CONTENTS	iii
TABLES	viii
1 Scope	1
2 Terms and Definitions	1
3 Symbols and abbreviated terms	1
4 Notation	2
4.1 Introduction	2
4.2 Table Decorations	2
4.3 Handle and Parameter Demarcation	4
4.4 AuthorizationSize and ParameterSize	4
4.5 Return Code Alias	4
5 Command Processing	5
5.1 Introduction	5
5.2 Command Header Validation	5
5.3 Mode Checks	6
5.4 Handle Area Validation	6
5.5 Session Area Validation	8
5.6 Authorization Checks	9
5.7 Parameter Decryption	11
5.8 Parameter Unmarshaling	11
5.9 Command Post Processing	12
6 Response Values	14
6.1 Tag	14
6.2 Response Codes	14
7 Implementation Dependent	17
8 Detailed Actions Assumptions	18
8.1 Introduction	18
8.2 Pre-processing	18
8.3 Post Processing	18
9 Start-up	19
9.1 Introduction	19
9.2 <code>_TPM_Init</code>	19
9.3 <code>TPM2_Startup</code>	21
9.4 <code>TPM2_Shutdown</code>	26
10 Testing	29
10.1 Introduction	29
10.2 <code>TPM2_SelfTest</code>	30
10.3 <code>TPM2_IncrementalSelfTest</code>	33
10.4 <code>TPM2_GetTestResult</code>	36
11 Session Commands	39
11.1 <code>TPM2_StartAuthSession</code>	39
11.2 <code>TPM2_PolicyRestart</code>	44
12 Object Commands	47

12.1	TPM2_Create	47
12.2	TPM2_Load	52
12.3	TPM2_LoadExternal	55
12.4	TPM2_ReadPublic	59
12.5	TPM2_ActivateCredential	62
12.6	TPM2_MakeCredential	65
12.7	TPM2_Unseal	68
12.8	TPM2_ObjectChangeAuth	71
12.9	TPM2_CreateLoaded	74
13	Duplication Commands	77
13.1	TPM2_Duplicate	77
13.2	TPM2_Rewrap	80
13.3	TPM2_Import	83
14	Asymmetric Primitives	87
14.1	Introduction	87
14.2	TPM2_RSA_Encrypt	87
14.3	TPM2_RSA_Decrypt	91
14.4	TPM2_ECDH_KeyGen	94
14.5	TPM2_ECDH_ZGen	97
14.6	TPM2_ECC_Parameters	100
14.7	TPM2_ZGen_2Phase	103
14.8	TPM2_ECC_Encrypt	106
14.9	TPM2_ECC_Decrypt	108
15	Symmetric Primitives	110
15.1	Introduction	110
15.2	TPM2_EncryptDecrypt	112
15.3	TPM2_EncryptDecrypt2	115
15.4	TPM2_Hash	117
15.5	TPM2_HMAC	120
15.6	TPM2_MAC	123
16	Random Number Generator	126
16.1	TPM2_GetRandom	126
16.2	TPM2_StirRandom	129
17	Hash/HMAC/Event Sequences	132
17.1	Introduction	132
17.2	TPM2_HMAC_Start	132
17.3	TPM2_MAC_Start	135
17.4	TPM2_HashSequenceStart	138
17.5	TPM2_SequenceUpdate	141
17.6	TPM2_SequenceComplete	144
17.7	TPM2_EventSequenceComplete	147
18	Attestation Commands	150
18.1	Introduction	150
18.2	TPM2_Certify	152
18.3	TPM2_CertifyCreation	155

18.4	TPM2_Quote	158
18.5	TPM2_GetSessionAuditDigest	161
18.6	TPM2_GetCommandAuditDigest	164
18.7	TPM2_GetTime	167
18.8	TPM2_CertifyX509	170
19	Ephemeral EC Keys	174
19.1	Introduction	174
19.2	TPM2_Commit	175
19.3	TPM2_EC_Ephemeral	178
20	Signing and Signature Verification	181
20.1	TPM2_VerifySignature	181
20.2	TPM2_Sign	184
21	Command Audit	187
21.1	Introduction	187
21.2	TPM2_SetCommandCodeAuditStatus	188
22	Integrity Collection (PCR)	191
22.1	Introduction	191
22.2	TPM2_PCR_Extend	192
22.3	TPM2_PCR_Event	195
22.4	TPM2_PCR_Read	198
22.5	TPM2_PCR_Allocate	201
22.6	TPM2_PCR_SetAuthPolicy	204
22.7	TPM2_PCR_SetAuthValue	207
22.8	TPM2_PCR_Reset	210
22.9	_TPM_Hash_Start	213
22.10	_TPM_Hash_Data	215
22.11	_TPM_Hash_End	217
23	Enhanced Authorization (EA) Commands	219
23.1	Introduction	219
23.2	Signed Authorization Actions	220
23.3	TPM2_PolicySigned	223
23.4	TPM2_PolicySecret	227
23.5	TPM2_PolicyTicket	230
23.6	TPM2_PolicyOR	233
23.7	TPM2_PolicyPCR	236
23.8	TPM2_PolicyLocality	240
23.9	TPM2_PolicyNV	243
23.10	TPM2_PolicyCounterTimer	247
23.11	TPM2_PolicyCommandCode	251
23.12	TPM2_PolicyPhysicalPresence	254
23.13	TPM2_PolicyCpHash	257
23.14	TPM2_PolicyNameHash	260
23.15	TPM2_PolicyDuplicationSelect	263
23.16	TPM2_PolicyAuthorize	266
23.17	TPM2_PolicyAuthValue	269
23.18	TPM2_PolicyPassword	272

23.19	TPM2_PolicyGetDigest	275
23.20	TPM2_PolicyNvWritten	278
23.21	TPM2_PolicyTemplate	281
23.22	TPM2_PolicyAuthorizeNV	284
23.23	TPM2_PolicyCapability	287
23.24	TPM2_PolicyParameters	291
24	Hierarchy Commands	294
24.1	TPM2_CreatePrimary	294
24.2	TPM2_HierarchyControl	297
24.3	TPM2_SetPrimaryPolicy	300
24.4	TPM2_ChangePPS	303
24.5	TPM2_ChangeEPS	306
24.6	TPM2_Clear	309
24.7	TPM2_ClearControl	312
24.8	TPM2_HierarchyChangeAuth	315
25	Dictionary Attack Functions	318
25.1	Introduction	318
25.2	TPM2_DictionaryAttackLockReset	318
25.3	TPM2_DictionaryAttackParameters	321
26	Miscellaneous Management Functions	324
26.1	Introduction	324
26.2	TPM2_PP_Commands	324
26.3	TPM2_SetAlgorithmSet	327
27	Field Upgrade	330
27.1	Introduction	330
27.2	TPM2_FieldUpgradeStart	332
27.3	TPM2_FieldUpgradeData	335
27.4	TPM2_FirmwareRead	338
28	Context Management	341
28.1	Introduction	341
28.2	TPM2_ContextSave	341
28.3	TPM2_ContextLoad	344
28.4	TPM2_FlushContext	347
28.5	TPM2_EvictControl	350
29	Clocks and Timers	354
29.1	TPM2_ReadClock	354
29.2	TPM2_ClockSet	357
29.3	TPM2_ClockRateAdjust	360
30	Capability Commands	363
30.1	Introduction	363
30.2	TPM2_GetCapability	363
30.3	TPM2_TestParms	369
30.1	TPM2_SetCapability	372
31	Non-volatile Storage	375

31.1	Introduction.....	375
31.2	NV Counters.....	377
31.3	TPM2_NV_DefineSpace.....	378
31.4	TPM2_NV_UndefineSpace.....	382
31.5	TPM2_NV_UndefineSpaceSpecial.....	385
31.6	TPM2_NV_ReadPublic.....	388
31.7	TPM2_NV_Write.....	391
31.8	TPM2_NV_Increment.....	394
31.9	TPM2_NV_Extend.....	397
31.10	TPM2_NV_SetBits.....	400
31.11	TPM2_NV_WriteLock.....	403
31.12	TPM2_NV_GlobalWriteLock.....	406
31.13	TPM2_NV_Read.....	409
31.14	TPM2_NV_ReadLock.....	412
31.15	TPM2_NV_ChangeAuth.....	415
31.16	TPM2_NV_Certify.....	418
31.17	TPM2_NV_DefineSpace2.....	421
31.18	TPM2_NV_ReadPublic2.....	424
32	Attached Components.....	427
32.1	Introduction.....	427
32.2	TPM2_AC_GetCapability.....	428
32.3	TPM2_AC_Send.....	429
32.4	TPM2_Policy_AC_SendSelect.....	431
33	Authenticated Countdown Timer.....	433
33.1	Introduction.....	433
33.2	TPM2_ACT_SetTimeout.....	433
34	Vendor Specific.....	436
34.1	Introduction.....	436
34.2	TPM2_Vendor_TCG_Test.....	436

Trusted Platform Module Library

Part 3: Commands

1 Scope

This TPM 2.0 Part 3 of the *Trusted Platform Module Library* specification contains the definitions of the TPM commands. These commands make use of the constants, flags, structures, and union definitions defined in TPM 2.0 Part 2.

The detailed description of the operation of the commands is written in the C language with extensive comments. The behavior of the C code in this TPM 2.0 Part 3 is normative but does not fully describe the behavior of a TPM. The combination of this TPM 2.0 Part 3 and TPM 2.0 Part 4 is sufficient to fully describe the required behavior of a TPM.

The code in parts 3 and 4 is written to define the behavior of a compliant TPM. In some cases (e.g., firmware update), it is not possible to provide a compliant implementation. In those cases, any implementation provided by the vendor that meets the general description of the function provided in TPM 2.0 Part 3 would be compliant.

The code in parts 3 and 4 is not written to meet any particular level of conformance nor does this specification require that a TPM meet any particular level of conformance.

2 Terms and Definitions

For the purposes of this document, the terms and definitions given in TPM 2.0 Part 1 apply.

3 Symbols and abbreviated terms

For the purposes of this document, the symbols and abbreviated terms given in TPM 2.0 Part 1 apply.

4 Notation

4.1 Introduction

For the purposes of this document, the notation given in TPM 2.0 Part 1 applies.

Command and response tables use various decorations to indicate the fields of the command and the allowed types. These decorations are specified in clause 4.2.

4.2 Table Decorations

4.2.1 Introduction

The symbols and terms in the Notation column of Table 1 are used in the tables for the command schematics. These values indicate various qualifiers for the parameters or descriptions with which they are associated.

Table 1 — Command Modifiers and Decoration

Notation	Meaning
+	A Type decoration – see clause 4.2.2
@	A Name decoration - see clause 4.2.3
+PP	A Description modifier – see clause 4.2.4
+{PP}	A Description modifier – see clause 4.2.5
{NV}	A Description modifier – see clause 4.2.6
{F}	A Description modifier – see clause 4.2.7
{E}	A Description modifier – see clause 4.2.8
Auth Index:	A Description modifier – see clause 4.2.9
Auth Role:	A Description modifier – see clause 4.2.10

4.2.2 Type Decoration +

When appended to a value in the Type column of a command, this symbol indicates that the parameter is allowed to use the optional value of the data type (see TPM 2.0 Part 2, *Conditional Types*). The optional value is usually TPM_RH_NULL for a handle or TPM_ALG_NULL for an algorithm selector.

NOTE This decoration is not appended to response parameters

4.2.3 Name @

A Name decoration – When this symbol precedes a handle parameter in the “Name” column, it indicates that an authorization session is required for use of the entity associated with the handle. If a handle does not have this symbol, then an authorization session is not allowed.

4.2.4 Description Modifier +PP

This modifier may follow TPM_RH_PLATFORM in the “Description” column to indicate that Physical Presence is required when *platformAuth/platformPolicy* is provided.

4.2.5 Description Modifier +{PP}

This modifier may follow TPM_RH_PLATFORM to indicate that Physical Presence may be required when *platformAuth/platformPolicy* is provided. The commands with this notation may be in the *setList* or *clearList* of TPM2_PP_Commands().

4.2.6 Description Modifier {NV}

This modifier may follow the *commandCode* in the “Description” column to indicate that the command may result in an update of NV memory and be subject to rate throttling by the TPM. If the command code does not have this notation, then a write to NV memory does not occur as part of the command actions.

Any command that uses authorization may cause a write to NV if there is an authorization failure. A TPM may use the occasion of command execution to update the NV copy of clock.

4.2.7 Description Modifier {F}

This modifier indicates that the “flushed” attribute will be SET in the TPMA_CC for the command. The modifier may follow the *commandCode* in the “Description” column to indicate that any transient handle context used by the command will be flushed from the TPM when the command completes. This may be combined with the {NV} modifier but not with the {E} modifier.

EXAMPLE 1 {NV F}

EXAMPLE 2 TPM2_SequenceComplete() will flush the context associated with the *sequenceHandle*.

4.2.8 Description Modifier {E}

This modifier indicates that the “extensive” attribute will be SET in the TPMA_CC for the command. This modifier may follow the *commandCode* in the “Description” column to indicate that the command may flush many objects and re-enumeration of the loaded context likely will be required. This may be combined with the {NV} modifier but not with the {F} modifier.

EXAMPLE 1 {NV E}

EXAMPLE 2 TPM2_Clear() will flush all contexts associated with the Storage hierarchy and the Endorsement hierarchy.

4.2.9 Auth Index

When a handle has a “@” decoration, the “Description” column will contain an “Auth Index:” entry for the handle. This entry indicates the number of the authorization session. The authorization sessions associated with handles will occur in the session area in the order of the handles with the “@” modifier. Sessions used only for encryption/decryption or only for audit will follow the handles used for authorization.

4.2.10 Auth Role

This will be in the “Description” column of a handle with the “@” decoration. It may have a value of USER, ADMIN or DUP.

If the handle has the Auth Role of USER and the handle is an Object, the type of authorization is determined by the setting of *userWithAuth* in the Object's attributes. If the handle is TPM_RH_OWNER, TPM_RH_ENDORSEMENT, or TPM_RH_PLATFORM, operation is as if *userWithAuth* is SET. If the

handle references an NV Index, then the allowed authorizations are determined by the settings of the attributes of the NV Index as described in TPM 2.0 Part 2, "TPMA_NV (NV Index Attributes)."

If the Auth Role is ADMIN and the handle is an Object, the type of authorization is determined by the setting of *adminWithPolicy* in the Object's attributes. If the handle is TPM_RH_OWNER, TPM_RH_ENDORSEMENT, or TPM_RH_PLATFORM, operation is as if *adminWithPolicy* is SET. If the handle is an NV index, operation is as if *adminWithPolicy* is SET (see clause 5.6 e)2)).

If the DUP role is selected, authorization may only be with a policy session (DUP role only applies to Objects).

When either ADMIN or DUP role is selected, a policy command that selects the command being authorized is required to be part of the policy.

EXAMPLE TPM2_Certify requires the ADMIN role for the first handle (*objectHandle*). The policy authorization for *objectHandle* is required to contain TPM2_PolicyCommandCode(commandCode == TPM_CC_Certify). This sets the state of the policy so that it can be used for ADMIN role authorization in TPM2_Certify().

4.3 Handle and Parameter Demarcation

The demarcations between the header, handle, and parameter parts are indicated by:

Table 2 — Separators

Separator	Meaning
//////	the values immediately following are in the handle area
=====	the values immediately following are in the parameter area

4.4 AuthorizationSize and ParameterSize

Authorization sessions are not shown in the command or response schematics. When the tag of a command or response is TPM_ST_SESSIONS, then a 32-bit value will be present in the command/response buffer to indicate the size of the authorization field or the parameter field. This value shall immediately follow the handle area (which may contain no handles). For a command, this value (*authorizationSize*) indicates the size of the Authorization Area and shall have a value of 9 or more. For a response, this value (*parameterSize*) indicates the size of the parameter area and may have a value of zero.

If the *authorizationSize* field is present in the command, *parameterSize* will be present in the response, but only if the *responseCode* is TPM_RC_SUCCESS.

When authorization is required to use the TPM entity associated with a handle, then at least one session will be present. To indicate this, the command *tag* Description field contains TPM_ST_SESSIONS. Additional sessions for audit, encrypt, and decrypt may be present.

When the command *tag* Description field contains TPM_ST_NO_SESSIONS, then no sessions are allowed and the *authorizationSize* field is not present.

When a command allows use of sessions when not required, the command *tag* Description field will indicate the types of sessions that may be used with the command.

4.5 Return Code Alias

For the RC_FMT1 return codes that may add a parameter, handle, or session number, the prefix TPM_RCS_ is an alias for TPM_RC_.

TPM_RC_n is added, where n is the parameter, handle, or session number. In addition, TPM_RC_H is added for handle, TPM_RC_P for parameter, and TPM_RC_S for session errors.

NOTE TPM_RCS_ is a programming convention used in the reference code. The reference code only adds numbers to TPM_RCS_ return codes, never TPM_RC_ return codes. Only return codes that can have a number added have the TPM_RCS_ alias defined. Attempting to use a TPM_RCS_ return code that does not have the TPM_RCS_ alias will cause a compiler error.

EXAMPLE 1 Since TPM_RC_VALUE can have a number added, TPM_RCS_VALUE is defined. A program can use the construct "TPM_RCS_VALUE + number". Since TPM_RC_SIGNATURE cannot have a number added, TPM_RCS_SIGNATURE is not defined. A program using the construct "TPM_RCS_SIGNATURE + number" will not compile, alerting the programmer that the construct is incorrect.

By convention, the number to be added is of the form RC_CommandName_ParameterName where CommandName is the name of the command with the TPM2_ prefix removed. The parameter name alone is insufficient because the same parameter name could be in a different position in different commands.

EXAMPLE 2 TPM2_HMAC_Start() with parameters that result in TPM_ALG_NULL as the hash algorithm will return TPM_RC_VALUE plus the parameter number. Since *hashAlg* is the second parameter, This code results:

```
#define RC_HMAC_Start_hashAlg (TPM_RC_P + TPM_RC_2)

return TPM_RCS_VALUE + RC_HMAC_Start_hashAlg;
```

5 Command Processing

5.1 Introduction

Clause 5 defines the command validations that are required of any implementation and the response code returned if the indicated check fails. Unless stated otherwise, the order of the checks is not normative and different TPM may give different responses when a command has multiple errors.

In the description below, some statements that describe a check may be followed by a response code in parentheses. This is the normative response code should the indicated check fail. A normative response code may also be included in the statement.

5.2 Command Header Validation

Before a TPM may begin the actions associated with a command, a set of command format and consistency checks shall be performed. These checks are listed below and should be performed in the indicated order.

- a) The TPM shall successfully unmarshal a TPMI_ST_COMMAND_TAG and verify that it is either TPM_ST_SESSIONS or TPM_ST_NO_SESSIONS (TPM_RC_BAD_TAG).
- b) The TPM shall successfully unmarshal a UINT32 as the *commandSize*. If the TPM has an interface buffer that is loaded by some hardware process, the number of octets in the input buffer for the command reported by the hardware process shall exactly match the value in *commandSize* (TPM_RC_COMMAND_SIZE).

NOTE A TPM can have direct access to system memory and unmarshal directly from that memory.

- c) The TPM shall successfully unmarshal a TPM_CC and verify that the command is implemented (TPM_RC_COMMAND_CODE).

5.3 Mode Checks

The following mode checks shall be performed in the order listed:

- a) If the TPM is in Failure mode, then the *commandCode* is TPM_CC_GetTestResult or TPM_CC_GetCapability (TPM_RC_FAILURE) and the command *tag* is TPM_ST_NO_SESSIONS (TPM_RC_FAILURE).

NOTE 1 In Failure mode, the TPM has no cryptographic capability and processing of sessions is not supported.

- b) The TPM is in Field Upgrade mode (FUM), the *commandCode* is TPM_CC_FieldUpgradeData (TPM_RC_UPGRADE).

- c) If the TPM has not been initialized (TPM2_Startup()), then the *commandCode* is TPM_CC_Startup (TPM_RC_INITIALIZE).

NOTE 2 The TPM can enter Failure mode during *_TPM_Init* processing, before TPM2_Startup(). Since the platform firmware cannot know that the TPM is in Failure mode without accessing it, and since the first command is required to be TPM2_Startup(), the expected sequence will be that platform firmware (the CRTM) will issue TPM2_Startup() and receive TPM_RC_FAILURE indicating that the TPM is in Failure mode.

There can be failures where a TPM cannot record that it received TPM2_Startup(). In those cases, a TPM in failure mode may process TPM2_GetTestResult(), TPM2_GetCapability(), or the field upgrade commands. As a side effect, that TPM may process TPM2_GetTestResult(), TPM2_GetCapability() or the field upgrade commands before TPM2_Startup().

This is a corner case exception to the rule that TPM2_Startup() must be the first command.

The mode checks may be performed before or after the command header validation.

5.4 Handle Area Validation

After successfully unmarshaling and validating the command header, the TPM shall perform the following checks on the handles and sessions. These checks may be performed in any order.

NOTE 1 A TPM is required to perform the handle area validation before the authorization checks because an authorization cannot be performed unless the authorization values and attributes for the referenced entity are known by the TPM. For them to be known, the referenced entity must be in the TPM and accessible.

- a) The TPM shall successfully unmarshal the number of handles required by the command and validate that the value of the handle is consistent with the command syntax. If not, the TPM shall return TPM_RC_VALUE.

NOTE 2 The TPM is permitted to unmarshal a handle and validate that it references an entity on the TPM before unmarshaling a subsequent handle.

NOTE 3 If the submitted command contains fewer handles than required by the syntax of the command, the TPM is permitted to continue to read into the next area and attempt to interpret the data as a handle.

b) For all handles in the handle area of the command, the TPM will validate that the referenced entity is present in the TPM.

1) If the handle references a transient object, the handle shall reference a loaded object (TPM_RC_REFERENCE_H0 + N where N is the number of the handle in the command).

NOTE 4 If the hierarchy for a transient object is disabled, then the transient objects will be flushed so this check will fail.

2) If the handle references a persistent object, then

i) the hierarchy associated with the object (platform or storage, based on the handle value) is enabled (TPM_RC_HANDLE);

ii) the handle shall reference a persistent object that is currently in TPM non-volatile memory (TPM_RC_HANDLE);

iii) if the handle references a persistent object that is associated with the endorsement hierarchy, that the endorsement hierarchy is not disabled (TPM_RC_HANDLE); and

NOTE 5 The reference implementation keeps an internal attribute, passed down from a primary key to its descendants, indicating the object's hierarchy.

iv) if the TPM implementation moves a persistent object to RAM for command processing then sufficient RAM space is available (TPM_RC_OBJECT_MEMORY).

3) If the handle references an NV Index, then

i) an Index exists that corresponds to the handle (TPM_RC_HANDLE); and

ii) the hierarchy associated with the existing NV Index is not disabled (TPM_RC_HANDLE).

iii) If the command requires write access to the index data, then TPMA_NV_WRITELOCKED is not SET (TPM_RC_NV_LOCKED)

iv) If the command requires read access to the index data, then TPMA_NV_READLOCKED is not SET (TPM_RC_NV_LOCKED)

4) If the handle references a session, then the session context shall be present in TPM memory (TPM_RC_REFERENCE_H0 + N).

5) If the handle references a primary seed for a hierarchy (TPM_RH_ENDORSEMENT, TPM_RH_OWNER, or TPM_RH_PLATFORM) then the enable for the hierarchy is SET (TPM_RC_HIERARCHY).

6) If the handle references a PCR, then the value is within the range of PCR supported by the TPM (TPM_RC_VALUE)

NOTE 6 In the reference implementation, this TPM_RC_VALUE is returned by the unmarshaling code for a TPMI_DH_PCR.

5.5 Session Area Validation

- a) If the tag is TPM_ST_SESSIONS and the command requires TPM_ST_NO_SESSIONS, the TPM will return TPM_RC_AUTH_CONTEXT.
- b) If the tag is TPM_ST_NO_SESSIONS and the command requires TPM_ST_SESSIONS, the TPM will return TPM_RC_AUTH_MISSING.
- c) If the tag is TPM_ST_SESSIONS, the TPM will attempt to unmarshal an *authorizationSize* and return TPM_RC_AUTHSIZE if the value is not within an acceptable range.
 - 1) The minimum value is $(\text{sizeof}(\text{TPM_HANDLE}) + \text{sizeof}(\text{UINT16}) + \text{sizeof}(\text{TPMA_SESSION}) + \text{sizeof}(\text{UINT16}))$.
 - 2) The maximum value of *authorizationSize* is equal to $\text{commandSize} - (\text{sizeof}(\text{TPM_ST}) + \text{sizeof}(\text{UINT32}) + \text{sizeof}(\text{TPM_CC}) + (N * \text{sizeof}(\text{TPM_HANDLE})) + \text{sizeof}(\text{UINT32}))$ where N is the number of handles associated with the *commandCode* and may be zero.

NOTE 1 $(\text{sizeof}(\text{TPM_ST}) + \text{sizeof}(\text{UINT32}) + \text{sizeof}(\text{TPM_CC}))$ is the size of a command header. The last UINT32 contains the *authorizationSize* octets, which are not counted as being in the authorization session area.

- d) The TPM will unmarshal the authorization sessions and perform the following validations:
 - 1) If the session handle is not a handle for an HMAC session, a handle for a policy session, or, TPM_RS_PW then the TPM shall return TPM_RC_HANDLE.
 - 2) If the session is not loaded, the TPM will return the warning TPM_RC_REFERENCE_S0 + N where N is the number of the session. The first session is session zero, N = 0.

NOTE 2 If the HMAC and policy session contexts use the same memory, the type of the context is required to match the type of the handle.

- 3) If the maximum allowed number of sessions have been unmarshaled and fewer octets than indicated in *authorizationSize* were unmarshaled (that is, *authorizationSize* is too large), the TPM shall return TPM_RC_AUTHSIZE.
- 4) The consistency of the authorization session attributes is checked.
 - i) Only one session is allowed for:
 - (a) session auditing (TPM_RC_ATTRIBUTES) – this session may be used for encrypt or decrypt but may not be a session that is also used for authorization (including a policy session);
 - (b) decrypting a command parameter (TPM_RC_ATTRIBUTES) – this may be any of the authorization sessions, or the audit session, or a session may be added for the single purpose of decrypting a command parameter, as long as the total number of sessions does not exceed three; and
 - (c) encrypting a response parameter (TPM_RC_ATTRIBUTES) – this may be any of the authorization sessions, or the audit session if present, or a session may be added for the single purpose of encrypting a response parameter, as long as the total number of sessions does not exceed three.

NOTE 3 A session used for decrypting a command parameter can also be used for encrypting a response parameter.

- ii) If a session is not being used for authorization, at least one of decrypt, encrypt, or audit must be SET. (TPM_RC_ATTRIBUTES).
- 5) An authorization session is present for each of the handles with the “@” decoration (TPM_RC_AUTH_MISSING).

5.6 Authorization Checks

After unmarshaling and validating the handles and the consistency of the authorization sessions, the authorizations shall be checked. Authorization checks only apply to handles if the handle in the command schematic has the “@” decoration. Authorization checks must be performed in this order.

- a) The public and sensitive portions of the object shall be present on the TPM (TPM_RC_AUTH_UNAVAILABLE).
- b) If the associated handle is TPM_RH_PLATFORM, and the command requires confirmation with physical presence, then physical presence is asserted (TPM_RC_PP).
- c) If the object or NV Index is subject to DA protection, and the authorization is with an HMAC or password, then the TPM is not in lockout (TPM_RC_LOCKOUT).

NOTE 1 An object is subject to DA protection if its *noDA* attribute is CLEAR. An NV Index is subject to DA protection if its *TPMA_NV_NO_DA* attribute is CLEAR.

NOTE 2 An HMAC or password is required in a policy session when the policy contains *TPM2_PolicyAuthValue()* or *TPM2_PolicyPassword()*.

- d) If the command requires a handle to have DUP role authorization, then the associated authorization session is a policy session (TPM_RC_AUTH_TYPE).
- e) If the command requires a handle to have ADMIN role authorization:
 - 1) If the entity being authorized is an object and its *adminWithPolicy* attribute is SET, or a hierarchy, then the authorization session is a policy session (TPM_RC_AUTH_TYPE).

NOTE 3 If *adminWithPolicy* is CLEAR, then any type of authorization session is allowed.

- 2) If the entity being authorized is an NV Index, then the associated authorization session is a policy session.

NOTE 4 The only commands that are currently defined that require use of ADMIN role authorization are commands that operate on objects and NV Indices.

- f) If the command requires a handle to have ADMIN or DUP role authorization and the entity is being authorized with a policy session, that *TPM2_PolicyCommandCode* is part of the policy. (TPM_RC_POLICY_FAIL).
- g) If the command requires a handle to have USER role authorization:
 - 1) If the entity being authorized is an object and its *userWithAuth* attribute is CLEAR, then the associated authorization session is a policy session (TPM_RC_POLICY_FAIL).

NOTE 5 There is no check for a hierarchy, because a hierarchy operates as if *userWithAuth* is SET.

- 2) If the entity being authorized is an NV Index;
 - i) if the authorization session is a policy session;
 - (a) the TPMA_NV_POLICYWRITE attribute of the NV Index is SET if the command modifies the NV Index data (TPM_RC_AUTH_UNAVAILABLE);
 - (b) the TPMA_NV_POLICYREAD attribute of the NV Index is SET if the command reads the NV Index data (TPM_RC_AUTH_UNAVAILABLE);
 - ii) if the authorization is an HMAC session or a password;
 - (a) the TPMA_NV_AUTHWRITE attribute of the NV Index is SET if the command modifies the NV Index data (TPM_RC_AUTH_UNAVAILABLE);
 - (b) the TPMA_NV_AUTHREAD attribute of the NV Index is SET if the command reads the NV Index data or is TPM2_PolicySecret (TPM_RC_AUTH_UNAVAILABLE).
- h) If the authorization is provided by a policy session, then:
 - 1) if *policySession→timeOut* has been set, the session shall not have expired (TPM_RC_EXPIRED);
 - 2) if *policySession→cpHash* has been set, it shall match the *cpHash* of the command (TPM_RC_POLICY_FAIL);
 - 3) if *policySession→commandCode* has been set, then *commandCode* of the command shall match (TPM_RC_POLICY_CC);
 - 4) *policySession→policyDigest* shall match the *authPolicy* associated with the handle (TPM_RC_POLICY_FAIL);
 - 5) if *policySession→pcrUpdateCounter* has been set, then it shall match the value of *pcrUpdateCounter* (TPM_RC_PCR_CHANGED);
 - 6) if *policySession→commandLocality* has been set, it shall match the locality of the command (TPM_RC_LOCALITY),
 - 7) if *policySession→cpHash* contains a template, and the command is TPM2_Create(), TPM2_CreatePrimary(), or TPM2_CreateLoaded(), then the *inPublic* parameter matches the contents of *policySession→cpHash*; and
 - 8) if the policy requires that an *authValue* be provided in order to satisfy the policy, then *session.hmac* is not an Empty Buffer.
- i) If the authorization uses an HMAC, then the HMAC is properly constructed using the *authValue* associated with the handle and/or the session secret (TPM_RC_AUTH_FAIL or TPM_RC_BAD_AUTH).

NOTE 6 A policy session can require proof of knowledge of the *authValue* of the object being authorized.

- j) If the authorization uses a password, then the password matches the *authValue* associated with the handle (TPM_RC_AUTH_FAIL or TPM_RC_BAD_AUTH).

If the TPM returns an error other than TPM_RC_AUTH_FAIL, then the TPM shall not alter any TPM state. If the TPM returns TPM_RC_AUTH_FAIL, then the TPM shall not alter any TPM state other than *failedTries*.

NOTE 7 The TPM is permitted to decrease *failedTries* regardless of any other processing performed by the TPM. That is, the TPM can exit Lockout mode, regardless of the return code.

5.7 Parameter Decryption

If an authorization session has the `TPMA_SESSION.decrypt` attribute SET, and the command does not allow a command parameter to be encrypted, then the TPM will return `TPM_RC_ATTRIBUTES`. Otherwise, the TPM will decrypt the parameter using the values associated with the session before parsing parameters.

NOTE The size of the parameter to be encrypted can be zero.

5.8 Parameter Unmarshaling

5.8.1 Introduction

The detailed actions for each command assume that the input parameters of the command have been unmarshaled into a command-specific structure with the structure defined by the command schematic. Additionally, a response-specific output structure is assumed which will receive the values produced by the detailed actions.

NOTE An implementation is not required to process parameters in this manner or to separate the parameter parsing from the command actions. This method was chosen for the specification so that the normative behavior described by the detailed actions would be clear and unencumbered.

Unmarshaling is the process of processing the parameters in the input buffer and preparing the parameters for use by the command-specific action code. No data movement need take place, but it is required that the TPM validate that the parameters meet the requirements of the expected data type as defined in TPM 2.0 Part 2.

5.8.2 Unmarshaling Errors

When an error is encountered while unmarshaling a command parameter, an error response code is returned, and no command processing occurs. A table defining a data type may have response codes embedded in the table to indicate the error returned when the input value does not match the parameters of the table.

NOTE In the reference implementation, a parameter number is added to the response code so that the offending parameter can be isolated. This is optional.

In many cases, the table contains no specific response code value, and the return code will be determined as defined in Table 3.

Table 3 — Unmarshaling Errors

Response Code	Meaning
TPM_RC_ASYMMETRIC	a parameter that should be an asymmetric algorithm selection does not have a value that is supported by the TPM
TPM_RC_BAD_TAG	a parameter that should be a command tag selection has a value that is not supported by the TPM
TPM_RC_COMMAND_CODE	a parameter that should be a command code does not have a value that is supported by the TPM
TPM_RC_HASH	a parameter that should be a hash algorithm selection does not have a value that is supported by the TPM
TPM_RC_INSUFFICIENT	the input buffer did not contain enough octets to allow unmarshaling of the expected data type;
TPM_RC_KDF	a parameter that should be a key derivation scheme (KDF) selection does not have a value that is supported by the TPM
TPM_RC_KEY_SIZE	a parameter that is a key size has a value that is not supported by the TPM
TPM_RC_MODE	a parameter that should be a symmetric encryption mode selection does not have a value that is supported by the TPM
TPM_RC_RESERVED	a non-zero value was found in a reserved field of an attribute structure (TPMA_)
TPM_RC_SCHEME	a parameter that should be signing or encryption scheme selection does not have a value that is supported by the TPM
TPM_RC_SIZE	the value of a size parameter is larger or smaller than allowed
TPM_RC_SYMMETRIC	a parameter that should be a symmetric algorithm selection does not have a value that is supported by the TPM
TPM_RC_TAG	a parameter that should be a structure tag has a value that is not supported by the TPM
TPM_RC_TYPE	The type parameter of a TPMT_PUBLIC or TPMT_SENSITIVE has a value that is not supported by the TPM
TPM_RC_VALUE	a parameter does not have one of its allowed values

In some commands, a parameter may not be used because of various options of that command. However, the unmarshaling code is required to validate that all parameters have values that are allowed by the TPM 2.0 Part 2 definition of the parameter type even if that parameter is not used in the command actions.

5.9 Command Post Processing

When the code that implements the detailed actions of the command completes, it returns a response code. If that code is not TPM_RC_SUCCESS, the post processing code will not update any session or audit data and will return a 10-octet response packet.

If the command completes successfully, the tag of the command determines if any authorization sessions will be in the response. If so, the TPM will encrypt the first parameter of the response if indicated by the authorization attributes. The TPM will then generate a new nonce value for each session and, if appropriate, generate an HMAC.

If authorization HMAC computations are performed on the response, the HMAC keys used in the response will be the same as the HMAC keys used in processing the HMAC in the command.

NOTE 1 This primarily affects authorizations associated with a first write to an NV Index using a bound session. The computation of the HMAC in the response is performed as if the Name of the Index did not change as a consequence of the command actions. The session binding to the NV Index will not persist to any subsequent command.

NOTE 2 The authorization attributes were validated during the session area validation to ensure that only one session was used for parameter encryption of the response and that the command allowed encryption in the response.

NOTE 3 No session nonce value is used for a password authorization, but the session data is present.

Additionally, if the command is being audited by Command Audit, the audit digest is updated with the *cpHash* of the command and *rpHash* of the response.

6 Response Values

6.1 Tag

When a command completes successfully, the *tag* parameter in the response shall have the same value as the *tag* parameter in the command (TPM_ST_SESSIONS or TPM_ST_NO_SESSIONS). When a command fails (the *responseCode* is not TPM_RC_SUCCESS), then the *tag* parameter in the response shall be TPM_ST_NO_SESSIONS.

A special case exists when the command *tag* parameter is not an allowed value (TPM_ST_SESSIONS or TPM_ST_NO_SESSIONS). For this case, it is assumed that the system software is attempting to send a command formatted for a TPM 1.2, but the TPM is not capable of executing TPM 1.2 commands. So that the TPM 1.2 compatible software will have a recognizable response, the TPM sets *tag* to TPM_ST_RSP_COMMAND, *responseSize* to 00 00 00 0A₁₆ and *responseCode* to TPM_RC_BAD_TAG. This is the same response as the TPM 1.2 fatal error for TPM_BADTAG.

6.2 Response Codes

The normal response for any command is TPM_RC_SUCCESS. Any other value indicates that the command did not complete and the state of the TPM is unchanged. An exception to this general rule is that the logic associated with dictionary attack protection is allowed to be modified when an authorization failure occurs.

Commands have response codes that are specific to that command, and those response codes are enumerated in the detailed actions of each command. The codes associated with the unmarshaling of parameters are documented Table 3. Another set of response code values are not command specific and indicate a problem that is not specific to the command. That is, if the indicated problem is remedied, the same command could be resubmitted and may complete normally.

The response codes that are not command specific are listed and described in Table 4.

The reference code for the command actions may have code that generates specific response codes associated with a specific check, but the listing of responses may not have that response code listed.

