### 1 3.1. Executive summary

2 **Dryland areas are expected to become more vulnerable to desertification due to increasing number,**  
3 **frequency and intensity of extreme climatic events** (*high confidence*) {3.2.1, 3.3.2, 3.6.1, 3.6.2}.  
4 Desertification is land degradation in drylands, and the range and the intensity of desertification increased  
5 in some dryland areas over the past several decades {3.3.1}. Expansion of drylands, as measured by the  
6 aridity index, has already occurred in north-eastern Brazil, southern Argentina, the southwest of the United  
7 States, eastern Africa, the Middle East, Central Asia, the Sahel, Zambia and Zimbabwe, some regions of  
8 the Mediterranean area, North-Eastern China and sub-Himalayan India during the last three decades as  
9 compared to the period of 1951–1980 {3.3.1.2}. However, the CO<sub>2</sub>-fertilisation effect is *likely* to be  
10 mitigating the expansion of dryland areas in terms of changes in vegetation cover. Biomass productivity-  
11 based desertification hotspots currently cover about 10% of the drylands, directly affecting about 277  
12 million people {3.2.1, 3.3}. Future climate changes with increasing frequency, intensity and scales of  
13 extreme weather events, for example droughts and heat waves, are expected to further exacerbate the  
14 vulnerability and risk of humans and ecosystems to desertification, in particular, drought and/or aridity are  
15 projected to increase as a result of 1.5°C to a 2°C global warming (*high confidence*) {3.2.1, 3.3.2, 3.6.1}.

16 **Attribution of desertification to climate variability and change and human activities is context-**  
17 **dependent** (*high confidence*). Climate variability and change, particularly through increase both in land  
18 surface air temperature and evapotranspiration, and decrease in precipitation, are *likely* to have played a  
19 larger role, in interaction with human drivers, in causing desertification than previously estimated for some  
20 dryland areas (*medium evidence, medium agreement*) {3.3.2}. The major human drivers of desertification  
21 interacting with climate change are expansion of croplands and urban areas, unsustainable land  
22 management practices and increased pressure on land from population and income growth (*robust evidence,*  
23 *high agreement*) {3.2.4.2}. Poverty and migration also exacerbate desertification under a changing climate  
24 {3.2.4.2} (*limited evidence, medium agreement*).

25 **Desertification exacerbates climate change through several mechanisms such as changes in**  
26 **vegetation cover, surface albedo, sand and dust aerosols and greenhouse gases fluxes** (*high*  
27 *confidence*). Through its effect on vegetation and soils, desertification changes the absorption and release  
28 of associated greenhouse gases (GHGs) {3.4.3}. The extent of areas in which dryness controls CO<sub>2</sub>  
29 exchange (rather than temperature) has increased by 6% since 1948 and is expected to increase by at least  
30 another 8% by 2050 if the expansion continues at the same rate. In these areas, net carbon uptake is about  
31 27% lower than in other areas {3.6.2}. Vegetation loss and drying of surface cover due to desertification  
32 increases the frequency of dust storms (*high confidence*). Dust particles intercept, reflect and absorb solar  
33 radiation in the atmosphere, reducing the heat energy available at the land surface and increasing the  
34 temperature of the atmosphere. Depending on the types and amounts of aerosols present, sand and dust  
35 storms increase the cloud reflectivity and decrease the chances of precipitation {3.4.1}. Deposition of dust  
36 storms on the oceans was found to have a direct effect of cooling, while the indirect effect of dust storms  
37 as a source of nutrients for the upper ocean biota is contested {3.4.1.1}.

38 **The interaction of climate change and desertification reduces the provision of dryland ecosystem**  
39 **services and lowers ecosystem health, including loss of biodiversity, affecting food security and**  
40 **human well-being** (*high confidence*). Desertification processes, coupled with climate change, are expected  
41 to cause reductions in crop and livestock productivity, increases in soil erosion, and soil salinity in dryland  
42 areas in Latin America, Caribbean and sub-Saharan Africa by 2055 (*high confidence*) {3.5.1.1}.  
43 Desertification has already contributed to the global loss of biodiversity (*medium confidence*) {3.5.1.2}.  
44 Wildlife are *likely* to be negatively affected by coupled effects of climate change and desertification. A

1 reduction in the quality and quantity of resources available to herbivores is *likely* to have synergistic  
2 consequences for predators, potentially disrupting ecological cascades (*limited evidence, low agreement*)  
3 {3.5.1.2}. Future desertification with climate change will bring high risk for the ecosystem services and  
4 biodiversity in drylands due to increasing frequency and intensity of droughts, dust storms, and soil erosion.  
5 The distribution of areas affected by desertification is also projected to change due to changes in drylands  
6 areas following climate change, in particular from a 1.5°C to a 2°C global warming (*low confidence*)  
7 {3.6.2}.

8 **Increasing population pressures combined with climate change are *likely* to push dryland populations**  
9 **beyond their resilience thresholds and the limits for their autonomous adaptation, requiring policy**  
10 **interventions aimed at maintaining and strengthening their resilience and adaptive capacities** (*robust*  
11 *evidence, medium agreement*). The combination of pressures coming from climate change and  
12 desertification contribute, in interaction with other contextual factors, to migration, conflict, poverty, food  
13 insecurity, and increased disease burden (*medium confidence*) {3.5.2}. Migration is increasingly used as an  
14 adaptation response in the context of environmental change (*medium evidence, high agreement*). However,  
15 environmentally-induced migration is complex and its attribution to environmental change should account  
16 for multiple drivers of mobility as well as other adaptation measures undertaken by populations exposed to  
17 environmental risk (*high confidence*) {3.5.2.4}.

18 **Higher frequency, intensity and scales of dust storms due to climate change-desertification**  
19 **interactions will reduce human wellbeing in drylands and beyond** (*high confidence*). Increased dust  
20 storm activity because of desertification and climate change has a high potential for negative human health  
21 impacts due to associated respiratory and cardiovascular illnesses (*medium evidence, high agreement*)  
22 {3.5.2.8}. Higher intensity of sand storms and sand dune movements under climate change also cause  
23 damage to transportation and solar energy generating infrastructures (*high confidence*) {3.5.2.9, 3.5.2.10}.

24 **Site-specific technological solutions, based both on new scientific innovations and indigenous and**  
25 **local knowledge, are available to avoid, reduce and reverse desertification, simultaneously**  
26 **contributing to climate change mitigation and adaptation** (*high confidence*). Sustainable land  
27 management (SLM) practices in drylands contribute to climate change mitigation and adaptation, increase  
28 agricultural productivity, and have substantial co-benefits for the attainment of Sustainable Development  
29 Goals (*high confidence*) {3.5.2, 3.7.1}. Integrated soil and water conservation measures increase vegetation  
30 coverage and density (*medium confidence*). Conservation agriculture contributes to carbon sequestration in  
31 dryland areas (*medium confidence*). It also increases climate change adaptation capacities of agricultural  
32 households (*high confidence*). The combined use of salt-tolerant crops, improved irrigation practices,  
33 chemical remediation measures and appropriate mulch and compost (that are low in salts) is effective in  
34 reducing salinity-induced desertification (*medium confidence*). Rangeland management systems such as  
35 sustainable grazing approaches and re-vegetation increases rangeland productivity (*medium confidence*).  
36 Agroforestry practices generate diverse ecological benefits, including soil and water conservation,  
37 increased carbon sequestration, and reduced erosion. Afforestation programs for the creation of windbreaks  
38 in the form of “green walls”, “green belts”, and “green dams” helped to stabilise and reduce sand storms,  
39 avert aeolian desertification, and served as carbon sinks {3.7.1, 3.8.2}.

40 **Investments into land restoration and rehabilitation in dryland areas have positive economic returns**  
41 (*high confidence*). Each dollar invested into land restoration has social returns of 2–5 dollars over a 30-year  
42 period globally {3.7.1}. Despite their benefits in addressing desertification, mitigating and adapting to  
43 climate change, many SLM practices are not widely adopted due to insecure property rights, lack of access

1 to credit and agricultural advisory services, and insufficient private incentives (*robust evidence, high*  
2 *agreement*) {3.7.1, 3.7.2}.

3 **Indigenous and local knowledge distilled into traditional agroecological practices contributes to**  
4 **enhancing resilience against climate change and combating desertification** (*medium confidence*).  
5 Dryland populations have historically developed traditional agroecological practices which are well  
6 adapted to resource-sparse dryland environments {3.7.1, 3.7.2}. However, there is *robust evidence*  
7 documenting losses of traditional agroecological knowledge. Traditional agroecological practices are also  
8 increasingly unable to cope with growing demand pressures and environmental changes {3.7.2}. Innovative  
9 combinations of indigenous and local knowledge and modern agronomic practices can contribute to  
10 overcoming combined challenges of climate change and desertification (*medium evidence, medium*  
11 *confidence*).

12 **Policy frameworks promoting the adoption of sustainable land management solutions contribute to**  
13 **addressing desertification as well as mitigating and adapting to climate change, with significant co-**  
14 **benefits for poverty reduction and food security among dryland populations** (*medium confidence*). On-  
15 farm and off-farm livelihood diversification strategies increase the resilience of rural agricultural  
16 households against extreme weather events, such as droughts, and desertification (*high confidence*).  
17 Strengthening collective action is important for addressing desertification causes and impacts, and for  
18 adapting to climate change (*medium confidence*). Access to markets, such as those based on new  
19 information and communication technologies, raises agricultural profitability and motivates investment into  
20 climate change adaptation and SLM (*medium confidence*) {3.7.2, 3.7.3}. Promoting schemes that provide  
21 payments for ecosystem services gives additional incentives to land users to adopt SLM practices (*medium*  
22 *evidence, high agreement*) {3.7.3}.

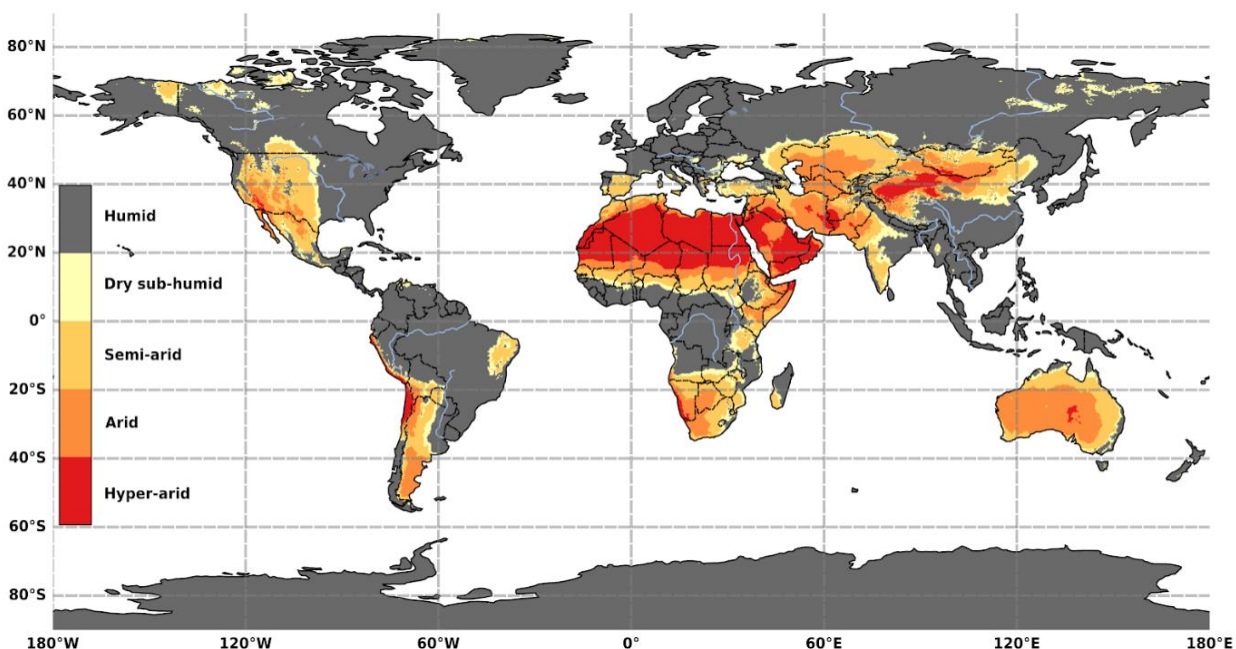

23 **Improving human and institutional capacities and accessibility to information, including to early**  
24 **warning, hydro-meteorological and remote sensing-based earth monitoring systems, and expanded**  
25 **use of digital technologies are high return investments for measuring progress in addressing**  
26 **desertification under changing climate** (*low evidence, high agreement*). Effective national, regional and  
27 international monitoring and early warning systems help combat desertification and extreme events  
28 (*medium confidence*) {3.8.6}. Adoption of land degradation neutrality policies lead to balancing of  
29 ecosystem service performance and land improvement (*low evidence, high agreement*). Increasing  
30 investments into strengthening research, education and extension services accelerates the achievement of  
31 land degradation neutrality targets (*high confidence*). Expanded use of new information and communication  
32 technologies, remotely sensed information and of “citizen science” for data collection helps in measuring  
33 progress towards achieving the land degradation neutrality target and raising public awareness and  
34 participation in sustainable land management (*low evidence, high agreement*) {3.7.2, 3.7.3}.

## 1 3.2. The Nature of Desertification

### 2 3.2.1. Introduction

3 Desertification is land degradation in arid, semi-arid, and dry sub-humid areas resulting from many factors,  
 4 including human activities and climatic variations (UNCCD, 1994; Glossary). Arid, semi-arid, and dry sub-  
 5 humid areas, together with hyper-arid areas, constitute drylands (UNEP, 1992). Consequently, although  
 6 land degradation occurs anywhere across the world, it is defined as desertification when it occurs in  
 7 drylands. Desertification is not limited to only irreversible forms of land degradation, nor is it limited to  
 8 processes of desert expansion, but is used to represent all forms and levels of land degradation occurring in  
 9 drylands. In turn, land degradation is a deterioration or persistent decline in land conditions resulting in  
 10 long-term reduction or loss of the biological productivity of land, its ecological complexity, and/or its  
 11 human values, caused by direct and/or indirect human-induced processes or impacts, including climate  
 12 change (Chapter 4; Glossary). Thus, desertification is manifested through the reduced provision of the sum  
 13 of dryland ecosystem services (Verstraete et al., 2009; Safriel et al., 2005; Scholes, 2009).

14 The geographic classification of drylands is often based on the aridity index - the ratio of average annual  
 15 precipitation amount (P) to potential evapotranspiration amount (PET) (Figure 3.1, Glossary). Hyper-arid  
 16 areas, where the aridity index is below 0.05, are included in drylands (Section 3.8.4), but are excluded from  
 17 the definition of desertification (UNCCD, 1994). Moreover, aridity is different from drought: aridity is a  
 18 long-term climatic feature, whereas drought is a temporary climatic event (Maliva and Missimer, 2012).  
 19 Droughts are not restricted to drylands, but occur both in drylands and humid areas (Wilhite et al., 2014).  
 20 IPCC (2014) defines drought as “a period of abnormally dry weather long enough to cause a serious  
 21 hydrological imbalance” (Section 3.8.6; Glossary).

22  
 23 **Figure 3.1 Geographical distribution of drylands, delimited based on the Aridity Index. The classification of**  
 24 **the aridity index (AI) is: Humid  $AI > 0.65$ , Dry sub-humid  $0.50 < AI < 0.65$ , Semi-arid  $0.20 < AI < 0.50$ , Arid**  
 25  **$0.05 < AI < 0.20$ , Hyper-arid  $AI < 0.05$ . Data: TerraClimate precipitation and potential evapotranspiration**  
 26 **(1980-2015) (Abatzoglou et al., 2018)**

1 Safriel et al. (2005) earlier estimated that drylands occupy about 41.3% of the Earth’s land surface. A more  
 2 recent estimate suggested that drylands cover about 45.4% of the global land area, the difference being  
 3 mainly due to improved data, capturing the expansion of drylands towards northern latitudes (Průvák,  
 4 2016). Although climate change is expected to decrease the aridity index, implying more arid conditions in  
 5 the future due to increases in potential evaporation, the assumptions that underpin the potential evaporation  
 6 calculation are not consistent with a changing CO<sub>2</sub> environment (Roderick et al., 2015; Greve et al., 2017).  
 7 Given that future climate is characterised by significant increases in CO<sub>2</sub>, the usefulness of currently applied  
 8 aridity index thresholds to estimate dryland areas is limited under climate change. If instead of the aridity  
 9 index, other variables such as precipitation, soil moisture, and primary productivity are used to identify  
 10 dryland areas, there is no clear indication that the extent of drylands will change overall under climate  
 11 change (Roderick et al., 2015; Greve et al., 2017; Lemordant et al., 2018). Thus, some dryland borders will  
 12 expand, while some others will contract.

13 The majority of dryland areas, approximately 70%, are located in Africa and Asia (Figure 3.2). The biggest  
 14 land use/cover in drylands, if deserts are excluded, in terms of area are grasslands, followed by forests and  
 15 croplands (Figure 3.3). The category of “other lands” in Figure 3.3 includes bare soil, ice, rock, and all  
 16 other land areas that are not included within the other five categories (FAO, 2016). Thus, hyper-arid areas  
 17 contain mostly deserts, with some small exceptions, for example, where grasslands and croplands are  
 18 cultivated under oasis conditions (Section 3.8.4). Moreover, FAO (2016) defines grasslands as permanent  
 19 pastures and meadows used continuously for more than 5 years. In drylands, transhumance often leads to  
 20 non-permanent pasture systems, thus, some of the areas under “other land” category are also used as non-  
 21 permanent pastures (Ramankutty et al., 2008; Fetzel et al., 2017; Erb et al., 2016).

22  
 23 **Figure 3.2 Dryland categories across geographic areas. Data: TerraClimate precipitation and potential**  
 24 **evapotranspiration (1980-2015) (Abatzoglou et al., 2018)**

1

2  
3 **Figure 3.3 Land use and land cover in drylands (in million hectares) and share of each dryland category in**  
4 **global land area (in percentages). Source: FAO (2016) and own calculations for the shares in the global land**  
5 **area**

6 Earlier global assessments of desertification since the 1970s, based on qualitative expert evaluations,  
7 estimated the extent of desertification to be between 4% and 70% of the area of drylands (Safriel, 2007).  
8 More recent estimates, based on remotely sensed data, show that about 24–29% of the global land area  
9 experienced a reduction in biomass productivity between 1980s and 2000s (Bai et al., 2008; Le et al.,  
10 2016b). The figures by Bai et al. (2008) show that only 28% of the global areas with biomass productivity  
11 loss are located in drylands. Analysis of the figures by Le et al. (2016b) show that about 10% of drylands,  
12 excluding hyper-arid areas, experienced significant declines in biomass productivity between 1980s and  
13 2000s.

14 Available assessments of the global extent and severity of desertification are still relatively crude  
15 approximations with considerable uncertainties, for example, due to confounding effects of invasive bush  
16 encroachment in some dryland regions. Different indicator sets and approaches have been developed for  
17 monitoring and assessment of desertification from national to global scales (Imeson 2012; Sommer et al.,  
18 2011; Zucca et al., 2012; Bestelmeyer et al., 2013). Many indicators of desertification only include a single  
19 factor or characteristic of desertification, such as the patch size distribution of vegetation (Maestre and  
20 Escudero, 2009; Kéfi et al., 2010), NDVI (Piao et al., 2005), drought-tolerant plant species (An et al., 2007),  
21 grass cover (Bestelmeyer et al., 2013), land productivity dynamics trend (Baskan et al., 2017), ecosystem  
22 net primary productivity (Zhou et al., 2015) or environmentally sensitive land area index (Symeonakis et  
23 al., 2014). In addition, some synthetic indicators of desertification have also been used to assess  
24 desertification extent and desertification process, such as climate, land use, soil, and socioeconomic  
25 parameters (Dharumarajan et al., 2018), or changes in climate, land use, vegetation cover, soil properties

1 and population as the desertification vulnerability index (Salvati et al., 2009). Current data availability and  
2 methodological challenges do not allow for accurately and comprehensively mapping desertification at a  
3 global scale (Cherlet et al., 2018). However, the emerging partial evidence points to a lower extent of  
4 desertification than previously estimated (Section 3.3).

5 The present assessment of desertification under changing climate is conceptually structured taking into  
6 account that it is the links within coupled social-ecological systems that drive desertification-climate change  
7 interactions, at each level from drivers (Section 3.2.4) and feedbacks (Section 3.4), to observed and  
8 projected impacts (Sections 3.5 and 3.6), and responses (Section 3.7). Moreover, this assessment highlights  
9 that dryland populations are highly vulnerable to desertification and climate change (Section 3.3 and 3.5).  
10 However, the evidence does not support the narrative of an inevitable vicious cycle of resource degradation  
11 and poverty in drylands due to desertification and climate change (Section 3.2.4.3). On the contrary, dryland  
12 populations also have significant past experience and sources of resilience embodied in indigenous and  
13 local knowledge and practices in order to successfully adapt to climatic changes and address desertification  
14 (Section 3.7.2). However, increasing population pressures combined with climate change can push dryland  
15 populations beyond their resilience thresholds and the limits for their autonomous adaptation, requiring  
16 policy interventions aimed at maintaining and strengthening their resilience and adaptive capacities. The  
17 assessment finds that policies promoting sustainable land management in drylands will contribute to climate  
18 change mitigation and adaptation, with substantial co-benefits in terms of sustainable development.

### 20 **3.2.2. Desertification in previous IPCC and related reports**

21 The Fifth Assessment report (AR5) of the IPCC includes some discussion of desertification. In AR5  
22 Working Group I desertification is mentioned as a forcing agent for the production of atmospheric dust  
23 (IPCC, 2013). In AR5 Working Group II desertification is identified as a process that can lead to reductions  
24 in crop yields and the resilience of agricultural and pastoral livelihoods, while processes such as soil  
25 degradation are identified as increasing the risk of desertification (IPCC, 2014). For Africa, AR5 Working  
26 Group II notes “Climate change will amplify existing stress on water availability and on agricultural  
27 systems particularly in semi-arid environments (*high confidence*).” AR5 Working Group III identifies  
28 desertification as one of a number of often overlapping issues that must be dealt with when considering  
29 governance of mitigation and adaptation (Fleurbaey et al., 2014).

30 The IPCC Special Report on Global Warming of 1.5°C (IPCC, 2018) pointed out that there is *limited*  
31 *evidence and medium agreement* that the extent of deserts will increase in the coming decades. However,  
32 the deserts are expected to become drier and warmer more rapidly than other terrestrial areas (IPCC, 2018).  
33 IPCC (2018) assessed as “*low confidence*” that desertification linked to climate change will directly or  
34 indirectly influence soil health and productivity due to accelerated soil erosion in drylands. IPCC (2018)  
35 also had “*low confidence*” in the projections of future increases in dust storms with higher aridity.

36 The recent Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES)  
37 Assessment report on land degradation and restoration (IPBES, 2018) is also of particular relevance. While  
38 acknowledging a wide variety of past estimates of the area undergoing degradation such that there is *low*  
39 *agreement* about where degradation is taking place, IPBES (2018) nevertheless concludes that  
40 desertification is occurring on all continents and affects more than the total population of the drylands due  
41 to effects outside the drylands through migration. They recognise that “at a regional or global scale,  
42 distinguishing the impacts of climate change and variability from anthropogenic degradation remains  
43 problematic (unresolved).” They also identify that “there is growing concern over the impacts that climate

1 change may have on degradation (inconclusive).” However, this issue is not examined in great detail and  
2 is not the focus of IPBES (2018).

3 The third edition of the World Atlas of Desertification (Cherlet et al., 2018) argues against the idea of  
4 deterministically mapping land degradation globally, or its subset - desertification, indicating that the  
5 complexity of interactions between social, economic, and environmental systems make land degradation  
6 not amenable to mapping at a global scale. Instead, Cherlet et al. (2018) present global maps showing the  
7 convergence of various pressures on land resources. For example, although climate variability, particularly  
8 related to droughts, is recognised as a limit to sustainability, Cherlet et al. (2018) do not focus on climate  
9 change *per se*. Various sources of pressures on land and limits to sustainability emphasise the interactions  
10 within coupled social-ecological systems in driving desertification (Cherlet et al., 2018).

### 11 12 **3.2.3. Dryland Populations: Vulnerability and Resilience to Desertification and Climate** 13 **Change**

14 Drylands are home to approximately 37.5% of the global population (Netherlands Environmental  
15 Assessment Agency (PBL), 2017), that is about 2.7 billion people. The highest number of people live in  
16 the drylands of South Asia (Figure 3.4), followed by Sub-Saharan Africa and Latin America (PBL, 2017).  
17 The population in drylands is projected to increase about twice as rapidly as those in non-drylands to reach  
18 4 billion people by 2050 (PBL, 2017). This is due to higher population growth rates in drylands.

19 In terms of the number of people affected by desertification, the earlier estimates by MEA (2005) and  
20 Reynolds et al. (2007) indicated that desertification was directly affecting 250 million people and indirectly  
21 1 billion people. Similarly, the data from Le et al. (2016b) show that approximately 277 million people  
22 reside in dryland areas which experienced significant loss in biomass productivity between 1982–1984 and  
23 2004–2006.

24 Dryland populations are highly vulnerable (Glossary) to desertification and climate change (Howe et al.,  
25 2013; Huang et al., 2016, 2017; Liu et al., 2016; Thornton et al., 2014; Lawrence et al., 2018), because their  
26 livelihoods are predominantly dependent on agriculture; one of the most susceptible sectors to climate  
27 change (Rosenzweig et al., 2014; Schlenker and Lobell, 2010). Climate change is projected to have  
28 substantial impacts on all types of agricultural livelihood systems in drylands (CGIAR-RPDS, 2014)  
29 (Sections 3.5.1 and 3.5.2). One key vulnerable group in drylands are pastoral and agropastoral households<sup>1</sup>.  
30 It is estimated that there are about 120 million people practicing pastoralism and agropastoralism globally  
31 (Rass, 2006), predominantly in drylands, of whom 30–63 million are nomadic pastoralists (Dong, 2016;  
32 Carr-Hill, 2013)<sup>2</sup>. Pastoral production systems represent an adaptation to high seasonal climate variability  
33 and low biomass productivity in dryland ecosystems (Varghese and Singh, 2016; Krätli and Schareika,  
34 2010), which require large areas for livestock grazing through migratory pastoralism (Snorek et al., 2014).  
35 Grazing lands across dryland environments are being degraded, and/or being converted to crop production,  
36 limiting the opportunities for migratory livestock systems, and leading to conflicts with sedentary crop  
37 producers (Abbass, 2014; Dimelu et al., 2016). These processes, coupled with ethnic differences, perceived

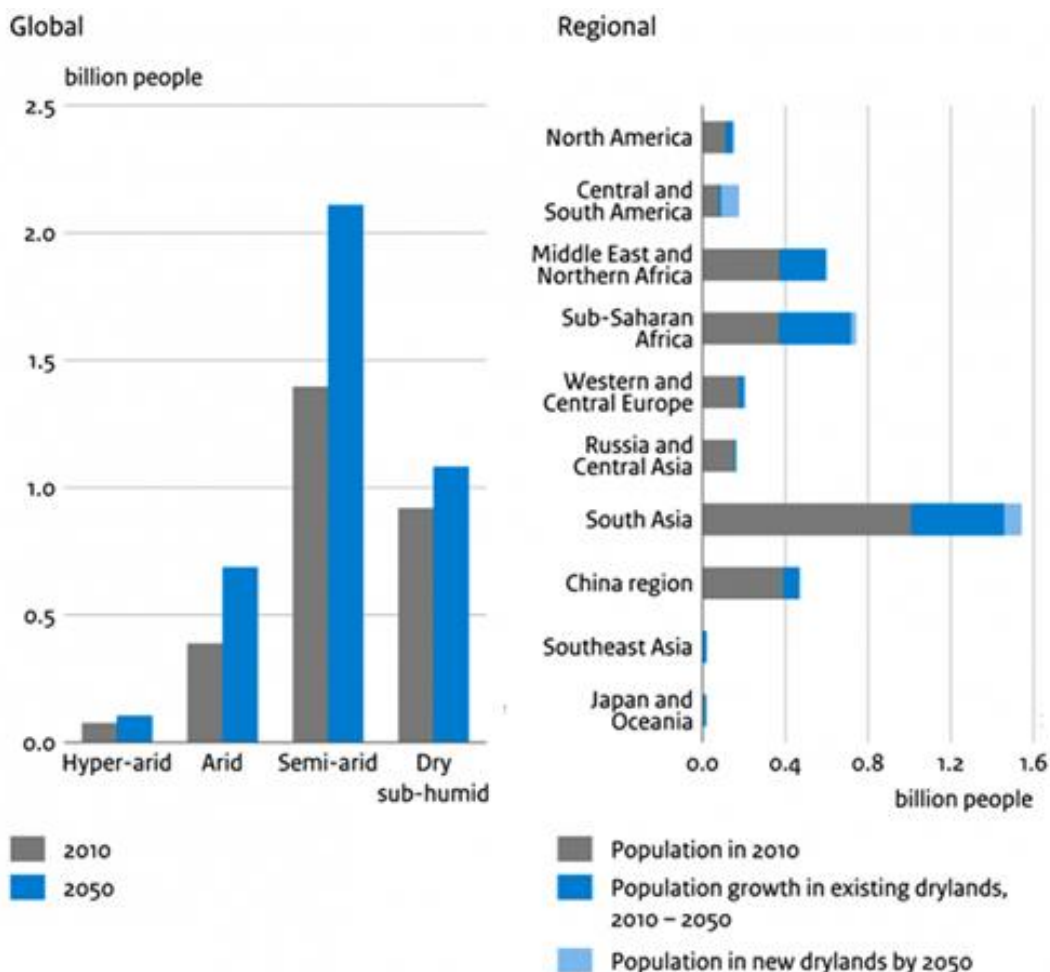

---

<sup>1</sup>FOOTNOTE: Pastoralists derive more than 50% of their income from livestock and livestock products, whereas agropastoralists generate more than 50% of their income from crop production and at least 25% from livestock production (Swift, 1988).

<sup>2</sup>FOOTNOTE: The estimates of the number of pastoralists, and especially of nomadic pastoralists, are very uncertain, because often nomadic pastoralists are not fully captured in national surveys and censuses (Carr-Hill, 2013).

1 security threats, misunderstanding of pastoral rationality, have led to increasing marginalisation of pastoral  
 2 communities and disruption of their economic and cultural structures (Elhadary, 2014; Morton, 2010). As  
 3 a result, pastoral communities are not well prepared to deal with increasing weather/climate variability and  
 4 weather/climate extremes due to changing climate (Dong, 2016; López-i-Gelats et al., 2016).

5

6

7

**Figure 3.4 Current and projected population in drylands. Source: (PBL, 2017)**

8 There is an increasing concentration of poverty in the dryland areas of Sub-Saharan Africa and India (von  
 9 Braun and Gatzweiler, 2014; Barbier and Hochard, 2016). Rapid economic growth and poverty reduction  
 10 in China over the last three decades decreased the absolute global numbers of dryland populations living in  
 11 poverty. Only between 1981 and 2001, the share of the people living under poverty in China declined from  
 12 53% to 8% (Ravallion and Chen, 2007), translating to about 426 million people getting out of poverty.  
 13 However, the areas affected by desertification remain among the poorest in China (Yang et al., 2008; Liu  
 14 et al., 2017). Multidimensional poverty, prevalent in many dryland areas, is a key source of vulnerability  
 15 (Safriel et al., 2005; Thornton et al., 2014; Fraser et al., 2011; Thomas, 2008). Multidimensional poverty  
 16 incorporates both income-based poverty, but also other dimensions such as poor healthcare services, lack  
 17 of education, lack of access to water, sanitation and energy, disempowerment, and threat from violence  
 18 (Bourguignon and Chakravarty, 2003; Alkire et al., 2010; Alkire and Santos, 2014). Contributing elements  
 19 to this multidimensional poverty in drylands are rapid population growth, fragile institutional environment,

1 lack of infrastructure, geographic isolation and low market access, insecure land tenure systems, low  
2 agricultural productivity (Sietz et al., 2011; Reynolds et al., 2011; Safriel and Adeel, 2008; Stafford Smith,  
3 2016). However, an up-to-date quantification of poverty in drylands, particularly of multi-dimensional  
4 aspects of poverty, and of its sub-national variations, are currently not available. Even in high-income  
5 countries, dryland areas depending on agricultural livelihoods represent relatively poorer locations  
6 nationally, with lack of livelihood opportunities, for example in Italy (Salvati, 2014). Moreover, in many  
7 drylands areas, female-headed households, women and subsistence farmers (both male and female) are  
8 more vulnerable to the impacts of desertification and climate change (Nyantakyi-Frimpong and Bezner-  
9 Kerr, 2015; Sultana, 2014; Rahman, 2013). Local cultural traditions and patriarchal relationships were  
10 found to contribute to higher vulnerability of women and female-headed households through restrictions  
11 on their access to productive resources (Nyantakyi-Frimpong and Bezner-Kerr, 2015; Sultana, 2014;  
12 Rahman, 2013) (Sections 3.5.2 and 3.7.3).

13 Despite these environmental, socio-economic and institutional constraints, dryland populations have  
14 historically demonstrated remarkable resilience (Glossary), ingenuity and innovations, distilled into  
15 indigenous and local knowledge (Glossary) to cope with high climatic variability and sustain livelihoods  
16 (Safriel and Adeel, 2008; Davies, 2017; Sections 3.7.1 and 3.7.2). Indigenous and local knowledge has been  
17 used for centuries to manage dynamic interactions between local communities and ecosystems in dryland  
18 areas. For example, in the Middle East and North Africa (MENA), informal bylaws were enforced by the  
19 Bedouin communities for regulating grazing, collection and cutting of herbs and wood, limiting rangeland  
20 degradation (Hussein, 2011). Pastoralists in Mongolia developed indigenous classifications of pasture  
21 resources which facilitated ecologically optimal grazing practices (Fernandez-Gimenez, 2000) (Section  
22 3.7.2). However, climate change is increasing the exposure of dryland populations to extreme weather  
23 events, such as droughts, floods and dust storms, testing their adaptive capacities, potentially beyond  
24 historical precedents (Orlowsky and Seneviratne, 2012; Huang et al., 2016). Out of 424.7 million people  
25 exposed to droughts in Sub-Saharan Africa in 2010, Cervigni et al. (2016) estimated that about 23% were  
26 not able to cope with them, implying that following a drought shock these households' incomes will fall  
27 below the poverty line. Policy actions promoting the adoption of sustainable land management (SLM)  
28 (Glossary; Chapter 4) practices in dryland areas, based on both indigenous and local knowledge and modern  
29 science, and expanding alternative livelihood opportunities outside agriculture can contribute to climate  
30 change adaptation and mitigation, addressing desertification, with co-benefits for attaining other  
31 Sustainable Development Goals (Safriel and Adeel, 2008; Schwilch et al., 2014; Cowie et al., 2018; Nkonya  
32 et al., 2016a; Stafford Smith et al., 2017; IPBES, 2018; Liniger et al., 2017).

33

### 34 **3.2.4. Processes and Drivers of Desertification under Climate Change**

#### 35 ***3.2.4.1 Processes of Desertification and Their Climatic Drivers***

36 **Processes of desertification** are mechanisms by which drylands are degraded. Desertification consists of  
37 both abiotic and biotic processes. These processes are classified under broad categories of degradation of  
38 physical, chemical and biological properties of terrestrial ecosystems. The number of desertification  
39 processes is large and they are extensively covered elsewhere (Racine, 2008; Lal, 2016; IPBES, 2018;  
40 UNCCD, 2017). Those which are particularly relevant for this assessment in terms of their links to climate  
41 change are: for physical processes - soil erosion by water and wind, and soil structure degradation; for  
42 chemical processes - secondary salinisation and nutrient depletion; for biological processes - changes in  
43 vegetation cover and composition, including through over/under grazing, deforestation and biodiversity  
44 loss (Chapter 4; Glossary).

1 **Drivers of desertification** are factors which trigger desertification processes. Initial studies of  
2 desertification during the early-to-mid 20th century attributed it entirely to human activities. In one of the  
3 influential publications of that time, Lavauden (1927) stated that: "Desertification is purely artificial. It is  
4 only the act of the man..." However, such a uni-causal view of desertification was shown to be invalid  
5 (Geist and Lambin, 2004; Reynolds et al., 2007) (Sections 3.2.4.2, 3.2.4.3). By definition, processes and  
6 drivers of desertification are similar to the processes and drivers of land degradation. For this reason, they  
7 are summarised in Cross-Chapter Table 4.1 in Chapter 4.

