acid sequence. The wild-type GNE-encoding nucleic acid sequence may, optionally, be delivered to a patient in connection with a lipid nanoparticle, either via muscular injection or intravenous administration.

[0006] According to yet further embodiments of the invention, novel compositions are provided for expressing wild-type GNE in a system. The compositions preferably include a wild-type GNE-encoding nucleic acid sequence disposed within or connected to a lipid nanoparticle. The lipid nanoparticle may, optionally, be decorated with agents that are capable of recognizing and binding to muscle cells, muscle tissue, or components of the foregoing.

BRIEF DESCRIPTION OF THE FIGURES

[0007] The file of this patent application contains at least one drawing executed in color. Copies of this patent with color drawing(s) will be provided by the United States Patent and Trademark Office upon request and payment of the necessary fee.

BRIEF DESCRIPTION OF THE SEQUENCE LISTING

[0022] **SEQ ID NO: 1 - 6** are the nucleic acid sequences of the PCR primers listed in Table-1 below.

[0023] **SEQ ID NO: 7 - 8** are GNE-specific PCR primers.

[0024] **SEQ ID NO: 9** is the nucleic acid sequence of the PUMVC3-wt-DNA construct described herein and shown in Figure 1.

[0025] **SEQ ID NO: 10** is the GNE-encoding sequence contained within the PUMVC3-wt-DNA construct.

[0026] **SEQ ID NO: 11** is the wild-type amino acid sequence of GNE.

[0027] **SEQ ID NO: 12** is the modified nucleic acid sequence for GNE-R266Q.

[0028] **SEQ ID NO: 13** is the modified amino acid sequence for GNE-R266Q.

[0029] **SEQ ID NO: 14** is the mutated nucleic acid sequence for GNE-M712T (a mutation that causes HIBM2).

[0030] **SEQ ID NO: 15** is the mutated amino acid sequence for GNE-M712T (a mutation that causes HIBM2).

DETAILED DESCRIPTION OF THE INVENTION

[0031] According to certain embodiments of the present invention, methods for modulating the production of sialic acid in a system are provided. The methods generally comprise providing the system with a wild-type GNE-encoding nucleic acid sequence. The wild-type GNE-encoding nucleic acid sequence may, preferably, comprise a promoter operably connected thereto. The promoter will preferably be functional and capable of driving the expression of the GNE-encoding nucleic acid sequence in the target cell (or target extra-cellular space). A non-limiting example of a promoter that may be operably connected to a GNE-encoding sequence is the CMV promoter, which is shown to be operably connected to the wild-type GNE-encoding nucleic acid sequence of the PUMVC3-wt-DNA construct (Figure 1).

[0032] As used herein, the terms "GNE-encoding nucleic acid sequence," "wild-type GNE-encoding sequence," "GNE-encoding sequence," and similar terms refer to a nucleic acid sequence that encodes the wild-type bifunctional enzyme UDP-GlcNAc 2-epimerase / ManNAc kinase (GNE/MNK), which is represented by the amino acid sequence of SEQ ID NO: 11. A GNE-encoding sequence may only include a nucleic acid sequence that encodes the wild-type form of GNE, such as SEQ ID NO: 10. Alternatively, the GNE-encoding sequence may comprise the nucleic acid sequence that encodes the wild-type form of GNE, along with other transcriptional control elements, such as a promoter, termination sequence, and/or other elements. A non-limiting example of such a GNE-encoding sequence is the pUMVC3 GNE construct shown in Figure 1, which consists of the nucleic acid sequence of SEQ ID NO: 9.

[0033] The terms “GNE-encoding nucleic acid sequence,” “wild-type GNE-encoding sequence,” “GNE-encoding sequence,” and similar terms are further meant to include a nucleic acid sequence which, by virtue of the degeneracy of the genetic code, is not identical with that shown in any of the sequences shown in the Sequence Listing appended hereto, but which still encodes the amino acid sequence of the wild-type GNE (SEQ ID NO: 11), or a modified nucleic acid sequence that encodes a different amino acid sequence, provided that the resulting GNE protein retains substantially the same (or even an improved) activity of the wild-type GNE protein. A non-limiting example of such a modified GNE protein includes the GNE isoform R266Q described herein (SEQ ID NO: 13). That is, modifications to a GNE-encoding sequence that alter the amino acid sequence of the wild-type GNE protein in such a way that one amino acid is replaced with a similar amino acid are encompassed by the present invention, as well as other modifications which do not substantially negatively affect GNE activity because the change (whether it be substitution, deletion or insertion) does not negatively affect the active site of the GNE protein.

[0034] As used herein, the term “system” refers to any biological system that is capable of receiving a GNE-encoding sequence described herein, including any type of cell or biological organism. In addition, a “system” may further include an intercellular space within a biological organism.

[0035] According to certain embodiments of the invention, the GNE-encoding sequence may be disposed in or connected to an appropriate carrier or delivery vehicle. Various strategies may be employed to deliver the GNE-encoding sequences described

herein into target cells, including the use of lipid carriers (lipid nanoparticles), viral vectors, biodegradable polymers, polymer microspheres (e.g., 50 nm or smaller), and various conjugate systems and related cytofectins.

[0036] The use of liposomes or other particle forming compositions is a preferred delivery vehicle for the GNE-encoding sequences described herein. Liposomes are attractive carriers insofar as they protect biological molecules, such as the GNE-encoding sequences described herein, from degradation while improving cellular uptake. One of the most commonly used classes of liposome formulations for delivering polyanions (e.g., DNA) is that which contains cationic lipids.