Table 4 — Command-Independent Response Codes

Response Code	Meaning
TPM_RC_CANCELED	This response code may be returned by a TPM that supports command cancel. When the TPM receives an indication that the current command should be cancelled, the TPM may complete the command or return this code. If this code is returned, then the TPM state is not changed, and the same command may be retried.
TPM_RC_CONTEXT_GAP	This response code can be returned for commands that manage session contexts. It indicates that the gap between the lowest numbered active session and the highest numbered session is at the limits of the session tracking logic. The remedy is to load the session context with the lowest number so that its tracking number can be updated.
TPM_RC_LOCKOUT	This response indicates that authorizations for objects subject to DA protection are not allowed at this time because the TPM is in DA lockout mode. The remedy is to wait or to execute TPM2_DictionaryAttackLockoutReset().
TPM_RC_MEMORY	A TPM may use a common pool of memory for objects, sessions, and other purposes. When the TPM does not have enough memory available to perform the actions of the command, it may return TPM_RC_MEMORY. This indicates that the TPM resource manager may flush either sessions or objects in order to make memory available for the command execution. A TPM may choose to return TPM_RC_OBJECT_MEMORY or TPM_RC_SESSION_MEMORY if it needs contexts of a particular type to be flushed.
TPM_RC_NV_RATE	This response code indicates that the TPM is rate-limiting writes to the NV memory in order to prevent wearout. This response is possible for any command that explicitly writes to NV or commands that incidentally use NV such as a command that uses authorization session that may need to update the dictionary attack logic.
TPM_RC_NV_UNAVAILABLE	This response code is similar to TPM_RC_NV_RATE but indicates that access to NV memory is currently not available and the command is not allowed to proceed until it is. This would occur in a system where the NV memory used by the TPM is not exclusive to the TPM and is a shared system resource.
TPM_RC_OBJECT_HANDLES	This response code indicates that the TPM has exhausted its handle space and no new objects can be loaded unless the TPM is rebooted. This does not occur in the reference implementation because of the way that object handles are allocated. However, other implementations are allowed to assign each object a unique handle each time the object is loaded. A TPM using this implementation would be able to load 2 ²⁴ objects before the object space is exhausted.
TPM_RC_OBJECT_MEMORY	This response code can be returned by any command that causes the TPM to need an object 'slot'. The most common case where this might be returned is when an object is loaded (TPM2_Load, TPM2_CreatePrimary(), or TPM2_ContextLoad()). However, the TPM implementation is allowed to use object slots for other reasons. In the reference implementation, the TPM copies a referenced persistent object into RAM for the duration of the command. If all the slots are previously occupied, the TPM may return this value. A TPM is allowed to use object slots for other purposes and return this value. The remedy when this response is returned is for the TPM resource manager to flush a transient object.
TPM_RC_REFERENCE_Hx	<p>This response code indicates that a handle in the handle area of the command is not associated with a loaded object. The value of 'x' is in the range 0 to 6 with a value of 0 indicating the 1st handle and 6 representing the 7th. Upper values are provided for future use. The TPM resource manager needs to find the correct object and load it. It may then adjust the handle and retry the command.</p> <p>NOTE Usually, this error indicates that the TPM resource manager has a corrupted database.</p>

Response Code	Meaning
TPM_RC_REFERENCE_Sx	This response code indicates that a handle in the session area of the command is not associated with a loaded session. The value of 'x' is in the range 0 to 6 with a value of 0 indicating the 1 st session handle and 6 representing the 7 th . Upper values are provided for future use. The TPM resource manager needs to find the correct session and load it. It may then retry the command. NOTE Usually, this error indicates that the TPM resource manager has a corrupted database.
TPM_RC_RETRY	the TPM was not able to start the command
TPM_RC_SESSION_HANDLES	This response code indicates that the TPM does not have a handle to assign to a new session. This response is only returned by TPM2_StartAuthSession(). It is listed here because the command is not in error and the TPM resource manager can remedy the situation by flushing a session (TPM2_FlushContext()).
TPM_RC_SESSION_MEMORY	This response code can be returned by any command that causes the TPM to need a session 'slot'. The most common case where this might be returned is when a session is loaded (TPM2_StartAuthSession() or TPM2_ContextLoad()). However, the TPM implementation is allowed to use object slots for other purposes. The remedy when this response is returned is for the TPM resource manager to flush a transient object.
TPM_RC_SUCCESS	Normal completion for any command. If the responseCode is TPM_RC_SUCCESS, then the rest of the response has the format indicated in the response schematic. Otherwise, the response is a 10 octet value indicating an error.
TPM_RC_TESTING	This response code indicates that the TPM is performing tests and cannot respond to the request at this time. The command may be retried.
TPM_RC_YIELDED	the TPM has suspended operation on the command; forward progress was made, and the command may be retried (see TPM 2.0 Part 1, <i>Multi-tasking</i>). NOTE This cannot occur on the reference implementation.

7 Implementation Dependent

The actions code for each command makes assumptions about the behavior of various sub-systems. There are many possible implementations of the subsystems that would achieve equivalent results. The actions code is not written to anticipate all possible implementations of the sub-systems. Therefore, it is the responsibility of the implementer to ensure that the necessary changes are made to the actions code when the sub-system behavior changes.

8 Detailed Actions Assumptions

8.1 Introduction

The C code in the Detailed Actions for each command is written with a set of assumptions about the processing performed before the action code is called and the processing that will be done after the action code completes.

8.2 Pre-processing

Before calling the command actions code, the following actions have occurred.

- Verification that the handles in the handle area reference entities that are resident on the TPM.

NOTE If a handle is in the parameter portion of the command, the associated entity does not have to be loaded, but the handle is required to be the correct type.

- If use of a handle requires authorization, the Password, HMAC, or Policy session associated with the handle has been verified.
- If a command parameter was encrypted using parameter encryption, it was decrypted before being unmarshaled.
- If the command uses handles or parameters, the calling stack contains a pointer to a data structure (*in*) that holds the unmarshaled values for the handles and command parameters. If the response has handles or parameters, the calling stack contains a pointer to a data structure (*out*) to hold the handles and response parameters generated by the command.
- All parameters of the *in* structure have been validated and meet the requirements of the parameter type as defined in TPM 2.0 Part 2.
- Space set aside for the out structure is sufficient to hold the largest *out* structure that could be produced by the command

8.3 Post Processing

When the function implementing the command actions completes,

- response parameters that require parameter encryption will be encrypted after the command actions complete;
- audit and session contexts will be updated if the command response is TPM_RC_SUCCESS; and
- the command header and command response parameters will be marshaled to the response buffer.

9 Start-up

9.1 Introduction

Clause 9 contains the commands used to manage the startup and restart state of a TPM.

9.2 `_TPM_Init`

9.2.1 General Description

`_TPM_Init` initializes a TPM.

Initialization actions include testing code required to execute the next expected command. If the TPM is in FUM, the next expected command is `TPM2_FieldUpgradeData()`; otherwise, the next expected command is `TPM2_Startup()`.

NOTE 1 If the TPM performs self-tests after receiving `_TPM_Init()` and the TPM enters Failure mode before receiving `TPM2_Startup()` or `TPM2_FieldUpgradeData()`, then the TPM is permitted to accept `TPM2_GetTestResult()` or `TPM2_GetCapability()`.

The means of signaling `_TPM_Init` shall be defined in the platform-specific specifications that define the physical interface to the TPM. The platform shall send this indication whenever the platform starts its boot process and only when the platform starts its boot process.

There shall be no software method of generating this indication that does not also reset the platform and begin execution of the CRTM.

NOTE 2 In the reference implementation, this signal causes an internal flag (*s_initialized*) to be CLEAR. While this flag is CLEAR, the TPM will only accept the next expected command described above.

9.2.2 Detailed Actions

[[_TPM_Init]]

9.3 TPM2_Startup

9.3.1 General Description

TPM2_Startup() is always preceded by `_TPM_Init`, which is the physical indication that TPM initialization is necessary because of a system-wide reset. TPM2_Startup() is only valid after `_TPM_Init`. Additional TPM2_Startup() commands are not allowed after it has completed successfully. If a TPM requires TPM2_Startup() and another command is received, or if the TPM receives TPM2_Startup() when it is not required, the TPM shall return `TPM_RC_INITIALIZE`.

NOTE 1 See clause 9.2.1 for other command options for a TPM supporting field upgrade mode.

NOTE 2 `_TPM_Hash_Start`, `_TPM_Hash_Data`, and `_TPM_Hash_End` are not commands, and a platform-specific specification may allow these indications between `_TPM_Init` and TPM2_Startup().

If in Failure mode, the TPM shall accept TPM2_GetTestResult() and TPM2_GetCapability() even if TPM2_Startup() is not completed successfully or processed at all.

A platform-specific specification may restrict the localities at which TPM2_Startup() may be received.

A Shutdown/Startup sequence determines the way in which the TPM will operate in response to TPM2_Startup(). The three sequences are:

TPM Reset – This is a Startup(CLEAR) preceded by either Shutdown(CLEAR) or no TPM2_Shutdown(). On TPM Reset, all variables go back to their default initialization state.

NOTE 3 Only those values that are specified as having a default initialization state are changed by TPM Reset. Persistent values that have no default initialization state are not changed by this command. Values such as seeds have no default initialization state and only change due to specific commands.

TPM Restart – This is a Startup(CLEAR) preceded by Shutdown(STATE). This preserves much of the previous state of the TPM except that PCR and the controls associated with the Platform hierarchy are all returned to their default initialization state;

TPM Resume – This is a Startup(STATE) preceded by Shutdown(STATE). This preserves the previous state of the TPM including the static Root of Trust for Measurement (S-RTM) PCR and the platform controls other than the *phEnable*.

If a TPM receives Startup(STATE) and that was not preceded by Shutdown(STATE), the TPM shall return `TPM_RC_VALUE`.

If, during TPM Restart or TPM Resume, the TPM fails to restore the state saved at the last Shutdown(STATE), the TPM shall enter Failure Mode and return `TPM_RC_FAILURE`.

On any TPM2_Startup(),

- *phEnable* shall be SET;
- all transient contexts (objects, sessions, and sequences) shall be flushed from TPM memory;

NOTE 4 See Part 1 Time for a description of the `TPMS_TIME_INFO.time` behavior.

- use of *lockoutAuth* shall be enabled if *lockoutRecovery* is zero.

Additional actions are performed based on the Shutdown/Startup sequence.

On TPM Reset:

- *platformAuth* and *platformPolicy* shall be set to the Empty Buffer,
- change *nullProof* and *nullSeed*,
- For each NV Index with TPMA_NV_WRITEDEFINE CLEAR or TPMA_NV_WRITTEN CLEAR, TPMA_NV_WRITELOCKED shall be CLEAR,
- For each NV Index with TPMA_NV_ORDERLY SET, TPMA_NV_WRITTEN shall be CLEAR unless the type is TPM_NT_COUNTER,
- On a disorderly reset, advance the orderly counters,
- For each NV Index with TPMA_NV_CLEAR_STCLEAR SET, TPMA_NV_WRITTEN shall be CLEAR,
- tracking data for saved session contexts shall be set to its initial value,
- the object context sequence number is reset to zero,
- a new context encryption key shall be generated,
- TPMS_CLOCK_INFO.*restartCount* shall be reset to zero,
- TPMS_CLOCK_INFO.*resetCount* shall be incremented,
- the PCR Update Counter (*pcrUpdateCounter*) shall be clear to zero,

NOTE 5 Because the PCR update counter is permitted to be incremented when a PCR is reset, the PCR resets performed as part of this command can result in the PCR update counter being non-zero at the end of this command.

- *phEnableNV*, *shEnable* and *ehEnable* shall be SET, and
- PCR in all banks are reset to their default initial conditions as determined by the relevant platform-specific specification and the H-CRTM state (for exceptions, see TPM 2.0 Part 1, *H-CRTM before TPM2_Startup()* and *TPM2_Startup without H-CRTM*),
- For each ACT the timeout is reset to zero, the *signaled* attribute is set to CLEAR, its *authPolicy* is set to the Empty Buffer, and its hashAlg is set to TPM_ALG_NULL.

NOTE 6 PCR can be initialized any time between _TPM_Init and the end of TPM2_Startup(). PCR that are preserved by TPM Resume will need to be restored during TPM2_Startup().

NOTE 7 See "Initializing PCR" in TPM 2.0 Part 1 for a description of the default initial conditions for a PCR.

On TPM Restart:

- TPMS_CLOCK_INFO.*restartCount* shall be incremented,
- *phEnableNV*, *shEnable* and *ehEnable* shall be SET,
- *platformAuth* and *platformPolicy* shall be set to the Empty Buffer,
- For each NV index with TPMA_NV_WRITEDEFINE CLEAR or TPMA_NV_WRITTEN CLEAR, TPMA_NV_WRITELOCKED shall be CLEAR,
- For each NV index with TPMA_NV_CLEAR_STCLEAR SET, TPMA_NV_WRITTEN shall be CLEAR, and
- PCR in all banks are reset to their default initial conditions as determined by the relevant platform-specific specification and the H-CRTM state (for exceptions, see TPM 2.0 Part 1, *H-CRTM before TPM2_Startup()* and *TPM2_Startup without H-CRTM*),

NOTE 8 The PCR Update Counter (*pcrUpdateCounter*) is not modified.

- For each ACT the timeout is reset to zero, the *signaled* attribute is set to CLEAR, its *authPolicy* is set to the Empty Buffer and its hashAlg is set to TPM_ALG_NULL.

On TPM Resume:

- the H-CRTM startup method is the same for this TPM2_Startup() as for the previous TPM2_Startup(); (TPM_RC_LOCALITY)
- TPMS_CLOCK_INFO.*restartCount* shall be incremented; and
- PCR that are specified in a platform-specific specification to be preserved on TPM Resume are restored to their saved state and other PCR are set to their initial value as determined by a platform-specific specification. For constraints, see TPM 2.0 Part 1, *H-CRTM before TPM2_Startup() and TPM2_Startup without H-CRTM*.
- The ACT timeout, the ACT *signaled* attribute and the ACT specific *authPolicy* values are preserved.

Other TPM state may change as required to meet the needs of the implementation.

If the *startupType* is TPM_SU_STATE and the TPM requires TPM_SU_CLEAR, then the TPM shall return TPM_RC_VALUE.

NOTE 9 The TPM will require TPM_SU_CLEAR when no shutdown was performed or after Shutdown(CLEAR).

NOTE 10 If *startupType* is neither TPM_SU_STATE nor TPM_SU_CLEAR, then the unmarshaling code returns TPM_RC_VALUE.

[[Startup]]

9.4 TPM2_Shutdown

9.4.1 General Description

This command is used to prepare the TPM for a power cycle. The *shutdownType* parameter indicates how the subsequent TPM2_Startup() will be processed.

For a *shutdownType* of any type, the volatile portion of Clock is saved to NV memory and the orderly shutdown indication is SET. NV Indexes with the TPMA_NV_ORDERLY attribute will be updated.

For a *shutdownType* of TPM_SU_STATE, the following additional items are saved:

- tracking information for saved session contexts;
- the session context counter;
- PCR that are designated as being preserved by TPM2_Shutdown(TPM_SU_STATE);
- the PCR Update Counter (pcrUpdateCounter);
- flags associated with supporting the TPMA_NV_WRITESTCLEAR and TPMA_NV_READSTCLEAR attributes;
- the counter value and authPolicy for each ACT; and

NOTE If a counter has not been updated since the last TPM2_Startup(), then the saved value will be one half of the current counter value.

- the command audit digest and count.

The following items shall not be saved and will not be in TPM memory after the next TPM2_Startup:

- TPM-memory-resident session contexts;
- TPM-memory-resident transient objects; or
- TPM-memory-resident hash contexts created by TPM2_HashSequenceStart().

Some values may be either derived from other values or saved to NV memory.

This command saves TPM state but does not change the state other than the internal indication that the context has been saved. The TPM shall continue to accept commands. If a subsequent command changes TPM state saved by this command, then the effect of this command is nullified. The TPM MAY nullify this command for any subsequent command rather than check whether the command changed state saved by this command. If this command is nullified, and if no TPM2_Shutdown() occurs before the next TPM2_Startup(), then the next TPM2_Startup() shall be TPM2_Startup(CLEAR).

9.4.2 Command and Response

[[Shutdown]]

10 Testing

10.1 Introduction

Compliance to standards for hardware security modules may require that the TPM test its functions before the results that depend on those functions may be returned. The TPM may perform operations using testable functions before those functions have been tested as long as the TPM returns no value that depends on the correctness of the testable function.

EXAMPLE TPM2_PCR_Extend() can be executed before the hash algorithms have been tested. However, until the hash algorithms have been tested, the contents of a PCR cannot be used in any command if that command may result in a value being returned to the TPM user. This means that TPM2_PCR_Read() or TPM2_PolicyPCR() could not complete until the hashes have been checked but other TPM2_PCR_Extend() commands may be executed even though the operation uses previous PCR values.

If a command is received that requires return of a value that depends on untested functions, the TPM shall test the required functions before completing the command.

Once the TPM has received TPM2_SelfTest() and before completion of all tests, the TPM is required to return TPM_RC_TESTING for any command that uses a function that requires a test.

If a self-test fails at any time, the TPM will enter Failure mode. While in Failure mode, the TPM will return TPM_RC_FAILURE for any command other than TPM2_GetTestResult() and TPM2_GetCapability(). The TPM will remain in Failure mode until the next _TPM_Init.

10.2 TPM2_SelfTest

10.2.1 General Description

This command causes the TPM to perform a test of its capabilities. If the *fullTest* is YES, the TPM will test all functions. If *fullTest* = NO, the TPM will only test those functions that have not previously been tested.

If any tests are required, the TPM shall either

- return TPM_RC_TESTING and begin self-test of the required functions, or

NOTE 1 If *fullTest* is NO, and all functions have been tested, the TPM shall return TPM_RC_SUCCESS.

- perform the tests and return the test result when complete. On failure, the TPM shall return TPM_RC_FAILURE.

If the TPM uses option a), the TPM shall return TPM_RC_TESTING for any command that requires use of a testable function, even if the functions required for completion of the command have already been tested.

NOTE 2 This command can cause the TPM to continue processing after it has returned the response. So that software can be notified of the completion of the testing, the interface can include controls that would allow the TPM to generate an interrupt when the “background” processing is complete. This would be in addition to the interrupt that may be available for signaling normal command completion. It is not necessary that there be two interrupts, but the interface should provide a way to indicate the nature of the interrupt (normal command or deferred command).

NOTE 3 The PC Client platform specific TPM, in response to *fullTest* YES, will not return TPM_RC_TESTING. It will block until all tests are complete.

10.2.2 Command and Response

TPM_RC	responseCode	

10.2.3 Detailed Actions

[[SelfTest]]

10.3 TPM2_IncrementalSelfTest

10.3.1 General Description

This command causes the TPM to perform a test of the selected algorithms.

NOTE 1 The *toTest* list indicates the algorithms that software would like the TPM to test in anticipation of future use. This allows tests to be done so that a future command will not be delayed due to testing.

The implementation may treat algorithms on the *toTest* list as either 'test each completely' or 'test this combination.'

EXAMPLE 1 If the *toTest* list includes AES and CTR mode, it can be interpreted as a request to test only AES in CTR mode. Alternatively, it may be interpreted as a request to test AES in all modes and CTR mode for all symmetric algorithms.

If *toTest* contains an algorithm that has already been tested, it will not be tested again.

NOTE 2 The only way to force retesting of an algorithm is with `TPM2_SelfTest(fullTest = YES)`.

The TPM will return in *todoList* a list of algorithms that are yet to be tested. This list is not the list of algorithms that are scheduled to be tested but the algorithms/functions that have not been tested. Only the algorithms on the *toTest* list are scheduled to be tested by this command.

NOTE 3 An algorithm remains on the *todoList* while any part of it remains untested.

EXAMPLE 2 A symmetric algorithm remains untested until it is tested with all its modes.

Making *toTest* an empty list allows the determination of the algorithms that remain untested without triggering any testing.

If *toTest* is not an empty list, the TPM shall return `TPM_RC_SUCCESS` for this command and then return `TPM_RC_TESTING` for any subsequent command (including `TPM2_IncrementalSelfTest()`) until the requested testing is complete.

NOTE 4 If *todoList* is empty, then no additional tests are required and `TPM_RC_TESTING` will not be returned in subsequent commands and no additional delay will occur in a command due to testing.

NOTE 5 If none of the algorithms listed in *toTest* is in the *todoList*, then no tests will be performed.

NOTE 6 The TPM cannot return `TPM_RC_TESTING` for the first call to this command even when testing is not complete because response parameters can only be returned with the `TPM_RC_SUCCESS` return code.

If all the parameters in this command are valid, the TPM returns `TPM_RC_SUCCESS` and the *todoList* (which may be empty).

NOTE 7 An implementation is permitted to perform all requested tests before returning `TPM_RC_SUCCESS`, or it is permitted to return `TPM_RC_SUCCESS` for this command and then return `TPM_RC_TESTING` for all subsequent commands (including `TPM2_IncrementalSelfTest()`) until the requested tests are complete.

10.3.2 Command and Response

10.3.3 Detailed Actions

[[IncrementalSelfTest]]

10.4 TPM2_GetTestResult

10.4.1 General Description

This command returns manufacturer-specific information regarding the results of a self-test and an indication of the test status.

If TPM2_SelfTest() has not been executed and a testable function has not been tested, *testResult* will be TPM_RC_NEEDS_TEST. If TPM2_SelfTest() has been received and the tests are not complete, *testResult* will be TPM_RC_TESTING.

If testing of all functions is complete without functional failures, *testResult* will be TPM_RC_SUCCESS. If any test failed, *testResult* will be TPM_RC_FAILURE.

This command will operate when the TPM is in Failure mode so that software can determine the test status of the TPM and so that diagnostic information can be obtained for use in failure analysis. If the TPM is in Failure mode, then *tag* is required to be TPM_ST_NO_SESSIONS or the TPM shall return TPM_RC_FAILURE.

NOTE The reference implementation can return a 32-bit value *s_failFunction*. This simply gives a unique value to each of the possible places where a failure could occur. It is not intended to provide a pointer to the function. *__func__* is a pointer to a character string but the failure mode code can only return 32-bit values. It is expected that the manufacturer can disambiguate this value if a customer's TPM goes into failure mode.

10.4.2 Command and Response

[[GetTestResult]]

11 Session Commands

11.1 TPM2_StartAuthSession

11.1.1 General Description

This command is used to start an authorization session using alternative methods of establishing the session key (*sessionKey*). The session key is then used to derive values used for authorization and for encrypting parameters.

This command allows injection of a secret into the TPM using either asymmetric or symmetric encryption. The type of *tpmKey* determines how the value in *encryptedSalt* is encrypted. The decrypted secret value is used to compute the *sessionKey*.

NOTE 1 If *tpmKey* is TPM_RH_NULL, then *encryptedSalt* is required to be an Empty Buffer.

The label value of “SECRET” (see TPM 2.0 Part 1, *Terms and Definitions*) is used in the recovery of the secret value.

The TPM generates the *sessionKey* from the recovered secret value.

No authorization is required for *tpmKey* or *bind*.

NOTE 2 The justification for using *tpmKey* without providing authorization is that the result of using the key is not available to the caller, except indirectly through the *sessionKey*. This does not represent a point of attack on the authorization value of the key.

NOTE 3 If a *bind* entity is subject to DA protection, use of the session is subject to DA regardless of the DA status of the entity being authorized. If the caller attempts to use the session without knowing the *sessionKey* value, the authorization failure will trigger the dictionary attack logic.

The entity referenced with the *bind* parameter contributes an authorization value to the *sessionKey* generation process.

If both *tpmKey* and *bind* are TPM_RH_NULL, then *sessionKey* is set to the Empty Buffer. If *tpmKey* is not TPM_RH_NULL, then *encryptedSalt* is used in the computation of *sessionKey*. If *bind* is not TPM_RH_NULL, the *authValue* of *bind* is used in the *sessionKey* computation and *policySession*→*bindEntity* (*policySession*→*cpHash*) is set.

If *symmetric* specifies a block cipher, then TPM_ALG_CFB is the only allowed value for the *mode* field in the *symmetric* parameter (TPM_RC_MODE).

This command starts an authorization session and returns the session handle along with an initial *nonceTPM* in the response.

If the TPM does not have a free slot for an authorization session, it shall return TPM_RC_SESSION_HANDLES.

If the TPM implements a “gap” scheme for assigning *contextID* values, then the TPM shall return TPM_RC_CONTEXT_GAP if creating the session would prevent recycling of old saved contexts (see TPM 2.0 Part 1, *Context Management*).

If *tpmKey* is not TPM_ALG_NULL, then *encryptedSalt* shall be a TPM2B_ENCRYPTED_SECRET of the proper type for *tpmKey*. The TPM shall return TPM_RC_HANDLE if the sensitive portion of *tpmKey* is not loaded. The TPM shall return TPM_RC_VALUE if:

a) *tpmKey* references an RSA key and

- 1) the size of *encryptedSalt* is not the same as the size of the public modulus of *tpmKey*,
- 2) *encryptedSalt* has a value that is greater than the public modulus of *tpmKey*,
- 3) *encryptedSalt* is not a properly encoded OAEP value, or
- 4) the decrypted *salt* value is larger than the size of the digest produced by the *nameAlg* of *tpmKey*;
or

NOTE 4 The *asymScheme* of the key object is ignored in this case and *TPM_ALG_OAEP* is used, even if *asymScheme* is set to *TPM_ALG_NULL*.

b) *tpmKey* references an ECC key and *encryptedSalt*

- 1) does not contain a *TPMS_ECC_POINT* or
- 2) is not a point on the curve of *tpmKey*;

NOTE 5 When ECC is used, the point multiply process produces a value (Z) that is used in a KDF to produce the final secret value. The size of the secret value is an input parameter to the KDF, and the result will be set to be the size of the digest produced by the *nameAlg* of *tpmKey*.

The TPM shall return *TPM_RC_KEY* if *tpmKey* does not reference an asymmetric key. The TPM shall return *TPM_RC_VALUE* if the scheme of the key is not *TPM_ALG_OAEP* or *TPM_ALG_NULL*. The TPM shall return *TPM_RC_ATTRIBUTES* if *tpmKey* does not have the *decrypt* attribute SET.

NOTE 6 While *TPM_RC_VALUE* is preferred, *TPM_RC_SCHEME* is acceptable.

NOTE 7 *tpmKey* is typically a *restricted* key so an attacker cannot use *tpmKey* to decrypt the salt. Otherwise, the use of *tpmKey* to decrypt has to be under control of the caller.

If *bind* references a transient object, then the TPM shall return *TPM_RC_HANDLE* if the sensitive portion of the object is not loaded.

For all session types, this command will cause initialization of the *sessionKey* and may establish binding between the session and an entity (the *bind* entity). If *sessionType* is *TPM_SE_POLICY* or *TPM_SE_TRIAL*, the additional session initialization is:

- set *policySession*→*policyDigest* to a Zero Digest (the digest size for *policySession*→*policyDigest* is the size of the digest produced by *authHash*);
- authorization may be given at any locality;
- authorization may apply to any command code;
- authorization may apply to any command parameters or handles;
- the authorization has no time limit;
- an *authValue* is not needed when the authorization is used;
- the session is not bound;
- the session is not an audit session; and
- the time at which the policy session was created is recorded.

Additionally, if *sessionType* is *TPM_SE_TRIAL*, the session will not be usable for authorization but can be used to compute the *authPolicy* for an object.

NOTE 8 Although this command changes the session allocation information in the TPM, it does not invalidate a saved context. That is, *TPM2_Shutdown()* is not required after this command in order to re-establish the orderly state of the TPM. This is because the created context will occupy an available slot in the TPM and sessions in the TPM do not survive any *TPM2_Startup()*. However, if a created session is context saved, the orderly state does change.

The TPM shall return TPM_RC_SIZE if *nonceCaller* is less than 16 octets or is greater than the size of the digest produced by *authHash*.

11.1.2 Command and Response

Table 15 — TPM2_StartAuthSession Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS if an audit, decrypt, or encrypt session is present; otherwise, TPM_ST_NO_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_StartAuthSession
TPMI_DH_OBJECT+	tpmKey	handle of a loaded decrypt key used to encrypt <i>salt</i> may be TPM_RH_NULL Auth Index: None
TPMI_DH_ENTITY+	bind	entity providing the <i>authValue</i> may be TPM_RH_NULL Auth Index: None
TPM2B_NONCE	nonceCaller	initial <i>nonceCaller</i> , sets nonceTPM size for the session shall be at least 16 octets
TPM2B_ENCRYPTED_SECRET	encryptedSalt	value encrypted according to the type of <i>tpmKey</i> If <i>tpmKey</i> is TPM_RH_NULL, this shall be the Empty Buffer.
TPM_SE	sessionType	indicates the type of the session; simple HMAC or policy (including a trial policy)
TPMT_SYM_DEF+	symmetric	the algorithm and key size for parameter encryption may select TPM_ALG_NULL
TPMI_ALG_HASH	authHash	hash algorithm to use for the session Shall be a hash algorithm supported by the TPM and not TPM_ALG_NULL

Table 16 — TPM2_StartAuthSession Response

Type	Name	Description
TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode

TPM2B_NONCE	nonceTPM	the initial nonce from the TPM, used in the computation of the <i>sessionKey</i>

11.1.3 Detailed Actions

[[StartAuthSession]]

11.2 TPM2_PolicyRestart

11.2.1 General Description

This command allows a policy authorization session to be returned to its initial state. This command is used after the TPM returns TPM_RC_PCR_CHANGED. That response code indicates that a policy will fail because the PCR have changed after TPM2_PolicyPCR() was executed. Restarting the session allows the authorizations to be replayed because the session restarts with the same *nonceTPM*. If the PCR are valid for the policy, the policy may then succeed.

This command does not reset the policy ID or the policy start time.

11.2.2 Command and Response

Table 17 — TPM2_PolicyRestart Command

12 Object Commands

12.1 TPM2_Create

12.1.1 General Description

This command is used to create an object that can be loaded into a TPM using TPM2_Load(). If the command completes successfully, the TPM will create the new object and return the object's creation data (*creationData*), its public area (*outPublic*), and its encrypted sensitive area (*outPrivate*). Preservation of the returned data is the responsibility of the caller. The object will need to be loaded (TPM2_Load()) before it may be used. The only difference between the *inPublic* TPMT_PUBLIC template and the *outPublic* TPMT_PUBLIC object is in the *unique* field.

NOTE 1 This command may require temporary use of a transient resource, even though the object does not remain loaded after the command (see TPM 2.0 Part 1, Transient Resources).

TPM2B_PUBLIC template (*inPublic*) contains all of the fields necessary to define the properties of the new object. The setting for these fields is defined in "Public Area Template" in Part 1 of this specification and in "TPMA_OBJECT" in Part 2 of this specification. The size of the *unique* field shall not be checked for consistency with the other object parameters.

NOTE 2 For interoperability, it is recommended that the *unique* field not be set to a value that is larger than allowed by object parameters, so that the unmarshaling will not fail. A size of zero is recommended. After unmarshaling, the TPM does not use the input *unique* field. It is, however, used in TPM2_CreatePrimary() and TPM2_CreateLoaded.

EXAMPLE 1 It is recommended that a TPM_ALG_RSA object with a *keyBits* of 2048 in the object's parameters have a *unique* field that is no larger than 256 bytes.

EXAMPLE 2 It is recommended that a TPM_ALG_KEYEDHASH or a TPM_ALG_SYMCIPHER object have a *unique* field that is no larger than the digest produced by the object's *nameAlg*.

The *parentHandle* parameter shall reference a loaded decryption key that has both the public and sensitive area loaded.

When defining the object, the caller provides a template structure for the object in a TPM2B_PUBLIC structure (*inPublic*), an initial value for the object's *authValue* (*inSensitive.userAuth*), and, if the object is a symmetric object, an optional initial data value (*inSensitive.data*). The TPM shall validate the consistency of the attributes of *inPublic* according to the Creation rules in "TPMA_OBJECT" in TPM 2.0 Part 2.

The *inSensitive* parameter may be encrypted using parameter encryption.

The methods in clause 12.1 are used by both TPM2_Create() and TPM2_CreatePrimary(). When a value is indicated as being TPM-generated, the value is filled in by bits from the RNG if the command is TPM2_Create() and with values from KDFa() if the command is TPM2_CreatePrimary(). The parameters of each creation value are specified in TPM 2.0 Part 1.

The *sensitiveDataOrigin* attribute of *inPublic* shall be SET if *inSensitive.data* is an Empty Buffer and CLEAR if *inSensitive.data* is not an Empty Buffer or the TPM shall return TPM_RC_ATTRIBUTES.

If the Object is a not a *keyedHash* object, and the *sign* and *encrypt* attributes are CLEAR, the TPM shall return TPM_RC_ATTRIBUTES.

The TPM will create new data for the sensitive area and compute a TPMT_PUBLIC.*unique* from the sensitive area based on the object type:

- a) For a symmetric key:
- 1) If *inSensitive.sensitive.data* is the Empty Buffer, a TPM-generated key value is placed in the new object's *TPMT_SENSITIVE.sensitive.sym*. The size of the key will be determined by *inPublic.publicArea.parameters*.
 - 2) If *inSensitive.sensitive.data* is not the Empty Buffer, the TPM will validate that the size of *inSensitive.data* is no larger than the key size indicated in the *inPublic template* (*TPM_RC_SIZE*) and copy the *inSensitive.data* to *TPMT_SENSITIVE.sensitive.sym* of the new object.
 - 3) A TPM-generated obfuscation value is placed in *TPMT_SENSITIVE.sensitive.seedValue*. The size of the obfuscation value is the size of the digest produced by the *nameAlg* in *inPublic*. This value prevents the public *unique* value from leaking information about the *sensitive* area.
 - 4) The *TPMT_PUBLIC.unique.sym* value for the new object is then generated, as shown in equation (1) below, by hashing the key and obfuscation values in the *TPMT_SENSITIVE* with the *nameAlg* of the object.

$$unique := H_{nameAlg}(sensitive.seedValue.buffer || sensitive.any.buffer) \quad (1)$$

- b) If the Object is an asymmetric key:
- 1) If *inSensitive.sensitive.data* is not the Empty Buffer, then the TPM shall return *TPM_RC_VALUE*.
 - 2) A TPM-generated private key value is created with the size determined by the parameters of *inPublic.publicArea.parameters*.
 - 3) If the key is a Storage Key, a TPM-generated *TPMT_SENSITIVE.seedValue* value is created; otherwise, *TPMT_SENSITIVE.seedValue.size* is set to zero.

NOTE 3 An Object that is not a storage key has no child Objects to encrypt, so it does not need a symmetric key.

- 4) The public *unique* value is computed from the private key according to the methods of the key type.
- 5) If the key is an ECC key and the scheme required by the *curveID* is not the same as *scheme* in the public area of the template, then the TPM shall return *TPM_RC_SCHEME*.
- 6) If the key is an ECC key and the KDF required by the *curveID* is not the same as *kdf* in the public area of the template, then the TPM shall return *TPM_RC_KDF*.

NOTE 4 There is currently no command in which the caller may specify the KDF to be used with an ECC decryption key. Since there is no use for this capability, the reference implementation requires that the *kdf* in the template be set to *TPM_ALG_NULL* or *TPM_RC_KDF* is returned.

- c) If the Object is a *keyedHash* object:
- 1) If *inSensitive.sensitive.data* is an Empty Buffer, and both *sign* and *decrypt* are CLEAR in the attributes of *inPublic*, the TPM shall return *TPM_RC_ATTRIBUTES*. This would be a data object with no data.

NOTE 5 Revisions 1.34 and earlier reference code did not check the error case of *sensitiveDataOrigin* SET and an Empty Buffer. Thus, some TPM implementations did not include this error check.

- 2) If *sign* and *decrypt* are both CLEAR or both SET and the *scheme* in the public area of the template is not *TPM_ALG_NULL*, the TPM shall return *TPM_RC_SCHEME*.

NOTE 6 Revisions 1.38 and earlier did not enforce this error case.

- 3) If *inSensitive.sensitive.data* is not an Empty Buffer, the TPM will copy the *inSensitive.sensitive.data* to TPMT_SENSITIVE.*sensitive.bits* of the new object.

NOTE 7 The size of *inSensitive.sensitive.data* is limited to be no larger than MAX_SYM_DATA.

- 4) If *inSensitive.sensitive.data* is an Empty Buffer, a TPM-generated key value that is the size of the digest produced by the *nameAlg* in *inPublic* is placed in TPMT_SENSITIVE.*sensitive.bits*.
- 5) A TPM-generated obfuscation value that is the size of the digest produced by the *nameAlg* of *inPublic* is placed in TPMT_SENSITIVE.*seedValue*.
- 6) The TPMT_PUBLIC.*unique.keyedHash* value for the new object is then generated, as shown in equation (1) above, by hashing the key and obfuscation values in the TPMT_SENSITIVE with the *nameAlg* of the object.

For TPM2_Load(), the TPM will apply normal symmetric protections to the created TPMT_SENSITIVE to create *outPublic*.

NOTE 8 The encryption key is derived from the symmetric seed in the sensitive area of the parent.

In addition to *outPublic* and *outPrivate*, the TPM will build a TPMS_CREATION_DATA structure for the object. TPMS_CREATION_DATA.*outsideInfo* is set to *outsideInfo*. This structure is returned in *creationData*. Additionally, the digest of this structure is returned in *creationHash*, and, finally, a TPMT_TK_CREATION is created so that the association between the creation data and the object may be validated by TPM2_CertifyCreation().

NOTE 9 *creationData* and *creationHash* provide information about the parent storage keys back to the hierarchy root. They do not contain information about the object. *creationTicket* includes the object Name and thus the linkage between the object and its ancestors.

If the object being created is a Storage Key and *fixedParent* is SET in the attributes of *inPublic*, then the symmetric algorithms and parameters of *inPublic* are required to match those of the parent. The algorithms that must match are *inPublic.nameAlg*, and the values in *inPublic.parameters* that select the symmetric scheme. If *inPublic.nameAlg* does not match, the TPM shall return TPM_RC_HASH. If the symmetric scheme of the key does not match, the parent, the TPM shall return TPM_RC_SYMMETRIC. The TPM shall not use different response code to differentiate between mismatches of the components of *inPublic.parameters*. However, after this verification, when using the scheme to encrypt child objects, the TPM ignores the symmetric mode and uses TPM_ALG_CFB.

NOTE 9 The symmetric scheme is a TPMT_SYM_DEF_OBJECT. In a symmetric block cipher, it is at *inPublic.parameters.symDetail.sym* and in an asymmetric object is at *inPublic.parameters.asymDetail.symmetric*.

NOTE 10 Prior to revision 01.34, the parent asymmetric algorithms were also checked for *fixedParent* storage keys.

12.1.2 Command and Response

Table 19 — TPM2_Create Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_Create
TPMI_DH_OBJECT	@parentHandle	handle of parent for new object Auth Index: 1 Auth Role: USER
TPM2B_SENSITIVE_CREATE	inSensitive	the sensitive data
TPM2B_PUBLIC	inPublic	the public template
TPM2B_DATA	outsideInfo	data that will be included in the creation data for this object to provide permanent, verifiable linkage between this object and some object owner data
TPML_PCR_SELECTION	creationPCR	PCR that will be used in creation data

TPM2B_DIGEST	creationHash	digest of <i>creationData.creationData</i> using <i>nameAlg</i> of <i>outPublic</i>
TPMT_TK_CREATION	creationTicket	ticket used by TPM2_CertifyCreation() to validate that the creation data was produced by the TPM

12.1.3 Detailed Actions

[[Create]]

12.2 TPM2_Load

12.2.1 General Description

This command is used to load objects into the TPM. This command is used when both a TPM2B_PUBLIC and TPM2B_PRIVATE are to be loaded. If only a TPM2B_PUBLIC is to be loaded, the TPM2_LoadExternal command is used.

NOTE 1 Loading an object is not the same as restoring a saved object context.