8 Erosion refers to removal of soil by the physical forces of water, wind, or through farming activities such  
9 as tillage (Pierson and Williams, 2016). There is a significant potential for climate change to increase global  
10 soil erosion by water, as precipitation volumes and intensity are projected to increase (Panthou et al., 2014;  
11 Nearing et al., 2015). On the other hand, there is *low evidence* concerning climate change impacts on wind  
12 erosion (Cross-Chapter Table 4.1 in Chapter 4; Section 3.8.1).

13 Saline and sodic soils occur naturally in arid, semiarid and dry sub-humid regions of the world. Climate  
14 change or hydrological change can cause soil salinisation due to the increase of the mineralised ground  
15 water level. However, secondary salinisation occurs when concentration of dissolved salts in water and soil  
16 is increased by anthropogenic processes, mainly through poorly managed irrigation schemes. The threat of  
17 soil and groundwater salinisation induced by sea level rise and sea water intrusion are amplified by climate  
18 change (Section 4.11.6 in Chapter 4).

19 A major consequence of desertification is the reduction in soil carbon (C) and transfer of C from soil to the  
20 atmosphere (Lal, 2009). Global warming is expected to accelerate soil organic carbon turnover, in some  
21 areas leading to soil organic carbon decline (Section 3.4.3; Section 3.6.2).

22 North Atlantic sea surface temperature (SST) anomalies are positively correlated with Sahel rainfall  
23 anomalies (Knight et al., 2006; Martin et al., 2014; Sheen et al., 2017). While the eastern tropical Pacific  
24 SST anomalies have a negative correlation with Sahel rainfall (Pomposi et al., 2016), a cooler north Atlantic  
25 is related to a drier Sahel, with this relationship enhanced if there is a simultaneous relative warming of the  
26 south Atlantic (Hoerling et al., 2006). Huber and Fensholt (2011) explored the relationship between SST  
27 anomalies and satellite observed Sahel vegetation dynamics finding similar relationships but with  
28 substantial west-east variations in both the significant SST regions and the vegetation response. Concerning  
29 the paleoclimatic evidence on aridification after the early Holocene "Green Sahara" period (11,000 to 5000  
30 years before present), Tierney et al. (2017) indicate that a cooling of the north Atlantic played a role (Collins  
31 et al., 2017; Otto-Bliesner et al., 2014; Niedermeyer et al., 2009) similar to that found in modern  
32 observations. Besides these SST relationships, aerosols have also been suggested as a potential driver of  
33 the Sahel droughts (Rotstayn and Lohmann, 2002; Booth et al., 2012; Ackerley et al., 2011).

34 Invasive plants contributed to desertification and loss of ecosystem services in many dryland areas in the  
35 last century (Section 3.8.3). Extensive woody plant encroachment altered runoff and soil erosion across  
36 much of the drylands and significantly contributed to desertification. Rising CO<sub>2</sub> levels due to global  
37 warming favour more rapid expansion of some invasive plant species in some regions. An example is the  
38 Great Basin region in western North America where over 20% of Great Basin ecosystems have been  
39 significantly altered by invasive plants, especially exotic annual grasses and invasive conifers resulting in  
40 loss of biodiversity. This land cover conversion has resulted in desertification and reductions in forage  
41 availability, wildlife habitat, and biodiversity (Pierson et al., 2011, 2013; Miller et al., 2013).

42 Predicted increases in temperature and the severity of drought events across dryland areas of the world are  
43 *likely* to increase chances of wildfire occurrence (Jolly et al. 2015; Williams and Funk 2010; Clarke and  
44 Evans 2018). This includes the semiarid and dry sub-humid areas of the world, where fire can have a

1 profound influence on observed vegetation and particularly the relative abundance of grasses to woody  
2 plants (Bond et al., 2003; Bond and Keeley, 2005).

3

#### 4 **3.2.4.2. Anthropogenic Drivers of Desertification under Climate Change**

5 There are numerous drivers of desertification related to human activities. The literature on these human  
6 drivers of desertification is substantial (D’Odorico et al., 2013; Sietz et al., 2011b; Yan and Cai, 2015; Sterk  
7 et al., 2016; Varghese and Singh, 2016; to list a few) and there have been several comprehensive reviews  
8 and assessments of these drivers very recently (IPBES, 2018; UNCCD, 2017; Nkonya et al., 2016b,d;  
9 Cherlet et al., 2018). IPBES (2018) identified cropland expansion, unsustainable land management  
10 practices, urban expansion, infrastructure development, and extractive industries as the main drivers of land  
11 degradation. IPBES (2018) also found that the ultimate driver of land degradation is high and growing  
12 consumption, escalated by population growth. What is particularly relevant in the context of the present  
13 assessment is to evaluate if, how and which human drivers of desertification will be modified by climate  
14 change effects.

15

16 Some of the major forms of desertification are related to land use conversions, including transformation of  
17 rangelands and woodlands into croplands in order to meet growing food demands (Bestelmeyer et al., 2015;  
18 D’Odorico et al., 2013). Climate change is projected to have negative impacts on crop yields across dryland  
19 areas (Section 3.5.1; Chapter 5), potentially reducing local production of food and feed. Without research  
20 breakthroughs to mitigate these productivity losses through higher agricultural productivity, and reducing  
21 food waste and loss, meeting increasing food demands of growing populations will require expansion of  
22 cropped areas to more marginal and easily degradable areas (with most prime areas in drylands already  
23 being under cultivation), thus intensifying degradation processes (Lambin, 2012; Lambin et al., 2013;  
24 Eitelberg et al., 2015). Although local food demands could also be met by importing from other areas, this  
25 would mean increasing the pressure on land in other areas (Lambin and Meyfroidt, 2011). The net effects  
26 of such global agricultural production shifts on desertification are not known.

27 Climate change will exacerbate poverty among some categories of dryland populations (Section 3.5.2).  
28 Depending on the context, this impact comes through changes in agricultural productivity, agricultural  
29 prices and extreme weather events (Hertel and Lobell, 2014; Hallegatte and Rozenberg, 2017). There is  
30 *robust evidence and high agreement* that poverty limits both capacities to adapt to climate change and  
31 availability of financial resources to invest into sustainable land management (SLM) (Sections 3.6.2, 3.7.2,  
32 3.7.3; Gerber et al., 2014; Way, 2016; Vu et al., 2014).

33 Another key human driver which will interact with climate change is labour mobility. Although strong  
34 impacts of climate change on migration are contested, in some places, it is *likely* to provide an added  
35 incentive to migrate (Section 3.5.2.7). Out-migration will have several contradictory effects on  
36 desertification. On one hand, it reduces an immediate pressure on land if it leads to less dependence on land  
37 for livelihoods (Chen et al., 2014; Liu et al., 2016a). Moreover, migrant remittances could be re-invested  
38 into sustainable land management. Out-migration could allow land consolidation, gradually leading to  
39 mechanisation and agricultural intensification (Wang et al., 2014, 2018). On the other hand, it increases the  
40 costs of labour-intensive SLM practices due to lower availability of rural agricultural labour and/or higher  
41 rural wages. Out-migration increases the pressure on land if higher wages that rural migrants earn in urban  
42 centres will lead to their higher food consumption. Moreover, migrant remittances could also be used for  
43 land use expansion to marginal areas (Taylor et al., 2016; Gray and Bilsborrow, 2014). The net effect of

1 these countervailing mechanisms is context-dependent (Qin and Liao, 2016). There is very little literature  
2 evaluating these joint effects of climate change, desertification and migration (Chapter 7).

3 Besides these factors, there are many other institutional, policy and socio-economic drivers of  
4 desertification, such as land tenure insecurity, lack of property rights, lack of access to markets, and to rural  
5 advisory services, lack of technical knowledge and skills, agricultural price distortions, agricultural support  
6 and subsidies contributing to desertification, and lack of economic incentive (D’Odorico et al., 2013; Geist  
7 and Lambin 2004; Moussa et al., 2016; Mythili and Goedecke 2016; Sow et al., 2016; Tun et al., 2015;  
8 García-Ruiz, 2010). There is no evidence that these factors will be materially affected by climate change,  
9 however, serving as drivers of unsustainable land management practices, they do play a role in modulating  
10 responses for climate change adaptation and mitigation. Section 3.7.3 on policy responses discusses these  
11 factors from such a perspective.

### 13 ***3.2.4.3 Interaction of Drivers: Desertification Syndrome versus Drylands Development Paradigm***

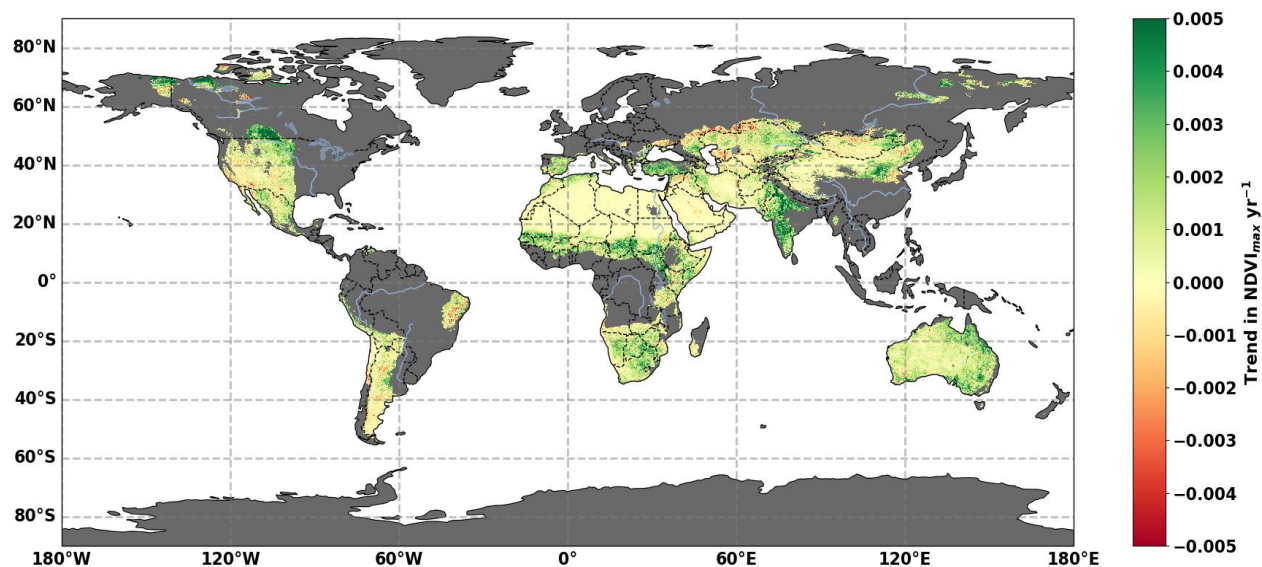

14 Two broad narratives have historically emerged to describe responses of dryland populations to  
15 environmental degradation. The first is “desertification paradigm” which describes the vicious cycle of  
16 resource degradation and poverty, whereby dryland populations apply unsustainable agricultural practices  
17 leading to desertification, and exacerbating their poverty, which then subsequently further limits their  
18 capacities to invest into sustainable land management (Safriel and Adeel, 2008; MEA, 2005b). The  
19 alternative paradigm is one of “drylands development”, which refers to social and technical ingenuity of  
20 dryland populations as a driver of dryland sustainability (Reynolds et al., 2007; Safriel and Adeel, 2008;  
21 MEA, 2005b). Reynolds et al. (2007) indicate that in drylands, which are a non-equilibrium system, there  
22 is a high temporal climatic variability. The major difference between these two frameworks is that the  
23 “drylands development paradigm” recognises that human activities are not the sole and/or most important  
24 drivers of desertification, but there are simultaneous interactions of human and climatic drivers within  
25 coupled social-ecological systems. This non-equilibrium nature of drylands led Behnke and Mortimore  
26 (2016), and earlier Swift (1996), to conclude that the concept of desertification as irreversible degradation  
27 distorts policy and governance in the dryland areas. Mortimore (2016) suggested that instead of externally  
28 imposed technical solutions, what is needed is for local populations to adapt to this variable environment  
29 which they cannot control.

31 As demonstrated by the plethora of attribution studies discussed in Section 3.3.2, the quantified evidence  
32 on which factors, human or climatic, are more important in influencing the state of drylands is mixed. This  
33 is because anthropogenic and climatic drivers interact in complex ways in causing desertification  
34 (D’Odorico et al., 2013; Polley et al., 2013; Ravi et al., 2010). However, these biophysical and socio-  
35 economic drivers of desertification usually interact in typical patterns (Geist and Lambin, 2004; Scholes,  
36 2009; D’Odorico et al., 2013; Polley et al., 2013; Ravi et al., 2010). The main assumption behind these  
37 typical patterns is that there is a limited set of biophysical and socio-economic factors, whose distinct  
38 patterns of interactions explain desertification. More recent efforts were focused on more spatially explicit  
39 clustering of different patterns of vulnerability in drylands (Sietz et al., 2011b; Kok et al., 2016; Sietz et al.,  
40 2017). Despite this progress in identifying dryland vulnerability typologies, the resulting considerable  
41 numbers of clusters and archetypes are not always mutually consistent, their translation into more context-  
42 specific national or sub-national policies and programs is not yet evident.

### 1 3.3. Observations of Desertification and Attribution

#### 2 3.3.1. Status and Trends of Desertification

3 Current estimates of the extent and severity of desertification vary greatly due to missing and/or unreliable  
 4 information (Gibbs and Salmon, 2015). The multiplicity and complexity of the processes of desertification  
 5 make its quantification difficult (Prince 2016; Cherlet et al., 2018). The most common definition for the  
 6 drylands is based on defined thresholds of the Aridity Index (AI) (UNEP, 1992), which is the ratio of  
 7 precipitation to potential evapotranspiration (Glossary). The AI thresholds for dryland climate classes as  
 8 defined in Middleton and Thomas (1997) are: hyper-arid  $AI \leq 0.05$ ; arid  $0.05 < AI \leq 0.2$ ; semi-arid  $0.2 <$   
 9  $AI \leq 0.5$ ; dry sub-humid  $0.5 < AI \leq 0.65$ . The AI decreased in many parts of the world over the last several  
 10 decades and based on these constant AI thresholds this has been interpreted as expanding the extent of  
 11 drylands in some regions (*robust evidence, high agreement*) (Feng and Fu, 2013; Asadi Zarch et al., 2015;  
 12 Ji et al., 2015; Spinoni et al., 2015; Huang et al., 2016). The expansion of the drylands does not imply  
 13 desertification by itself, if there is no long-term loss of the biological productivity of drylands, their  
 14 ecological complexity, and/or their human values.

15  
 16 **Figure 3.5 Trend in the Annual Maximum NDVI 1982-2015 (GIMMS NDVI3g v1) calculated using the Theil-**  
 17 **Sen estimator which is a median based estimator, and is robust to outliers. Non-dryland regions (Aridity**  
 18 **Index > 0.65) are masked in grey**

19 The use of the AI to define changing aridity levels and dryland extent in an environment with changing  
 20 atmospheric CO<sub>2</sub> has been strongly challenged (Roderick et al., 2015; Milly and Dunne, 2016). The  
 21 suggestion that most of the world has become more arid, since the AI has decreased, is not supported by  
 22 changes observed in precipitation, evaporation or drought (Sheffield et al., 2012; Greve et al., 2014). A key  
 23 issue is the assumption in the calculation of potential evapotranspiration that stomatal conductance remains  
 24 constant which is invalid if atmospheric CO<sub>2</sub> changes. Given that atmospheric CO<sub>2</sub> has been increasing  
 25 over the last century or more, and is projected to continue increasing, this means that AI with constant  
 26 thresholds (or any other measure that relies on potential evapotranspiration) is not an appropriate way to  
 27 estimate aridity or dryland extent (Donohue et al., 2013; Roderick et al., 2015; Greve et al., 2017). This  
 28 issue at least partially explains the apparent contradiction between the drylands becoming more arid  
 29 according to the AI and also becoming greener according to satellite observations (Fensholt et al., 2012;

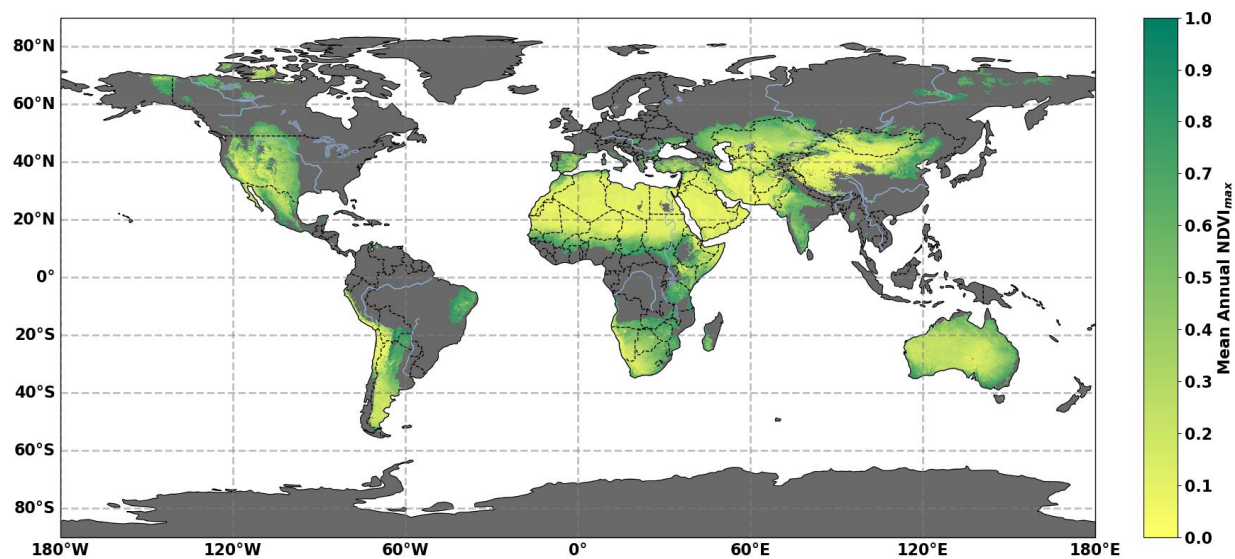

1 Andela et al., 2013; Figure 3.5). Other climate type classifications based on various combinations of  
2 temperature and precipitation (Köppen-Trewartha, Köppen-Geiger) have also been used to examine  
3 historical changes in climate zones and, while not agreeing entirely with the aridity index, they also found  
4 a tendency toward drier climate types (Feng et al., 2014; Spinoni et al., 2015).

5 Depending on the definitions applied and methodologies used in evaluation, the status and extent of  
6 desertification globally and regionally still show substantial variations (D'Odorico et al., 2013). The four  
7 methodological approaches applied for assessing the extent of desertification: expert judgement, satellite  
8 observation of net primary productivity and use of biophysical models together provide a relatively holistic  
9 assessment but none on its own captures the whole picture (Gibbs and Salmon, 2015; Vogt et al., 2011; see  
10 also Chapter 4).

### 11 12 *3.3.1.1. Global Scale*

13 Complex human-environment interactions coupled with biophysical, social, economic and political  
14 environments unique to any given location on drylands render desertification difficult to be mapped at a  
15 global scale (Cherlet et al., 2018). Early attempts to assess desertification focused on expert knowledge to  
16 achieve global coverage rapidly and cost-effectively. **Expert judgement** continues to play an important  
17 role because degradation remains a subjective quality whose benchmarks vary among locations (Sonneveld  
18 and Dent, 2007). On its initial quantification attempts, GLASOD (Global Assessment of Human-Induced  
19 Soil Degradation) estimated nearly 2 billion hectares (22.5% of the global land) had been degraded by early  
20 1990s since mid-20<sup>th</sup> century. GLASOD was criticised for perceived subjectiveness and exaggeration  
21 (Helldén and Tottrup, 2008). Dregne and Chou (1992) found 3 billion ha in drylands were undergoing  
22 degradation. Significant improvements have been made through the efforts of WOCAT (World Overview  
23 of Conservation Approaches and Technologies), LADA (Land Degradation Assessment in Drylands) and  
24 DESIRE (Desertification Mitigation and Remediation of Land) who jointly developed a mapping tool for  
25 participatory expert assessment, using which land experts can estimate current area coverage, type and  
26 trends of land degradation (Reed et al., 2011).

27 A number of studies have used **satellite-based remote sensing** to investigate long-term changes in the  
28 vegetation and thus identify parts of the drylands undergoing desertification. Satellite data provides  
29 information at the resolution of the sensor which can be relatively coarse (up to 25 km) and interpretations  
30 of the data at sub-pixel levels are challenging. The most widely used remotely sensed vegetation index is  
31 the Normalized Difference Vegetation Index (NDVI) providing a measure of canopy greenness, which is  
32 related to the quantity of standing biomass at a given point (Bai et al., 2008; de Jong et al., 2011; Fensholt  
33 et al., 2012; Andela et al., 2013; Fensholt et al., 2015; Le et al., 2016b, Figure 3.6). A main challenge  
34 associated with NDVI is that although biomass and productivity are closely related in some systems, they  
35 can differ widely when looking across land uses and ecosystem types, giving a false positive in some  
36 instances (Aynekulu et al., 2017). For example, bush encroachment in rangelands and intensive  
37 monocropping with high fertiliser application gives an indication of increased productivity in satellite data  
38 though it is land degradation. All studies show a mixture of positive and negative NDVI trends, with  
39 positive trends dominating globally. According to this measure there are regions undergoing desertification,  
40 however, the drylands are greening on average (Figure 3.5).

1  
2 **Figure 3.6 Mean Annual Maximum NDVI 1982-2015 (GIMMS NDVI3g v1). Non-dryland regions (Aridity**  
3 **Index > 0.65) are masked in grey**

4 A simple linear trend in NDVI is an unsuitable measure for dryland degradation for several reasons  
5 (Wessels et al., 2012; de Jong et al., 2013; Higginbottom and Symeonakis, 2014; Le et al., 2016b). The  
6 NDVI is strongly coupled to precipitation in the drylands and precipitation has high inter-annual variability.  
7 This means that the NDVI trend can be dominated by any precipitation trend and is sensitive to wet or dry  
8 periods, particularly if they fall near the beginning or end of the time series. Degradation may only occur  
9 during part of the time series, while NDVI is stable or even improving during the rest of the time series.  
10 This reduces the strength and representativeness of a linear trend. Other factors such as CO<sub>2</sub> fertilisation  
11 also influence the NDVI trend. Various techniques have been proposed to address these issues, including  
12 the residual trends (RESTREND) method to account for rainfall variability (Evans and Geerken, 2004),  
13 time-series break point identification methods to find major shifts in the vegetation trends (Verbesselt et  
14 al., 2010; de Jong et al., 2013), and methods to explicitly account for the effect of CO<sub>2</sub> fertilisation (Le et  
15 al., 2016b).

16 Using the RESTREND method, Andela et al. (2013) found that human activity contributed to a mixture of  
17 improving and degrading regions in the drylands. In some locations these regions differed substantially  
18 from those identified using the NDVI trend alone, including an increase in the area being desertified in  
19 southern Africa and northern Australia, and a decrease in southeast and west Australia and Mongolia. De  
20 Jong et al. (2013) examined the NDVI time series for major shifts in vegetation activity and found that 74%  
21 of drylands experienced such a shift between 1981 and 2011. This suggests that monotonic linear trends  
22 are unlikely to accurately capture the changes that have occurred in the majority of the drylands. Le et al.  
23 (2016b) explicitly accounted for CO<sub>2</sub> fertilisation effect and found that the extent of degraded areas in the  
24 world is 3% larger when compared to the linear NDVI trend. After also accounting for factors such as  
25 fertiliser use, Le et al. (2016) reported that about 29% of the global land area contained biomass-based land  
26 degradation hotspots.

27 Besides NDVI, there are many vegetation indices derived from satellite data in the optical and infrared  
28 wavelengths. Each of these datasets has been derived to overcome some limitation in existing indices. For  
29 example, the Enhanced Vegetation Index (EVI) was designed to provide more information when dense  
30 vegetation is present and the NDVI signal can saturate. Studies have compared these indices globally

1 (Zhang et al., 2017) and specifically over drylands (Wu, 2014). In general, the data from these vegetation  
2 indices are available only since around 2000, while NDVI data is available since 1982. With less than 20  
3 years of data, the trend analysis remains problematic with vegetation indices other than NDVI. However,  
4 given the various advantages in terms of resolution and other characteristics, these newer vegetation indices  
5 will become more useful in the future as more data accumulates.

6 Another vegetation index, Vegetation Optical Depth (VOD), has also been available since the 1980s. VOD  
7 is based on microwave measurements and is linearly related to total above ground biomass water content.  
8 Unlike NDVI which is only sensitive to green canopy cover, VOD is also sensitive to water in woody parts  
9 of the vegetation and hence provides a view of vegetation dynamics that can be complementary to NDVI.  
10 Liu et al. (2013) used VOD trends to investigate biomass changes and found that VOD was closely related  
11 to precipitation changes in drylands. To complement their work with NDVI, Andela et al. (2013) also  
12 applied the RESTREND method to VOD. By interpreting NDVI and VOD trends together they were able  
13 to differentiate changes to the herbaceous and woody components of the biomass. They reported that many  
14 dryland regions are experiencing an increase in the woody fraction often associated with shrub  
15 encroachment and suggest that this was aided by CO<sub>2</sub> fertilisation.

16 A major shortcoming of these studies based on vegetation datasets derived from satellite images is that they  
17 do not account for changes in vegetation composition, thus leading to inaccuracies in the estimation of the  
18 extent of degraded areas in drylands. For example, drylands of Eastern Africa currently face growing  
19 encroachment of invasive plant species, such as *Prosopis juliflora* (Ayanu et al., 2015), which effectively  
20 constitutes land degradation since it leads to losses in economic productivity of affected areas but appears  
21 as a greening in the satellite data. Another case study in central Senegal found degradation manifested  
22 through a reduction in species richness despite satellite observed greening (Herrmann and Tappan, 2013).  
23 A number of efforts to identify changes in vegetation composition from satellite have been made (Geerken  
24 et al., 2005; Evans and Geerken, 2006; Geerken, 2009; Verbesselt et al., 2010; Verbesselt, et al., 2010;  
25 Brandt et al., 2016a,b). These depend on well identified reference NDVI time series for particular vegetation  
26 groupings, and can only differentiate vegetation types that have distinct spectral evolution signatures and  
27 generally require extensive ground observations for validation. A recent alternative satellite based approach  
28 to differentiating woody from herbaceous vegetation involves the combined use of optical/infrared based  
29 vegetation indices, indicating greenness, with microwave based Vegetation Optical Depth (VOD) which is  
30 sensitive to both woody and leafy vegetation components (Andela et al., 2013; Tian et al., 2017).

31 **Biophysical models** use global data sets that describe climate patterns and soil groups, combined with  
32 observations of land use, to define classes of potential productivity and map general land degradation  
33 (Gibbs and Salmon, 2015). Terms used to describe marginal agricultural land are abandoned farmland,  
34 degraded land, wasteland and idle land. For example, Cai et al. (2011) mapped marginal agricultural land  
35 that can be utilised for biofuel production using a biophysical model of agricultural productivity based on  
36 spatial descriptions of soil groups, soil productivity, topography, average air temperature and precipitation,  
37 combined with expert opinions and global land cover datasets. According to Cai et al. (2011) marginal areas  
38 with low-productivity cropping were designated as abandoned, idle, or wasted, while marginal areas with  
39 fully utilised for agriculture designated as degraded. Uncertainties associated with this method arise from  
40 data limitations and spatial heterogeneities of socioeconomic conditions and agricultural technologies used.

41 Land productivity is a proxy for above ground Net Primary Productivity. The Land Productivity Dynamics  
42 (LPD) dataset shows land's capacity to sustain primary productivity. During the period from 1999 to 2013,  
43 primary productivity declines were observed on approximately 37% of the area of Australia, 27% of South  
44 America and 22% of Africa (UNCCD, 2017). According to UNCCD (2017), approximately 9% of global

1 land area with more than 50% of cropland and 5% of global rangeland is exposed to between eight and 143  
2 global change issues (GCIs) that trigger land change processes that are relevant to land degradation.  
3 According to Cherlet et al. (2018), Africa has more GCIs than any other continent with 76% of the total  
4 area having five to seven GCIs. The dominant GCIs are high population density and change, low income  
5 levels, fires, high livestock densities and fertiliser deficiencies. For Asia, 65% of low density cropland has  
6 between four and six GCIs with dominant GCIs being population density and change, high livestock  
7 densities, low income and water stress. Agricultural plains of Bangladesh and Myanmar, for example, are  
8 experiencing population pressure resulting in increased irrigation schemes and high livestock densities  
9 (Cherlet et al., 2018).

10 Overall, more efforts are required for improved estimations and mapping of desertified areas, using a  
11 combination of rapidly expanding sources of remotely sensed data and ground observations. This is a  
12 critical gap, especially in the context of measuring progress towards achieving the land degradation-  
13 neutrality target by 2030 in the framework of Sustainable Development Goals (SDGs).

14

### 15 **3.3.1.2. Regional Scales**

16 While global scale studies provide information for any region of interest, there are many studies that focused  
17 on sub-continental scales often using *in-situ* observations and providing more in-depth analysis and  
18 understanding. Regional studies are important and critical because effects of climate change and variability  
19 show varied characteristics in different climate regions and time scales. Here we discuss studies relevant  
20 for each UNCCD annex region.

21

#### 22 **3.3.1.2.1 Africa**

23 It is estimated that desertification is affecting 46 of 57 nations in Africa (Právělie, 2016). Horn of Africa  
24 and parts of northern Africa experienced drying over the last three decades, whereas wetter conditions were  
25 experienced in central Africa and the Sahel (Damberg and AghaKouchak, 2014). Desertification in the  
26 Sahel has been a significant area of research since the 1970s, which in concert with a large scale drought at  
27 that time, culminated in the UN Convention to Combat Desertification in 1994. Significant changes have  
28 occurred in the landscapes of the Sahel region of West Africa with cropland areas doubling since 1975, and  
29 the settlement area increasing by about 150% (Traore et al., 2014). From satellite and rainfall data, a  
30 greening trend in the Sahelian belt has been observed since the 1980s (Huber et al., 2011; Brandt et al.,  
31 2015; Rishmawi et al., 2016; Tian et al., 2016; Leroux et al., 2017; Herrmann and Hutchinson, 2005).  
32 Greening in southern Africa has been observed too but it is relatively weak compared to other regions in  
33 the continent (Helldén and Tottrup, 2008; Fensholt et al., 2012). However, greening can also be  
34 accompanied by desertification due to factors such as decreasing species richness, changes in species  
35 composition and shrub encroachment (Mbow et al., 2013; Herrmann and Tappan, 2013; Kaptué et al., 2015;  
36 Herrmann and Sop, 2016). For example, some of the observed greening in Southern Africa has been  
37 associated with shrub encroachment (Saha et al., 2015). Soil loss through run-off is 16 times higher in bare  
38 degraded soils of the Sahel than in the sub-humid zones where soils are more structured. Moderate or higher  
39 severity degradation over recent decades has been identified in many river basins including the Nile (42%),  
40 the Niger (50%), the Senegal (51%), the Volta (67%), the Limpopo (66%) and the Lake Chad (26%)  
41 (Thiombiano and Tourino-Soto, 2007). Although many studies demonstrate that there was neither a  
42 progressive southwards extension nor large-scale expansion of less productive lands (e.g., Anyamba and  
43 Tucker (2005), Thomas and Nigam (2018) found out that the Sahara had expanded by 10% over the 20<sup>th</sup>  
44 century by taking a long-term perspective (Section 3.3.2).

1 In arid Algerian High Plateaus, desertification due to both climatic and human causes led to the loss of  
2 indigenous plant biodiversity and overall loss of vegetation between 1975 and 2006 (Hirche et al., 2011).  
3 The greening process for the Sahel region (Helldén and Tottrup, 2008) was not observed in the North  
4 African steppes. Ayoub (1998) identified 64 million hectares in Sudan as degraded, with the Central North  
5 Kordofan state being most affected. However, the reforestation measures in the last decade sustained by  
6 improved rainfall conditions have led to low-medium regrowth conditions in about 20% of the area  
7 (Dawelbait and Morari, 2012).

8 Based on NDVI residuals computed by Gichenje and Godinho (2018), using annual mean data of the NDVI  
9 and soil moisture relationship, Kenya experienced persistent negative trends (browning) over 21.6% of the  
10 country, and persistent positive trends (greening) in 8.9% of the country for the period 1992–2015.  
11 Grasslands increased by 12,171 km<sup>2</sup>, bare land decreased by 9,877 km<sup>2</sup> and forestland decreased by 7,182  
12 km<sup>2</sup> during the same period. Habitat fragmentation, decline in pastoral grazing range, loss of wildlife  
13 dispersal areas and increase in livestock population density are considered to be the main drivers for  
14 vegetation structure loss in the northern rangelands of Kenya (Otuoma et al., 2009). For instance, in Meru  
15 conservancy, open wooded grasslands have decreased by 42% and bushland vegetation increased by 42%  
16 since 1980.

17 In Burkina Faso, Dimobe et al. (2015) estimated that from 1984 to 2001, tree savannahs, bare soils and  
18 agricultural lands increased by 17.55%, 18.79% and 21.79%, respectively, while woodland, gallery forest,  
19 shrub savannahs and water bodies decreased by 22.02%, 5.03%, 40.08% and 31.2%, respectively. From  
20 2001 to 2013, gallery forests decreased by 14.33%, tree savannahs by 22.30% and shrub savannahs by  
21 5.14%, while agricultural lands increased by 167.87% and woodlands by 3.21%. Desertification occurred  
22 at a higher rate in areas bordering Bontioli wildlife reserve compared to the protected and inaccessible  
23 areas.

24 In evaluating hydrological responses of land degradation on the Owena River basin in Nigeria, Aladejana  
25 et al. (2018) showed that between 1986 and 2015, 18.56% of the forest cover around the basin was lost of  
26 which 16.19% was converted to agricultural land. For the period 1982–2003, Le et al. (2012) found that  
27 8% of the Volta River basin's landmass had been degraded with 65% of the land losing its soil quality and  
28 vegetation productivity.

29 In the Okavango river Basin in Southern Africa, conversion of land towards higher utilisation intensities,  
30 unsustainable agricultural practises and overexploitation of the savannah ecosystems have been observed  
31 in recent decades (Weinzierl et al. 2016).

32

### 33 *3.3.1.2.2 Middle East and Europe*

34 Drylands cover 33.8% of the lands of the Northern Mediterranean countries; approximately 69% of Spain,  
35 66% of Cyprus, and between 16% and 62% in Greece, Portugal, Italy and France (Zdruli, 2011). The  
36 estimates from Rubio and Recatalá (2006) show that there are 30 million hectares of semi-arid drylands in  
37 the whole Mediterranean region. Desertification in the region is driven by irrigation developments and  
38 encroachment of cultivation on rangelands (Safriel, 2009) caused by population growth, agricultural  
39 policies and markets. Damberg and AghaKouchak (2014) found that parts of the Mediterranean region  
40 experienced drying over the last three decades, whereas wetter conditions were experienced in parts of  
41 eastern Europe. Helldén and Tottrup (2008) observed a greening trend in the Mediterranean between 1982–  
42 2003, while Fensholt et al. (2012) also show a dominance of greening in Eastern Europe.

43

1 Developed in the framework of the MEDALUS and DESERTLINKS projects, the Environmental  
2 Sensitivity Areas (ESA) approach has been used to estimate land vulnerability to desertification in the  
3 Mediterranean Europe (e.g., Contador et al., 2009; Salvati and Bajocco, 2011). The process assesses  
4 climate, soil, vegetation and land management to arrive at the Environmental Sensitivity index (ESI)  
5 (Ferrara et al., 2012). Other indices have also been developed in the European context (Santini et al., 2010;  
6 Kairis et al., 2014; Prāvālie et al., 2017). These indices provide guidance on locations where attention to  
7 sustainable land use practices is required to avoid possible future desertification. The European  
8 Environment Agency (EEA) indicated that 14 Mha, 8% of the territory of the European Union (in Bulgaria,  
9 Cyprus, Greece, Italy, Romania, Spain and Portugal), had a “very high” and “high sensitivity” to  
10 desertification (European Court of Auditors, 2018). This figure increases to 40 Mha (23% of the EU  
11 territory) if “moderately” sensitive areas included (Prāvālie et al. 2017; European Court of Auditors 2018).

12  
13 Turkey is considered highly vulnerable to drought, land degradation and desertification (Türkeş, 1999;  
14 Türkeş, 2003). About 60% of Turkey’s land area (i.e., of 5.77% semi-arid, 24.75% dry sub-humid and  
15 28.54% moist sub-humid) is characterised with hydro-climatological conditions favourable for  
16 desertification (Türkeş, 2013). Consistent with these findings, ÇEMGM (2017) estimated that about half of  
17 Turkey’s land area (48.6%) is under moderate to high desertification risk.