[0037] Lipid aggregates may be formed with macromolecules using cationic lipids alone or including other lipids and amphiphiles, such as phosphatidylethanolamine. It is well-known in the art that both the composition of the lipid formulation, as well as its method of preparation, have an effect on the structure and size of the resultant anionic macromolecule-cationic lipid aggregate. These factors can be modulated to optimize delivery of polyanions to specific cell types *in vitro* and *in vivo*.

[0038] The use of cationic lipids for cellular delivery of the GNE-encoding compositions described herein has several advantages. The encapsulation of anionic compositions using cationic lipids is essentially quantitative due to electrostatic interaction. In addition, it is believed that the cationic lipids interact with the negatively charged cell membranes, thereby initiating cellular membrane transport.

[0039] Experiments have shown that plasmid DNA may be encapsulated in small particles, which generally consist of a single plasmid encapsulated within a bilayer lipid

vesicle (Wheeler, *et al.*, 1999, Gene Therapy 6, 271-281). These particles often contain the fusogenic lipid dioleoylphosphatidylethanolamine (DOPE), low levels of a cationic lipid, and can be stabilized in aqueous media by the presence of a poly(ethylene glycol) (PEG) coating.

[0040] These lipid particles have systemic applications, as they exhibit extended circulation lifetimes following intravenous (i.v.) injection, can accumulate preferentially in various tissues and organs due to the enhanced vascular permeability in such regions, and can be designed to escape the lysosomal pathway of endocytosis by disruption of endosomal membranes. These properties can be useful in delivering biologically active molecules, such as GNE-encoding sequences, to various cell types for experimental and therapeutic applications, such as to muscle tissue cells. Various lipid nucleic acid particles and methods of preparation thereof are described in U.S. Patent Application Publication Nos. 2008-0020058, 2003-0077829, 2003-0108886, 2006-0051405, 2006-0083780, 2003-0104044, 2006-0051405, 2004-0142025, 2006-00837880, 2005-0064595, 2005-0175682, 2005-0118253, 2005-0255153 and 2005-0008689; and U.S. Pat. Nos. 5,885,613; 6,586,001; 6,858,225; 6,858,224; 6,815,432; 6,586,410; 6,534,484; and 6,287,591, all of which are incorporated herein by reference in their entirety.

[0041] The invention provides that the GNE-encoding sequences, and/or the associated delivery vehicles used therewith, may be targeted towards specific cell types, for example, muscle cells, muscle tissue, and the like. For example, the liposomal nanoparticles can be directed to bind to cell surfaces by a number of specific

interactions. This binding facilitates the uptake of the DNA into the cell by one of several well understood cell entry pathways. Rapid sequestration of the nanoparticles (e.g., liposomes) by these interactions reduces their time in the peripheral circulation, thereby decreasing the likelihood of degradation and nonspecific uptake. General targeting agents include, but are not limited to, transferrin (Trf) which binds to the transferrin receptor (TrfR) on a cell surface - or using an antibody (or a derivative thereof) that binds to the TrfR on the cell surface. Muscle has a relatively high proportion of TrfR on its cell surfaces. Another target for sequestration is the epidermal growth factor receptor (EGFR), which is prevalent on the surface of muscle cells and other epitheloid cell types. Erbitux (an EGFR monoclonal antibody approved for human use) is an exemplary agent for EGFR-targeting, which may also be used to decorate the liposomal nanoparticles described herein. Additional targeting moieties can be, but are not limited to, lectins or small molecules (peptides or carbohydrates) which recognize and bind to specific targets found only on (or are more restricted to) muscle cells. The advantage of smaller (and possibly higher affinity) molecules is that they could be present at a higher density on the surface of the nanoparticles employed.

[0042] The GNE-encoding sequences described herein, which preferably are used and delivered to a system in connection with an appropriate delivery vehicle (such as a liposome or lipid nanoparticle), may be administered to a system using any of various well-know techniques. For example, in the case of a mammal, the GNE-encoding sequences may be administered to a mammal via parenteral injection. The term "parenteral," as used herein, includes subcutaneous, intracutaneous, intravenous, intramuscular, intraarticular, intraarterial, intrasynovial, or infusion techniques.

[0043] The GNE-encoding sequences and related compositions may contain any conventional non-toxic pharmaceutically-acceptable carriers, adjuvants or vehicles. In some cases, the pH of the formulation may be adjusted with pharmaceutically acceptable acids, bases or buffers to enhance the stability of the formulated composition or its delivery form. For example, sterile injectable aqueous or oleaginous suspensions may be formulated according to the known art using suitable dispersing or wetting agents and suspending agents. The sterile injectable preparation may also be a sterile injectable solution, suspension or emulsion in a nontoxic parenterally acceptable diluent or solvent. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, U.S.P. and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose, any bland fixed oil may be employed, including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid may be used in the preparation of injectables.

[0044] According to certain embodiments, a Plasma-Lyte[®] carrier may be employed and used to deliver a GNE-encoding sequence, particularly for parenteral injection. (Baxter Laboratories, Inc., Morton Grove, Illinois). Plasma-Lyte[®] is a sterile, non-pyrogenic isotonic solution that may be used for intravenous administration. Each 100 mL volume contains 526 mg of Sodium Chloride, USP (NaCl); 502 mg of Sodium Gluconate (C₆H₁₁NaO₇); 368 mg of Sodium Acetate Trihydrate, USP (C₂H₃NaO₂•3H₂O); 37 mg of Potassium Chloride, USP (KCl); and 30 mg of Magnesium Chloride, USP (MgCl₂•6H₂O). It contains no antimicrobial agents. The pH is preferably adjusted with sodium hydroxide to about 7.4 (6.5 to 8.0).

[0045] The injectable formulations used to deliver GNE-encoding sequences may be sterilized, for example, by filtration through a bacterial-retaining filter, or by incorporating sterilizing agents in the form of sterile solid compositions, which can be dissolved or dispersed in sterile water, Plasma-Lyte[®] or other sterile injectable medium prior to use.