The object's TPMA_OBJECT attributes will be checked according to the rules defined in "TPMA_OBJECT" in TPM 2.0 Part 2 of this specification. If the Object is a not a *keyedHash* object, and the *sign* and *encrypt* attributes are CLEAR, the TPM shall return TPM_RC_ATTRIBUTES.

Objects loaded using this command will have a Name. The Name is the concatenation of *nameAlg* and the digest of the public area using the *nameAlg*.

NOTE 2 *nameAlg* is a parameter in the public area of the inPublic structure.

If *inPrivate.size* is zero, the load will fail.

The integrity value shall be checked before the private area is decrypted and unmarshalled.

NOTE 3 Checking the integrity before the data is decrypted and unmarshalled prevents attacks on the sensitive area by fuzzing the data and looking at the differences in the response codes.

The command returns a handle for the loaded object and the Name that the TPM computed for *inPublic.public* (that is, the digest of the TPMT_PUBLIC structure in *inPublic*).

NOTE 4 The TPM-computed Name is provided as a convenience to the caller for those cases where the caller does not implement the hash algorithms specified in the *nameAlg* of the object.

NOTE 5 The returned handle is associated with the object until the object is flushed (TPM2_FlushContext) or until the next TPM2_Startup.

For all objects, the size of the key in the sensitive area shall be consistent with the key size indicated in the public area or the TPM shall return TPM_RC_KEY_SIZE.

Before use, a loaded object shall be checked to validate that the public and sensitive portions are properly linked, cryptographically. Use of an object includes use in any policy command. If the parts of the object are not properly linked, the TPM shall return TPM_RC_BINDING. If a weak symmetric key is in the sensitive portion, the TPM shall return TPM_RC_KEY.

EXAMPLE 1 For a symmetric object, the unique value in the public area is the digest of the sensitive key and the obfuscation value.

EXAMPLE 2 For a two-prime RSA key, the remainder when dividing the public modulus by the private primes is zero and it is possible to form a private exponent from the two prime factors of the public modulus.

EXAMPLE 3 For an ECC key, the public point shall be $f(x)$ where x is the private key.

12.2.2 Command and Response

Table 21 — TPM2_Load Command

Type	Name	Description

TPM2B_NAME	name	Name of the loaded object

12.2.3 Detailed Actions

[[Load]]

12.3 TPM2_LoadExternal

12.3.1 General Description

This command is used to load an object that is not a Protected Object into the TPM. The command allows loading of a public area or both a public and sensitive area.

NOTE 1 Typical use for loading a public area is to allow the TPM to validate an asymmetric signature. Typical use for loading both a public and sensitive area is to allow the TPM to be used as a crypto accelerator.

Load of a public external object area allows the object to be associated with a hierarchy so that the correct algorithms may be used when creating tickets. The *hierarchy* parameter provides this association. If the public and sensitive portions of the object are loaded, *hierarchy* is required to be TPM_RH_NULL.

NOTE 2 If both the public and private portions of an object are loaded, the object is not allowed to appear to be part of a hierarchy.

The object's TPMA_OBJECT attributes will be checked according to the rules defined in "TPMA_OBJECT" in TPM 2.0 Part 2. In particular, *fixedTPM*, *fixedParent*, and *restricted* shall be CLEAR if *inPrivate* is not the Empty Buffer.

NOTE 3 The duplication status of a public key needs to be able to be the same as the full key which may be resident on a different TPM. If both the public and private parts of the key are loaded, then it is not possible for the key to be either *fixedTPM* or *fixedParent* since its private area would not be available in the clear to load.

Objects loaded using this command will have a Name. The Name is the *nameAlg* of the object concatenated with the digest of the public area using the *nameAlg*. The Qualified Name for the object will be the same as its Name. The TPM will validate that the *authPolicy* is either the size of the digest produced by *nameAlg* or the Empty Buffer.

NOTE 4 If *nameAlg* is TPM_ALG_NULL, then the Name is the Empty Buffer. When the authorization value for an object with no Name is computed, no Name value is included in the HMAC. To ensure that these unnamed entities are not substituted, it is recommended that they have an *authValue* that is statistically unique.

NOTE 5 The digest size for TPM_ALG_NULL is zero.

If the *nameAlg* is TPM_ALG_NULL, the TPM cannot, and thus shall not verify the integrity HMAC on the sensitive area. The TPM will still perform cryptographic validity checks (e.g., the ECC public point is on the curve) and public/private keypair consistency checks.

The TPM will validate that the size of the key in the sensitive area is consistent with the size indicated in the public area. If it is not, the TPM shall return TPM_RC_KEY_SIZE.

NOTE 6 For an ECC object, the TPM will verify that the public key is on the curve of the key before the public area is used.

If *nameAlg* is not TPM_ALG_NULL, then the same consistency checks between *inPublic* and *inPrivate* are made as for TPM2_Load().

NOTE 7 Consistency checks are necessary because an object with a Name needs to have the public and sensitive portions cryptographically bound so that an attacker cannot mix public and sensitive areas.

The command returns a handle for the loaded object and the Name that the TPM computed for *inPublic.public* (that is, the TPMT_PUBLIC structure in *inPublic*).

NOTE 8 The TPM-computed Name is provided as a convenience to the caller for those cases where the caller does not implement the hash algorithm specified in the *nameAlg* of the object.

The *hierarchy* parameter associates the external object with a hierarchy. External objects are flushed when their associated hierarchy is disabled. If *hierarchy* is TPM_RH_NULL, the object is part of no hierarchy, and there is no implicit flush.

If *hierarchy* is TPM_RH_NULL or *nameAlg* is TPM_ALG_NULL, a ticket produced using the object shall be a NULL Ticket.

EXAMPLE If a key is loaded with *hierarchy* set to TPM_RH_NULL, then TPM2_VerifySignature() will produce a NULL Ticket of the required type.

External objects are Temporary Objects. The saved external object contexts shall be invalidated at the next TPM Reset.

If a weak symmetric key is in the sensitive area, the TPM shall return TPM_RC_KEY.

For an RSA key, the private exponent is computed using the two prime factors of the public modulus. One of the primes is P, and the second prime (Q) is found by dividing the public modulus by P. A TPM may return an error (TPM_RC_BINDING) if the bit size of P and Q are not the same.”

12.3.2 Command and Response

Table 23 — TPM2_LoadExternal Command

12.3.3 Detailed Actions

[[LoadExternal]]

12.4 TPM2_ReadPublic

12.4.1 General Description

This command allows access to the public area of a loaded object.

Use of the *objectHandle* does not require authorization.

NOTE Since the caller is not likely to know the public area of the object associated with *objectHandle*, it would not be possible to include the Name associated with *objectHandle* in the *cpHash* computation.

If *objectHandle* references a sequence object, the TPM shall return TPM_RC_SEQUENCE.

12.4.2 Command and Response

Table 25 — TPM2_ReadPublic Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS if an audit or encrypt session is present; otherwise, TPM_ST_NO_SESSIONS

TPM2B_NAME	qualifiedName	the Qualified Name of the object

12.4.3 Detailed Actions

[[ReadPublic]]

12.5 TPM2_ActivateCredential

12.5.1 General Description

This command enables the association of a credential with an object in a way that ensures that the TPM has validated the parameters of the credentialed object.

If both the public and private portions of *activateHandle* and *keyHandle* are not loaded, then the TPM shall return TPM_RC_AUTH_UNAVAILABLE.

If *keyHandle* is not a Storage Key, then the TPM shall return TPM_RC_TYPE.

Authorization for *activateHandle* requires the ADMIN role.

The key associated with *keyHandle* is used to recover a seed from secret, which is the encrypted seed. The Name of the object associated with *activateHandle*, and the recovered seed are used in a KDF to recover the symmetric key. The recovered seed (but not the Name) is used in a KDF to recover the HMAC key.

The HMAC is used to validate that the *credentialBlob* is associated with *activateHandle* and that the data in *credentialBlob* has not been modified. The linkage to the object associated with *activateHandle* is achieved by including the Name in the HMAC calculation.

If the integrity checks succeed, *credentialBlob* is decrypted and returned as *certInfo*.

NOTE The output *certInfo* parameter is an application defined value. It is typically a symmetric key or seed that is used to decrypt a certificate. See the TPM2_MakeCredential *credential* input parameter.

12.5.2 Command and Response

Table 27 — TPM2_ActivateCredential Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS

TPM2B_DIGEST	certInfo	the decrypted information the data should be no larger than the size of the digest of the <i>nameAlg</i> associated with <i>keyHandle</i>

12.5.3 Detailed Actions

[[ActivateCredential]]

12.6 TPM2_MakeCredential

12.6.1 General Description

This command allows the TPM to perform the actions required of a Certificate Authority (CA) in creating a TPM2B_ID_OBJECT containing an activation credential.

NOTE The input *credential* parameter is an application defined value. It might be a symmetric key or seed that is used to encrypt a certificate, or it might be a challenge such as a random number. See the TPM2_ActivateCredential *certInfo* output parameter.

The TPM will produce a TPM2B_ID_OBJECT according to the methods in “Credential Protection” in TPM 2.0 Part 1.

The loaded public area referenced by *handle* is required to be the public area of a Storage key, otherwise, the credential cannot be properly sealed.

This command does not use any TPM secrets, nor does it require authorization. It is a convenience function, using the TPM to perform cryptographic calculations that could be done externally.

12.6.2 Command and Response

Table 29 — TPM2_MakeCredential Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS if an audit, encrypt, or decrypt session is present; otherwise, TPM_ST_NO_SESSIONS

12.6.3 Detailed Actions

[[MakeCredential]]

12.7 TPM2_Unseal

12.7.1 General Description

This command returns the data in a loaded Sealed Data Object.

NOTE 1 A random, TPM-generated, Sealed Data Object can be created by the TPM with TPM2_Create() or TPM2_CreatePrimary() using the template for a Sealed Data Object.

NOTE 2 TPM 1.2 hard coded PCR authorization. TPM 2.0 PCR authorization requires a policy.

The returned value may be encrypted using authorization session encryption.

If either *restricted*, *decrypt*, or *sign* is SET in the attributes of *itemHandle*, then the TPM shall return TPM_RC_ATTRIBUTES. If the *type* of *itemHandle* is not TPM_ALG_KEYEDHASH, then the TPM shall return TPM_RC_TYPE.

12.7.3 Detailed Actions

[[Unseal]]

12.8 TPM2_ObjectChangeAuth

12.8.1 General Description

This command is used to change the authorization secret for a TPM-resident object.

If successful, a new private area for the TPM-resident object associated with *objectHandle* is returned, which includes the new authorization value.

This command does not change the authorization of the TPM-resident object on which it operates. Therefore, the old authValue (of the TPM-resident object) is used when generating the response HMAC key if required.

NOTE 1 The returned *outPrivate* will need to be loaded before the new authorization will apply.

NOTE 2 The TPM-resident object can be persistent and changing the authorization value of the persistent object could prevent other users from accessing the object. This is why this command does not change the TPM-resident object.

EXAMPLE If a persistent key is being used as a Storage Root Key and the authorization of the key is a well-known value so that the key can be used generally, then changing the authorization value in the persistent key would deny access to other users.

This command may not be used to change the authorization value for an NV Index or a Primary Object.

NOTE 3 If an NV Index is to have a new authorization, it is done with TPM2_NV_ChangeAuth().

NOTE 4 If a Primary Object is to have a new authorization, it needs to be recreated (TPM2_CreatePrimary()).

12.8.3 Detailed Actions

[[ObjectChangeAuth]]

12.9 TPM2_CreateLoaded

12.9.1 General Description

This command creates an object and loads it in the TPM. This command allows creation of any type of object (Primary, Ordinary, or Derived) depending on the type of *parentHandle*. If *parentHandle* references a Primary Seed, then a Primary Object is created; if *parentHandle* references a Storage Parent, then an Ordinary Object is created; and if *parentHandle* references a Derivation Parent, then a Derived Object is generated.

The input validation is the same as for TPM2_Create() and TPM2_CreatePrimary() with one exception: when *parentHandle* references a Derivation Parent, then *sensitiveDataOrigin* in *inPublic* is required to be CLEAR.

NOTE 1 In the general descriptions of TPM2_Create() and TPM2_CreatePrimary() the validations refer to a TPMT_PUBLIC structure that is in *inPublic*. For TPM2_CreateLoaded(), *inPublic* is a TPM2B_TEMPLATE that can contain a TPMT_PUBLIC that is used for object creation. For object derivation, the *unique* field can contain a *label* and *context* that are used in the derivation process. To allow both the TPMT_PUBLIC and the derivation variation, a TPM2B_TEMPLATE is used. When referring to the checks in TPM2_Create() and TPM2_CreatePrimary(), TPM2B_TEMPLATE should be assumed to contain a TPMT_PUBLIC.

If *parentHandle* references a Derivation Parent, then the TPM may return TPM_RC_TYPE if the key type to be generated is an RSA key.

If *parentHandle* references a Derivation Parent or a Primary Seed, then *outPrivate* will be an Empty Buffer.

NOTE 2 Returning *outPrivate* would imply that the returned primary or derived object can be loaded, and it cannot. It can only be re-derived.

A primary key cannot be loaded is because loading a key is a way to attack the protections of a key (e.g., using DPA). A saved context for a primary object is protected. The TPM will go into failure mode if the integrity of a saved context is good but the fingerprint doesn't decrypt. It is not possible to have these protections on loaded objects because this would be a simple way for an attacker to put the TPM into failure mode. Saved contexts are assumed to be under control of the driver but loaded objects are not.

If all objects were derived from their parents, then load could not be used as an attack. However, that would preclude importation of objects and key hierarchies.

NOTE 3 Unlike TPM2_Create() and TPM2_CreatePrimary(), this command does not return creation data. If creation data is needed, then TPM2_Create() or TPM2_CreatePrimary() should be used.

NOTE 4 If *parentHandle* references a Derivation Parent, the bits of the Label and Context are used in the creation of the key. This differs from TPM2_CreatePrimary(), where the bits of the template are used. This means that different templates (specifically, different public attributes) will result in the same key for the same Label and Context.

12.9.3 Detailed Actions

[[CreateLoaded]]

13 Duplication Commands

13.1 TPM2_Duplicate

13.1.1 General Description

This command duplicates a loaded object so that it may be used in a different hierarchy. The new parent key for the duplicate may be on the same or different TPM or TPM_RH_NULL. Only the public area of *newParentHandle* is required to be loaded.

NOTE 1 Since the new parent may only be extant on a different TPM, it is likely that the new parent's sensitive area could not be loaded in the TPM from which *objectHandle* is being duplicated.

If *encryptedDuplication* is SET in the object being duplicated, then the TPM shall return TPM_RC_SYMMETRIC if *symmetricAlg.algorithm* is TPM_ALG_NULL or TPM_RC_HIERARCHY if *newParentHandle* is TPM_RH_NULL.

The authorization for this command shall be with a policy session.

If *fixedParent* of *objectHandle*→*attributes* is SET, the TPM shall return TPM_RC_ATTRIBUTES. If *objectHandle*→*nameAlg* is TPM_ALG_NULL, the TPM shall return TPM_RC_TYPE.

The *policySession*→*commandCode* parameter in the policy session is required to be TPM_CC_Duplicate to indicate that authorization for duplication has been provided. This indicates that the policy that is being used is a policy that is for duplication, and not a policy that would approve another use. That is, authority to use an object does not grant authority to duplicate the object.

The policy is likely to include cpHash in order to restrict where duplication can occur. If TPM2_PolicyCpHash() has been executed as part of the policy, the *policySession*→*cpHash* is compared to the cpHash of the command.

If TPM2_PolicyDuplicationSelect() has been executed as part of the policy, the *policySession*→*nameHash* is compared to

$$\mathbf{H}_{policyAlg}(objectHandle \rightarrow Name || newParentHandle \rightarrow Name) \quad (2)$$

If the compared hashes are not the same, then the TPM shall return TPM_RC_POLICY_FAIL.

NOTE 2 It is allowed that *policySession*→*nameHash* and *policySession*→*cpHash* share the same memory space.

NOTE 3 A duplication policy is not required to have either TPM2_PolicyDuplicationSelect() or TPM2_PolicyCpHash() as part of the policy. If neither is present, then the duplication policy may be satisfied with a policy that only contains TPM2_PolicyCommandCode(*code* = TPM_CC_Duplicate).

The TPM shall follow the process of encryption defined in the "Duplication" subclause of "Protected Storage Hierarchy" in TPM 2.0 Part 1.

13.1.2 Command and Response

Table 37 — TPM2_Duplicate Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_Duplicate

TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode	
TPM2B_DATA	encryptionKeyOut	If the caller provided an encryption key or if <i>symmetricAlg</i> was TPM_ALG_NULL, then this will be the Empty Buffer; otherwise, it shall contain the TPM-generated, symmetric encryption key for the inner wrapper.
TPM2B_PRIVATE	duplicate	private area that may be encrypted by <i>encryptionKeyIn</i> ; and may be doubly encrypted
TPM2B_ENCRYPTED_SECRET	outSymSeed	seed protected by the asymmetric algorithms of new parent (NP)

13.1.3 Detailed Actions

[[Duplicate]]

13.2 TPM2_Rewrap

13.2.1 General Description

This command allows the TPM to serve in the role as a Duplication Authority. If proper authorization for use of the *oldParent* is provided, then an HMAC key and a symmetric key are recovered from *inSymSeed* and used to integrity check and decrypt *inDuplicate*. A new protection seed value is generated according to the methods appropriate for *newParent* and the blob is re-encrypted and a new integrity value is computed. The re-encrypted blob is returned in *outDuplicate*, and the symmetric key returned in *outSymKey*.

In the rewrap process, L is “DUPLICATE” (see TPM 2.0 Part 1, *Terms and Definitions*).

If *inSymSeed* has a zero length, then *oldParent* is required to be TPM_RH_NULL and no decryption of *inDuplicate* takes place.

If *newParent* is TPM_RH_NULL, then no encryption is performed on *outDuplicate*. *outSymSeed* will have a zero length (see TPM 2.0 Part 2, *encryptedDuplication*).

13.2.2 Command and Response

13.2.3 Detailed Actions

[[Rewrap]]

13.3 TPM2_Import

13.3.1 General Description

This command allows an object to be encrypted using the symmetric encryption values of a Storage Key. After encryption, the object may be loaded and used in the new hierarchy. The imported object (*duplicate*) may be singly encrypted, multiply encrypted, or unencrypted.

If *fixedTPM* or *fixedParent* is SET in *objectPublic*, the TPM shall return TPM_RC_ATTRIBUTES.

If *encryptedDuplication* is SET in the object referenced by *parentHandle* and *encryptedDuplication* is CLEAR in *objectPublic*, the TPM may return TPM_RC_ATTRIBUTES.

If *encryptedDuplication* is SET in *objectPublic*, then *inSymSeed* and *encryptionKey* shall not be Empty buffers (TPM_RC_ATTRIBUTES). Recovery of the sensitive data of the object occurs in the TPM in a multi-step process in the following order:

a) If *inSymSeed* has a non-zero size:

- 1) The asymmetric parameters and private key of *parentHandle* are used to recover the seed used in the creation of the HMAC key and encryption keys used to protect the duplication blob.

NOTE 1 When recovering the seed from *inSymSeed*, *L* is "DUPLICATE".

- 2) The integrity value in *duplicate.buffer.integrityOuter* is used to verify the integrity of the data blob, which is the remainder of *duplicate.buffer* (TPM_RC_INTEGRITY).

NOTE 2 The data blob will contain a TPMT_SENSITIVE and can contain a TPM2B_DIGEST for the *innerIntegrity*.

- 3) The symmetric key recovered in 1) is used to decrypt the data blob.

NOTE 3 Checking the integrity before the data is used prevents attacks on the sensitive area by fuzzing the data and looking at the differences in the response codes.

b) If *encryptionKey* is not an Empty Buffer:

- 1) Use *encryptionKey* to decrypt the inner blob.
- 2) Use the TPM2B_DIGEST at the start of the inner blob to verify the integrity of the inner blob (TPM_RC_INTEGRITY).

c) Unmarshal the sensitive area

NOTE 4 It is not necessary to validate that the sensitive area data is cryptographically bound to the public area other than that the Name of the public area is included in the HMAC. However, if the binding is not validated by this command, the binding must be checked each time the object is loaded. For an object that is imported under a parent with *fixedTPM* SET, binding need only be checked at import. If the parent has *fixedTPM* CLEAR, then the binding needs to be checked each time the object is loaded, or before the TPM performs an operation for which the binding affects the outcome of the operation (for example, TPM2_PolicySigned() or TPM2_Certify()).

Similarly, if the new parent's *fixedTPM* is set, the *encryptedDuplication* state need only be checked at import.

If the new parent is not *fixedTPM*, then that object will be loadable on any TPM (including SW versions) on which the new parent exists. This means that, each time an object is loaded under a parent that is not *fixedTPM*, it is necessary to validate all of the properties of that object. If the parent is *fixedTPM*, then the new private blob is integrity protected by the TPM that "owns" the parent. So, it is sufficient to validate the object's properties (attribute and public-private binding) on import and not again.

If a weak symmetric key is being imported, the TPM shall return TPM_RC_KEY.

After integrity checks and decryption, the TPM will create a new symmetrically encrypted private area using the encryption key of the parent.

NOTE 5 The symmetric re-encryption is the normal integrity generation and symmetric encryption applied to a child object.

NOTE 6 Revision 01.16 of this specification required the ECC private key in *duplicate* to be padded.

13.3.2 Command and Response

13.3.3 Detailed Actions

[[Import]]

14 Asymmetric Primitives

14.1 Introduction

The commands in clause 14 provide low-level primitives for access to the asymmetric algorithms implemented in the TPM. Many of these commands are only allowed if the asymmetric key is an unrestricted key.

14.2 TPM2_RSA_Encrypt

14.2.1 General Description

This command performs RSA encryption using the indicated padding scheme according to IETF RFC 8017. If the *scheme* of *keyHandle* is TPM_ALG_NULL, then the caller may use *inScheme* to specify the padding scheme. If *scheme* of *keyHandle* is not TPM_ALG_NULL, then *inScheme* shall either be TPM_ALG_NULL or be the same as *scheme* (TPM_RC_SCHEME).

The key referenced by *keyHandle* is required to be an RSA key (TPM_RC_KEY).

The three types of allowed padding are:

- 1) TPM_ALG_OAEP – Data is OAEP padded as described in 7.1 of IETF RFC 8017 (PKCS#1). The only supported mask generation is MGF1.
- 2) TPM_ALG_RSAES – Data is padded as described in 7.2 of IETF RFC 8017 (PKCS#1).
- 3) TPM_ALG_NULL – Data is not padded by the TPM and the TPM will treat *message* as an unsigned integer and perform a modular exponentiation of *message* using the public exponent of the key referenced by *keyHandle*. This scheme is only used if both the *scheme* in the key referenced by *keyHandle* is TPM_ALG_NULL, and the *inScheme* parameter of the command is TPM_ALG_NULL. The input value cannot be larger than the public modulus of the key referenced by *keyHandle*.

Table 43 — Padding Scheme Selection

<i>keyHandle</i> → <i>scheme</i>	<i>inScheme</i>	padding scheme used
TPM_ALG_NULL	TPM_ALG_NULL	none
	TPM_ALG_RSAES	RSAES
	TPM_ALG_OAEP	OAEP
TPM_ALG_RSAES	TPM_ALG_NULL	RSAES
	TPM_ALG_RSAES	RSAES
	TPM_ALG_OAEP	error (TPM_RC_SCHEME)
TPM_ALG_OAEP	TPM_ALG_NULL	OAEP
	TPM_ALG_RSAES	error (TPM_RC_SCHEME)
	TPM_ALG_OAEP	OAEP

After padding, the data is RSAEP encrypted according to 5.1.1 of IETF RFC 8017 (PKCS#1).

If *inScheme* is used, and the scheme requires a hash algorithm it may not be TPM_ALG_NULL.

NOTE 1 Because only the public portion of the key needs to be loaded for this command, the caller can manipulate the attributes of the key in any way desired. As a result, the TPM shall not check the consistency of the attributes. The only property checking is that the key is an RSA key and that the padding scheme is supported.

The *message* parameter is limited in size by the padding scheme according to the following table:

Table 44 — Message Size Limits Based on Padding

Scheme	Maximum Message Length (<i>mLen</i>) in Octets	Comments
TPM_ALG_OAEP	$mLen \leq k - 2hLen - 2$	
TPM_ALG_RSAES	$mLen \leq k - 11$	
TPM_ALG_NULL	$mLen \leq k$	The numeric value of the message must be less than the numeric value of the public modulus (<i>n</i>).
NOTES <i>k</i> := the number of bytes in the public modulus <i>hLen</i> := the number of octets in the digest produced by the hash algorithm used in the process		

The *label* parameter is optional. If provided (*label.size* != 0) then the TPM shall return TPM_RC_VALUE if the last octet in *label* is not zero. The terminating octet of zero is included in the *label* used in the padding scheme.

NOTE 2 If the scheme does not use a label, the TPM will still verify that label is properly formatted if label is present.

NOTE 3 Specifications before version 1.54 stated that *label* is truncated after the first zero octet. Applications should not include embedded zero bytes for compatibility.

The function returns padded and encrypted value *outData*.

The *message* parameter in the command may be encrypted using parameter encryption.

NOTE 4 Only the public area of *keyHandle* is required to be loaded. A public key can be loaded with any desired scheme. If the scheme is to be changed, a different public area needs to be loaded.

14.2.2 Command and Response

Table 45 — TPM2_RSA_Encrypt Command

TPM_RC	responseCode	
TPM2B_PUBLIC_KEY_RSA	outData	encrypted output

14.2.3 Detailed Actions

[[RSA_Encrypt]]

14.3 TPM2_RSA_Decrypt

14.3.1 General Description

This command performs RSA decryption using the indicated padding scheme according to IETF RFC 8017 ((PKCS#1).

The scheme selection for this command is the same as for TPM2_RSA_Encrypt() and is shown in Table 43.

The key referenced by *keyHandle* shall be an RSA key (TPM_RC_KEY) with *restricted* CLEAR and *decrypt* SET (TPM_RC_ATTRIBUTES).

This command uses the private key of *keyHandle* for this operation and authorization is required.

The TPM will perform a modular exponentiation of ciphertext using the private exponent associated with *keyHandle* (this is described in IETF RFC 8017 (PKCS#1), clause 5.1.2). It will then validate the padding according to the selected scheme. If the padding checks fail, TPM_RC_VALUE is returned. Otherwise, the data is returned with the padding removed. If no padding is used, the returned value is an unsigned integer value that is the result of the modular exponentiation of *cipherText* using the private exponent of *keyHandle*. The returned value may include leading octets zeros so that it is the same size as the public modulus. For the other padding schemes, the returned value will be smaller than the public modulus but will contain all the data remaining after padding is removed and this may include leading zeros if the original encrypted value contained leading zeros.

If a label is used in the padding process of the scheme during encryption, the *label* parameter is required to be present in the decryption process and *label* is required to be the same in both cases. If label is not the same, the decrypt operation is very likely to fail ((TPM_RC_VALUE). If *label* is present (*label.size* != 0), it shall be a byte stream whose last byte is zero or the TPM will return TPM_RC_VALUE.

NOTE The size of *label* includes the terminating null.

The *message* parameter in the response may be encrypted using parameter encryption.

If *inScheme* is used, and the scheme requires a hash algorithm it may not be TPM_ALG_NULL.

If the scheme does not require a label, the value in *label* is not used but the size of the label field is checked for consistency with the indicated data type (TPM2B_DATA). That is, the field may not be larger than allowed for a TPM2B_DATA.

14.3.3 Detailed Actions

[[RSA_Decrypt]]

14.4 TPM2_ECDH_KeyGen

14.4.1 General Description

This command uses the TPM to generate an ephemeral key pair (d_e, Q_e) where $Q_e := [d_e]G$. It uses the private ephemeral key and a loaded public key (Q_S) to compute the shared secret value $(P := [hd_e]Q_S)$.

keyHandle shall refer to a loaded, ECC key (TPM_RC_KEY). The sensitive portion of this key need not be loaded.

The curve parameters of the loaded ECC key are used to generate the ephemeral key.

NOTE This function is the equivalent of encrypting data to another object's public key. The *seed* value is used in a KDF to generate a symmetric key and that key is used to encrypt the data. Once the data is encrypted and the symmetric key discarded, only the object with the private portion of the *keyHandle* will be able to decrypt it.

The *zPoint* in the response may be encrypted using parameter encryption.

14.4.2 Command and Response

14.4.3 Detailed Actions

[[ECDH_KeyGen]]

14.5 TPM2_ECDH_ZGen

14.5.1 General Description

This command uses the TPM to recover the Z value from a public point (Q_B) and a private key (d_s). It will perform the multiplication of the provided *inPoint* (Q_B) with the private key (d_s) and return the coordinates of the resultant point ($Z = (x_Z, y_Z) := [hd_s]Q_B$; where h is the cofactor of the curve).

keyHandle shall refer to a loaded, ECC key (TPM_RC_KEY) with the *restricted* attribute CLEAR and the *decrypt* attribute SET (TPM_RC_ATTRIBUTES).

NOTE While TPM_RC_ATTRIBUTES is preferred, TPM_RC_KEY is acceptable.

The *scheme* of the key referenced by *keyHandle* is required to be either TPM_ALG_ECDH or TPM_ALG_NULL (TPM_RC_SCHEME).

inPoint is required to be on the curve of the key referenced by *keyHandle* (TPM_RC_ECC_POINT).

The parameters of the key referenced by *keyHandle* are used to perform the point multiplication.

14.6 TPM2_ECC_Parameters

14.6.1 General Description

This command returns the parameters of an ECC curve identified by its TCG-assigned *curveID*.

The value returned is the same as that from the TCG Algorithm Registry but may not be the same size.

EXAMPLE The value 01 can be returned as 00000001.

[[ECC_Parameters]]

14.7 TPM2_ZGen_2Phase

14.7.1 General Description

This command supports two-phase key exchange protocols. The command is used in combination with TPM2_EC_Ephemeral(). TPM2_EC_Ephemeral() generates an ephemeral key and returns the public point of that ephemeral key along with a numeric value that allows the TPM to regenerate the associated private key.

The input parameters for this command are a static public key ($inQsU$), an ephemeral key ($inQeU$) from party B, and the *commitCounter* returned by TPM2_EC_Ephemeral(). The TPM uses the counter value to regenerate the ephemeral private key ($d_{e,v}$) and the associated public key ($Q_{e,v}$). *keyA* provides the static ephemeral elements $d_{s,v}$ and $Q_{s,v}$. This provides the two pairs of ephemeral and static keys that are required for the schemes supported by this command.

The TPM will compute Z or Z_s and Z_e according to the selected scheme. If the scheme is not a two-phase key exchange scheme or if the scheme is not supported, the TPM will return TPM_RC_SCHEME.

It is an error if $inQsB$ or $inQeB$ are not on the curve of *keyA* (TPM_RC_ECC_POINT).

The two-phase key schemes that were assigned an algorithm ID as of the time of the publication of this specification are TPM_ALG_ECDH, TPM_ALG_ECMQV, and TPM_ALG_SM2.

If this command is supported, then support for TPM_ALG_ECDH is required. Support for TPM_ALG_ECMQV or TPM_ALG_SM2 is optional.

NOTE 1 If SM2 is supported and this command is supported, then the implementation is required to support the key exchange protocol of SM2, part 3.

For TPM_ALG_ECDH *outZ1* will be Z_s and *outZ2* will be Z_e as defined in clause 6.1.1.2 of SP800-56A.

NOTE 2 An unrestricted decryption key using ECDH can be used in either TPM2_ECDH_ZGen() or TPM2_ZGen_2Phase as the computation done with the private part of *keyA* is the same in both cases.

For TPM_ALG_ECMQV or TPM_ALG_SM2 *outZ1* will be Z and *outZ2* will be an Empty Point.

NOTE 3 An Empty Point has two Empty Buffers as coordinates meaning the minimum *size* value for *outZ2* will be four.

If the input scheme is TPM_ALG_ECDH, then *outZ1* will be Z_s and *outZ2* will be Z_e . For schemes like MQV (including SM2), *outZ1* will contain the computed value and *outZ2* will be an Empty Point.

NOTE 4 The Z values returned by the TPM are a full point and not just an x-coordinate.

If a computation of either Z produces the point at infinity, then the corresponding Z value will be an Empty Point.

14.7.3 Detailed Actions

[[ZGen_2Phase]]

14.8 TPM2_ECC_Encrypt

14.8.1 General Description

This command performs ECC encryption as described in Part 1, Annex C.

The key referenced by *keyHandle* (*key*) is required to be an ECC key (TPM_RC_KEY).

The TPM does not verify the *objectAttributes* of *key*.

NOTE 1 The TPM cannot check the integrity of *objectAttributes* when only the public portion of *key* is loaded.

If the default key scheme is TPM_ALG_NULL, an appropriate *inScheme* is required. If the default key scheme is not TPM_ALG_NULL, the key scheme and *inScheme* must be the same, and the scheme must be a valid encryption scheme.

NOTE 2 The key scheme and input scheme are checked in the same way for both this command and for TPM2_ECC_Decrypt(). This consistency is to simplify the TPM.

As determined by the encryption scheme, the function returns a public ephemeral key (C1), encrypted data (C2), and an integrity value (C3).

The *plainText* parameter in the command may be encrypted using parameter encryption.

NOTE 3 TPM2_ECC_Encrypt() was added in revision 01.61.

14.8.2 Command and Response

14.9 TPM2_ECC_Decrypt

14.9.1 General Description

This command performs ECC decryption.

The key referenced by *keyHandle* shall be an ECC key (TPM_RC_KEY) with *restricted* CLEAR and *decrypt* SET (TPM_RC_ATTRIBUTES).

This command uses the private key of *keyHandle* for this operation and authorization is required.

If the default key scheme is TPM_ALG_NULL, an appropriate *inScheme* is required. If the default key scheme is not TPM_ALG_NULL, the key scheme and *inScheme* must be the same, and the scheme must be a valid decryption scheme.

The function returns decrypted value *plainText*.

The *ciphertext* parameter in the command may be encrypted using parameter encryption.

NOTE TPM2_ECC_Decrypt() was added in revision 01.61.

[[ECC_Decrypt]]

15 Symmetric Primitives

15.1 Introduction

The commands in clause 15 provide low-level primitives for access to the symmetric algorithms implemented in the TPM that operate on blocks of data. These include symmetric encryption and decryption as well as hash and HMAC. All of the commands in this group are stateless. That is, they have no persistent state that is retained in the TPM when the command is complete.

For hashing, HMAC, and Events that require large blocks of data with retained state, the sequence commands are provided (see clause 17).

Some of the symmetric encryption/decryption modes use an IV. When an IV is used, it may be an initiation value or a chained value from a previous stage. The chaining for each mode is described in Table 61.

Table 61 — Symmetric Chaining Process

Mode	Chaining process
TPM_ALG_CTR	<p>The TPM will increment the entire IV provided by the caller. The next count value will be returned to the caller as <i>ivOut</i>. This can be the input value to the next encrypt or decrypt operation.</p> <p><i>ivIn</i> is required to be the size of a block encrypted by the selected algorithm and key combination. If the size of <i>ivIn</i> is not correct, the TPM shall return TPM_RC_SIZE.</p> <p>EXAMPLE 1 AES requires that <i>ivIn</i> be 128 bits (16 octets).</p> <p><i>ivOut</i> will be the size of a cipher block and not the size of the last encrypted block.</p> <p>NOTE <i>ivOut</i> will be the value of the counter after the last block is encrypted.</p> <p>EXAMPLE 2 If <i>ivIn</i> were 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00₁₆ and four data blocks were encrypted, <i>ivOut</i> will have a value of 00 00 00 00 00 00 00 00 00 00 00 00 00 00 04₁₆.</p> <p>All the bits of the IV are incremented as if it were an unsigned integer.</p>
TPM_ALG_OFB	<p>In Output Feedback (OFB), the output of the pseudo-random function (the block encryption algorithm) is XORed with a plaintext block to produce a ciphertext block. <i>ivOut</i> will be the value that was XORed with the last plaintext block. That value can be used as the <i>ivIn</i> for a next buffer.</p> <p><i>ivIn</i> is required to be the size of a block encrypted by the selected algorithm and key combination. If the size of <i>ivIn</i> is not correct, the TPM shall return TPM_RC_SIZE.</p> <p><i>ivOut</i> will be the size of a cipher block and not the size of the last encrypted block.</p>
TPM_ALG_CBC	<p>For Cipher Block Chaining (CBC), a block of ciphertext is XORed with the next plaintext block and that block is encrypted. The encrypted block is then input to the encryption of the next block. The last ciphertext block then is used as an IV for the next buffer.</p> <p>Even though the last ciphertext block is evident in the encrypted data, it is also returned in <i>ivOut</i>.</p> <p><i>ivIn</i> is required to be the size of a block encrypted by the selected algorithm and key combination. If the size of <i>ivIn</i> is not correct, the TPM shall return TPM_RC_SIZE.</p> <p><i>inData</i> is required to be an even multiple of the block encrypted by the selected algorithm and key combination. If the size of <i>inData</i> is not correct, the TPM shall return TPM_RC_SIZE.</p>
TPM_ALG_CFB	<p>Similar to CBC in that the last ciphertext block is an input to the encryption of the next block. <i>ivOut</i> will be the value that was XORed with the last plaintext block. That value can be used as the <i>ivIn</i> for a next buffer.</p> <p><i>ivIn</i> is required to be the size of a block encrypted by the selected algorithm and key combination. If the size of <i>ivIn</i> is not correct, the TPM shall return TPM_RC_SIZE.</p> <p><i>ivOut</i> will be the size of a cipher block and not the size of the last encrypted block.</p>
TPM_ALG_ECB	<p>Electronic Codebook (ECB) has no chaining. Each block of plaintext is encrypted using the key. ECB does not support chaining and <i>ivIn</i> shall be the Empty Buffer. <i>ivOut</i> will be the Empty Buffer.</p> <p><i>inData</i> is required to be an even multiple of the block encrypted by the selected algorithm and key combination. If the size of <i>inData</i> is not correct, the TPM shall return TPM_RC_SIZE.</p>

15.2 TPM2_EncryptDecrypt

15.2.1 General Description

NOTE 1 This command is deprecated, and TPM2_EncryptDecrypt2() is preferred. This should be reflected in platform-specific specifications.

NOTE 2 A TPM often will not implement this command for commercial reasons. Platform-specific specifications may provide additional details about this.

This command performs symmetric encryption or decryption using the symmetric key referenced by *keyHandle* and the selected mode.

keyHandle shall reference a symmetric cipher object (TPM_RC_KEY) with the *restricted* attribute CLEAR (TPM_RC_ATTRIBUTES).

If the *decrypt* parameter of the command is TRUE, then the *decrypt* attribute of the key is required to be SET (TPM_RC_ATTRIBUTES). If the *decrypt* parameter of the command is FALSE, then the *sign* attribute of the key is required to be SET (TPM_RC_ATTRIBUTES).