18 Desertification has increased substantially in Iran since the 1930s. Despite numerous efforts to rehabilitate  
19 degraded areas and combat desertification, it still poses a major threat to agricultural livelihoods in the  
20 country (Amiraslani and Dragovich, 2011). Ahmady-Birgani et al. (2017) showed a progressing sand dune  
21 movement and subsequent desertification in the Rigboland sand sea area in central Iran.

22 In north-west Jordan, three quarters of variation in soil erosion was related to topography, while the  
23 remaining share was due to wind erosion (Al-Bakri et al., 2016).

#### 24 25 *3.3.1.2.3 Asia*

26 Prāvālie (2016) found that desertification is currently affecting 38 of 48 countries in Asia. Damberg and  
27 AghaKouchak (2014) found that northern India experienced drying over the last three decades. Helldén and  
28 Tottrup (2008) highlighted a greening up trend in East Asia between 1982 and 2003. The changes in  
29 drylands in Asia over the period 1982–2011 were mixed, with some areas experiencing vegetation  
30 improvement while others showed reduced vegetation (Miao et al., 2015).

31  
32 Xue et al. (2017) used remote sensing (RS) images from four periods (1975, 1990, 2000, and 2015) to  
33 classify the intensity of wind-driven desertified land in north Shanxi in China, and found that desertification  
34 experienced three major development stages: slower expansion during 1975–1990 at a rate of 96.58 km<sup>2</sup>  
35 yr<sup>-1</sup>, rapid expansion during 1990–2000, and a reversion during 2000–2015 with a net decrease. Throughout  
36 the 18<sup>th</sup> and 19<sup>th</sup> centuries, sandy desertification took place on the Mongolian Plateau, north-eastern China,  
37 and the Yellow River basin (Lamchin et al., 2016) due to shifts in monsoons and wind activity during the  
38 Little Ice Age with a significant increase in aridity observed in the Northern region (Hua et al., 2014).

39  
40 Central Asian countries are facing a massive environmental catastrophe associated with the drying up of  
41 the Aral Sea due to anthropogenic causes (Micklin, 2007). The mean temperatures increased by 0.18°C per  
42 decade between 1901 and 2003 in the region (Chen et al., 2009), a rate twice the average over the northern  
43 hemisphere (Jones and Moberg, 2003). Precipitation was higher between 1930 and 2009 (Chen et al. 2011;  
44 Li et al. 2006). NDVI and gridded high-resolution land data analysis (1984–2013) showed that shrub and

1 sparse vegetation density significantly decreased due to droughts in the Karakum and Kyzylkum Deserts,  
2 the Ustyurt Plateau and the wetland delta of the Aral Sea.

3 Desertification through salinisation is a major concern across the drylands in Asia as it impacts both food  
4 and water security and it's highly likely to be exacerbated by climate change (D'Odorico et al., 2013).  
5 Examples of major river basins undergoing salinisation include: Indo-Gangetic Basin in India (Lal and  
6 Stewart, 2012), Indus Basin in Pakistan (Aslam and Prathapar, 2006), Yellow River Basin in China  
7 (Chengrui and Dregne, 2001), Yinchuan Plain, a major irrigation agriculture district in northwest China  
8 (Zhou et al., 2013), Aral Sea Basin of Central Asia (Cai et al., 2003).

9

#### 10 *3.3.1.2.4 Australia*

11 Damberg and AghaKouchak (2014) found that wetter conditions were experienced in northern Australia  
12 over the last three decades. A widespread greening was identified between 1981 and 2006 over much of  
13 Australia, except for eastern Australia where large areas with decreases were present, based on Advanced  
14 High Resolution Radiometer (AVHRR) satellite data (Donohue et al., 2009). From 2002 to 2009 much of  
15 eastern Australia was affected by drought. For the period 1982–2013, Burrell et al. (2017) also found  
16 widespread greening over Australia and greening in eastern Australia over the post-drought period. This  
17 dramatic change in the trend found for eastern Australia emphasises the dominant role played by  
18 precipitation in the drylands. Burrell et al. (2017) also applied a RESTREND analysis to account for this  
19 precipitation influence finding that for most of the continent precipitation accounted for some of the  
20 vegetation increase, with some scattered regions experiencing degradation due to anthropogenic and other  
21 causes. The RESTREND methodology was extended to account for the non-monotonic nature of the  
22 vegetation change called Time Series Segmentation RESTREND (TSS-RESTREND). It was found that  
23 degradation due to anthropogenic and other causes was larger than otherwise predicted particularly near the  
24 central west coast, and affected just over 5% of Australia. Salinisation has also been found to be degrading  
25 parts of the Murray-Darling Basin in Australia (Rengasamy, 2006). Eldridge and Soliveres (2014) examined  
26 areas undergoing woody encroachment in eastern Australia and found that rather than degrading the  
27 landscape the shrubs often enhanced ecosystem services.

28

#### 29 *3.3.1.2.5 Latin America and the Caribbean*

30 In Latin America and the Caribbean, 25% of the total land area are drylands. Granados-Sánchez et al. (2012)  
31 estimated that 516 million hectares in Latin America are susceptible to desertification, while Morales  
32 and Parada (2005) estimated about 378 Mha undergoing severe degradation. South and Central America  
33 have a total degraded land area of 300 Mha, with a decreasing trend in net primary productivity, and decline  
34 in ecosystem productivity (Zdruli et al., 2010). In Guatemala, the area undergoing desertification is  
35 estimated to be up to 12% of the total land area, especially in regions where deforestation is rampant,  
36 resulting from the expansion of the agricultural frontier based on subsistence agriculture (Morales and  
37 Parada, 2005). In Bolivia, Chile, Ecuador and Peru, between 27% and 43% of the total land area are affected  
38 by desertification. Around 77% of the Bolivia's population is living in degraded areas. Morales et al. (2011)  
39 showed that 75% of land in Argentina, 8% in Brazil (94% as per Vieira et al. (2015), 34% in Peru is  
40 undergoing some form of degradation. Parts of the dry Chaco and Caldenal regions in Argentina have  
41 undergone widespread degradation over the last century (Verón et al., 2017; Fernández et al., 2009).  
42 Bisigato and Laphitz (2009) identified overgrazing as a cause of degradation in the Patagonian Monte  
43 region of Argentina. The Caatinga region of western Brazil is estimated to have experienced widespread  
44 desertification with up to 50% of the area being degraded (Leal et al., 2005).

### 3.3.1.2.6 North America

Damberg and AghaKouchak (2014) found that south-western United States and Texas experienced drying over the last three decades. Using desertification trend risk index (DTRI) based on Landsat images, Becerril-Pina Rocio et al. (2015) showed that semi-arid regions of central and parts of western and southern Querétaro state in Mexico are severely degraded. Desertification in the form of shrub encroachment has been occurring over the last century in the Jornada Basin within the Chihuahuan Desert in New Mexico, USA (Rachal et al., 2012). This encroachment is observed over a fairly wide area of western North American grasslands and seems to spread at a faster rate despite grazing restrictions intended to curb the spread (Yanoff and Muldavin, 2008; Browning and Archer, 2011; Van Auken, 2009). Also, sand dune encroachment has been identified as a cause of desertification in California, USA (Lam et al., 2011). The major river basins of San Joaquin Valley and Colorado River Basin is undergoing salinisation (Qadir et al., 2007).

### 3.3.2. Attribution of Desertification

Desertification is a result of complex interactions within coupled social-ecological systems. Thus, the relative contribution of climatic, anthropogenic and other factors to desertification will vary depending on specific regional contexts. The high natural climate variability in dryland regions is a major cause of vegetation changes but does not necessarily imply degradation. Drought is not degradation as the land productivity may return entirely once the drought ends (Kassas, 1995). However, if droughts increase in frequency, intensity and/or duration they overwhelm the vegetation ability to recover and cause degradation. Assuming a stationary climate and no human influence, rainfall variability results in fluctuations in vegetation dynamics which can be considered temporary as the ecosystem tends to recover with rainfall, and desertification does not occur. Climate change on the other hand, exemplified by a non-stationary climate, can gradually cause a persistent change in the ecosystem through aridification. Assuming no human influence, this 'natural' climatic version of desertification can take place over longer periods of time as the ecosystem slowly adjusts to a new climatic norm through progressive changes in the plant community composition. Accounting for this climatic variability is required before attributions to other causes of desertification can be made.

For attributing vegetation changes to climate versus other causes, the RESTREND (residual trend) method analyses the correlation between annual maximum NDVI (or other vegetation index) and precipitation by testing accumulation and lag periods for the precipitation (Evans and Geerken, 2004). The identified relationship with the highest correlation represents the maximum amount of vegetation variability that can be explained by the precipitation. Using this relationship, the climate component of the NDVI time series can be reconstructed, and the difference between this and the original time series is attributed to anthropogenic and other causes. Evans and Geerken (2004) applied the technique to the Syrian rangelands and found around twice as much area was being degraded by anthropogenic and other factors compared to examining the NDVI trends alone.

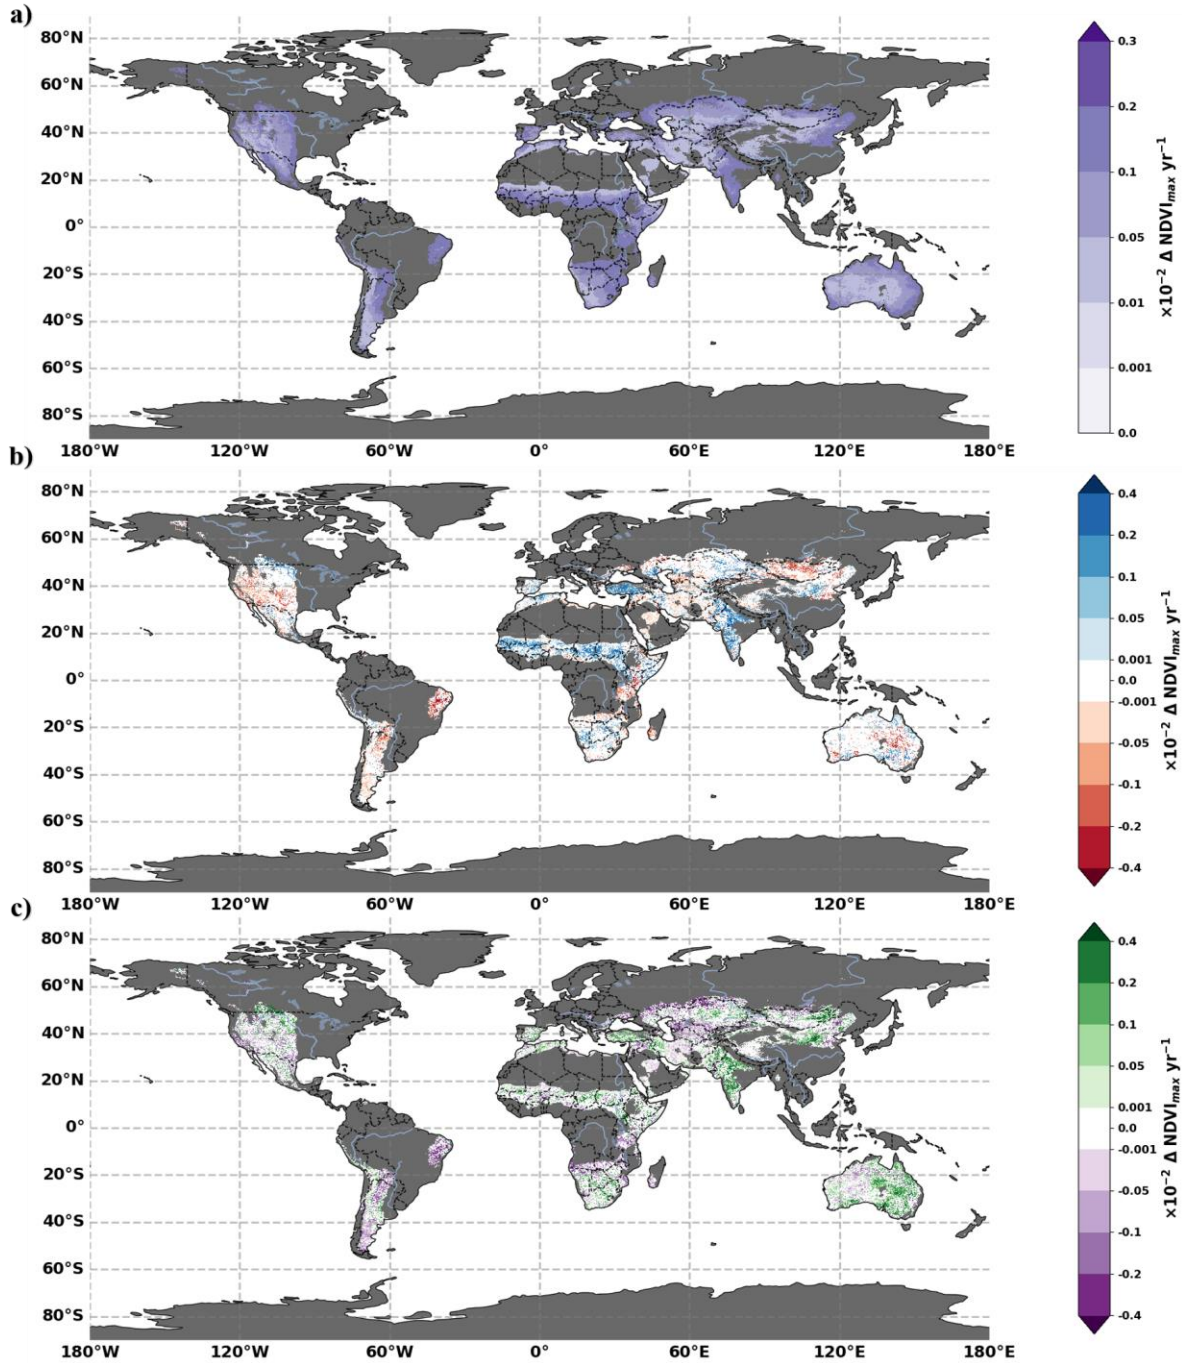

The RESTREND method, or minor variations of it, has been applied extensively. Herrmann and Hutchinson (2005) examined the African Sahel from 1982 to 2003. They found that climate was responsible for widespread greening, and anthropogenic and other factors were mostly producing land improvements or no change. However, pockets of desertification were identified in Nigeria and Sudan. Similar results were also found from 1982 to 2007 by Huber et al. (2011). Wessels et al. (2007) applied RESTREND to South Africa. They show that RESTREND produced a more accurate identification of degraded land than Rain Use Efficiency. In this case RESTREND identified a smaller area undergoing desertification due to

1 anthropogenic and other non-climate causes compared to the NDVI trends. Li et al. (2012) used  
2 RESTREND to identify desertification in Inner Mongolia China. They show significant changes to the  
3 locations and extent of human-caused desertification in response to policy changes. Liu et al. (2013b)  
4 extended the climate component of RESTREND to include temperature and applied this to VOD  
5 observations of the cold drylands of Mongolia. They found the area undergoing desertification due to non-  
6 climatic causes is much smaller than the area with negative VOD trends, and suggested that increases in  
7 goat density and wildfire occurrence are causal factors in those areas. RESTREND has also been applied  
8 in the Sahel (Leroux et al., 2017), Somalia (Omuto et al., 2010), West Africa (Ibrahim et al., 2015), China  
9 (Yin et al., 2014), Central Asia (Jiang et al., 2017) and Australia (Burrell et al., 2017). These studies  
10 represent the best regional, remote sensing based attribution studies to date, noting that RESTREND has  
11 some limitations.

12 One assumption in RESTREND is that any trend is linear throughout the period examined. That is there are  
13 no discontinuities or break points in the trend. To overcome this limitation, Burrell et al. (2017) introduced  
14 the Time Series Segmentation-RESTREND (TSS-RESTREND) which allows a breakpoint within the  
15 period examined. Using TSS-RESTREND over Australia they identified more than double the degrading  
16 area than could be identified with a standard RESTREND analysis. The occurrence and drivers of abrupt  
17 change (turning points) in ecosystem functioning were also examined by Horion et al. (2016) over the semi-  
18 arid Northern Eurasian agricultural frontier. They combined Earth observation trend shifts in rain-use  
19 efficiency (RUE), field data and expert knowledge, to map environmental hotspots of change and attribute  
20 them to climate and human activities. One third of the area showed significant change in RUE mainly  
21 occurring around the fall of the Soviet Union or as the result of major droughts. Recent human-induced  
22 turning points in ecosystems functioning were uncovered nearby Volgograd (Russia) and around Lake  
23 Balkhash (Kazakhstan), respectively, attributed to recultivation, increased salinisation, and increased  
24 grazing.

25 Attribution of vegetation changes to human activity has also been done within modelling frameworks  
26 (Figure 3.7). In these methods ecosystem type models are used to simulate potential natural vegetation  
27 dynamics, and this is compared to the observed state. The difference is attributed to human activities.  
28 Applied to the Sahel region during the period of 1982–2002, it showed that people had a minor influence  
29 on vegetation changes (Seaquist et al., 2009). Similar model/observation comparison performed at global  
30 scales found that CO<sub>2</sub> fertilisation was the strongest forcing at global scales, with climate having regionally  
31 varying effects (Mao et al., 2013; Zhu et al., 2016). Land use/land cover change was a dominant forcing in  
32 localised areas. The use of this method to examine vegetation changes in China (1982–2009) attributed  
33 most of the greening trend to CO<sub>2</sub> fertilisation and nitrogen deposition, explaining 85% and 41% of the  
34 trend, respectively (Piao et al., 2015). In the northern extratropical land surface, the observed greening was  
35 consistent with increases in greenhouse gases (notably CO<sub>2</sub>) and the related climate change, and not  
36 consistent with a natural climate that does not include anthropogenic increase in greenhouse gases (Mao et  
37 al., 2016).

**Figure 3.7 The Drivers of Dryland Vegetation Change.** The mean annual change in NDVI<sub>max</sub> between 1982 and 2015 (See Figure 3.7 for total change using GIMMS NDVI3g v1 dataset) attributable to a) CO<sub>2</sub> fertilisation b) climate and c) land use. The change attributable to CO<sub>2</sub> fertilisation was calculated using the CO<sub>2</sub> fertilisation relationship described in Franks et al. (2013). The Time Series Segmented Residual Trends (TSS-RESTREND) method (Burrell et al., 2017) applied to the CO<sub>2</sub> adjusted NDVI was used to separate Climate and Land Use. A multi climate dataset ensemble was used to reduce the impact of dataset errors (Burrell et al., 2018). Non-dryland regions (Aridity Index > 0.65) are masked in dark grey. Areas where the change did not meet the multi-run ensemble significance criteria, or are smaller than the error in the sensors (±0.00001) are masked in white

1 Probabilistic event attribution (PEA) methodology showed that the dominant influence for droughts in  
2 Eastern Africa during 2016–2017 October November December ‘short rains’ season was the prevailing sea  
3 surface temperature patterns (La Niña in that case), although temperature trends indicate that the drought  
4 conditions were hotter than it would have been without climate change. There was no detectable trend in  
5 rainfall, but small changes in the risk of poor rains linked to climate change could not be excluded (Uhe et  
6 al., 2017). A strong warming tendency in the western Indian Ocean has been attributed to increases in  
7 greenhouse gasses (*medium confidence*) (Verdin et al., 2005; Williams and Funk, 2011).

8 There are numerous local case studies on attribution of desertification, which use different periods, focus  
9 on different land uses and covers and consider different desertification processes. For example, natural  
10 climate cycles (the cold phase of Atlantic Multi-Decadal Oscillation and Pacific Decadal Oscillation) has  
11 been attributed to two-thirds of the observed expansion of the Sahara Desert from 1920–2003 (Thomas and  
12 Nigam, 2018). Drought is considered the main driver of desertification in Africa (Masih et al., 2014)  
13 especially in rangelands. However, other studies suggest that although droughts may contribute to  
14 desertification, the underlying causes are human activities, for instance, pressures on land in southern Mali  
15 are *likely* to have doubled background dust loads over the Atlantic Ocean since the mid-1960s (Aguirre  
16 Salado et al., 2012; Moulin and Chiapello, 2004; Section 3.4.1). Brandt et al. (2016b) found that woody  
17 vegetation trends are negatively correlated with human population density while changes in land use, water  
18 pumping and flow diversion have enhanced drying of wetlands and salinisation of freshwater aquifers in  
19 Israel (Inbar, 2007). The dryland territory of China has been found to be very sensitive to both climatic  
20 variations and land use/land cover changes (Fu et al., 2000; Liu et al., 2008; Liu and Tian, 2010; Zhao et  
21 al., 2013, 2006). Evidence shows that socioeconomic factors were dominant in causing desertification in  
22 north Shanxi, China, between 1983 and 2012, accounting for about 80% of desertification expansion (Feng  
23 et al., 2015). Encroachment of shrubs into the northern Chihuahuan Desert (USA) since the mid-1800s is  
24 mainly attributed to overgrazing and nutrient depletion, which impedes successful grass establishment  
25 (Kidron and Gutschick, 2017). In Iran, human and climatic factors combined were attributed to severe  
26 droughts between 1950 and 2010 (Modarres et al., 2016). Human activities led to rangeland degradation in  
27 Pakistan and Mongolia during 2000-2011 (Lei et al., 2011). More equal shares of climatic and human  
28 factors were attributed for changes in rangeland improvement and degradation in China (Yang et al., 2016).

29 This kaleidoscope of local case studies demonstrate how attribution of desertification is still challenging,  
30 and this is due to several reasons. Firstly, desertification is caused by a combination of factors that change  
31 over time and vary by location. Secondly, in drylands, vegetation responds closely to rainfall fluctuations  
32 so the interaction between biomass change and rainfall trends needs to be ‘removed’ before attributing  
33 desertification to human activities. Thirdly, human activities and climatic drivers impact  
34 vegetation/ecosystem changes at different rates. Finally, desertification manifests as a gradual change in  
35 ecosystem composition and structure (e.g., woody shrub invasion into grasslands). Although initiated at a  
36 limited location, ecosystem change may propagate throughout an extensive area via a series of feedback  
37 mechanisms. This complicates the attribution of desertification to human and climatic causes as the process  
38 can develop independently once started.

39 Rasmussen et al. (2016) studied the generic reasons behind the overall lack of scientific agreement in trends  
40 of environmental changes in the Sahel supported by contrasting empirical evidence. The study distinguished  
41 between divergences in interpretations emerging from conceptualisations, definitions and choice of  
42 indicators, and biases, for example, related to selection of study sites, methodological choices, measurement  
43 accuracy, perceptions among interlocutors, and selection of temporal and spatial scales of analysis. High  
44 resolution, multi-sensor airborne platforms provide a way to address some of these issues (Asner et al.,  
45 2012).

1 The major conclusion of this section is that, with all the shortcomings of individual case studies, relative  
2 roles of climatic and human drivers are context-specific and evolve over time (*high confidence*).  
3 Biophysical research on attribution and socio-economic research on drivers of land degradation have long  
4 studied the same topic, but in parallel, with little interdisciplinary integration. Interdisciplinary work to  
5 identify typical patterns, or typologies, of such interactions of biophysical and human drivers of  
6 desertification (not only of dryland vulnerability), and their relative shares, done globally in comparable  
7 ways, will help in the formulation of better informed policies to address desertification and achieve land  
8 degradation neutrality.

9

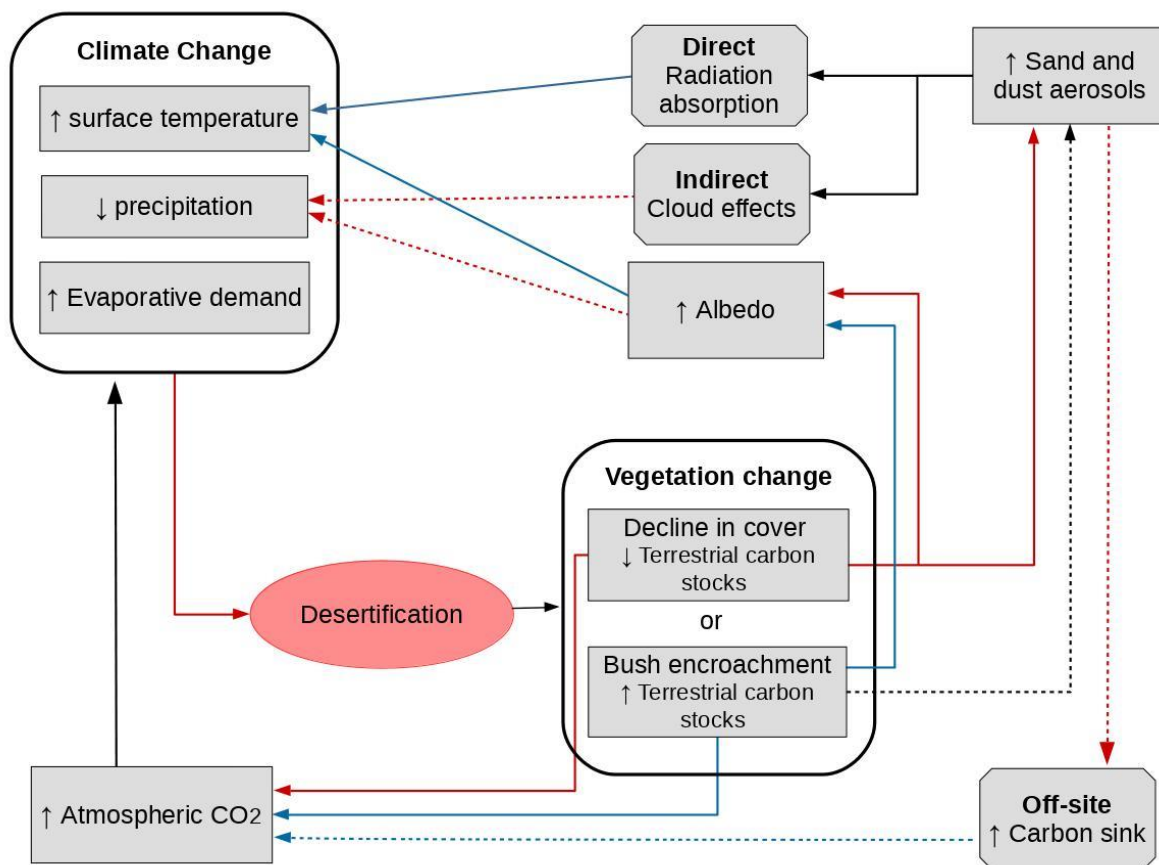

### 10 **3.4. Desertification Feedbacks to Climate**

11 Climate change and desertification have strong mutual interactions, and the land use and land cover changes  
12 associated with desertification contribute to climatic changes, whereas changes in precipitation,  
13 temperature, wind speed, and their variabilities due to climatic changes constitute factors affecting  
14 desertification (Sivakumar, 2007). These climate-desertification interactions require multi-faceted  
15 approaches to limit negative impacts on human wellbeing (Adeel et al., 2005; Archer and Tadross, 2009).

16 While climate change can drive desertification (3.2.4.1), the process of desertification can also alter the  
17 local climate providing a feedback. This feedback can lead to either a damping of the desertification process  
18 (negative feedback) or an enhancement of the desertification process (positive feedback). These feedbacks  
19 can alter the carbon cycle, and hence the level of atmospheric CO<sub>2</sub> and its related global climate change, or  
20 they can alter the surface energy and water budgets directly impacting the local climate. While these  
21 feedbacks occur in all climate zones (Chapter 2), here we focus on their effects in dryland regions and  
22 assess the literature concerning the major desertification feedbacks to climate. The main feedback pathways  
23 discussed are summarised in Figure 3.8.

24 Drylands are characterised by limited soil moisture availability compared to more humid regions. Thus, the  
25 sensible heat accounts for a higher proportion of the surface net radiation than latent heat in these regions  
26 (Wang and Dickinson, 2013). This tight coupling between the surface energy balance and the soil moisture  
27 in semi-arid and dry sub-humid zones makes these regions susceptible to land-atmosphere feedback loops  
28 that can amplify changes to the water cycle (Seneviratne et al., 2010). Changes to the land surface caused  
29 by desertification can change the surface energy budget, altering the soil moisture and triggering these  
30 feedbacks.

### 6 3.4.1. Sand and Dust Aerosols

7 Sand and mineral dust are frequently mobilised from sparsely vegetated drylands forming “sand storms” or  
8 “dust storms”. The African continent is the most important source of desert dust, nearly 30% of atmospheric  
9 suspended dust comes from the Sahara (Gonzalez-Martin et al., 2014; Middleton, 2017). These events can  
10 play an important role in the local energy balance. Through reducing vegetation cover and drying the  
11 surface conditions, desertification can increase the frequency of these events. Biological soil crusts have  
12 been shown to effectively stabilise dryland soils and thus their loss due to intense land use and/or climate  
13 change can be expected to cause an increase in sand and dust storms (Field et al., 2010; Rodriguez-Caballero  
14 et al., 2018). These events impact the regional climate in several ways (Choobari et al., 2014). The direct  
15 effect is the interception, reflection and absorption of solar radiation in the atmosphere, reducing the energy  
16 available at the land surface and increasing the temperature of the atmosphere in layers with sand and dust  
17 present (Kaufman et al., 2002; Middleton, 2017). The heating of the dust layer can cause changes in the  
18 relative humidity and atmospheric stability, which can alter cloud lifetimes and water content. This has  
19 been referred to as the semi-direct effect (Huang et al., 2017). Aerosols also have an indirect effect on  
20 climate through their role as cloud condensation nuclei, changing cloud radiative properties as well as the  
21 evolution and development of precipitation (Kaufman et al., 2002). While these indirect effects are more  
22 variable than the direct effects, depending on the types and amounts of aerosols present, the general

1 tendency is toward an increase in the number, but a reduction in the size of cloud droplets, increasing the  
2 cloud reflectivity and decreasing the chances of rain. These effects are referred to as aerosol-radiation and  
3 aerosol-cloud interactions (Boucher et al., 2013).

4 There is *high confidence* that there is a negative relationship between vegetation green-up and the  
5 occurrence of dust storms (Engelstaedter et al., 2003; Fan et al., 2015; Yu et al., 2015; Zou and Zhai, 2004).  
6 Changes in groundwater can affect vegetation and the generation of atmospheric dust in dryland regions  
7 (Elmore et al., 2008). This can occur through shallow groundwater processes such as the vertical movement  
8 of salt to the surface causing salinisation, supply of near surface soil moisture, and sustenance of  
9 groundwater dependent vegetation. Groundwater dependent ecosystems have been identified in many  
10 dryland regions around the world (e.g. Decker et al., 2013; Lamontagne et al., 2005; Patten et al., 2008). In  
11 these locations decreases in groundwater levels have the potential to decrease vegetation cover.

12 Desertification can decrease the amount of green cover and hence increase the occurrence of sand and dust  
13 storms. This would increase the amount of shortwave cooling associated with the direct effect. There is  
14 *high confidence* that the semi-direct and indirect effects of this dust would tend to decrease precipitation  
15 and hence provide a positive feedback to desertification (Huang et al., 2009; Konare et al., 2008; Rosenfeld  
16 et al., 2001; Solmon et al., 2012; Zhao et al., 2015). However, the combined effect of dust has also been  
17 found to increase precipitation in some areas (Islam and Almazroui, 2012; Lau et al., 2009; Sun et al.,  
18 2012). The overall combined effect of dust aerosols on desertification remains uncertain with *low*  
19 *agreement* between studies that find positive (Huang et al., 2014) , negative (Miller et al., 2004) or no  
20 feedback on desertification (Zhao et al., 2015).

21

#### 22 **3.4.1.1. Off-site Feedbacks**

23 Aerosols can act as a vehicle for the long-range transport of nutrients to oceans (Okin et al., 2011) and  
24 terrestrial land surfaces (Das et al., 2013). In several locations, notably the Atlantic Ocean, west of northern  
25 Africa and the Pacific Ocean east of northern China, a considerable amount of mineral dust aerosols,  
26 sourced from nearby drylands, reaches the oceans. It was estimated that 60% of dust transported off Africa  
27 is deposited in the Atlantic Ocean (Kaufman et al., 2005), while 50% of the dust generated in Asia reaches  
28 the Pacific Ocean or further (Uno et al., 2009; Zhang et al., 1997). The Sahara is also a major source of dust  
29 for the Mediterranean basin (Varga et al., 2014). The direct effect of dust on the ocean surface has been  
30 found to be a cooling effect (Doherty and Evan, 2014; Evan and Mukhopadhyay, 2010; Evan et al., 2009),  
31 with the tropical North Atlantic mixed layer cooling by over 1°C (Evan et al., 2009).

32 It has been suggested that dust may act as a source of nutrients for the upper ocean biota, enhancing the  
33 biological activity and related carbon sink. However, while some observational studies support this  
34 hypothesis (Lenes et al., 2001; Shaw et al., 2008), others find little or no response in the biological activity  
35 (Neuer et al., 2004). The overall response depends on the environmental controls on the ocean biota, the  
36 type of aerosols including their chemical constituents, and the chemical environment in which they dissolve  
37 (Boyd et al., 2010).

38 Dust deposited on snow can cause increases in melt (Painter et al., 2018), impacting a region's hydrological  
39 cycle.

40

### 1 **3.4.2. Changes in Surface Albedo**

2 The hypothesis that changing surface albedo in dryland regions will feedback on the local climate has been  
3 around since at least Charney et al. (1975). They used a climate model to show that over North Africa, an  
4 increase in albedo produced a decrease in available energy at the surface, a decrease in the surface  
5 temperature, a shallower planetary boundary layer and a reduction in precipitation. Since lower  
6 precipitation was associated with lower soil moisture and an increase in surface albedo, this represents a  
7 positive feedback.

8 More recent modelling work demonstrated this albedo feedback can occur in desert regions worldwide,  
9 including those outside the hyper-arid zone (Zeng and Yoon, 2009). Similar albedo feedbacks have also  
10 been found in regional studies over the Middle East (Zaitchik et al., 2007), Australia (Evans et al., 2017;  
11 Meng et al., 2014a; Meng et al., 2014b), South America (Lee and Berbery, 2012) and the USA (Zaitchik et  
12 al., 2013).

13 Recent work has also found albedo in dryland regions can be associated with soil surface communities of  
14 lichens, mosses and cyanobacteria (Rodriguez-Caballero et al., 2018). These communities compose the soil  
15 crust in these ecosystems and due to the sparse vegetation cover, directly influence the albedo. These  
16 communities are sensitive to climate changes with field experiments indicating albedo changes greater than  
17 30% are possible. Thus, changes in these communities could trigger surface albedo feedback processes  
18 (Rutherford et al., 2017).

19 A further pertinent feedback relationship exists between changes in land-cover, albedo, carbon stocks and  
20 associated GHG emissions, particularly in drylands with low levels of cloud cover. One of the first studies  
21 to focus on the subject was Rotenberg and Yakir (2010), who used the concept of ‘radiative forcing’ to  
22 compare the relative climatic effect of a change in albedo with a change in atmospheric GHGs due to the  
23 presence of forest within drylands. Based on this initial analysis, it was estimated that the change in surface  
24 albedo due to the degradation of semi-arid areas over the past few decades has decreased radiative forcing  
25 equivalent to approximately 20% of global anthropogenic GHG emissions to date (Rotenberg and Yakir,  
26 2010).

27

### 28 **3.4.3. Changes in Vegetation and Greenhouse Gas Fluxes**

29 Terrestrial ecosystems have the ability to alter atmospheric GHGs through a number of processes  
30 (Schlesinger et al., 1990). This may be through a change in plant and soil carbon stocks, either sequestering  
31 atmospheric carbon dioxide during growth or releasing carbon during combustion and respiration, or  
32 through processes such as enteric fermentation of domestic and wild ruminants that lead to the release of  
33 methane and nitrous oxide (Sivakumar, 2007). When evaluating the effect of desertification, the net balance  
34 of all the processes and associated GHG fluxes needs to be considered.

35 Desertification usually leads to a loss in productivity and a decline in above- and below-ground carbon  
36 stocks (Abril et al., 2005; Asner et al., 2003). Drivers such as overgrazing lead to a decrease in both plant  
37 as well as soil organic carbon pools (Abdalla et al., 2018). While dryland ecosystems are often characterised  
38 by open vegetation, it should be noted that not all drylands necessarily have low biomass and carbon stocks  
39 in an intact state (Lechmere-Oertel et al., 2005; Maestre et al., 2012). Vegetation types such as the  
40 subtropical thicket of South Africa have over 70 tonnes of Carbon per hectare ( $t C ha^{-1}$ ) in an intact state,  
41 greater than 60% of which is released into the atmosphere during degradation through overgrazing

1 (Lechmere-Oertel et al., 2005; Powell, 2009). In comparison, semi-arid grasslands and savannahs areas  
2 with similar rainfall, may have only 5-35 t C ha<sup>-1</sup> (Scholes and Walker, 1993; Woomer et al., 2004).