[0046] In order to prolong the expression of a GNE-encoding sequence within a system (or to prolong the effect thereof), it may be desirable to slow the absorption of the composition from subcutaneous or intramuscular injection. This may be accomplished by the use of a liquid suspension of crystalline or amorphous material with poor water solubility. The rate of absorption of the composition may then depend upon its rate of dissolution, which, in turn, may depend upon crystal size and crystalline form.

[0047] Alternatively, delayed absorption of a parenterally administered GNE-encoding sequence may be accomplished by dissolving or suspending the composition in an oil vehicle. Injectable depot forms may be prepared by forming microencapsule matrices of the GNE-encoding sequence in biodegradable polymers such as polylactide-polyglycolide. Depending upon the ratio of GNE-encoding sequence material to polymer and the nature of the particular polymer employed, the rate of GNE-encoding sequence release can be controlled. Examples of other biodegradable polymers include poly(orthoesters) and poly(anhydrides). As described above, depot injectable formulations may also be prepared by entrapping the GNE-encoding

sequence in liposomes (or even microemulsions) that are compatible with the target body tissues, such as muscular tissue.

[0048] In addition to methods for modulating the production of sialic acid in a system, the present invention further encompasses methods for producing wild-type GNE in a system. According to such embodiments, the system (*e.g.*, the muscle cells of a human patient) may comprise a mutated endogenous GNE-encoding sequence (*e.g.*, the GNE-M712T sequence of SEQ ID NO: 14). In other words, the present invention includes providing, for example, a cell or muscular tissue that harbors a mutated (defective) GNE-encoding sequence with a functional wild-type GNE encoding sequence. The wild-type GNE encoding sequence may be delivered to such a system using, for example, the liposomes or lipid nanoparticles described herein, via parenteral injection.

[0049] According to additional related embodiments of the present invention, methods for treating, preventing, and/or ameliorating the effects of Hereditary Inclusion Body Myopathy (HIBM2) are provided. Such methods generally comprise providing a patient with a therapeutically effective amount of a wild-type GNE-encoding nucleic acid sequence. In certain embodiments, the wild-type GNE-encoding nucleic acid sequence may, preferably, be delivered to a patient in connection with a lipid nanoparticle and a carrier similar to that of Plasma-Lyte[®], via parenteral injection.

[0050] The phrase "therapeutically effective amount" of a wild-type GNE-encoding nucleic acid sequence refers to a sufficient amount of the sequence to express sufficient levels of wild-type GNE, at a reasonable benefit-to-risk ratio, to

increase sialic acid production in the targeted cells and/or to otherwise treat, prevent, and/or ameliorate the effects of HIBM2 in a patient. It will be understood, however, that the total daily usage of the wild-type GNE-encoding nucleic acid sequence and related compositions of the present invention will be decided by the attending physician, within the scope of sound medical judgment.

[0051] The specific therapeutically effective dose level for any particular patient may depend upon a variety of factors, including the severity of a patient's HIBM2 disorder; the activity of the specific GNE-encoding sequence employed; the delivery vehicle employed; the age, body weight, general health, gender and diet of the patient; the time of administration, route of administration, and rate of excretion of the specific GNE-encoding sequence employed; the duration of the treatment; drugs used in combination or contemporaneously with the specific GNE-encoding sequence employed; and like factors well-known in the medical arts.

[0052] Upon improvement of a patient's condition, a maintenance dose of a GNE-encoding sequence may be administered, if necessary. Subsequently, the dosage or frequency of administration, or both, may be reduced, as a function of the symptoms, to a level at which the improved condition is retained when the symptoms have been alleviated to the desired level.

[0053] According to yet further embodiments of the invention, novel compositions are provided for expressing wild-type GNE in a system. The compositions preferably include a wild-type GNE-encoding nucleic acid sequence. As described herein, the GNE-encoding nucleic acid sequence may comprise various transcriptional control

elements, such as a promoter, termination sequence, and others. A non-limiting example of a composition encompassed by the present invention includes the pUMVC3-GNE expression vector described herein, shown in Figure 1, and represented by SEQ ID NO: 9. Also as described relative to other embodiments of the present invention, the GNE-encoding nucleic acid sequence may be disposed within or connected to an appropriate vehicle for delivery to a system, such as a liposome or lipid nanoparticle. Still further, according to such embodiments, the delivery vehicle may, optionally, be decorated with agents that are capable of recognizing and binding to target cells or tissues, such as muscle cells or muscle tissues.

EXAMPLES

[0054] Example 1 – Expression of exogenous GNE in CHO-Lec3 cells.

[0055] In the following example, several GNE expression vectors from human cDNA were created. Three different GNE forms, wild type, M712T, and R266Q, were robustly expressed in GNE deficient cells (Lec3 cells). All enzymes demonstrated similar protein expression levels, albeit distinct enzymatic activities. As the following will show, the transfected GNE expressing cell lines produced significantly more sialic acid than untransfected cells.

[0056] *Example 1 Methodology.*

[0057] *GNE Cloning.* Parental vectors containing the GNE cDNA were provided by Daniel Darvish (HIBM Research Group, Encino, CA) and included pGNE-NB8 (wild type), pGNE-MB18 (M712T mutant), and pGNE-R266Q (R266Q mutant). The

destination vector, pUMVC3, was purchased from Aldevron (Fargo, ND). The subcloning vector, pDrive (Qiagen, Valencia, CA), was used to shuttle the R266Q mutant from the parent vector to the destination vector.

[0058] Wild type and M712T GNE was cloned from the parent vector into pUMVC3 via Eco RI restriction digest, gel purification, and T4 ligation. The R266Q mutant GNE was cloned from the parent vector into pDrive via Hind III + Xba I digest and then moved to pUMVC3 via Sal I + Xba I. (Figure 1). All pUMVC3-GNE clones were sequenced by Seqwright (Houston, TX) with the primers set forth in the Table-1 below.