NOTE 3 A key is permitted to have both *decrypt* and *sign* SET.

If the mode of the key is not TPM_ALG_NULL, then that is the only mode that can be used with the key and the caller is required to set *mode* either to TPM_ALG_NULL or to the same mode as the key (TPM_RC_MODE). If the mode of the key is TPM_ALG_NULL, then the caller may set *mode* to any valid symmetric encryption/decryption mode but may not select TPM_ALG_NULL (TPM_RC_MODE).

If the TPM allows this command to be canceled before completion, then the TPM may produce incremental results and return TPM_RC_SUCCESS rather than TPM_RC_CANCELED. In such case, *outData* may be less than *inData*.

NOTE 4 If all the data is encrypted/decrypted, the size of *outData* will be the same as *inData*.

15.2.2 Command and Response

Table 62 — TPM2_EncryptDecrypt Command

15.2.3 Detailed Actions

[[EncryptDecrypt]]

15.3 TPM2_EncryptDecrypt2

15.3.1 General Description

This command is identical to TPM2_EncryptDecrypt(), except that the *inData* parameter is the first parameter. This permits *inData* to be parameter encrypted.

NOTE 1 In platform specification updates, this command is preferred and TPM2_EncryptDecrypt() should be deprecated.

NOTE 2 A TPM often will not implement this command for commercial reasons. Platform-specific specifications may provide additional details about this.

15.3.2 Command and Response

Table 64 — TPM2_EncryptDecrypt2 Command

[[EncryptDecrypt2]]

15.4 TPM2_Hash

15.4.1 General Description

This command performs a hash operation on a data buffer and returns the results.

NOTE If the data buffer to be hashed is larger than will fit into the TPM's input buffer, then the sequence hash commands will need to be used.

If the results of the hash will be used in a signing operation that uses a restricted signing key, then the ticket returned by this command can indicate that the hash is safe to sign.

If the digest is not safe to sign, then the TPM will return a TPMT_TK_HASHCHECK with the hierarchy set to TPM_RH_NULL and *digest* set to the Empty Buffer.

If *hierarchy* is TPM_RH_NULL, then *digest* in the ticket will be the Empty Buffer.

15.4.2 Command and Response

15.4.3 Detailed Actions

[[HASH]]

15.5 TPM2_HMAC

15.5.1 General Description

This command performs an HMAC on the supplied data using the indicated hash algorithm.

NOTE 1 A TPM can implement either TPM2_HMAC() or TPM2_MAC() but not both, as they have the same command code and there is no way to distinguish them. A TPM that supports TPM2_MAC() will support any code that was written to use TPM2_HMAC(), but a TPM that supports TPM2_HMAC() will not support a MAC based on symmetric block ciphers.

The caller shall provide proper authorization for use of *handle*.

If the *sign* attribute is not SET in the key referenced by *handle*, then the TPM shall return TPM_RC_KEY. If the key type is not TPM_ALG_KEYEDHASH then the TPM shall return TPM_RC_TYPE. If the key referenced by *handle* has the *restricted* attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 2 For symmetric signing with a restricted key, see TPM2_Sign(). TPM2_HMAC() has no ticket parameter, which is required with a restricted key.

If the default scheme of the key referenced by *handle* is not TPM_ALG_NULL, then the *hashAlg* parameter is required to be either the same as the key's default or TPM_ALG_NULL (TPM_RC_VALUE). If the default scheme of the key is TPM_ALG_NULL, then *hashAlg* is required to be a valid hash and not TPM_ALG_NULL (TPM_RC_VALUE) (see hash selection matrix in

Table 76).

NOTE 3 A key can only have both *sign* and *decrypt* SET if the key is unrestricted. When both *sign* and *decrypt* are set, there is no default scheme for the key and the hash algorithm must be specified.

15.5.2 Command and Response

15.5.3 Detailed Actions

[[HMAC]]

15.6 TPM2_MAC

15.6.1 General Description

This command performs an HMAC or a block cipher MAC on the supplied data using the indicated algorithm.

NOTE 1 A TPM can implement either TPM2_HMAC() or TPM2_MAC() but not both as they have the same command code and there is no way to distinguish them. A TPM that supports TPM2_MAC() will support any code that was written to use TPM2_HMAC() but a TPM that supports TPM2_HMAC () will not support a MAC based on symmetric block ciphers.

The caller shall provide proper authorization for use of *handle*.

If the *sign* attribute is not SET in the key referenced by *handle*, then the TPM shall return TPM_RC_KEY. If the key type is neither TPM_ALG_KEYEDHASH nor TPM_ALG_SYMCIPHER then the TPM shall return TPM_RC_TYPE. If the key referenced by *handle* has the *restricted* attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 2 For symmetric signing with a restricted key, see TPM2_Sign(). TPM2_MAC() has no ticket parameter, which is required with a restricted key.

If the default scheme or mode of the key referenced by *handle* is not TPM_ALG_NULL, then the *inScheme* parameter is required to be either the same as the key's default or TPM_ALG_NULL (TPM_RC_VALUE).

If the default scheme of an HMAC key is TPM_ALG_NULL, then *inScheme* is required to be a valid hash and not TPM_ALG_NULL (TPM_RC_VALUE) (see algorithm selection matrix in

Table 79).

If the default mode of a symmetric cipher key is TPM_ALG_NULL, then *inScheme* is required to be a valid block cipher mode for authentication and not TPM_ALG_NULL (TPM_RC_VALUE)

NOTE 3 A key can only have both sign and decrypt SET if the key is unrestricted. When both sign and decrypt are set, there is no default scheme for the key and *inScheme* may not be TPM_ALG_NULL.

NOTE 4 TPM2_MAC() was added in revision 01.43.

[[MAC]]

16 Random Number Generator

16.1 TPM2_GetRandom

16.1.1 General Description

This command returns the next *bytesRequested* octets from the random number generator (RNG).

NOTE 1 It is recommended that a TPM implement the RNG in a manner that would allow it to return RNG octets such that, as long as the value of *bytesRequested* is not greater than the maximum digest size, the frequency of *bytesRequested* being more than the number of octets available is an infrequent occurrence.

If *bytesRequested* is more than will fit into a TPM2B_DIGEST on the TPM, no error is returned but the TPM will only return as much data as will fit into a TPM2B_DIGEST buffer for the TPM.

NOTE 2 TPM2B_DIGEST is large enough to hold the largest digest that may be produced by the TPM. Because that digest size changes according to the implemented hashes, the maximum amount of data returned by this command is TPM implementation-dependent.

16.1.2 Command and Response

[[StirRandom]]

17 Hash/HMAC/Event Sequences

17.1 Introduction

All of the commands in this group are to support sequences for which an intermediate state must be maintained. For a description of sequences, see “Hash, MAC, and Event Sequences” in TPM 2.0 Part 1.

A TPM may implement either TPM2_HMAC_Start() or TPM2_MAC_Start() but not both as they have the same command code and there is no way to distinguish them. A TPM that supports TPM2_MAC_Start() will support any code that was written to use TPM2_HMAC_Start() but a TPM that supports TPM2_HMAC_Start() will not support a MAC based on symmetric block ciphers.

17.2 TPM2_HMAC_Start

17.2.1 General Description

This command starts an HMAC sequence. The TPM will create and initialize an HMAC sequence structure, assign a handle to the sequence, and set the *authValue* of the sequence object to the value in *auth*.

NOTE 1 The structure of a sequence object is vendor-dependent.

The caller shall provide proper authorization for use of *handle*.

If the *sign* attribute is not SET in the key referenced by *handle*, then the TPM shall return TPM_RC_KEY. If the key type is not TPM_ALG_KEYEDHASH then the TPM shall return TPM_RC_TYPE. If the key referenced by *handle* has the *restricted* attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 2 For symmetric signing with a restricted key, see TPM2_Sign(). TPM2_HMAC_Start() has no ticket parameter, which is required with a restricted key.

If the default scheme of the key referenced by *handle* is not TPM_ALG_NULL, then the *hashAlg* parameter is required to be either the same as the key’s default or TPM_ALG_NULL (TPM_RC_VALUE). If the default scheme of the key is TPM_ALG_NULL, then *hashAlg* is required to be a valid hash and not TPM_ALG_NULL (TPM_RC_VALUE).

Table 76 — Hash Selection Matrix

<i>handle</i> → <i>restricted</i> (key's restricted attribute)	<i>handle</i> → <i>scheme</i> (hash algorithm from key's scheme)	<i>hashAlg</i>	hash used
CLEAR (unrestricted)	TPM_ALG_NULL ⁽¹⁾	TPM_ALG_NULL	error ⁽¹⁾ (TPM_RC_VALUE)
CLEAR	TPM_ALG_NULL	valid hash	<i>hashAlg</i>

TPMI_DH_OBJECT	sequenceHandle	a handle to reference the sequence

17.2.3 Detailed Actions

[[HMAC_Start]]

17.3 TPM2_MAC_Start

17.3.1 General Description

This command starts a MAC sequence. The TPM will create and initialize a MAC sequence structure, assign a handle to the sequence, and set the *authValue* of the sequence object to the value in *auth*.

NOTE 1 The structure of a sequence object is vendor-dependent.

The caller shall provide proper authorization for use of *handle*.

If the *sign* attribute is not SET in the key referenced by *handle*, then the TPM shall return TPM_RC_KEY. If the key type is not TPM_ALG_KEYEDHASH or TPM_ALG_SYMCIPHER then the TPM shall return TPM_RC_TYPE. If the key referenced by *handle* has the *restricted* attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 2 For symmetric signing with a restricted key, see TPM2_Sign(). TPM2_MAC_Start() has no ticket parameter, which is required with a restricted key.

If the default scheme of the key referenced by *handle* is not TPM_ALG_NULL, then the *inScheme* parameter is required to be either the same as the key's default or TPM_ALG_NULL (TPM_RC_VALUE). If the default scheme of the key is TPM_ALG_NULL, then *inScheme* is required to be a valid hash or symmetric MAC scheme and not TPM_ALG_NULL (TPM_RC_VALUE).

Table 79 — Algorithm Selection Matrix

<i>handle</i> → <i>restricted</i> (key's restricted attribute)	<i>handle</i> → <i>scheme</i> (algorithm from key's scheme)	<i>inScheme</i>	algorithm used
CLEAR (unrestricted)	TPM_ALG_NULL ⁽¹⁾	TPM_ALG_NULL	error ⁽¹⁾ (TPM_RC_VALUE)
CLEAR	TPM_ALG_NULL	valid hash or symmetric MAC	<i>inScheme</i>
CLEAR	not TPM_ALG_NULL	TPM_ALG_NULL or same as <i>handle</i> → <i>scheme</i>	<i>handle</i> → <i>scheme</i>
CLEAR	not TPM_ALG_NULL	not TPM_ALG_NULL	error (TPM_RC_VALUE) if <i>inScheme</i> ≠ <i>handle</i> → <i>scheme</i>
SET (restricted)	don't care	don't care	TPM_RC_ATTRIBUTES
NOTES: 1) A hash algorithm is required for the HMAC. 2) hashAlg shall be TPM_ALG_NULL for handle referencing a CMAC key.			

NOTE 3 For a TPM_ALG_SYMCIPHER key, the symmetric block cipher algorithm is part of the key definition.

NOTE 4 TPM2_MAC_Start() was added in revision 01.43.

17.3.3 Detailed Actions

[[MAC_Start]]

17.4 TPM2_HashSequenceStart

17.4.1 General Description

This command starts a hash or an Event Sequence. If *hashAlg* is an implemented hash, then a hash sequence is started. If *hashAlg* is TPM_ALG_NULL, then an Event Sequence is started. If *hashAlg* is neither an implemented algorithm nor TPM_ALG_NULL, then the TPM shall return TPM_RC_HASH.

Depending on *hashAlg*, the TPM will create and initialize a Hash Sequence context or an Event Sequence context. Additionally, it will assign a handle to the context and set the *authValue* of the context to the value in *auth*. A sequence context for an Event (*hashAlg* = TPM_ALG_NULL) contains a hash context for each of the PCR banks implemented on the TPM.

17.4.2 Command and Response

17.4.3 Detailed Actions

[[HashSequenceStart]]

17.5 TPM2_SequenceUpdate

17.5.1 General Description

This command is used to add data to a hash or HMAC sequence. The amount of data in buffer may be any size up to the limits of the TPM.

NOTE 1 In all TPMs, a *buffer* size of 1,024 octets is allowed.

Proper authorization for the sequence object associated with *sequenceHandle* is required. If an authorization or audit of this command requires computation of a *cpHash* and an *rpHash*, the Name associated with *sequenceHandle* will be the Empty Buffer.

If the command does not return TPM_RC_SUCCESS, the state of the sequence is unmodified.

If the sequence is intended to produce a digest that will be signed by a restricted signing key, then the first block of data shall contain at least size of(TPM_GENERATED) octets and the first octets shall not be TPM_GENERATED_VALUE.

NOTE 2 This requirement allows the TPM to validate that the first block is safe to sign without having to accumulate octets over multiple calls.

17.5.2 Command and Response

17.5.3 Detailed Actions

[[SequenceUpdate]]

17.6 TPM2_SequenceComplete

17.6.1 General Description

This command adds the last part of data, if any, to a hash/HMAC sequence and returns the result.

NOTE 1 This command is not used to complete an Event Sequence. TPM2_EventSequenceComplete() is used for that purpose.

For a hash sequence, if the results of the hash will be used in a signing operation that uses a restricted signing key, then the ticket returned by this command can indicate that the hash is safe to sign. The *hierarchy* parameter determines the ticket lifetime, since the ticket is integrity protected with the hierarchy proof.

NOTE 2 The *hierarchy* parameter is not related to the signing key hierarchy.

If the *digest* is not safe to sign, then *validation* will be a TPMT_TK_HASHCHECK with the hierarchy set to TPM_RH_NULL and *digest* set to the Empty Buffer.

If *hierarchy* is TPM_RH_NULL, then *digest* in the ticket will be the Empty Buffer.

NOTE 3 Regardless of the contents of the first octets of the hashed message, if the first buffer sent to the TPM had fewer than sizeof(TPM_GENERATED) octets, then the TPM will operate as if *digest* is not safe to sign.

NOTE 4 The ticket is only required for a signing operation that uses a restricted signing key. It is always returned but can be ignored if not needed.

If *sequenceHandle* references an Event Sequence, then the TPM shall return TPM_RC_MODE.

Proper authorization for the sequence object associated with *sequenceHandle* is required. If an authorization or audit of this command requires computation of a *cpHash* and an *rpHash*, the Name associated with *sequenceHandle* will be the Empty Buffer.

If this command completes successfully, the *sequenceHandle* object will be flushed.

17.6.2 Command and Response

17.6.3 Detailed Actions

[[SequenceComplete]]

17.7 TPM2_EventSequenceComplete

17.7.1 General Description

This command adds the last part of data, if any, to an Event Sequence and returns the result in a digest list. If *pcrHandle* references a PCR and not TPM_RH_NULL, then the returned digest list is processed in the same manner as the digest list input parameter to TPM2_PCR_Extend(). That is, if a bank contains a PCR associated with *pcrHandle*, it is extended with the associated digest value from the list.

If *sequenceHandle* references a hash or HMAC sequence, the TPM shall return TPM_RC_MODE.

Proper authorization for the sequence object associated with *sequenceHandle* is required. If an authorization or audit of this command requires computation of a *cpHash* and an *rpHash*, the Name associated with *sequenceHandle* will be the Empty Buffer.

If this command completes successfully, the *sequenceHandle* object will be flushed.

NOTE: Unlike TPM2_PCR_Event(), a digest is always returned for each implemented hash algorithm. There is no option to only return digests for which *pcrHandle* is allocated.

17.7.2 Command and Response

17.7.3 Detailed Actions

`[[EventSequenceComplete]]`

18 Attestation Commands

18.1 Introduction

The attestation commands cause the TPM to sign an internally generated data structure. The contents of the data structure vary according to the command.

If the *sign* attribute is not SET in the key referenced by *signHandle* then the TPM shall return TPM_RC_KEY.

All signing commands include a parameter (typically *inScheme*) for the caller to specify a scheme to be used for the signing operation. This scheme will be applied only if the scheme of the key is TPM_ALG_NULL or the key handle is TPM_RH_NULL. If the scheme for *signHandle* is not TPM_ALG_NULL, then *inScheme.scheme* shall be TPM_ALG_NULL or the same as *scheme* in the public area of the key. If the scheme for *signHandle* is TPM_ALG_NULL or the key handle is TPM_RH_NULL, then *inScheme* will be used for the signing operation and may not be TPM_ALG_NULL. The TPM shall return TPM_RC_SCHEME to indicate that the scheme is not appropriate.

For a signing key that is not restricted, the caller may specify the scheme to be used as long as the scheme is compatible with the family of the key (for example, TPM_ALG_RSAPSS cannot be selected for an ECC key). If the caller sets *scheme* to TPM_ALG_NULL, then the default scheme of the key is used. For a restricted signing key, the key's scheme cannot be TPM_ALG_NULL and cannot be overridden.

If the handle for the signing key (*signHandle*) is TPM_RH_NULL, then all of the actions of the command are performed, and the attestation block is “signed” with the NULL Signature.

NOTE 1 This mechanism is provided so that additional commands are not required to access the data that might be in an attestation structure.

NOTE 2 When *signHandle* is TPM_RH_NULL, *scheme* is still required to be a valid signing scheme (may be TPM_ALG_NULL), but the scheme will have no effect on the format of the signature. It will always be the NULL Signature.

NOTE 3 For TPM2_Quote, a TPM may optionally return TPM_RC_SCHEME if *signHandle* is TPM_RH_NULL.

NOTE 4 Attestation commands typically use a *restricted*, *sensitiveDataOrigin* signing key. A key that is not *restricted* can sign any digest and would permit a forged attestation. It is common to use a *fixedTPM* key.

TPM2_NV_Certify() is an attestation command that is documented in 31.16. The remaining attestation commands are collected in the remainder of clause 18.

Each of the attestation structures contains a TPMS_CLOCK_INFO structure and a firmware version number. These values may be considered privacy-sensitive because they would aid in the correlation of attestations by different keys. To provide improved privacy, the *resetCount*, *restartCount*, and *firmwareVersion* numbers are obfuscated when the signing key is not in the Endorsement or Platform hierarchies.

The obfuscation value is computed by:

$$\text{obfuscation} := \text{KDFa}(\text{signHandle} \rightarrow \text{nameAlg}, \text{shProof}, \text{“OBFUSCATE”}, \text{signHandle} \rightarrow \text{QN}, 0, 128) \quad (3)$$

Of the returned 128 bits, 64 bits are added to the *versionNumber* field of the attestation structure; 32 bits are added to the *clockInfo.resetCount* and 32 bits are added to the *clockInfo.restartCount*. The order in which the bits are added is implementation-dependent.

NOTE 5 The obfuscation value for each signing key will be unique to that key in a specific location. That is, each version of a duplicated signing key will have a different obfuscation value.

When the signing key is TPM_RH_NULL, the data structure is produced but not signed; and the values in the signed data structure are obfuscated. When computing the obfuscation value for TPM_RH_NULL, the hash used for context integrity is used.

NOTE 6 The QN for TPM_RH_NULL is TPM_RH_NULL.

If the signing scheme of *signHandle* is an anonymous scheme, then the attestation blocks will not contain the Qualified Name of the *signHandle*.

Each of the attestation structures allows the caller to provide some qualifying data (*qualifyingData*). For most signing schemes, this value will be placed in the TPMS_ATTEST.*extraData* parameter that is then hashed and signed. However, for some schemes such as ECDA, the *qualifyingData* is used in a different manner (for details, see “ECDA” in TPM 2.0 Part 1).

18.2 TPM2_Certify

18.2.1 General Description

The purpose of this command is to prove that an object with a specific Name is loaded in the TPM. By certifying that the object is loaded, the TPM warrants that a public area with a given Name is self-consistent and associated with a valid sensitive area. If a relying party has a public area that has the same Name as a Name certified with this command, then the values in that public area are correct.

NOTE 1 See clause 18.1 for description of how the signing scheme is selected.

Authorization for *objectHandle* requires ADMIN role authorization. If performed with a policy session, the session shall have a *policySession→commandCode* set to TPM_CC_Certify. This indicates that the policy that is being used is a policy that is for certification, and not a policy that would approve another use. That is, authority to use an object does not grant authority to certify the object.

The object may be any object that is loaded with TPM2_Load() or TPM2_CreatePrimary(). An object that only has its public area loaded cannot be certified.

NOTE 2 The restriction occurs because the Name is used to identify the object being certified. If the TPM has not validated that the public area is associated with a matched sensitive area, then the public area may not represent a valid object and cannot be certified.

The certification includes the Name and Qualified Name of the certified object as well as the Name and the Qualified Name of the certifying object.

NOTE 3 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

18.2.2 Command and Response

18.2.3 Detailed Actions

[[Certify]]

18.3 TPM2_CertifyCreation

18.3.1 General Description

This command is used to prove the association between an object and its creation data. The TPM will validate that the ticket was produced by the TPM and that the ticket validates the association between a loaded public area and the provided hash of the creation data (*creationHash*).

NOTE 1 See clause 18.1 for description of how the signing scheme is selected.

NOTE 2 This command is more straightforward for child keys. Since primary keys are repeatable, the same key can be generated with different creation data. The *outsideInfo* parameter can be used to provide creation ticket freshness.

The TPM will create a test ticket using the Name associated with *objectHandle* and *creationHash* as:

$$\mathbf{HMAC}(\mathit{proof}, (\text{TPM_ST_CREATION} \parallel \mathit{objectHandle} \rightarrow \mathit{Name} \parallel \mathit{creationHash})) \quad (4)$$

This ticket is then compared to creation ticket. If the tickets are not the same, the TPM shall return TPM_RC_TICKET.

If the ticket is valid, then the TPM will create a TPMS_ATTEST structure and place *creationHash* of the command in the *creationHash* field of the structure. The Name associated with *objectHandle* will be included in the attestation data that is then signed using the key associated with *signHandle*.

NOTE 3 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

objectHandle may be any object that is loaded with TPM2_Load() or TPM2_CreatePrimary().

18.3.2 Command and Response

18.3.3 Detailed Actions

[[CertifyCreation]]

18.4 TPM2_Quote

18.4.1 General Description

This command is used to quote PCR values.

The TPM will hash the list of PCR selected by *PCRselect* using the hash algorithm in the selected signing scheme. If the selected signing scheme or the scheme hash algorithm is TPM_ALG_NULL, then the TPM shall return TPM_RC_SCHEME.

NOTE 1 See clause 18.1 for description of how the signing scheme is selected.

The digest is computed as the hash of the concatenation of all of the digest values of the selected PCR.

The concatenation of PCR is described in TPM 2.0 Part 1, *Selecting Multiple PCR*.

NOTE 2 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

NOTE 3 A TPM may optionally return TPM_RC_SCHEME if *signHandle* is TPM_RH_NULL.

NOTE 4 Unlike TPM 1.2, TPM2_Quote does not return the PCR values. See Part 1, "Attesting to PCR" for a discussion of this issue.

18.4.2 Command and Response

18.4.3 Detailed Actions

[[Quote]]

18.5 TPM2_GetSessionAuditDigest

18.5.1 General Description

This command returns a digital signature of the audit session digest.

NOTE 1 See clause 18.1 for description of how the signing scheme is selected.

If *sessionHandle* is not an audit session, the TPM shall return TPM_RC_TYPE.

NOTE 2 A session does not become an audit session until the successful completion of the command in which the session is first used as an audit session.

This command requires authorization from the privacy administrator of the TPM (expressed with Endorsement Authorization) as well as authorization to use the key associated with *signHandle*.

If this command is audited, then the audit digest that is signed will not include the digest of this command because the audit digest is only updated when the command completes successfully.

This command does not cause the audit session to be closed and does not reset the digest value.

NOTE 3 If *sessionHandle* is used as an audit session for this command, the command is audited in the same manner as any other command.

NOTE 4 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

18.5.2 Command and Response

Table 96 — TPM2_GetSessionAuditDigest Command

TPMT_SIGNATURE	signature	the signature over <i>auditInfo</i>

18.5.3 Detailed Actions

[[GetSessionAuditDigest]]

18.6 TPM2_GetCommandAuditDigest

18.6.1 General Description

This command returns the current value of the command audit digest, a digest of the commands being audited, and the audit hash algorithm. These values are placed in an attestation structure and signed with the key referenced by *signHandle*.

NOTE 1 See clause 18.1 for description of how the signing scheme is selected.

When this command completes successfully, and *signHandle* is not TPM_RH_NULL, the audit digest is cleared. If *signHandle* is TPM_RH_NULL, *signature* is the Empty Buffer and the audit digest is not cleared.

NOTE 2 The way that the TPM tracks that the digest is clear is vendor-dependent. The reference implementation resets the size of the digest to zero.

If this command is being audited, then the signed digest produced by the command will not include the command. At the end of this command, the audit digest will be extended with *cpHash* and the *rpHash* of the command, which would change the command audit digest signed by the next invocation of this command.

This command requires authorization from the privacy administrator of the TPM (expressed with Endorsement Authorization) as well as authorization to use the key associated with *signHandle*.

18.6.2 Command and Response

18.6.3 Detailed Actions

[[GetCommandAuditDigest]]

18.7 TPM2_GetTime

18.7.1 General Description

This command returns the current values of *Time* and *Clock*.

NOTE 1 See clause 18.1 for description of how the signing scheme is selected.

The values of *Clock*, *resetCount* and *restartCount* appear in two places in *timeInfo*: once in *TPMS_ATTEST.clockInfo* and again in *TPMS_ATTEST.attested.time.clockInfo*. The firmware version number also appears in two places (*TPMS_ATTEST.firmwareVersion* and *TPMS_ATTEST.attested.time.firmwareVersion*). If *signHandle* is in the endorsement or platform hierarchies, both copies of the data will be the same. However, if *signHandle* is in the storage hierarchy or is *TPM_RH_NULL*, the values in *TPMS_ATTEST.clockInfo* and *TPMS_ATTEST.firmwareVersion* are obfuscated but the values in *TPMS_ATTEST.attested.time* are not.

NOTE 2 The purpose of this duplication is to allow an entity who is trusted by the privacy Administrator to correlate the obfuscated values with the clear-text values. This command requires Endorsement Authorization.

NOTE 3 If *signHandle* is *TPM_RH_NULL*, the *TPMS_ATTEST* structure is returned and *signature* is a NULL Signature.

18.8 TPM2_CertifyX509

18.8.1 General Description

The purpose of this command is to generate an X.509 certificate that proves an object with a specific public key and attributes is loaded in the TPM. In contrast to TPM2_Certify, which uses a TCG-defined data structure to convey attestation information, TPM2_CertifyX509() encodes the attestation information in a DER-encoded X.509 certificate that is compliant with RFC5280 *Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile*.

As described in RFC, an X.509 certificate contains a collection of data that is hashed and signed. The full signature is the combination of the *to be signed* (TBS) data, a description of the signature algorithm, and the signature over the TBS data. The elements of the TBS data structure are DER-encoded values. They are:

- 1) Version [0] – integer value of 2 indicating version 3
- 2) Certificate Serial Number – integer value
- 3) Signature Algorithm Identifier – values (usually a collection of OIDs) identifying the algorithm used for the signature
- 4) Issuer Name – X.501 type *Name* to identify the entity that has authorized the use of *signHandle* to create the certificate.
- 5) Validity – two time values indicating the period during which the certificate is valid
- 6) Subject Name – X.501 type *Name* that identifies the entity that authorized the use of *objectHandle*
- 7) Subject Public Key Info – the public key associated with *objectHandle*,
- 8) Extensions [3] – a set of values that “provide methods for associating additional attributes with users or public keys and for managing relationships between CAs.”

NOTE 1: The numbers in square brackets (e.g., [0]) indicate application-specific tag values that are used to identify the type of the field.

NOTE 2: RFC 5280 describes two fields (issuerUniqueID and subjectUniqueID) but goes on to say: “CAs conforming to this profile MUST NOT generate certificates with unique identifiers.” The TPM does not allow them to be present.

The caller provides a partial certificate (*partialCertificate*) parameter that contains four or five of the elements enumerated above in a DER encoded SEQUENCE. They are:

- 1) Signature Algorithm Identifier (optional)
- 2) Issuer (mandatory)
- 3) Validity (mandatory)
- 4) Subject Name (mandatory)
- 5) Extensions (mandatory)

The fields are required to be in the order in which they are listed above.

NOTE 3: If one or more mandatory fields (Issuer, Validity, Subject Name, Extensions) are duplicated in the *partialCertificate*, the result of the command is unspecified.

If the fields listed above are not in the order listed, the command, the result of the command is unspecified.

If the Validity field is not compliant with RFC5280, the command can return successfully if the TPM does not parse the field.

NOTE 4: The TPM determines if the Signature Algorithm Identifier element is present by counting the elements.

The optional Signature Algorithm Identifier may be provided by the caller. If it is not present, the TPM will generate the value based on the selected signing scheme. If the caller provides this value, then the TPM will use it in the completed TBS. The TPM will not validate that the provided values are compatible with the signing scheme. If the caller does not provide this field and the TPM does not have OID values for the signing scheme, then the TPM will return an error (TPM_RC_SCHEME).

NOTE 5: The TPM may implement signing schemes for which OIDs are not defined at the time the TPM was manufactured. Those schemes may still be used if the caller can provide the Signature Algorithm Identifier.

The Extensions element is required to contain a Key Usage extension. The TPM will extract the Key Usage values and verify that the attributes of *objectHandle* are consistent with the selected values (TPM_RC_ATTRIBUTES) (see TPM 2.0 Part 2, *TPMA_X509_KEY_USAGE*).

The Extensions element may contain a TPMA_OBJECT extension. If present, the TPM will extract the value and verify that the extension value exactly matches the TPMA_OBJECT of *objectKey* (TPM_RC_ATTRIBUTES). The element uses the TCG OID *tcg-tpmaObject*, 2.23.133.10.1.1.1. It is a SEQUENCE containing that OID and an OCTET STRING encapsulating a 4-byte BIT STRING holding the big endian TPMA_OBJECT.

signHandle is required to have the *sign* attribute SET (TPM_RC_KEY).

NOTE 6: See clause 18.1 for description of how the signing scheme is selected.

Authorization for *objectHandle* requires ADMIN role authorization. If performed with a policy session, the session shall have a *policySession*→*commandCode* set to TPM_CC_CertifyX509. This indicates that the policy that is being used is a policy that is for certification, and not a policy that would approve another use. That is, authority to use an object does not grant authority to certify the object.

If *objectHandle* does not have a sensitive area loaded, the TPM will return an error (TPM_RC_AUTH_UNAVAILABLE).

NOTE 7: The command requires that authorization be provided for use of *objectHandle*. An object that only has its *publicArea* loaded does not have an authorization value and the *authPolicy* has no meaning as the sensitive area is not present.

The TPM will create the Version, the Certificate Serial Number, the Subject Public Key Info, and, if not provided by the caller, the Signature Algorithm Identifier. These TPM-created values will be combined with the provided values to make a full TBSCertificate structure (see RFC 5280, clause 4.1). The TPM will then sign the certificate using the selected signing scheme.

The TPM-created values will be returned in *addedToCertificate*. If the TPM creates the Signature Algorithm Identifier, it will be in *addedToCertificate* before the Subject Public Key Info. The TPM returns *tbsDigest* as a debugging aid.

NOTE 8: These returned fields allow the caller to unambiguously create a full RFC5280-defined TBSCertificate.

NOTE 9: This command was added in revision 01.53.

18.8.2 Command and Response

Table 102 — TPM2_CertifyX509 Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS
UINT32	commandSize

TPM2B_MAX_BUFFER	addedToCertificate	a DER encoded SEQUENCE containing the DER encoded fields added to partialCertificate to make it a complete RFC5280 TBSCertificate.
TPM2B_DIGEST	tbsDigest	the digest that was signed
TPMT_SIGNATURE	signature	The signature over <i>tbsDigest</i>

18.8.3 Detailed Actions

[[certifyX509]]

19 Ephemeral EC Keys

19.1 Introduction

The TPM generates keys that have different lifetimes. TPM keys in a hierarchy can be persistent for as long as the seed of the hierarchy is unchanged and these keys may be used multiple times. Other TPM-generated keys are only useful for a single operation. Some of these single-use keys are used in the command in which they are created. Examples of this use are TPM2_Duplicate() where an ephemeral key is created for a single pass key exchange with another TPM. However, there are other cases, such as anonymous attestation, where the protocol requires two passes where the public part of the ephemeral key is used outside of the TPM before the final command "consumes" the ephemeral key.

For these uses, TPM2_Commit() or TPM2_EC_Ephemeral() may be used to have the TPM create an ephemeral EC key and return the public part of the key for external use. Then in a subsequent command, the caller provides a reference to the ephemeral key so that the TPM can retrieve or recreate the associated private key.

When an ephemeral EC key is created, it is assigned a number and that number is returned to the caller as the identifier for the key. This number is not a handle. A handle is assigned to a key that may be context saved but these ephemeral EC keys may not be saved and do not have a full key context. When a subsequent command uses the ephemeral key, the caller provides the number of the ephemeral key. The TPM uses that number to either look up or recompute the associated private key. After the key is used, the TPM records the fact that the key has been used so that it cannot be used again.

As mentioned, the TPM can keep each assigned private ephemeral key in memory until it is used. However, this could consume a large amount of memory. To limit the memory size, the TPM is allowed to restrict the number of pending private keys – keys that have been allocated but not used.

NOTE The minimum number of ephemeral keys is determined by a platform specific specification

To further reduce the memory requirements for the ephemeral private keys, the TPM is allowed to use pseudo-random values for the ephemeral keys. Instead of keeping the full value of the key in memory, the TPM can use a counter as input to a KDF. Incrementing the counter will cause the TPM to generate a new pseudo-random value.

Using the counter to generate pseudo-random private ephemeral keys greatly simplifies tracking of key usage. When a counter value is used to create a key, a bit in an array may be set to indicate that the key use is pending. When the ephemeral key is consumed, the bit is cleared. This prevents the key from being used more than once.

Since the TPM is allowed to restrict the number of pending ephemeral keys, the array size can be limited. For example, a 128-bit array would allow 128 keys to be "pending".

The management of the array is described in greater detail in the *Split Operations* clause in Annex C of TPM 2.0 Part 1.

19.2 TPM2_Commit

19.2.1 General Description

TPM2_Commit() performs the first part of an ECC anonymous signing operation. The TPM will perform the point multiplications on the provided points and return intermediate signing values. The *signHandle* parameter shall refer to an ECC key and the signing scheme must be anonymous (TPM_RC_SCHEME).

NOTE 1 Currently, TPM_ALG_ECDSA is the only defined anonymous scheme.

NOTE 2 This command cannot be used with a sign+decrypt key because that type of key is required to have a scheme of TPM_ALG_NULL.

For this command, *p1*, *s2* and *y2* are optional parameters. If *s2* is an Empty Buffer, then the TPM shall return TPM_RC_SIZE if *y2* is not an Empty Buffer.

The algorithm is specified in the TPM 2.0 Part 1 Annex for ECC, TPM2_Commit().

19.2.2 Command and Response

Table 104 — TPM2_Commit Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_Commit
TPMI_DH_OBJECT	@signHandle	handle of the key that will be used in the signing operation Auth Index: 1 Auth Role: USER
TPM2B_ECC_POINT	P1	a point (M) on the curve used by <i>signHandle</i>
TPM2B_SENSITIVE_DATA	s2	octet array used to derive x-coordinate of a base point
TPM2B_ECC_PARAMETER	y2	y coordinate of the point associated with s2

TPM2B_ECC_POINT	E	ECC point $E := [r]P1$
UINT16	counter	least-significant 16 bits of <i>commitCount</i>

19.2.3 Detailed Actions

[[Commit]]

19.3 TPM2_EC_Ephemeral

19.3.1 General Description

TPM2_EC_Ephemeral() creates an ephemeral key for use in a two-phase key exchange protocol.

The TPM will use the commit mechanism to assign an ephemeral key r and compute a public point $Q := [r]G$ where G is the generator point associated with *curveID*.

19.3.2 Command and Response

Table 106 — TPM2_EC_Ephemeral Command

[[EC_Ephemeral]]

20 Signing and Signature Verification

20.1 TPM2_VerifySignature

20.1.1 General Description

This command uses loaded keys to validate a signature on a message with the message digest passed to the TPM.

If the signature check succeeds, then the TPM will produce a TPMT_TK_VERIFIED. Otherwise, the TPM shall return TPM_RC_SIGNATURE.

If the key is in the NULL hierarchy, then *digest* in the ticket will be the Empty Buffer.

NOTE 1 A valid ticket can be used in subsequent commands to provide proof to the TPM that the TPM has validated the signature over the message using the key referenced by *keyHandle*. For example, see clause 23.16 TPM2_PolicyAuthorize.

If *keyHandle* references an asymmetric key, only the public portion of the key needs to be loaded. If *keyHandle* references a symmetric key, both the public and private portions need to be loaded.

NOTE 2 The sensitive area of the symmetric object is required to allow verification of the symmetric signature (the HMAC).

20.1.2 Command and Response

TPMT_TK_VERIFIED	validation	

20.1.3 Detailed Actions

[[VerifySignature]]

20.2 TPM2_Sign

20.2.1 General Description

This command causes the TPM to sign an externally provided hash with the specified symmetric or asymmetric signing key.

NOTE 1 If *keyHandle* references an unrestricted signing key, a digest can be signed using either this command or an HMAC command.

If *keyHandle* references a restricted signing key, then *validation* shall be provided, indicating that the TPM performed the hash of the data and *validation* shall indicate that hashed data did not start with TPM_GENERATED_VALUE.

NOTE 2 If the hashed data did start with TPM_GENERATED_VALUE, then the validation will be a NULL ticket.

The *x509sign* attribute of *keyHandle* may not be SET (TPM_RC_ATTRIBUTES).

If the scheme of *keyHandle* is not TPM_ALG_NULL, then *inScheme* shall either be the same scheme as *keyHandle* or TPM_ALG_NULL. If the *sign* attribute is not SET in the key referenced by *handle*, then the TPM shall return TPM_RC_KEY.

If the scheme of *keyHandle* is TPM_ALG_NULL, the TPM will sign using *inScheme*; otherwise, it will sign using the scheme of *keyHandle*.

NOTE 3 When the signing scheme uses a hash algorithm, the algorithm is defined in the qualifying data of the scheme. This is the same algorithm that is required to be used in producing *digest*. The size of *digest* must match that of the hash algorithm in the scheme.

If *inScheme* is not a valid signing scheme for the type of *keyHandle* (or TPM_ALG_NULL), then the TPM shall return TPM_RC_SCHEME.

If the scheme of *keyHandle* is an anonymous *scheme*, then *inScheme* shall have the same scheme algorithm as *keyHandle* and *inScheme* will contain a counter value that will be used in the signing process.