3 At the same time, it is expected that a decline in plant productivity may lead to a decrease in fuel loads and  
4 a reduction in carbon dioxide, nitrous oxide and methane emissions from fire. In a similar manner,  
5 decreasing productivity may lead to a reduction in ruminant animals that in turn would decrease methane  
6 emissions. Few studies have focussed on changes in these sources of emissions due to desertification and  
7 it remains a field that requires further research.

8 In comparison to desertification through the suppression of primary production, the process of woody plant  
9 encroachment can result in significantly different climatic feedbacks. Increasing woody plant cover in open  
10 rangeland ecosystems leads to an increase in woody carbon stocks both above- and below- ground (Asner  
11 et al., 2003; Hughes et al., 2006). For example, within the drylands of Texas, shrub encroachment led to a  
12 32% increase in aboveground carbon stocks over a period of 69 years (3.8 t C ha<sup>-1</sup> to 5.0 t C ha<sup>-1</sup>) (Asner et  
13 al., 2003). Encroachment by taller woody species, can lead to significantly higher observed biomass and  
14 carbon stocks, for example, encroachment by *Dichrostachys cinerea* and several *Vachellia* species in the  
15 sub-humid savannahs of north-west South Africa led to an increase of 31–46 t C ha<sup>-1</sup> over a 50–65 year  
16 period (1936–2001) (Hudak et al., 2003). In terms of potential changes in soil organic carbon stocks, the  
17 effect may be dependent on annual rainfall and soil type. Whereas increasing woody cover generally leads  
18 to an increase in soil organic carbon stocks in drylands that have less than 800 mm of annual rainfall,  
19 encroachment can lead to a loss of soil carbon in more mesic ecosystems (Barger et al., 2011; Jackson et  
20 al., 2002).

21 The suppression of the grass layer through the process of woody encroachment may lead to a decrease in  
22 carbon stocks within this relatively small carbon pool (Magandana, 2016). In addition, increasing woody  
23 cover may lead to a decrease and even halt in surface fires and associated GHG emissions. In analysis of  
24 drivers of fire in southern Africa, Archibald et al. (2009) note that there is a potential threshold around 40%  
25 canopy cover, above which surface grass fires are rare. Whereas there have been a number of studies on  
26 changes in carbon stocks due to desertification in North America, southern Africa and Australia, a global  
27 assessment of the net change in carbon stocks as well as fire and ruminant GHG emissions due to woody  
28 plant encroachment remains to be undertaken.

29

## 30 **3.5. Impacts of Desertification on Natural and Socio-Economic Systems under** 31 **Climate Change**

### 32 **3.5.1. Natural and Managed Ecosystems**

#### 33 ***3.5.1.1. Impacts on Ecosystems and their Services in Drylands***

34 The Millennium Ecosystem Assessment (2005) proposed four classes of ecosystem services: provisioning,  
35 regulating, supporting and cultural services. These ecosystem services in drylands are vulnerable to the  
36 impacts of climate change due to high variability in temperature, precipitation and soil fertility (Enfors and  
37 Gordon, 2008; Mortimore, 2005). Desertification coupled with climate change negatively impacts  
38 provisioning services, particularly food and fodder production (Hopkins and Del Prado, 2007). Zika and  
39 Erb (2009) reported a rough estimation of Net Primary Productivity (NPP) losses between 0.8 and 2.0 Pg  
40 C yr<sup>-1</sup> due to dryland degradation, comparing the potential NPP and the NPP calculated for the year 2000.  
41 Furthermore, desertification-climate change interactions modify the prevalence of livestock diseases, the  
42 composition of plant species and biological diversity (D'Odorico and Bhattachan, 2012; Thornton et al.,

1 2009). Climate change, together with human population growth and global economic integration, is causing  
2 the abandonment of cattle rearing in favour of small ruminant husbandry as well as shifts into other forms  
3 of land use such as settled irrigated agriculture in East Africa (Homewood et al., 2001). Changes in  
4 temperature can have a direct impact on animals in the form of increased physiological stress (Rojas-  
5 Downing et al., 2017), increased water requirements for drinking and cooling, a decrease in the production  
6 of milk, meat and eggs, increased stress during conception and reproduction (Nardone et al., 2010) or an  
7 increase in seasonal diseases and epidemics (Thornton et al., 2009; Nardone et al., 2010). Furthermore,  
8 changes in temperature can indirectly impact livestock through reducing the productivity and quality of  
9 feed crops and forages (Thornton et al., 2009; Polley et al., 2013). Warm and humid conditions causing  
10 heat stress increase livestock mortality (Howden et al., 2008). On the other hand, fewer days with extreme  
11 cold temperatures during winters in the temperate zones are associated with lower livestock mortality. In  
12 addition, the ecosystem water availability is negatively affected by the combination of drought with  
13 increments in temperature at the late 20th and early 21st centuries; for example, (Woodhouse et al., 2010)  
14 estimated a reduction from 2-8% of the Colorado river runoff for each 1°C increment of temperature.

15 Among regulating services, desertification can influence levels of atmospheric carbon dioxide. In drylands,  
16 the majority of carbon is stored below ground in the form of biomass and soil organic carbon (SOC) (FAO,  
17 1995). Drivers of soil degradation, mainly by land-use change, lead to reductions in SOC and organic  
18 matter inputs into soil (Albaladejo et al., 2013; Almagro et al., 2010; Hoffmann et al., 2012; Lavee et al.,  
19 1998; Rey et al., 2011), increasing soil salinity and soil erosion (Lavee et al., 1998; Martinez-Mena et al.,  
20 2008) and intensive grazing (Sharkhuu et al., 2016). In contrast, if the soil management includes soil  
21 conservation practices combined with irrigation, the cropland has a higher SOC content than native  
22 shrubland or native pastures, as shown in China (Liu et al., 2011). However, water management must be  
23 sustainable to ensure its availability for these results to persist. If restored, the degraded woodlands,  
24 grasslands, and deserts of the world could sequester up to 3.5 GtC yr<sup>-1</sup> over this century (Yang et al., 2016),  
25 which is about 37% of 2017 fossil fuel carbon emissions (Le Quéré et al., 2018).

26 Precipitation, by affecting soil moisture content, is considered to be the principal determinant of the capacity  
27 of drylands to sequester carbon (Fay et al., 2008; Hao et al., 2008; Mi et al., 2015; Serrano-Ortiz et al.,  
28 2015; Vargas et al., 2012; Sharkhuu et al., 2016). Low annual rainfall resulted in the release of carbon into  
29 the atmosphere for a number of sites located in Mongolia, China and North America (Biederman et al.,  
30 2017; Chen et al., 2009; Fay et al., 2008; Hao et al., 2008; Mi et al., 2015; Sharkhuu et al., 2016). Low soil  
31 water availability promotes soil microbial respiration, yet there is insufficient moisture to stimulate plant  
32 productivity (Austin et al., 2004), resulting in net carbon emissions at an ecosystem level. In contrast, years  
33 of good rainfall in drylands resulted in the sequestration of carbon (Biederman et al., 2017; Chen et al.,  
34 2009; Hao et al., 2008). In an exceptionally rainy year (2011) in the southern hemisphere, the semiarid  
35 ecosystems of this region contributed 51% of the global net carbon sink (Poulter et al., 2014). These results  
36 suggest that arid ecosystems could be an important global carbon sink depending on soil water availability  
37 (*medium evidence, high agreement*). However, drylands are generally predicted to become warmer and  
38 drier in the future with an increasing frequency of extreme drought and high rainfall events (Donat et al.,  
39 2016).

40 When desertification and climate change reduces vegetation cover below 25% (threshold that has a  
41 biological significance), this would alter the soil surface, affect the albedo and the water balance (Gonzalez-  
42 Martin et al., 2014). In such situations, the dust storms have no more obstacles, increasing the wind erosion.  
43 Mineral aerosols have an important influence on the dispersal of soil nutrients and lead to changes in soil  
44 characteristics (Peñate et al., 2013). Thereby, the soil formation as a supporting ecosystem service is  
45 negatively affected. Moreover, dust storms reduce crop yields by loss of plant tissue caused by sandblasting

1 (resulting loss of plant leaves and hence reduced photosynthetic activity), exposing crop roots, crop seed  
2 burial under sand deposits, and leading to losses of nutrients and fertiliser from top soil (Stefanski and  
3 Sivakumar 2009). Dust storms also impact crop yields by reducing the quantity of water available for  
4 irrigation because it could decrease the storage capacity of reservoirs by siltation and block conveyance  
5 canals (Middleton, 2017; Middleton and Kang, 2017; Stefanski and Sivakumar, 2009). Livestock  
6 productivity is reduced by injuries caused by dust storms (Stefanski and Sivakumar, 2009).

### 8 **3.5.1.2. Impacts on Biodiversity: Plant and Wildlife**

#### 9 *3.5.1.2.1. Plant Biodiversity*

10 Over 20% of global plant biodiversity centres are located within drylands (White and Nackoney, 2003).  
11 Furthermore, plant species located within these areas are characterised by high genetic diversity within  
12 populations (Martínez-Palacios et al., 1999). The plant species within these ecosystems are often highly  
13 threatened by climate change and desertification (Millennium Ecosystem Assessment, 2005; Reynolds et  
14 al., 2007). Increasing aridity exacerbates the risk of extinction of some plant species, especially those that  
15 are already threatened due to small populations or restricted habitats (Gitay et al., 2002). For example,  
16 species richness decreased from 234 species in 1978 to 95 in 2011 following long periods of drought and  
17 human driven degradation on the steppe land of south western Algeria (Observatoire du Sahara et du Sahel,  
18 2013). Similarly, drought and overgrazing led to loss of biodiversity in Pakistan, where only drought-  
19 adapted species have by now survived on arid rangelands (Akhter and Arshad, 2006). Similar trends were  
20 observed in desert steppes of Mongolia (Khishigbayar et al., 2015).

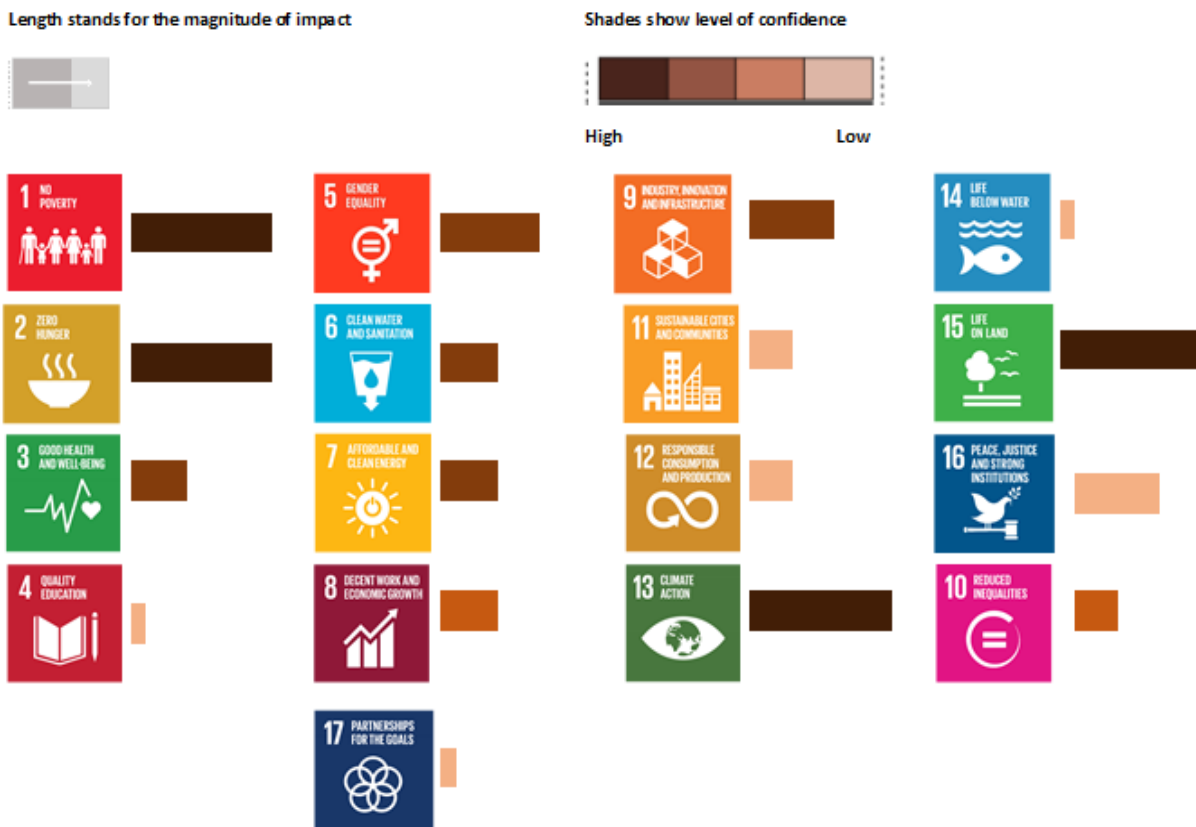

21 The seed banks of annual species can often survive over the long-term, germinating in wet years, suggesting  
22 that these species could be resilient to some aspects of climate change (Vetter et al., 2005). Yet, Hiernaux  
23 and Houérou (2006) showed that overgrazing in the Sahel tended to decrease the seed bank of annuals  
24 which could make them vulnerable to climate change over time. Perennial species, considered as the  
25 structuring element of the ecosystem, are usually less affected as they have deeper roots, xeromorphic  
26 properties and physiological mechanisms that increase drought tolerance (Le Houérou, 1996). However, in  
27 North Africa, long-term monitoring (1978–2014) has shown that important plant perennial species have  
28 also disappeared due to drought (*Stipa tenacissima* and *Artemisia herba alba*) (Observatoire du Sahara et  
29 du Sahel, 2013).

#### 30 *3.5.1.2.2. Wildlife biodiversity*

31 Dryland ecosystems have high levels of faunal diversity and endemism (Whitford, 2002; Millennium  
32 Ecosystem Assessment, 2005). Over 30% of the endemic bird areas are located within these regions, which  
33 is also home to 25% of vertebrate species (Millennium Ecosystem Assessment, 2005; Maestre et al., 2012).  
34 Yet, many species within drylands are threatened with extinction (Durant et al., 2014; Walther, 2016).  
35 Desert animal species have an array of adaptations to conserve body water and are able to withstand  
36 remarkably high body temperatures. Yet, perturbations from normal body temperatures are likely to  
37 represent a stress to these species (Hetem et al., 2016). The direct effects of reduced rainfall and water  
38 availability are likely to be exacerbated by the indirect effects of desertification through a reduction in  
39 primary productivity. A reduction in the quality and quantity of resources available to herbivores can have  
40 knock-on consequences for predators and may ultimately disrupt trophic cascades (Rey et al., 2017).  
41 Responses to desertification are likely to be species-specific and mechanistic models are not yet able to  
42 accurately predict individual species responses to the multitude of factors associated with desertification  
43 (Fuller et al., 2016).

1 **3.5.2. Socio-economic Systems**

2 The impacts of climate change-desertification interactions on socio-economic development in drylands are  
 3 complex. Figure 3.9 schematically represents qualitatively our assessment of the magnitudes and the  
 4 uncertainties associated with these impacts using the framework of Sustainable Development Goals  
 5 (SDGs). The impacts of desertification and climate change are difficult to isolate from the effects of other  
 6 socio-economic, institutional and political factors that simultaneously affect these dimensions of  
 7 sustainable development (Pradhan et al., 2017). It is *very likely*, however, that climate change will  
 8 exacerbate the already high vulnerability of dryland populations to desertification, and that the combination  
 9 of pressures coming from climate change and desertification will amplify, in interaction with other  
 10 contextual factors, poverty, food and nutritional insecurity, disease burden, lack of access to water and  
 11 sanitation, and the likelihood of conflict (Sections 3.5.2.1 – 3.5.2.7). Desertification is embedded in SDG  
 12 15 (target 15.3) and climate change is under SDG 13, the high confidence and high magnitude impacts  
 13 depicted for these SDGs (Figure 3.9) represent the strong interactions between desertification-climate  
 14 change interactions and achieving the targets of SDGs 13 and 15. The following sub-sections present the  
 15 literature and the assessment which serves as the basis for Figure 3.9.

16  
 17 **Figure 3.9 Socio-economic impacts of desertification and climate change with the SDG framework**

18 **3.5.2.1 Food and Nutritional Insecurity**

19 About 815 million people globally were food insecure in 2016, of whom 62% are in Asia, 30% in Africa  
 20 and 5% in Latin America and the Caribbean (FAO et al., 2017). Sub-Saharan Africa and South Asia had  
 21 the highest share of undernourished populations in the world in 2016, with 22.7% and 14.4%, respectively.  
 22 The drylands of Eastern Africa represent the global hotspot of food insecurity, where 33.9% of the

1 population are undernourished (FAO et al., 2017). The climate change-desertification interactions affect all  
2 four dimensions of food security: availability, access, utilisation and stability (for more detailed discussion  
3 see Chapter 5). The major mechanism through which climate change and desertification affect food security  
4 is through their impacts on agricultural productivity. There is *robust evidence* pointing to negative impacts  
5 of climate change on crop yields in dryland areas (*high agreement*) (Hochman et al., 2017; Nelson et al.,  
6 2010; Zhao et al., 2017); Section 3.5.1; Chapter 5). Nkonya et al. (2016a) estimated that cultivating wheat,  
7 maize, and rice with unsustainable land management practices is currently resulting in global losses of 56.6  
8 billion USD annually, with another 8.7 billion USD of annual losses due to lower livestock productivity  
9 caused by rangeland degradation. However, these numbers are global, not specific to desertification, and  
10 are estimated only for three crops. It is not clear to what level of food insecurity these losses translate.  
11 Despite a lack of global level estimates of the impacts of desertification on all the dimensions of food  
12 security, there is *robust evidence* on the losses in agricultural productivity and incomes due to  
13 desertification (Kirui, 2016; Moussa et al., 2016; Mythili and Goedecke, 2016; Tun et al., 2015). Negative  
14 impacts on crop yields and higher agricultural prices worsen existing food insecurity, especially for net-  
15 food buying rural households and urban dwellers. In contrast, there is a limited number of studies  
16 quantitatively tracing desertification impacts on stability and utilisation dimensions of food security.

17 Overall, there is *robust evidence and high agreement* for the high potential negative impact of climate  
18 change on agricultural productivity in drylands (Hochman et al., 2017; Mendelsohn, 2008; Nelson et al.,  
19 2010; C. Zhao et al., 2017, chapter 5). Although there is a lack of estimates on the aggregate impact of  
20 desertification on food security in drylands, local case studies point to significant losses of agricultural  
21 productivity and production due to desertification (Kirui, 2016; Moussa et al., 2016; Mythili and Goedecke,  
22 2016; Tun et al., 2015). Climate change and desertification are not the sole drivers of food insecurity, but  
23 especially in the areas with high dependence on agriculture, they are among the main contributors.

24

### 25 **3.5.2.2 Poverty**

26 The relationship between desertification and poverty, understood from multidimensional perspectives  
27 (Section 3.2.3), is often conceptualised as a vicious cycle, where desertification and poverty cause each  
28 other. This is because poor households have a higher dependence on environmental income (Thondhlana  
29 and Muchapondwa, 2014), so any degradation of the environmental resource base exacerbates their poverty,  
30 in the worst cases trapping them in poverty (Lybbert et al., 2004). Risk-averseness among poor households,  
31 in this context, is considered to lead to under-investment into sustainable land management practices  
32 (Teklewold and Kohlin, 2011), contributing to desertification and also making them more vulnerable to  
33 climate change. It is *very likely* that climate change will have substantial impacts on poverty in drylands  
34 (Hallegatte and Rozenberg, 2017; Hertel and Lobell, 2014). The impacts of climate change on poverty vary  
35 significantly depending on whether the household is a net agricultural buyer or seller. Modelling results  
36 showed that poverty rates would increase by about one-third among the urban households and non-  
37 agricultural self-employed in Malawi, Uganda, Zambia, and Bangladesh due to high agricultural prices and  
38 low agricultural productivity under climate change (Hertel et al., 2010). On the contrary, modelled poverty  
39 rates fell substantially among agricultural households in Chile, Indonesia, Philippines and Thailand,  
40 because higher prices compensated for productivity losses (Hertel et al., 2010).

41

42 Most of the research on links between poverty and desertification (or more broadly, land degradation)  
43 focused on whether or not poverty is a cause of land degradation (Gerber et al., 2014; Vu et al., 2014; Way,  
44 2016). However, the literature quantifying to what extent desertification contributes to poverty *per se* is  
45 thin, that is beyond the impacts of desertification on agricultural productivity and incomes. Moreover, at

1 the global scale, there is little quantified evidence causally linking desertification to poverty, as the related  
2 literature remains qualitative or correlational (Barbier and Hochard, 2016). At the local level, on the other  
3 hand, there is *medium evidence* quantifying the impacts of desertification on multidimensional poverty. For  
4 example, it was found that land degradation decreased agricultural incomes in Ghana by 4.2 billion USD  
5 between 2006 and 2015, increasing the national poverty rate in 2015 by 5.4% (Diao and Sarpong, 2011).  
6 Land degradation increased the probability of household poverty by 35% in Malawi and 48% in Tanzania  
7 (Kirui, 2016). Desertification in China was found to have resulted in substantial losses in income, food  
8 production and jobs (Jiang et al., 2014). On the other hand, Ge et al. (2015), using a case study from Inner  
9 Mongolia in China, indicated that desertification is positively related to growing incomes in the short run,  
10 while in the long run higher incomes help in reducing desertification. This relationship corresponds to the  
11 Environmental Kuznets Curve, which hypothesises that environmental degradation initially rises and  
12 subsequently falls with rising income (Stern, 2017). There is *limited evidence* on the validity of this  
13 hypothesis regarding desertification.

14

### 15 **3.5.2.3 Pastoral Communities**

16 Pastoral production systems occupy a significant portion of the world (Rass, 2006; Dong, 2016). Due to  
17 frequent droughts and conflicts, aggravated by climate change, pastoral households are becoming more  
18 food insecure (Gomes, 2006). The Sahelian droughts of the 1960s show an example of how droughts could  
19 inflict a heavy toll on livestock resources and crop productivity, resulting in hunger, out-migration and  
20 suffering for millions of pastoralists (Hein and De Ridder, 2006; Molua and Lambi, 2007). During these  
21 Sahelian droughts low and erratic rainfall exacerbated the desertification processes, leading to ecological  
22 changes that forced people to use marginal lands and ecosystems. Similarly, the rate of rangeland  
23 degradation is increasing nowadays because of environmental changes and overexploitation of the  
24 resources (Kassahun et al., 2008; Vetter, 2005). Desertification coupled with climate change is negatively  
25 affecting livestock feed and grazing species (Hopkins and Del Prado, 2007), changing the composition in  
26 favour of species with low forage quality, ultimately reducing livestock productivity (D'Odorico et al.,  
27 2013; Dibari et al., 2016), and increasing livestock disease prevalence (Thornton et al., 2009).

28 There is *robust evidence and high agreement* that weak adaptive capacity, coupled with negative effects  
29 from other climate-related factors, are predisposing pastoralists to increased poverty from desertification  
30 and climate change (Giannini et al., 2008; IPCC, 2007). On the other hand, misguided policies such as  
31 enforced sedentarisation and in certain cases protected area delineation (fencing), which restrict livestock  
32 mobility have hampered optimal use of grazing land resources (Du, 2012); and led to degradation of  
33 resources and out-migration of people in search of better livelihoods (Gebeye, 2016; Liao et al., 2015; Yeh,  
34 2009). Restrictions on the mobile lifestyle is reducing the resilient adaptive capacity of pastoralists to  
35 natural calamities including extreme and variable weather conditions, drought and climate change  
36 (Schilling et al., 2014).

37 Furthermore, the exacerbation of the desertification phenomenon due to agricultural intensification  
38 (D'Odorico et al., 2013) and land fragmentation caused by encroachment of agriculture into rangelands  
39 (Otuoma et al., 2009) is threatening pastoral livelihoods. For example, commercial cotton production is  
40 crowding out pastoral systems in Benin (Tamou et al., 2018). Food shortages and the urgency to produce  
41 enough crop for public consumption are leading to the encroachment of agriculture into productive  
42 rangelands and those converted rangelands are frequently prime lands used by pastoralists to produce feed  
43 and graze their livestock during dry years (Dodd, 1994). Many pastoralists are having to switch to other  
44 forms of land uses such as settled irrigated agriculture, shifting from rearing cattle to rearing small  
45 ruminants because of climate change, desertification, human population growth, and as a result of global

1 economy integration (Homewood et al., 2001). The sustainability of pastoral systems is therefore coming  
2 into question because of social and political marginalisation of the system (Davies et al., 2016) and also  
3 because of the fierce competition it is facing from other livelihood sources such as crop farming (De Haan  
4 et al., 2016). Moreover, the impacts of future climate change and desertification could be unprecedented  
5 in scale (Galvin, 2008), affecting political stability (Raleigh 2010), resulting in continued displacement and  
6 out-migration of pastoral communities into other geographical areas (Bassett and Turner, 2007).

#### 8 **3.5.2.4. Impacts on Water Scarcity and Use**

9 Reduced water retention capacity of degraded soils amplifies floods (de la Paix et al., 2011), reinforces  
10 degradation processes through soil erosion, and reduces annual intake of water to aquifers, exacerbating  
11 existing water scarcities (le Roux et al., 2017; Cano et al., 2018). Moreover, secondary salinisation in the  
12 irrigated drylands often requires annual leaching with considerable amounts of water (Greene et al., 2016;  
13 Wichelns and Qadir, 2015). All these processes reduce water availability for other needs. In this context,  
14 climate change is *likely* to intensify water scarcity in many dryland areas and increase the severity and  
15 frequency of droughts (IPCC, 2013; Section 3.8.5). Higher water scarcity will imply growing use of  
16 wastewater effluents for irrigation (Pedrero et al., 2010). The use of untreated wastewater is *likely* to  
17 exacerbate desertification processes (Tal, 2016; Singh et al., 2004; Qishlaqi et al., 2008; Hanjra et al., 2012),  
18 with negative human health impacts (Faour-Klingbeil and Todd, 2018; Hanjra et al., 2012). Climate change,  
19 thus, will amplify the need for integrated land and water management for sustainable development.

#### 21 **3.5.2.5. Gender-differentiated Impacts**

22 Environmental issues such as desertification and impacts of climate change have been increasingly  
23 investigated through a gender lens because of the significant differences of men and women (Bose, 2015;  
24 Broeckhoven and Cliquet, 2015; Kaijser and Kronsell, 2014; Kiptot et al., 2014; Villamor and van  
25 Noordwijk, 2016). These differences emanate from socially structured gender-specific roles and  
26 responsibilities, daily activities, access and control over resources, decision making and opportunities that  
27 lead men and women to interact differently with natural resources and landscapes. However, it is recognised  
28 that women will be impacted more than men by environmental degradation (Arora-Jonsson, 2011; Gurung  
29 et al., 2006).

30 Despite these known differences between men and women, gender issues have been marginally addressed  
31 in many conservation efforts which often remain gender-blind particularly in land restoration and  
32 rehabilitation efforts. Assessments of the gender dimension of desertification and climate change impacts  
33 are still very scarce, particularly at the macro or landscape level, because of two main reasons. First, because  
34 the impacts of climate change on men and women and their responses to desertification are context specific  
35 (or place-based). For example, in the drylands of Sub-Saharan Africa, the most common significant  
36 predicted consequence of climate change is the overall decrease in available water. Women, who are  
37 primary natural resource managers and providers of food security in the region, are often expected to fetch  
38 water and to collect fuelwood from increasingly remote areas (Mekonnen et al., 2017; Scheurlen, 2015).  
39 Whereas, men migrate to nearby towns or other countries for better opportunities, leaving women behind  
40 with more responsibilities. And yet, women are usually excluded from local decision making on actions  
41 regarding desertification and climate change. On the other hand, the comparative case study from Southeast  
42 Asian countries showed that women, due to their increasing productive roles, could become agents of either  
43 land degradation or restoration (Catacutan and Villamor, 2016). Second, these socially constructed gender-  
44 specific roles and responsibilities are not static because they are shaped by other factors such as wealth,

1 age, ethnicity, and formal education (Kaijser and Kronsell, 2014; Villamor et al., 2014). Hence, women's  
2 and men's environmental knowledge and priorities for restoration often differ (Sijapati-Basnett et al., 2017).  
3 In some areas where sustainable land options (i.e., agroforestry) are being promoted, women were not able  
4 to participate due to culturally-embedded asymmetries in power relations between men and women  
5 (Catacutan and Villamor, 2016). Nonetheless, women particularly in the rural areas remain heavily involved  
6 in securing food for their households. Food security for them is associated with land productivity and  
7 women's contribution to address desertification problem is crucial.

### 9 **3.5.2.6 Conflicts**

10 Degradation of the natural resource base and ecosystem services in drylands due to climate change-  
11 desertification interactions amplify, in interaction with contextual factors, some conflicts in some regions  
12 (*medium evidence, medium agreement*). The related triggers of conflicts, to which desertification and  
13 climate change feed, are higher food prices (Arezki and Bruckner, 2011; Bush, 2010; Bellemare, 2015),  
14 droughts (Gleick, 2014; Hsiang et al., 2013; Hsiang and Meng, 2014; Maystadt and Ecker, 2014; Mehta,  
15 2017), competition between pastoralist communities and crop producers for access to land (Abbass, 2014;  
16 Benjaminsen et al., 2012; Huho et al., 2011). There is *high confidence* that desertification and climate  
17 change do not cause conflict and civil strife by themselves, but add to the overall conflict potential. For  
18 example, the likelihood of new civil conflicts throughout the tropics were found to double during El Niño  
19 years relative to La Niña years. The El Niño–Southern Oscillation (ENSO) was suggested to have  
20 contributed to 21% of all civil conflicts since 1950 (Hsiang et al., 2011). Each one standard deviation  
21 increase in temperatures or rainfall was found to increase interpersonal violence by 4% and intergroup  
22 conflict by 14% (Hsiang et al., 2013). Similarly, a one-standard deviation increase in dryness was found to  
23 raise the likelihood of riots in Sub-Saharan African countries by 8.3% during the 1990–2011 period (Almer  
24 et al., 2017). It was also suggested that drought played a direct role in the Syrian conflict (Gleick, 2014),  
25 where drought, considered to be the longest and most intense in the last 900 years (Cook et al., 2016),  
26 considerably decreased crop yields and displaced hundreds of thousands people (Kelley et al., 2015; Trigo  
27 et al., 2010). However, the attribution of this drought in Syria to climate change is challenged (Selby et al.,  
28 2017, see also Chapter 5, section 5.6.2.1). On the other hand, droughts and heatwaves were not found to  
29 significantly affect the level of regional conflict in East Africa (Owain and Maslin, 2018). The droughts  
30 and desertification in the Sahel are *likely* to have played a relatively minor role in the conflicts in the Sahel  
31 in the 1980s, with the major reasons for the conflicts during this period being political, especially the  
32 marginalisation of pastoralists (Benjaminsen, 2016), corruption and rent-seeking (Benjaminsen et al.,  
33 2012). Similarly, the role of environmental factors as the key drivers of conflicts were questioned in the  
34 case of Sudan (Verhoeven, 2011) and Syria (De Châtel, 2014). Selection bias, when the literature focuses  
35 on the same few regions where conflicts occurred and relates them to climate change, is a major  
36 shortcoming, as it ignores other cases where conflicts did not occur (Adams et al., 2018) despite degradation  
37 of the natural resource base and extreme weather events. The emerging consensus is that climate change,  
38 with its interactions with desertification, is only a contributing factor to some conflicts in some regions  
39 (Butler and Kefford, 2018; Gleick, 2014; Kelley et al., 2015; Raleigh, 2010), where there may already be a  
40 conflict potential due to other reasons (Adano et al., 2012), for example, ethnic divisions (Schleussner et  
41 al., 2016) or widespread availability of small arms (e.g. after the fall of the Idi Amin government in Uganda)  
42 (Mkutu, 2007).

### 3.5.2.7 Migration

Environmentally-induced migration is complex and should account for multiple drivers of mobility as well as other adaptation measures undertaken by populations exposed to environmental risk (*high agreement*). This nuanced view is in stark contrast with the forecasts of large-scale environmental displacements suggested especially by the early literature (Myers, 2002; Myers and Kent, 1995), but reiterated in the recent World Bank report predicting that by 2050, more than 143 million people would be forced to move internally if no climate action is taken (World Bank, 2018). In a similar vein, Missirian and Schlenker (2017) predict that under continued future warming, by the end of the 21<sup>st</sup> century, the asylum applications to the European Union will increase by 28% up to 188% depending on the climate scenario. However, even though the modelling efforts have greatly improved over the years (Hunter et al., 2015; McLeman, 2011; Sherbinin and Bai, 2018), the estimates are still based on the number of people exposed to risk rather than the number of people who would actually engage in migration as a response to this risk (Gemenne, 2011; McLeman, 2013) and they do not take into account individual agency in migration decision nor adaptive capacities of individuals (Hartmann, 2010; Kniveton et al., 2011; Piguet, 2010). Accordingly, the available micro-level evidence suggests that climate-related shocks are one of the drivers of migration (London Government Office for Science and Foresight, 2011; Melde et al., 2017; Adger et al., 2014), but the individual responses to climate risk are more complex than commonly assumed (Gray and Mueller, 2012). For example, despite strong focus on natural disasters, neither flooding (Gray and Mueller, 2012; Mueller et al., 2014) nor earthquakes (Halliday, 2006) induce mobility; but instead, slow-onset changes, especially those provoking crop failures and heat stress, do affect household or individual migration decisions (Gray and Mueller, 2012; Missirian and Schlenker, 2017; Mueller et al., 2014). Out-migration from drought-prone areas has received particular attention (de Sherbinin et al., 2012; Ezra and Kiros, 2001) and indeed, a substantial body of literature suggests that households engage in local or internal migration as a response to drought (Findlay, 2011; Gray and Mueller, 2012), while international migration decreases with drought in some contexts (Henry et al., 2004), but might increase international mobility in contexts where migration networks are well established (Feng et al., 2010; Nawrotzki and DeWaard, 2016; Nawrotzki et al., 2015; Nawrotzki et al., 2016). Similarly, the evidence is not conclusive with respect to the effect of environmental drivers, in particular desertification, on mobility. While it has not consistently entailed out-migration in the case of Ecuadorian Andes (Gray, 2009, 2010) environmental and land degradation increased mobility in Kenya and Nepal (Gray, 2011; Massey et al., 2010), but marginally decreased mobility in Uganda (Gray, 2011). These results suggest that in some contexts, environmental shocks actually undermine household's financial capacity to undertake migration (Nawrotzki and Bakhtsiyarava, 2017), especially in the case of the poorest households (Koubi et al., 2016; Kubik and Maurel, 2016; McKenzie and Yang, 2015).

### 3.5.2.8 Dust Storms and Human Health

The frequency of dust storms is increasing due to land use and climatic changes in some regions of the world (Gu et al., 2010; Indoitu et al., 2015; Rashki et al., 2012; Tan et al., 2012; Türkeş, 2017) (*high confidence*). There is *robust evidence and high agreement* that dust storms have negative impacts on human health (Díaz et al., 2017; Goudarzi et al., 2017; Goudie, 2014; Samoli et al., 2011). In view of growing intensity, frequency and scale of dust storms due to climate change-desertification interactions, these health impacts are *very likely* to increase in the future. More research on health impacts and related costs of dust storms as well as on public health response measures can help in mitigating these health impacts.

Dust storms transport particulate matter, pollutants and potential allergens that are dangerous for human health over long distances (Goudie and Middleton, 2006; Sprigg, 2016). Particulate matter (PM), i.e. the suspended particles in the air having sizes between 10 micrometer (PM10) and 2.5 micrometer (PM2.5) or

1 less, have damaging effects on human health (Díaz et al., 2017; Goudarzi et al., 2017; Goudie, 2014; Samoli  
2 et al., 2011). The health effects of dust storms are largest in areas in the immediate vicinity of their origin,  
3 primarily the Sahara Desert, followed by Central and Eastern Asia, the Middle East and Australia (Zhang  
4 et al., 2016), however, there is *robust evidence* showing that the negative health effects of dust storms reach  
5 a much wider area (Bennett et al., 2006; Díaz et al., 2017; Kashima et al., 2016; Lee et al., 2014; Samoli et  
6 al., 2011; Zhang et al., 2016).