Table-1

GNE-F1	5'-TGTGAGGACCATGATCGCATCCTT-3'	SEQ ID NO: 1
GNE-F2	5'-ACCTCCGAGTTGCAATAGTCAGCA-3'	SEQ ID NO: 2
GNE-R1	5'-AATCAGGCCCATCCAGAGACACAA-3'	SEQ ID NO: 3
GNE-R2	5'-TTCCAATCTGACGTGTTCCCAGGT-3'	SEQ ID NO: 4
UMVC-F	5'-CGCCACCAGACATAATAGCTGACA-3'	SEQ ID NO: 5
UMVC-R	5'-TAGCCAGAAGTCAGATGCTCAAGG-3'	SEQ ID NO: 6

[0059] Positive pUMVC3-GNE clones were grown overnight in 175 mls LB broth + 50 µg/ml Kan and 150 mls culture was used for a Qiagen (Valencia, CA) HiSpeed Plasmid Maxi kit according to the manufacturer protocols.

[0060] *DNA:lipid complex.* The DNA:lipid complex used in this example was produced by mixing, at room temperature, 1,2-Dioleoyl-3-Trimethylammonium-Propane (DOTAP) with test DNA (pUMVC3-GNE). DOTAP is a commercially-available lipid particle that is offered by Avanti Polar Lipids, Inc. (Alabaster, Alabama). The DOTAP

was mixed with the pUMVC3-GNE DNA in a manner to achieve the desired total volume, which exhibited a final ratio of 0.5 µg DNA : 4 mM DOTAP, in a final volume of 1 µl.

[0061] *Cell Culture.* GNE-deficient CHO-Lec3 cells were provided by Albert Einstein College of Medicine. The cells were grown at 37°C in 5% CO₂ in alpha-MEM media supplemented with 4 mM L-glutamine and 10% heat inactivated, Fetal Bovine Serum. Cells for transient transfections were plated at 1x10⁶ cells per well in 6-well plates and grown overnight. Lec3 cells were weaned to reduced serum conditions by reducing the FBS by 2.5% per passage.

[0062] *Transient Transfections.* Lec3 cells were transfected for 6 hours with DNA:lipid complex per well in OptiMEM (Invitrogen, Carlsbad CA), then the media was changed to normal alpha-MEM growth media and the cells were cultured overnight. DNA:lipid complexes were formed by mixing 4 µg DNA + 10 µl Lipofectamine 2000 (Invitrogen) according to the manufacturers protocol. Twenty-four hours post-transfection, cells were harvested by trypsin digest and washed once with PBS before subsequent western blot or enzyme/sugar assays.

[0063] *mRNA Quantitation.* Total RNA was extracted from 1.5 million transfected CHO-Lec3 cells using the RNeasy kit according to the manufacturers instructions (Qiagen, Valencia, CA). The purified RNA was quantified by 260/280 ratio using a NanoDrop1000 spectrophotometer (NanoDrop, Wilmington, DE). Five hundred nanograms of total RNA was converted to cDNA using oligo dT primers and the TaqMan reverse transcription kit (ABI, Foster City, CA). Using the Sybr Green PCR

master mix (ABI, Foster City, CA) along with 25 ng cDNA and 0.2 pM primers (GNE-F3 = 5'-cggaagaagggcattgagcatc-3' (SEQ ID NO: 7) and GNE-R3 = 5'-ttgtcttgggtgtcagcatcc-3' (SEQ ID NO: 8)), 25 μ l PCR reactions were compared against serial dilutions of a known concentration of pUMVC3GNE-wt DNA. The Sybr Green fluorescence was detected using the iQ5 real-time PCR detection system (BioRad, Hercules, CA) and the PCR conditions: 95°C – 10 minutes to activate the enzyme and (95°C – 15 seconds and 58°C – 60 seconds) x 45 cycles to amplify the product. Fifteen microliters of the PCR reaction was run on a 4% pre-cast agarose E-gel (Invitrogen, Carlsbad, CA) and the image was captured using the G-box chemiluminescence detection system (Frederick, MD).

[0064] *Western Blot.* Approximately 5×10^5 cells were used for Western blot analysis. Cell pellets were lysed using 20 μ l Cell lytic (Sigma, St. Louis, MO), plus 1% protease inhibitors. The cell debris were spun down at maximum speed for 5 minutes and the supernatant was mixed 1:1 with Laemmli buffer (BioRad, Hercules, CA) containing 5% β -ME. Protein samples were separated by polyacrylamide electrophoresis at 100V for 2 hours on 10% denaturing gels, followed by transfer to a PVDF membrane using 100 volts for 2 hours. The membranes were probed for GNE and GapDH using chicken anti-GNE (1:10,000 dilution) and mouse anti-GapDH (1:50,000 dilution) overnight. Primary antibodies were detected using HRP-labeled secondary antibodies and they were visualized using the West Dura detection reagent (Pierce, Rockford, IL) and the G-box chemiluminescence camera (Syngene, Frederick, MD).