EXAMPLE For ECDA, *inScheme.details.ecdaa.count* will contain the count value.

If *validation* is provided, then the hash algorithm used in computing the digest is required to be the hash algorithm specified in the scheme of *keyHandle* (TPM_RC_TICKET).

If the *validation* parameter is not the Empty Buffer, then it will be checked even if the key referenced by *keyHandle* is not a restricted signing key.

NOTE 4 If *keyHandle* is both a sign and decrypt key, *keyHandle* will have a scheme of TPM_ALG_NULL. If *validation* is provided, then it must be a NULL validation ticket or the ticket validation will fail.

20.2.2 Command and Response

Table 110 — TPM2_Sign Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_Sign

20.2.3 Detailed Actions

[[Sign]]

21 Command Audit

21.1 Introduction

If a command has been selected for command audit, the command audit status will be updated when that command completes successfully. The digest is updated as:

$$commandAuditDigest_{new} := H_{auditAlg}(commandAuditDigest_{old} || cpHash || rpHash) \quad (5)$$

where

$H_{auditAlg}$	hash function using the algorithm of the audit sequence
$commandAuditDigest$	accumulated digest
$cpHash$	the command parameter hash
$rpHash$	the response parameter hash

$auditAlg$, the hash algorithm, is set using `TPM2_SetCommandCodeAuditStatus()`.

`TPM2_Shutdown()` cannot be audited but `TPM2_Startup()` can be audited. If the $cpHash$ of the `TPM2_Startup()` is `TPM_SU_STATE`, that would indicate that a `TPM2_Shutdown()` had been successfully executed.

`TPM2_SetCommandCodeAuditStatus()` is always audited, except when it is used to change $auditAlg$.

If the TPM is in Failure mode, command audit is not functional.

21.2 TPM2_SetCommandCodeAuditStatus

21.2.1 General Description

This command may be used by the Privacy Administrator or platform to change the audit status of a command or to set the hash algorithm used for the audit digest, but not both at the same time.

If the *auditAlg* parameter is a supported hash algorithm and not the same as the current algorithm, then the TPM will check both *setList* and *clearList* are empty (zero length). If so, then the algorithm is changed, and the audit digest is cleared. If *auditAlg* is TPM_ALG_NULL or the same as the current algorithm, then the algorithm and audit digest are unchanged and the *setList* and *clearList* will be processed.

NOTE 1 Because the audit digest is cleared, the audit counter will increment the next time that an audited command is executed.

Use of TPM2_SetCommandCodeAuditStatus() to change the list of audited commands is an audited event. If TPM_CC_SetCommandCodeAuditStatus is in *clearList*, the fact that it is in *clearList* is ignored.

NOTE 2 Use of this command to change the audit hash algorithm is not audited and the digest is reset when the command completes. The change in the audit hash algorithm is the evidence that this command was used to change the algorithm.

The commands in *setList* indicate the commands to be added to the list of audited commands and the commands in *clearList* indicate the commands that will no longer be audited. It is not an error if a command in *setList* is already audited or is not implemented. It is not an error if a command in *clearList* is not currently being audited or is not implemented.

If a command code is in both *setList* and *clearList*, then it will not be audited (that is, *setList* shall be processed first).

21.2.2 Command and Response

21.2.3 Detailed Actions

`[[SetCommandCodeAuditStatus]]`

22 Integrity Collection (PCR)

22.1 Introduction

In TPM 1.2, an Event was hashed using SHA-1 and then the 20-octet digest was extended to a PCR using TPM_Extend(). This specification allows the use of multiple PCR at a given Index, each using a different hash algorithm. Rather than require that the external software generate multiple hashes of the Event with each being extended to a different PCR, the Event data may be sent to the TPM for hashing. This ensures that the resulting digests will properly reflect the algorithms chosen for the PCR even if the calling software is unable to implement the hash algorithm.

NOTE 1 There is continued support for software hashing of events with TPM2_PCR_Extend().

To support recording of an Event that is larger than the TPM input buffer, the caller may use the command sequence described in clause 17.

Change to a PCR requires authorization. The authorization may be with either an authorization value or an authorization policy. The platform-specific specifications determine which PCR may be controlled by policy. All other PCR are controlled by authorization.

If a PCR may be associated with a policy, then the algorithm ID of that policy determines whether the policy is to be applied. If the algorithm ID is not TPM_ALG_NULL, then the policy digest associated with the PCR must match the *policySession*→*policyDigest* in a policy session. If the algorithm ID is TPM_ALG_NULL, then no policy is present, and the authorization requires an EmptyAuth.

If a platform-specific specification indicates that PCR are grouped, then all the PCR in the group use the same authorization policy or authorization value.

pcrUpdateCounter counter will be incremented on the successful completion of any command that modifies (Extends or resets) a PCR unless the platform-specific specification explicitly excludes the PCR from being counted.

NOTE 2 If a command causes PCR in multiple banks to change, the PCR Update Counter must be incremented once for each bank. The commands that extend PCR are: TPM2_PCR_Extend, TPM2_PCR_Event, and TPM2_EventSequenceComplete.

 If a command resets PCR in multiple banks, the PCR Update Counter must be incremented only once. The commands that reset PCR are: TPM2_PCR_Reset, and TPM2_Startup.

A platform-specific specification may designate a set of PCR that are under control of the TCB. These PCR may not be modified without the proper authorization. Updates of these PCR shall not cause the PCR Update Counter to increment.

EXAMPLE Updates of the TCB PCR will not cause the PCR update counter to increment because these PCR are changed at the whim of the TCB and may not represent the trust state of the platform.

22.2 TPM2_PCR_Extend

22.2.1 General Description

This command is used to cause an update to the indicated PCR. The *digests* parameter contains one or more tagged digest values identified by an algorithm ID. For each digest, the PCR associated with *pcrHandle* is Extended into the bank identified by the tag (*hashAlg*).

EXAMPLE A SHA1 digest would be Extended into the SHA1 bank and a SHA256 digest would be Extended into the SHA256 bank.

For each list entry, the TPM will check to see if *pcrNum* is implemented for that algorithm. If so, the TPM shall perform the following operation:

$$PCR.digest_{new}[pcrNum][alg] := H_{alg}(PCR.digest_{old}[pcrNum][alg] || data[alg].buffer) \quad (6)$$

where

$H_{alg}()$	hash function using the hash algorithm associated with the PCR instance
<i>PCR.digest</i>	the digest value in a PCR
<i>pcrNum</i>	the PCR numeric selector (<i>pcrHandle</i>)
<i>alg</i>	the PCR algorithm selector for the digest
<i>data[alg].buffer</i>	the bank-specific data to be extended

If no digest value is specified for a bank, then the PCR in that bank is not modified.

NOTE 1 This allows consistent operation of the digests list for all of the Event recording commands.

If a digest is present and the PCR in that bank is not implemented, the digest value is not used.

NOTE 2 If the caller includes digests for algorithms that are not implemented, then the TPM will fail the call because the unmarshalling of *digests* will fail. Each of the entries in the list is a TPMT_HA, which is a hash algorithm followed by a digest. If the algorithm is not implemented, unmarshalling of the *hashAlg* will fail and the TPM will return TPM_RC_HASH.

If the TPM unmarshals the *hashAlg* of a list entry and the unmarshaled value is not a hash algorithm implemented on the TPM, the TPM shall return TPM_RC_HASH.

The *pcrHandle* parameter is allowed to reference TPM_RH_NULL. If so, the input parameters are processed but no action is taken by the TPM. This permits the caller to probe for implemented hash algorithms as an alternative to TPM2_GetCapability.

NOTE 3 This command allows a list of digests so that PCR in all banks may be updated in a single command. While the semantics of this command allow multiple extends to a single PCR bank, this is not the preferred use and the limit on the number of entries in the list make this use somewhat impractical.

22.2.2 Command and Response

Table 114 — TPM2_PCR_Extend Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS

Table 115 — TPM2_PCR_Extend Response

Type	Name	Description
TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode	.

22.2.3 Detailed Actions

[[PCR_Extend]]

22.3 TPM2_PCR_Event

22.3.1 General Description

This command is used to cause an update to the indicated PCR.

The data in *eventData* is hashed using the hash algorithm associated with each bank in which the indicated PCR has been allocated. After the data is hashed, the *digests* list is returned. If the *pcrHandle* references an implemented PCR and not TPM_RH_NULL, the *digests* list is processed as in TPM2_PCR_Extend().

A TPM shall support an *eventData.size* of zero through 1,024 inclusive (*eventData.size* is an octet count). An *eventData.size* of zero indicates that there is no data, but the indicated operations will still occur.

EXAMPLE 1 If the command implements PCR[2] in a SHA1 bank and a SHA256 bank, then an extend to PCR[2] will cause *eventData* to be hashed twice, once with SHA1 and once with SHA256. The SHA1 hash of *eventData* will be Extended to PCR[2] in the SHA1 bank and the SHA256 hash of *eventData* will be Extended to PCR[2] of the SHA256 bank.

On successful command completion, *digests* will contain the list of tagged digests of *eventData* that was computed in preparation for extending the data into the PCR. At the option of the TPM, the list may contain a digest for each bank, or it may only contain a digest for each bank in which *pcrHandle* is extant. If *pcrHandle* is TPM_RH_NULL, the TPM may return either an empty list or a digest for each bank.

EXAMPLE 2 Assume a TPM that implements a SHA1 bank and a SHA256 bank and that PCR[22] is only implemented in the SHA1 bank. If *pcrHandle* references PCR[22], then *digests* may contain either a SHA1 and a SHA256 digest or just a SHA1 digest.

22.3.3 Detailed Actions

[[PCR_Event]]

22.4 TPM2_PCR_Read

22.4.1 General Description

This command returns the values of all PCR specified in *pcrSelectionIn*.

The TPM will process the list of TPMS_PCR_SELECTION in *pcrSelectionIn* in order. Within each TPMS_PCR_SELECTION, the TPM will process the bits in the *pcrSelect* array in ascending PCR order (see TPM 2.0 Part 1, *Selecting Multiple PCR*). If a bit is SET, and the indicated PCR is present, then the TPM will add the digest of the PCR to the list of values to be returned in *pcrValues*.

The TPM will continue processing bits until all have been processed or until *pcrValues* would be too large to fit into the output buffer if additional values were added.

The returned *pcrSelectionOut* will have a bit SET in its *pcrSelect* structures for each value present in *pcrValues*.

The current value of the PCR Update Counter is returned in *pcrUpdateCounter*.

The returned list may be empty if none of the selected PCR are implemented.

NOTE If no PCR are returned from a bank, the selector for the bank will be present in *pcrSelectionOut*.

No authorization is required to read a PCR and any implemented PCR may be read from any locality.

22.4.2 Command and Response

Table 118 — TPM2_PCR_Read Command

22.4.3 Detailed Actions

[[PCR_Read]]

22.5 TPM2_PCR_Allocate

22.5.1 General Description

This command is used to set the desired PCR allocation of PCR and algorithms. This command requires Platform Authorization.

The TPM will evaluate the request and, if sufficient memory is available for the requested allocation, the TPM will store the allocation request for use during the next `_TPM_Init` operation. The PCR allocation in place when this command is executed will be retained until the next `_TPM_Init`. If this command is received multiple times before a `_TPM_Init`, each one overwrites the previous stored allocation.

This command will only change the allocations of banks that are listed in *pcrAllocation*.

EXAMPLE 1 If a TPM supports SHA1 and SHA256, then it maintains an allocation for two banks (one of which could be empty). If *pcrAllocation* only has a selector for the SHA1 bank, then only the allocation of the SHA1 bank will be changed and the SHA256 bank will remain unchanged. To change the allocation of a TPM from 24 SHA1 PCR and no SHA256 PCR to 24 SHA256 PCR and no SHA1 PCR, the *pcrAllocation* would have to have two selections: one for the empty SHA1 bank and one for the SHA256 bank with 24 PCR.

If a bank is listed more than once, then the last selection in the *pcrAllocation* list is the one that the TPM will attempt to allocate.

NOTE 1 This does not mean to imply that *pcrAllocation.count* can exceed `HASH_COUNT`, the number of digests implemented in the TPM.

EXAMPLE 2 If `HASH_COUNT` is 2, *pcrAllocation* can specify SHA-256 twice, and the second one is used. However, if `SHA_256` is specified three times, the unmarshaling may fail and the TPM may return an error.

This command shall not allocate more PCR in any bank than there are PCR attribute definitions. The PCR attribute definitions indicate how a PCR is to be managed – if it is resettable, the locality for update, etc. In the response to this command, the TPM returns the maximum number of PCR allowed for any bank.

When PCR are allocated, if `DRTM_PCR` is defined, the resulting allocation must have at least one bank with the D-RTM PCR allocated. If `HCRTM_PCR` is defined, the resulting allocation must have at least one bank with the HCRTM_PCR allocated. If not, the TPM returns `TPM_RC_PCR`.

The TPM may return `TPM_RC_SUCCESS` even though the request fails. This is to allow the TPM to return information about the size needed for the requested allocation and the size available. If the *sizeNeeded* parameter in the return is less than or equal to the *sizeAvailable* parameter, then the *allocationSuccess* parameter will be YES. Alternatively, if the request fails, The TPM may return `TPM_RC_NO_RESULT`.

NOTE 2 An example for this type of failure is a TPM that can only support one bank at a time and cannot support arbitrary distribution of PCR among banks.

After this command, `TPM2_Shutdown()` is only allowed to have a *startupType* equal to `TPM_SU_CLEAR` until after the next `_TPM_Init`.

NOTE 3 Even if this command does not cause the PCR allocation to change, the TPM cannot have its state saved. This is done in order to simplify the implementation. There is no need to optimize this command as it is not expected to be used more than once in the lifetime of the TPM (it can be used any number of times but there is no justification for optimization).

UINT32	sizeAvailable	Number of octets available. Computed before the allocation.

22.5.3 Detailed Actions

[[PCR_Allocate]]

22.6 TPM2_PCR_SetAuthPolicy

22.6.1 General Description

This command is used to associate a policy with a PCR or group of PCR. The policy determines the conditions under which a PCR may be extended or reset.

A policy may only be associated with a PCR that has been defined by a platform-specific specification as allowing a policy. If the TPM implementation does not allow a policy for *pcrNum*, the TPM shall return TPM_RC_VALUE.

A platform-specific specification may group PCR so that they share a common policy. In such case, a *pcrNum* that selects any of the PCR in the group will change the policy for all PCR in the group.

The policy setting is persistent and may only be changed by TPM2_PCR_SetAuthPolicy() or by TPM2_ChangePPS().

Before this command is first executed on a TPM or after TPM2_ChangePPS(), the access control on the PCR will be set to the default value defined in the platform-specific specification.

NOTE 1 It is expected that the typical default will be with the policy hash set to TPM_ALG_NULL and an Empty Buffer for the *authPolicy* value. This will allow an *EmptyAuth* to be used as the authorization value.

If the size of the data buffer in *authPolicy* is not the size of a digest produced by *hashAlg*, the TPM shall return TPM_RC_SIZE.

NOTE 2 If *hashAlg* is TPM_ALG_NULL, then the size is required to be zero.

This command requires platformAuth/platformPolicy.

NOTE 3 If the PCR is in multiple policy sets, the policy will be changed in only one set. The set that is changed will be implementation dependent.

22.6.3 Detailed Actions

[[PCR_SetAuthPolicy]]

22.7 TPM2_PCR_SetAuthValue

22.7.1 General Description

This command changes the *authValue* of a PCR or group of PCR.

An *authValue* may only be associated with a PCR that has been defined by a platform-specific specification as allowing an authorization value. If the TPM implementation does not allow an authorization for *pcrNum*, the TPM shall return TPM_RC_VALUE. A platform-specific specification may group PCR so that they share a common authorization value. In such case, a *pcrNum* that selects any of the PCR in the group will change the *authValue* value for all PCR in the group.

The authorization setting is set to EmptyAuth on each STARTUP(CLEAR) or by TPM2_Clear(). The authorization setting is preserved by SHUTDOWN(STATE).

22.7.3 Detailed Actions

[[PCR_SetAuthValue]]

22.8 TPM2_PCR_Reset

22.8.1 General Description

If the attribute of a PCR allows the PCR to be reset and proper authorization is provided, then this command may be used to set the PCR in all banks to zero. The attributes of the PCR may restrict the locality that can perform the reset operation.

NOTE 1 The definition of TPMI_DH_PCR in TPM 2.0 Part 2 indicates that if *pcrHandle* is out of the allowed range for PCR, then the appropriate return value is TPM_RC_VALUE.

If *pcrHandle* references a PCR that cannot be reset, the TPM shall return TPM_RC_LOCALITY.

NOTE 2 TPM_RC_LOCALITY is returned because the reset attributes are defined on a per-locality basis.

22.8.2 Command and Response

22.8.3 Detailed Actions

[[PCR_Reset]]

22.9 _TPM_Hash_Start

22.9.1 Description

This indication from the TPM interface indicates the start of an H-CRTM measurement sequence. On receipt of this indication, the TPM will initialize an H-CRTM Event Sequence context.

If no object memory is available for creation of the sequence context, the TPM will flush the context of an object so that creation of the sequence context will always succeed.

A platform-specific specification may allow this indication before TPM2_Startup().

NOTE If this indication occurs after TPM2_Startup(), it is the responsibility of software to ensure that an object context slot is available or to deal with the consequences of having the TPM select an arbitrary object to be flushed. If this indication occurs before TPM2_Startup() then all context slots are available.

22.9.2 Detailed Actions

`[[_TPM_Hash_Start]]`

22.10 `_TPM_Hash_Data`

22.10.1 Description

This indication from the TPM interface indicates arrival of one or more octets of data that are to be included in the H-CRTM Event Sequence sequence context created by the `_TPM_Hash_Start` indication. The context holds data for each hash algorithm for each PCR bank implemented on the TPM.

If no H-CRTM Event Sequence context exists, this indication is discarded, and no other action is performed.

22.10.2 Detailed Actions

`[[_TPM_Hash_Data]]`

22.11 _TPM_Hash_End

22.11.1 Description

This indication from the TPM interface indicates the end of the H-CRTM measurement. This indication is discarded, and no other action performed if the TPM does not contain an H-CRTM Event Sequence context.

NOTE 1 An H-CRTM Event Sequence context is created by `_TPM_Hash_Start()`.

If the H-CRTM Event Sequence occurs after `TPM2_Startup()`, the TPM will set all of the PCR designated in the platform-specific specifications as resettable by this event to the value indicated in the platform specific specification and increment *restartCount*. The TPM will then Extend the Event Sequence digest/digests into the designated D-RTM PCR (PCR[17]).

$$\text{PCR}[17][\text{hashAlg}] := \mathbf{H}_{\text{hashAlg}}(\text{initial_value} || \mathbf{H}_{\text{hashAlg}}(\text{hash_data})) \quad (7)$$

where

<i>hashAlg</i>	hash algorithm associated with a bank of PCR
<i>initial_value</i>	initialization value specified in the platform-specific specification (should be 0...0)
<i>hash_data</i>	all the octets of data received in <code>_TPM_Hash_Data</code> indications

A `_TPM_Hash_End` indication that occurs after `TPM2_Startup()` will increment *pcrUpdateCounter* unless a platform-specific specification excludes modifications of PCR[DRTM] from causing an increment.

A platform-specific specification may allow an H-CRTM Event Sequence before `TPM2_Startup()`. If so, `_TPM_Hash_End` will complete the digest, initialize PCR[0] with a digest-size value of 4, and then extend the H-CRTM Event Sequence data into PCR[0].

$$\text{PCR}[0][\text{hashAlg}] := \mathbf{H}_{\text{hashAlg}}(0\dots04 || \mathbf{H}_{\text{hashAlg}}(\text{hash_data})) \quad (8)$$

NOTE 2 The entire sequence of `_TPM_Hash_Start`, `_TPM_Hash_Data`, and `_TPM_Hash_End` are required to complete before `TPM2_Startup()` or the sequence will have no effect on the TPM.

NOTE 3 PCR[0] does not need to be updated according to (8) until the end of `TPM2_Startup()`.

22.11.2 Detailed Actions

`[[_TPM_Hash_End]]`

23 Enhanced Authorization (EA) Commands

23.1 Introduction

The commands in clause 23 are used for policy evaluation. When successful, each command will update the *policySession*→*policyDigest* in a policy session context in order to establish that the authorizations required to use an object have been provided. Many of the commands will also modify other parts of a policy context so that the caller may constrain the scope of the authorization that is provided.

NOTE 1 Many of the terms used in clause 23 are described in detail in TPM 2.0 Part 1 and are not redefined in clause 23.

The *policySession* parameter of the command is the handle of the policy session context to be modified by the command.

If the *policySession* parameter indicates a trial policy session, then the *policySession*→*policyDigest* will be updated and the indicated validations are not performed. However, any authorizations required to perform the policy command will be checked and dictionary attack logic invoked as necessary.

NOTE 2 If software is used to create policies, no authorization values are used. For example, TPM_PolicySecret requires an authorization in a trial policy session, but not in a policy calculation outside the TPM.

NOTE 3 A policy session is set to a trial policy by TPM2_StartAuthSession(*sessionType* = TPM_SE_TRIAL).

NOTE 4 Unless there is an unmarshaling error in the parameters of the command, these commands will return TPM_RC_SUCCESS when *policySession* references a trial session.

NOTE 5 Policy context other than the *policySession*→*policyDigest* may be updated for a trial policy but it is not required.

23.2 Signed Authorization Actions

23.2.1 Introduction

The TPM2_PolicySigned, TPM_PolicySecret, and TPM2_PolicyTicket commands use many of the same functions. Clause 23.2 consolidates those functions to simplify the document and to ensure uniformity of the operations.

23.2.2 Policy Parameter Checks

These parameter checks will be performed when indicated in the description of each of the commands:

- a) *nonceTPM* – If this parameter is not the Empty Buffer, and it does not match *policySession→nonceTPM*, then the TPM shall return TPM_RC_VALUE.

NOTE 1 The *nonceTPM* returned from TPM2_StartAuthSession is a minimum of 16 bytes.

- b) *expiration* – If this parameter is not zero, then:

- 1) if *nonceTPM* is not an Empty Buffer, then the absolute value of *expiration* is converted to milliseconds and added to *policySession→startTime* to create the *timeout* value and proceed to c).
- 2) If *nonceTPM* is an Empty Buffer, then the absolute value of *expiration* is converted to milliseconds and used as the *timeout* value and proceed to c).

However, *timeout* can only be changed to a smaller value (see *timeout* in clause 23.2.4).

- c) *timeout* – If *timeout* is less than the current value of *Time*, or the current *timeEpoch* is not the same as *policySession→timeEpoch*, the TPM shall return TPM_RC_EXPIRED

- d) *cpHashA* – If this parameter is not an Empty Buffer

NOTE 2 *cpHashA* is the hash of the command to be executed using this policy session in the authorization. The algorithm used to compute this hash is required to be the algorithm of the policy session.

- 1) the TPM shall return TPM_RC_CPHASH if *policySession→cpHash* is set and the contents of *policySession→cpHash* are not the same as *cpHashA*; or

NOTE 3 *cpHash* is the expected cpHash value held in the policy session context.

- 2) the TPM shall return TPM_RC_SIZE if *cpHashA* is not the same size as *policySession→policyDigest*.

NOTE 4 *policySession→policyDigest* is the size of the digest produced by the hash algorithm used to compute *policyDigest*.

23.2.3 Policy Digest Update Function (PolicyUpdate())

This is the update process for $policySession \rightarrow policyDigest$ used by TPM2_PolicySigned(), TPM2_PolicySecret(), TPM2_PolicyTicket(), and TPM2_PolicyAuthorize(). The function prototype for the update function is:

$$\mathbf{PolicyUpdate}(commandCode, arg2, arg3) \quad (9)$$

where

$arg2$ a TPM2B_NAME

$arg3$ a TPM2B

These parameters are used to update $policySession \rightarrow policyDigest$ by

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || commandCode || arg2.name) \quad (10)$$

followed by

$$policyDigest_{new+1} := H_{policyAlg}(policyDigest_{new} || arg3.buffer) \quad (11)$$

where

$H_{policyAlg}()$ the hash algorithm chosen when the policy session was started

NOTE 1 If $arg3$ is a TPM2B_NAME, then $arg3.buffer$ will actually be an $arg3.name$.

NOTE 2 The $arg2.size$ and $arg3.size$ fields are not included in the hashes.

NOTE 3 **PolicyUpdate()** uses two hash operations because $arg2$ and $arg3$ are variable-sized and the concatenation of $arg2$ and $arg3$ in a single hash could produce the same digest even though $arg2$ and $arg3$ are different. For example, $arg2 = 1\ 2\ 3$ and $arg3 = 4\ 5\ 6$ would produce the same digest as $arg2 = 1\ 2$ and $arg3 = 3\ 4\ 5\ 6$. Processing of the arguments separately in different Extend operation ensures that the digest produced by **PolicyUpdate()** will be different if $arg2$ and $arg3$ are different.

23.2.4 Policy Context Updates

When a policy command modifies some part of the policy session context other than the $policySession \rightarrow policyDigest$, the following rules apply.

- **cpHash** – this parameter may only be changed if it contains its initialization value (an Empty Buffer). If **cpHash** is not the Empty Buffer when a policy command attempts to update it, the TPM will return an error (TPM_RC_CPHASH) if the current and update values are not the same.
- **timeOut** – this parameter may only be changed to a smaller value. If a command attempts to update this value with a larger value (longer into the future), the TPM will discard the update value. This is not an error condition.
- **commandCode** – once set by a policy command, this value may not be changed except by TPM2_PolicyRestart(). If a policy command tries to change this to a different value, an error is returned (TPM_RC_POLICY_CC).
- **pcrUpdateCounter** – this parameter is updated by TPM2_PolicyPCR(). This value may only be set once during a policy. Each time TPM2_PolicyPCR() executes, it checks to see if $policySession \rightarrow pcrUpdateCounter$ has its default state, indicating that this is the first TPM2_PolicyPCR(). If it has its default value, then $policySession \rightarrow pcrUpdateCounter$ is set to the current value of **pcrUpdateCounter**. If $policySession \rightarrow pcrUpdateCounter$ does not have its default value and its value is not the same as **pcrUpdateCounter**, the TPM shall return TPM_RC_PCR_CHANGED.

NOTE 1 If this parameter and **pcrUpdateCounter** are not the same, it indicates that PCR have changed since checked by the previous TPM2_PolicyPCR(). Since they have changed, the previous PCR validation is no longer valid.

- **commandLocality** – this parameter is the logical AND of all enabled localities. All localities are enabled for a policy when the policy session is created. TPM2_PolicyLocalities() selectively disables localities. Once use of a policy for a locality has been disabled, it cannot be enabled except by TPM2_PolicyRestart().
- **isPPRequired** – once SET, this parameter may only be CLEARED by TPM2_PolicyRestart().
- **isAuthValueNeeded** – once SET, this parameter may only be CLEARED by TPM2_PolicyPassword() or TPM2_PolicyRestart().
- **isPasswordNeeded** – once SET, this parameter may only be CLEARED by TPM2_PolicyAuthValue() or TPM2_PolicyRestart(),

NOTE 2 Both TPM2_PolicyAuthValue() and TPM2_PolicyPassword() change *policySession*→*policyDigest* in the same way. The different commands simply indicate to the TPM the format used for the *authValue* (HMAC or clear text). Both commands could be in the same policy. The final instance of these commands determines the format.

23.2.5 Policy Ticket Creation

For TPM2_PolicySigned() or TPM2_PolicySecret(), if the caller specified a negative value for *expiration*, then the TPM will return a ticket that includes a value indicating when the authorization expires. Otherwise, the TPM will return a NULL Ticket.

NOTE 1 If the *authHandle* in TPM2_PolicySecret() references a PIN Pass Index, then the command may succeed but a NULL Ticket will be returned.

The required computation for the digest in the authorization ticket is:

$$\text{HMAC}_{\text{contextAlg}}(\text{proof}, (\text{TPM_ST_AUTH_xxx} \parallel \text{cpHash} \parallel \text{policyRef} \parallel \text{authName} \parallel \text{timeout} \parallel [\text{timeEpoch}] \parallel [\text{resetCount}])) \quad (12)$$

where

HMAC_{contextAlg} ()	an HMAC using the context integrity hash
<i>proof</i>	a TPM secret value associated with the hierarchy of the object associated with <i>authName</i>
TPM_ST_AUTH_xxx	either TPM_ST_AUTH_SIGNED or TPM_ST_AUTH_SECRET; used to ensure that the ticket is properly used
<i>cpHash</i>	optional hash of the authorized command
<i>policyRef</i>	optional reference to a policy value
<i>authName</i>	Name of the object that signed the authorization
<i>timeout</i>	implementation-specific value indicating when the authorization expires
<i>timeEpoch</i>	implementation-specific representation of the <i>timeEpoch</i> at the time the ticket was created

NOTE 2 Not included if *timeout* is zero.

resetCount implementation-specific representation of the TPM's *totalResetCount*

NOTE 3 Not included if *timeout* is zero or if *nonceTPM* was include in the authorization.

23.3 TPM2_PolicySigned

23.3.1 General Description

This command includes a signed authorization in a policy. The command ties the policy to a signing key by including the Name of the signing key in the *policyDigest*

If *policySession* is a trial session, the TPM will not check the signature and will update *policySession*→*policyDigest* as described in clause 23.2.3 as if a properly signed authorization was received, but no ticket will be produced.

If *policySession* is not a trial session, the TPM will validate *auth* and only perform the update if it is a valid signature over the fields of the command.

The authorizing entity will sign a digest of the authorization qualifiers: *nonceTPM*, *expiration*, *cpHashA*, and *policyRef*. The digest is computed as:

$$aHash := H_{authAlg}(nonceTPM || expiration || cpHashA || policyRef) \quad (13)$$

where

$H_{authAlg}()$ the hash associated with the auth parameter of this command

NOTE 1 Each signature and key combination indicates the scheme, and each scheme has an associated hash.

nonceTPM the nonceTPM parameter from the TPM2_StartAuthSession() response. If the authorization is not limited to this session, the size of this value is zero.

expiration time limit on authorization set by authorizing object. This 32-bit value is set to zero if the expiration time is not being set.

cpHashA digest of the command parameters for the command being approved using the hash algorithm of the policy session. Set to an Empty Digest if the authorization is not limited to a specific command.

NOTE 3 This is not the *cpHash* of this TPM2_PolicySigned() command.

policyRef an opaque value determined by the authorizing entity. Set to the Empty Buffer if no value is present.

NOTE 4 The *nonceTPM*, *cpHashA*, and *policyRef* qualifiers used to compute *aHash* use the TPM2B buffer but do not prepend the size.

EXAMPLE The computation for an *aHash* if there are no restrictions is:

$$aHash := H_{authAlg}(00\ 00\ 00\ 00_{16})$$

which is the hash of an expiration time of zero.

The *aHash* is signed by the key associated with a key whose handle is *authObject*. The signature and signing parameters are combined to create the *auth* parameter.

The TPM will perform the parameter checks listed in clause 23.2.2

If the parameter checks succeed, the TPM will construct a test digest (*tHash*) over the provided parameters using the same formulation as shown in equation (13) above.

If *tHash* does not match the digest of the signed *aHash*, then the authorization fails and the TPM shall return TPM_RC_POLICY_FAIL and make no change to *policySession*→*policyDigest*.

When all validations have succeeded, *policySession*→*policyDigest* is updated by **PolicyUpdate()** (see clause 23.2.3).

PolicyUpdate(TPM_CC_PolicySigned, *authObject*→*Name*, *policyRef*) (14)

authObject→*Name* is a TPM2B_NAME. *policySession* is updated as described in clause 23.2.4. The TPM will optionally produce a ticket as described in clause 23.2.5.

Authorization to use *authObject* is not required.

23.3.2 Command and Response

Table 128 — TPM2_PolicySigned Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS if an audit, encrypt, or decrypt session is present; otherwise, TPM_ST_NO_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_PolicySigned
TPMI_DH_OBJECT	authObject	handle for a key that will validate the signature Auth Index: None
TPMI_SH_POLICY	policySession	handle for the policy session being extended Auth Index: None
TPM2B_NONCE	nonceTPM	the policy nonce for the session This can be the Empty Buffer.
TPM2B_DIGEST	cpHashA	digest of the command parameters to which this authorization is limited This is not the <i>cpHash</i> for this command but the <i>cpHash</i> for the command to which this policy session will be applied. If it is not limited, the parameter will be the Empty Buffer.
TPM2B_NONCE	policyRef	a reference to a policy relating to the authorization – may be the Empty Buffer Size is limited to be no larger than the nonce size supported on the TPM.
INT32	expiration	time when authorization will expire, measured in seconds from the time that <i>nonceTPM</i> was generated If <i>expiration</i> is non-negative, a NULL Ticket is returned (see clause 23.2.5).
TPMT_SIGNATURE	auth	signed authorization (not optional)

Table 129 — TPM2_PolicySigned Response

Type	Name	Description
TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode	
TPM2B_TIMEOUT	timeout	implementation-specific time value, used to indicate to the TPM when the ticket expires If <i>policyTicket</i> is a NULL Ticket, then this shall be the Empty Buffer.
TPMT_TK_AUTH	policyTicket	produced if the command succeeds and <i>expiration</i> in the command was non-zero; this ticket will use the TPMT_ST_AUTH_SIGNED structure tag (see clause 23.2.5).

23.3.3 Detailed Actions

[[PolicySigned]]

23.4 TPM2_PolicySecret

23.4.1 General Description

This command includes a secret-based authorization to a policy. The caller proves knowledge of the secret value using an authorization session using the *authValue* associated with *authHandle*. A password session, an HMAC session, or a policy session containing TPM2_PolicyAuthValue() or TPM2_PolicyPassword() will satisfy this requirement.

If a policy session is used and use of the *authValue* of *authHandle* is not required, the TPM will return TPM_RC_MODE. That is, the session for *authHandle* must have either *isAuthValueNeeded* or *isPasswordNeeded* SET.

The secret is the *authValue* of the entity whose handle is *authHandle*, which may be any TPM entity with a handle and an associated *authValue*. This includes the reserved handles (for example, Platform, Storage, and Endorsement), NV Indexes, and loaded objects. *authEntity* is the entity referenced by *authHandle*. If *authEntity* references an Ordinary object, it must have *userWithAuth* SET.

NOTE 1 The *userWithAuth* requirement permits the implementation to use common authorization code.

If *authEntity* references a non-PIN Index, TPMA_NV_AUTHREAD is required to be SET in the Index. If *authEntity* references an NV PIN index, TPMA_NV_WRITTEN is required to be SET and *pinCount* must be less than *pinLimit*.

NOTE 2 The authorization value for a hierarchy cannot be used in this command if the hierarchy is disabled.

If the authorization check fails, then the normal dictionary attack logic is invoked. If *authEntity* references a NV PIN Pass index, a successful authorization check increments *pinCount*. If *authEntity* references a NV PIN Fail index, a failing authorization check increments *pinCount*. The authorization is checked even for a trial policy session.

If the authorization provided by the authorization session is valid, the command parameters are checked as described in clause 23.2.2.

When all validations have succeeded, *policySession*→*policyDigest* is updated by **PolicyUpdate()** (see clause 23.2.3).

PolicyUpdate(TPM_CC_PolicySecret, *authEntity*→*Name*, *policyRef*) (15)

authEntity→*Name* is a TPM2B_NAME. *policySession* is updated as described in clause 23.2.4. The TPM will optionally produce a ticket as described in clause 23.2.5.

If the session is a trial session, *policySession*→*policyDigest* is updated if the authorization is valid.

NOTE 2 If an HMAC is used to convey the authorization, a separate session is needed for the authorization. Because the HMAC in that authorization will include a nonce that prevents replay of the authorization, the value of the *nonceTPM* parameter in this command is limited. It is retained mostly to provide processing consistency with TPM2_PolicySigned().

23.4.2 Command and Response

Table 130 — TPM2_PolicySecret Command

Type	Name	Description

TPM_RC	responseCode	
TPM2B_TIMEOUT	timeout	implementation-specific time value used to indicate to the TPM when the ticket expires
TPMT_TK_AUTH	policyTicket	produced if the command succeeds and <i>expiration</i> in the command was non-zero (see clause 23.2.5). This ticket will use the TPMT_ST_AUTH_SECRET structure tag

23.4.3 Detailed Actions

[[PolicySecret]]

23.5 TPM2_PolicyTicket

23.5.1 General Description

This command is similar to TPM2_PolicySigned() except that it takes a ticket instead of a signed authorization. The ticket represents a validated authorization that had an expiration time associated with it.

The parameters of this command are checked as described in clause 23.2.2.

If the checks succeed, the TPM uses the *timeout*, *cpHashA*, *policyRef*, and *authName* to construct a ticket to compare with the value in *ticket*. If these tickets match, then the TPM will create a TPM2B_NAME (*objectName*) using *authName* and update the context of *policySession* by **PolicyUpdate()** (see clause 23.2.3).

PolicyUpdate(*commandCode*, *authName*, *policyRef*) (16)

If the structure tag of ticket is TPM_ST_AUTH_SECRET, then *commandCode* will be TPM_CC_PolicySecret. If the structure tag of ticket is TPM_ST_AUTH_SIGNED, then *commandCode* will be TPM_CC_PolicySigned.

policySession is updated as described in clause 23.2.4.

23.5.3 Detailed Actions

[[PolicyTicket]]

23.6 TPM2_PolicyOR

23.6.1 General Description

This command allows options in authorizations without requiring that the TPM evaluate all of the options. If a policy may be satisfied by different sets of conditions, the TPM need only evaluate one set that satisfies the policy. This command will indicate that one of the required sets of conditions has been satisfied.

$policySession \rightarrow policyDigest$ is compared against the list of provided values. If the current $policySession \rightarrow policyDigest$ does not match any value in the list, the TPM shall return TPM_RC_VALUE. Otherwise, the TPM will reset $policySession \rightarrow policyDigest$ to a Zero Digest. Then $policySession \rightarrow policyDigest$ is extended by the concatenation of TPM_CC_PolicyOR and the concatenation of all of the digests.

If $policySession$ is a trial session, the TPM will assume that $policySession \rightarrow policyDigest$ matches one of the list entries and compute the new value of $policyDigest$.

The algorithm for computing the new value for $policyDigest$ of $policySession$ is:

- a) Concatenate all the digest values in $pHashList$:

$$digests := pHashList.digests[1].buffer || \dots || pHashList.digests[n].buffer \quad (17)$$

NOTE 1 The TPM will not return an error if the size of an entry is not the same as the size of the digest of the policy. However, that entry cannot match $policyDigest$.

- b) Reset $policyDigest$ to a Zero Digest.

- c) Extend the command code and the hashes computed in step a) above:

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyOR || digests) \quad (18)$$

NOTE 2 The computation in b) and c) above is equivalent to:

$$policyDigest_{new} := H_{policyAlg}(0 \dots 0 || TPM_CC_PolicyOR || digests)$$

A TPM shall support a list with at least eight tagged digest values.