7  
8 The primary health effects of dust storms include damage to the respiratory and cardiovascular systems  
9 (Goudie, 2013). Dust particles with a diameter smaller than 2.5µm were associated with global  
10 cardiopulmonary mortality of about 402,000 people in 2005, with 3.47 million years of life lost in that  
11 single year (Giannadaki et al., 2014). If globally only 1.8% of cardiopulmonary deaths were caused by dust  
12 storms, in the countries of the Sahara region, Middle East, South and East Asia, dust storms were suggested  
13 to be the reason for 15–50% of all cardiopulmonary deaths. A 10µgm<sup>-3</sup> increase in PM10 dust particles was  
14 associated with mean increases in non-accidental mortality from 0.33% to 0.51% across different calendar  
15 seasons in China, Japan and South Korea (Kim et al., 2017). A review of impacts of Saharan dust storms  
16 on Europe showed no significant association between fine particles (PM2.5) and total or cause- specific  
17 daily mortality (Karanasiou et al., 2012). However, a conclusion on the health impact of coarser fractions  
18 (PM10 and PM2.5–10) could not be reached (Karanasiou et al., 2012). In Kermanshah, Iran, 92% of  
19 morbidity and mortality cases happened during days with PM10 concentrations lower than 150 µg/m<sup>3</sup>, with  
20 the highest health damage occurring in the range of 100–109 µg/m<sup>3</sup> of PM10 concentrations. The percentage  
21 of all-cause deaths attributed to fine particulate matter in Iranian cities affected by Middle Eastern dust  
22 storms (MED) were 0.56–5.02%, while the same percentage for non-affected cities were 0.16–4.13%  
23 (Hopke et al., 2018). In case of lung cancer deaths, the percentage of deaths attributed to fine particles in  
24 MED-affected cities were between 13.74% and 26.47%, that was higher than those for cities with  
25 anthropogenic air pollution (Hadei et al., 2017). The Meningococcal Meningitis epidemics occur in the  
26 Sahelian region during the dry seasons with dusty conditions (Molesworth et al., 2003). Despite a strong  
27 concentration of dust storms in the Sahara region, the Middle East and Central Asia, there is relatively little  
28 research on human health impacts of dust storms in these regions.

### 30 **3.5.2.9 Dust Storms and Impacts on Transport Infrastructure**

31 Sand storms and movement of sand dunes threaten the safety and operation of railway and road  
32 infrastructure in arid and hyper-arid areas, and lead to road and airport closures due to reductions in  
33 visibility. There are numerous historical examples of how moving sand dunes led to the forced  
34 decommissioning of early railway lines built in Sudan, Algeria, Namibia and Saudi Arabia in the late 19<sup>th</sup>  
35 and early 20<sup>th</sup> century (Bruno et al., 2018). Currently, the highest concentration of railways vulnerable to  
36 sand movements are located in north-western China, Middle East and North Africa (Bruno et al., 2018;  
37 Cheng and Xue, 2014). In China, sand dune movements are periodically disrupting the railway transport in  
38 Linhai-Ceke line in north-western China and Lanzhou-Xinjiang High-speed Railway in western China, with  
39 considerable clean-up and maintenance costs (Bruno et al., 2018; Zhang et al., 2010). There are large-scale  
40 plans for expansion of railway networks in arid areas of China, Central Asia, North Africa, the Middle East,  
41 and Eastern Africa. For example, “The Belt and Road Initiative” promoted by China, the Gulf Railway  
42 project by the countries of the Arab Gulf Cooperation Council (GCC), or Lamu Port, South Sudan, Ethiopia  
43 Transport Corridor in Eastern Africa. These investments have long-term return and operation periods. Their  
44 construction and associated engineering solutions will therefore benefit from careful consideration of  
45 potential desertification and climate change effects on sand storms and dune movements.

1  
2 **3.5.2.10 Dust Storms and Impacts on Energy Infrastructure**  
3 There is *robust evidence and high agreement* that dust depositions during dust storms negatively affect the  
4 operational potential of solar power generating equipment and can reduce effective electricity distribution  
5 in high-voltage transmission lines (Costa et al., 2016; Lopez-Garcia et al., 2016; Maliszewski et al., 2012;  
6 Mani and Pillai, 2010; Mejia and Kleissl, 2013; Mejia et al., 2014; Middleton, 2017; Sarver et al., 2013).  
7 The extent of the impact depends on numerous factors such as frequency and intensity of dust depositions,  
8 dust particle size and morphology, tilt angles of solar power installations, and exposure period (Jiang et al.,  
9 2011; Sarver et al., 2013). Direct exposure to desert dust storm can reduce energy generation efficiency of  
10 solar panels by 70–80% in one hour (Ghazi et al., 2014), whereas even in relatively dust free areas such as  
11 United Kingdom (UK), one month without cleaning of solar panels could reduce their energy generation  
12 by 5–6% (Ghazi et al., 2013). This has important implications for climate change mitigation efforts using  
13 the expansion of solar energy generation in dryland areas for substituting fossil fuels. Abundant access to  
14 solar energy in many dryland areas makes them high potential locations for the installation of solar energy  
15 generating infrastructure. Increasing desertification, resulting in higher frequency and intensity of dust  
16 storms, thus, imposes additional costs for climate change mitigation through deployment of solar energy  
17 generation in dryland areas. Most frequently used solutions to this problem involve physically wiping or  
18 washing the surface of solar devices with water. However, these result in additional costs in terms of already  
19 scarce water resources and labour (Middleton, 2017).

20

## 21 **3.6. Future Projections**

### 22 **3.6.1. Future Projections of Desertification**

23 Assessing the impact of climate change on future desertification is difficult as several environmental and  
24 anthropogenic variables interact to determine its dynamics. The majority of modelling studies regarding the  
25 future evolution of desertification rely on the analysis of specific climate change scenarios and Global  
26 Climate Models and their effect on a few processes or drivers that trigger desertification.

27 With regards to climate impacts, the analysis of global and regional climate models concludes that under  
28 all representative concentration pathways (RCPs) potential evapotranspiration (PET) would increase  
29 worldwide as a consequence of increasing surface temperatures and surface water vapour deficit (Sherwood  
30 and Fu, 2014). Consequently, there would be associated changes in aridity indices that depend on this  
31 variable (*high agreement, robust evidence*) (Zarch et al., 2015; Cook et al., 2014; Dai, 2011; Dominguez et  
32 al., 2010; Feng and Fu, 2013; Ficklin et al., 2016; Greve and Seneviratne, 1999; Lin et al., 2015; Scheff and  
33 Frierson, 2015). Due to the large increase in PET and decrease in precipitation over some subtropical land  
34 areas, aridity index will decrease in some drylands (Zhao and Dai, 2015), with one model estimating an  
35 approximately 10% increase in hyper-arid areas globally (Zeng and Yoon, 2009). Observations in recent  
36 decades indicate that the Hadley cell has expanded poleward in both hemispheres (Fu et al., 2006; Hu and  
37 Fu, 2007; Johanson et al., 2009; Seidel and Randel, 2007), and under all RCPs would continue expanding  
38 (Johanson et al., 2009; Lu et al., 2007). This expansion leads to the poleward extension of sub-tropical dry  
39 zones and hence an expansion in drylands (Scheff and Frierson, 2012). Increases in PET are projected to  
40 continue due to climate change (Cook et al., 2014; Fu et al., 2016; Lin et al., 2015; Scheff and Frierson,  
41 2015), decreasing the aridity index (AI), and this was interpreted as an expansion of global dryland areas  
42 by approximately 10% by the end of this century under RCP8.5 (Feng and Fu, 2013).

1 Regional modelling studies confirm the outcomes of Global Climate Models (Africa: Terink et al., 2013;  
2 China: Yin et al., 2015; Brazil: Marengo and Bernasconi, 2015; Cook et al., 2012; Greece: Nastos et al.,  
3 2013; Italy: Coppola and Giorgi, 2009). According to the IPCC AR5 (IPCC, 2013), decreases in soil  
4 moisture are detected in the Mediterranean, Southwest USA and southern African regions. This is in line  
5 with alterations in the Hadley circulation and higher surface temperatures. This surface drying will continue  
6 to the end of this century under the RCP8.5 scenario (*high confidence*). IPCC 1.5°C (IPCC, 2018) report  
7 concluded with “*medium confidence*” that global warming by more than 1.5°C increases considerably the  
8 risk of aridity for the Mediterranean area and Southern Africa. Miao et al. (2015) showed an acceleration  
9 of desertification trends under the RCP8.5 scenario in the middle and northern part of Central Asia and  
10 some parts of north western China.

11 The projected increases in the aridity index have *very high confidence*. However, several studies have  
12 challenged the use of the AI, and PET more generally, as reliable measures of the amount of moisture  
13 available to sustain life in terrestrial ecosystems (Greve et al., 2017; Milly and Dunne, 2016). Work on CO<sub>2</sub>  
14 fertilisation suggested that PET is not a good indicator of water use as increasing CO<sub>2</sub> increases plant water  
15 use efficiency and hence there is more plant productivity with less evapotranspiration (Lemordant et al.,  
16 2018; Swann et al., 2016). Roderick et al. (2015) and Greve et al. (2017) showed that in climate models,  
17 evapotranspiration does not increase at the same rate as PET and suggest that the AI is not a good measure  
18 of aridity in an environment with changing atmospheric CO<sub>2</sub>. Evidence from precipitation, runoff or  
19 photosynthetic uptake of CO<sub>2</sub> suggest that a future warmer world will be less arid. This indicates that  
20 constant AI thresholds used to define climate classes may not be the right approach in a changing climate.

21 Climate strongly affects the mechanisms that explain wind erosion driven desertification. Wang et al.  
22 (2009) assessed future wind erosion driven desertification in arid and semiarid China using a range of SRES  
23 scenarios and HadCM3 simulations. The majority of scenarios showed a decrease in desertification by  
24 2039, increasing thereafter.

25 Global estimates of the impact of climate change on soil salinisation show that under the IS92a emissions  
26 scenario the area at risk of salinisation would increase in the future (*limited evidence, high agreement*;  
27 Schofield and Kirkby, 2003). Climate change has an influence on soil salinisation that induces further land  
28 degradation through several mechanisms that vary in their level of complexity. However, only a few  
29 examples can be found to illustrate this range of impacts, including the effect of groundwater table depletion  
30 (Rengasamy 2006) and irrigation management (Sivakumar, 2007), salt migration in coastal aquifers with  
31 decreasing water tables (Sherif and Singh, 1999; Section 4.11.6 in Chapter 4), and surface hydrology and  
32 vegetation that affect wetlands and favour salinisation (Nielsen and Brock, 2009).

### 33 34 **3.6.1.1. Future Vulnerability and Risk to Desertification**

35 Following the conceptual framework developed in previous IPCC assessments future risks are assessed by  
36 examining changes in exposure (i.e., presence of people, livelihoods and/or ecosystems, see Glossary),  
37 changes in vulnerability (predisposition to be adversely affected, see Glossary) and changes in the nature  
38 and magnitude of hazards (climate event that causes damage, see Glossary). Climate change is expected to  
39 further exacerbate the vulnerability of dryland ecosystems to desertification by increasing PET globally  
40 (Sherwood and Fu, 2014). Temperature increases between 2°C and 4°C are projected in drylands by the  
41 end of the 21<sup>st</sup> century under RCP4.5 and RCP8.5 scenarios, respectively (IPCC, 2013). Droughts also  
42 increase vulnerability to land degradation in arid zones. An assessment by Carrão et al. (2017) showed an  
43 increase in global drought hazards by mid-(2021–2050) and late-century (2071–2099) compared to a  
44 baseline (1971–2000) under all RCPs in global Mediterranean ecosystems and the Amazon region. In Latin  
45 America, Morales et al. (2011) indicated that areas affected by drought will increase significantly by 2100

1 under SRES scenarios A2 and B2. The countries expected to be affected include Guatemala, El Salvador,  
2 Honduras and Nicaragua. Globally, climate change is predicted to intensify the occurrence and severity of  
3 droughts (*medium evidence, high agreement*) (Dai, 2013; Sheffield and Wood, 2008; Swann et al., 2016;  
4 Wang, 2005; Zhao and Dai, 2015). Ukkola et al. (2018) showed large discrepancies between CMIP5 models  
5 for all types of droughts, with only precipitation drought metrics having enough agreement to provide  
6 confidence in model projections.

7 Drylands are characterised by the high climatic variability. Climate impacts on desertification are not only  
8 defined by projected trends in mean temperature and precipitation values, but are also strongly dependent  
9 on changes in climate variability and extremes (Reyer et al., 2013). The responses of ecosystems depend  
10 on diverse vegetation types. Drier ecosystems are more sensitive to changes in precipitation and temperature  
11 (Li et al., 2018; Seddon et al., 2016; You et al., 2018), increasing vulnerability to desertification. It has also  
12 been reported that areas with high variability in precipitation tend to have lower livestock densities and that  
13 those societies that have a strong dependence on livestock that graze natural forage are especially affected  
14 (Sloat et al., 2018). Social vulnerability in drylands increases as a consequence of climate change that  
15 threatens the viability of pastoral food systems (Dougill et al., 2010; López-i-Gelats et al., 2016). Social  
16 drivers can also play an important role with regards to future vulnerability (Máñez Costa et al., 2011). In  
17 the arid region of north-western China, it is estimated that under RCP4.5 areas of increased vulnerability to  
18 climate change and land desertification will largely surpass those that will experience decreased  
19 vulnerability (Liu et al., 2016).

### 21 **3.6.2. Future Projections of Impacts**

22 Future climate change is expected to affect the potential for increased soil erosion. Yang et al. (2003) use a  
23 Revised Universal Soil Loss Equation (RUSLE) model to study global soil erosion under historical, present  
24 and future conditions of both cropland and climate. Soil erosion potential has increased by about 17%, and  
25 climate change will increase this further in the future. In northern Iran, under the SRES A2 emission  
26 scenario the mean erosion potential is projected to grow by 45% till 2050 (Zare et al., 2016). In northern  
27 Australia, a decrease or an increase in rainfall post 2030 will influence the erosion rates and erosion patterns  
28 (Serpa et al., 2015). WGII AR5 concluded the impact of increases in heavy rainfall and temperature on soil  
29 erosion will be modulated by soil management practices, rainfall seasonality and land cover (Jiménez  
30 Cisneros et al., 2014).

31 Rodríguez-Caballero et al. (2018) analysed the cover of biological soil crusts under current and future  
32 environmental conditions utilizing an environmental niche modelling approach. Their results suggest that  
33 biological soil crusts currently cover about 16 million km<sup>2</sup> in drylands. Under RCP scenarios 2.6 to 8.5, 25–  
34 40% of this cover will be lost by 2070 with climate and land use being equally relevant in this process. The  
35 predicted loss is expected to substantially reduce their contribution to nitrogen cycling and to enhance dust  
36 emissions.

37 Potential dryland expansion implies lower carbon sequestration and higher risk of desertification (Huang  
38 et al., 2017), with severe impacts on land usability and threatening food security. At the level of biomes,  
39 soil carbon uptake is determined mostly by weather variability. The area of the land surface in which  
40 dryness controls CO<sub>2</sub> exchange has risen by 6% and is projected to expand by at least another 8% by 2050.  
41 In these regions net carbon uptake is about 27% lower than elsewhere (Yi et al., 2014). Evan et al. (2016)  
42 project a decrease in African dust emission associated with a slowdown of the tropical circulation in the  
43 high CO<sub>2</sub> RCP8.5 scenario.

1 World Bank (2009) projected that, without the carbon fertilisation effect, climate change will reduce the  
2 mean yields for 11 major global crops, such as millet, field pea, sugar beet, sweet potato, wheat, rice, maize,  
3 soybean, groundnut, sunflower, and rapeseed, by 15% in Sub-Saharan Africa, by 11% in Middle East and  
4 North Africa, by 18% in South Asia, and by 6% in Latin America and Caribbean by 2046–2055, compared  
5 with 1996–2005. A separate meta-analysis suggested a similar order of reduction in yields in Africa and  
6 South Asia due to climate change by 2050 (Knox et al., 2012). Schlenker and Lobell (2010) estimated that  
7 in sub-Saharan Africa, crop production may be reduced by 17–22% due to climate change by 2050. At the  
8 local level, climate change impacts on crop yields vary by location (Chapter 5). Negative impacts of climate  
9 change on agricultural productivity contribute to higher food prices. The imbalance between supply and  
10 demand for agricultural products is projected to increase agricultural prices in the range of 31% for rice to  
11 100% for maize by 2050 (Nelson et al., 2010), and cereal prices in the range between a 32% increase and  
12 a 16% decrease by 2030 (Hertel et al., 2010).

13 Desertification under climate change will threaten biodiversity in drylands (*low confidence*). A study in  
14 Colorado Plateau, USA showed that changes in climate in drylands may damage the biocrust communities  
15 by promoting rapid mortality of foundational species (Rutherford et al., 2017), while in southern California  
16 deserts climate change-driven extreme heat and drought may surpass the survival thresholds of some desert  
17 species (Bachelet et al., 2016). In semiarid Mediterranean shrublands in eastern Spain, plant species  
18 richness and plant cover are reduced by climate change and soil erosion (García-Fayos and Bochet, 2009).  
19 The main drivers of species extinctions are land use change, habitat pollution, over-exploitation, and species  
20 invasion, while the climate change is indirectly linked to species extinctions (Settele et al., 2014). Malcolm  
21 et al. (2006) found that more than 2000 plant species located within dryland biodiversity hotspots could  
22 become extinct within 100 years starting 2004 (within the Cape Floristic Region, Mediterranean Basin and  
23 Southwest Australia). Furthermore, it is suggested that climate change could cause the loss of 17% of  
24 species within shrubland and 8% within hot deserts by 2050 (van Vuuren et al., 2006) (*low confidence*). A  
25 study in the semi-arid Chinese Altai Mountains showed that mammal species richness will decline and rates  
26 of species turnover will increase, and more than 50% of their current ranges will be lost (Ye et al., 2018).

27 Changing climate and land use have resulted in higher aridity and more droughts in some drylands, with  
28 the rising role of abiotic controls of desertification (Fischlin et al., 2007). In a 2°C world, annual water  
29 discharge is projected to decline and heatwaves are projected to pose risk to food production by 2070 (Waha  
30 et al., 2017). The forecasts for Sub-Saharan Africa point to higher temperatures, increase in the number of  
31 heatwaves, and increasing aridity will affect the rain-fed agricultural systems (Serdeczny et al., 2017). A  
32 study by Wang et al. (2009) in arid and semiarid China showed decreased livestock productivity and grain  
33 yields from 2040 to 2099, threatening food security. In Central Asia, projections indicate a decrease in crop  
34 yields, and negative impacts of prolonged heat waves on population health (Reyer et al., 2017).

35  
36

### 37 **3.7. Responses to Desertification under Climate Change**

38 Increasing population pressures and potentially unprecedented nature of climatic changes could push  
39 dryland populations beyond their resilience thresholds, requiring policy and technology interventions aimed  
40 at maintaining and strengthening their resilience and adaptive capacities, and preventing them from  
41 following development trajectories consistent with the “desertification paradigm”. This section of the  
42 chapter considers each of these response options, starting from technological innovations and sustainable  
43 land management practices, through social responses undertaken by dryland households and communities  
44 at micro-level, and finally to broader policy responses.

1 Achieving sustainable development of dryland livelihoods requires avoiding dryland degradation through  
2 SLM and restoring and rehabilitating the degraded drylands due to their potential wealth of global and local  
3 ecosystem benefits and importance to human livelihoods and economies (Thomas, 2008).

4 A broad suite of on the ground response measures exist to address the syndromes of desertification (Scholes,  
5 2009), be it in the form of improved fire and grazing management, the control of erosion; integrated crop,  
6 soil and water management, among others (Liniger and Critchley, 2007; Scholes, 2009). However, firstly,  
7 it is recognised that such actions require financial, institutional and policy support to remain sustainable  
8 over the long-term (Stringer et al., 2007). Secondly, actions need to be considered as part of coupled socio-  
9 economic systems in the broader context of dryland development and long-term SLM (Reynolds et al.,  
10 2007a; Stringer et al., 2017).

11 A description and assessment of predominant on the ground actions and forms of supporting planning and  
12 policy focusing on drylands is made here in Chapter 3. The response section in Chapter 4 considers the  
13 broader process of developing SLM together with high-level responses to land degradation. Chapter 6 then  
14 considers potential interlinkages in the form of co-benefits, trade-offs and synergies of SLM measures.

15

### 16 **3.7.1. Technologies and SLM Practices: on the Ground Actions**

17 A broad range of activities and measures can potentially avoid, reduce and reverse degradation across the  
18 dryland areas of the world. Many of these actions are also contribute to climate change adaptation and  
19 mitigation goals, with further sustainable development co-benefits. An assessment is made of six activities  
20 and measures that have historically been widely considered across the biomes and anthromes of the dryland  
21 domain (Figure 3.10). The suite of actions is not exhaustive, but rather a set of activities that are particularly  
22 pertinent to global dryland ecosystems. They are not necessarily exclusive to drylands and are often  
23 implemented across a range of biomes and anthromes (Figure 3.10). The use of anthromes as a structuring  
24 element for response options is based on the essential role of interactions between social and ecological  
25 systems in driving desertification within coupled socio-ecological systems (Cherlet et al., 2018). The  
26 concept of the anthromes is explored further in Chapters 4 and 6.

27 The assessment of each action is twofold: firstly, to assess the ability of each action to address  
28 desertification and enhance climate change resilience, and secondly, to assess the potential impact of future  
29 climate change on the effectiveness of each action.

30

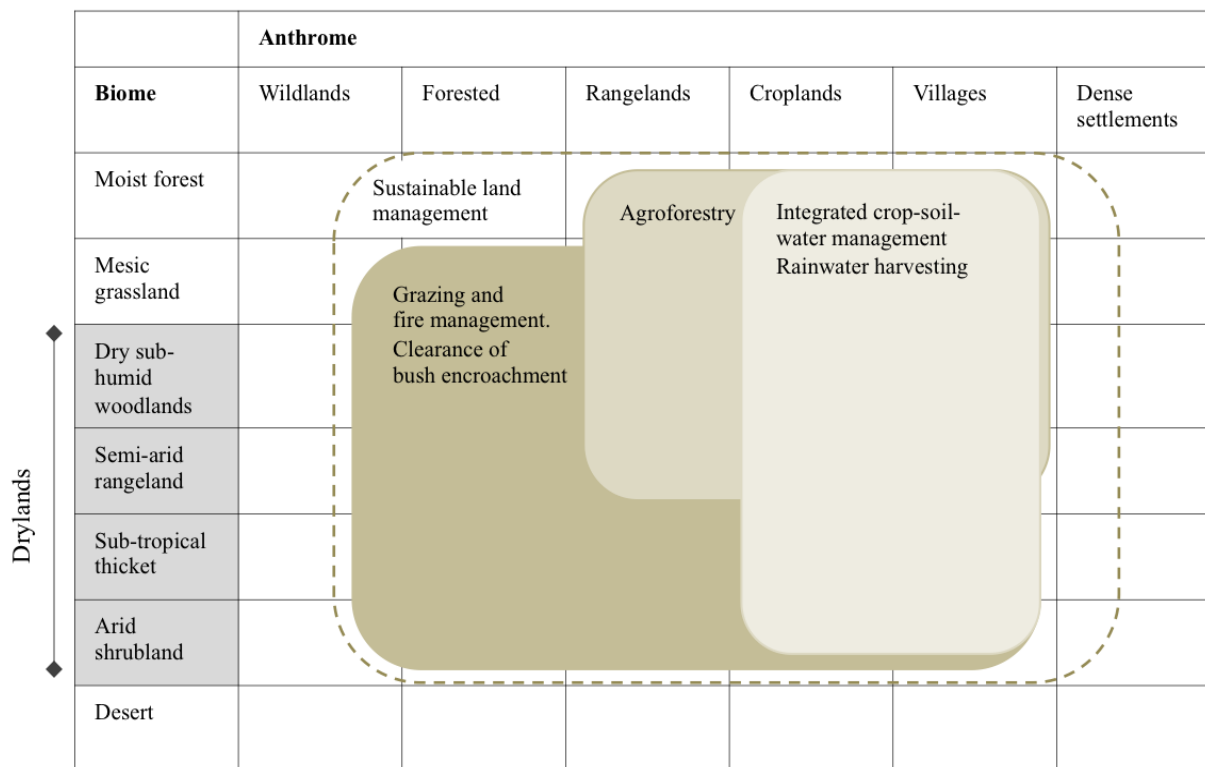

Figure 3.10 The typical distribution of on the ground actions across global biomes and anthromes

3.7.1.1. Integrated Crop-Soil-Water Management

Forms of integrated cropland management have been practiced in drylands for over thousands of years (Knörzer et al., 2009). Actions include planting a diversity of species, reducing tillage, applying organic compost and fertiliser, and maintaining vegetation and mulch cover.

In the contemporary era, these actions have been adopted within the context of SLM and ‘conservation agriculture’ to address desertification and the impact of climate change. Conservation agriculture provides a range of benefits through potentially mitigating climate change and improving agricultural production, water quality and the conservation of biodiversity (Dumanski et al., 2006). In particular, conservation agriculture helps to conserve and improve the health of topsoil that is predisposed to erosion and is essential for production of crops and further ecosystem services (Derpsch, 2005).

There is *robust evidence and medium agreement* that various cropping methods including, changing crop rotations, intercropping (inter- and intra- row planting of companion crops) and relay cropping (temporally differentiated planting of companion crops) can be used to increase production, increase the diversity of species, maintain cover over a larger fraction of the year, increase soil nitrogen and decrease the abundance of pests (Altieri and Koohafkan, 2008; Tanveer et al., 2017; Wilhelm and Wortmann, 2004; Zhang et al., 2007). For example, intercropping maize and sorghum with *Desmodium* (an insect repellent forage legume) and *Brachiaria* (an insect trapping grass) is being promoted in drylands of east and central Africa as climate-smart and profitable compared to conventional practices (Khan et al., 2014). This practice led to the productivity of maize increasing by two-three fold, while over 80% of stem borers were removed (Khan et al., 2014).

Surface runoff is a principle contributor to the degradation of soil resources, negatively impacting ecosystem services in turn. Semi-permeable stone bunds (often referred to by the French term "digue

1 filtrante") are used in dryland areas to reduce the velocity of runoff and erosion (Stroosnijder, 2003; Taye  
2 et al., 2015). Furthermore, adequate soil cover and mulching can reduce runoff (González-Núñez et al., 2004;  
3 Mwangi et al., 2015) as well as the use of cover crops such as deep and coarse rooted legume plant species  
4 (e.g., *Melilotus*, *Lathyrus* and *Linum*) that can reduce the loss of rainfall by up to 17% (Ramos et al., 2015;  
5 Yu et al., 2006).

6 A wide variety of traditional soil and water conservation methods including zai (historically practiced in  
7 West Africa), micro basins, earthen bunds and ridges (Nyamadzawo et al., 2013), *fanya juus* infiltration  
8 pits (Twomlow et al., 2008) and contour stone bunds (Garrity et al., 2010) are used in response to drought  
9 and climate variability. The use of zai (small basins traditionally used to capture surface runoff), together  
10 with the application of nitrogen fertiliser, has led up to 2000% and 250% increase in potato and bean yield  
11 respectively in Ethiopian highlands. This in turned raised household income by 20-fold (Amede et al.,  
12 2011). Integrated use of the various forms of planting pits resulted in an increase in yields of up to 300%  
13 increase in South African drylands (Twomlow et al., 2008). Zai in combination with contour stone bunds,  
14 the application of manure and tree planting can result in enhanced crop and biomass production. Up to 94%  
15 of the cultivated land was rehabilitated in areas where such methods were implemented for an extended  
16 period of time (Reij, 2009).

17 A further method employed to avoid and reverse degradation in croplands is the use of different forms of  
18 agroforestry and shelter belts (for an example, see Section 3.8.2). Tree based wind shelters were established  
19 in the pastoral regions of Northern China in the late 1970s (Yu et al., 2006). The size of shelter belts was  
20 chosen based on local conditions, wind speed and types of plant species used. Mixed species were used in  
21 50–600 m long and 4–30 m wide belts in a perpendicular orientation to wind direction (Wang et al., 2008).  
22 Shelter belts reportedly reduced wind speed, reduced soil temperature by up to 40% and increased soil  
23 moisture by 30%.

24

### 25 **3.7.1.2. Grazing and Fire Management in Drylands**

26 Humankind's use of grazing animals started approximately 8000 years ago (Mignon-Grasteau et al., 2005).  
27 In time, animal husbandry has come to form one of the principle land use options in dryland ecosystems,  
28 in which the majority of the world's grazing lands and livestock production are located (Safriel et al., 2005).  
29 Light to moderate grazing pressure has generally been shown to have minimal impact on integrity of  
30 rangelands and the ecosystem services they provide (Papanastasis et al., 2017). When correctly  
31 implemented, sustainable grazing and livestock management provides a source of food, fibre, leather, and  
32 transportation. However, overgrazing by livestock has been documented as a key driver of desertification  
33 in some contexts (D'Odorico et al., 2013; Geist and Lambin, 2004; Havstad et al., 2006; Huang et al.,  
34 2007; Manzano and Nívar, 2000), with a resulting loss of ecosystem services in terms of a reduction in  
35 livestock production, carbon sequestered in soils and the regulation of water flow and erosion. In addition  
36 to reducing litter and basal cover, intense livestock pressure can severely impact biological soil crusts,  
37 inhibiting the important role they perform in controlling erosion and fixing nutrients (Pointing and Belnap,  
38 2012; Weber et al., 2016).

39

40 Sustainable grazing and fire regimes are time and place dependent and must be developed in a context  
41 specific manner. They require the systematic monitoring of climate, vegetation and animal health to adjust  
42 livestock numbers accordingly. It is also crucial that monitoring be linked to drought contingency planning  
43 and timely management actions to avoid desertification (Torell et al., 2010; Stafford Smith and Foran,  
44 1992). Continuous heavy grazing during droughts can result in a loss of basal cover, an increase in woody

1 plants, accelerated soil erosion, increases in exotic invasive weeds and loss of ecosystem services (Archer  
2 et al., 2017). Methods to achieve sustainable grazing regimes include adjusting: 1) season of use; 2) duration  
3 of use; 3) stocking rate (animals per unit area); 4) type of livestock and balance of grazers and browsers; 5)  
4 class of livestock (e.g., yearlings vs bulls for cattle); 6) herding; 7) fencing to control access; 8) access to  
5 water; 9) location of mineral block; 10) shade structures; 11) supplemental feeding; 12) predator control  
6 and 13) silvo-pastoral practices (Bailey, 2005; Bailey et al., 2008; Fuhlendorf and Engle, 2004; Ganskopp,  
7 2001; Viswanath et al., 2018). Further management practices in the form of implementing appropriate fire  
8 regimes, the application of fertiliser, woody plant control, and reseedling can be used to restore and  
9 sustainably manage grazing lands (Fuhlendorf and Engle, 2004; Briske et al., 2011).

10 Within many dryland areas, the concept of Holistic Planned Grazing has been advocated as a process  
11 through which to enhance livestock production and restore and sustainably maintain rangeland structure,  
12 function and diversity (Savory and Parsons, 1980; Savory, 1983). The concept follows a set of key  
13 principles that aim to simulate the effect that herds of indigenous herbivores historically had on land,  
14 particularly short-duration, high-intensity grazing with long periods of rest to allow vegetation to recover  
15 (Hawkins et al., 2017). Although there are studies that indicate that farmers in certain areas have noted an  
16 increase in production and biodiversity (e.g. Stinner et al., 1997), more recent reviews and comparative  
17 assessments have questioned its effectiveness and found no difference in principle rangeland indicators  
18 when compared to season-long continuous grazing regimes (Carter et al. 2014; Nordborg and Roos 2016;  
19 Hawkins et al. 2017).

20 However, if an ecological tipping point has been exceeded, restoration to a historic state may not be  
21 economical or ecologically feasible (D’Odorico et al. 2013). In general, preventing desertification is  
22 strongly preferable and more cost-effective than allowing land to degrade and then attempting to restore it  
23 (IPBES 2018). For this reason, the Land Degradation Neutrality framework response hierarchy prioritises  
24 avoiding and reducing land degradation, before restoration measures: *Avoid > Reduce > Reverse* (Cowie  
25 et al., 2018; Orr et al., 2017).

26

### 27 **3.7.1.3. Clearance of Bush Encroachment**

28 The encroachment of open grassland and savannah ecosystems by woody species has occurred for at least  
29 the past 100 years (Archer et al., 2017; O’Connor et al., 2014), with clearly documented trends in southern  
30 Africa (Dougill et al., 2016; Joubert et al., 2008; O’Connor et al., 2014), North America (Archer et al.,  
31 2017; Barger et al., 2011) and Australia (Eldridge and Soliveres, 2014). Dependent on the type and intensity  
32 of encroachment, it may lead to a net loss of ecosystem services and be viewed as a form of ecosystem  
33 degradation and desertification. At intense levels, where a closing woody plant canopy inhibits grass  
34 production, bush encroachment can lead to a decrease in stream flow, fodder production and further  
35 ecosystem services, resulting in desertification (Dougill et al., 2016; O’Connor et al., 2014). However, there  
36 are circumstances where bush encroachment may lead to a net increase in ecosystem services, especially at  
37 intermediate levels of encroachment (Eldridge et al., 2011; Eldridge and Soliveres, 2014). In certain areas,  
38 an intermediate level of woody cover may be desired where the ability of the landscape to produce fodder  
39 for livestock is retained, while the production of wood and associated products increases. This may be  
40 particularly important in regions such as southern Africa where 95% of rural households depend on wood  
41 fuel from surrounding landscapes as well as livestock production (Shackleton and Shackleton, 2004).

42

1 Where bush encroachment has been assessed as a form of degradation, there are often substantial efforts to  
2 clear woody species. Early bush clearing efforts can be found in Namibia where a national program is aimed  
3 at clearing woody species through mechanical measures (harvesting of trees or clearance by bulldozers and  
4 heavy rollers) as well as the application of arboricides (Smit et al., 2015). However, the long-term success  
5 of clearance and improved fire and grazing management remains to be evaluated, especially restoration  
6 back towards an ‘original state’ with associated ecosystem services and biodiversity. In particular regions,  
7 for example, northern Namibia, the rapid reestablishment of woody seedlings following clearing has raised  
8 questions about whether full clearance and restoration is possible (Smit et al., 2015). The underlying drivers  
9 of encroachment need to be addressed, in particular overgrazing and fire regimes that may have led to the  
10 initial encroachment (Eldridge and Soliveres, 2014). If these primary drivers of woody plant encroachment  
11 cannot be addressed, it is likely that the landscape will be invaded once again. In such cases, a new form of  
12 “emerging ecosystem” (Milton, 2003) may need to be explored that includes both improved livestock and  
13 fire management as well as the utilisation of biomass as a long-term commodity and source of revenue  
14 (Smit et al., 2015).

15 Lastly, the cost of clearing and the economic feasibility of generating products such as sawn timber, fencing  
16 poles, fuel wood and commercial energy production opportunities remains to be assessed in full. Initial  
17 studies in Namibia and South Africa (Stafford-Smith et al., 2017) indicate that there may be good  
18 opportunity, but factors such as the cost of transport can substantially influence the financial feasibility of  
19 implementation. This remains an area where additional research is required.

20

#### 21 **3.7.1.4. Rainwater Harvesting**

22 Rainwater harvesting (RWH) provides a means of increasing the amount of water available for agriculture  
23 and livelihoods through the capture and storage of runoff and peak flow. It is often highlighted as a practical  
24 response to climate change and dryness (i.e., long-term aridity and low seasonal precipitation) as it forms  
25 a partial buffer against rainfall variability that is already relatively high within drylands and predicted to  
26 become more acute over time (Dile et al., 2013; Vohland and Barry, 2009). For these reasons, RWH is  
27 recommended by the UNCCD and is widely implemented by government and non-governmental agencies,  
28 often as part of a broader suite of rural development and water, agriculture and land management activities  
29 (Dile et al., 2013; Vohland and Barry, 2009; Yosef and Asmamaw, 2015).

30

31 One of the primary reasons for implementing RWH is to improve agricultural output and resilience. There  
32 is *high agreement* that the implementation of RWH systems leads to an increase in agricultural production  
33 in drylands (see reviews by Biazin et al., 2012; Bouma et al., 2016; Dile et al., 2013). A meta-analysis of  
34 changes in crop production due to the adoption of RWH techniques across the drylands of Africa and Asia  
35 noted an average increase in yields of 78%, ranging from –28% to 468% (Bouma et al., 2016). Of particular  
36 relevance to anticipated climate change in drylands, is that across the dataset of 158 assessments, studies in  
37 dry years with rainfall below 330 mm had the highest observed yield improvements.