[0065] *Sialic Acid Quantitation.* Approximately 4×10^6 cells were used for the quantification of membrane-bound sialic acid by the thiobarbituric acid method. Cells were resuspended in water and lysed by passage through a 25 gauge needle 20 times and centrifuged. The supernatant was used for Bradford protein estimation and the remaining pellet was resuspended in 100 μ l 2M acetic acid and incubated for 1 hour at 80°C to release glycoconjugate-bound sialic acids. 137 μ l of periodic acid solution (2.5 mg/ml in 57 mM H₂SO₄) were added and incubated for 15 minutes at 37°C. Next, 50 μ l of sodium arsenite solution (25 mg/ml in 0.5 M HCl) were added and the tubes were shaken vigorously to ensure complete elimination of the yellow-brown color. Following this step, 100 μ l of 2-thiobarbituric acid solution (71 mg/ml adjusted to pH 9.0 with NaOH) were added and the samples were heated to 100°C for 7.5 minutes. The solution was extracted with 1 ml of butanol/5% 12M HCl and the phases were separated by centrifugation. The absorbance of the organic phase was measured at 549 nm. The amount of sialic acid was measured as nmol sialic acid/mg of protein.

[0066] *Kinase and Epimerase Activity.* UDP-GlcNAc 2-epimerase activity was determined by a colorimetric assay. It contained 45 mM Na₂HPO₄, pH 7.5, 10 mM MgCl₂, 1 mM UDP-GlcNAc and variable amounts of protein in a final volume of 200 μ l. The reaction was performed at 37°C for 30 minutes and stopped by boiling for 1 minute. The released ManNAc was detected using the Morgan-Elson method. In brief, 150 μ l of sample were mixed with 30 μ l of 0.8 M H₂BO₃, pH 9.1, and boiled for 3 minute. Next, 800 μ l of DMAB solution (1% (w/v) 4-dimethylamino benzaldehyde in acetic acid/1.25% 10N HCl) was added and incubated at 37°C for 30 minutes. The absorbance was read at 578 nm.

[0067] ManNAc kinase activity was measured by a radiometric assay. It contained 60 mM Tris/HCl, pH 8.1, 10 mM MgCl₂, 5 mM ManNAc, 50 nCi [¹⁴C]ManNAc, 10 mM ATP, and variable amounts of protein in a final volume of 200 µl. The reaction was performed at 37°C for 30 minutes and stopped by addition of 300 µl of ethanol. Radio-labeled compounds were separated by paper chromatography and radioactivity was determined by liquid scintillation counting.

[0068] *Statistical Analysis.* Three independent experiments for enzyme activity and sialic acid expression were performed. The average and standard deviation was calculated using Microsoft Excel. A student's *t*-test was used to determine p-values for each treated group, relative to the untreated sample.

[0069] *Example 1 Results.*

[0070] *GNE clones.* The GNE cDNA clones that were tested included a human wild type cDNA and two human mutant cDNAs. The mutants included the M712T GNE deficient clone and the R266Q sialuria clone. Sialuria is a human disease caused by point mutations in the CMP-sialic acid binding site of GNE, leading to a loss of feedback inhibition and mass production of sialic acids. GNE cDNAs were subcloned from their original vectors to the expression vector, pUMVC3, by restriction digest cloning. Clones were screened by directional restriction enzyme digest to confirm the GNE insert was in the correct orientation. Positive clones were sequenced in both orientations to confirm that no mutations occurred during the cloning process. The resulting chromatograms were compared against the GNE sequence from GenBank (accession # NM_005467) and the wild type did not exhibit any mutations, while the M712T and

R266Q clones contained only the expected point mutations (Figure 2). Positive pUMVC3-GNE clones were scaled using a maxi prep plasmid purification procedure and sequenced again to confirm that no mutations occurred. These DNA stocks were used for all subsequent experiments.

[0071] *Gene protein expression.* Plasmid UMVC3-GNE DNA was transiently transfected into CHO-Lec3 cells and grown in 10% serum for 24 hours, and then the cells were harvested and analyzed for recombinant GNE expression. A GNE Western blot illustrated that the untreated Lec3 cells (which were not transfected) do not express GNE and CHO-Lec3 cells transfected with different pUMVC3 clones express high levels of recombinant GNE (Figure 3). The expression level was relatively equivalent, regardless of GNE isoform. In a second experiment, recombinant GNE was expressed following transfection of CHO-Lec3 cells grown in 10% or 2.5% fetal bovine serum (FBS), due to the ability of CHO cells to incorporate sialic acids from the culture media. Again, GNE protein expression was relatively equivalent, regardless of GNE isoform and the concentration of FBS (Figure 4).

[0072] *Wt-GNE mRNA quantitation.* CHO-Lec3 cells were grown in 10% serum and transiently transfected with pUMVC3-GNE-wt DNA for 24 hours to quantitate the amount of recombinant GNE RNA that was expressed. Total RNA was extracted and RT-qPCR was performed to amplify a 230 bp fragment from the GNE transcript. Serial dilutions of pUMVC3-GNE-wt were used to determine that the concentration of GNE-wt expressed in transfected Lec3 cells was equal to 4.1 pg/ μ l. The dynamic range of the qPCR was from 5 ng – 5 fg and there was no GNE mRNA product detected in control

(untransfected) CHO-Lec3 cells (the cT value for untransfected cells was greater than 42 cycles, which is less than 5 fg). Therefore, recombinant GNE mRNA expression was detected in transfected Lec3 cells, while untransfected cells had undetectable amounts of GNE mRNA. (Figure 5).

[0073] *GNE enzyme assays.* In addition to the Western blot assay, an aliquot of the transfected cell pellets were assayed for enzyme activity. As shown in Table 2 below, both epimerase and kinase activity were quantified in Lec3 cells with or without recombinant GNE protein

Table-2

GNE enzyme activity of CHO Lec3 cells transfected with different plasmids

<u>Lec3 Cells + DNA</u>	<u>Epimerase Act (mU/mg)</u>	<u>p-value</u>	<u>Kinase Act (mU/mg)</u>	<u>p-value</u>
Untreated	1±0.7		2±1.4	
WT GNE	22±0.2	0.0003*	35±0.7	0.0006*
M712T GNE	31±1.4	0.0007*	37±5.4	0.0063*
R266Q GNE	26±2.9	0.0035*	33±2.6	0.0023*

*comparison to untreated

[0074] Lec3 cells alone had both epimerase and kinase activities less than 3 mU/mg, which displays background activity. Cells expressing wild type, M712T, or R266Q GNE had an average of 22, 31, and 26 mU/mg of epimerase activity, respectively. The same Lec3 samples displayed an average of 35, 37, and 33 mU/mg of kinase activity. All of the cells expressing recombinant GNE had enzyme activity significantly above the non-treated cells with a p-value ≤ 0.006 for both epimerase and kinase activities. There was no statistical difference in enzyme activity between the three different GNE isoforms, with p-values ranging from 0.11 – 0.47.