NOTE 3 If policies are to be portable between TPMs, then they should not use more than eight values.

23.6.3 Detailed Actions

[[PolicyOR]]

23.7 TPM2_PolicyPCR

23.7.1 General Description

This command is used to cause conditional gating of a policy based on PCR. This command together with TPM2_PolicyOR() allows one group of authorizations to occur when PCR are in one state and a different set of authorizations when the PCR are in a different state.

The TPM will modify the *pcrs* parameter so that bits that correspond to unimplemented PCR are CLEAR. If *policySession* is not a trial policy session, the TPM will use the modified value of *pcrs* to select PCR values to hash according to TPM 2.0 Part 1, *Selecting Multiple PCR*. The hash algorithm of the policy session is used to compute a digest (*digestTPM*) of the selected PCR. If *pcrDigest* does not have a length of zero, then it is compared to *digestTPM*; and if the values do not match, the TPM shall return TPM_RC_VALUE and make no change to *policySession*→*policyDigest*. If the values match, or if the length of *pcrDigest* is zero, then *policySession*→*policyDigest* is extended by:

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyPCR || pcrs || digestTPM) \quad (19)$$

where

<i>pcrs</i>	the <i>pcrs</i> parameter with bits corresponding to unimplemented PCR set to 0
<i>digestTPM</i>	the digest of the selected PCR using the hash algorithm of the policy session

NOTE 1 If the caller provides the expected PCR value, the intention is that the policy evaluation stop at that point if the PCR do not match. If the caller does not provide the expected PCR value, then the validity of the settings will not be determined until an attempt is made to use the policy for authorization. If the policy is constructed such that the PCR check comes before user authorization checks, this early termination would allow software to avoid unnecessary prompts for user input to satisfy a policy that would fail later due to incorrect PCR values.

After this command completes successfully, the TPM shall return TPM_RC_PCR_CHANGED if the policy session is used for authorization and the PCR are not known to be correct.

The TPM uses a “generation” number (*pcrUpdateCounter*) that is incremented each time PCR are updated (unless the PCR being changed is specified not to cause a change to this counter). The value of this counter is stored in the policy session context (*policySession*→*pcrUpdateCounter*) when this command is executed. When the policy is used for authorization, the current value of the counter is compared to the value in the policy session context and the authorization will fail if the values are not the same.

When this command is executed, *policySession*→*pcrUpdateCounter* is checked to see if it has been previously set (in the reference implementation, it has a value of zero if not previously set). If it has been set, it will be compared with the current value of *pcrUpdateCounter* to determine if any PCR changes have occurred. If the values are different, the TPM shall return TPM_RC_PCR_CHANGED.

NOTE 2 Since the *pcrUpdateCounter* is updated if any PCR is extended (except those specified not to do so), this means that the command will fail even if a PCR not specified in the policy is updated. This is an optimization for the purposes of conserving internal TPM memory. This would be a rare occurrence, and, if this should occur, the policy could be reset using the TPM2_PolicyRestart command and rerun.

If *policySession*→*pcrUpdateCounter* has not been set, then it is set to the current value of *pcrUpdateCounter*.

If this command is used for a trial *policySession*, *policySession*→*policyDigest* will be updated using the values from the command rather than the values from a digest of the TPM PCR. If the caller does not provide PCR settings (*pcrDigest* has a length of zero), the TPM may (and it is preferred to) use the

current TPM PCR settings (*digestTPM*) in the calculation for the new *policyDigest*. The TPM may return an error if the caller does not provide a PCR digest for a trial policy session, but this is not the preferred behavior.

The TPM will not check any PCR and will compute:

$$policyDigest_{new} := \mathbf{H}_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyPCR || pcrs || pcrDigest) \quad (20)$$

In this computation, *pcrs* is the input parameter without modification.

NOTE 3 The *pcrs* parameter is expected to match the configuration of the TPM for which the policy is being computed which may not be the same as the TPM on which the trial policy is being computed.

NOTE 4 Although no PCR are checked in a trial policy session, *pcrDigest* is expected to correspond to some useful PCR values. It is legal, but pointless, to have the TPM aid in calculating a *policyDigest* corresponding to PCR values that are not useful in practice.

23.7.3 Detailed Actions

[[PolicyPCR]]

23.8 TPM2_PolicyLocality

23.8.1 General Description

This command indicates that the authorization will be limited to a specific locality.

policySession→*commandLocality* is a parameter kept in the session context. When the policy session is started, this parameter is initialized to a value that allows the policy to apply to any locality.

If *locality* has a value greater than 31, then an extended locality is indicated. For an extended locality, the TPM will validate that *policySession*→*commandLocality* has not previously been set or that the current value of *policySession*→*commandLocality* is the same as *locality* (TPM_RC_RANGE).

When *locality* is not an extended locality, the TPM will validate that the *policySession*→*commandLocality* is not set to an extended locality value (TPM_RC_RANGE). If not the TPM will disable any locality not SET in the *locality* parameter. If the result of disabling localities results in no locality being enabled, the TPM will return TPM_RC_RANGE.

If no error occurred in the validation of *locality*, *policySession*→*policyDigest* is extended with

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyLocality || locality) \quad (21)$$

Then *policySession*→*commandLocality* is updated to indicate which localities are still allowed after execution of TPM2_PolicyLocality().

When the policy session is used to authorize a command, the authorization will fail if the locality used for the command is not one of the enabled localities in *policySession*→*commandLocality*.

23.8.3 Detailed Actions

[[PolicyLocality]]

23.9 TPM2_PolicyNV

23.9.1 General Description

This command is used to cause conditional gating of a policy based on the contents of an NV Index. It is an immediate assertion. The NV index is validated during the TPM2_PolicyNV() command, not when the session is used for authorization.

The authorization to read the NV Index must succeed even if *policySession* is a trial policy session.

If *policySession* is a trial policy session, the TPM will update *policySession*→*policyDigest* as shown in equations (22) and (23) below and return TPM_RC_SUCCESS. It will not perform any further validation. The remainder of this general description would apply only if *policySession* is not a trial policy session.

An authorization session providing authorization to read the NV Index shall be provided.

If TPMA_NV_WRITTEN is not SET in the NV Index, the TPM shall return TPM_RC_NV_UNINITIALIZED. If TPMA_NV_READLOCKED of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

For an NV Index with the TPM_NT_COUNTER or TPM_NT_BITS attribute SET, the TPM may ignore the *offset* parameter and use an offset of 0. Therefore, it is recommended that the caller set the *offset* parameter to 0 for interoperability.

If *offset* and the *size* field of *data* add to a value that is greater than the *dataSize* field of the NV Index referenced by *nvIndex*, the TPM shall return an error (TPM_RC_NV_RANGE). The implementation may return an error (TPM_RC_VALUE) if it performs an additional check and determines that *offset* is greater than the *dataSize* field of the NV Index.

operandA begins at *offset* into the NV index contents and has a size equal to the size of *operandB*. The TPM will perform the indicated arithmetic check using *operandA* and *operandB*. If the check fails, the TPM shall return TPM_RC_POLICY and not change *policySession*→*policyDigest*. If the check succeeds, the TPM will hash the arguments:

$$args := H_{policyAlg}(operandB.buffer || offset || operation) \quad (22)$$

where

$H_{policyAlg}()$	hash function using the algorithm of the policy session
<i>operandB</i>	the value used for the comparison
<i>offset</i>	offset from the start of the NV Index data to start the comparison
<i>operation</i>	the operation parameter indicating the comparison being performed

The value of *args* and the Name of the NV Index are extended to *policySession*→*policyDigest* by

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyNV || args || nvIndex \rightarrow Name) \quad (23)$$

where

$H_{policyAlg}()$	hash function using the algorithm of the policy session
<i>args</i>	value computed in equation (22)
<i>nvIndex</i> → <i>Name</i>	the Name of the NV Index

The signed arithmetic operations are performed using twos-complement.

NOTE When comparing two negative values, TPMs prior to revision 1.66 might have implemented the signed arithmetic operations using signed-magnitude.

Magnitude comparisons assume that the octet at offset zero in the referenced NV location and in *operandB* contain the most significant octet of the data.

TPM_RC	responseCode	

23.9.3 Detailed Actions

[[PolicyNV]]

23.10 TPM2_PolicyCounterTimer

23.10.1 General Description

This command is used to cause conditional gating of a policy based on the contents of the TPMS_TIME_INFO structure.

If *policySession* is a trial policy session, the TPM will update *policySession*→*policyDigest* as shown in equations (24) and (25) below and return TPM_RC_SUCCESS. It will not perform any validation. The remainder of this general description would apply only if *policySession* is not a trial policy session.

The TPM will perform the indicated arithmetic check on the indicated portion of the TPMS_TIME_INFO structure. If the check fails, the TPM shall return TPM_RC_POLICY and not change *policySession*→*policyDigest*. If the check succeeds, the TPM will hash the arguments:

$$args := H_{policyAlg}(operandB.buffer || offset || operation) \quad (24)$$

where

$H_{policyAlg}()$	hash function using the algorithm of the policy session
<i>operandB.buffer</i>	the value used for the comparison
<i>offset</i>	offset from the start of the TPMS_TIME_INFO structure at which the comparison starts
<i>operation</i>	the operation parameter indicating the comparison being performed

NOTE There is no security related reason for the double hash.

The value of *args* is extended to *policySession*→*policyDigest* by

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyCounterTimer || args) \quad (25)$$

where

$H_{policyAlg}()$	hash function using the algorithm of the policy session
<i>args</i>	value computed in equation (24)

The signed arithmetic operations are performed using twos-complement. The indicated portion of the TPMS_TIME_INFO structure begins at *offset* and has a length of *operandB.size*. If the number of octets to be compared overflows the TPMS_TIME_INFO structure, the TPM returns TPM_RC_RANGE. If *offset* is greater than the size of the marshaled TPMS_TIME_INFO structure, the TPM returns TPM_RC_VALUE. The structure is marshaled into its canonical form with no padding. The TPM does not check for alignment of the offset with a TPMS_TIME_INFO structure member.

NOTE 1 When comparing two negative values, TPMs prior to revision 1.66 might have implemented the signed arithmetic operations using signed-magnitude.

Magnitude comparisons assume that the octet at offset zero in the referenced location and in *operandB* contain the most significant octet of the data.

If *operation* is TPM_EO_UNSIGNED_LT and the comparison is specifically against *Time* in the TPMS_TIME_INFO structure (*offset* = 0), then the comparison value will indicate a time in seconds since the *nonceTPM* for the policy session was generated after which the policy session expires and cannot be used for authorization.

NOTE 2 This special case for TPM_EO_UNSIGNED_LT was added in revision 1.65.

When used to set an expiration time, the value in *operandB* is used like the *expiration* parameter of `TPM2_PolicySigned()` or `TPM2_PolicySecret()`. The differences are that the *operandB* parameter is a 64-bit, unsigned value instead of a 32-bit signed value.

EXAMPLE This enables time limited key usage. A policy can be designed to permit a key to be authorized for e.g., one hour.

NOTE 4 A TPM implementation is allowed to reject (`TPM_RC_VALUE`) an expiration value with a decimal value larger than 2,147,483,647 (corresponds to 68 years).

For the comparison, *operandB* is converted to a 64-bit integer (*limit*) and *policySession→startTime* is added. If the resulting value of *limit* is less than TPM Time, then the TPM returns an error (`TPM_RC_EXPIRED`). Otherwise, the policy session context is updated:

$$policySession \rightarrow policyExpiration := \min(policySession \rightarrow policyExpiration, limit) \quad (26)$$

EXAMPLE If *OperandB* has a *buffer* size of 8 bytes with a value of `0016, 0016, 0016, 0016, 0016, 0016, 0516`, then the authorization is valid for 5 seconds from the time the policy session's *nonceTpm* was generated.

23.10.3 Detailed Actions

[[PolicyCounterTimer]]

23.11 TPM2_PolicyCommandCode

23.11.1 General Description

This command indicates that the authorization will be limited to a specific command code.

If *policySession*→*commandCode* has its default value, then it will be set to *code*. If *policySession*→*commandCode* does not have its default value, then the TPM will return TPM_RC_VALUE if the two values are not the same.

If *code* is not implemented, the TPM will return TPM_RC_POLICY_CC.

If the TPM does not return an error, it will update *policySession*→*policyDigest* by

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyCommandCode || code) \quad (27)$$

NOTE 1 If a previous TPM2_PolicyCommandCode() had been executed, then it is probable that the policy expression is improperly formed but the TPM does not return an error if *code* is the same.

NOTE 2 A TPM2_PolicyOR() would be used to allow an authorization to be used for multiple commands.

When the policy session is used to authorize a command, the TPM will fail the command if the *commandCode* of that command does not match *policySession*→*commandCode*.

This command, or TPM2_PolicyDuplicationSelect(), is required to enable the policy to be used for ADMIN role authorization.

EXAMPLE Before TPM2_Certify() can be executed, TPM2_PolicyCommandCode() with *code* set to TPM_CC_Certify is required.

23.12.3 Detailed Actions

[[PolicyPhysicalPresence]]

23.13 TPM2_PolicyCpHash

23.13.1 General Description

This command is used to allow a policy to be bound to a specific command with specific parameters, executing against specific objects. To bind a policy to a specific command code only, TPM2_PolicyCommandCode() can be used. To bind a policy to a specific command and parameters, but not specific objects, TPM2_PolicyParameters() can be used. To bind a policy to specific objects, but not a specific command or parameters, TPM2_PolicyNameHash() can be used.

Only one of the following:

- A bound session (created with TPM2_StartAuthSession())
- TPM2_PolicyCpHash()
- TPM2_PolicyNameHash()
- TPM2_PolicyParameters()
- TPM2_PolicyTemplate()

can be used for a policy session. Because they are mutually exclusive, they can share *policySession*→*cpHash*.

If *policySession*→*cpHash* is already set and not the same as *cpHashA*, then the TPM shall return TPM_RC_CPHASH. If *cpHashA* does not have the size of the *policySession*→*policyDigest*, the TPM shall return TPM_RC_SIZE.

NOTE 1 If a previous TPM2_PolicyCpHash() had been executed, then it is probable that the policy expression is improperly formed but the TPM does not return an error if *cpHash* is the same.

If the *cpHashA* checks succeed, *policySession*→*cpHash* is set to *cpHashA* and *policySession*→*policyDigest* is updated with

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyCpHash || cpHashA) \quad (29)$$

NOTE 2 If TPM2_PolicyCpHash() is run with command parameter encryption, the TPM stores the decrypted *cpHashA* in *policySession*→*cpHash*. When this policy session is used later for authorization, the stored decrypted *cpHashA* is unlikely to match the command's *cpHash* if the command uses command parameter encryption since the command's *cpHash* will be calculated on the encrypted data.

23.13.2 Command and Response

23.13.3 Detailed Actions

[[PolicyCpHash]]

23.14 TPM2_PolicyNameHash

23.14.1 General Description

This command allows a policy to be bound to a specific set of TPM entities without being bound to the parameters of the command. This is most useful for commands such as TPM2_Duplicate() and for TPM2_PCR_Event() when the referenced PCR requires a policy.

The *nameHash* parameter contains the digest of the Names associated with the handles to be used in the authorized command.

EXAMPLE For the TPM2_Duplicate() command, two handles are provided. One is the handle of the object being duplicated and the other is the handle of the new parent. For that command, *nameHash* would contain:

$$nameHash := H_{policyAlg}(objectHandle \rightarrow Name || newParentHandle \rightarrow Name)$$

Only one of the following:

- A bound session (created with TPM2_StartAuthSession())
- TPM2_PolicyCpHash()
- TPM2_PolicyNameHash()
- TPM2_PolicyParameters()
- TPM2_PolicyTemplate()

can be used for a policy session. Because they are mutually exclusive, they can share use *policySession*→*cpHash*.

If *policySession*→*cpHash* is already set, the TPM shall return TPM_RC_CPHASH. If the size of *nameHash* is not the size of *policySession*→*policyDigest*, the TPM shall return TPM_RC_SIZE. Otherwise, *policySession*→*cpHash* is set to *nameHash*.

If this command completes successfully, when the policy session is used for authorization, the *policySession*→*cpHash* will be compared to the digest of the Names associated with the handles in the command.

The *policySession*→*policyDigest* will be updated with

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyNameHash || nameHash) \quad (30)$$

NOTE 2 This command can only be used with TPM2_PolicyAuthorize() or TPM2_PolicyAuthorizeNV. The owner of the object being duplicated provides approval for their object to be migrated to a specific new parent.

Without this approval, the Name of the Object would need to be known at the time that Object's policy is created. However, since the Name of the Object includes its policy, the Name is not known. The Name can be known by the authorizing entity.

TPM_RC	responseCode	

23.14.3 Detailed Actions

[[PolicyNameHash]]

23.15 TPM2_PolicyDuplicationSelect

23.15.1 General Description

This command allows qualification of duplication to allow duplication to a selected new parent.

If this command not used in conjunction with a TPM2_PolicyAuthorize() Command, then only the new parent is selected and *includeObject* should be CLEAR.

EXAMPLE When an object is created when the list of allowed duplication targets is known, the policy would be created with *includeObject* CLEAR.

NOTE 1 Only the new parent may be selected because, without TPM2_PolicyAuthorize(), the Name of the Object to be duplicated would need to be known at the time that Object's policy is created. However, since the Name of the Object includes its policy, the Name is not known. The Name can be known by the authorizing entity (a PolicyAuthorize Command) in which case *includeObject* may be SET.

If used in conjunction with TPM2_PolicyAuthorize(), then the authorizer of the new policy has the option of selecting just the new parent or of selecting both the new parent and the duplication Object.

NOTE 2 If the authorizing entity for an TPM2_PolicyAuthorize() only specifies the new parent, then that authorization may be applied to the duplication of any number of other Objects. If the authorizing entity specifies both a new parent and the duplicated Object, then the authorization only applies to that pairing of Object and new parent.

If either *policySession*→*cpHash* or *policySession*→*nameHash* has been previously set, the TPM shall return TPM_RC_CPHASH. Otherwise, *policySession*→*nameHash* will be set to:

$$nameHash := H_{policyAlg}(objectName.name || newParentName.name) \quad (31)$$

NOTE 3 It is allowed that *policySession*→*nameHash* and *policySession*→*cpHash* share the same memory space.

NOTE 4 The Name in these equations uses Name.name, indicating that the UINT16 size is not included in the hash.

The *policySession*→*policyDigest* will be updated according to the setting of *includeObject*. If equal to YES, *policySession*→*policyDigest* is updated by:

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyDuplicationSelect || objectName.name || newParentName.name || includeObject) \quad (32)$$

If *includeObject* is NO, *policySession*→*policyDigest* is updated by:

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyDuplicationSelect || newParentName.name || includeObject) \quad (33)$$

NOTE 5 *policySession*→*nameHash* receives the digest of both Names so that the check performed in TPM2_Duplicate() may be the same regardless of which Names are included in *policySession*→*policyDigest*. This means that, when TPM2_PolicyDuplicationSelect() is executed, it is only valid for a specific pair of duplication object and new parent.

If the command succeeds, *policySession*→*commandCode* is set to TPM_CC_Duplicate.

NOTE 6 The normal use of this command is before a TPM2_PolicyAuthorize(). An authorized entity would approve a *policyDigest* that allowed duplication to a specific new parent. The authorizing entity may want to limit the authorization so that the approval allows only a specific object to be duplicated to the new parent. In that case, the authorizing entity would approve the *policyDigest* of equation (32).

23.15.3 Detailed Actions

[[PolicyDuplicationSelect]]

23.16 TPM2_PolicyAuthorize

23.16.1 General Description

This command allows policies to change. If a policy were static, then it would be difficult to add users to a policy. This command lets a policy authority sign a new policy so that it may be used in an existing policy.

The authorizing entity signs a structure that contains

$$aHash := H_{aHashAlg}(approvedPolicy || policyRef) \quad (34)$$

The *aHashAlg* is required to be the *nameAlg* of the key used to sign the *aHash*. The *aHash* value is then signed (symmetric or asymmetric) by *keySign*. That signature is then checked by the TPM in 20.1 TPM2_VerifySignature() which produces a ticket by

$$HMAC(proof, (TPM_ST_VERIFIED || aHash || keySign \rightarrow name)) \quad (35)$$

NOTE 1 The reason for the validation is because of the expectation that the policy will be used multiple times and it is more efficient to check a ticket than to load an object each time to check a signature.

The ticket is then used in TPM2_PolicyAuthorize() to validate the parameters.

The *keySign* parameter is required to be a valid object name using *nameAlg* other than TPM_ALG_NULL. If the first two octets of *keySign* are not a valid hash algorithm, the TPM shall return TPM_RC_HASH. If the remainder of the Name is not the size of the indicated digest, the TPM shall return TPM_RC_SIZE.

The TPM validates that the *approvedPolicy* matches the current value of *policySession*→*policyDigest* and if not, shall return TPM_RC_VALUE.

The TPM then validates that the parameters to TPM2_PolicyAuthorize() match the values used to generate the ticket. If so, the TPM will reset *policySession*→*policyDigest* to a Zero Digest. Then it will update *policySession*→*policyDigest* with **PolicyUpdate()** (see clause 23.2.3).

$$\mathbf{PolicyUpdate}(TPM_CC_PolicyAuthorize, keySign, policyRef) \quad (36)$$

If the ticket is not valid, the TPM shall return TPM_RC_POLICY.

If *policySession* is a trial session, *policySession*→*policyDigest* is extended as if the ticket is valid without actual verification.

NOTE 2 The unmarshaling process requires that a proper TPMT_TK_VERIFIED be provided for *checkTicket* but it may be a NULL Ticket. A NULL ticket is useful in a trial policy, where the caller uses the TPM to perform policy calculations but does not have a valid authorization ticket.

23.16.2 Command and Response

Table 154 — TPM2_PolicyAuthorize Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS if an audit or decrypt session is present; otherwise, TPM_ST_NO_SESSIONS
UINT32	commandSize

23.16.3 Detailed Actions

[[PolicyAuthorize]]

23.17 TPM2_PolicyAuthValue

23.17.1 General Description

This command allows a policy to be bound to the authorization value of the authorized entity.

When this command completes successfully, *policySession*→*isAuthValueNeeded* is SET to indicate that the *authValue* will be included in *hmacKey* when the authorization HMAC is computed for the command being authorized using this session. Additionally, *policySession*→*isPasswordNeeded* will be CLEAR.

NOTE 1 If a policy does not use this command, then the *hmacKey* for the authorized command would only use *sessionKey*. If *sessionKey* is not present, then the *hmacKey* is an Empty Buffer and no HMAC would be computed.

If successful, *policySession*→*policyDigest* will be updated with

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyAuthValue) \quad (37)$$

NOTE 2 Using a policy that contains TPM2_PolicyPassword() inside a salted and/or bound policy session is equivalent to using it inside an unsalted, unbound policy session.

Design TPM2_PolicyAuthValue-based policies for use in salted and/or bound policy sessions such that TPM2_PolicyAuthValue() is called (using the salted and/or bound session as an audit session) before other policy commands, so that the TPM2_PolicyAuthValue() call can be verified not to have been substituted with TPM2_PolicyPassword(), before proceeding to satisfy the rest of the policy (e.g., before having a signer sign a session nonce for TPM2_PolicySigned()).

23.17.2 Command and Response

UINT32	responseSize	
TPM_RC	responseCode	

23.17.3 Detailed Actions

[[PolicyAuthValue]]

23.18 TPM2_PolicyPassword

23.18.1 General Description

This command allows a policy to be bound to the authorization value of the authorized object.

When this command completes successfully, *policySession*→*isPasswordNeeded* is SET to indicate that *authValue* of the authorized object will be checked when the session is used for authorization. The caller will provide the *authValue* in clear text in the *hmac* parameter of the authorization. The comparison of *hmac* to *authValue* is performed as if the authorization is a password.

NOTE 1 The parameter field in the policy session where the authorization value is provided is called *hmac*. If TPM2_PolicyPassword() is part of the sequence, then the field will contain a password and not an HMAC.

If successful, *policySession*→*policyDigest* will be updated with

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyAuthValue) \quad (38)$$

NOTE 2 This is the same extend value as used with TPM2_PolicyAuthValue so that the evaluation may be done using either an HMAC or a password with no change to the *authPolicy* of the object. The reason that two commands are present is to indicate to the TPM if the *hmac* field in the authorization will contain an HMAC or a password value.

When this command is successful, *policySession*→*isAuthValueNeeded* will be CLEAR.

23.19.3 Detailed Actions

[[PolicyGetDigest]]

23.20 TPM2_PolicyNvWritten

23.20.1 General Description

This command allows a policy to be bound to the TPMA_NV_WRITTEN attributes. This is a deferred assertion. Values are stored in the policy session context and checked when the policy is used for authorization.

If *policySession→checkNVWritten* is CLEAR, it is SET and *policySession→nvWrittenState* is set to *writtenSet*. If *policySession→checkNVWritten* is SET, the TPM will return TPM_RC_VALUE if *policySession→nvWrittenState* and *writtenSet* are not the same.

If the TPM does not return an error, it will update *policySession→policyDigest* by

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyNvWritten || writtenSet) \quad (39)$$

When the policy session is used to authorize a command, the TPM will fail the command if *policySession→checkNVWritten* is SET and *nvIndex→attributes→TPMA_NV_WRITTEN* does not match *policySession→nvWrittenState*.

NOTE 1 A typical use case is a simple policy for the first write during manufacturing provisioning that would require TPMA_NV_WRITTEN CLEAR and a more complex policy for later use that would require TPMA_NV_WRITTEN SET.

NOTE 2 When an Index is written, it has a different authorization name than an Index that has not been written. It is possible to use this change in the NV Index to create a write-once Index.

23.20.3 Detailed Actions

[[PolicyNvWRitten]]

23.21 TPM2_PolicyTemplate

23.21.1 General Description

This command allows a policy to be bound to a specific creation template. This is most useful for an object creation command such as TPM2_Create(), TPM2_CreatePrimary(), or TPM2_CreateLoaded().

The *templateHash* parameter should contain the digest of the template that will be required for the *inPublic* parameter of an Object creation command.

Only one of the following:

- A bound session (created with TPM2_StartAuthSession())
- TPM2_PolicyCpHash()
- TPM2_PolicyNameHash()
- TPM2_PolicyParameters()
- TPM2_PolicyTemplate()

can be used for a policy session. Because they are mutually exclusive, they can share *policySession→cpHash*.

If *policySession→isTemplateSet* is SET and *policySession→cpHash* is not equal to *templateHash*, the TPM shall return TPM_RC_VALUE.

NOTE 1 Revision 01.38 of this specification permitted the TPM to return TPM_RC_CPHASH.

Otherwise, if *policySession→cpHash* is already set, the TPM shall return TPM_RC_CPHASH.

NOTE 2 Revision 01.38 of this specification permitted the TPM to return TPM_RC_VALUE.

If the size of *templateHash* is not the size of *policySession→policyDigest*, the TPM shall return TPM_RC_SIZE. Otherwise, *policySession→cpHash* is set to *templateHash*.

NOTE 3 The digest calculation includes the TPM2B buffer but not the TPM2B size.

If this command completes successfully, when the policy session is used for authorization, the *policySession→cpHash* will be compared to the digest of the *inPublic* parameter.

NOTE 4 This allows the space normally used to hold *policySession→cpHash* to be used for *policySession→templateHash* instead.

The *policySession→policyDigest* will be updated with

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyTemplate || templateHash) \quad (40)$$

UINT32	responseSize	
TPM_RC	responseCode	

23.21.3 Detailed Actions

[[PolicyTemplate]]

23.22 TPM2_PolicyAuthorizeNV

23.22.1 General Description

This command provides a capability that is the equivalent of a revocable policy. With TPM2_PolicyAuthorize(), the authorization ticket never expires, so the authorization may not be withdrawn. With this command, the approved policy is kept in an NV Index location so that the policy may be changed as needed to render the old policy unusable.

NOTE 1 This command is useful for Objects but of limited value for other policies that are persistently stored in TPM NV, such as the OwnerPolicy.

An authorization session providing authorization to read the NV Index shall be provided.

The authorization to read the NV Index must succeed even if *policySession* is a trial policy session.

If *policySession* is a trial policy session, the TPM will update *policySession*→*policyDigest* as shown in equation (41) below and return TPM_RC_SUCCESS. It will not perform any further validation. The remainder of this general description would apply only if *policySession* is not a trial policy session.

NOTE 2 If read access is controlled by policy, the policy should include a branch that authorizes a TPM2_PolicyAuthorizeNV().

If TPMA_NV_WRITTEN is not SET in the Index referenced by *nvIndex*, the TPM shall return TPM_RC_NV_UNINITIALIZED. If TPMA_NV_READLOCKED of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

The *dataSize* of the NV Index referenced by *nvIndex* is required to be at least large enough to hold a properly formatted TPMT_HA (TPM_RC_INSUFFICIENT).

NOTE 3 A TPMT_HA contains a TPM_ALG_ID followed a digest that is consistent in size with the hash algorithm indicated by the TPM_ALG_ID.

It is an error (TPM_RC_HASH) if the first two octets of the Index are not a TPM_ALG_ID for a hash algorithm implemented on the TPM or if the indicated hash algorithm does not match *policySession*→*authHash*.

NOTE 4 The TPM_ALG_ID is stored in the first two octets in big endian format.

The TPM will compare *policySession*→*policyDigest* to the contents of the NV Index, starting at the first octet after the TPM_ALG_ID (the third octet) and return TPM_RC_VALUE if they are not the same.

NOTE 5 If the Index does not contain enough bytes for the compare, then TPM_RC_INSUFFICIENT is generated as indicated above.

NOTE 6 The *dataSize* of the Index may be larger than is required for this command. This permits the Index to include metadata.

If the comparison is successful, the TPM will reset *policySession*→*policyDigest* to a Zero Digest. Then it will update *policySession*→*policyDigest* with

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyAuthorizeNV || nvIndex \rightarrow Name) \quad (41)$$

23.22.2 Command and Response

23.22.3 Detailed Actions

[[PolicyAuthorizeNV]]

23.23 TPM2_PolicyCapability

23.23.1 General Description

This command is used to cause conditional gating of a policy based on the value of a TPM capability. It is an immediate assertion.

The TPM will use the parameters of this command to fetch the indicated property that is used by the TPM in the requested logical operation.

If the requested TPM *property* does not exist, the TPM will return TPM_RC_POLICY unless the *operation* is TPM_EO_NEQ.

If the requested property exists, it will have a property type as indicated in Table 168 — Capability Contents

Table 168 — Capability Contents

<i>capability</i>	<i>property</i>	<i>property type</i>
TPM_CAP_ALGS	TPM_ALG_ID	TPMS_ALG_PROPERTY
TPM_CAP_HANDLES	TPM_HANDLE	TPM_HANDLE
TPM_CAP_COMMANDS	TPM_CC	TPMA_CC
TPM_CAP_PP_COMMANDS	TPM_CC	TPM_CC
TPM_CAP_AUDIT_COMMANDS	TPM_CC	TPM_CC
TPM_CAP_TPM_PROPERTIES	TPM_PT	TPMS_TAGGED_PROPERTY
TPM_CAP_PCR_PROPERTIES	TPM_PT_PCR	TPMS_TAGGED_PCR_SELECT
TPM_CAP_ECC_CURVES	TPM_ECC_CURVE	TPM_ECC_CURVE
TPM_CAP_AUTH_POLICIES	TPM_RH	TPMS_TAGGED_POLICY
TPM_CAP_ACT	TPM_HANDLE	TPMS_ACT_DATA
TPM_CAP_VENDOR_PROPERTY	manufacturer specific	manufacturer-specific values

The TPM will perform the indicated logical operation (*operation*) using the property structure as operandA. If the operands do not have the desired relationship, then the TPM returns TPM_RC_POLICY.

If *property* is other than a value listed above, then the TPM returns TPM_RC_VALUE.

EXAMPLE 1 If property is TPM_CAP_PCERS, then the TPM returns TPM_RC_VALUE.

EXAMPLE 2 The *capability* TPM_CAP_TPM_PROPERTIES with a *property* TPM_PT_REVISION uses the TPMS_TAGGED_PROPERTY as operandA. An *offset* of 4 references the UINT32 *value*. This permits a policy based on the TPM revision. If the TPM does not support TPM_PT_REVISION, the property does not exist.

EXAMPLE 3 The *capability* TPM_CAP_ACT with the *property* TPM_RH_ACT_0 uses the TPMS_ACT_DATA as operandA. An *offset* of 8 references the TPMA_ACT member. With a bit field *operation*, this permits a policy based on the *signaled* bit. If the TPM does not support TPM_RH_ACT_0, the property does not exist.

If the policy check succeeds, the TPM will hash the parameters of the command by:

$$args := H_{policyAlg}(operandB.buffer || offset || operation || capability || property) \quad (42)$$

using the hash algorithm of the policy session.

The value of *args* is extended to *policySession* → *policyDigest* by

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyCapability || args) \quad (43)$$

where:

$H_{policyAlg}()$ hash function using the algorithm of the policy session
args value computed in equation (42)

This command may be used with a trial policy.

NOTE TPM2_PolicyCapability() was added in revision 01.65.

[[PolicyCapability]]

23.24 TPM2_PolicyParameters

23.24.1 General Description

This command is used to allow a policy to be bound to a specific command and command parameters, but not specific objects. To bind a policy to a specific command code only, TPM2_PolicyCommandCode() can be used. To bind a policy to a specific command, parameters, and objects, TPM2_PolicyCpHash() can be used. To bind a policy to specific objects, but not a specific command or parameters, TPM2_PolicyNameHash() can be used.

Only one of the following:

- A bound session (created with TPM2_StartAuthSession())
- TPM2_PolicyCpHash()
- TPM2_PolicyNameHash()
- TPM2_PolicyParameters()
- TPM2_PolicyTemplate()

can be used for a policy session. Because they are mutually exclusive, they can share $policySession \rightarrow cpHash$.

If $policySession \rightarrow cpHash$ is already set, the TPM shall return TPM_RC_CPHASH. If the size of $pHash$ is not the size of $policySession \rightarrow policyDigest$, the TPM shall return TPM_RC_SIZE. Otherwise, $policySession \rightarrow cpHash$ is set to $pHash$.

If this command completes successfully, when the policy session is used for authorization, the $policySession \rightarrow cpHash$ will be compared to $pHash$, the digest of the parameter.

The $pHash$ is the hash of the $commandCode$ and all of the parameters of the command being authorized by the policy session. That is, $pHash$ is calculated using a modified form of Part 1, clause “Command Parameter Hash” where the Names are skipped.

NOTE 1 $commandTag$, $commandSize$ and the Names of the associated objects are not included in $pHash$.

NOTE 2 The TPM calculates $pHash$ on the decrypted parameters, even if TPM2_PolicyParameters() is run with command parameter encryption. When this policy session is used later for authorization, it is unlikely be useful if the command uses command parameter encryption since the command's $pHash$ will be calculated on the encrypted data.

This is a deferred assertion and the $pHash$ is checked when $policySession$ is used to authorize a command.

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_PolicyParameters || pHash) \quad (44)$$

NOTE TPM2_PolicyParameters() was added in revision 01.70.

[[PolicyParameters]]

24 Hierarchy Commands

24.1 TPM2_CreatePrimary

24.1.1 General Description

This command is used to create a Primary Object under one of the Primary Seeds or a Temporary Object under TPM_RH_NULL. The command uses a TPM2B_PUBLIC as a template for the object to be created. The size of the *unique* field shall not be checked for consistency with the other object parameters. The command will create and load a Primary Object. The sensitive area is not returned.

NOTE 1 Since the sensitive data is not returned, the key cannot be reloaded. It can either be made persistent or it can be recreated.

NOTE 2 For interoperability, the *unique* field should not be set to a value that is larger than allowed by object parameters, so that the unmarshaling will not fail.

NOTE 3 An Empty Buffer is a legal *unique* field value.

EXAMPLE 1 A TPM_ALG_RSA object with a *keyBits* of 2048 in the object's parameters should have a *unique* field that is no larger than 256 bytes.

NOTE 4 It is recommended that a TPM_ALG_KEYEDHASH or a TPM_ALG_SYMCIPHER object have a *unique* field this is no larger than the digest produced by the object's *nameAlg*.

Any type of object and attributes combination that is allowed by TPM2_Create() may be created by this command. The constraints on templates and parameters are the same as TPM2_Create() except that a Primary Storage Key and a Temporary Storage Key are not constrained to use the algorithms of their parents.

For setting of the attributes of the created object, *fixedParent*, *fixedTPM*, *decrypt*, and *restricted* are implied to be SET in the parent (a Permanent Handle). If *primaryHandle* is a firmware-limited hierarchy, then *firmwareLimited* is implied to be SET in the parent. If *primaryHandle* is an SVN-limited hierarchy, then *svnLimited* is implied to be SET in the parent. The remaining attributes are implied to be CLEAR.

The TPM will derive the object from the Primary Seed indicated in *primaryHandle* using an approved KDF.

All of the bits of the template are used in the creation of the Primary Key. Methods for creating a Primary Object from a Primary Seed are described in TPM 2.0 Part 1 and implemented in TPM 2.0 Part 4.

If this command is called multiple times with the same *inPublic* parameter, *inSensitive.data*, and Primary Seed, the TPM shall produce the same Primary Object.

NOTE 4 If the Primary Seed is changed, the Primary Objects generated with the new seed will be statistically unique even if the parameters of the call are the same.

This command requires authorization. Authorization for a Primary Object attached to the Platform Primary Seed (PPS) shall be provided by *platformAuth* or *platformPolicy*. Authorization for a Primary Object attached to the Storage Primary Seed (SPS) shall be provided by *ownerAuth* or *ownerPolicy*. Authorization for a Primary Key attached to the Endorsement Primary Seed (EPS) shall be provided by *endorsementAuth* or *endorsementPolicy*.

24.1.2 Command and Response

Table 173 — TPM2_CreatePrimary Command

Type	Name	Description

TPM2B_CREATION_DATA	creationData	contains a TPMS_CREATION_DATA
TPM2B_DIGEST	creationHash	digest of <i>creationData.creationData</i> using <i>nameAlg</i> of <i>outPublic</i>
TPMT_TK_CREATION	creationTicket	ticket used by TPM2_CertifyCreation() to validate that the creation data was produced by the TPM
TPM2B_NAME	name	the name of the created object

24.1.3 Detailed Actions

[[CreatePrimary]]

24.2 TPM2_HierarchyControl

24.2.1 General Description

This command enables and disables use of a hierarchy and its associated NV storage. The command allows *phEnable*, *phEnableNV*, *shEnable*, and *ehEnable* to be changed when the proper authorization is provided.

This command may be used to CLEAR *phEnable* and *phEnableNV* if *platformAuth/platformPolicy* is provided. *phEnable* may not be SET using this command.

This command may be used to CLEAR *shEnable* if either *platformAuth/platformPolicy* or *ownerAuth/ownerPolicy* is provided. *shEnable* may be SET if *platformAuth/platformPolicy* is provided.