38 RWH can result in modified landscapes and impact ecosystem functioning at a range of temporal and spatial  
39 scales (Vohland and Barry, 2009). For example, at a plot scale, RWH structures may increase available  
40 water and enhance agricultural production, biomass accumulation, soil organic carbon and nutrient  
41 availability (Singh et al., 2012; Vohland and Barry, 2009; Yosef and Asmamaw, 2015). However, at a  
42 catchment scale, it may reduce runoff and important flows to wetlands and downstream urban economies  
43 (Meijer et al., 2013).

1 Yet despite delivering a clear set of benefits, initial adoption and long-term sustainability may be inhibited  
2 by a number of economic and institutional reasons. There is a growing focus in recent literature on the  
3 governance of RWH systems, including financial, institutional, social, and water and land use planning  
4 considerations that impact the sustainability of not only new measures, but those that have been in place  
5 for hundreds of years (Bitterman et al., 2016).

6 Initial adoption is often inhibited by socio-economic status of parties living in drylands (Bahta and  
7 Lombard, 2017; Kajisa et al., 2007). Based on broad model of costs and returns, Bouma et al. (2016)  
8 illustrated that period required to pay-back the capital investment in RWH is approximately 2 years in Asia  
9 and 15 years in African drylands. While remaining viable and delivering a broad suite of benefits, this  
10 relatively high upfront cost may explain why some farmers are reluctant to invest.

11 Aside from potential economic constraints, broader consideration of how RWH incorporated in coupled  
12 human-ecological landscapes is required (Dile et al., 2013). The effectiveness of RWH interventions, even  
13 those that have been in place for hundreds of years, may be affected by invasive species, urbanisation and  
14 a lack of their consideration in broader land use planning (Bitterman et al., 2016). Furthermore, the  
15 inappropriate storage of water in warm climates can lead to an increase in water related diseases and  
16 associated health issues unless managed correctly (Boelee et al., 2013). Whereas the outcomes of RWH at  
17 a plot scale are well understood, its integration into modern emerging dryland landscapes requires further  
18 investigation. This includes considering its broader role in assisting communities to adapt to climate change.  
19 Although its ability to improve the resilience of dryland agriculture is relatively well known, a broader  
20 understanding of its impact on landscape resilience and disaster risk reduction is required.

### 22 *3.7.1.5 Use of Halophytes for the Revegetation of Saline Lands*

23 Soil salinity can severely limit the growth and productivity of crops (Jan et al., 2017) and lead to a decrease  
24 in available arable land. Salinity reduces the productive capacity of soil through numerous morphological,  
25 physiological and biochemical processes, which lead to high seed mortality, poor or delayed germination,  
26 poor crop stand, stunted growth and reduced yield (Ahmad et al., 2010; Ashraf et al., 2012). Saline land  
27 usually becomes loosely structured, powdery and highly erosive. This increases the erosion of soil by wind  
28 as well as water through particle-laden runoff (Hameed et al., 2008; Qadir et al., 2009). The salinity of land  
29 can increase to an extent where the cultivation of normal crops becomes impossible.

30 In terms of response options, leaching and drainage provides a possible solution, but can be prohibitively  
31 expensive. An alternative, more economical option, is the growth of halophytes (plants that are adapted to  
32 grow under highly saline conditions) that allow saline land to be used in a productive manner. Adoption of  
33 such crops is not new; they were used during the ancient civilisation of Mesopotamia, and they in effect,  
34 allow farmers to reclaim farmland (Gul and Khan, 2003). The biomass produced can be used as forage,  
35 food, feed, essential oils, biofuel, timber, fuelwood (Chughtai et al., 2015; Mahmood et al., 2016; Sharma  
36 et al., 2016). A further co-benefit is the opportunity to mitigate climate change through the enhancement of  
37 terrestrial carbon stocks as land is revegetated (Dagar et al., 2014; Wicke et al., 2013).

38 In Pakistan, where about 6.2 million hectares of fertile land is affected by salinity, pioneering work on  
39 utilising salt tolerant plants for the revegetation of saline lands (Biosaline Agriculture) was done in the early  
40 1970s at the Nuclear Institute for Agriculture (NIAB, 1997). Under this approach, a succession of plants is  
41 grown, ranging from highly salt tolerant grasses and woody plants, to salt tolerant crops, and the produced  
42 biomass is used for various economical purposes. A number of local and exotic varieties were initially  
43 screened for salt tolerance in lab- and greenhouse based studies, and then distributed to further saline areas

1 with similar land and socioeconomic conditions (Ashraf et al., 2010). The selected salt tolerant species  
2 included tree species (*Acacia ampliceps*, *A. nilotica*, *Eucalyptus camaldulensis*, *Prosopis juliflora*,  
3 *Azadirachta indica*) (Awan and Mahmood, 2017), forage plants (*Leptochloa fusca*, *Sporobolus arabicus*,  
4 *Brachiaria mutica*, *Echinochloa* sp., *Sesbania* and *Atriplex* spp.) and crop species including varieties of  
5 barley (*Hordeum vulgare*), cotton (*Gossypium hirsutum*), wheat (*Triticum aestivum*) and *Brassica* spp  
6 (Mahmood et al., 2016).

7 In India and elsewhere, tree species including *Prosopis juliflora*, *Dalbergia sissoo*, *Eucalyptus tereticornis*  
8 have been used to revegetate saline land. Certain biofuel crops in the form of *Ricinus communis* (Abideen  
9 et al., 2014), *Euphorbia antisyphilitica* (Dagar et al., 2014), *Karelinia caspia* (Akinshina et al., 2016) and  
10 *Salicornia* spp. (Sanandiya and Siddhanta, 2014) are grown in saline areas and *Panicum turgidum* (Koyro  
11 et al., 2013) has been grown as fodder crop on degraded soils with brackish water.

12

### 13 **3.7.1.6 Incentivising Sustainable Land Management and Restoration**

14 The adoption of SLM practices depends on the compatibility of the technology with prevailing socio-  
15 economic and bio-physical conditions (Sanz et al., 2017). Globally, it was shown that every dollar invested  
16 into restoring degraded lands yields social returns in the range of 2–5 dollars over a 30-year period (Nkonya  
17 et al., 2016a). A similar range of returns from land restoration activities were found in Central Asia  
18 (Mirzabaev et al., 2016), Ethiopia (Gebreselassie et al., 2016), India (Mythili and Goedecke, 2016), Kenya  
19 (Mulinge et al., 2016) Niger (Moussa et al., 2016) and Senegal (Sow et al., 2016). Despite these relatively  
20 high returns, there is *robust evidence* that the adoption of SLM practices remains low (Cordingley et al.,  
21 2015; Giger et al., 2015; Lokonon and Mbaye, 2018). Part of the reason for these low adoption rates is that  
22 the major share of the returns from SLM are social benefits, namely in the form of non-provisioning  
23 ecosystem services (Nkonya, et al., 2016a). The adoption of SLM technologies does not always provide  
24 implementers with immediate private benefits (Schmidt et al., 2017), high initial investment costs,  
25 institutional and governance constraints and a lack of access to technologies and equipment may inhibit  
26 their adoption further (Sanz et al., 2017; Giger et al., 2015; Schmidt et al., 2017). Furthermore, market  
27 failures in the form of lack of access to credit, input and output markets, and insecure land tenure (Section  
28 3.2.3) result in the lack of adoption of SLM technologies (Moussa et al., 2016). Enabling policy frameworks  
29 contribute to overcoming these market failures (Section 3.7.3). Measures to expand payments for ecosystem  
30 services, or inclusion of subsidies that support SLM adoption in existing agricultural support policies, are  
31 *likely* to lead to a higher level of adoption of SLM and land restoration activities (Schiappacasse et al.,  
32 2012; Lambin et al., 2014; van Zanten et al., 2014; Reed et al., 2015; Bouma and Wösten, 2016; Section  
33 3.7.3).

34

### 35 **3.7.2. Socio-economic Responses**

36 Socio-economic and policy responses are often crucial in enhancing the adoption of SLM practices  
37 (Fleskens and Stringer, 2014; Cordingley et al., 2015; Nyanga et al., 2016) and for assisting agricultural  
38 households to diversify their sources of income (Shiferaw and Djido, 2016; Barrett et al., 2017). Technology  
39 and socio-economic responses are not independent, but are in continuously evolving interaction (Hornbeck,  
40 2012; Liu and Lan, 2015).

41

### 3.7.2.1. Socio-economic Responses for Combating Desertification Under Climate Change

Desertification limits the choice of potential climate change mitigation and adaptation response options. Furthermore, many additional factors, for example, a lack of access to markets or insecurity of land tenure, hinder the adoption of SLM. An important consideration is that these factors are largely beyond the control of individuals or local communities and require broader policy interventions (Section 3.7.3). Nevertheless, local collective action and indigenous and local knowledge are still crucial to the ability of households to respond to the combined challenge of climate change and desertification.

**The use of indigenous and local knowledge** enhances the success of SLM and its ability to address desertification (Altieri and Nicholls, 2017; Engdawork and Hans-Rudolf, 2016). There are abundant examples of how indigenous and local knowledge, also often referred to as agroecological techniques (Altieri, 2018), has allowed livelihood systems in drylands to be maintained despite environmental constraints.

An example is the numerous traditional water harvesting techniques that are used across the drylands to adapt to dry spells and climate change. These include creating planting pits (“zai”, “ngoro”) and micro-basins, contouring hill slopes and terracing (Biazin et al., 2012) (Section 3.7.1). Traditional “ndiva” water harvesting system in Tanzania enables the capture of runoff water from highland areas to downstream community-managed micro-dams for subsequent farm delivery through small scale canal networks (Enfors and Gordon, 2008).

A further example are pastoralist communities located in drylands who have developed numerous methods to sustainably manage rangelands. Pastoralist communities in Morocco developed the “agdal” system of seasonally alternating use of rangelands to limit overgrazing (Dominguez, 2014) as well as to manage forests in the Moroccan High Atlas Mountains (Auclair et al., 2011). Across North Africa and the Middle East, a similar rotational grazing system “hema” was historically practiced by the Bedouin communities (Hussein, 2011; Louhaichi and Tastad, 2010). The Beni-Amer herders in the Horn of Africa have developed complex livestock breeding and selection systems (Fre, 2018).

Although well adapted to resource-sparse dryland environments, traditional practices are currently not able to cope with increased demand and environmental changes (Enfors and Gordon, 2008; Engdawork and Hans-Rudolf, 2016). Moreover, there is *robust evidence* documenting the marginalisation or loss of indigenous and local knowledge (Fernández-Giménez and Fillat Estaque, 2012; Hussein, 2011; Kodirekkala, 2017; Moreno-Calles et al., 2012; Dominguez, 2014). In this context, innovative combinations of indigenous and local knowledge and modern management practices can contribute to overcoming the combined challenge of climate change and desertification (Engdawork and Hans-Rudolf, 2016; Guzman et al., 2018).

**Collective action** is a result of social capital and has the potential to contribute to the sustainable management of common resources and climate change adaptation (Adger, 2003; Engdawork and Hans-Rudolf, 2016; Eriksen and Lind, 2009; Ostrom, 2009; Rodima-Taylor et al., 2012). Social capital is divided into structural and cognitive forms, structural corresponding to strong networks (including outside one’s immediate community) and cognitive encompassing mutual trust and cooperation within communities (van Rijn et al., 2012; Woolcock and Narayan, 2000). Social capital is more important for economic growth in settings with weak formal institutions, and less so in those with strong enforcement of formal institutions (Ahlerup et al., 2009). There are cases throughout the drylands showing that community bylaws and collective action successfully limited land degradation and facilitated SLM (Ajayi et al., 2016; Infante, 2017; Kassie et al., 2013; Nyangena, 2008; Willy and Holm-Müller, 2013; Wossen et al., 2015). However, there are also cases when they did not improve SLM where they were not strictly enforced (Teshome et al.,

1 2016). Collective action for implementing responses to dryland degradation is often hindered by local  
2 asymmetric power relations and “elite capture” (Kihiu, 2016; Stringer et al., 2007).

3 This illustrates that different levels and types of social capital result in different levels of collective action.  
4 In a sample of East, West and southern African countries, structural social capital in the form of access to  
5 networks outside one’s own community was suggested to stimulate the adoption of agricultural innovations,  
6 whereas cognitive social capital, associated with inward-looking community norms of trust and  
7 cooperation, was found to have a negative relationship with the adoption of agricultural innovations (van  
8 Rijn et al., 2012). The latter is indirectly corroborated by observations of the impact of community-based  
9 rangeland management organisations in Mongolia. Although levels of cognitive social capital did not differ  
10 between them, communities with strong links to outside networks were able to apply more innovative  
11 rangeland management practices in comparison to communities without such links (Ulambayar et al.,  
12 2017).

13 **Farmer-led innovations.** Agricultural households are not just passive adopters of externally developed  
14 technologies, but are active experimenters and innovators (Reij and Waters-Bayer, 2001; Tambo and  
15 Wünscher, 2015; Waters-Bayer et al., 2009). SLM technologies co-generated through direct participation  
16 of agricultural households have higher chances of being accepted by them (Bonney et al., 2016; Le et al.,  
17 2016a; Vente et al., 2016). Usually farmer-driven innovations are more frugal and better adapted to their  
18 resource scarcities than externally introduced technologies (Gupta et al., 2016). Farmer-to-farmer sharing  
19 of their own innovations and mutual learning positively contribute to higher technology adoption rates (Dey  
20 et al., 2017). This innovative ability can be given a new dynamism by combining it with emerging external  
21 technologies. For example, emerging low-cost phone applications that are linked to soil and water  
22 monitoring sensors can provide farmers with previously inaccessible information and guidance (Cornell et  
23 al., 2013; Herrick et al., 2017; McKinley et al., 2017; Steger et al., 2017).

24 Despite the ingenuity, innovation and collective action of dryland residents, their adoption of SLM practices  
25 remains insufficient to address desertification and adapt to climate change due to the highlighted constraints  
26 to the use of indigenous and local knowledge and collective action, as well as economic and institutional  
27 barriers for SLM adoption (Banadda, 2010; Cordingley et al., 2015; Lokonon and Mbaye, 2018; Mulinge  
28 et al., 2016; Nkonya et al., 2016c; Wildemeersch et al., 2015; Sections 3.2.4.2 and 3.7.1.6). Sustainable  
29 development of drylands under these socio-economic and environmental (climate change-desertification)  
30 conditions will also depend on the ability of dryland agricultural households to diversify their livelihoods  
31 sources (Boserup, 1965; Safriel and Adeel, 2008).

32

### 33 **3.7.2.2. Socio-Economic Responses for Economic Diversification**

34 **Livelihood diversification** through non-farm employment increases the resilience of rural households  
35 against desertification and extreme weather events by diversifying their income and consumption (*robust*  
36 *evidence, high agreement*). Moreover, it can provide the funds to invest into SLM (Belay et al., 2017; Bryan  
37 et al., 2009; Dumenu and Obeng, 2016; Salik et al., 2017; Shiferaw et al., 2009; Varghese and Singh, 2016).  
38 Access to non-agricultural employment is especially important for smallholder pastoral households as their  
39 small herd sizes make them less resilient to drought (Lybbert et al. 2004). However, access to alternative  
40 opportunities is limited in the rural areas of many developing countries, especially for women and  
41 marginalised groups who lack education and social networks (Reardon et al., 2008).

42

43 **Migration** is frequently used as an adaptation strategy to environmental change (*medium evidence, high*  
44 *agreement*). Migration is a form of livelihood diversification and a potential response option to

1 desertification and increasing risk to agricultural livelihoods under climate change (Walther et al., 2002).  
2 Migration can be short-term (e.g., seasonal) or long-term, internal within a country or international. There  
3 is *medium evidence* showing rural households responding to desertification and droughts through all forms  
4 of migration, for example, during the Dust Bowl in the United States in the 1930s (Hornbeck, 2012), and  
5 during droughts in Burkina Faso in the 2000s (Barbier et al., 2009) and in Mexico in the 1990s (Nawrotzki  
6 et al., 2016). There is *robust evidence* showing that migration decisions are influenced by a complex set of  
7 different factors, with desertification and climate change playing relatively lesser roles (Liehr et al., 2016)  
8 (3.5.2). Barrios et al. (2006) found that urbanisation in Sub-Saharan Africa was partially influenced by  
9 climatic factors during the 1950 to 2000 period, in parallel to liberalisation of internal restrictions on labour  
10 movements: with 1% reduction in rainfall associated with 0.45% increase in urbanisation. This migration  
11 favoured more industrially-diverse urban areas in Sub-Saharan Africa (Henderson et al., 2017), because  
12 they offer more diverse employment opportunities and higher wages. Similar trends were also observed in  
13 Iran in response to water scarcity (Madani et al., 2016). However, migration involves some initial  
14 investments. For this reason, reductions in agricultural incomes due to climate change or desertification  
15 have the potential to decrease out-migration among the poorest agricultural households who become less  
16 able to afford migration (Cattaneo and Peri, 2016), thus increasing social inequalities. On the other hand,  
17 there is *high agreement* that households with migrant worker members are more resilient against extreme  
18 weather events and environmental degradation as compared to non-migrant households who are more  
19 dependent on agricultural income (Liehr et al., 2016; Salik et al., 2017; Sikder and Higgins, 2017).  
20 Remittances from migrant household members potentially contribute to SLM adoptions, however,  
21 substantial out-migration was also found to constrain the implementation of labour-intensive land  
22 management practices (Chen et al., 2014; Liu et al., 2016).

23

### 24 **3.7.3. Policy Responses**

25 Many socio-economic factors shaping individual responses to desertification typically operate at larger  
26 scales (Scholes, 2009). Individual households and communities do not exercise control over these factors,  
27 such as land tenure insecurity, lack of property rights, lack of access to markets, availability of rural  
28 advisory services, and agricultural price distortions. These factors are shaped by national government  
29 policies and international markets. As in the case with socio-economic responses, policy responses are  
30 classified below in two ways: those which seek to combat desertification under changing climate through  
31 avoiding, reducing and reversing it (Cowie et al., 2018; Orr et al., 2017); and those which seek to provide  
32 alternative livelihood sources through economic diversification. These options are mutually complementary  
33 and contribute to all the three hierarchical elements of the Land Degradation Neutrality framework, namely,  
34 avoiding, reducing and reversing land degradation (Cowie et al., 2018; Orr et al., 2017).

35

#### 36 **3.7.3.1. Policy Responses towards Combating Desertification under Climate Change**

37 Policy responses to combat desertification take numerous forms. Below we discuss some major ones  
38 consistently highlighted across the literature also in connection with climate change, because these response  
39 options were found to strengthen adaptation capacities and to contribute to climate change mitigation. They  
40 include improving market access, gender empowerment, expanding access to rural advisory services,  
41 strengthening land tenure security, payments for ecosystem services, decentralised natural resource  
42 management, investing into research and monitoring of desertification and dust storms, and investing into  
43 modern renewable energy sources.

1 ***Policies aiming at improving market access***, that is the ability to access output and input markets at lower  
2 costs by farming households, help agricultural producers to sell more of their produce at higher prices.  
3 Increased profits both motivate and enable them to invest more into sustainable land management. High  
4 access to input, output and credit markets is a major determinant for the adoption of sustainable land  
5 management practices in a wide number of settings across the drylands (Aw-Hassan et al., 2016; Kirui,  
6 2016; Mythili and Goedecke, 2016; Nkonya and Anderson, 2015; Sow et al., 2016). Lack of access to credit  
7 limits adjustments and agricultural responses to the impacts of desertification-climatic interaction, with  
8 long-term consequences on the livelihoods and incomes, as was shown for the case of the American Dust  
9 Bowl during 1930s (Hornbeck, 2012). Government policies aimed at improving market access usually  
10 involve constructing and upgrading rural-urban transportation infrastructures. However, besides  
11 infrastructural constraints, providing improved access often involves relieving institutional constraints to  
12 market access (Little, 2010).

13 ***Gender empowerment***. A greater emphasis on understanding gender-specific differences over land-use and  
14 land management practices as an entry point is *likely* to make land restoration projects more successful  
15 (Broeckhoven and Cliquet, 2015; Carr and Thompson, 2014; Catacutan and Villamor, 2016; Dah-gbeto and  
16 Villamor, 2016). This includes taking into account the differences of men and women in processing similar  
17 information as well as their perception to risk and uncertainties (Slovic, 1999). In relation to representation  
18 and authority to make decisions in land management and governance, women's participation remains  
19 lacking particularly in the dryland regions. Thus, ensuring women's rights means accepting women as equal  
20 members of the community and citizens of the state (Nelson et al., 2015). This includes equitable access of  
21 women to resources (including extension services), networks, and markets. In areas where socio-cultural  
22 norms and practices devalue women and undermine their participation, actions for empowering women will  
23 require changes in customary norms, recognition of women's (land) rights in government policies and  
24 programs to assure that their interests are better represented. In addition, several novel concepts are recently  
25 applied for an in-depth understanding of gender in relation to science-policy interface. Among these are the  
26 concepts of intersectionality (Thompson-Hall et al., 2016), bounded rationality for gendered decision  
27 making (Villamor and van Noordwijk, 2016), anticipatory learning (Dah-gbeto and Villamor, 2016) and  
28 systematic leverage points (Manlosa et al., 2018), which all aim to improve gender equality within agro-  
29 ecological landscapes through systems approach.

30 ***Expanding access to rural advisory services***. Awareness of desertification and associated land degradation  
31 problems was found to be a significant factor to incentivising the adoption of sustainable land management  
32 practices (Kassie et al., 2015; Nkonya et al., 2015; Nyanga et al., 2016). Agricultural initiatives to improve  
33 the adaptive capacities of vulnerable populations were more successful when they were conducted through  
34 reorganised social institutions and improved communication (Osbaahr et al., 2008). Improved  
35 communication and education could be facilitated by wider use of new information and communication  
36 technologies (Peters et al., 2015). Investments into education were associated with higher investments into  
37 soil conservation measures (Tenge et al., 2004). Bryan et al. (2009) found that access to information was  
38 the prominent facilitator of climate change adaptation in Ethiopia. However, resource constraints of rural  
39 advisory services, and disconnects between advisory policy and climate policy can hinder the dissemination  
40 of climate smart agricultural technologies (Morton, 2017). Lack of knowledge was also found to be a  
41 significant barrier to implementation of soil rehabilitation programs in the Mediterranean region (Reichardt,  
42 2010). Rural advisory services will be able to facilitate SLM best when they also serve as platforms for  
43 sharing indigenous and local knowledge and farmer innovations (Mapfumo et al., 2016). Participatory  
44 research initiatives conducted jointly with farmers have higher chances of resulting in technology adoption  
45 (Bonney et al., 2016; Le et al., 2016a; Vente et al., 2016; Rusike et al., 2006). Moreover, rural advisory

1 services are often more successful in disseminating technological innovations when they adopt  
2 commodity/value chain approaches, remain open to engagement in input supply, make use of new  
3 opportunities presented by ICTs, and facilitate mutual learning between multiple stakeholders (Morton,  
4 2017).

5 ***Strengthening land tenure security.*** There is *robust evidence* that strengthening land tenure security is a  
6 major factor contributing to the adoption of soil conservation measures in croplands (Aw-Hassan et al.,  
7 2016; Kirui, 2016; Mythili and Goedecke, 2016; Sow et al., 2016). Moreover, land tenure security leads to  
8 more investment in trees (Deininger and Jin, 2006; Etongo et al., 2015). Secure land tenure increased  
9 investments into SLM practices in Ghana but it did not affect farm productivity (Abdulai et al., 2011).  
10 Secure land tenure, especially for communally managed lands, helps reduce arbitrary appropriations of land  
11 for large scale commercial farms (Baumgartner, 2017; Dell'Angelo et al., 2017; Aha and Ayitey, 2017). In  
12 contrast, privatisation of rangeland tenures in Botswana and Kenya led to the loss of communal grazing  
13 lands and actually increased rangeland degradation (Basupi et al., 2017; Kihui, 2016) as pastoralists needed  
14 to graze livestock on now smaller communal pastures. Since food insecurity in drylands is driven mainly  
15 by climate risks, there is *robust evidence and high agreement* that institutions need to respond with flexible  
16 tenure, allowing mobility for pastoralist communities, and not fragmenting their areas of movement  
17 (Behnke, 1994; Turner et al., 2016; Holden and Ghebru, 2016; Wario et al., 2016; Liao et al., 2017). More  
18 research is needed on the optimal tenure mix, including low-cost land certification, redistribution reforms,  
19 market-assisted reforms and gender focused reforms, as well as collective forms of land tenure such as  
20 communal land tenure and cooperative land tenure.

21 ***Payment for ecosystem services (PES)*** provide incentives for the land restoration and SLM (Lambin et al.,  
22 2014; Reed et al., 2015; Schiappacasse et al., 2012). Several studies illustrate that social cost of  
23 desertification are larger than its private cost (Costanza et al., 2014; Nkonya et al., 2016a). Therefore,  
24 although SLM can generate positive externalities that are often public goods, individual land custodians  
25 underinvest in SLM as they are unable to reap all the benefits. Payment for ecosystem services provides a  
26 mechanism through which some of these benefits can be transferred to land users, thereby stimulating  
27 further investment in SLM. However, PES has not worked well in countries with fragile institutions  
28 (Karsenty and Ongolo, 2012). Equity and justice in distributing the payments for ecosystem services were  
29 found to be key for the success of the PES programs in Yunnan, China (He and Sikor, 2015). Yet, when  
30 reviewing the performance of PES programs in the tropics, Calvet-Mir et al. (2015), found that they are  
31 generally effective in terms of environmental outcomes, despite being sometimes unfair. It is suggested that  
32 the implementation of PES will be improved through decentralised approaches giving local communities a  
33 larger role in the decision making process (He and Lang, 2015).

34 ***Decentralisation of natural resource management.*** Local institutions often play a vital role in  
35 implementing SLM initiatives (Gibson et al., 2005). Pastoralists involved in community-based natural  
36 resource management in Mongolia had greater capacity to adapt to extreme winter frosts resulting in less  
37 damage to their livestock (Fernández-Giménez et al., 2015). Decreasing the power and role of traditional  
38 community institutions, due to top-down public policies, resulted in lower success rates in community-  
39 based programs focused on rangeland management in Dirre, Ethiopia (Abdu and Robinson, 2017).  
40 Decentralised governance leads to improved management in forested landscapes (Ostrom and Nagendra,  
41 2006; Dressler et al., 2010). However, when local elites were placed in control, decentralised natural  
42 resource management negatively impacted the livelihoods of the poor who were dependent on forest  
43 products (Dressler et al., 2010).

1 ***Investing in research and development.*** Desertification has received substantial research attention over  
2 recent decades (Turner et al., 2007). There is also a growing research interest on climate change adaptation  
3 and mitigation interventions related to desertification drivers (Grainger, 2009). Agricultural research on  
4 SLM practices has generated a significant number of new innovations and technologies that increase crop  
5 yields without degrading the land (see Section 3.7.1). There is *high agreement and robust evidence* that  
6 such technologies help improve the food security of smallholder dryland farming households (Harris and  
7 Orr, 2014, Chapter 6). Strengthening research on desertification is of paramount importance not only to  
8 meet Sustainable Development Goals (SDGs) but also effectively manage ecosystems based on solid  
9 scientific knowledge. Research is needed on degradation mechanisms and environmental restoration  
10 methods, and on unravelling the impact of globalisation on drylands (Bisaro et al., 2011); and ecological  
11 ramifications of climate change and its impact on ecosystem services and biodiversity (Ren et al., 2008).  
12 Sources of desert dust, the process of their emission and transportation over long distances before  
13 redeposition are insufficiently studied (Middleton, 2017). In addition, the impact of desert dust on  
14 ecosystems and human and animal health is not fully understood. More investment into research institutes  
15 and training the younger generation of researchers helps addressing the combined challenges of  
16 desertification and climate change (Akhtar-Schuster et al., 2011; Verstraete et al., 2011). This includes  
17 improved knowledge management systems that allows stakeholders to work in a coordinated manner by  
18 enhancing timely, targeted and contextualised information sharing (Chasek et al., 2011). Knowledge and  
19 flow of knowledge on desertification is currently highly fragmented, constraining effectiveness of those  
20 engaged in assessing and monitoring the phenomenon at various levels (Reed et al. 2011).

21 ***Investing into monitoring of desertification and deserts storms.*** Actions to combat desertification are  
22 numerous and diversified, but often lack effectiveness because they are not based on scientific data from  
23 long-term ecological and socio-economic observations (Sergeant et al., 2012). Risks related to climate  
24 change further emphasise the need for reliable and long-term environmental data (Cornet, 2012; Haase et  
25 al., 2018). For monitoring desertification, integration of biophysical (climate, ecological factors,  
26 biodiversity) and socio-economic aspects (use of natural resources by local population) provides a basis for  
27 better vulnerability prediction and assessment (OSS, 2012; Vogt et al., 2011b). Creation of sandstorm alert  
28 systems can help strengthen research on siltation and desert dust (Nickovic et al., 2012). Some well-known  
29 examples of previous monitoring observatories and related initiatives include the observation stations of  
30 the "Arid Zones" program of UNESCO (1952–1960), the study sites of the International Biological Program  
31 (IBP), the observatories of the Long Term Ecological Research Program of the USA, Integrated Carbon  
32 Observation System (ICOS), National Ecological, Observatory Network (NEON; USA), Terrestrial  
33 Ecosystem Research Network (TERN; Australia), the DESERTLINKS project by the European Union;  
34 Cameleo (Changes in Arid Mediterranean Ecosystems on the long term and Earth Observation), ROSELT  
35 (Network of Observatories of Long-Term Ecological Monitoring) is a program initiated by the OSS at the  
36 level of the countries of the Sahel and North Africa (OSS, 2012) - whose experiences could be evaluated  
37 for the design of future successful programs.

38 ***Developing modern renewable energy sources.*** Populations in most developing countries continue to rely  
39 on traditional biomass, including fuelwood, crop straws and livestock manure, for a major share of their  
40 energy needs, with the highest dependence in sub-Saharan Africa (IEA 2013; Amugune et al. 2017). Use  
41 of biomass for energy, mostly fuelwood (especially as charcoal), was associated with deforestation and  
42 desertification in some dryland areas (Neufeldt et al., 2015; Iiyama et al., 2014; Mekuria et al., 2018; Zulu,  
43 2010), while in some other areas there was no link between fuelwood collection and desertification (Simon  
44 and Peterson 2018; Twine and Holdo 2016; Swemmer et al. 2018). Jiang et al. (2014) indicated that  
45 providing improved access to alternative energy sources such as solar energy and biogas could help reduce

1 the use of fuelwood in south-western China, thus alleviating the spread of desertification. Transition to  
2 renewable energy sources in high-income countries in dryland areas primarily contributes to reducing  
3 greenhouse gas emissions and mitigating climate change, with some other co-benefits such as  
4 diversification of energy sources (Bang, 2010), while the impacts on desertification are less evident. The  
5 transitions to renewable energy are being promoted by governments across drylands (Sen and Ganguly,  
6 2017; Hong et al., 2013; Cancino-Solórzano et al., 2016) even in fossil-fuel rich countries (Stambouli et al.,  
7 2012; Vidadili et al., 2017; Farnoosh et al., 2014; Dehkordi et al., 2017), despite important social, political  
8 and technical barriers to expanding renewable energy production (Afsharzade et al., 2016; Karatayev et al.,  
9 2016; Baker et al., 2014). Improving the social awareness about the benefits of transitioning to renewable  
10 energy resources, such as hydro-energy, solar and wind energy contributes to their improved adoption  
11 (Aliyu et al., 2017).

12

### 13 **3.7.3.2. Policy Responses towards Economic Diversification**

14 Despite policy responses for combating desertification, climate change, population pressures and growing  
15 food demands, as well as the need to reduce poverty and strengthen food security, are *very likely* to put  
16 strong pressures on the land (Cherlet et al., 2018; see also Chapter 6 and 7). Sustainable development of  
17 drylands and their resilience to combined challenges of desertification and climate change will thus also  
18 depend on the ability of governments to promote policies for economic diversification within agriculture  
19 and in non-agricultural sectors in order make dryland areas less vulnerable to desertification and climate  
20 change.

21 ***Investing into irrigation and agricultural commercialisation.*** Investments into expanding irrigation in  
22 dryland areas can help improve labour productivity and boost production and income revenue from  
23 agriculture and livestock sectors, the major driving factor being profitability. Barrett et al. (2017) noted  
24 faster poverty rate reduction and economic growth enhancement is realised when countries transition into  
25 the production of non-staple, high value commodities and manage to build a robust agro-industry sector.  
26 However, such a transition did not improve farmers' livelihoods in all cases (Reardon et al., 2009). High  
27 value cash crop/animal production is being bolstered by wide scale use of technologies, for example,  
28 mechanisation, inorganic fertilisers, crop protection and animal health products. Market oriented  
29 crop/animal production facilitates social and economic progress with labour increasingly shifting out of  
30 agriculture into non-agricultural sectors (Cour, 2001). Modernised farming, improved access to inputs,  
31 credit and technologies enhances competitiveness in local and international markets (Reardon et al., 2009).

32 ***Structural transformations*** in rural economies implies that the development of non-agricultural sectors  
33 facilitate movement of labour from land-based livelihoods, vulnerable to desertification and climate change,  
34 to non-agricultural activities (Haggblade et al., 2010). The movement of labour from agriculture to non-  
35 agricultural sectors is determined by relative labour productivities in these sectors (Shiferaw and Djido,  
36 2016). Given already high underemployment in the farm sector, increasing labour productivity in the non-  
37 farm sector was found as the main driver of labour movements from farm sector to non-farm sector  
38 (Shiferaw and Djido, 2016). More investments into education can facilitate this process (Headey et al.,  
39 2014). However, in some contexts, such as pastoralist communities in Xinjiang, China, income  
40 diversification was not found to improve the welfare of pastoral households. Economic transformations  
41 also occur by the way of urbanisation, through the shift of underutilised labour in rural areas into gainful  
42 employment in urban areas (Jedwab and Vollrath, 2015). The larger share of world population will be living  
43 in urban centres in the 21<sup>st</sup> century and this will require innovative means of agricultural production with  
44 minimum ecological footprint and less dependence on fossil fuels (Revi and Rosenzweig, 2013).

1 Furthermore, this period will demand effective ways of managing ecosystems and mitigation of  
2 desertification while addressing the demand of cities. Although there is some evidence of urbanisation  
3 leading to the loss of indigenous and local ecological knowledge, however, indigenous and local knowledge  
4 systems are constantly evolving, and are also getting integrated into urban environments (Júnior et al.,  
5 2016; Reyes-García et al., 2013; van Andel and Carvalheiro, 2013). Urban areas are attracting an increasing  
6 number of rural residents across the developing world (Angel et al., 2011; Cour, 2001; Dahiya, 2012).  
7 Urban development is also contributing to expedited agricultural commercialisation by providing  
8 sustainable market outlet for cash and high value crop and livestock products. At the same time,  
9 urbanisation also poses numerous challenges in the form of rapid urban sprawl and pressures on  
10 infrastructure and public services, unemployment and associated social risks, which have considerable  
11 implications on climate change adaptive capacities (Bulkeley, 2013; Garschagen and Romero-Lankao,  
12 2015).

13

## 14 **3.8. Hotspots and Case Studies**

15 Desertification has been addressed in drylands over decades using different strategies. Some examples of  
16 hotspots and responses to desertification and climate change are presented in this section.