[0075] *Sialic acid assays.* Transfected Lec3 cells also were tested for cell surface sialic acid expression. All Lec3 samples had approximately 6.0 nmol/mg membrane bound sialic acid, with the exception of Lec3 cells transfected with the R266Q GNE, which had a 1.5-fold higher amount. The R266Q mutant lacks the feedback inhibition of GNE and is known to cause an overproduction of intracellular sialic acids. Lec3 cells seem to be undersialylated, and this could only be overcome by expression of the sialuria mutant and not by the about 100-fold overexpression of wild-type GNE compared to wild-type CHO cells.

[0076] No differences between wild type (wt) and M712T GNE were observed. This was likely due to the incorporation of sialic acids from the cell culture medium, as it is known that sialic acids from FBS can bypass the defective GNE pathway. In this case, differences between wild type and M712T could be masked by the bypass. Therefore, the cell culture conditions were altered by reducing the percent serum (FBS) in the media. As shown in Table-3 below, as the serum level was reduced, sialic acid production decreased, with a marked decrease demonstrated at 2.5% FBS.

Table-3

<u>%FBS</u>	<u>Sialic Acid (nmol/mg)</u>	<u>p-value</u>
10	8.05±0.27	
5.0	7.26±0.61	0.2996*
2.5	4.69±1.20	0.0096*
*comparison to 10% FBS		

[0077] Sialic acid levels continued to decrease as the cell culture media approached serum free conditions, but the cell morphology and growth characteristics

were altered. It was determined that the 2.5% FBS concentration of the cell culture media was optimal in order to test the impact of GNE gene transfection in Lec3 cells. Lec3 cells were thus grown in 2.5% FBS and transfected with pUMVC3-GNE clones. GNE expression was concurrently confirmed via Western blot (Figure 4). Significant increase of sialic acid production was indeed demonstrated, again with the best effect of the R226Q mutant (Figure 6: $p=0.0157$ for GNE-wt; $p=0.0566$ for GNE R266Q). A slight, but significant, difference between wt and M712T GNE was observed, indicating that the re-sialylation capability of the mutant is lower than that of the wild-type, suggesting a similar mechanism in HIBM muscle.

[0078] Studies on HIBM2 reveal mutations in the GNE gene associated with glycosylation errors in the muscle membrane, which may lead to defective muscle function. Loss of GNE activity in HIBM2 is thought to impair sialic acid production and interfere with proper sialylation of glycoconjugates. The reactivities to lectins are also variable in some myofibers, suggesting that hyposialylation and abnormal glycosylation in muscles may contribute to the focal accumulations of autophagic vacuoles and/or amyloid deposits in affected patient muscle tissue. The foregoing example demonstrates the effect of a novel GNE gene/CMV promoter plasmid for mRNA and protein expression in GNE deficient CHO-Lec 3 cells, which were shown to be capable of restoring GNE/MNK enzyme function and subsequent induction of sialic acid production.

[0079] Example 2 – Expression of exogenous GNE *in vivo*.

[0080] The following example demonstrates the ability of the GNE-encoding sequences described herein to be transfected into live mice, and to stimulate GNE expression in the muscular tissue of such mice.

[0081] *DNA:lipid complex.* The materials used in this example included pUMVC3-wt-DNA (Figure 1) and 1,2-Dioleoyl-3-Trimethylammonium-Propane (DOTAP):Cholesterol (DOTAP:Chol), which together represented a lipid nanoparticle / DNA complex. The DNA:lipid complex used in this example was produced by mixing, at room temperature, DOTAP:Chol with test DNA (wild-type, M712T, or R266Q pUMVC3-GNE). DOTAP:Chol is a commercially-available lipid particle that is offered by Avanti Polar Lipids, Inc. (Alabaster, Alabama). The DOTAP:Chol was mixed with the pUMVC3-GNE DNA in a manner to achieve the desired total volume, which exhibited a final ratio of 0.5 μ g DNA : 4 mM DOTAP:Chol, in a final volume of 1 μ l.

[0082] *Intramuscular toxicology.* A set of mice (10-12 week old, nominally 20 g BALB/c mice), with each set consisting of 6 female mice and 6 male mice, were provided with either (1) 10 μ g (80 μ l) of GMP DNA reconstituted in Plasma-Lyte[®], (2) 40 μ g (80 μ l) of GMP DNA reconstituted in Plasma-Lyte[®], or (3) 0 μ g (80 μ l) of GMP DNA (which served as the control and consisted of empty liposomes and Plasma-Lyte[®]). Another set of mice were not injected at all, and served as an additional control. A single injection was made, the mice were sacrificed at 2 weeks post-injection, and their organs and fluids were harvested. Toxicity was assessed at 24-48 hours, 1 week, and 2 weeks post-injection. Toxicity was assessed based on serum chemistry profiles, CBC analysis, gross toxicity, and immunohistochemistry analysis of muscle tissue.

[0083] As shown in Figure 7, none of the mice provided with the above-described compositions exhibited toxicity at 24 hours, 48 hours, 1 week, or 2 weeks post-injection.