This command may be used to CLEAR *ehEnable* if either *platformAuth/platformPolicy* or *endorsementAuth/endorsementPolicy* is provided. *ehEnable* may be SET if *platformAuth/platformPolicy* is provided.

When this command is used to CLEAR *phEnable*, *shEnable*, or *ehEnable*, the TPM will disable use of any persistent entity associated with the disabled hierarchy and will flush any transient objects associated with the disabled hierarchy.

When this command is used to CLEAR *shEnable*, the TPM will disable access to any NV index that has TPMA_NV_PLATFORMCREATE CLEAR (indicating that the NV Index was defined using Owner Authorization). As long as *shEnable* is CLEAR, the TPM will return an error in response to any command that attempts to operate upon an NV index that has TPMA_NV_PLATFORMCREATE CLEAR.

When this command is used to CLEAR *phEnableNV*, the TPM will disable access to any NV index that has TPMA_NV_PLATFORMCREATE SET (indicating that the NV Index was defined using Platform Authorization). As long as *phEnableNV* is CLEAR, the TPM will return an error in response to any command that attempts to operate upon an NV index that has TPMA_NV_PLATFORMCREATE SET.

24.2.3 Detailed Actions

[[HierarchyControl]]

24.3 TPM2_SetPrimaryPolicy

24.3.1 General Description

This command allows setting of the authorization policy for the lockout (*lockoutPolicy*), the platform hierarchy (*platformPolicy*), the storage hierarchy (*ownerPolicy*), and the endorsement hierarchy (*endorsementPolicy*). On TPMs implementing Authenticated Countdown Timers (ACT), this command may also be used to set the authorization policy for an ACT.

The command requires an authorization session. The session shall use the *authValue* associated with *authHandle* or the current policy associated with *authHandle*.

The policy that is changed is the policy associated with *authHandle*.

If the enable associated with *authHandle* is not SET, then the associated authorization values (*authValue* or *authPolicy*) may not be used, and the TPM returns TPM_RC_HIERARCHY.

When *hashAlg* is not TPM_ALG_NULL, if the size of *authPolicy* is not consistent with the hash algorithm, the TPM returns TPM_RC_SIZE.

24.3.2 Command and Response

Table 177 — TPM2_SetPrimaryPolicy Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_SetPrimaryPolicy {NV}

TPM2B_DIGEST	authPolicy	an authorization policy digest; may be the Empty Buffer If <i>hashAlg</i> is TPM_ALG_NULL, then this shall be an Empty Buffer.
TPMI_ALG_HASH+	hashAlg	the hash algorithm to use for the policy If the <i>authPolicy</i> is an Empty Buffer, then this field shall be TPM_ALG_NULL.

Table 178 — TPM2_SetPrimaryPolicy Response

Type	Name	Description
TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode	

24.3.3 Detailed Actions

[[SetPrimaryPolicy]]

24.4 TPM2_ChangePPS

24.4.1 General Description

This replaces the current platform primary seed (PPS) with a value from the RNG and sets *platformPolicy* to the default initialization value (the Empty Buffer).

NOTE 1 A policy that is the Empty Buffer can match no policy.

NOTE 2 Platform Authorization is not changed.

All resident transient and persistent objects in the Platform hierarchy are flushed.

Saved contexts in the Platform hierarchy that were created under the old PPS will no longer be able to be loaded.

The policy hash algorithm for PCR is reset to TPM_ALG_NULL.

This command does not clear any NV Index values.

NOTE 3 Index values belonging to the Platform are preserved because the indexes may have configuration information that will be the same after the PPS changes. The Platform may remove the indexes that are no longer needed using TPM2_NV_UndefineSpace().

This command requires Platform Authorization.

24.4.2 Command and Response

24.4.3 Detailed Actions

[[ChangePPS]]

24.5 TPM2_ChangeEPS

24.5.1 General Description

This replaces the current endorsement primary seed (EPS) with a value from the RNG and sets the Endorsement hierarchy controls to their default initialization values: *ehEnable* is SET, *endorsementAuth* and *endorsementPolicy* are both set to the Empty Buffer. It will flush any resident objects (transient or persistent) in the Endorsement hierarchy and not allow objects in the hierarchy associated with the previous EPS to be loaded.

NOTE 1 In the reference implementation, *ehProof* is a non-volatile value from the RNG. It is allowed that the *ehProof* be generated by a KDF using both the EPS and SPS as inputs. If generated with a KDF, the *ehProof* can be generated on an as-needed basis or made a non-volatile value.

NOTE 2 Users should use this command with extreme caution. Changing the EPS removes existing EKs, and their associated EK certificates cannot be used to validate any new EK.

This command requires Platform Authorization.

24.5.2 Command and Response

Table 181 — TPM2_ChangeEPS Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_ChangeEPS {NV E}

UINT32	responseSize	
TPM_RC	responseCode	

24.5.3 Detailed Actions

[[ChangeEPS]]

24.6 TPM2_Clear

24.6.1 General Description

This command removes all TPM context associated with a specific Owner.

The clear operation will:

- flush resident objects (persistent and volatile) in the Storage and Endorsement hierarchies;
- delete any NV Index with `TPMA_NV_PLATFORMCREATE == CLEAR`;
- change the storage primary seed (SPS) to a new value from the TPM's random number generator (RNG),
- change *shProof* and *ehProof*,

NOTE 1 The proof values are permitted to be set from the RNG or derived from the associated new Primary Seed. If derived from the Primary Seeds, the derivation of *ehProof* shall use both the SPS and EPS. The computation shall use the SPS as an HMAC key and the derived value may then be a parameter in a second HMAC in which the EPS is the HMAC key. The reference design uses values from the RNG.

- SET *shEnable* and *ehEnable*;
- set *ownerAuth*, *endorsementAuth*, and *lockoutAuth* to the Empty Buffer;
- set *ownerPolicy*, *endorsementPolicy*, and *lockoutPolicy* to the Empty Buffer;
- set *Clock* to zero;
- set *resetCount* to zero;
- set *restartCount* to zero; and
- set *Safe* to YES.
- increment *pcrUpdateCounter*

NOTE 2 This permits an application to create a policy session that is invalidated on TPM2_Clear. The policy needs, ideally as the first term, TPM2_PolicyPCR(). The session is invalidated even if the PCR selection is empty.

This command requires Platform Authorization or Lockout Authorization. If TPM2_ClearControl() has disabled this command, the TPM shall return TPM_RC_DISABLED.

NOTE3 This is a change from TPM 1.2, where *ownerAuth* authorized TPM_OwnerClear().

If this command is authorized using *lockoutAuth*, the HMAC in the response shall use the new *lockoutAuth* value (that is, the Empty Buffer) when computing the response HMAC.

24.6.3 Detailed Actions

[[Clear]]

24.7 TPM2_ClearControl

24.7.1 General Description

TPM2_ClearControl() disables and enables the execution of TPM2_Clear().

The TPM will SET the TPM's TPMA_PERMANENT.*disableClear* attribute if *disable* is YES and will CLEAR the attribute if *disable* is NO. When the attribute is SET, TPM2_Clear() may not be executed.

NOTE This is to simplify the logic of TPM2_Clear(). TPM2_ClearControl() can be called using Platform Authorization to CLEAR the *disableClear* attribute and then execute TPM2_Clear().

Lockout Authorization may be used to SET *disableClear* but not to CLEAR it.

Platform Authorization may be used to SET or CLEAR *disableClear*.

[[ClearControl]]

24.8 TPM2_HierarchyChangeAuth

24.8.1 General Description

This command allows the authorization secret for a hierarchy or lockout to be changed using the current authorization value as the command authorization.

If *authHandle* is TPM_RH_PLATFORM, then *platformAuth* is changed. If *authHandle* is TPM_RH_OWNER, then *ownerAuth* is changed. If *authHandle* is TPM_RH_ENDORSEMENT, then *endorsementAuth* is changed. If *authHandle* is TPM_RH_LOCKOUT, then *lockoutAuth* is changed. The HMAC in the response shall use the new authorization value when computing the response HMAC.

If *authHandle* is TPM_RH_PLATFORM, then Physical Presence may need to be asserted for this command to succeed (see clause 26.2).

The authorization value may be no larger than the digest produced by the hash algorithm used for context integrity.

EXAMPLE If SHA384 is used in the computation of the integrity values for saved contexts, then the largest authorization value is 48 octets.

NOTE *platformAuth* is used as the ACT *authValue*.

[[HierarchyChangeAuth]]

25 Dictionary Attack Functions

25.1 Introduction

A TPM is required to have support for logic that will help prevent a dictionary attack on an authorization value. The protection is provided by a counter that increments when a password authorization or an HMAC authorization fails. When the counter reaches a predefined value, the TPM will not accept, for some time interval, further requests that require authorization and the TPM is in Lockout mode. While the TPM is in Lockout mode, the TPM will return TPM_RC_LOCKOUT if the command requires use of an object's or Index's *authValue* unless the authorization applies to an entry in the Platform hierarchy.

NOTE 1 Authorizations for objects and NV Index values in the Platform hierarchy are never locked out. However, a command that requires multiple authorizations will not be accepted when the TPM is in Lockout mode unless all of the authorizations reference objects and indexes in the Platform hierarchy.

If the TPM is continuously powered for the duration of *newRecoveryTime* and no authorization failures occur, the authorization failure counter will be decremented by one. This property is called "self-healing." Self-healing shall not cause the count of failed attempts to decrement below zero.

The count of failed attempts, the lockout interval, and self-healing interval are settable using TPM2_DictionaryAttackParameters(). The lockout parameters and the current value of the lockout counter can be read with TPM2_GetCapability().

Dictionary attack protection does not apply to an entity associated with a permanent handle (handle type == TPM_HT_PERMANENT) other than TPM_RH_LOCKOUT

25.2 TPM2_DictionaryAttackLockReset

25.2.1 General Description

This command cancels the effect of a TPM lockout due to a number of successive authorization failures. If this command is properly authorized, the lockout counter is set to zero.

Only one *lockoutAuth* authorization failure is allowed for this command during a *lockoutRecovery* interval (set using TPM2_DictionaryAttackParameters()).

Type	Name	Description
TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode	

25.2.3 Detailed Actions

[[DictionaryAttackLockReset]]

25.3 TPM2_DictionaryAttackParameters

25.3.1 General Description

This command changes the lockout parameters.

The command requires Lockout Authorization.

The timeout parameters (*newRecoveryTime* and *lockoutRecovery*) indicate values that are measured with respect to the *Time* and not *Clock*.

NOTE Use of *Time* means that the TPM shall be continuously powered for the duration of a timeout.

If *newRecoveryTime* is zero, then DA protection is disabled. Authorizations are checked but authorization failures will not cause the TPM to enter lockout.

If *newMaxTries* is zero, the TPM will be in lockout and use of DA protected entities will be disabled.

If *lockoutRecovery* is zero, then the recovery interval is `_TPM_Init` followed by `TPM2_Startup()`.

Only one *lockoutAuth* authorization failure is allowed for this command during a *lockoutRecovery* interval.

25.3.2 Command and Response

[[DictionaryAttackParameters]]

26 Miscellaneous Management Functions

26.1 Introduction

Clause 26 contains commands that do not logically group with any other commands.

26.2 TPM2_PP_Commands

26.2.1 General Description

This command is used to determine which commands require assertion of Physical Presence (PP) in addition to *platformAuth/platformPolicy*.

This command requires that *auth* is TPM_RH_PLATFORM and that Physical Presence be asserted.

After this command executes successfully, the commands listed in *setList* will be added to the list of commands that require that Physical Presence be asserted when the handle associated with the authorization is TPM_RH_PLATFORM. The commands in *clearList* will no longer require assertion of Physical Presence in order to authorize a command.

If a command is not in either list, its state is not changed. If a command is in both lists, then it will no longer require Physical Presence (for example, *setList* is processed first).

Only commands with handle types of TPMI_RH_PLATFORM, TPMI_RH_PROVISION, TPMI_RH_CLEAR, or TPMI_RH_HIERARCHY can be gated with Physical Presence. If any other command is in either list, it is discarded.

When a command requires that Physical Presence be provided, then Physical Presence shall be asserted for either an HMAC or a Policy authorization.

NOTE 1 Physical Presence may be made a requirement of any policy.

NOTE 2 If the TPM does not implement this command, the command list is vendor specific. A platform-specific specification may require that the command list be initialized in a specific way.

TPM2_PP_Commands() always requires assertion of Physical Presence.

26.2.2 Command and Response

26.2.3 Detailed Actions

[[PP_Commands]]

26.3 TPM2_SetAlgorithmSet

26.3.1 General Description

This command allows the platform to change the set of algorithms that are used by the TPM. The *algorithmSet* setting is a vendor-dependent value.

If the changing of the algorithm set results in a change of the algorithms of PCR banks, then the TPM will need to be reset (`_TPM_Init` and `TPM2_Startup(TPM_SU_CLEAR)`) before the new PCR settings take effect. After this command executes successfully, if *startupType* in the next `TPM2_Startup()` is not `TPM_SU_CLEAR`, the TPM shall return `TPM_RC_VALUE` and may enter Failure mode.

Other than PCR, when an algorithm is no longer supported, the behavior of this command is vendor-dependent.

EXAMPLE Entities can remain resident. Persistent objects, transient objects, or sessions can be flushed. NV Indexes may be undefined. Policies may be erased.

NOTE The reference implementation does not have support for this command. In particular, it does not support use of this command to selectively disable algorithms. Proper support would require modification of the unmarshaling code so that each time an algorithm is unmarshaled, it would be verified as being enabled.

26.3.3 Detailed Actions

[[SetAlgorithmSet]]

27 Field Upgrade

27.1 Introduction

Clause 27 contains the commands for managing field upgrade of the firmware in the TPM. The field upgrade scheme may be used for replacement or augmentation of the firmware installed in the TPM.

EXAMPLE 1 If an algorithm is found to be flawed, a patch of that algorithm might be installed using the firmware upgrade process. The patch might be a replacement of a portion of the code or a complete replacement of the firmware.

EXAMPLE 2 If an additional set of ECC parameters is needed, the firmware process can be used to add the parameters to the TPM data set.

The field upgrade process uses two commands (TPM2_FieldUpgradeStart() and TPM2_FieldUpgradeData()). TPM2_FieldUpgradeStart() validates that a signature on the provided digest is from the TPM manufacturer, and that proper authorization is provided using *platformPolicy*.

NOTE 1 The *platformPolicy* for field upgraded is defined by the PM and may include requirements that the upgrade be signed by the PM or the TPM owner and include any other constraints that are desired by the PM.

If the proper authorization is given, the TPM will retain the signed digest and enter the Field Upgrade mode (FUM). While in FUM, the TPM will accept TPM2_FieldUpgradeData() commands. It may accept other commands if it is able to complete them using the previously installed firmware. Otherwise, it will return TPM_RC_UPGRADE.

Each block of the field upgrade shall contain the digest of the next block of the field upgrade data. That digest shall be included in the digest of the previous block. The digest of the first block is signed by the TPM manufacturer. That signature and first block digest are the parameters for TPM2_FieldUpgradeStart(). The digest is saved in the TPM as the required digest for the next field upgrade data block and as the identifier of the field upgrade sequence.

For each field upgrade data block that is sent to the TPM by TPM2_FieldUpgradeData(), the TPM shall validate that the digest matches the required digest and if not, shall return TPM_RC_VALUE. The TPM shall extract the digest of the next expected block and return that value to the caller, along with the digest of the first data block of the update sequence.

The system may attempt to abandon the firmware upgrade by using a zero-length buffer in TPM2_FieldUpgradeData(). If the TPM is able to resume operation using the firmware present when the upgrade started, then the TPM will indicate that it has abandon the update by setting the digest of the next block to the Empty Buffer. If the TPM cannot abandon the update, it will return the expected next digest.

The system may also attempt to abandon the update because of a power interruption. If the TPM is able to resume normal operations, then it will respond normally to TPM2_Startup(). If the TPM is not able to resume normal operations, then it will respond to any command but TPM2_FieldUpgradeData() with TPM_RC_UPGRADE.

After a TPM_Init, system software may not be able to resume the field upgrade that was in process when the power interruption occurred. In such case, the TPM firmware may be reset to one of two other values:

- the original firmware that was installed at the factory (“initial firmware”); or
- the firmware that was in the TPM when the field upgrade process started (“previous firmware”).

The TPM retains the digest of the first block for these firmware images and checks to see if the first block after TPM_Init matches either of those digests. If so, the firmware update process restarts, and the original firmware may be loaded.

NOTE 2 The TPM is required to accept the previous firmware as either a vendor-provided update or as recovered from the TPM using TPM2_FirmwareRead().

When the last block of the firmware upgrade is loaded into the TPM (indicated to the TPM by data in the data block in a TPM vendor-specific manner), the TPM will complete the upgrade process. If the TPM is able to resume normal operations without a reboot, it will set the hash algorithm of the next block to TPM_ALG_NULL and return TPM_RC_SUCCESS. If a reboot is required, the TPM shall return TPM_RC_REBOOT in response to the last TPM2_FieldUpgradeData() and all subsequent TPM commands until a _TPM_Init is received.

NOTE 3 Because no additional data is allowed when the response code is not TPM_RC_SUCCESS, the TPM returns TPM_RC_SUCCESS for all calls to TPM2_FieldUpgradeData() except the last. In this manner, the TPM is able to indicate the digest of the next block. If a _TPM_Init occurs while the TPM is in FUM, the next block may be the digest for the first block of the original firmware. If it is not, then the TPM will not accept the original firmware until the next _TPM_Init when the TPM is in FUM.

During the field upgrade process, either the one specified in clause 27 or a vendor proprietary field upgrade process, the TPM should preserve:

- Primary Seeds (and the primary keys generated from them);
- Hierarchy *authValue*, *authPolicy*, and *proof* values;
- Lockout *authValue* and authorization failure count values;
- PCR *authValue* and *authPolicy* values;
- NV Index allocations and contents;
- Persistent object allocations and contents; and
- Clock.

NOTE 4 A platform manufacturer may provide a means to change preserved data to accommodate a case where a field upgrade fixes a flaw that might have compromised TPM secrets.

27.2 TPM2_FieldUpgradeStart

27.2.1 General Description

This command uses *platformPolicy* and a TPM Vendor Authorization Key to authorize a Field Upgrade Manifest.

If the signature checks succeed, the authorization is valid and the TPM will accept TPM2_FieldUpgradeData().

This signature is checked against the loaded key referenced by *keyHandle*. This key will have a Name that is the same as a value that is part of the TPM firmware data. If the signature is not valid, the TPM shall return TPM_RC_SIGNATURE.

NOTE A loaded key is used rather than a hard-coded key to reduce the amount of memory needed for this key data in case more than one vendor key is needed.

27.2.2 Command and Response

Table 197 — TPM2_FieldUpgradeStart Command

27.2.3 Detailed Actions

[[FieldUpgradeStart]]

27.3 TPM2_FieldUpgradeData

27.3.1 General Description

This command will take the actual field upgrade image to be installed on the TPM. The exact format of *fuData* is vendor-specific. This command is only possible following a successful TPM2_FieldUpgradeStart(). If the TPM has not received a properly authorized TPM2_FieldUpgradeStart(), then the TPM shall return TPM_RC_FIELDUPGRADE.

The TPM will validate that the digest of *fuData* matches an expected value. If so, the TPM may buffer or immediately apply the update. If the digest of *fuData* does not match an expected value, the TPM shall return TPM_RC_VALUE.

27.3.2 Command and Response

TPMT_HA	firstDigest	tagged digest of the first block of the sequence

27.3.3 Detailed Actions

[[FieldUpgradeData]]

27.4 TPM2_FirmwareRead

27.4.1 General Description

This command is used to read a copy of the current firmware installed in the TPM.

The presumption is that the data will be returned in reverse order so that the last block in the sequence would be the first block given to the TPM in case of a failure recovery. If the TPM2_FirmwareRead sequence completes successfully, then the data provided from the TPM will be sufficient to allow the TPM to recover from an abandoned upgrade of this firmware.

To start the sequence of retrieving the data, the caller sets *sequenceNumber* to zero. When the TPM has returned all the firmware data, the TPM will return the Empty Buffer as *fuData*.

The contents of *fuData* are opaque to the caller.

NOTE 1 The caller should retain the ordering of the update blocks so that the blocks sent to the TPM have the same size and inverse order as the blocks returned by a sequence of calls to this command.

NOTE 2 Support for this command is optional even if the TPM implements TPM2_FieldUpgradeStart() and TPM2_FieldUpgradeData().

28 Context Management

28.1 Introduction

Three of the commands in clause 28 (TPM2_ContextSave(), TPM2_ContextLoad(), and TPM2_FlushContext()) implement the resource management described in the "Context Management" clause in TPM 2.0 Part 1.

The fourth command in clause 28 (TPM2_EvictControl()) is used to control the persistence of loadable objects in TPM memory. Background for this command may be found in the "Owner and Platform Evict Objects" clause in TPM 2.0 Part 1.

28.2 TPM2_ContextSave

28.2.1 General Description

This command saves a session context, object context, or sequence object context outside the TPM.

No authorization sessions of any type are allowed with this command and tag is required to be TPM_ST_NO_SESSIONS.

NOTE This preclusion avoids complex issues of dealing with the same session in *handle* and in the session area. While it might be possible to provide specificity, it would add unnecessary complexity to the TPM and, because this capability would provide no application benefit, use of authorization sessions for audit or encryption is prohibited.

The TPM shall encrypt and integrity protect the TPM2B_CONTEXT_SENSITIVE *context* as described in the "Context Protections" clause in TPM 2.0 Part 1.

See the "Context Data" clause in TPM 2.0 Part 2 for a description of the *context* structure in the response.

28.2.2 Command and Response

28.2.3 Detailed Actions

[[ContextSave]]

28.3 TPM2_ContextLoad

28.3.1 General Description

This command is used to reload a context that has been saved by TPM2_ContextSave().

No authorization sessions of any type are allowed with this command and tag is required to be TPM_ST_NO_SESSIONS (see note in clause 28.2.1).

The TPM will return TPM_RC_HIERARCHY if the context is associated with a hierarchy that is disabled.

NOTE Contexts for authorization sessions and for sequence objects belong to the NULL hierarchy, which is never disabled.

See the "Context Data" clause in TPM 2.0 Part 2 for a description of the values in the *context* parameter.

If the integrity HMAC of the saved context is not valid, the TPM shall return TPM_RC_INTEGRITY.

The TPM shall perform a check on the decrypted context as described in the "Context Confidentiality Protection" clause of TPM 2.0 Part 1 and enter failure mode if the check fails.

28.3.2 Command and Response

28.3.3 Detailed Actions

[[ContextLoad]]

28.4 TPM2_FlushContext

28.4.1 General Description

This command causes all context associated with a loaded object, sequence object, or session to be removed from TPM memory.

This command may not be used to remove a persistent object from the TPM. Use TPM2_EvictControl to remove a persistent object.

A session does not have to be loaded in TPM memory to have its context flushed. The saved session context associated with the indicated handle is invalidated. When flushing a session, the upper byte of the handle is ignored.

EXAMPLE A command to flush session handle 0x20000000 will flush session handle 0x03000000.

No sessions of any type are allowed with this command and tag is required to be TPM_ST_NO_SESSIONS (see note in clause 28.2.1).

If the handle is for a Transient Object and the handle is not associated with a loaded object, then the TPM shall return TPM_RC_HANDLE.

If the handle is for an authorization session and the handle does not reference a loaded or active session, then the TPM shall return TPM_RC_HANDLE.

NOTE *flushHandle* is a parameter and not a handle. If it were in the handle area, the TPM would validate that the context for the referenced entity is in the TPM. When a TPM2_FlushContext references a saved session context, it is not necessary for the context to be in the TPM. When the *flushHandle* is in the parameter area, the TPM does not validate that associated context is actually in the TPM.

28.4.2 Command and Response

TPM_RC	responseCode	

28.4.3 Detailed Actions

[[FlushContext]]

28.5 TPM2_EvictControl

28.5.1 General Description

This command allows certain Transient Objects to be made persistent or a persistent object to be evicted.

NOTE 1 A transient object is one that may be removed from TPM memory using either TPM2_FlushContext or TPM2_Startup(). A persistent object is not removed from TPM memory by TPM2_FlushContext() or TPM2_Startup().

If *objectHandle* is a Transient Object, then this call makes a persistent copy of the object and assigns *persistentHandle* to the persistent version of the object. If *objectHandle* is a persistent object, then the call evicts the persistent object. The call does not affect the transient object.

Before execution of TPM2_EvictControl code below, the TPM verifies that *objectHandle* references an object that is resident on the TPM and that *persistentHandle* is a valid handle for a persistent object.

NOTE 2 This requirement simplifies the unmarshaling code so that it only need check that *persistentHandle* is always a persistent object.

If *objectHandle* references a Transient Object:

- a) The TPM shall return TPM_RC_ATTRIBUTES if
 - 1) it is in the hierarchy of TPM_RH_NULL or a firmware-limited or SVN-limited hierarchy,
 - 2) only the public portion of the object is loaded, or
- NOTE 3 This is for NV space efficiency. Loading an object whose private part is empty would unnecessarily consume NV resources.
- 3) the *stClear* is SET in the object or in an ancestor key.
- b) The TPM shall return TPM_RC_HIERARCHY if the object is not in the proper hierarchy as determined by *auth*.
 - 1) If *auth* is TPM_RH_PLATFORM, the proper hierarchy is the Platform hierarchy.
 - 2) If *auth* is TPM_RH_OWNER, the proper hierarchy is either the Storage or the Endorsement hierarchy.
 - c) The TPM shall return TPM_RC_RANGE if *persistentHandle* is not in the proper range as determined by *auth*.
 - 1) If *auth* is TPM_RH_OWNER, then *persistentHandle* shall be in the inclusive range of 81 00 00 00₁₆ to 81 7F FF FF₁₆.
 - 2) If *auth* is TPM_RH_PLATFORM, then *persistentHandle* shall be in the inclusive range of 81 80 00 00₁₆ to 81 FF FF FF₁₆.

NOTE 4 This separation permits the platform (the platform OEM) a range of indexes that will not interfere with indexes used by the TPM owner (the OS or applications).

- d) The TPM shall return TPM_RC_NV_DEFINED if a persistent object exists with the same handle as *persistentHandle*.
- e) The TPM shall return TPM_RC_NV_SPACE if insufficient space is available to make the object persistent.
- f) The TPM shall return TPM_RC_NV_SPACE if execution of this command will prevent the TPM from being able to hold two transient objects of any kind.

NOTE 5 This requirement anticipates that a TPM may be implemented such that all TPM memory is non-volatile and not subject to endurance issues. In such case, there is no movement of an object between memory of different types, and it is necessary that the TPM ensure that it is always possible for the management software to move objects to/from TPM memory in order to ensure that the objects required for command execution can be context restored.

- g) If the TPM returns TPM_RC_SUCCESS, the object referenced by *objectHandle* will not be flushed and both *objectHandle* and *persistentHandle* may be used to access the object.

If *objectHandle* references a persistent object:

- h) The TPM shall return TPM_RC_RANGE if *objectHandle* is not in the proper range as determined by *auth*. If *auth* is TPM_RC_OWNER, *objectHandle* shall be in the inclusive range of 81 00 00 00₁₆ to 81 7F FF FF₁₆. If *auth* is TPM_RC_PLATFORM, *objectHandle* may be any valid persistent object handle.
- i) If *objectHandle* is not the same value as *persistentHandle*, return TPM_RC_HANDLE.
- j) If the TPM returns TPM_RC_SUCCESS, *objectHandle* will be removed from persistent memory and no longer be accessible.

NOTE 5 The persistent object is not converted to a transient object, as this would prevent the immediate revocation of an object by removing it from persistent memory.

TPM_RC	responseCode	
TPMS_TIME_INFO	currentTime	

29.1.3 Detailed Actions

[[ReadClock]]

29.2 TPM2_ClockSet

29.2.1 General Description

This command is used to advance the value of the TPM's *Clock*. The command will fail if *newTime* is less than the current value of *Clock* or if the new time is greater than FF FF 00 00 00 00 00 00₁₆. If both of these checks succeed, *Clock* is set to *newTime*. If either of these checks fails, the TPM shall return TPM_RC_VALUE and make no change to *Clock*.

NOTE This maximum setting would prevent *Clock* from rolling over to zero for approximately 8,000 years at the real time *Clock* update rate. If the *Clock* update rate was set so that TPM time was passing 33 percent faster than real time, it would still be more than 6,000 years before *Clock* would roll over to zero. Because *Clock* will not roll over in the lifetime of the TPM, there is no need for external software to deal with the possibility that *Clock* may wrap around.

If the value of *Clock* after the update makes the volatile and non-volatile versions of TPMS_CLOCK_INFO.*clock* differ by more than the reported update interval, then the TPM shall update the non-volatile version of TPMS_CLOCK_INFO.*clock* before returning.

This command requires Platform Authorization or Owner Authorization.

29.2.3 Detailed Actions

[[ClockSet]]

29.3 TPM2_ClockRateAdjust

29.3.1 General Description

This command adjusts the rate of advance of *Clock* and *Time* to provide a better approximation to real time.

The *rateAdjust* value is relative to the current rate and not the nominal rate of advance.

EXAMPLE 1 If this command had been called three times with *rateAdjust* = TPM_CLOCK_COARSE_SLOWER and once with *rateAdjust* = TPM_CLOCK_COARSE_FASTER, the net effect will be as if the command had been called twice with *rateAdjust* = TPM_CLOCK_COARSE_SLOWER.

The range of adjustment shall be sufficient to allow *Clock* and *Time* to advance at real time but no more. If the requested adjustment would make the rate advance faster or slower than the nominal accuracy of the input frequency, the TPM shall return TPM_RC_VALUE.

EXAMPLE 2 If the frequency tolerance of the TPM's input clock is +/-10 percent, then the TPM will return TPM_RC_VALUE if the adjustment would make *Clock* run more than 10 percent faster or slower than nominal. That is, if the input oscillator were nominally 100 megahertz (MHz), then 1 millisecond (ms) would normally take 100,000 counts. The update *Clock* should be adjustable so that 1 ms is between 90,000 and 110,000 counts.

The interpretation of "fine" and "coarse" adjustments is implementation-specific.

The nominal rate of advance for *Clock* and *Time* shall be accurate to within 15 percent. That is, with no adjustment applied, *Clock* and *Time* shall be advanced at a rate within 15 percent of actual time.

NOTE If the adjustments are incorrect, it will be possible to make the difference between advance of *Clock/Time* and real time to be as much as 1.15² or ~1.33.

Changes to the current *Clock* update rate adjustment need not be persisted across TPM power cycles.

29.3.3 Detailed Actions

[[ClockRateAdjust]]

30 Capability Commands

30.1 Introduction

The TPM has numerous values that indicate the state, capabilities, and properties of the TPM. These values are needed for proper management of the TPM. The TPM2_GetCapability() command is used to access these values.

TPM2_GetCapability() allows reporting of multiple values in a single call. The values are grouped according to type.

NOTE TPM2_TestParms() is used to determine if a TPM supports a particular combination of algorithm parameters

The TPM can permit specific data (such as TPM configurations) to be set in the TPM; this data is set with TPM2_SetCapability(). TPM2_SetCapability() sets only one property at a time.

30.2 TPM2_GetCapability

30.2.1 General Description

This command returns various information regarding the TPM and its current state.

The *capability* parameter determines the category of data returned. The *property* parameter selects the first value of the selected category to be returned. If there is no property that corresponds to the value of *property*, the next higher value is returned, if it exists.

EXAMPLE 1 The list of handles of transient objects currently loaded in the TPM may be read one at a time. On the first read, set the property to TRANSIENT_FIRST and *propertyCount* to one. If a transient object is present, the lowest numbered handle is returned and *moreData* will be YES if transient objects with higher handles are loaded. On the subsequent call, use returned handle value plus 1 in order to access the next higher handle.

The *propertyCount* parameter indicates the number of capabilities in the indicated group that are requested. The TPM will return no more than the number of requested values (*propertyCount*) or until the last property of the requested type has been returned.

NOTE 1 The type of the capability is derived from a combination of *capability* and *property*.

NOTE 2 If the *property* selects an unimplemented property, the next higher implemented property is returned.

When all of the properties of the requested type have been returned, the *moreData* parameter in the response will be set to NO. Otherwise, it will be set to YES.

NOTE 3 The *moreData* parameter will be YES if there are more properties even if the requested number of capabilities has been returned.

The TPM is not required to return more than one value at a time. It is not required to provide the same number of values in response to subsequent requests.

EXAMPLE 2 A TPM may return 4 properties in response to a TPM2_GetCapability(*capability* = TPM_CAP_TPM_PROPERTY, *property* = TPM_PT_MANUFACTURER, *propertyCount* = 8) and for a latter request with the same parameters, the TPM may return as few as one and as many as 8 values.

When the TPM is in Failure mode, a TPM is required to allow use of this command for access of the following capabilities:

- TPM_PT_MANUFACTURER
- TPM_PT_VENDOR_STRING_1
- TPM_PT_VENDOR_STRING_2 (NOTE 4)
- TPM_PT_VENDOR_STRING_3 (NOTE 4)
- TPM_PT_VENDOR_STRING_4 (NOTE 4)
- TPM_PT_VENDOR_TPM_TYPE
- TPM_PT_FIRMWARE_VERSION_1
- TPM_PT_FIRMWARE_VERSION_2

NOTE 4 If the vendor string does not require one of these values, the property type does not need to exist.

A vendor may optionally allow the TPM to return other values.

If in Failure mode and a capability is requested that is not available in Failure mode, the TPM shall return no value.

EXAMPLE 3 Assume the TPM is in Failure mode and the TPM only supports reporting of the minimum required set of properties (the limited subset of TPML_TAGGED_TPM_PROPERTY values). If a TPM2_GetCapability is received requesting a capability that has a property type value greater than TPM_PT_FIRMWARE_VERSION_2, the TPM can return a zero-length list with the moreData parameter set to NO or return the property TPM_PT_FIRMWARE_VERSION_2. If the property type is less than TPM_PT_MANUFACTURER, the TPM will return properties beginning with TPM_PT_MANUFACTURER.

In Failure mode, *tag* is required to be TPM_ST_NO_SESSIONS or the TPM shall return TPM_RC_FAILURE.

The capability categories and the types of the return values are:

<i>capability</i>	<i>property</i>	Return Type
TPM_CAP_ALGS	TPM_ALG_ID ⁽¹⁾	TPML_ALG_PROPERTY
TPM_CAP_HANDLES	TPM_HANDLE	TPML_HANDLE
TPM_CAP_COMMANDS	TPM_CC	TPML_CCA
TPM_CAP_PP_COMMANDS	TPM_CC	TPML_CC
TPM_CAP_AUDIT_COMMANDS	TPM_CC	TPML_CC
TPM_CAP_PCERS	Reserved	TPML_PCR_SELECTION
TPM_CAP_TPM_PROPERTIES	TPM_PT	TPML_TAGGED_TPM_PROPERTY
TPM_CAP_PCR_PROPERTIES	TPM_PT_PCR	TPML_TAGGED_PCR_PROPERTY
TPM_CAP_ECC_CURVES	TPM_ECC_CURVE ⁽¹⁾	TPML_ECC_CURVE
TPM_CAP_AUTH_POLICIES ⁽³⁾	TPM_HANDLE ⁽²⁾	TPML_TAGGED_POLICY
TPM_CAP_ACT ⁽⁴⁾	TPM_HANDLE ⁽²⁾	TPML_ACT_DATA
TPM_CAP_VENDOR_PROPERTY	manufacturer specific	manufacturer-specific values
NOTES: (1) The TPM_ALG_ID or TPM_ECC_CURVE is cast to a UINT32 (2) The TPM will return TPM_RC_VALUE if the handle does not reference the range for permanent handles. (3) TPM_CAP_AUTH_POLICIES was added in revision 01.32. (4) TPM_CAP_ACT was added in revision 01.56.		

- TPM_CAP_ALGS – Returns a list of TPMS_ALG_PROPERTIES. Each entry is an algorithm ID and a set of properties of the algorithm.
- TPM_CAP_HANDLES – Returns a list of all of the handles within the handle range of the *property* parameter. The range of the returned handles is determined by the handle type (the most-significant octet (MSO) of the *property*). Any of the defined handle types is allowed

EXAMPLE 4 If the MSO of *property* is TPM_HT_NV_INDEX, then the TPM will return a list of NV Index values.

EXAMPLE 5 If the MSO of *property* is TPM_HT_PCR, then the TPM will return a list of PCR.

- For this capability, use of TPM_HT_LOADED_SESSION and TPM_HT_SAVED_SESSION is allowed. Requesting handles with a handle type of TPM_HT_LOADED_SESSION will return handles for loaded sessions. The returned handle values will have a handle type of either TPM_HT_HMAC_SESSION or TPM_HT_POLICY_SESSION. If saved sessions are requested, all returned values will have the TPM_HT_HMAC_SESSION handle type because the TPM does not track the session type of saved sessions.

NOTE 5 TPM_HT_LOADED_SESSION and TPM_HT_HMAC_SESSION have the same value, as do TPM_HT_SAVED_SESSION and TPM_HT_POLICY_SESSION. It is not possible to request that the TPM return a list of loaded HMAC sessions without including the policy sessions.

- For this capability, TPM_RH_SVN_OWNER_BASE, TPM_RH_SVN_ENDORSEMENT_BASE, TPM_RH_SVN_PLATFORM_BASE, and TPM_RH_NULL_BASE handles may be returned. There are separate handles for each SVN from 0 to the firmware's current SVN (up to UINT16_MAX), which are not returned. Instead, only the handles associated with SVN 0 are returned (i.e., 0x40010000, 0x40020000, 0x40030000, and 0x40040000). The user can query the firmware's current SVN via TPM2_GetCapability to determine which SVN-specific handles are available for use.
- TPM_CAP_COMMANDS – Returns a list of the command attributes for all of the commands implemented in the TPM, starting with the TPM_CC indicated by the *property* parameter. If vendor specific commands are implemented, the vendor-specific command attribute with the lowest *commandIndex*, is returned after the non-vendor-specific (base) command.

NOTE 6 The type of the *property* parameter is a TPM_CC while the type of the returned list is TPML_CCA.

- TPM_CAP_PP_COMMANDS – Returns a list of all of the commands currently requiring Physical Presence for confirmation of platform authorization. The list will start with the TPM_CC indicated by *property*.
- TPM_CAP_AUDIT_COMMANDS – Returns a list of all of the commands currently set for command audit.
- TPM_CAP_PCERS – Returns the current allocation of PCR in a TPML_PCR_SELECTION. The *property* parameter shall be zero. The TPM will always respond to this command with the full PCR allocation and *moreData* will be NO.

The TPML_PCR_SELECTION must include a TPMS_PCR_SELECTION for each PCR bank in which there is at least one allocated PCR. The TPML_PCR_SELECTION may return a TPMS_PCR_SELECTION for each implemented PCR bank. The TPML_PCR_SELECTION may return a TPMS_PCR_SELECTION for each implemented hash algorithm.