### 17 **3.8.1. Case Study on Climate Change and Soil Erosion in Drylands**

#### 18 ***3.8.1.1. Global Status of Soil Erosion and its Main Drivers***

19 Soil erosion is present in nearly all geographic regions. Wind erosion, is a significant process, affecting  
20 41% of the global land area, especially arid and semi-arid areas (Moharana et al., 2016). At a country scale,  
21 in the case of Chile, erosion rates reach up to  $100 \text{ t ha}^{-1}\text{yr}^{-1}$ , having increased substantially over the last 50  
22 years (Ellies, 2000). More than 10% of the country exhibits high erosion rates (greater than  $1 \text{ t ha}^{-1}\text{yr}^{-1}$ )  
23 (Bonilla et al., 2010). Using the Universal Soil Loss Equation, it has been estimated that soil erosion can  
24 be as high as  $300 \text{ t ha}^{-1}\text{yr}^{-1}$  (equivalent to a net loss of 18 mm per year) in Spain (López-Bermúdez, 1990).  
25 In Turkey, the amount of sediment recently released through erosion into seas was estimated to be 168  
26 million tonnes per year, which is considerably lower than the 500 million ton per year that was estimated  
27 to be lost in the 1970s (ÇEMGM, 2017). The decrease in erosion rates is attributed to an increase in spatial  
28 extent of forest land, the rehabilitation of degraded forests, erosion control, prevention of overgrazing, and  
29 improvement in irrigation technologies. Despite its global importance, estimates of soil erosion differ  
30 significantly, depending on scale, study period and method used (García-Ruiz et al., 2015), ranging from  
31 approximately  $20 \text{ Gt yr}^{-1}$  to more than  $200 \text{ Gt yr}^{-1}$  (Boix-Fayos et al., 2006; FAO, 2015). In addition to the  
32 loss of soil, erosion has a direct and negative impact on soil nutrients and organic matter, thereby impacting  
33 land's productive capacity. Globally, water erosion is estimated to result in the loss of 23–42 MtN and  
34 14.6–26.4 MtP annually (Pierzynski et al., 2017). Soil organic carbon stocks are also affected by erosion as  
35 topsoil is lost. Wind erosion results in a loss of fine soil particles (silt and clay), reducing the ability of soil  
36 to sequester carbon (Wiesmeier et al., 2015).

37

#### 38 ***3.8.1.2. Observed Trends in Arid Lands***

39 The results of soil erosion models indicate that water erosion is a global phenomenon. At a continental  
40 level, in the year 2001, South America was predicted to have the highest rate of soil erosion rate ( $3.53 \text{ Mg}$   
41  $\text{ha}^{-1}\text{yr}^{-1}$ ), followed by Africa ( $3.51 \text{ Mg ha}^{-1}\text{yr}^{-1}$ ) and Asia ( $3.47 \text{ Mg ha}^{-1}\text{yr}^{-1}$ ) (Borrelli et al., 2017). Within  
42 the United States, average soil erosion rates on all cropland have decreased more than 38% since 1982 due

1 to better soil management practices (Kertis, 2013). The national average annual erosion rate on non-Federal  
2 US rangeland is estimated to be 1.41 t ha<sup>-1</sup>yr<sup>-1</sup>. Over 18% of the non-Federal rangelands might benefit from  
3 treatment to reduce soil loss to below 2.24 t ha<sup>-1</sup>yr<sup>-1</sup> (Weltz et al., 2014). Within China, rainfall erosivity  
4 has shown a positive trend in dryland areas between 1961 and 2012 (Yang and Lu, 2015). Zhang et al.  
5 (2015) state that while water erosion area in Xinjiang has decreased by 23.2%, the erosion considered as  
6 severe or intense was still increasing. In the case of Chile, there has been a significant increasing trend in  
7 soil erosion, while in 1970 only a small fraction of the territory had been affected by erosion, in year 2000,  
8 erosion effected one quarter of the country (Mathieu et al., 2007). Soil loss due to erosion is much higher  
9 on bare land compared to cultivated land. Nabi et al. (2008) estimated the soil erosion rate from barren  
10 lands in Soan river basin in the Potohar region of Pakistan to be 63.41 t ha<sup>-1</sup>yr<sup>-1</sup> and that from the cropped  
11 land to be 18.76 t ha<sup>-1</sup>yr<sup>-1</sup>. In Pakistan, the highest rate of erosion was estimated to be 150–160 t ha<sup>-1</sup>yr<sup>-1</sup>  
12 (Anjum et al., 2010). In the semi-arid regions of Brazil, no major changes in runoff and sediment transport  
13 were observed (Santos et al., 2017). In Mediterranean Europe, Guerra et al. (2016) found a reduction of  
14 erosion due to greater effectiveness of soil erosion prevention between 2001 and 2013.

### 16 **3.8.1.3. Climate Change Impacts on Erosion in Arid Lands**

17 There are several erosion mechanisms that will be highly affected by future climate change. Intensification  
18 of glacier retreat could increase soil erosion in certain regions (dependent on other variables) as eroded  
19 material is transported when ice moves over the underlying bedrock. The same occurs with sea level rise  
20 and storm surge intensities that increase soil erosion in coastal areas (Kalhor et al., 2017). Land use change  
21 and deforestation aggravates the effect of climate on erosion (Gutiérrez-Elorza, 2006). Accelerated erosion  
22 and sediment transport as a result of deforestation reduces the lifespan of dams, irrigation systems and local  
23 infrastructure. A particularly notable example is Warsak dam in Pakistan, built in Khyber Pakhtunkhwa  
24 province on the Kabul River in 1960, which was completely filled with sediment in three years. Similarly,  
25 the lifespan of other major dams, Tarbela and Mangla, was reduced by more than 10 years (Nabi et al.,  
26 2008). Changes in the intensity and seasonal distribution of precipitation, as projected by most climate  
27 change scenarios, increase the frequency and intensity of flood events and can intensify erosion processes  
28 (*robust evidence; high agreement*) (Molnar, 2001; Nearing et al., 2015; Ziadat and Taimeh, 2013).

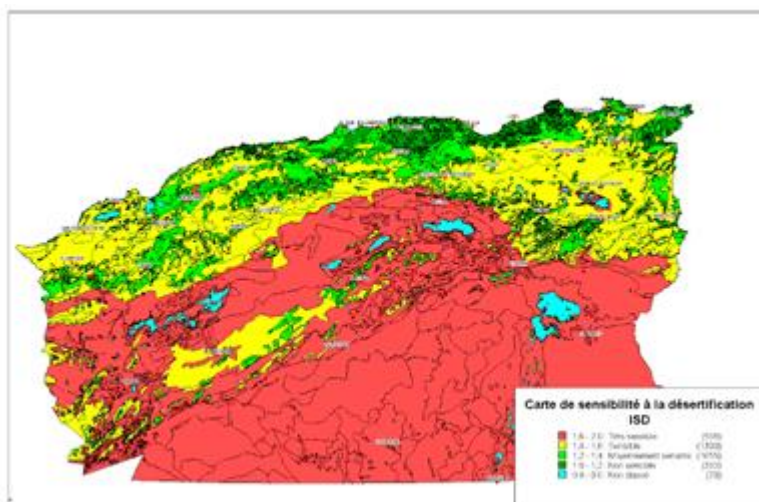

### 30 **3.8.1.4. Successful Restoration and Rehabilitation Examples**

#### 31 **3.8.1.4.1 Soil Erosion and Desertification in Algeria**

32 In Algeria, desertification mainly affects the steppes of arid and semi-arid regions where the economy is  
33 based on pastoral farming. Algerian steppes are marked by great interannual rainfall variability. Rainfall  
34 has declined about 18% to 27% and the dry season has increased by two months in the last century.  
35 Associated with this drying, floods are often observed, increasing the vulnerability of soils to erosion  
36 (Belala et al., 2018; Hirche et al., 2011).

37 The population of the steppes has increased substantially, from 1,024,777 inhabitants in 1968 to 7,500,000  
38 in 2008, an average annual growth rate of 2.5% (last census in 2008 by National Statistical Office). The  
39 population of livestock, predominantly sheep, has grown exponentially since 1968, leading to severe  
40 overgrazing, trampling and soil compaction, which greatly increases the risk of erosion (Nedjraoui and  
41 Bédrani, 2008). Prevalent wind erosion is due to prevailing climatic conditions and anthropogenic action  
42 that reduces the vegetation cover (Hirche et al., 2018; Le Houérou, 1996). Wind carries away fine particles  
43 such as sands and clays and leaves a lag gavel pavement which is unproductive. Water erosion transports  
44 soil and nutrients offsite resulting in a loss of soil fertility and water holding capacity.

1  
2 The national map of soil sensitivity to erosion (Salamani et al., 2012) provides a stark picture of the amount  
3 of area at risk of soil erosion in the steppe and pre-Saharan areas of Algeria (Figure 3.11). More than three  
4 million hectares of land in the steppe provinces (Naama, El-bayadh, Djelfa, M'sila, Tebessa) experience  
5 intense wind activity and are particularly high-risk areas for soil erosion. Nearly 600,000 ha of land in the  
6 steppe zone are totally desertified without the possibility of biological recovery.  
7

8  
9 **Figure 3.11 Map of sensitivity to desertification of northern Algeria (Salamani et al., 2012)**

10  
11 Combating soil erosion has therefore been one of the priority objectives of the state authorities since the  
12 beginning of the 1970s. Many ecological and socio-economic programs have been launched at different  
13 times. These programs aim to revitalise degraded areas and improve the management of livestock and  
14 natural resources. The Last National Reforestation assessment documented the successful reforestation of  
15 60% of the area (895,260 ha) since 2000. Additional work is planned, 2015–2019, to extend the forested  
16 area for the protection and restoration of rangelands from silting.  
17

#### 18 3.8.1.4.2 *No-Till Practices in Central Chile*

19 Over the last few decades there has been an increasing interest in the development of No-Till (also called  
20 zero tillage) technologies as a way to minimise soil disturbance, reduce the combustion of fossil fuels and  
21 increase soil organic matter. No-Till in conjunction with the adoption of strategic cover crops have  
22 positively impacted soil biology with increases in soil organic matter. Early evaluations by Crovetto (1998)  
23 showed that No-Till farm (after seven years) had doubled the biological activity indicators of traditional  
24 farming and even surpassed those found in pasture (grown for the last 15 years). Besides erosion control,  
25 additional benefits are an increase of water holding capacity and reduction in bulk density. The influence  
26 of this iconic farm has resulted in the adoption of soil conservation practices and specially No-Till in  
27 dryland areas of the Mediterranean climate region of central Chile (Martínez et al., 2011).  
28

#### 29 3.8.1.4.3 *Combating Wind Erosion and Deflation in Turkey: The Greening Desert of Karapınar*

30 The Karapınar district is located on the plains between the Konya and Ereğli districts of Turkey. It is  
31 characterised by a semi-arid climate and annual average precipitation of 250–300 mm (Türkeş, 2003;  
32 Türkeş and Tatlı, 2011). In areas where vegetation was overgrazed or inappropriately tilled, the surface soil

1 horizon was removed through erosion processes resulting in the creation of a large drifting dunes that  
 2 threaten settlements around Karapınar (Groneman, 1968). Such dune movement had begun to affect the  
 3 Karapınar settlement in 1956 (Kantarıcı et al., 2011). Consequently, the Karapınar town and nearby villages  
 4 faced danger of abandonment due to out-migration in early 1960s (Figure 3.12). The reasons for increasing  
 5 wind erosion in the Karapınar district can be summarised as follows: sandy material originated from an old  
 6 lake bed and was mobilised following drying of lake; hot and semi-arid climate conditions along with high  
 7 seasonality in precipitation and year-to-year variability; overgrazing and use of pasture plants for fuel;  
 8 excess tillage, particularly the Shock-Disc Plough that degrades soil structure and buries the productive  
 9 surface horizon; and Karapınar is located in an area with strong prevailing winds.

10

11 **Figure 3.12 (1) A general view of a nearby village of Karapınar town in early 1960s (Çarkacı, 1999). (2) A**  
 12 **present view of the Karapınar wind erosion area that has been opened to sustainable and productive**  
 13 **agricultural practices for many years (Photograph: Murat Türkes, 17.06.2013). (3) Construction of Cane**  
 14 **Screens in early 1960s in order to decrease speed of the wind and prevent movement of the sand**  
 15 **accumulations and dunes, which was one of the physical measures during the prevention and mitigation**  
 16 **period (Çarkacı, 1999). (4) A view of present mix vegetation in most of the Karapınar wind erosion area, the**

 18 **continental climate conditions along with a warm/hot temperature regime over the district (Photograph:**  
 19 **Murat Türkes, 17.06.2013)**

20

21 Restoration and mitigation strategies were initiated in 1959 and today, 4,300 ha of this land has been  
 22 restored (Akay and Yildirim, 2010) (Figure 3.12-2), using specific measures: (1) Physical measures:

1 construction of cane screens to decrease wind speed and prevent sand movement (Figure 3.12Figure 3.11-  
2 3); (2) Restoration of cover: increasing grass cover between screens using seeds collected from local  
3 pastures or the cultivation of rye (*Secale* sp.) and wheat grass (*Agropyron elongatum*) that are known to  
4 grow in arid and hot conditions; (3) Afforestation: saplings obtained from nursery gardens were planted  
5 and grown between these screens. Main tree species selected were oleaster (*Eleagnus* sp.), acacia (*Robinia*  
6 *pseudeaccacia*), ash (*Fraxinus* sp.), elm (*Ulmus* sp.) and maple (*Acer* sp.) (Figure 3.12-4). Economic  
7 growth occurred after controlling erosion and new tree nurseries have been established with modern  
8 irrigation. Potential negative consequences through the excessive use of water can be mitigated through  
9 engagement with local stakeholders and transdisciplinary learning processes, as well as by restoring the  
10 traditional land uses in the semi-arid Konya closed basin (Akça et al., 2016).

11

### 12 **3.8.2 Case Study on Green Walls, Green Dams and Green Belts**

13 In order to combat desertification and to adapt to and mitigate climate change, the measures and actions of  
14 the Green Dam, Green Belt or Green Great Wall have been applied in East Asia (e.g., China), Mediterranean  
15 area (e.g., Turkey), and Africa (e.g., Algeria, Sahara and the Sahel region).

16

#### 17 **3.8.2.1. The Experiences of Combating Desertification in China**

18 Arid and semiarid areas of China, including north-eastern, northern and north-western regions, cover an  
19 area of more than 1.6 million km<sup>2</sup>, with annual rainfall of below 450 mm. Over the past several centuries,  
20 more than 60% of areas in arid and semiarid regions were used as pastoral and agricultural lands. The  
21 coupled impacts of past climate change and human activity have caused desertification and dust storms to  
22 become a serious problem in the region (Xu et al., 2010). In 1958, the Chinese government recognised that  
23 desertification and dust storms jeopardised livelihoods of nearly 200 million people, and afforestation  
24 programs for combating desertification have been initiated since 1978. China is committed to go beyond  
25 the “Land-Degradation Neutrality” objective as indicated by the following programs that have been  
26 implemented. The Chinese Government began the Three North’s Forest Shelterbelt program in Northeast  
27 China, North China, and Northwest China, with the goal to combat desertification and to control dust storms  
28 by improving forest cover in arid and semiarid regions. The project is implemented in three stages (1978–  
29 2000, 2001–2020, and 2021–2050). In addition, the Chinese government launched Beijing and Tianjin  
30 Sandstorm Source Treatment Project (2001–2010), Returning Farmlands to Forest Project (2003–present),  
31 Returning Grazing Land to Grassland Project (2003–present) to combat desertification, and for adaptation  
32 and mitigation of climate change (State Forestry Administration of China, 2015; Tao, 2014; Wang et al.,  
33 2013b).

34 The results of the fifth monitoring (2010–2014) showed: (1) Compared with 2009, the area of degraded  
35 land decreased by 12,120 km<sup>2</sup> over a five-year period; (2) In 2014, the average coverage of vegetation in  
36 the sand area was 18.33%, an increase of 0.7% compared with 17.63% in 2009, and the carbon sequestration  
37 increased by 8.5%; (3) Compared with 2009, the amount of wind erosion decreased by 33%, the average  
38 annual occurrence of sandstorms decreased by 20.3% in 2014; (4) As of 2014, 203,700 km<sup>2</sup> of degraded  
39 land were effectively managed, accounting for 38.4% of the 530,000 km<sup>2</sup> of manageable desertified land;  
40 (5) The sandy area created 5.4 million ha of fruit production with annual output of 4.86 10<sup>10</sup> kg of fresh and  
41 dried fruits, accounting for 33.9% of the national annual output (State Forestry Administration of China,  
42 2015). This has become an important pillar for economic development and a high priority for peasants as a  
43 method to eradicate poverty (State Forestry Administration of China, 2015).

1 Stable investment mechanisms for combating desertification have been established along with tax relief  
2 policies and financial support policies for guiding the country in its fight against desertification. The  
3 investments in scientific and technological innovation for combating desertification have been improved,  
4 the technologies for vegetation restoration under drought conditions have been developed, the  
5 popularisation and application of new technologies have been accelerated, and the trainings of technicians  
6 for farmers and herdsmen have been strengthened. To improve the monitoring capability and technical level  
7 of desertification, the monitoring network system has been strengthened, and the popularisation and  
8 application of modern technologies are intensified (e.g., information and remote sensing). Special laws on  
9 combating desertification have been decreed by the government. The provincial government  
10 responsibilities for desertification prevention and controlling objectives and laws have been strictly  
11 implemented.

12

### 13 **3.8.2.2. The Green Dam in Algeria**

14 After independence, the Algerian government had the reconstruction of forests destroyed by the war and  
15 the steppes by desertification among its top priorities (Belaaz, 2003). In 1972, the government invested in  
16 the “Green Dam” (“Barrage Vert”) project to stop desertification. This was the first significant experiment  
17 to combat desertification, influence the local climate and decrease the aridity by restoring a barrier of trees.  
18 The Green Dam extends across arid and semi-arid zones between the isohyets 300 and 200 mm. It is a 3  
19 Mha band of plantation running from east to west (Figure 3.13). It is over 1,200 km long (from the Algerian-  
20 Moroccan border to the Algerian-Tunisian border) and has an average width of about 20 km. The soils in  
21 the area are shallow, low in organic matter and susceptible to erosion. The population is low (3 to 92 hab  
22 km<sup>-2</sup>), but has a high rate of growth (1.6 to 4.3).

23

24 The main objectives of the project were to conserve natural resources, improve the living conditions of  
25 local residents and avoid their exodus to urban areas. During the first four decades (1970–2000) the success  
26 rate was low (42%) due to lack of participation by the local population and the choice of species (Bensaid,  
27 1995). The experience of previous years led to the launch of integrated management assessments, the  
28 improvement of tree and fodder shrub plantations, and the development of water conservation techniques.  
29 Reforestation during this period was carried out using multiple species, including fruit trees to increase and  
30 diversify sources of income of the population.

31 The evaluation of the Green Dam from 1972 to 2015 (General Forest Direction) shows that 300,000 ha of  
32 forest plantation have been planted, which represents 10% of the project area. Estimates of the success rate  
33 of reforestation vary considerably between 30% and 75%, depending on the region. Currently, in line with  
34 the New Rural Renewal Policy, the government has planned to relaunch the rehabilitation of the Green  
35 Dam by incorporating new concepts related to sustainable development, combating desertification, and  
36 adaptation to climate change. Through demonstration, the Green Dam has inspired several African nations  
37 to build a Great Green Wall to combat land degradation, mitigate climate change effects, loss of biodiversity  
38 and poverty in a region that stretches from Senegal to Djibouti (Sahara and Sahel Observatory, 2016).

1  
2 **Figure 3.13 Localisation of green Dam in Algeria (Saifi et al., 2015). Note: The green coloured band**  
3 **represents the location of the green dam, the yellow band delineates the national border of Algeria**

#### 4 **3.8.2.3. Afforestation and Erosion Control in the Green Belt of Turkey**

5 Turkey has a high level of land degradation and erosion due to its topographical structure, sensitivity of  
6 land to erosion, climate and improper agricultural practices including destruction of range and forest lands  
7 (Yurtoglu, 2015). A cooperative project “The National Afforestation and Erosion Control Mobilization  
8 Action Plan (NAECMAP)” was implemented by Turkey’s Ministry of Environment and Forestry (MOEF)  
9 (now the Ministry of Agriculture and Forestry) to reduce GHG emissions and increase carbon sequestration.  
10 Public institutions, municipalities, non-governmental organisations and community assigned by National  
11 Afforestation and Erosion Control Mobilization Law no. 4122 were organised to combat desertification.  
12 NAECMAP (2008 to 2012) prescribed coordinated work among public bodies and parties undertaking of  
13 afforestation, rehabilitation and erosion control work over an area of 2.3 million ha. The MOEF aimed to  
14 implement over an area of 2.16 million ha, with other institutions covering an area of 136,000 ha. The total  
15 cost of these activities was estimated to be more than 2.7 billion Turkish Liras.

16 The NAECMAP had following objectives: Rehabilitation of forests and 10% canopy closure, restoring  
17 productivity with minimum cost and effort; Decreasing GHG emissions and increasing carbon sequestration  
18 through rehabilitation of infertile forests and afforestation where possible; Restoring intact ecosystems to  
19 minimise the adverse impacts of climate change and desertification on livelihoods; Preventing floods and  
20 overflows that lead to loss of lives and goods; regulating water run-off in watersheds and improving water  
21 quality; Reducing pressure on remaining forests by establishing new forests to meet country’s need for  
22 wood; Raising public awareness of importance of caring for forests by establishing the planting of saplings  
23 as a common tradition practised by citizens every year.

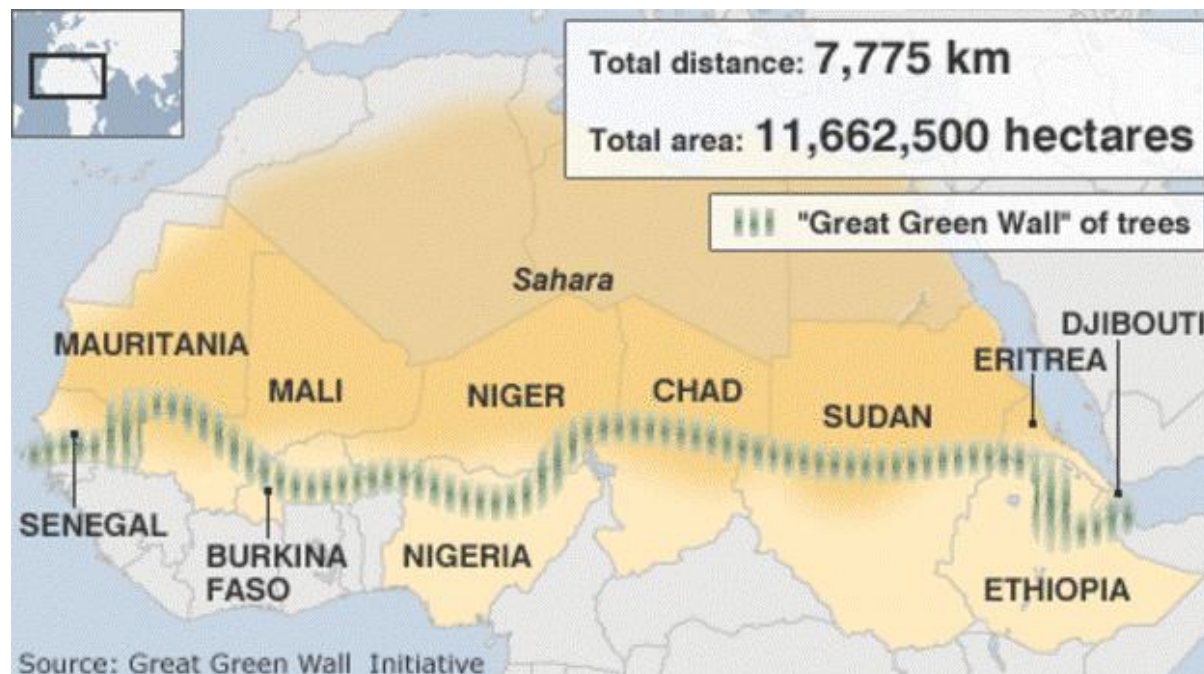

1  
2 **Figure 3.14 Each year of the mobilisation, 300,000 people were employed for seed and seedling production,**  
3 **afforestation, rehabilitation and erosion control work in Turkey. It also addresses a growing need for**  
4 **recreational space in urban areas of Turkey**

5 In 1973, forest covered 20.2 million ha of land and by 2012 an additional 1.5 million ha of land had been  
6 forested through the program. During the five years of the NAECMAP, Turkey achieved the afforestation  
7 of 210,169 ha; soil protection and afforestation in 315,889 ha; and private afforestation in 49,385 ha (Figure  
8 3.14). Some 1.75 million ha of degraded forest and 37,880 ha of degraded rangeland were rehabilitated. In  
9 addition, erosion control and revegetation was done along 8,135 km of highways and 2,262 km of village  
10 roads together with that in 27,000 school yards, 1,095 health centres and 9,826 sanctuaries and cemeteries.  
11 In the scope of the ‘Schools get life’ initiative, school orchards are being planted. Green belt afforestation  
12 was also achieved around cities (Figure 3.14). Over the five years, 109 million seedlings were distributed  
13 to the public free of charge. NAECMAP also provided employment opportunities to the rural population  
14 employing 300,000 people for six months.

#### 16 **3.8.2.4. The Great Green Wall of the Sahara and the Sahel Initiative**

17 The Great Green Wall is an initiative of the Heads of State and Government of the Sahelo-Saharan countries  
18 to mitigate and adapt to climate change, and to improve the food security of the Sahel and Saharan peoples.  
19 Launched in 2007, this regional project aims to restore Africa's degraded arid landscapes, reduce the loss  
20 of biodiversity and support local communities to sustainable use of forests and rangelands. The Great Green  
21 Wall focuses on establishing plantations and neighbouring projects covering a distance of 7,775 km from  
22 Senegal on the Atlantic coast to Eritrea on the Red Sea coast, with a width of 15 km (Figure 3.15). The wall  
23 passes through Djibouti, Eritrea, Ethiopia, Sudan, Chad, Niger, Nigeria, Mali, Burkina Faso and Mauritania  
24 and Senegal.

25 The choice of woody and herbaceous species that will be used to restore degraded ecosystems is based on  
26 biophysical and socio-economic criteria, including socio-economic value (food, pastoral, commercial,  
27 energetic, medicinal, cultural); ecological importance (carbon sequestration, soil cover, water infiltration)  
28 and species that are resilient to climate change and variability. The Pan African Agency of the Great Green  
29 Wall (PAGGW) was created in 2010 under the auspices of the African Union and CEN-SAD to manage  
30 the project. The initiative is implemented at the level of each country by a national structure. A monitoring  
31 and evaluation system has been defined, allowing nations to measure outcomes and to propose the necessary  
32 adjustments.

1  
2 **Figure 3.15 The Great Green Wall**

3 The implementation of the initiative has already started in several countries. For example, the FAO's Action  
4 Against Desertification project is restoring 18,000 hectares of land in 2018 through planting native tree  
5 species in Burkina Faso, Ethiopia, The Gambia, Niger, Nigeria and Senegal (Sacande, 2018). Berrahmouni  
6 et al. (2016) estimated that 166 million hectares can be restored, requiring the restoration of 10 million  
7 hectares per year to achieve Land Degradation Neutrality targets by 2030. Despite this early implementation  
8 actions on the ground, the achievement of the planned targets is questionable and challenging without  
9 significant additional funding.

10  
11 **3.8.3. Case Study on Invasive Plant Species**

12 **3.8.3.1. Introduction**

13 The spread of invasive plants can be exacerbated by climate change (Bradley et al., 2010; Davis et al.,  
14 2000). In general, it is expected that the distribution of invasive plant species with high tolerance to drought  
15 or high temperatures may increase under most climate change scenarios (medium to high confidence;  
16 Settele et al., 2014). Invasive plants are considered a major risk to native biodiversity and can disturb the  
17 nutrient dynamics and water balance in affected ecosystems (Ehrendfeld, 2003). Compared to more mesic  
18 regions, the number of species that succeed in invading dryland areas is low (Bradley et al., 2012), yet they  
19 have a considerable impact on biodiversity and ecosystem services (Le Maitre et al., 2011, 2015; Newton  
20 et al., 2011). Moreover, increasing human populations in dryland areas are responsible for creating new  
21 invasion opportunities (Safriel and Adeel, 2005).

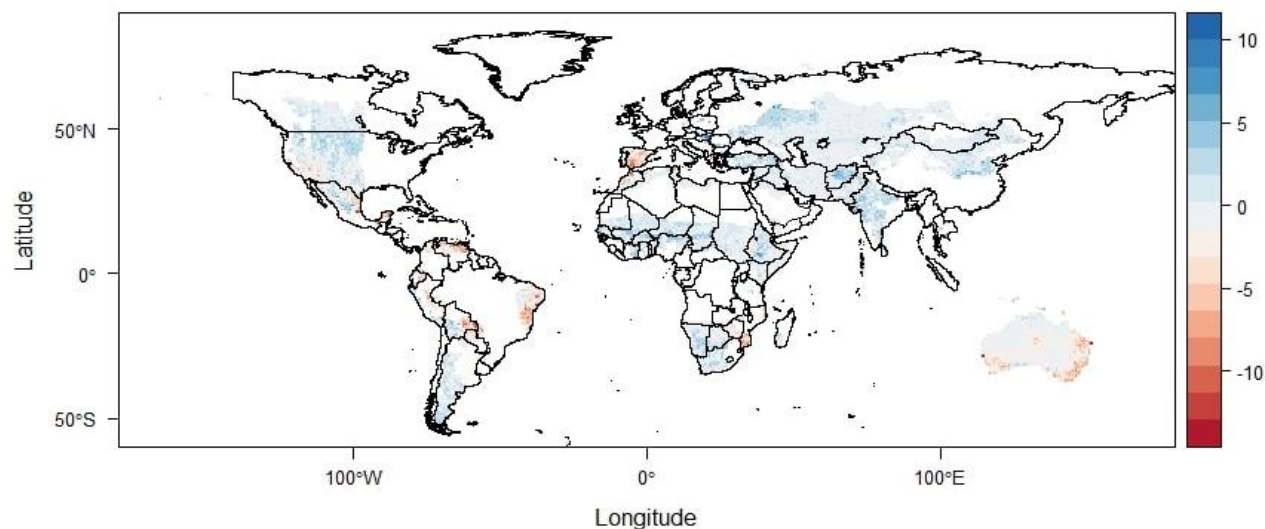

22  
23 Current drivers of species introductions include population growth, expanding global trade and travel, land  
24 degradation and changes in climate (Richardson et al., 2011; Chytrý et al., 2012; Seebens et al., 2018). For  
25 example, Davis et al. (2000) suggests that high rainfall variability promotes the success of alien plant  
26 species - as reported for semiarid grasslands and Mediterranean-type ecosystems (Cassidy et al., 2004;

1 Reynolds et al., 2004; Sala et al., 2006). Furthermore, Panda et al. (2018) demonstrated that many invasive  
 2 species could withstand elevated temperature and moisture scarcity caused by climate change and Dukes et  
 3 al. (2011) observed that the invasive plant *Centaurea solstitialis* grew six time larger under elevated  
 4 atmospheric CO<sub>2</sub> expected in future climate change scenarios.

5 Climate change is most likely going to aggravate the problem as existing species continue to spread  
 6 unabated and other species develop invasive characteristics (Hellmann et al., 2008). Although the effects  
 7 of climate change on invasive species distributions have been relatively well explored, the greater impact  
 8 on ecosystems is less well understood (Bradley et al., 2010; Eldridge et al., 2011).

9 Due to the time lag between the initial release of invasive species and their impact, the consequence of  
 10 invasions are not immediately detected and may only be noticed centuries after introduction (Rouget et al.,  
 11 2016). Climate change and invading species may act in concert (Bellard et al., 2013; Hellmann et al., 2008;  
 12 Seebens et al., 2015). For example, invasion often changes the size and structure of fuel loads, which can  
 13 lead to an increase in the frequency and intensity of fire (Evans et al., 2015). In areas where the climate is  
 14 becoming warmer, an increase in the likelihood of suitable weather conditions for fire may in turn promote  
 15 invasive species, which in turn may lead to further desertification.

16 Overall, the mean number of invasive species predicted to find suitable climate conditions in dryland areas  
 17 is anticipated to decrease slightly by 2050 (Lowe et al., 2000). At a regional scale, Bellard et al. (2013)  
 18 predicted increasing risk in Africa and Asia, with declining risk in Australia (Figure 3.16). This projection  
 19 does not represent an exhaustive list of invasive alien species occurring in drylands.

20

21 **Figure 3.16 Difference between the number of invasive alien species (n=99, from Bellard et al. (2013))**  
 22 **predicted to occur by 2050 (under A1B scenario) and current period “2000”**

23 A set of three case studies in Ethiopia, Mexico and the USA is presented to describe the nuanced nature of  
 24 invading plant species, their impact on drylands and their relationship with climate change.

### 25 3.8.3.2. Description of the Problem

26 **Ethiopia.** The two invasive plants that inflict the heaviest damage are *Parthenium hysterophorus* and  
 27 *Prosopis juliflora* (Adkins and Shabbir, 2014). It is assumed that *Prosopis juliflora* (mesquite) was  
 28 introduced in the 1970s and has since spread rapidly. Likewise, a recent study reported that *Parthenium*  
 29 *hysterophorus* L has spread into 32 out of 34 districts in the northernmost region of Ethiopia, Tigray (Teka,  
 30 2016). The weed is a substantial agricultural and natural resource problem and forms a significant health

1 hazard (Reda, 2011). The eastern belt of Africa including Ethiopia presents a very suitable habitat, and the  
2 weed is expected to spread further in the region in the future (Mainali et al., 2015).

3 **Mexico.** Buffelgrass (*Cenchrus ciliaris* L.) is a native species from southern Asia and East Africa was  
4 introduced into Texas and northern Mexico in the 1930s and 1940s, as it is highly productive in drought  
5 conditions (Cox et al., 1988; Rao et al., 1996). In the Sonora desert of Mexico, the distribution of buffelgrass  
6 has increased exponentially, covering 1Mha in Sonora State (Castellanos-Villegas et al., 2002).  
7 Furthermore, its potential distribution extended to 53% of Sonora State and 12% of semiarid and arid  
8 ecosystems in Mexico (Arriaga et al., 2004).

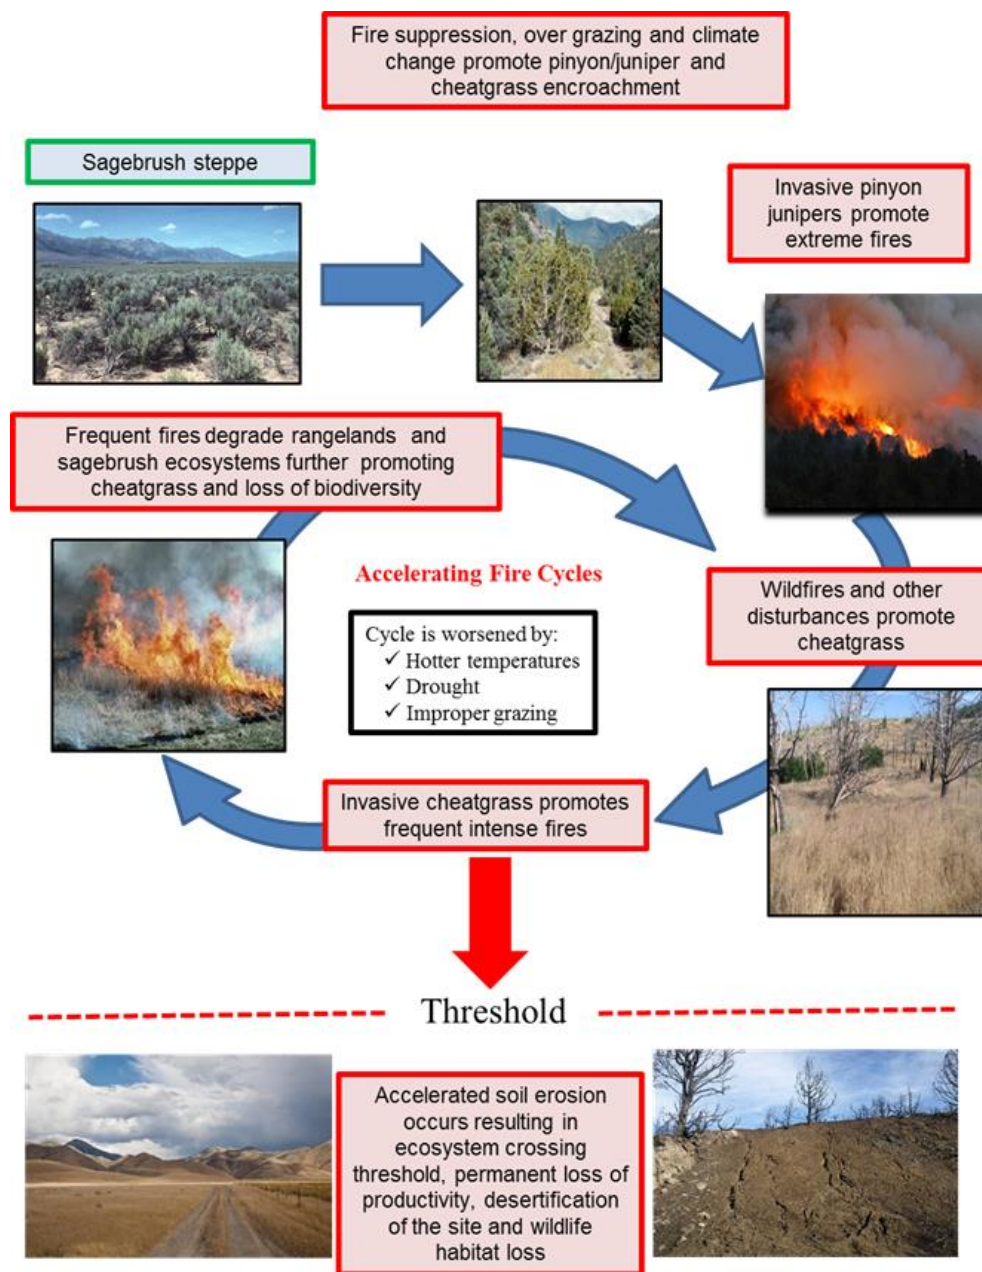

9 **United States.** Sagebrush ecosystems have declined from 25 to 13 Mha since the late 1800s (Miller et al.,  
10 2011). A major cause is the introduction of non-native cheatgrass (*Bromus tectorum*), which is the most  
11 prolific invasive plant in the United States (Figure 3.17). Cheatgrass infests more than 10 M ha in the Great  
12 Basin and is expanding every year (Balch et al., 2013). It provides a fine-textured fuel that increases the  
13 intensity, frequency and spatial extent of fire (Balch et al., 2013). Historically, wildfire frequency was 60  
14 to 110 years in Wyoming big sagebrush communities and has increased to five years following the  
15 introduction of cheatgrass (Pilliod et al., 2017; Balch et al., 2013).