[0084] *Intravenous toxicology.* A set of mice (10-12 week old, nominally 20 g BALB/c mice), with each set consisting of 6 female mice and 6 male mice, were also provided with either (1) 10 μg (200 μl) of GMP DNA reconstituted in Plasma-Lyte[®], (2) 40 μg (200 μl) of GMP DNA reconstituted in Plasma-Lyte[®], (3) 100 μg (200 μl) of GMP DNA reconstituted in Plasma-Lyte[®], or (4) 0 μg (200 μl) of GMP DNA (which served as the control and consisted of empty liposomes and Plasma-Lyte[®]). An intravenous dose was made, the mice were sacrificed at 2 weeks post-dosage, and their organs and fluids were harvested. Toxicity was assessed at 24-48 hours, 1 week, and 2 weeks post-injection. Toxicity was assessed as described above.

[0085] As shown in Figure 8, none of the mice that were provided with 10 μg of GMP DNA exhibited toxicity at 24 hours, 48 hours, 1 week, or 2 weeks post-injection, and only 2 female mice exhibited acute toxicity at 24 hours post-dosage (with all other mice at all other time points not exhibiting any signs of toxicity). Still referring to Figure 8, three female mice that were provided with 100 μg died at 24 hours post-dosage, and another female mouse died at 48 hours post-dosage. All 6 males exhibited acute toxicity at 24 hours post-dosage. However, these 6 mice all survived, and did not exhibit signs of toxicity at 48 hours, 1 week, or 2 weeks post-dosage. Figure 9 summarizes the survival data of these mice that were injected intravenously with GMP grade DNA (reconstituted in Plasma-Lyte[®]).

[0086] *Comparison of Plasma-Lyte® to Water.* In order to identify a preferred carrier in which a GNE-encoding sequence may be disposed, a toxicological comparison was made between Plasma-Lyte® and water. Plasma-Lyte® is a sterile, non-pyrogenic isotonic solution that may be used for intravenous administration. Each 100 mL volume contains 526 mg of Sodium Chloride, USP (NaCl); 502 mg of Sodium Gluconate (C₆H₁₁NaO₇); 368 mg of Sodium Acetate Trihydrate, USP (C₂H₃NaO₂•3H₂O); 37 mg of Potassium Chloride, USP (KCl); and 30 mg of Magnesium Chloride, USP (MgCl₂•6H₂O). It contains no antimicrobial agents. The pH is preferably adjusted with sodium hydroxide to about 7.4 (6.5 to 8.0).

[0087] Referring to Figures 10-12, a group of four mice were provided with either 40 µg, 10 µg, or 0 µg of GMP-GNE reconstituted in Plasma-Lyte® via intramuscular injections (Figure 10); 100 µg, 40 µg, 10 µg, or 0 µg GMP-GNE reconstituted in Plasma-Lyte® via intravenous injections (Figure 11); or 100 µg, 40 µg, or 0 µg GMP-GNE reconstituted in water via intravenous injections (Figure 12). The GMP-GNE reconstituted in Plasma-Lyte® exhibited significantly improved (lower) toxicological properties (Figures 10-11), when compared to the GMP-GNE reconstituted in water (Figure 12).

[0088] *GNE Expression in Mice.* Three sets of 10-12 week old, nominally 20 g BALB/c mice, with each set including four mice, were provided with intramuscular injections of varying amounts of GNE-encoding compositions, namely, the pUMVC3-wt-DNA construct (Figure 1), represented by SEQ ID NO: 9, and 1,2-Dioleoyl-3-

Trimethylammonium-Propane (DOTAP):Cholesterol – together representing the lipid nanoparticle / GNE-encoding complex described above.

[0089] In this example, a first group was injected with 0 μg of GNE-encoding DNA, a second group was injected with 10 μg of GNE-encoding DNA, and a third group was injected with 40 μg of GNE-encoding DNA. At two weeks post-injection, the mice were sacrificed and the injected muscle tissue was harvested.

[0090] Next, total RNA was collected from the muscle tissues. The amount of GNE mRNA transcript contained within each sample was next measured via RT-PCR, using GNE-specific primers (and a standard curve was constructed using varying amounts of RNA of known concentration, which was used for extrapolating the quantitative amount of GNE mRNA within each test sample). Table-4 below summarizes the average amount (ng) of GNE mRNA measured by RT-PCR (from two mice within each of the three groups).

Table-4

<u>Dose</u>	<u>Mouse #</u>	<u>ng GNE / mg Muscle</u>	<u>Avg. ng/mg</u>	<u>Std. Dev.</u>	<u>Fold Change</u>
0 μg GNE	32	0.00E+00	1.36E-09	1.92E-09	1
	33	2.71E-09			
	34				
	35				
10 μg GNE	8		2.46E-07	8.00E-08	182
	9				
	10	3.03E-07			
	11	1.90E-07			
40 μg GNE	20		1.51E-06	8.24E-07	1115
	21	2.09E-06			
	22	9.29E-07			
	23				

[0091] These data are further summarized in Figure 13, which shows the amount of GNE mRNA that was measured for each group (0, 10 and 40 μg of GNE-encoding DNA) normalized against the total amount of muscle tissue from which the RNA was extracted. As shown therein, the 10 μg dose of GNE-encoding DNA resulted in a significant level of GNE expression (a 182-fold increase in GNE expression levels relative to the 0 μg sample), and the 40 μg dose of GNE-encoding DNA resulted in an even greater level of GNE expression (a 1115-fold increase in GNE expression levels relative to the 0 μg sample). These data are consistent with the PCR results shown in the gel of Figure 14.

[0092] Although illustrative embodiments of the present invention have been described herein, it should be understood that the invention is not limited to those described, and that various other changes or modifications may be made by one skilled in the art without departing from the scope or spirit of the invention.