- TPM_CAP_TPM_PROPERTIES – Returns a list of tagged properties. The tag is a TPM_PT and the property is a 32-bit value. The properties are returned in groups. Each property group is on a 256-value boundary (that is, the boundary occurs when the TPM_PT is evenly divisible by 256). The TPM will only return values in the same group as the *property* parameter in the command.
- TPM_CAP_PCR_PROPERTIES – Returns a list of tagged PCR properties. The tag is a TPM_PT_PCR and the property is a TPMS_PCR_SELECT.

The input command property is a TPM_PT_PCR (see TPM 2.0 Part 2 for PCR properties to be requested) that specifies the first property to be returned. If *propertyCount* is greater than 1, the list of properties begins with that property and proceeds in TPM_PT_PCR sequence.

Each item in the list is a TPMS_PCR_SELECT structure that contains a bitmap of all PCR.

NOTE 7 A PCR index in all banks (all hash algorithms) has the same properties, so the hash algorithm is not specified here.

- TPM_CAP_TPM_ECC_CURVES – Returns a list of ECC curve identifiers currently available for use in the TPM.
- TPM_CAP_AUTH_POLICIES - Returns a list of tagged policies reporting the authorization policies for the permanent handles.
- TPM_CAP_ACT – Returns a list of TPMS_ACT_DATA, each of which contains the handle for the ACT, the remaining time before it expires, and the ACT attributes.

The *moreData* parameter will have a value of YES if there are more values of the requested type that were not returned.

If no next capability exists, the TPM will return a zero-length list and *moreData* will have a value of NO.

NOTE 8 Additional settable capabilities may be defined by a TCG Registry.

30.2.3 Detailed Actions

[[GetCapability]]

30.3 TPM2_TestParms

30.3.1 General Description

This command is used to check to see if specific combinations of algorithm parameters are supported.

The TPM will unmarshal the provided TPMT_PUBLIC_PARMS. If the parameters unmarshal correctly, then the TPM will return TPM_RC_SUCCESS, indicating that the parameters are valid for the TPM. The TPM will return the appropriate unmarshaling error if a parameter is not valid.

30.1 TPM2_SetCapability

30.1.1 General Description

This command is used to set specific data in the TPM, such as TPM configurations, which may change the TPM's function and behavior.

Examples of TPM configurations are enabling or disabling TPM features or activating the TPM to operate in a special mode that restricts the TPM's functionality.

Similar to TPM2_GetCapability(), the data to be set is determined via a capability and property value, where a capability groups several properties of the same type.

Unlike TPM2_GetCapability(), which returns a list of properties, TPM2_SetCapability() sets only one property at a time.

NOTE 1 Setting one property at a time simplifies the implementation and error handling.

Properties set with TPM2_SetCapability() may be read with TPM2_GetCapability() as both commands use the same capability and property type.

NOTE 2 Some (settable) properties may be exempt from being readable with TPM2_GetCapability(), e.g., if the data is considered confidential.

NOTE 3 The *setCapabilityData* parameter is a sized buffer to enable parameter encryption. This allows e.g. the vendor-specific authorization values (TPM_RH_AUTH_00-FF) to be set using this command.

The authorization for this command depends on the capability value.

NOTE 4 TPM2_SetCapability() was added in revision 1.79.

30.1.3 Detailed Actions

[[SetCapability]]

31 Non-volatile Storage

31.1 Introduction

The NV commands are used to create, update, read, and delete allocations of space in NV memory. Before an Index may be used, it must be defined (TPM2_NV_DefineSpace()).

An Index may be modified if the proper write authorization is provided or read if the proper read authorization is provided. Different controls are available for reading and writing.

An Index may have an Index-specific *authValue* and *authPolicy*. The *authValue* may be used to authorize reading if TPMA_NV_AUTHREAD is SET and writing if TPMA_NV_AUTHWRITE is SET. The *authPolicy* may be used to authorize reading if TPMA_NV_POLICYREAD is SET and writing if TPMA_NV_POLICYWRITE is SET.

For commands that have both *authHandle* and *nvIndex* parameters, *authHandle* can be an NV Index, Platform Authorization, or Owner Authorization. If *authHandle* is an NV Index, it must be the same as *nvIndex* (TPM_RC_NV_AUTHORIZATION).

TPMA_NV_PPREAD and TPMA_NV_PPWRITE indicate if reading or writing of the NV Index may be authorized by *platformAuth* or *platformPolicy*.

TPMA_NV_OWNERREAD and TPMA_NV_OWNERWRITE indicate if reading or writing of the NV Index may be authorized by *ownerAuth* or *ownerPolicy*.

If an operation on an NV index requires authorization, and the *authHandle* parameter is the handle of an NV Index, then the *nvIndex* parameter must have the same value or the TPM will return TPM_RC_NV_AUTHORIZATION.

NOTE 1 This check ensures that the authorization that was provided is associated with the NV Index being authorized.

For creating an Index, Owner Authorization may not be used if *shEnable* is CLEAR and Platform Authorization may not be used if *phEnable* or *phEnableNV* is CLEAR.

If an Index was defined using Platform Authorization, then that Index is not accessible when *phEnableNV* is CLEAR. If an Index was defined using Owner Authorization, then that Index is not accessible when *shEnable* is CLEAR.

For read access control, any combination of TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, or TPMA_NV_POLICYREAD is allowed as long as at least one is SET.

For write access control, any combination of TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, or TPMA_NV_POLICYWRITE is allowed as long as at least one is SET.

If an Index has been defined and not written, then any operation on the NV Index that requires read authorization will fail (TPM_RC_NV_INITIALIZED). This check may be made before or after other authorization checks but shall be performed before checking the NV Index *authValue*. An authorization failure due to the NV Index not having been written shall not be logged by the dictionary attack logic.

If TPMA_NV_CLEAR_STCLEAR is SET, then the TPMA_NV_WRITTEN will be CLEAR on each TPM2_Startup(TPM_SU_CLEAR). TPMA_NV_CLEAR_STCLEAR shall not be SET if the *nvIndexType* is TPM_NT_COUNTER.

The code in the “Detailed Actions” clause of each command is written to interface with an implementation-dependent library that allows access to NV memory. The actions assume no specific layout of the structure of the NV data.

Only one NV Index may be directly referenced in a command.

NOTE 2

This means that, if *authHandle* references an NV Index, then *nvIndex* will have the same value. However, this does not limit the number of changes that may occur as side effects. For example, any number of NV Indexes might be relocated as a result of deleting or adding a NV Index.

Table 223 — Command to handle type mapping

TPM2_NV_Commands	TPM_HT Types Supported	TPMI_NV Type	TPM2B NV Public

NV_UndefineSpace NV_UndefineSpaceSpecial	TPM_HT_NV_INDEX TPM_HT_EXTERNAL_NV	TPMI_RH_NV_DEFINED_INDEX	
NV_Read NV_Write Etc.	TPM_HT_NV_INDEX TPM_HT_EXTERNAL_NV TPM_HT_PERMANENT_NV	TPMI_RH_NV_INDEX	
NV_ReadPublic	TPM_HT_NV_INDEX	TPMI_RH_NV_LEGACY_INDEX	NV_PUBLIC
NV_ReadPublic2	TPM_HT_NV_INDEX TPM_HT_EXTERNAL_NV TPM_HT_PERMANENT_NV	TPMI_RH_NV_INDEX	NV_PUBLIC_2
	TPM_HT_EXTERNAL_NV	TPMI_RH_NV_EXP_INDEX	NV_PUBLIC_EXP_ATTR

31.2 NV Counters

When an Index has the TPM_NT_COUNTER attribute, it behaves as a monotonic counter and may only be updated using TPM2_NV_Increment().

When an NV counter is created, the TPM shall initialize the 8-octet counter value with a number that is greater than any count value for any NV counter on the TPM since the time of TPM manufacture.

An NV counter may be defined with the TPMA_NV_ORDERLY attribute to indicate that the NV Index is expected to be modified at a high frequency and that the data is only persisted to NV when the TPM goes through an orderly shutdown process. The TPM may update the counter value in RAM and occasionally update the non-volatile version of the counter. An orderly shutdown is one occasion to update the non-volatile count. If the difference between the volatile and non-volatile version of the counter becomes as large as MAX_ORDERLY_COUNT, this shall be another occasion for updating the non-volatile count.

Before an NV counter can be used, the TPM shall validate that the count is not less than a previously reported value. If the TPMA_NV_ORDERLY attribute is not SET, or if the TPM experienced an orderly shutdown, then the count is assumed to be correct. If the TPMA_NV_ORDERLY attribute is SET, and the TPM shutdown was not orderly, then the TPM shall OR MAX_ORDERLY_COUNT to the contents of the non-volatile counter and set that as the current count.

NOTE 1 Because the TPM would have updated the NV Index if the difference between the count values was equal to MAX_ORDERLY_COUNT + 1, the highest value that could have been in the NV Index is MAX_ORDERLY_COUNT so it is safe to restore that value.

NOTE 2 The TPM is permitted to implement the RAM portion of the counter such that the effective value of the NV counter is the sum of both the volatile and non-volatile parts. If so, then the TPM may initialize the RAM version of the counter to MAX_ORDERLY_COUNT and no update of NV is necessary.

NOTE 3 When a new NV counter is created, the TPM can search all the counters to determine which has the highest value. In this search, the TPM would use the sum of the non-volatile and RAM portions of the counter. The RAM portion of the counter shall be properly initialized to reflect shutdown process (orderly or not) of the TPM.

31.3 TPM2_NV_DefineSpace

31.3.1 General Description

This command defines the attributes of an NV Index and causes the TPM to reserve space to hold the data associated with the NV Index. If a definition already exists at the NV Index, the TPM will return TPM_RC_NV_DEFINED.

The TPM will return TPM_RC_ATTRIBUTES if *nvIndexType* has a reserved value in *publicInfo*.

NOTE 1 It is not required that any of these three attributes be set.

The TPM shall return TPM_RC_ATTRIBUTES if TPMA_NV_WRITTEN, TPMA_NV_READLOCKED, or TPMA_NV_WRITELOCKED is SET.

If *nvIndexType* is TPM_NT_COUNTER, TPM_NT_BITS, TPM_NT_PIN_FAIL, or TPM_NT_PIN_PASS, then *publicInfo*→*dataSize* shall be set to eight (8) or the TPM shall return TPM_RC_SIZE.

If *nvIndexType* is TPM_NT_EXTEND, then *publicInfo*→*dataSize* shall match the digest size of the *publicInfo.nameAlg* or the TPM shall return TPM_RC_SIZE.

NOTE 2 TPM_RC_ATTRIBUTES could be returned by a TPM that is based on the reference code of older versions of the specification but the correct response for this error is TPM_RC_SIZE.

If the NV Index is an ordinary Index and *publicInfo*→*dataSize* is larger than supported by the TPM implementation, then the TPM shall return TPM_RC_SIZE.

If *publicInfo*→*dataSize* is larger than MAX_NV_BUFFER_SIZE and TPMA_NV_WRITEALL is SET, then the TPM shall return TPM_RC_SIZE.

NOTE 3 The limit for the data size can vary according to the type of the index. For example, if the index has TPMA_NV_ORDERLY SET, then the maximum size of an ordinary NV Index may be less than the size of an ordinary NV Index that has TPMA_NV_ORDERLY CLEAR.

At least one of TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, or TPMA_NV_POLICYREAD shall be SET or the TPM shall return TPM_RC_ATTRIBUTES.

At least one of TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, or TPMA_NV_POLICYWRITE shall be SET or the TPM shall return TPM_RC_ATTRIBUTES.

If TPMA_NV_CLEAR_STCLEAR is SET, then *nvIndexType* shall not be TPM_NT_COUNTER or the TPM shall return TPM_RC_ATTRIBUTES.

If *platformAuth/platformPolicy* is used for authorization, then TPMA_NV_PLATFORMCREATE shall be SET in *publicInfo*. If *ownerAuth/ownerPolicy* is used for authorization, TPMA_NV_PLATFORMCREATE shall be CLEAR in *publicInfo*. If TPMA_NV_PLATFORMCREATE is not set correctly for the authorization, the TPM shall return TPM_RC_ATTRIBUTES.

If TPMA_NV_POLICY_DELETE is SET, then the authorization shall be with Platform Authorization or the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 4 All NV Indices created by the owner are removed by TPM2_Clear(). In contrast, the platform is permitted to create Indices that can never be deleted, because such Indices might be essential for proper platform operation. It could be impossible to delete an Index if its policy cannot be satisfied, for example.

If *nvIndexType* is TPM_NT_PIN_FAIL, then TPMA_NV_NO_DA shall be SET. Otherwise, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 5 The intent of a PIN Fail index is that its DA protection is on a per-index basis, not based on the global DA protection. This avoids conflict over which type of dictionary attack protection is in use.

If *nvIndexType* is TPM_NT_PIN_FAIL or TPM_NT_PIN_PASS, then at least one of TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, or TPMA_NV_POLICYWRITE shall be SET or the TPM shall return TPM_RC_ATTRIBUTES. TPMA_NV_AUTHWRITE shall be CLEAR. Otherwise, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 6 If TPMA_NV_AUTHWRITE was SET for a PIN Pass index, a user knowing the authorization value could decrease pinCount or increase pinLimit, defeating the purpose of a PIN Pass index. The requirement is also enforced for a PIN Fail index for consistency.

If the implementation does not support TPM2_NV_Increment(), the TPM shall return TPM_RC_ATTRIBUTES if *nvIndexType* is TPM_NT_COUNTER.

If the implementation does not support TPM2_NV_SetBits(), the TPM shall return TPM_RC_ATTRIBUTES if *nvIndexType* is TPM_NT_BITS.

If the implementation does not support TPM2_NV_Extend(), the TPM shall return TPM_RC_ATTRIBUTES if *nvIndexType* is TPM_NT_EXTEND.

If the implementation does not support TPM2_NV_UndefineSpaceSpecial(), the TPM shall return TPM_RC_ATTRIBUTES if TPMA_NV_POLICY_DELETE is SET.

After the successful completion of this command, the NV Index exists but TPMA_NV_WRITTEN will be CLEAR. Any access of the NV data will return TPM_RC_NV_UNINITIALIZED.

In some implementations, an NV Index with the TPM_NT_COUNTER attribute may require special TPM resources that provide higher endurance than regular NV. For those implementations, if this command fails because of lack of resources, the TPM will return TPM_RC_NV_SPACE.

The value of *auth* is saved in the created structure. The size of *auth* is limited to be no larger than the size of the digest produced by the NV Index's *nameAlg* (TPM_RC_SIZE).

`[[NV_DefineSpace]]`

31.4 TPM2_NV_UndefineSpace

31.4.1 General Description

This command removes an Index from the TPM.

If *nvIndex* is not defined, the TPM shall return TPM_RC_HANDLE.

If *nvIndex* references an Index that has its TPMA_NV_PLATFORMCREATE attribute SET, the TPM shall return TPM_RC_NV_AUTHORIZATION unless Platform Authorization is provided.

If *nvIndex* references an Index that has its TPMA_NV_POLICY_DELETE attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE An Index with TPMA_NV_PLATFORMCREATE CLEAR may be deleted with Platform Authorization as long as shEnable is SET. If shEnable is CLEAR, indexes created using Owner Authorization are not accessible even for deletion by the platform.

[[NV_UndefineSpace]]

31.5 TPM2_NV_UndefineSpaceSpecial

31.5.1 General Description

This command allows removal of a platform-created NV Index that has TPMA_NV_POLICY_DELETE SET.

This command requires that the policy of the NV Index be satisfied before the NV Index may be deleted. Because administrative role is required, the policy must contain a command that sets the policy command code to TPM_CC_NV_UndefineSpaceSpecial. This indicates that the policy that is being used is a policy that is for this command, and not a policy that would approve another use. That is, authority to use an entity does not grant authority to undefine the entity.

Since the index is deleted, the Empty Buffer is used as the authValue when generating the response HMAC.

If *nvIndex* is not defined, the TPM shall return TPM_RC_HANDLE.

If *nvIndex* references an Index that has its TPMA_NV_PLATFORMCREATE or TPMA_NV_POLICY_DELETE attribute CLEAR, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE An Index with TPMA_NV_PLATFORMCREATE CLEAR can be deleted with TPM2_NV_UndefineSpace() as long as shEnable is SET. If shEnable is CLEAR, indexes created using Owner Authorization are not accessible even for deletion by the platform.

31.6.3 Detailed Actions

`[[NV_ReadPublic]]`

31.7 TPM2_NV_Write

31.7.1 General Description

This command writes a value to an area in NV memory that was previously defined by TPM2_NV_DefineSpace().

Proper authorizations are required for this command as determined by TPMA_NV_PPWRITE; TPMA_NV_OWNERWRITE; TPMA_NV_AUTHWRITE; and, if TPMA_NV_POLICYWRITE is SET, the *authPolicy* of the NV Index.

If the TPMA_NV_WRITELOCKED attribute of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

NOTE 1 If authorization sessions are present, they are checked before checks to see if writes to the NV Index are locked.

If *nvIndexType* is TPM_NT_COUNTER, TPM_NT_BITS or TPM_NT_EXTEND, then the TPM shall return TPM_RC_ATTRIBUTES.

If *offset* and the *size* field of *data* add to a value that is greater than the *dataSize* field of the NV Index referenced by *nvIndex*, the TPM shall return an error (TPM_RC_NV_RANGE). The implementation may return an error (TPM_RC_VALUE) if it performs an additional check and determines that *offset* is greater than the *dataSize* field of the NV Index.

If the TPMA_NV_WRITEALL attribute of the NV Index is SET, then the TPM shall return TPM_RC_NV_RANGE if the size of the *data* parameter of the command is not the same as the *data* field of the NV Index.

If all checks succeed, the TPM will merge the *data.size* octets of *data.buffer* value into the *nvIndex→data* starting at *nvIndex→data[offset]*. If the NV memory is implemented with a technology that has endurance limitations, the TPM shall check that the merged data is different from the current contents of the NV Index and only perform a write to NV memory if they differ.

After successful completion of this command, TPMA_NV_WRITTEN for the NV Index will be SET.

NOTE 2 Once SET, TPMA_NV_WRITTEN remains SET until the NV Index is undefined or the NV Index is cleared.

31.7.3 Detailed Actions

[[NV_Write]]

31.8 TPM2_NV_Increment

31.8.1 General Description

This command is used to increment the value in an NV Index that has the TPM_NT_COUNTER attribute. The data value of the NV Index is incremented by one.

NOTE 1 The NV Index counter is an unsigned value.

If *nvIndexType* is not TPM_NT_COUNTER in the indicated NV Index, the TPM shall return TPM_RC_ATTRIBUTES.

Proper authorizations are required for this command as determined by TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, and, if TPMA_NV_POLICYWRITE is SET, the *authPolicy* of the NV Index.

If TPMA_NV_WRITELOCKED is SET, the TPM shall return TPM_RC_NV_LOCKED.

If TPMA_NV_WRITTEN is CLEAR, it will be SET.

If TPMA_NV_ORDERLY is SET, and the difference between the volatile and non-volatile versions of this field is greater than MAX_ORDERLY_COUNT, then the non-volatile version of the counter is updated.

NOTE 2 If a TPM implements TPMA_NV_ORDERLY and an Index is defined with TPMA_NV_ORDERLY and TPM_NT_COUNTER both SET, then in the event of a non-orderly shutdown, the non-volatile value for the counter Index will be advanced by MAX_ORDERLY_COUNT at the next TPM2_Startup().

NOTE 3 An allowed implementation would keep a counter value in NV and a resettable counter in RAM. The reported value of the NV Index would be the sum of the two values. When the RAM count increments past the maximum allowed value (MAX_ORDERLY_COUNT), the non-volatile version of the count is updated with the sum of the values and the RAM count is reset to zero.

31.8.2 Command and Response

`[[NV_Increment]]`

31.9 TPM2_NV_Extend

31.9.1 General Description

This command extends a value to an area in NV memory that was previously defined by TPM2_NV_DefineSpace.

If *nvIndexType* is not TPM_NT_EXTEND, then the TPM shall return TPM_RC_ATTRIBUTES.

Proper write authorizations are required for this command as determined by TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, and, if TPMA_NV_POLICYWRITE is SET, the *authPolicy* of the NV Index.

After successful completion of this command, TPMA_NV_WRITTEN for the NV Index will be SET.

NOTE 1 Once SET, TPMA_NV_WRITTEN remains SET until the NV Index is undefined, unless the TPMA_NV_CLEAR_STCLEAR attribute is SET and a TPM Reset or TPM Restart occurs.

If the TPMA_NV_WRITELOCKED attribute of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

NOTE 2 If authorization sessions are present, they are checked before checks to see if writes to the NV Index are locked.

NOTE 3 The *data.buffer* parameter does not have to be the defined size of the NV Index. It may be any size allowed by TPM2B_MAX_NV_BUFFER.

The Index will be updated by:

$$nvIndex \rightarrow data_{new} := H_{nameAlg}(nvIndex \rightarrow data_{old} || data.buffer) \quad (45)$$

where

<i>nvIndex</i> → <i>data</i> _{new}	the value of the data field in the NV Index after the command returns
$H_{nameAlg}()$	the hash algorithm indicated in <i>nvIndex</i> → <i>nameAlg</i>
<i>nvIndex</i> → <i>data</i> _{old}	the value of the data field in the NV Index before the command is called
<i>data.buffer</i>	the data buffer of the command parameter

NOTE 3 If TPMA_NV_WRITTEN is CLEAR, then *nvIndex*→*data*_{old} is a Zero Digest.

[[NV_Extend]]

31.10 TPM2_NV_SetBits

31.10.1 General Description

This command is used to SET bits in an NV Index that was created as a bit field. Any number of bits from 0 to 64 may be SET. The contents of *bits* are ORed with the current contents of the NV Index.

Proper authorizations are required for this command as determined by TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, and, if TPMA_NV_POLICYWRITE is SET, the *authPolicy* of the NV Index.

If TPMA_NV_WRITTEN is not SET, then, for the purposes of this command, the NV Index is considered to contain all zero bits and *data* is ORed with that value.

If TPM_NT_BITS is not SET, then the TPM shall return TPM_RC_ATTRIBUTES.

After successful completion of this command, TPMA_NV_WRITTEN for the NV Index will be SET.

NOTE TPMA_NV_WRITTEN will be SET even if no bits were SET.

31.10.2 Command and Response

31.11 TPM2_NV_WriteLock

31.11.1 General Description

If the TPMA_NV_WRITEDEFINE or TPMA_NV_WRITE_STCLEAR attributes of an NV location are SET, then this command may be used to inhibit further writes of the NV Index.

Proper write authorization is required for this command as determined by TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, and, if TPMA_NV_POLICYWRITE is SET the *authPolicy* of the NV Index.

If TPMA_NV_WRITELOCKED for the NV Index is already SET, the TPM shall return TPM_RC_SUCCESS if proper write authorization is provided and can always return TPM_RC_SUCCESS.

If neither TPMA_NV_WRITEDEFINE nor TPMA_NV_WRITE_STCLEAR of the NV Index is SET, then the TPM shall return TPM_RC_ATTRIBUTES.

If the command is properly authorized and TPMA_NV_WRITE_STCLEAR or TPMA_NV_WRITEDEFINE is SET, then the TPM shall SET TPMA_NV_WRITELOCKED for the NV Index. TPMA_NV_WRITELOCKED will be clear on the next TPM2_Startup(TPM_SU_CLEAR) if either TPMA_NV_WRITEDEFINE is CLEAR or TPMA_NV_WRITTEN is CLEAR.

31.11.3 Detailed Actions

`[[NV_WriteLock]]`

31.12 TPM2_NV_GlobalWriteLock

31.12.1 General Description

The command will SET TPMA_NV_WRITELOCKED for all indexes that have their TPMA_NV_GLOBALLOCK attribute SET.

If an Index has both TPMA_NV_GLOBALLOCK and TPMA_NV_WRITEDEFINE SET, then this command will permanently lock the NV Index for writing unless TPMA_NV_WRITTEN is CLEAR.

NOTE 1 If an Index is defined with TPMA_NV_GLOBALLOCK SET, then the global lock does not apply until the next time this command is executed.

This command requires either platformAuth/platformPolicy or ownerAuth/ownerPolicy. The Index will be locked whether the index was defined using Owner Authorization or Platform Authorization.

NOTE 2 Index locking is independent of TPMA_NV_PLATFORMCREATE and the type of authorization. For example, an index with TPMA_NV_PLATFORMCREATE SET will be locked if the command uses Owner Authorization.

This permits the owner to lock all indexes after the OS is present. The platform should not create an index with TPMA_NV_GLOBALLOCK SET unless it intends to allow the owner to lock the index.

`[[NV_GlobalWriteLock]]`

31.13 TPM2_NV_Read

31.13.1 General Description

This command reads a value from an area in NV memory previously defined by TPM2_NV_DefineSpace().

Proper authorizations are required for this command as determined by TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, and, if TPMA_NV_POLICYREAD is SET, the *authPolicy* of the NV Index.

If TPMA_NV_READLOCKED of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

If *offset* and the *size* field of *data* add to a value that is greater than the *dataSize* field of the NV Index referenced by *nvIndex*, the TPM shall return an error (TPM_RC_NV_RANGE). The implementation may return an error (TPM_RC_VALUE) if it performs an additional check and determines that *offset* is greater than the *dataSize* field of the NV Index.

For an NV Index with the TPM_NT_COUNTER or TPM_NT_BITS attribute SET, the TPM may ignore the *offset* parameter and use an offset of 0. Therefore, it is recommended that the caller set the *offset* parameter to 0 for interoperability.

NOTE 1 If authorization sessions are present, they are checked before the read-lock status of the NV Index is checked.

If the NV Index has been defined but the TPMA_NV_WRITTEN attribute is CLEAR, then this command shall return TPM_RC_NV_UNINITIALIZED even if *size* is zero.

The *data* parameter in the response may be encrypted using parameter encryption.

31.13.2 Command and Response

31.13.3 Detailed Actions

[[NV_Read]]

31.14 TPM2_NV_ReadLock

31.14.1 General Description

If TPMA_NV_READ_STCLEAR is SET in an Index, then this command may be used to prevent further reads of the NV Index until the next TPM2_Startup (TPM_SU_CLEAR).

Proper authorizations are required for this command as determined by TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, and, if TPMA_NV_POLICYREAD is SET, the *authPolicy* of the NV Index.

If TPMA_NV_READLOCKED for the NV Index is already SET:

- If proper read authorization is provided, the TPM shall return TPM_RC_SUCCESS.
- if proper read authorization is not provided, the TPM may return either TPM_RC_SUCCESS or an authorization error response.

If the command is properly authorized and TPMA_NV_READ_STCLEAR of the NV Index is SET, then the TPM shall SET TPMA_NV_READLOCKED for the NV Index. If TPMA_NV_READ_STCLEAR of the NV Index is CLEAR, then the TPM shall return TPM_RC_ATTRIBUTES. TPMA_NV_READLOCKED will be CLEAR by the next TPM2_Startup(TPM_SU_CLEAR).

An Index that had not been written may be locked for reading.

31.14.3 Detailed Actions

[[NV_ReadLock]]

31.15 TPM2_NV_ChangeAuth

31.15.1 General Description

This command allows the authorization secret for an NV Index to be changed.

If successful, the authorization secret (*authValue*) of the NV Index associated with *nvIndex* is changed.

This command requires that a policy session be used for authorization of *nvIndex* so that the ADMIN role may be asserted and that *commandCode* in the policy session context shall be TPM_CC_NV_ChangeAuth. That is, the policy must contain a specific authorization for changing the authorization value of the referenced entity.

NOTE The reason for this restriction is to ensure that the administrative actions on *nvIndex* require explicit approval while other commands may use policy that is not command-dependent.

The size of the *newAuth* value may be no larger than the size of the digest produced by the *nameAlg* of the NV Index.

Since the NV Index authorization is changed before the response HMAC is calculated, the *newAuth* value is used when generating the response HMAC key if required (see TPM 2.0 Part 4, *ComputeResponseHMAC()*).

31.15.2 Command and Response

31.15.3 Detailed Actions

[[NV_ChangeAuth]]

31.16 TPM2_NV_Certify

31.16.1 General Description

The purpose of this command is to certify the contents of an NV Index or portion of an NV Index.

If the *sign* attribute is not SET in the key referenced by *signHandle* then the TPM shall return TPM_RC_KEY.

If the NV Index has been defined but the TPMA_NV_WRITTEN attribute is CLEAR, then this command shall return TPM_RC_NV_UNINITIALIZED even if *size* is zero.

If proper authorization for reading the NV Index is provided, the portion of the NV Index selected by *size* and *offset* are included in an attestation block and signed using the key indicated by *signHandle*. The attestation includes *size* and *offset* so that the range of the data can be determined. It also includes the NV index Name.

For an NV Index with the TPM_NT_COUNTER or TPM_NT_BITS attribute SET, the TPM may ignore the *offset* parameter and use an offset of 0. Therefore, it is recommended that the caller set the *offset* parameter to 0 for interoperability.

If *offset* and *size* add to a value that is greater than the *dataSize* field of the NV Index referenced by *nvIndex*, the TPM shall return an error (TPM_RC_NV_RANGE). The implementation may return an error (TPM_RC_VALUE) if it performs an additional check and determines that *offset* is greater than the *dataSize* field of the NV Index, or if *size* is greater than MAX_NV_BUFFER_SIZE.

NOTE 1 See clause 18.1 for description of how the signing scheme is selected.

NOTE 2 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned, and *signature* is a NULL Signature.

If *size* and *offset* are both zero (0), then *certifyInfo* in the response will contain a TPMS_NV_DIGEST_CERTIFY_INFO, otherwise, it will contain a TPMS_NV_CERTIFY_INFO. The digest in the TPMS_NV_DIGEST_CERTIFY_INFO is created using the digest of the selected signing scheme.

NOTE 3 TPMS_NV_DIGEST_CERTIFY_INFO was added in revision 01.53. It permits TPM2_NV_Certify() to certify NV Index contents that are larger than MAX_NV_BUFFER_SIZE.

31.16.2 Command and Response

Table 250 — TPM2_NV_Certify Command

31.17 TPM2_NV_DefineSpace2

31.17.1 General Description

This command is identical to TPM2_NV_DefineSpace(), except that the *publicInfo* parameter is a TPM2B_NV_PUBLIC_2, allowing all types of NV indices that support DefineSpace to be defined.

The following types of NV indices are supported by this command:

- TPM_HT_NV_INDEX (the legacy NV index type)
- TPM_HT_EXTERNAL_NV

NOTE TPM2_NV_DefineSpace2() was added in revision 01.74.

31.18 TPM2_NV_ReadPublic2

31.18.1 General Description

This command is identical to TPM2_NV_ReadPublic(), except that it supports NV indices of all types, and returns the public area as a TPM2B_NV_PUBLIC_2.

The Name of a TPM_HT_NV_INDEX is consistent whether it is returned from TPM2_NV_ReadPublic() or TPM2_NV_ReadPublic2().

NOTE 1 The Name is the same because it is calculated using a marshaled TPMU_NV_PUBLIC_2, which is a TPMS_NV_PUBLIC in both commands. The TPMT_NV_PUBLIC_2 union tag *handleType* is not included.

NOTE 2 TPM2_NV_ReadPublic2() was added in revision 01.74.

31.18.2 Command and Response

32 Attached Components

32.1 Introduction

This clause contains commands that allow interaction with an Attached Component (AC).

NOTE The Attached Component feature was added in revision 01.40.

32.2 TPM2_AC_GetCapability

32.2.1 General Description

The purpose of this command is to obtain information about an Attached Component referenced by an AC handle.

The returned list contains 0 or more values starting at the first tagged value that is equal to or greater than *capability*.

The list returned in *capabilitiesData* contains tagged values that indicate the type of the value.

The TPM will return the lesser of a) the available values, b) the number requested in *count*, or c) the number that will fit within the available response buffer. If additional values with higher *capability* numbers are available, *moreData* will be YES.

NOTE TPM2_AC_GetCapability() was added in revision 01.40.

32.2.2 Command and Response

32.2.3 Detailed Actions

[[AC_GetCapability]]

32.3 TPM2_AC_Send

32.3.1 General Description

The purpose of this command is to send (copy) a loaded object from the TPM to an Attached Component.

The Object referenced by *sendObject* is required to have *fixedTpm*, *fixedParent*, and *encryptedDuplication* attributes CLEAR (TPM_RC_ATTRIBUTES). Authorization for *sendObject* is required to be a policy session. The *policySession→commandCode* of the policy session context is required to be TPM_CC_AC_Send (TPM_RC_POLICY_FAIL) to demonstrate that the policy is specific for this command.

Authorization to send to the *ac* is provided by the session associated with *authHandle*.

If an NV Alias is not defined for *ac*, then *authHandle* is required to be either TPM_RH_OWNER or TPM_RH_PLATFORM (TPM_RC_HANDLE).

If an NV Alias is defined for *ac*, then the authorization for *authHandle* is required to be compatible with the write authorization attributes (TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, and TPMA_NV_POLICYWRITE) in the NV Alias (TPM_RC_NV_AUTHORIZATION).

NOTE 1 If authorization for *authHandle* is the handle of an NV Index, then it is required to be the NV Alias value for *ac* (TPM_RC_NV_AUTHORIZATION).

If authorization succeeds, the TPM will attempt to send *acDataIn* and relevant portions of *sendObject* to the AC referenced by *ac*.

The TPM will return TPM_RC_SUCCESS if it succeeds in performing all the required authorizations and validations. If problems occur in the process of sending the object from the TPM to the AC, the response code will be TPM_RC_SUCCESS with the AC-dependent error reported in *acDataOut*.

NOTE 2 TPM2_AC_Send() was added in revision 01.40.

32.3.2 Command and Response

Table 258 — TPM2_AC_Send Command

32.3.3 Detailed Actions

[[AC_Send]]

32.4 TPM2_Policy_AC_SendSelect

32.4.1 General Description

This command allows qualification of the sending (copying) of an Object to an Attached Component (AC). Qualification includes selection of the receiving AC and the method of authentication for the AC, and, in certain circumstances, the Object to be sent may be specified.

If this command is not used in conjunction with TPM2_PolicyAuthorize(), then only the *authHandleName* and *acName* are selected and *includeObject* should be CLEAR.

NOTE 1 In the absence of TPM2_PolicyAuthorize(), a policy session cannot create a *policyDigest* that simultaneously equals the *authPolicy* in an Object and names that Object. This is because the *authPolicy* recorded in an Object is unable to include the Name of the Object as the Name of an Object depends on the Object's *authPolicy*.

NOTE 2 An object's *authPolicy* can incorporate the use of TPM2_PolicyAuthorize(). If the authorizing entity for the TPM2_PolicyAuthorize() command specifies only the *ac* and the *authHandle*, then the resultant *policyDigest* may be applied to the sending of any number of Objects. If the authorizing entity for the TPM2_PolicyAuthorize() also specifies the Name of the Object to be sent, then the resultant *policyDigest* applies only to that specific Object.

If either *policySession*→*cpHash* or *policySession*→*nameHash* has been previously set, the TPM shall return TPM_RC_CPHASH. Otherwise, *policySession*→*nameHash* will be set to:

$$nameHash := H_{policyAlg}(objectName || authHandleName || acName) \quad (46)$$

NOTE 3 A policy cannot specify both *cpHash* and *nameHash* because *policySession*→*nameHash* and *policySession*→*cpHash* may share the same memory space.

If the command succeeds, *policySession*→*policyDigest* will be updated according to the setting of the input parameter *includeObject*. If *includeObject* is SET, *policySession*→*policyDigest* is updated by:

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_Policy_AC_SendSelect || objectName || authHandleName || acName || includeObject) \quad (47)$$

but if *includeObject* is CLEAR, *policySession*→*policyDigest* is updated by:

$$policyDigest_{new} := H_{policyAlg}(policyDigest_{old} || TPM_CC_Policy_AC_SendSelect || authHandleName || acName || includeObject) \quad (48)$$

NOTE 4 *policySession*→*nameHash* receives the digest of all Names so that the check performed in TPM2_AC_Send() may be the same regardless of which Names are included in *policySession*→*policyDigest*. This means that, when TPM2_Policy_AC_SendSelect() is executed, it is only valid for a specific triple of *objectName*, *authHandleName*, and *acName*.

If the command succeeds, *policySession*→*commandCode* is set to TPM_CC_AC_Send.

NOTE 5 The normal use of TPM2_Policy_AC_SendSelect() is before a TPM2_PolicyAuthorize(). An authorized entity would approve a *policyDigest* that allows sending to a specific Attached Component. The authorizing entity may want to limit the authorization so that the approval allows only a specific Object to be sent to the Attached Component. In that case, the authorizing entity would approve the *policyDigest* of equation (48).

NOTE 6 TPM2_Policy_AC_SendSelect() was added in revision 01.40.

33 Authenticated Countdown Timer

33.1 Introduction

This clause contains commands that allow interaction with an Authenticated Countdown Timer (ACT).

NOTE The Authenticated Countdown Timer was added in revision 01.56.

33.2 TPM2_ACT_SetTimeout

33.2.1 General Description

This command is used to set the time remaining before an Authenticated Countdown Timer (ACT) expires.

This command sets TPMS_ACT_DATA.timeout (ACT Timeout) to *startTimeout*. The *startTimeout* value is an integer number of seconds and may be zero. The *startTimeout* parameter may be greater, equal, or less than the current value of ACT Timeout.

When ACT Timeout is non-zero, it will count down, once per second until it reaches zero, at which time the *signaled* attribute of the TPMA_ACT associated with *actHandle* is SET.

When ACT Timeout is zero and the *signaled* attribute is SET, writing a *startTimeout* of FF FF FF FF₁₆ will clear *signaled* and stop the counting.

There are four states for ACT Timeout and *startTimeout*. The *signaled* attribute will be set as follows:

- 1) If ACT Timeout is zero and *startTimeout* is non-zero, then *signaled* will be CLEAR.
- 2) If ACT Timeout is non-zero and *startTimeout* is non-zero, then *signaled* will be CLEAR.
- 3) If ACT Timeout is zero and *startTimeout* is zero, then *signaled* will be unchanged.
- 4) If ACT Timeout is non-zero and *startTimeout* is zero, then *signaled* will be SET.

When this command is successful, *preserveSignaled* will be CLEAR.

NOTE 1 The ACT signals on a transition from non-zero to zero. The transition can occur either due to TPM2_ACT_SetTimeout() or a decrement. The effect of *signaled* is platform dependent.

NOTE 2 It may take up to one second until ACT Timeout will be set and *signaled* will be CLEAR or SET by TPM2_ACT_SetTimeout() or TPM2_Startup(STATE). This allows the counting and signaling to take place synchronously with the hardware clock tick.

NOTE 3 TPM2_ACT_SetTimeout() was added in revision 01.56.