16 Tamarisk species are shrubs or small trees considered to be among the most aggressively invasive and  
17 potentially detrimental exotic plants in the U.S.A. (Kerns et al., 2009; Pearce and Smith, 2007; Nagler et  
18 al., 2010). Tamarisk were introduced into the U.S.A. as ornamentals and planted for erosion control and  
19 have spread across the western United States and northern Mexico (Pearce and Smith, 2007; Glenn et al.,  
20 2012). Tamarisk is now the third most frequently occurring woody riparian plant and the second most  
21 abundant species (out of 42 native and non-native species) evaluated along rivers in the western United  
22 States (Nagler et al., 2010). Tamarisks concentrates salts on and within underlying soils, utilises large  
23 amounts of water as facultative phreatophytes, replaces native riparian vegetation, reduces biodiversity of  
24 aquatic macroinvertebrates, provides poor quality habitat for most wildlife, alters decomposition processes,  
25 limits recreational opportunities, and changes flood regimes by narrowing river corridors (Sala et al., 1996;  
26 Di Tomaso, 1998; Bailey et al., 2001; Glenn et al., 2012; Bedano et al., 2014).

27 Climate change will alter the distribution and abundance of tamarisk via both direct effects on plants and  
28 indirect effects resulting from changes to stream flow, biotic interactions and human activities. Direct  
29 effects of warming will shift species distributions northward and upstream (Parmesan, 2006). Changes in  
30 the dynamics of highly managed stream flow and ground water regimes along rivers in the western U.S.A.  
31 which are already changing as a function of changing climate, will increase niches and opportunities to  
32 spread (Barnett et al., 2008). The largest impact on ecosystem services is predicted to be from tamarisks  
33 when both indirect and direct effects are accounted for (Ikeda et al., 2014). Habitat suitability model results  
34 indicate that 21 % of the northwestern region of the U.S.A supports suitable tamarisk habitat under projected  
35 climate changes. Climate change provides opportunity for tamarisk to move into Canada and disrupts its  
36 river systems and biodiversity (Pearce and Smith, 2007). Although uncertainty exists regarding future  
37 climate change on the rate of spread of invasive species, it is projected that a 2 to 10-fold increase in highly  
38 suitable tamarisk habitat will occur by the end of the century in the central region of the U.S.A. and into  
39 Canada as the species moves north with changes in temperature (Kerns et al., 2009).

40

1  
 2 **Figure 3.17 Invasive species cycle in the Great Basin region of the western U.S.A.** Note: Showing loss of  
 3 biodiversity and site degradation as a result of interaction between drought, overgrazing promoting open  
 4 space between sagebrush plants that are infilled by Juniper trees and cheatgrass (*Bromus tectorum*). This  
 5 promotes fire by increasing fine fuels and latter fuels to ignite the encroaching trees. The site then is colonised  
 6 by cheatgrass which promotes accelerated soil erosion and permanent loss of productivity. Endemic wildlife  
 7 species (e.g., sage grouse and pygmy rabbits) habitat is lost and these animals face possible extinction. Source:  
 8 Mark Weltz, United States Department of Agriculture, Agricultural Research Service

9 **3.8.4.3. Consequences**

10 **Ethiopia.** *Prosopis*, classified as the highest priority invader in the country, is threatening livestock  
 11 production and challenging the sustainability of the pastoral systems. A study by Etana et al. (2011)  
 12 indicated that *Parthenium* caused a 69% decline in the density of herbaceous species in Awash National  
 13 Park within a few years of introduction. In the presence of *Parthenium*, the growth and development of

1 crops is suppressed due to its allelopathic properties. McConnachie et al. (2011) estimated a 28% crop loss  
2 across the country, including a 40-90% reduction in sorghum yield in eastern Ethiopia alone (Tamado et  
3 al., 2002).

4 **Mexico.** Castellanos et al. (2016) reported that soil moisture was lower in the buffelgrass savannah cleared  
5 35 years ago than in the native semiarid shrubland, mainly during the summer. The ecohydrological changes  
6 induced by buffelgrass can therefore displace native plant species over the long term. Invasion by  
7 buffelgrass can also affect landscape productivity, as it is not as productive as native vegetation (Franklin  
8 and Molina-Freaner, 2010).

9 **United States:** The conversion of the sagebrush step biome into to annual grassland with higher fire  
10 frequencies has severely impacted livestock producers as grazing is not possible for a minimum of two  
11 years' post-fire. Furthermore, cheatgrass and wildfires reduce critical habitat for wildlife and negatively  
12 impact species richness and abundance – for example, the greater sage-grouse (*Centocercus urophasianus*)  
13 and pygmy rabbit (*Brachylagus idahoensis*) which are on the verge of listing for federal protection  
14 (Larrucea and Brussard, 2008; Crawford et al., 2004; Lockyer et al., 2015).

15

#### 16 **3.8.3.4. Interventions and Lessons Learned to Date**

17 **Ethiopia.** There is neither a comprehensive intervention plan nor a clear institutional mandate to deal with  
18 invasive weeds, however, there are fragmented efforts where local communities have tried to clear *Prosopis*  
19 by cutting and burning. *Parthenium* was declared a noxious weed in 2001 (Dinwiddie, 2014) and even  
20 though the measures were taken to arrest the spread of the invader, they are clearly inadequate. The lessons  
21 learned are related to actions that have contributed to current scenario. First, a lack of coordination and  
22 awareness - mesquite was introduced by development agencies as a drought tolerant shade tree with little  
23 consideration of its invasive nature. If research and development institutions had been aware, a containment  
24 strategy could have been implemented. The second major lesson is the cost of inaction. Research and  
25 development organisations did sound the alarm, but the warnings went largely unheeded, resulting in the  
26 spread of two invasive plant species that could have been avoided.

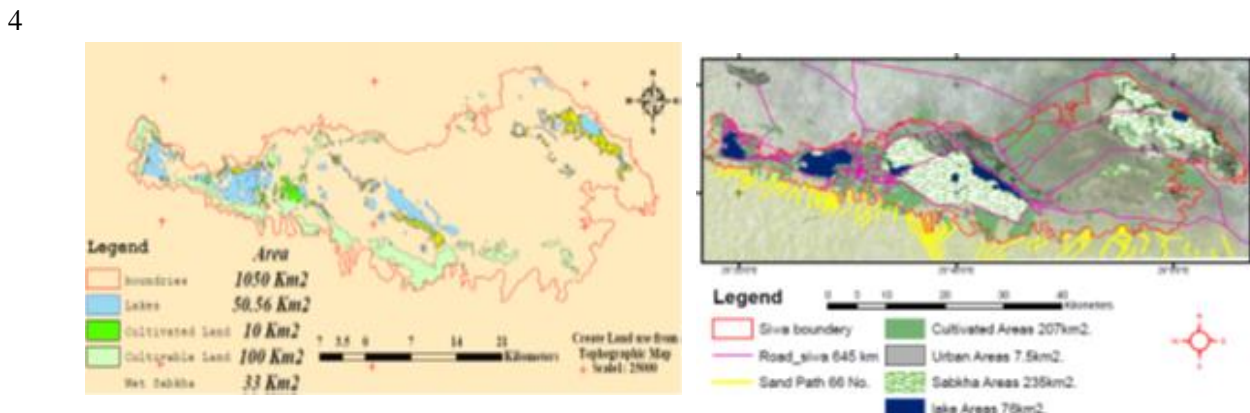

27

28 **Mexico.** Incorporation of buffelgrass is considered a good management practice by producers and the  
29 government. For this reason, no remedial actions are undertaken.

30 **United States.** Attempts to reduce cheatgrass impacts through reseeding have occurred for more than 60  
31 years (Hull and Stewart, 1949) with little success. Following fire, cheatgrass becomes dominant and  
32 recovery of native shrubs and grasses is unlikely, particularly in relatively low elevation sites with minimal  
33 annual precipitation (less than 200 mm per year) (Davies et al., 2012; Taylor et al., 2014). Current  
34 rehabilitation efforts emphasise the use of native and non-native perennial grasses, forbs, and shrubs  
35 (Bureau of Land Management, 2005). Recent literature suggests that these treatments are not consistently  
36 effective at displacing cheatgrass populations or re-establishing sage-grouse habitat with success varying  
37 with elevation and precipitation (Arkle et al., 2014; Knutson et al., 2014). Proper post-fire grazing rest,  
38 season-of-use, stocking rates, and subsequent management are essential to restore resilient sagebrush  
39 ecosystems before they cross a threshold and become an annual grassland (Chambers et al., 2014; Miller et  
40 al., 2011; Pellant et al., 2004). Projections of increasing temperature (Abatzoglou and Kolden, 2011), and  
41 observed reductions in and earlier melting of snowpack in the Great Basin region (Mote et al., 2005, 2018;  
42 Harpold and Brooks, 2018) suggest that there is a need to understand current and past climatic variability  
43 as this will drive wildfire and invasions of annual grasses.

1 to water mismanagement, improper drainage systems and climate warming. In support of that, Gad and  
 2 Abdel-Baki (2002), Marlet et al. (2009) and Askri et al. (2010) reported that the inefficiency of water use  
 3 by farmers is the major cause for secondary salinisation (Figure 3.19 and Figure 3.20).

5 **Figure 3.19 Images showing Siwa Oasis in 1929 (left) and 2017 (right). Lakes and wet Sabkha cover 50.6 and**  
 6 **33 km<sup>2</sup> in 1929, and 76 and 235 km<sup>2</sup> in 2017, respectively**

8 **Figure 3.20 Increase in water-table in Siwa Oasis**

9

10

11 The data from a meteorological station at Siwa Oasis showed that the average increase in temperature from  
 12 1990 to 2016 was +1.33°C (Figure 3.22) and in wind speed +0.87 mph (Figure 3.23). The increase in  
 13 these parameters over the years in the Oasis indicates that the evapotranspiration has substantially increased.  
 14 That accelerated the rate of soil salinisation in the Oasis. Safrieli et al. (2006) stated that the rate of increase  
 15 in temperature and rainfall in the western desert of Egypt was +0.8°C and +4% per decade, respectively, in

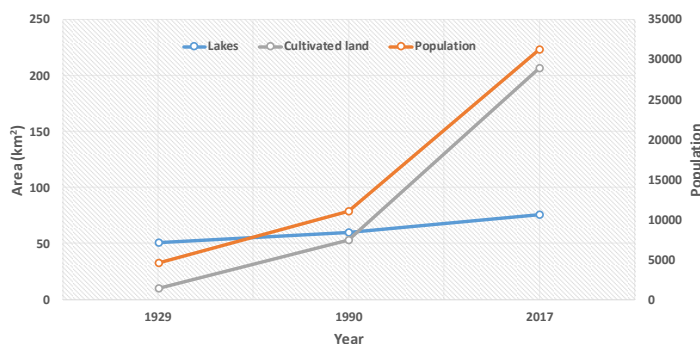

1 the period of 1976–2000. By using two different global emissions scenarios developed by IPCC (2011),  
 2 this increase is anticipated to range between +2°C and +4°C for temperature and 0% for rainfall per decade  
 3 in 2071–2100. Along with strong population growth, the cultivated land has increased from 1000 hectares  
 4 in 1929 to 20,700 hectares in 2017. This increase has been associated by the over-exploitation of the Oasis'  
 5 groundwater which causes waterlogging for cultivated land and was further exacerbated by the seasonally  
 6 high evaporation and evapotranspiration rates, intertwined with the improper setup of drainage systems  
 7 (Masoud and Koike, 2006). These conditions lead to the development of a thick salty layer that hampers  
 8 agricultural activities (Misak et al., 1997). As a result of the formation of large amounts of salts on the  
 9 edges of the lakes, salt trade has been recently flourished in the Oasis as a commodity for export to Europe.

Similar interactions of human activities and climatic factors are also observed in other oasis areas around the world. In China, the oases are mainly located in hyper-arid or arid zones of Xingjian, the Hexi corridor belonging to Gansu Province, in Northwest China. Over the past several decades, air temperature and the rainfall increased in the arid region of Northwest China (Chen et al., 2015; Wang et al., 2017), together with fluctuations in evaporation and water flows from glaciers (Chen et al., 2015), and land use changes in different oasis regions. For example, in the oasis along the Keriya River in southern Tarim Basin in Xingjian, cropland areas were expanded, while grassland areas were reduced (Muyibul et al., 2018). In Xingjian Altay Prefecture oasis zone, forests and bare lands, sand fixation area and available water resources decreased, whereas wind erosion increased in the adjacent desert area (Fu et al., 2017). Jinta oasis, a typical agricultural oasis in Hexi corridor, Gansu, China, expanded from 1963 to 2010, and water resource

1 use, land policies, population growth, and climate change all influenced the conversions between oasis and  
2 desert regions (Xie et al., 2014).

3 The attribution of impacts to climate change and human activities vary depending on the location (Song  
4 and Zhang, 2015). In the Tarim Basin oasis region, hyper aridity has been the main climate condition since  
5 the late Pleistocene, and variations in oasis area was mainly determined by fluctuations on water resources  
6 and climatic factors. Increasing population and economic growth caused the expansion of cultivated land  
7 and shrinking of native vegetation (Zhang et al., 2003). Following environmental changes over the past  
8 years, the ecosystem services in oasis regions in China also changed. In the oasis regions in the Manas  
9 River Basin of Xinjiang, China, over the past 60 years, agriculture and animal husbandry production  
10 services, and sandstorm and climate adjustment services increased, while the soil preservation and habitats  
11 carrying services decreased. The main drivers of these changes were the population growth and  
12 unsustainable agricultural activities. The regulation of ecosystem services for sandstorms and water  
13 resources were mainly influenced by climate change (Wei et al., 2018).

14 In the coming years, the inhabitants living in oasis regions will face challenges due to their limited  
15 adaptation capacity to global environmental change (Chen et al., 2018). Hence, efforts to increase  
16 adaptation capacity to climate change is crucial for sustainable development of oasis regions. This will  
17 require addressing the tradeoffs between environmental restoration and farmers' livelihoods (Chen et al.,  
18 2018). Managing grasslands and increasing investment into research on eco-agricultural technologies and  
19 enhancing protected areas in the mountain and desert areas can contribute to the sustainability of ecosystem  
20 services (Fu et al., 2017). Other sustainable land management practices to recover the relatively stable  
21 ecological zones between oases and deserts include establishment of straw checkerboards and planting  
22 drought-tolerant local natural shrubs, leveling sand dunes and drawing water for irrigation, closing dunes  
23 for grass reservation, and developing stable artificial protective forest (Su et al., 2007). Restoring  
24 groundwater by enhancing the surface water supply, decreasing groundwater utilisation, particularly  
25 sustainable use of the limited water and land resources, are all crucial to the sustainability in oasis regions  
26 (Hao et al., 2017). Ultimately, sustainability in oasis regions will require policies integrating the provision  
27 of ecosystem services and social and human welfare needs (Wang et al. 2017a).

28

### 29 **3.8.5. Desertification Watershed Management: a case study from Ethiopia and Jordan**

30 Desertification has resulted in significant loss of ecosystem processes and services as described in detail in  
31 this chapter. The techniques and processes to restore degraded watersheds are not linear and restoration or  
32 integrated watershed management (IWM) must address physical, biological and social approaches to  
33 achieve sustainable land management objectives (German et al., 2007). The use of indigenous, integrated  
34 natural resource conservation measures at watershed scale reportedly dates back thousands years among  
35 the indigenous communities of for example the Gedeo, Konso and Borana Oromo in Ethiopia (Chimdesa,  
36 2016). The modern implementation of IWM in Ethiopia dates to the recovery efforts implemented after the  
37 droughts of the 1970s and 1980s (Gashaw, 2015).

38 In Tigray and Amara regions of Ethiopia, a combination of trenches, gabions, stone check-dams, bund  
39 stabilisation, recharge pits, and sediment retention ponds combined with gully restoration through  
40 enhancing vegetation of resulted in significant reduction in soil loss and allowed for production of pigeon  
41 pea and establishment of woodlands with commercial benefits (Mekonen and Tesfahunegn, 2011).  
42 Decreases of soil loss between 59% and 89% have been documented in the Enabered watershed  
43 (Haregeweyn et al., 2012) and Agula watershed (Fenta et al. 2016), respectively. Encouraged by the positive  
44 outcomes farmers agreed to contribute 30–40% free labour for watershed development. The most effective

1 collective investment areas which motivated farmers to do more in protecting and developing their land and  
 2 environment were access to potable water supply, technologies and inputs; awareness raising functions and  
 3 governance (Adimassu et al., 2013).

4 In Abreha-We-Atsibeha, a small village in Tigray region of Ethiopia, the implementation of IWM has over  
 5 the last 23-years resulted in bare land area coverage declining from 33% in 1991 to 8.6% in 2014. Between  
 6 1984 and 2010, shrub land and forestland cover increased by about two-fold with a rate of 54.8 and 19.5 ha  
 7 yr<sup>-1</sup>, respectively (Biedemariam et al., 2017). There was a reduction by about four-fold in bare land 60.2 ha  
 8 yr<sup>-1</sup>. The production of cereals such as wheat has increased from 1.8 tons ha<sup>-1</sup> in 2001 to 2.95 tons ha<sup>-1</sup> in  
 9 2010. The enhancement in soil conditions and water availability allowed farmers to transition from cereal  
 10 crops to of cash earning from spices and vegetables.

11  
 12  
 13 **Figure 3.24 An example of how gullies are restored – the fully eroded gully (left) rehabilitated with vegetation**  
 14 **(center and right). Source: Alem et al. (2017)**

15  
 16 Population growth, migration into Jordan and changes in climate have resulted in desertification of the  
 17 Jordan Badia region. The Badia region covers more than 80% of the country's area and receives less than  
 18 200mm of rainfall per year, with some areas receiving less than 100mm (Al-Tabini et al., 2012). Climate  
 19 analysis has indicated a generally increasing dryness over the West Asia and Middle Eastern region (Zhang  
 20 et al., 2005; AlSarmi and Washington, 2011; Tanarhte et al., 2015) with reduction in average annual rainfall  
 21 in Jordan's Badia area (De Pauw et al., 2015). The incidence of extreme rainfall events has not declined  
 22 with a similar confidence over the region. Locally increased incidence of extreme events over the  
 23 Mediterranean region have been proposed (Giannakopoulos et al., 2009).

24 The practice of intensive and localised livestock herding, in combination with deep ploughing and  
 25 unproductive barley agriculture, are the main drivers of severe land degradation and depletion of the  
 26 rangeland's natural resources. This affected both the quantity and the diversity of vegetation as native plants  
 27 with a high nutrition value were replaced with invasive species with low palatability and nutritional content  
 28 (Abu-Zanat et al., 2004). The sparsely covered and crusted soils correspond with a low rainfall interception  
 29 and infiltration rate, which leads to increased surface runoff and subsequent erosion and gulying, speeding  
 30 up the drainage of rainwater from the watersheds that can result in downstream flooding in Amman, Jordan  
 31 (Oweis, 2017).

32 To restore the desertified Badia an IWM plan was developed using hillslope implemented water harvesting  
 33 micro catchments as a targeted restoration approach (Tabieh et al., 2015). Mechanized Micro Rainwater  
 34 Harvesting (MIRWH) technology using the 'Vallerani plough' (Antinori and Vallerani 1994; Ngigi 2003;  
 35 Gammoh and Oweis 2011) is being widely applied for rehabilitation of highly degraded rangeland areas in  
 36 Jordan. Tractor digs out small water harvesting pits on the contour of the slope (Figure 3.24) allowing the  
 37 retention, infiltration and the local storage of surface runoff in the soil (Oweis, 2017). The micro catchments

1 are planted native shrub seedlings, such as saltbush (*Atriplex halimus*), with enhance survival as a function  
 2 of increased soil moisture (Figure 3.25) and increased dry matter yields (>300 kg ha<sup>-1</sup>) that can serve as  
 3 forage for livestock (Tabieh et al., 2015; Oweis, 2017).

4

5 **Figure 3.25 Fresh Vallerani**  
 6 **micro water harvesting catchment (left) and aerial imaging showing micro water harvesting catchment**

8

9

10 **Figure 3.26 Illustration of enhanced soil water retention in the Mechanized Micro Rainwater Harvesting**  
 11 **compared to untreated Badia rangelands in Jordan**

12

13 Simultaneously to MIRWH upland measures, the gully erosion is being treated through intermitted stone  
 14 plug intervention (Figure 3.27), stabilising the gully beds, increasing soil moisture in proximity of the plugs  
 15 and dissipating the surface runoff’s energy, and mitigating further back-cutting erosion and quick drainage  
 16 of water. Eventually, the treated gully areas silt up and dense vegetation cover can re-establish. In addition,  
 17 grazing management practices are implemented to increase the longevity of the treatment. Eventually, the  
 18 recruitment processes and revegetation shall control the watershed’s hydrological regime through rainfall  
 19 interception, surface runoff deceleration and filtration, combined with the less erodible and enhanced  
 20 infiltration characteristics of the rehabilitated soils. In-depth understanding of the Badia’s rangeland status  
 21 transition, coupled with sustainable rangeland management, are still subject to further investigation,

1 development and adoption; required to eventually mitigate the ongoing degradation of the Middle Eastern  
2 rangeland ecosystems.

3 Oweis (2017) indicated costs of the fully automated Vallerani technique per hectare was approximately 32  
4 USD. The total cost of the restoration package included the production, planting, and maintenance of the  
5 shrub seedlings (USD 11.0 per ha). Tabieh et al. (2015) calculated a benefit cost ratio (BCR) of > 1.5 when  
6 revegetation degraded Badia areas through MIRWH and saltbush. However, costs will vary based on the  
7 seedling's costs and availability of trained labour.

#### 13 **Cross-Chapter Box 4: Case Study on Policy Responses to Drought**

14 **Contributing authors:** Margot Hurlbert (Canada), Muhammad Mohsin Iqbal (Pakistan), Joyce Kimutai  
15 (Kenya), Alisher Mirzabaev (Uzbekistan), Fasil Tena (Ethiopia)

16

17 Drought is a highly complex natural hazard. It is difficult to precisely identify its start and end. It is slow  
18 and gradual. It is context-dependent, but its impacts are diffuse, both direct and indirect, short-term and  
19 long-term (Few and Tebboth, 2018; Wilhite and Pulwarty, 2017). IPCC (2014) defines drought as “a period  
20 of abnormally dry weather long enough to cause a serious hydrological imbalance”. Although drought is  
21 considered abnormal relative to the water availability under the mean climatic characteristics, it is also a  
22 recurrent element of any climate, not only in drylands, but also in humid areas (Cook et al., 2014b;  
23 Seneviratne and Ciais, 2017; Wilhite et al., 2014). This recurrent nature of droughts requires pro-actively  
24 planned policy instruments both to be well-prepared to respond to droughts when they occur and also  
25 undertake ex ante actions to mitigate their impacts by strengthening the societal resilience against droughts  
26 (Gerber and Mirzabaev, 2017).

27 The previous assessment by the IPCC (2014) showed *low confidence* in emerging drought trends at the  
28 global scale since 1950, however, IPCC (2014) had a *high confidence* in the increase of frequency and  
29 intensity of droughts during the same period in some specific regions of the world, such as the  
30 Mediterranean and Western Africa. IPCC (2014) also had *medium confidence* in projected decreases in soil  
31 moisture and increases in the frequency and intensity of agricultural droughts in currently dry regions.  
32 Surface drying was expected to occur with *high confidence* in the Mediterranean, southwest USA and

1 southern Africa regions by 2100. For Eastern Africa, IPCC (2007) earlier projected a general upward trend  
2 in precipitation rates and heavy rainfall events in the twenty-first century, with reduced propensity for  
3 drought. However, some recent reports forecast drying over Eastern Africa (Cook and Vizy, 2013).

4 Droughts are among the costliest of natural hazards. Initial global estimates suggested that the global annual  
5 costs of drought equalled 80 billion USD (Carlowicz, 1996), of which around 6–8 billion USD were  
6 incurred in the USA (FEMA, 1995). Figures from the European Union showed that the annual damage  
7 caused by droughts in the EU was around 7.5 billion Euros in early 2000s (European Commission, 2007). On  
8 a sub-national level, Howitt et al. (2015) found that the drought in California in 2015 led to losses equal to  
9 2.7 billion USD. Taylor et al. (2014b) calculated that Uganda lost 237 million USD annually due to droughts  
10 between 2005 and 2015. The large-scale drought in Central and Southern Asia during 2000–2002 had also  
11 resulted in massive economic costs. In Pakistan, drought negatively affected the agriculture sector and  
12 caused its annual GDP growth to decrease from an average of 4.5% (during 1990–2000) to 2.6% during  
13 2000 and 0.07 % during 2001; the GDP growth regained 4.15% in 2002 when drought was over (Anjum et  
14 al., 2010). In Uzbekistan, it led to 130 million USD of losses (World Bank, 2005) and about 600,000 people  
15 were in need of food aid to the value of 19 million USD (World Bank, 2005).

16 Usually, these estimates capture only direct and on-site costs of droughts. Droughts have wide-ranging  
17 indirect and off-site costs, which are seldom quantified. These indirect effects are both biophysical and  
18 socio-economic. Droughts affect not only water quantity, but also water quality (Mosley, 2014). The costs  
19 of these water quality impacts are yet to be quantified adequately. Socio-economic indirect impacts of  
20 droughts are related to conflict, migration, poverty and short and long-term health consequences due to  
21 drought-caused undernutrition (Gray and Mueller, 2012; Johnstone and Mazo, 2011; Linke et al., 2015;  
22 Lohmann and Lechtenfeld, 2015). Research is required for developing methodologies that could allow for  
23 more comprehensive assessment of these indirect drought costs. Such methodologies require the collection  
24 of highly granular data; many countries do not do this due to high costs of data collection. However, the  
25 opportunities provided by remotely sensed data and novel analytical methods based in big data and artificial  
26 intelligence, including use of citizen science for data collection, could help in reducing these gaps.  
27 Moreover, it is important to bear in mind that droughts do not cause these indirect socio-economic  
28 consequences by themselves, but always together with other economic and institutional factors lowering  
29 societal resilience and adaptive capacities. Marginalisation of pastoral communities in dryland areas of  
30 Eastern Africa greatly amplifies the impacts of droughts on their livelihoods and food security (Opiyo et  
31 al., 2015; Rowhani et al., 2012; Silvestri et al., 2012; Sulieman and Elagib, 2012).

32 There are three broad (and sometimes overlapping) policy approaches for responding to droughts. Firstly,  
33 responding to drought when it occurs by providing direct drought relief is known as crisis management.  
34 Gerber and Mirzabaev (2017) suggested that crisis management is also the costliest among policy  
35 approaches to droughts because they incentivise the continuation of activities vulnerable to droughts.

36 The second approach involves development of drought preparedness plans which coordinate the policies  
37 for providing relief measures when droughts occur. Clarke and Hill (2013) found that combining resources  
38 to respond to droughts at regional level in Sub-Saharan Africa was more effective and cheaper than separate  
39 individual country drought relief funding. IFRC (2003) found that providing jobs to drought affected  
40 populations in building terraces and check dams helped to strengthen local resilience to future droughts  
41 more than providing direct food or cash aid.

42 The third category of responses to droughts involves drought risk mitigation. Drought risk mitigation is a  
43 set of proactive policies aimed at reducing the future impacts of droughts. Drought risk mitigation policies  
44 aim to limit the exposure to droughts and to increasing societal resilience to droughts (Vicente-Serrano et

1 al., 2012). For example, policies aimed at improving water use efficiency in different sectors of the  
2 economy, especially in agriculture and industry, or public advocacy campaigns raising societal awareness  
3 and bringing about behavioural change to reduce wasteful water consumption in the residential sector are  
4 among such drought risk mitigation policies (Tsakiris, 2017). Policies also include those addressing  
5 livelihood needs including marketing interventions such as destocking, or selling livestock, emergency  
6 livestock vaccination, negotiation of exceptional access for grazing to protected areas or commercial  
7 ranches (Catley et al., 2009; Morton and Barton, 2002; Abebe et al., 2008).

8 Reliable, relevant and timely climate and weather information available to and applied by key user groups  
9 including farmers, extension officers, policy makers and emergency response units could help monitor  
10 drought risks and respond appropriately (Sivakumar and Ndiang'ui, 2007). Improved knowledge and  
11 integration of weather and climate information can be achieved by strengthening drought early warning  
12 systems at different scales (Verbist et al., 2016). Famine Early Warning System Network (FEWSNet) in  
13 East Africa, CILSS/AGRHYMET for West Africa, and Southern African Development Community  
14 (SADC) regional early warning unit, for example, have been quite effective in monitoring and forecasting  
15 drought events in these regions, as well as an experimental Sub-Saharan drought monitoring and forecasting  
16 system (Sheffield et al., 2014). Every US dollar invested into strengthening hydro-meteorological and early  
17 warning services in developing countries was found to yield between 4 to 35 USD (Pulwarty and  
18 Sivakumar, 2014). Thus far there are weak links with community early warning systems and national and  
19 international ones (Wilhite et al., 2014). These indicators have been successfully linked with social media  
20 (Tang et al., 2015). There must be care exercised in these instruments not leading to perverse outcomes  
21 when linked to some forms of government support (Botterill and Hayes, 2012).

22 Although previous literature claimed such drought risk mitigation approaches to be much less costly than  
23 ex post drought relief, there has not been much research done on quantifying the cost differentials. Harou  
24 et al. (2010) found that establishment of water markets in California considerably reduced drought costs.  
25 Application of water saving technologies reduced drought costs in Iran by 282 million USD (Salami et al.,  
26 2009). Booker et al. (2005) calculated that interregional trade in water could reduce drought costs by 20–  
27 30% in the Rio Grande basin, USA. In response to drought some governments have declared emergencies  
28 and adopted a system of water rationing while in other jurisdictions water property rights dictate through  
29 seniority preference rights who does or does not receive water. A number of diverse water property  
30 instruments including instruments allowing water transfer, together with the technological and institutional  
31 ability to adjust water allocation, can improve responsive timely adjustment to drought (Hurlbert, 2018).  
32 Supply side managed water that only provides for proportionate reductions in water delivery, prevents the  
33 important adaptation of managing water according to need or demand (Hurlbert and Mussetta, 2016).  
34 Exclusive use of a water market to govern water allocation similarly prevents the recognition of the human  
35 right to water at times of drought preventing an important adaptation (Hurlbert, 2018). Drought mitigation  
36 activities at the macroeconomic level need to be complemented by similar measures at the household and  
37 community levels. There is *robust evidence* in the literature that secure land tenure, access to markets,  
38 access to agricultural advisory services, and off-farm employment facilitates the adoption of drought  
39 mitigation practices by farming households (Alam, 2015; Kusunose and Lybbert, 2014). Programs that  
40 provide financial assistance to agricultural producers to build water infrastructure (such as water storage  
41 dugouts, pipelines to provide water to livestock) have improved the adaptive capacity of agricultural  
42 programs as well as programs that assist producers in planning for environmental risk including drought,  
43 soil degradation, pests (Hurlbert, 2018).

44 All in all, the accumulated evidence shows that it will be increasingly costly to continue with policy  
45 responses to droughts based on drought relief measures. The excessive burden of drought relief funding on

1 public budgets have already led to a paradigm shift towards pro-active drought risk mitigation in such  
2 countries as USA and Australia. Climate change will only re-enforce the need for pro-active drought risk  
3 mitigation approaches, including increased investments into science and research for developing  
4 technological and policy options for drought risk mitigation.

### 5 **3.9. Knowledge Gaps and Key Uncertainties**

7 There are knowledge gaps on the extent of desertification at global and regional scales. Despite numerous  
8 related studies, consistent indicators for attributing desertification to climatic and/or human causes are still  
9 lacking due to methodological shortcomings. The knowledge of future climate change impacts on specific  
10 desertification processes, such as soil erosion, salinisation, nutrient depletion, and vegetation cover and  
11 composition change, as well as on dust storms remain limited, especially at the local level. At the global  
12 level, the evidence base is not strong and sufficiently granular on how climate change will modify the extent  
13 of desertified areas in drylands. Considering the non-equilibrium nature of drylands, with strong influence  
14 of climatic variations on the extent of desertification, this is a gap that could be filled within the currently  
15 available modelling tools. Previous studies have focused on the general characteristics of past and current  
16 desertification feedbacks to the climate system, however, the information on the future interactions between  
17 desertification and climate remains limited. Monitoring desertification to identify the interaction between  
18 desertification and climate using Earth observation systems could help fill this gap.

19 Knowledge gaps persists in the quantification of the impacts of desertification on natural and socio-  
20 economic systems. Future projections of combined impacts of desertification and climate change on  
21 ecosystem services, fauna and flora, are lacking, even though this topic is of considerable social importance.  
22 Available information is mostly on separate, individual impacts of either (mostly) climate change or  
23 desertification. Currently, there is a good understanding of various anthropogenic drivers of desertification.  
24 However, the knowledge is lacking on how these drivers will evolve in the future, how they will interact  
25 with future climate change, and what would be the effect on desertification.

26 Despite a lot of studies on separate responses to desertification or to climate change, the knowledge and  
27 understanding of the synergies and trade-offs among actions for combating desertification, adapting to and  
28 mitigating climate change, and various positive or negative externalities that they will generate in terms of  
29 other Sustainable Development Goals is limited. All these aspects are crucial for understanding climate  
30 change-desertification interactions and how they will affect people, ecosystems and biodiversity in the  
31 future. Filling these gaps requires considerable investments in research and data collection.

## Frequently Asked Questions

### **FAQ 3.1 How do climate change and desertification interact with land use? How can climate change induced desertification be avoided, reduced or reversed?**

Climate change and desertification have strong mutual interactions, and the land use and land cover changes associated with desertification contribute to climatic changes, whereas changes in precipitation, temperature, wind speed, and their variabilities due to climatic changes constitute factors affecting desertification. Desertification affects global climate change through the loss of fertile soil and vegetation. In fact, the soil of the drylands contains large amounts of carbon that could enter the atmosphere due to desertification, with important repercussions for the global climate system. The impact of global climate change on desertification is complex and knowledge on the subject is still insufficient. On the one hand, the increase in temperatures can have negative effects by increasing the evaporation of soil water, and some dryland regions will also have reduced rainfall. On the other hand, the increase of carbon dioxide in the atmosphere can enhance the growth of plants. Climate change could translate into an increased risk of aridity and desertification in many areas, although it is difficult to predict the effects of the subsequent loss of biodiversity on desertification.

Sustainable land management (SLM) practices can help avoid, reduce or reverse desertification, mitigate and adapt to climate change. Such SLM practices include conservation agriculture, afforestation and reforestation, crop diversification, planting drought-resilient crop varieties, and many others. Desertification limits choices for such land-based climate change adaptation and mitigation options.

### **FAQ 3.2 How could land-based options to mitigate climate change affect ecosystem services and biodiversity?**

Sustainable land management (SLM) practices which include actions of soil and water conservation in drylands could improve ecosystems services and protect biodiversity. Among provisioning services, conservation agriculture and rangeland management can increase plant biomass, and therefore, the production of food and fibers. Moreover, these practices, as well as, reforestation and afforestation practices can also increase the regulating and supporting services such as soil fertility, water availability and carbon sequestration. SLM practices also support biodiversity through habitat protection and reducing the invasion of alien species. Biodiversity protection results in higher genetic resources, which significantly contributes to human wellbeing through supporting a variety of provisioning ecosystem services.