What is claimed is:

1. A method for modulating the production of sialic acid in a system, which comprises providing the system with a wild-type GNE-encoding nucleic acid sequence.
2. The method of claim 1, wherein the wild-type GNE-encoding nucleic acid sequence comprises a promoter operably connected to the wild-type GNE-encoding nucleic acid sequence.
3. The method of claim 2, wherein the promoter is the CMV promoter.
4. The method of claim 2, wherein the wild-type GNE-encoding nucleic acid sequence is injected into the system, wherein the system comprises muscle tissue of a mammal.
5. The method of claim 2, wherein the wild-type GNE-encoding nucleic acid sequence is disposed within or is connected to a lipid nanoparticle.
6. The method of claim 5, wherein the wild-type GNE-encoding nucleic acid sequence consists of SEQ ID NO: 9.
7. The method of claim 5, wherein the lipid nanoparticle comprises one or more agents capable of recognizing and binding to a muscle cell or a component thereof.
8. A method for producing wild-type GNE in a system, wherein the system comprises a mutated endogenous GNE-encoding sequence, which comprises providing the system with a wild-type GNE-encoding nucleic acid sequence.

9. The method of claim 8, wherein the wild-type GNE-encoding nucleic acid sequence comprises a promoter operably connected to the wild-type GNE-encoding nucleic acid sequence.
10. The method of claim 9, wherein the promoter is the CMV promoter.
11. The method of claim 9, wherein the wild-type GNE-encoding nucleic acid sequence is injected into the system, wherein the system comprises muscle tissue of a mammal.
12. The method of claim 9, wherein the wild-type GNE-encoding nucleic acid sequence is disposed within or is connected to a lipid nanoparticle.
13. The method of claim 12, wherein the wild-type GNE-encoding nucleic acid sequence consists of SEQ ID NO: 9.
14. The method of claim 12, wherein the lipid nanoparticle comprises one or more agents capable of recognizing and binding to a muscle cell or a component thereof.
15. A method for treating, preventing, or ameliorating the effects of Hereditary Inclusion Body Myopathy, which comprises providing a patient with a wild-type GNE-encoding nucleic acid sequence.
16. The method of claim 15, wherein the wild-type GNE-encoding nucleic acid sequence comprises a promoter operably connected to the wild-type GNE-encoding nucleic acid sequence.
17. The method of claim 16, wherein the promoter is the CMV promoter.

18. The method of claim 16, wherein the wild-type GNE-encoding nucleic acid sequence is injected into muscle tissue of the patient.
19. The method of claim 16, wherein the wild-type GNE-encoding nucleic acid sequence is disposed within or is connected to a lipid nanoparticle.
20. The method of claim 19, wherein the wild-type GNE-encoding nucleic acid sequence consists of SEQ ID NO: 9.
21. The method of claim 19, wherein the lipid nanoparticle comprises one or more agents capable of recognizing and binding to a muscle cell or a component thereof.
22. The method of claim 21, wherein the lipid nanoparticle is administered to the patient intravenously.
23. A composition for expressing wild-type GNE in a system, which comprises a wild-type GNE-encoding nucleic acid sequence disposed within or connected to a lipid nanoparticle.
23. The composition of claim 22, wherein the lipid nanoparticle comprises one or more agents capable of recognizing and binding to a muscle cell or a component thereof.
24. The composition of claim 22, wherein the wild-type GNE-encoding nucleic acid sequence consists of SEQ ID NO: 9.

RE-PTL-100: Single Intramuscular injection with GNE GMP DNA in Plasma -Lyte A

Mice Injected on	Dose given IM	OD400 On 11/12/07	Number of Mice	Average pre-treatment weight in grams (range)	Toxicity at		
					24- 48 hrs	WK 1	WK 2
N/A	Uninjected		6F	17.4 (16.5- 19.2)	None	None	none
			6M	25.8 (23.8-27.9)	None	None	None
11/13/07 and 11/14/07	0 ug GMP DNA PL		6F	18.1 (16.1- 20)	None	None	None
			6M	25.4 (23.4-27.2)	None	None	None
11/13/07	10 ug GMP DNA PL		6F	18.5 (16.9-19.3)	None	None	None
			6M	26.1 (24.3- 27.9)	None	None	None
11/14/07	40 ug GMP DNA PL	0.783	6F	17.8 (16.6 -18.3)	None	None	None
			6M	26.2 (25.1-27.1)	None	None	None

FIG. 7 / 14

RE-PTL-101: Single Intravenous Injection of GNE GMP DNA in PL

Date Injections performed	Dose given IV	OD400 on 11/18/07	Mice	Average pre-treatment weight (gms)	Toxicity at				
					24 hrs	48 hrs	WK 1	WK 2	
11/20/07	10 ug GMP DNA PL		6F	17.7 (16.6 - 18.5g)	None	None	None	None	None
			6M	26.4 (25-27.6)	None	None	None	None	None
11/19/07 (F) and 11/20/07 (M)	40 ug GMP DNA PL		6F	18.2 (16.6 -19.9)	2F showed acute toxicity**	None	None	None	None
			6M	26.1 (24.2-28.3)	None	None	None	None	None
11/19/07	100 ug GMP DNA PL	0.933	6F	17.8 (17.1-20.4)	3F died, 2F showed acute toxicity**	1F died	None	None	None
			6M	25.5 (23.5-28.3)	All 6M showed acute toxicity**	None	None	None	None
11/21/07 (F) and 11/29/07 (M)	0 ug GMP DNA PL		6F	17.9 (17.2-19.8)	None	None	None	None	None
			6M	26.7 (25.6-27.6)	None	None	None	None	None

** Acute Toxicity: slow movement, ruffled coat, hunched back recovered by 48 hrs
